CONTENTS

CHAPTER 1  Getting Started  1

Is This Guide for You?  1

New Features in Firepower Device Manager/FTD 6.2  2

New Features in Firepower Device Manager/FTD 6.2.1  5

New Features in Firepower Device Manager/FTD 6.2.2  5

New Features in Firepower Device Manager/FTD Version 6.2.3  6

Logging Into the System  10

Logging Into Firepower Device Manager  11

Logging Into the Command Line Interface (CLI)  12

Changing Your Password  12

Setting User Profile Preferences  13

Creating Local User Accounts for the FTD CLI  13

Setting Up the System  15

Connect the Interfaces  16

Cabling for ASA 5506-X, 5506W-X, and 5506H-X  16

Cabling for ASA 5508-X and 5516-X  17

Cabling for ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X  18

Cabling for Firepower 2100  20

Virtual Cabling for Firepower Threat Defense Virtual  20

Cabling for ISA 3000  22

(Optional) Change Management Network Settings at the CLI  23

Complete the Initial Configuration Using the Setup Wizard  24

What to Do if You Do Not Obtain an IP Address for the Outside Interface  26

Configure the Wireless Access Point (ASA 5506W-X)  27

Default Configuration Prior to Initial Setup  30

Configuration After Initial Setup  32
CHAPTER 5  Objects  105

Object Types  105
Managing Objects  107
  Configuring Network Objects and Groups  108
  Configuring Port Objects and Groups  109
  Configuring Security Zones  110
  Configuring Application Filter Objects  111
  Configuring URL Objects and Groups  113
  Configuring Geolocation Objects  114
  Configuring Syslog Servers  115
  Configuring AD Identity Realms  116
    Troubleshooting Directory Server Connections  118
    Limitations on Number of Users  119
    Supported Directory Servers  119
    Determining the Directory Base DN  120

CHAPTER 6  Certificates  123

About Certificates  123
  Public Key Cryptography  124
  Certificate Types Used by Feature  124
  Example: Generating an Internal Certificate using OpenSSL  125
Configuring Certificates  126
  Uploading Internal and Internal CA Certificates  126
PART II

Security Policies 163

CHAPTER 9

SSL Decryption 165

About SSL Decryption 165

Why Implement SSL Decryption? 165

Actions You Can Apply to Encrypted Traffic 166

Decrypt Re-Sign 166

Decrypt Known Key 167

Do Not Decrypt 167

Block 168

Automatically Generated SSL Decryption Rules 168

Handling Undecryptable Traffic 168

License Requirements for SSL Decryption 168

Guidelines for SSL Decryption 169

How to Implement and Maintain the SSL Decryption Policy 169

Configuring SSL Decryption Policies 171

Enable the SSL Decryption Policy 172

Configure the Default SSL Decryption Action 173

Configure SSL Decryption Rules 174

Source/Destination Criteria for SSL Decryption Rules 176

Application Criteria for SSL Decryption Rules 177
### URL Criteria for SSL Decryption Rules 178
### User Criteria for SSL Decryption Rules 178
### Advanced Criteria for SSL Decryption Rules 179
### Configure Certificates for Known Key and Re-Sign Decryption 180
### Downloading the CA Certificate for Decrypt Re-Sign Rules 181
### Example: Blocking Older SSL/TLS Versions from the Network 182
### Monitoring and Troubleshooting SSL Decryption 184
### Handling Web Sites Where Decrypt Re-sign Works for a Browser but not an App (SSL or Certificate Authority Pinning) 184

## Chapter 10

### Identity Policies 187

- Identity Policy Overview 187
  - Establishing User Identity through Active Authentication 187
  - Dealing with Unknown Users 188
- Configuring Identity Policies 188
  - Configure Identity Policy Settings 189
  - Configure Identity Rules 190
- Enabling Transparent User Authentication 193
  - Requirements for Transparent Authentication 194
  - Configuring Internet Explorer for Transparent Authentication 194
  - Configuring Firefox for Transparent Authentication 195
- Monitoring Identity Policies 196
- Examples for Identity Policies 196

## Chapter 11

### Security Intelligence 197

- About Security Intelligence 197
  - Making Exceptions to the Blacklists 198
  - Security Intelligence Feed Categories 198
- License Requirements for Security Intelligence 199
- Configuring Security Intelligence 199
- Monitoring Security Intelligence 200
- Examples for Security Intelligence 200
Examples for Access Control  221

CHAPTER 13

Intrusion Policies  223

About Intrusion and Network Analysis Policies  223
  System-Defined Network Analysis and Intrusion Policies  223
Intrusion and Preprocessor Rules  224
  Intrusion Rule Attributes  224
  Default Intrusion Variable Set  226
  Generator Identifiers  227
Network Analysis Policies  228
  How the System Selects Network Analysis Policies using NAP Rules  228
  Best Practices for Applying Intrusion Policies to Optimize NAP Processing  230
License Requirements for Intrusion Policies  230
Managing Intrusion Policies  230
  Applying Intrusion Policies in Access Control Rules  231
  Changing Intrusion Rule Actions  231
  Configuring Syslog for Intrusion Events  232
Monitoring Intrusion Policies  233
Examples for Intrusion Policies  233

CHAPTER 14

Network Address Translation (NAT)  235

Why Use NAT?  235
NAT Basics  236
  NAT Terminology  236
  NAT Types  236
  NAT in Routed Mode  237
Auto NAT and Manual NAT  237
  Auto NAT  238
  Manual NAT  238
  Comparing Auto NAT and Manual NAT  238
NAT Rule Order  239
NAT Interfaces  240
Configuring Routing for NAT  241
  Addresses on the Same Network as the Mapped Interface  241
Examples for Site-to-Site VPN 340
Exempting Site-to-Site VPN Traffic from NAT 340
How to Provide Internet Access on the Outside Interface for External Site-to-Site VPN Users (Hair Pinning) 346

CHAPTER 16
Remote Access VPN 353
Remote Access VPN Overview 353
Maximum Concurrent VPN Sessions By Device Model 353
Downloading the AnyConnect Client Software 354
How Users Can Install the AnyConnect Software 354
Licensing Requirements for Remote Access VPN 355
Guidelines and Limitations for Remote Access VPN 356
Configuring Remote Access VPN 356
Configure and Upload Client Profiles 357
Configure a Remote Access VPN Connection 358
Control Access to Resources by Remote Access VPN Group 361
Verify the Remote Access VPN Configuration 362
Monitoring Remote Access VPN 364
Troubleshooting Remote Access VPNs 364
Troubleshooting SSL Connection Problems 364
Troubleshooting AnyConnect Download and Installation Problems 365
Troubleshooting AnyConnect Connection Problems 365
Troubleshooting RA VPN Traffic Flow Problems 366
Examples for Remote Access VPN 367
How to Provide Internet Access on the Outside Interface for Remote Access VPN Users (Hair Pinning) 367
How to Use a Directory Server on an Outside Network with Remote Access VPN 372

PART IV
System Administration 389

CHAPTER 17
System Settings 391
Configuring the Management Access List 391
Configuring Diagnostic Logging 393
Severity Levels 393
Configuring DHCP Server 394
Configuring DNS 396
Configuring the Management Interface 396
Configuring the Device Hostname 398
Configuring Network Time Protocol (NTP) 398
Configuring URL Filtering Preferences 399
Configuring Cloud Services 399
  Configuring Cloud Management (Cisco Defense Orchestrator) 400
Connecting to the Cisco Success Network 401

CHAPTER 18 System Management 403
Installing Software Updates 403
  Updating System Databases and Feeds 403
    Overview of System Database and Feed Updates 403
  Updating System Databases 404
  Upgrading Cisco Security Intelligence Feeds 406
Upgrading Firepower Threat Defense Software 406
Reimaging the Device 408
Back up and Restoring the System 408
  Backing Up the System Immediately 409
  Backing Up the System at a Scheduled Time 409
Setting up a Recurring Backup Schedule 410
Restoring a Backup 411
Managing Backup Files 411
Rebooting the System 412
Troubleshooting the System 412
  Pinging Addresses to Test Connectivity 413
  Tracing Routes to Hosts 415
Making the Firepower Threat Defense Device Appear on Traceroutes 416
Troubleshooting NTP 417
Troubleshooting DNS for the Management Interface 419
Analyzing CPU and Memory Usage 421
Viewing Logs 422
Creating a Troubleshooting File 423
Uncommon Management Tasks 424
Switching Between Local and Remote Management 424
Changing the Firewall Mode 426
Resetting the Configuration 429

Advanced Configuration 431
About Smart CLI and FlexConfig 431
Recommended Usage for Smart CLI and FlexConfig 432
CLI Commands in Smart CLI and FlexConfig Objects 432
Determine the ASA Software Version and Current CLI Configuration 433

How to Enable and Disable Global Default Inspections 451
How to Undo Your FlexConfig Changes 457
How to Enable Inspections for Unique Traffic Classes 458
Getting Started

The following topics explain how to get started configuring Firepower Threat Defense.

- Is This Guide for You?, on page 1
- New Features in Firepower Device Manager/FTD 6.2, on page 2
- Logging Into the System, on page 10
- Setting Up the System, on page 15
- Configuration Basics, on page 34

Is This Guide for You?

This guide explains how to configure Firepower Threat Defense using the Firepower Device Manager web-based configuration interface included on Firepower Threat Defense devices.

Firepower Device Manager lets you configure the basic features of the software that are most commonly used for small or mid-size networks. It is especially designed for networks that include a single device or just a few, where you do not want to use a high-powered multiple-device manager to control a large network containing many Firepower Threat Defense devices.

If you are managing large numbers of devices, or if you want to use the more complex features and configurations that Firepower Threat Defense allows, use Firepower Management Center to configure your devices instead of the integrated Firepower Device Manager.

You can use Firepower Device Manager on the following devices.

<table>
<thead>
<tr>
<th>Device Model</th>
<th>Minimum Firepower Threat Defense Software Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firepower 2110, 2120, 2130, 2140</td>
<td>6.2.1</td>
</tr>
<tr>
<td>Firepower Threat Defense Virtual for VMware</td>
<td>6.2.2</td>
</tr>
<tr>
<td>Firepower Threat Defense Virtual for Kernel-based Virtual Machine (KVM) hypervisor</td>
<td>6.2.3</td>
</tr>
<tr>
<td>ASA 5508-X, 5516-X</td>
<td>6.1</td>
</tr>
<tr>
<td>ASA 5525-X, 5545-X, 5555-X</td>
<td>6.1</td>
</tr>
</tbody>
</table>
### Minimum Firepower Threat Defense Software Version

<table>
<thead>
<tr>
<th>Device Model</th>
<th>Minimum Firepower Threat Defense Software Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASA 5506-X, 5506H-X, 5506W-X, 5512-X</td>
<td>6.1</td>
</tr>
<tr>
<td>ASA 5515-X</td>
<td>6.1</td>
</tr>
<tr>
<td>ISA 3000 (Cisco 3000 Series Industrial Security Appliances)</td>
<td>6.2.3</td>
</tr>
</tbody>
</table>

### New Features in Firepower Device Manager/FTD 6.2

**Released: January 23, 2017**

The following table lists the new features available in FTD 6.2 when configured using Firepower Device Manager.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drag and drop for access rules</td>
<td>You can drag and drop access rules to move them in the rules table.</td>
</tr>
<tr>
<td>FTD software upgrade</td>
<td>You can install software upgrades through Firepower Device Manager. Select <strong>Device &gt; Updates</strong>.</td>
</tr>
</tbody>
</table>
**Feature** | **Description**
--- | ---
FTD default configuration changes | For new or reimaged devices, the default configuration includes significant changes, including:

- **(ASA 5506-X, 5506W-X, 5506H-X.)** Except for the first data interface, and the Wi-Fi interface on an ASA 5506W-X, all other data interfaces on these device models are structured into the “inside” bridge group and enabled. There is a DHCP server on the inside bridge group. You can plug endpoints or switches into any bridged interface and endpoints get addresses on the 192.168.1.0/24 network.

- The inside interface IP address is now 192.168.1.1, and a DHCP server is defined on the interface with the address pool 192.168.1.5-192.168.1.254.

- HTTPS access is enabled on the inside interface, so you can open Firepower Device Manager through the inside interface at the default address, 192.168.1.1. For the ASA 5506-X models, you can do this through any inside bridge group member interface.

- The management port hosts a DHCP server for the 192.168.45.0/24 network. You can plug a workstation directly into the management port, get an IP address, and open Firepower Device Manager to configure the device.

- The OpenDNS public DNS servers are now the default DNS servers for the management interface. Previously, there were no default DNS servers. You can configure different DNS servers during device setup.

- The default gateway for the management IP address is to use the data interfaces to route to the Internet. Thus, you do not need to wire the Management physical interface to a network.
### Feature | Description
--- | ---
Management interface and access changes | Several changes to how the management address, and access to Firepower Device Manager, works:
  - You can now open data interfaces to HTTPS (for Firepower Device Manager) and SSH (for CLI) connections. You do not need a separate management network, or to connect the Management/Diagnostic physical port to the inside network, to manage the device. Select Device > System Settings > Management Access List.
  - The system can obtain system database updates through the gateway for the outside interface. You do not need to have an explicit route from the management interface or network to the Internet. The default is to use internal routes through the data interfaces. However, you can set a specific gateway if you prefer to use a separate management network. Select Device > System Settings > Management Interface.
  - You can use Firepower Device Manager to configure the management interface to obtain its IP address through DHCP. Select Device > System Settings > Management Interface.
  - You can configure a DHCP server on the management address if you configure a static address. Select Device > System Settings > Management Interface.

Miscellaneous user interface changes | The following are notable changes to the Firepower Device Manager user interface.
  - Device main menu item. In previous releases, this menu item was the host name of your device. Also, the page opened is called Device Summary instead of Device Dashboard.
  - You cannot select an alternative outside interface during initial device setup. The first data interface is the default outside interface.
  - Device > System Settings > Cloud Preferences is now called Device > System Settings > URL Filtering Preferences.
  - The System Settings > DHCP Server page is now organized on two tabs, with the table of DHCP servers separated from the global parameters.

Site-to-site VPN connections | You can configure site-to-site virtual private network (VPN) connections using preshared keys. You can configure IKEv1 and IKEv2 connections.
Integrated Routing and Bridging provides the ability to route between a bridge group and a routed interface. A bridge group is a group of interfaces that the FTD device bridges instead of routes. The FTD device is not a true bridge in that the FTD device continues to act as a firewall: access control between interfaces is controlled, and all of the usual firewall checks are in place.

This feature lets you configure bridge groups and to route between bridge groups and between a bridge group and a routed interface. The bridge group participates in routing by using a Bridge Virtual Interface (BVI) to act as a gateway for the bridge group. Integrated Routing and Bridging provides an alternative to using an external Layer 2 switch if you have extra interfaces on the FTD device to assign to the bridge group. The BVI can be a named interface and can participate separately from member interfaces in some features, such as DHCP server, where you configure other features on bridge group member interfaces, such as NAT and access control rules.

Select Device > Interfaces to configure a bridge group.

### New Features in Firepower Device Manager/FTD 6.2.1

**Released: May 15, 2017**

The following table lists the new features available in FTD 6.2.1 when configured using Firepower Device Manager.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remote access VPN configuration.</td>
<td>You can configure remote access SSL VPN for the AnyConnect client. Configure RA VPN from the Device &gt; Remote Access VPN group. Configure RA VPN licenses from the Device &gt; Smart License group.</td>
</tr>
<tr>
<td>Firepower 2100 series device configuration.</td>
<td>You can configure FTD on Firepower 2100 series devices using Firepower Device Manager.</td>
</tr>
</tbody>
</table>

*Note: This release applies to Firepower 2100 series only.*

### New Features in Firepower Device Manager/FTD 6.2.2

**Released: September 5, 2017**

The following table lists the new features available in FTD 6.2.2 when configured using Firepower Device Manager.
### Remote access VPN configuration for ASA 5500-X series devices.

You can configure remote access SSL VPN for the AnyConnect client on ASA 5500-X series devices. Configure RA VPN from the **Device > Remote Access VPN** group. Configure RA VPN licenses from the **Device > Smart License** group.

### Firepower Threat Defense Virtual for VMware device configuration.

You can configure FTD on Firepower Threat Defense Virtual for VMware devices using Firepower Device Manager. Other virtual platforms are not supported by Firepower Device Manager.

**Note** You must install a new 6.2.2 image to get Firepower Device Manager support. You cannot upgrade an existing virtual machine from an older version and then switch to Firepower Device Manager.

---

## New Features in Firepower Device Manager/FTD Version 6.2.3

**Released: March 29, 2018**

The following table lists the new features available in FTD 6.2.3 when configured using Firepower Device Manager.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSL/TLS Decryption</td>
<td>You can decrypt SSL/TLS connections so that you can inspect the contents of the connection. Without decryption, encrypted connections cannot be effectively inspected to identify intrusion and malware threats, or to enforce compliance with your URL and application usage polices. We added the <strong>Policies &gt; SSL Decryption</strong> page and <strong>Monitoring &gt; SSL Decryption</strong> dashboard.</td>
</tr>
<tr>
<td><strong>Attention</strong></td>
<td>Identity policies that implement active authentication automatically generate SSL decryption rules. If you upgrade from a release that does not support SSL decryption, the SSL decryption policy is automatically enabled if you have this type of rule. However, you must specify the certificate to use for Decrypt-Resign rules after completing the upgrade. Please edit the SSL decryption settings immediately after upgrade.</td>
</tr>
<tr>
<td>Security Intelligence Blacklisting</td>
<td>From the new <strong>Policies &gt; Security Intelligence</strong> page you can configure a Security Intelligence policy, which you can use to drop unwanted traffic based on source/destination IP address or destination URL. Any allowed connections will still be evaluated by access control policies and might eventually be dropped. You must enable the Threat license to use Security Intelligence. We also renamed the <strong>Policies</strong> dashboard to <strong>Access And SI Rules</strong>, and the dashboard now includes Security Intelligence rule-equivalents as well as access rules.</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>Intrusion Rule Tuning</td>
<td>You can change the action for intrusion rules within the pre-defined intrusion policies you apply with your access control rules. You can configure each rule to drop or generate events (alert) matching traffic, or disable the rule. You can change the action for enabled rules only (those set to drop or alert); you cannot enable a rule that is disabled by default. To tune intrusion rules, choose Policies &gt; Intrusion.</td>
</tr>
<tr>
<td>Automatic Network Analysis Policy (NAP) Assignment based on Intrusion Policy</td>
<td>In previous releases, the Balanced Security and Connectivity network analysis policy was always used for preprocessor settings, regardless of the intrusion policy assigned to a specific source/destination security zone and network object combination. Now, the system automatically generates NAP rules to assign the same-named NAP and intrusion policies to traffic based on those criteria. Note that if you use Layer 4 or 7 criteria to assign different intrusion policies to traffic that otherwise matches the same source/destination security zone and network object, you will not get perfectly matching NAP and intrusion policies. You cannot create custom network analysis policies.</td>
</tr>
<tr>
<td>Drill-down reports for the Threats, Attackers, and Targets dashboards</td>
<td>You can now click into the Threats, Attackers, and Targets dashboards to view more detail about the reported items. These dashboards are available on the Monitoring page. Because of these new reports, you will lose reporting data for these dashboards when upgrading from a pre-6.2.3 release.</td>
</tr>
<tr>
<td>Web Applications Dashboard</td>
<td>The new Web Applications dashboard shows the top web applications, such as Google, that are being used in the network. This dashboard augments the Applications dashboard, which provides protocol-oriented information, such as HTTP usage.</td>
</tr>
<tr>
<td>New Zones dashboard replaces the Ingress Zone and Egress Zone dashboards.</td>
<td>The new Zones dashboard shows the top security zone pairs for traffic entering and then exiting the device. This dashboard replaces the separate dashboards for Ingress and Egress zones.</td>
</tr>
<tr>
<td>New Malware Dashboard</td>
<td>The new Malware dashboard shows the top Malware action and disposition combinations. You can drill down to see information on the associated file types. You must configure file policies on access rules to see this information.</td>
</tr>
<tr>
<td>Self-signed internal certificates, and Internal CA certificates</td>
<td>You can now generate self-signed internal identity certificates. You can also upload or generate self-signed internal CA certificates for use with SSL decryption policies. Configure these features on the Objects &gt; Certificates page.</td>
</tr>
<tr>
<td>Ability to edit DHCP server settings when editing interface properties</td>
<td>You can now edit settings for a DHCP server configured on an interface at the same time you edit the interface properties. This makes it easy to redefine the DHCP address pool if you need to change the interface IP address to a different subnet.</td>
</tr>
</tbody>
</table>
### Feature

<table>
<thead>
<tr>
<th>Description</th>
<th>Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can connect to the Cisco Success Network to send data to Cisco. By enabling Cisco Success Network, you are providing usage information and statistics to Cisco which are essential for Cisco to provide you with technical support. This information also allows Cisco to improve the product and to make you aware of unused available features so that you can maximize the value of the product in your network. You can enable the connection when you register the device with the Cisco Smart Software Manager, or later at your choice. You can disable the connection at any time.</td>
<td>The Cisco Success Network sends usage and statistics data to Cisco to improve the product and provide effective technical support</td>
</tr>
<tr>
<td>Cisco Success Network is a cloud service. The Device &gt; System Settings &gt; Cloud Management page is renamed Cloud Services. You can configure Cisco Defense Orchestrator from the same page.</td>
<td>Firepower Threat Defense Virtual for Kernel-based Virtual Machine (KVM) hypervisor device configuration</td>
</tr>
<tr>
<td>You can configure FTD on Firepower Threat Defense Virtual for KVM devices using Firepower Device Manager. Previously, only VMware was supported.</td>
<td>You can configure FTD on Firepower Threat Defense Virtual for KVM devices using Firepower Device Manager. Previously, only VMware was supported.</td>
</tr>
<tr>
<td>Note You must install a new 6.2.3 image to get Firepower Device Manager support. You cannot upgrade an existing virtual machine from an older version and then switch to Firepower Device Manager.</td>
<td>Note You must install a new 6.2.3 image to get Firepower Device Manager support. You cannot upgrade an existing virtual machine from an older version and then switch to Firepower Device Manager.</td>
</tr>
<tr>
<td>You can configure FTD on ISA 3000 devices using Firepower Device Manager. Note that the ISA 3000 supports the Threat license only. It does not support the URL Filtering or Malware licenses. Thus, you cannot configure features that require the URL Filtering or Malware licenses on an ISA 3000.</td>
<td>ISA 3000 (Cisco 3000 Series Industrial Security Appliances) device configuration</td>
</tr>
<tr>
<td>When you update the intrusion rules database or VDB, or configure an update schedule, you can prevent the immediate deployment of the update. Because the update restarts the inspection engines, there is a momentary traffic drop during the deployment. By not deploying automatically, you can choose to initiate the deployment at a time when traffic drops will be least disruptive.</td>
<td>Optional deployment on update of the rules database or VDB</td>
</tr>
<tr>
<td>Note A VDB download can also restart Snort all by itself, and then again cause a restart on deployment. You cannot stop the restart on download.</td>
<td>Note A VDB download can also restart Snort all by itself, and then again cause a restart on deployment. You cannot stop the restart on download.</td>
</tr>
</tbody>
</table>
### Feature

| Improved messages that indicate whether a deployment restarts Snort. Also, a reduced need to restart Snort on deployment | Before you start a deployment, Firepower Device Manager indicates whether the configuration updates require a Snort restart. Snort restarts result in the momentary dropping of traffic. Thus, you now know whether a deployment will not impact traffic and can be done immediately, or will impact traffic, so that you can deploy at a less disruptive time.

In addition, in prior releases, Snort restarted on every deployment. Now, Snort restarts for the following reasons only:

- you enable or disable SSL decryption policies
- an updated rules database or VDB was downloaded
- you changed the MTU on one or more physical interface (but not subinterface) |

| CLI console in Firepower Device Manager | You can now open a CLI Console from Firepower Device Manager. The CLI Console mimics an SSH or console session, but allows a subset of commands only: show, ping, traceroute, and packet-tracer. Use the CLI Console for troubleshooting and device monitoring. |

| Support for blocking access to the management address | You can now remove all management access list entries for a protocol to prevent access to the management IP address. Previously, if you removed all entries, the system defaulted to allowing access from all client IP addresses. On upgrade to 6.2.3, if you previously had an empty management access list for a protocol (HTTPS or SSH), the system creates the default allow rule for all IP addresses. You can then delete these rules as needed.

In addition, Firepower Device Manager will recognize changes you make to the management access list from the CLI, including if you disable SSH or HTTPS access.

Ensure that you enable HTTPS access for at least one interface, or you will not be able to configure and manage the device. |
Smart CLI and FlexConfig allows you to configure features that are not yet directly supported through Firepower Device Manager policies and settings. Firepower Threat Defense uses ASA configuration commands to implement some features. If you are a knowledgeable and expert user of ASA configuration commands, you can configure these features on the device using the following methods:

- Smart CLI—(Preferred method.) A Smart CLI template is a pre-defined template for a particular feature. All of the commands needed for the feature are provided, and you simply need to select values for variables. The system validates your selection, so that you are more likely to configure a feature correctly. If a Smart CLI template exists for the feature you want, you must use this method. In this release, you can configure OSPFv2 using the Smart CLI.

- FlexConfig—The FlexConfig policy is a collection of FlexConfig objects. The FlexConfig objects are more free-form than Smart CLI templates, and the system does no CLI, variable, or data validation. You must know ASA configuration commands and follow the ASA configuration guides to create a valid sequence of commands.

Caution Cisco strongly recommends using Smart CLI and FlexConfig only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not blacklisted. Enabling features through Smart CLI or FlexConfig may cause unintended results with other configured features.

Firepower Threat Defense REST API, and an API Explorer

You can use a REST API to programmatically interact with a Firepower Threat Defense device that you are managing locally through Firepower Device Manager. There is an API Explorer that you can use to view object models and test the various calls you can make from a client program. To open the API Explorer, log into Firepower Device Manager, and then change the path on the URL to /#/api-explorer, for example, https://ftd.example.com/#/api-explorer.

### Logging Into the System

There are two interfaces to the Firepower Threat Defense device:

**Firepower Device Manager Web Interface**

Firepower Device Manager runs in your web browser. You use this interface to configure, manage, and monitor the system.

**Command Line Interface (CLI, Console)**

Use the CLI for troubleshooting. You can also use it for initial setup instead of Firepower Device Manager.

The following topics explain how to log into these interfaces and manage your user account.
Logging Into Firepower Device Manager

Use the Firepower Device Manager to configure, manage, and monitor the system. The features that you can configure through the browser are not configurable through the command-line interface (CLI); you must use the web interface to implement your security policies.

Use a current version of Firefox, Chrome, Safari, Edge, or Internet Explorer.

Note
If you type in the wrong password and fail to log in on 3 consecutive attempts, your account is locked for 5 minutes. You must wait before trying to log in again.

Before you begin
You can log into Firepower Device Manager using the admin username only. You cannot create additional users for Firepower Device Manager access.

Procedure

Step 1
Using a browser, open the home page of the system, for example, https://ftd.example.com.

You can use any of the following addresses. You can use the IPv4 or IPv6 address or the DNS name, if you have configured one.

- The management address. By default (on most platforms), this is 192.168.45.45 on the Management interface.

- The address of a data interface that you have opened for HTTPS access. By default (on platforms), the “inside” interface allows HTTPS access, so you can connect to the default inside address 192.168.1.1. On device models where the inside interface is a bridge group, you can connect to this address through any bridge group member interface.

Tip
If your browser is not configured to recognize the server certificate, you will see a warning about an untrusted certificate. Accept the certificate as an exception, or in your trusted root certificate store.

Step 2
Enter the admin username and password, then click Login.

The default admin password is Admin123.

Your session will expire after 30 minutes of inactivity, and you will be prompted to log in again. You can log out by selecting Log Out from the user icon drop-down menu in the upper right of the page.
Logging Into the Command Line Interface (CLI)

Use the command-line interface (CLI) to set up the system and do basic system troubleshooting. You cannot configure policies through a CLI session.

To log into the CLI, do one of the following:

- Use the console cable included with the device to connect your PC to the console using a terminal emulator set for 9600 baud, 8 data bits, no parity, 1 stop bit, no flow control. See the hardware guide for your device for more information about the console cable.

  Note
  On Firepower models, the CLI on the Console port is FXOS. You can get to the FTD CLI using the connect ftd command. Use the FXOS CLI for chassis-level troubleshooting only. Use the FTD CLI for basic configuration, monitoring, and normal system troubleshooting. See the FXOS documentation for information on FXOS commands.

- For Firepower Threat Defense Virtual, open the virtual console.

- Use an SSH client to make a connection to the management IP address. You can also connect to the address on a data interface if you open the interface for SSH connections (see Configuring the Management Access List, on page 391). SSH access to data interfaces is disabled by default. Log in using the admin username (default password is Admin123) or another CLI user account.

Tips

- You can create local user accounts that can log into the CLI using the configure user add command. However, these users can log into the CLI only. They cannot log into the Firepower Device Manager web interface.

Changing Your Password

You should periodically change your password. The following procedure explains how to change the password while logged into Firepower Device Manager.

  Note
  If you are logged into the CLI, you can change your password using the configure password command. You can change the password for a different CLI user with the configure user password username command.

Procedure

Step 1 Select Profile from the user icon drop-down list in the upper right of the menu.
Setting User Profile Preferences

You can set preferences for the user interface and change your password.

Procedure

Step 1 Select Profile from the user icon drop-down list in the upper right of the menu.

Step 2 On the Profile tab, configure the following and click Save.

• Time Zone for Scheduling Tasks—Select the time zone you want to use for scheduling tasks such as backups and updates. The browser time zone is used for dashboards and events, if you set a different zone.

• Color Theme—Select the color theme you want to use in the user interface.

Step 3 On the Password tab, you can enter a new password and click Change.

Creating Local User Accounts for the FTD CLI

You can create users for CLI access on FTD devices. These accounts do not allow access to the management application, but to the CLI only. The CLI is useful for troubleshooting and monitoring purposes.

You cannot create local user accounts on more than one device at a time. Each device has its own set of unique local user CLI accounts.

Procedure

Step 1 Log into the device CLI using an account with config privileges.

The admin user account has the required privileges, but any account with config privileges will work. You can use an SSH session or the Console port.

For certain device models, the Console port puts you into the FXOS CLI. Use the connect ftd command to get to the FTD CLI.

Step 2 Create the user account.
configure user add username \{basic | config\}

You can define the user with the following privilege levels:

- **config**—Gives the user configuration access. This gives the user full administrator rights to all commands.
- **basic**—Gives the user basic access. This does not allow the user to enter configuration commands.

**Example:**

The following example adds a user account named joecool with config access rights. The password is not shown as you type it.

```plaintext
> configure user add joecool config
Enter new password for user joecool: newpassword
Confirm new password for user joecool: newpassword
> show user
Login UID Auth Access Enabled Reset Exp Warn Str Lock Max
admin 1000 Local Config Enabled No Never N/A Dis No N/A
joecool 1001 Local Config Enabled No Never N/A Dis No 5
```

**Note**  
Tell users they can change their passwords using the `configure password` command.

**Step 3**  
(Optional.) Adjust the characteristics of the account to meet your security requirements.

You can use the following commands to change the default account behavior.

- **configure user aging username max_days warn_days**
  Sets an expiration date for the user's password. Specify the maximum number of days for the password to be valid followed by the number of days before expiration the user will be warned about the upcoming expiration. Both values are 1 to 9999, but the warning days must be less than the maximum days. When you create the account, there is no expiration date for the password.

- **configure user forcereset username**
  Forces the user to change the password on the next login.

- **configure user maxfailedlogins username number**
  Sets the maximum number of consecutive failed logins you will allow before locking the account, from 1 to 9999. Use the `configure user unlock` command to unlock accounts. The default for new accounts is 5 consecutive failed logins.

- **configure user minpasswdlen username number**
  Sets a minimum password length, which can be from 1 to 127.

- **configure user strengthcheck username \{enable | disable\}**
  Enables or disables password strength checking, which requires a user to meet specific password criteria when changing their password. When a user’s password expires or if the `configure user forcereset` command is used, this requirement is automatically enabled the next time the user logs in.

**Step 4**  
Manage user accounts as necessary.

Users can get locked out of their accounts, or you might need to remove accounts or fix other issues. Use the following commands to manage the user accounts on the system.
• configure user access  username  { basic  |  config }
  Changes the privileges for a user account.

• configure user delete  username
  Deletes the specified account.

• configure user disable  username
  Disables the specified account without deleting it. The user cannot log in until you enable the account.

• configure user enable  username
  Enables the specified account.

• configure user password  username
  Changes the password for the specified user. Users should normally change their own password using the configure password command.

• configure user unlock  username
  Unlocks a user account that was locked due to exceeding the maximum number of consecutive failed login attempts.

---

### Setting Up the System

You must complete an initial configuration to make the system function correctly in your network. Successful deployment includes attaching cables correctly and configuring the addresses needed to insert the device into your network and connect it to the Internet or other upstream router. The following procedure explains the process.

**Before you begin**

Before you start the initial setup, the device includes some default settings. For details, see Default Configuration Prior to Initial Setup, on page 30.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Connect the Interfaces, on page 16</td>
</tr>
<tr>
<td>Step 2</td>
<td>Complete the Initial Configuration Using the Setup Wizard, on page 24</td>
</tr>
<tr>
<td></td>
<td>For details about the resulting configuration, see Configuration After Initial Setup, on page 32.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Configure the Wireless Access Point (ASA 5506W-X), on page 27</td>
</tr>
</tbody>
</table>
Connect the Interfaces

The default configuration assumes that certain interfaces are used for the inside and outside networks. Initial configuration will be easier to complete if you connect network cables to the interfaces based on these expectations.

The default configuration for most models is designed to let you attach your workstation directly to the inside interface. For device models where the inside interface is a bridge group, you can attach to any member interface. Alternatively, you can also directly attach your workstation to the Management port. The interfaces are on different networks, so do not try to connect any of the inside interfaces and the Management port to the same network.

Do not connect any of the inside interfaces or the Management interface to a network that has an active DHCP server. This will conflict with the DHCP servers already running on the inside interface and Management interface. If you want to use a different DHCP server for the network, disable the unwanted DHCP server after initial setup.

The following topics show how to cable the system for this topology when using the inside interfaces to configure the device.

Cabling for ASA 5506-X, 5506W-X, and 5506H-X

- Attach GigabitEthernet 1/1 to the ISP/WAN modem or other outside device. By default, the IP address is obtained using DHCP, but you can set a static address during initial configuration.
• Attach GigabitEthernet 1/2 (or another of the inside bridge group member ports) to your workstation, the one you will use to configure the device. Configure the workstation to obtain an IP address using DHCP. The workstation gets an address on the 192.168.1.0/24 network.

Note
You have a couple of other options for connecting the management workstation. You can also directly connect it to the Management port. The workstation gets an address through DHCP on the 192.168.45.0/24 network. Another option is to leave your workstation attached to a switch, and attach that switch to one of the inside ports such as GigabitEthernet1/2. However, you must ensure that no other device on the switch's network is running a DHCP server, because it will conflict with the one running on the inside bridge group, 192.168.1.1.

• Optionally, attach other endpoints or switches to the other ports in the inside bridge group. You might want to wait until you complete the initial device setup before adding endpoints. If you add switches, ensure that there are no other DHCP servers running on those networks, as this conflicts with the DHCP server running on the inside bridge group.

Cabling for ASA 5508-X and 5516-X

Figure 3: Cabling the ASA 5508-X or 5516-X

• Connect your management computer to either of the following interfaces:
  • GigabitEthernet 1/2—Connect your management computer directly to GigabitEthernet 1/2 for initial configuration, or connect GigabitEthernet 1/2 to your inside network. GigabitEthernet 1/2 has a default IP address (192.168.1.1) and also runs a DHCP server to provide IP addresses to clients (including the management computer), so make sure these settings do not conflict with any existing inside network settings.
  • Management 1/1—Connect your management computer directly to Management 1/1 for initial configuration, or connect Management 1/1 to your management network. Management 1/1 has a default IP address (192.168.45.45) and also runs a DHCP server to provide IP addresses to clients (including the management computer), so make sure these settings do not conflict with any existing inside network settings.

If you need to change the Management 1/1 IP address from the default, you must also cable your management PC to the console port (cabling not shown). See (Optional) Change Management Network Settings at the CLI, on page 23.
You can later configure FDM management access from other interfaces.

- Connect the outside network to the GigabitEthernet1/1 interface.
- Connect other networks to the remaining interfaces.

Figure 4: Cabling the ASA 5500-X

- Connect your management computer to either of the following interfaces:
• GigabitEthernet 0/1—Connect your management computer directly to GigabitEthernet 0/1 for initial configuration, or connect GigabitEthernet 0/1 to your inside network. GigabitEthernet 0/1 has a default IP address (192.168.1.1) and also runs a DHCP server to provide IP addresses to clients (including the management computer), so make sure these settings do not conflict with any existing inside network settings.

• Management 0/0—Connect your management computer directly to Management 0/0 for initial configuration, or connect Management 0/0 to your management network. Management 0/0 has a default IP address (192.168.45.45) and also runs a DHCP server to provide IP addresses to clients (including the management computer), so make sure these settings do not conflict with any existing inside network settings.

If you need to change the Management 0/0 IP address from the default, you must also cable your management PC to the console port (cabling not shown). See (Optional) Change Management Network Settings at the CLI, on page 23.

You can later configure FDM management access from other interfaces.

• Connect the outside network to the GigabitEthernet 0/0 interface.

• Connect other networks to the remaining interfaces.

• Attach GigabitEthernet 0/0 to the ISP/WAN modem or other outside device. By default, the IP address is obtained using DHCP, but you can set a static address during initial configuration.

• Attach GigabitEthernet 0/1 to your workstation, the one you will use to configure the device. Configure the workstation to obtain an IP address using DHCP. The workstation gets an address on the 192.168.1.0/24 network.

---

Note

You have a couple of other options for connecting the management workstation. You can also directly connect it to the Management port. The workstation gets an address through DHCP on the 192.168.45.0/24 network. Another option is to leave your workstation attached to a switch, and attach that switch to GigabitEthernet0/1. However, you must ensure that no other device on the switch's network is running a DHCP server, because it will conflict with the one running on the inside interface, 192.168.1.1.
Cabling for Firepower 2100

Figure 5: Cabling the Firepower 2100

- Connect your management computer to either of the following interfaces:
  - Ethernet 1/2—Connect your management computer directly to Ethernet 1/2 for initial configuration, or connect Ethernet 1/2 to your inside network. Ethernet 1/2 has a default IP address (192.168.1.1) and also runs a DHCP server to provide IP addresses to clients (including the management computer), so make sure these settings do not conflict with any existing inside network settings.
  - Management 1/1 (labeled MGMT)—Connect your management computer directly to Management 1/1 for initial configuration, or connect Management 1/1 to your management network. Management 1/1 has a default IP address (192.168.45.45) and also runs a DHCP server to provide IP addresses to clients (including the management computer), so make sure these settings do not conflict with any existing inside network settings.

If you need to change the Management 1/1 IP address from the default, you must also cable your management PC to the console port (cabling not shown). See (Optional) Change Management Network Settings at the CLI, on page 23.

You can later configure FDM management access from other interfaces.

- Connect the outside network to the Ethernet1/1 interface (labeled WAN).
- Connect other networks to the remaining interfaces.

Virtual Cabling for Firepower Threat Defense Virtual

The Firepower Threat Defense Virtual default configuration puts the management interface and inside interface on the same subnet. You must have Internet connectivity on the management interface in order to use Smart Licensing and to obtain updates to system databases.
Thus, the default configuration is designed so that you can connect both the Management0/0 and GigabitEthernet0/1 (inside) to the same network on the virtual switch. The default management address uses the inside IP address as the gateway. Thus, the management interface routes through the inside interface, then through the outside interface, to get to the Internet.

You also have the option of attaching Management0/0 to a different subnet than the one used for the inside interface, as long as you use a network that has access to the Internet. Ensure that you configure the management interface IP address and gateway appropriately for the network.

Note that the management interface IP configuration is defined on Device > System Settings > Management Interface. It is not the same as the IP address for the Management0/0 (diagnostic) interface listed on Device > Interfaces > View Configuration.

---

**How VMware Network Adapters and Interfaces Map to Firepower Threat Defense Physical Interfaces**

You can configure up to 10 interfaces for a VMware Firepower Threat Defense Virtual device. You must configure a minimum of 4 interfaces.

Ensure that the Management0-0 source network is associated to a VM network that can access the Internet. This is required so that the system can contact the Cisco Smart Software Manager and also to download system database updates.

You assign the networks when you install the OVF. As long as you configure an interface, you can later change the virtual network through the VMware Client. However, if you need to add a new interface, the process is more cumbersome, as explained in Add Interfaces to Firepower Threat Defense Virtual, on page 151.

The following table explains how the VMware network adapter and source interface map to the Firepower Threat Defense Virtual physical interface names. For additional interfaces, the naming follows the same pattern, increasing the relevant numbers by one. All additional interfaces are data interfaces. For more information on assigning virtual networks to virtual machines, see the VMware online help.

*Table 2: Source to Destination Network Mapping*

<table>
<thead>
<tr>
<th>Network Adapter</th>
<th>Source Network</th>
<th>Destination Network (Physical Interface Name)</th>

</table>
Cabling for ISA 3000

*Figure 6: ISA 3000*

- Attach GigabitEthernet 1/1 to the ISP/WAN modem or other outside device. By default, the IP address is obtained using DHCP, but you can set a static address during initial configuration.

- Attach GigabitEthernet 1/2 (or another of the inside bridge group member ports) to your workstation, the one you will use to configure the device. Configure the workstation to obtain an IP address using DHCP. The workstation gets an address on the 192.168.1.0/24 network.

  **Note**

  You have a couple of other options for connecting the management workstation. You can also directly connect it to the Management port. The workstation gets an address through DHCP on the 192.168.45.0/24 network. Another option is to leave your workstation attached to a switch, and attach that switch to one of the inside ports such as GigabitEthernet1/2. However, you must ensure that no other device on the switch's network is running a DHCP server, because it will conflict with the one running on the inside bridge group, 192.168.1.1.

- Optionally, attach other endpoints or switches to the other ports in the inside bridge group. You might want to wait until you complete the initial device setup before adding endpoints. If you add switches, ensure that there are no other DHCP servers running on those networks, as this conflicts with the DHCP server running on the inside bridge group.
(Optional) Change Management Network Settings at the CLI

If cannot use the default IP address (for example, you are adding your device to an existing network), then you can connect to the console port and perform initial setup at the CLI, including setting the Management IP address, gateway, and other basic networking settings. You can only configure the Management interface settings; you must configure data interface settings in FDM.

Note
You cannot repeat the CLI setup script unless you clear the configuration; for example, by reimaging. All of these settings can be changed later at the CLI using `configure network` commands. See the FTD command reference.

Procedure

Step 1
Connect to the FTD console port. See Logging Into the Command Line Interface (CLI), on page 12 for more information.

Step 2
Log in with the username `admin` and the password `Admin123`.

Step 3
The first time you log in, you are prompted to accept the End User License Agreement (EULA) and to change the admin password. You are then presented with the CLI setup script. Defaults or previously-entered values appear in brackets. To accept previously entered values, press Enter.

See the following guidelines:

- **Enter the IPv4 default gateway for the management interface**—Enter either `data-interfaces` or the IP address of the gateway router. The `data-interfaces` setting sends outgoing management traffic over the backplane to exit a data interface. This setting is useful if you do not have a separate Management network that can access the internet. Traffic originating on the Management interface includes license registration and database updates that require internet access. If you use `data-interfaces`, you can still use FDM on the Management interface if you are directly-connected to the Management network, but for remote management on Management, you need to enter the IP address of a gateway router on the Management network. Note that FDM management on data interfaces is not affected by this setting.

- **If your networking information has changed, you will need to reconnect**—If you are connected with SSH to the default IP address but you change the IP address at initial setup, you will be disconnected. Reconnect with the new IP address and password. Console connections are not affected. Note also that the DHCP server on Management will be disabled if you change the IP address.

- **Manage the device locally? (yes/no) [yes]**—Enter yes to use FDM.

Example:

You must accept the EULA to continue.
Press <ENTER> to display the EULA:
End User License Agreement
[...]

Please enter 'YES' or press <ENTER> to AGREE to the EULA:

System initialization in progress. Please stand by.
You must change the password for 'admin' to continue.
Enter new password: ********
Confirm new password: ********
You must configure the network to continue.
You must configure at least one of IPv4 or IPv6.
Do you want to configure IPv4? (y/n) [y]:
Do you want to configure IPv6? (y/n) [n]:
Configure IPv4 via DHCP or manually? (dhcp/manual) [manual]:
Enter an IPv4 address for the management interface [192.168.45.45]: 10.10.10.15
Enter an IPv4 netmask for the management interface [255.255.255.0]: 255.255.255.192
Enter the IPv4 default gateway for the management interface [data-interfaces]: 10.10.10.1
Enter a fully qualified hostname for this system [firepower]: 5516X-1.cisco.com
Enter a comma-separated list of DNS servers or 'none' [208.67.222.222,208.67.220.220]:
Enter a comma-separated list of search domains or 'none' []:
If your networking information has changed, you will need to reconnect.
DHCP Server Disabled
The DHCP server has been disabled. You may re-enable with configure network ipv4
dhcp-server-enable
For HTTP Proxy configuration, run 'configure network http-proxy'

Manage the device locally? (yes/no) [yes]: yes

> Step 4 Log into FDM on the new Management IP address.

Complete the Initial Configuration Using the Setup Wizard

When you initially log into Firepower Device Manager, you are taken through the device setup wizard to complete the initial system configuration.

Before you begin

Ensure that you connect a data interface to your gateway device, for example, a cable modem or router. For edge deployments, this would be your Internet-facing gateway. For data center deployments, this would be a back-bone router. Use the default “outside” interface for your model (see Connect the Interfaces, on page 16 and Default Configuration Prior to Initial Setup, on page 30).

Then, connect your workstation to the “inside” interface for your hardware model. For models where the inside interface is a bridge group, you can connect to any bridge group member interface, which is any data port other than the outside interface. Alternatively, you can connect to the Management/Diagnostic physical interface. For Firepower Threat Defense Virtual, simply ensure that you have connectivity to the management IP address.

(Except for Firepower Threat Defense Virtual, which requires connectivity to the Internet from the management IP address.) The Management/Diagnostic physical interface does not need to be connected to a network. By default, the system obtains system licensing and database and other updates through the data interfaces, typically the outside interface, that connect to the Internet. If you instead want to use a separate management network, you can connect the Management/Diagnostic interface to a network and configure a separate management gateway after you complete initial setup.

To change the Management interface network settings if you cannot access the default IP address, see (Optional) Change Management Network Settings at the CLI, on page 23.
Procedure

Step 1  Log into Firepower Device Manager.
   a) Assuming you did not go through initial configuration in the CLI, open Firepower Device Manager at
      https://ip-address, where the address is one of the following.
      • If you are connected to the inside interface, or one of the inside bridge group data interfaces for
        models that have a default inside bridge group: https://192.168.1.1.
      • (Required for Firepower Threat Defense Virtual.) If you are connected to the Management physical
        interface: https://192.168.45.45.
   b) Log in with the username admin, password Admin123.

Step 2  If this is the first time logging into the system, and you did not use the CLI setup wizard, you are prompted
        to read and accept the End User License Agreement and change the admin password.
        You must complete these steps to continue.

Step 3  Configure the following options for the outside and management interfaces and click Next.
        Caution  Your settings are deployed to the device when you click Next. The interface will be named “outside”
        and it will be added to the “outside_zone” security zone. Ensure that your settings are correct.

Outside Interface
   • Configure IPv4—The IPv4 address for the outside interface. You can use DHCP or manually enter a
     static IP address, subnet mask, and gateway. You can also select Off to not configure an IPv4 address.
     Do not configure an IP address on the same subnet as the default inside address (see Default Configuration
     Prior to Initial Setup, on page 30), either statically or through DHCP.
   • Configure IPv6—The IPv6 address for the outside interface. You can use DHCP or manually enter a
     static IP address, prefix, and gateway. You can also select Off to not configure an IPv6 address.

Management Interface
   • DNS Servers—The DNS server for the system's management address. Enter one or more addresses of
     DNS servers for name resolution. The default is the OpenDNS public DNS servers. If you edit the fields
     and want to return to the default, click Use OpenDNS to reload the appropriate IP addresses into the
     fields. Your ISP might require that you use specific DNS servers. If after completing the wizard, you
     find that DNS resolution is not working, see Troubleshooting DNS for the Management Interface, on
     page 419.
   • Firewall Hostname—The hostname for the system's management address.

Step 4  Configure the system time settings and click Next.
   • Time Zone—Select the time zone for the system.
   • NTP Time Server—Select whether to use the default NTP servers or to manually enter the addresses
     of your NTP servers. You can add multiple servers to provide backups.

Step 5  Configure the smart licenses for the system.
        You must have a smart license account to obtain and apply the licenses that the system requires. Initially, you
        can use the 90-day evaluation license and set up smart licensing later.
To register the device now, click the link to log into your Smart Software Manager account, generate a new token, and copy the token into the edit box.

If you do not want to register the device yet, select the evaluation mode option. The evaluation period lasts up to 90 days. To later register the device and obtain smart licenses, click Device, then click the link in the Smart Licenses group.

**Step 6**

Click Finish.

---

**What to do next**

- If you want to use features covered by optional licenses, such as category-based URL filtering, intrusion inspection, or malware prevention, enable the required licenses. See Enabling or Disabling Optional Licenses, on page 84.

- If this is a new system, the other interfaces on device models that have a default inside bridge group are ready to use as members of the inside bridge group. You can connect end points directly to the interfaces. For models that have a single default physical interface, you can connect the other data interfaces to distinct networks and configure the interfaces. For bridge group member interfaces, you can also remove them from the bridge group and configure additional unique networks. For information on configuring interfaces, see How to Add a Subnet, on page 72 and Interfaces, on page 133.

- If you are managing the device through the inside interface or bridge group member interface, and you want to open CLI sessions through the inside interface, open the inside interface or bridge group to SSH connections. See Configuring the Management Access List, on page 391.

- Go through the use cases to learn how to use the product. See Use Cases for Firepower Threat Defense, on page 43.

---

**What to Do if You Do Not Obtain an IP Address for the Outside Interface**

The default device configuration includes a static IPv4 address for the inside interface. You cannot change this address through the initial device setup wizard, although you can change it afterwards.

The default inside IP address might conflict with other networks attached to the device. This is especially true if you use DHCP on the outside interface to obtain an address from your Internet Service Provider (ISP). Some ISPs use the same subnet as the inside network as the address pool. Because you cannot have two data interfaces with addresses on the same subnet, conflicting addresses from the ISP cannot be configured on the outside interface.

If there is a conflict between the inside static IP address and the DHCP-provided address on the outside interface, the connection diagram should show the outside interface as administratively UP, but with no IPv4 address.

The setup wizard will complete successfully in this case, and all the default NAT, access, and other policies and settings will be configured. Simply follow the procedure below to eliminate the conflict.

**Before you begin**

Verify that you have a healthy connection to the ISP. Although a subnet conflict will prevent you from getting an address on the outside interface, you will also fail to get one if you simply do not have a link to the ISP.
Procedure

**Step 1** Click **Device**, then click the link in the **Interfaces** summary.

**Step 2** Mouse over the **Actions** column for the inside interface and click the edit icon (etheus).

**Step 3** On the **IPv4 Address** tab, enter a static address on a unique subnet, for example, 192.168.2.1/24 or 192.168.46.1/24. Note that the default management address is 192.168.45.45/24, so do not use that subnet.

You also have the option to use DHCP to obtain an address if you have a DHCP server already running on the inside network. However, you must first click **Delete** in the **DHCP SERVER IS DEFINED FOR THIS INTERFACE** group to remove the DHCP server from the interface.

**Step 4** In the **DHCP SERVER IS DEFINED FOR THIS INTERFACE** area, click **Edit** and change the DHCP pool to a range on the new subnet, for example, 192.168.2.5-192.168.2.254.

**Step 5** Click **OK** to save the interface changes.

**Step 6** Click the **Deploy** button in the menu to deploy your changes.

**Step 7** Click **Deploy Now**.

After deployment completes, the connection graphic should show that the outside interface now has an IP address. Use a client on the inside network to verify you have connectivity to the Internet or other upstream network.

---

**Configure the Wireless Access Point (ASA 5506W-X)**

The ASA 5506W-X includes a Cisco Aironet 702i wireless access point integrated into the device. The wireless access point is disabled by default. Connect to the access point web interface so that you can enable the wireless radios and configure the SSID and security settings.

The access point connects internally over the GigabitEthernet1/9 interface. All Wi-Fi clients belong to the GigabitEthernet1/9 network. Your security policy determines how the Wi-Fi network can access any networks on other interfaces. The access point does not contain any external interfaces or switch ports.

The following procedure explains how to configure the access point. The procedure assumes that you completed the device setup wizard. If you instead manually configured the device, you might need to adjust the steps based on your configuration.

For more information, see the following manuals:

- For details about using the wireless LAN controller, see the [Cisco Wireless LAN Controller Software documentation](#).
- For details about the wireless access point hardware and software, see the [Cisco Aironet 700 Series documentation](#).
Before you begin

If you are unable to reach the access point, and the FTD device has the suggested configuration, and other networking issues are not found, then you may want to restore the access point default configuration. You must access the FTD CLI (connect to the console port, or configure SSH access). From the FTD CLI, enter the following commands.

```
> system support diagnostic-cli
Attaching to Diagnostic CLI ... Press 'Ctrl+a then d' to detach.
Type help or '?' for a list of available commands.

firepower> enable
Password: <press enter, by default, the password is blank>
firepower# hw-module module wlan recover configuration
```

If you need to troubleshoot the access point further, connect to the access point CLI using the `session wlan console` command.

Procedure

---

**Step 1** Configure and enable the wireless interface, GigabitEthernet1/9.

a) Click **Device**, then click the link in the **Interfaces** group to open the list of interfaces.

b) Click the edit icon ( chỉnh sửa) for the GigabitEthernet1/9 interface.

c) Configure the following options.

- **Interface Name**—Enter a name for the interface, for example, `wifi`.
- **Status**—Click the slider to enable the interface.
- **IPv4 Address**—Select **Static** for the address type, then enter an address and subnet mask. For example, 192.168.10.1/24.

d) Click **Save**.

**Step 2** Add the Wi-Fi interface to the same security zone as the inside interfaces.

The device setup wizard puts the members of the **inside** bridge group in a security zone named **inside_zone**. The Wi-Fi interface needs to be in the same zone so that you can reach the access point web interface (made possible by the default **Inside_Inside_Rule** access rule).

a) Click **Objects** in the menu, then select **Security Zones** from the table of contents.

b) Click the edit icon ( chỉnh sửa) for **inside_zone**.

c) Click + under **Interfaces** and select the **wifi** interface.

**Step 3** Verify that there is an access control rule to allow traffic between interfaces in the **inside_zone** security zone.

The device setup wizard creates a rule to allow traffic to flow from the **inside_zone** to the **outside_zone**, which allows inside users to get to the Internet.

The wizard also creates a rule to allow traffic to flow between the **inside_zone** and **inside_zone**, so that internal hosts can reach each other.

By adding the **wifi** interface to **inside_zone**, Wi-Fi users are also included in both of these rules, so that they can reach the Internet and other internal users.
If you did not complete the wizard, these rules might not exist. Because the default action is to block all traffic, you must create these rules. The following procedure explains how to create a rule to enable traffic between the interfaces in the inside_zone security zone.

a) Click Policies in the menu.
b) Click + above the Access Control table to add a rule.
c) Configure at least the following options in the rule.
   • Title—Enter a name for the rule. For example, Inside_Inside.
   • Action—Either Allow or Trust.
   • Source/Destination > Source Zones—Select inside_zone.
   • Source/Destination > Destination Zones—Select inside_zone.

d) Click OK.

**Step 4**
Configure the DHCP server on the wireless interface.

The DHCP server supplies IP addresses to devices that connect to the access point. It also supplies an address to the access point itself.

a) Click Device.
b) Click System Settings > DHCP Server.
c) Click the DHCP Servers tab.
d) Click + above the DHCP server table.
e) Configure the following DHCP server properties.
   • Enable DHCP Server—Click the slider to enable the DHCP server.
   • Interface—Select the wifi interface.
   • Address Pool—Enter the address pool for DHCP clients. For example, if you used the example address for the wireless interface, the pool would be 192.168.10.2-192.168.10.254. The pool must be on the same subnet as the IP address for the interface, and it cannot include the address of the interface or the broadcast address.

f) Click OK.

**Step 5**
Click the Deploy button in the menu, then click the Deploy Now button, to deploy your changes to the device.

Wait until the deployment finishes before you continue.

**Step 6**
Configure the wireless access point.

The wireless access point obtains its address from the DHCP pool defined for the wireless interface. It should get the first address in the pool. If you used the example addresses, this is 192.168.10.2. (Try the next address in the pool if the first one does not work.)

a) Use a new browser window to go to the wireless access point IP address, for example, http://192.168.10.2.

   The access point web interface should appear.

   You must be on the inside network, or a network that can route to it, to open this address.
b) Log in with the username cisco and password Cisco.

c) On the left, click Easy Setup > Network Configuration.

d) In the Radio Configuration area, for each of the Radio 2.4GHz and Radio 5GHz sections, set at least the following parameters and click Apply for each section.

- **SSID**—The Service Set Identifier. This is the name of the wireless network. Users will see this name when selecting a wireless network for their Wi-Fi connection.

- **Broadcast SSID in Beacon**—Select this option.

- **Universal Admin Mode: Disable**.

- **Security**—Select whichever security option you want to use.

**Step 7** While in the wireless access point web interface, enable the radios.

a) On the left, click Summary, and then on the main page under Network Interfaces, click the link for the 2.4 GHz radio.

b) Click the Settings tab.

c) For the Enable Radio setting, click the Enable radio button, and then click Apply at the bottom of the page.

d) Repeat the process for the 5 GHz radio.

---

### Default Configuration Prior to Initial Setup

Before you initially configure the Firepower Threat Defense device using the local manager (Firepower Device Manager), the device includes the following default configuration.

For many models, this configuration assumes that you open the Firepower Device Manager through the inside interface, typically by plugging your computer directly into the interface, and use the DHCP server defined on the inside interface to supply your computer with an IP address. Alternatively, you can plug your computer into the Management/Diagnostic physical interface and use DHCP to obtain an address. However, some models have different default configurations and management requirements. See the table below for details.

You can pre-configure many of these settings using the CLI setup ((Optional) Change Management Network Settings at the CLI, on page 23) before you perform setup using the FDM wizard.

### Default Configuration Settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Default</th>
<th>Can be changed during FDM initial configuration?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Password for admin user.</td>
<td>Admin123</td>
<td>Yes. You must change the default password.</td>
</tr>
<tr>
<td>Management IP address.</td>
<td>192.168.45.45</td>
<td>No.</td>
</tr>
</tbody>
</table>
### Default Configuration Prior to Initial Setup

<table>
<thead>
<tr>
<th>Setting</th>
<th>Default</th>
<th>Can be changed during FDM initial configuration?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management gateway.</td>
<td>The data interfaces on the device. Typically the outside interface becomes the route to the Internet. This gateway works for from-the-device traffic only. Firepower Threat Defense Virtual: 192.168.45.1</td>
<td>No.</td>
</tr>
<tr>
<td>DNS servers for the management interface.</td>
<td>The OpenDNS public DNS servers, 208.67.220.220 and 208.67.222.222.</td>
<td>Yes</td>
</tr>
<tr>
<td>DHCP auto-configuration for inside clients. (Auto-configuration supplies clients with addresses for WINS and DNS servers.)</td>
<td>Enabled on outside interface.</td>
<td>Yes, but indirectly. If you configure a static IPv4 address for the outside interface, DHCP server auto-configuration is disabled.</td>
</tr>
<tr>
<td>Outside interface IP address.</td>
<td>Obtained through DHCP from Internet Service Provider (ISP) or upstream router.</td>
<td>Yes.</td>
</tr>
</tbody>
</table>

### Default Interfaces by Device Model

You cannot select different inside and outside interfaces during initial configuration. To change the interface assignments after configuration, edit the interface and DHCP settings. You must remove an interface from the bridge group before you can configure it as a non-switched interface.

<table>
<thead>
<tr>
<th>Firepower Threat Defense device</th>
<th>Outside Interface</th>
<th>Inside Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASA 5506-X</td>
<td>GigabitEthernet1/1</td>
<td>BVII1, which contains all other data interfaces except the outside interface, and for the 5506W-X, the wireless interface GigabitEthernet1/9.</td>
</tr>
<tr>
<td>ASA 5506H-X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ASA 5506W-X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Configuration After Initial Setup

After you complete the setup wizard, the device configuration will include the following settings. The table shows whether a particular setting is something you explicitly chose or whether it was defined for you based on your other selections. Validate any "implied" configurations and edit them if they do not serve your needs.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Configuration</th>
<th>Explicit, implied, or default configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Password for admin user.</td>
<td>Whatever you entered.</td>
<td>Explicit.</td>
</tr>
<tr>
<td>Management IP address.</td>
<td>192.168.45.45</td>
<td>Default.</td>
</tr>
<tr>
<td>Management gateway.</td>
<td>The data interfaces on the device. Typically the outside interface becomes the route to the Internet. The management gateway works for from-the-device traffic only. Firepower Threat Defense Virtual: 192.168.45.1</td>
<td>Default.</td>
</tr>
<tr>
<td>DNS servers for the management interface.</td>
<td>Whatever you entered.</td>
<td>Explicit.</td>
</tr>
<tr>
<td>Management hostname.</td>
<td>firepower or whatever you entered.</td>
<td>Explicit.</td>
</tr>
<tr>
<td>Setting</td>
<td>Configuration</td>
<td>Explicit, implied, or default configuration</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>Management access through data interfaces.</td>
<td>A data interface management access list rule allows HTTPS access through the inside interface. For models that have an inside bridge group, this covers all member interfaces of the inside bridge group. SSH connections are not allowed. Both IPv4 and IPv6 connections are allowed. Firepower Threat Defense Virtual: No data interfaces have default management access rules.</td>
<td>Implied.</td>
</tr>
<tr>
<td>System time.</td>
<td>The time zone and NTP servers you selected.</td>
<td>Explicit.</td>
</tr>
<tr>
<td>Smart license.</td>
<td>Either registered with a base license, or the evaluation period activated, whichever you selected. Subscription licenses are not enabled. Go to the smart licensing page to enable them.</td>
<td>Explicit.</td>
</tr>
<tr>
<td>Inside interface IP address.</td>
<td>192.168.1.24</td>
<td>Default.</td>
</tr>
<tr>
<td></td>
<td>Firepower Threat Defense Virtual: 192.168.45.1/24</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Firepower Threat Defense Virtual: The address pool on the inside interface is 192.168.45.46 - 192.168.45.254.</td>
<td></td>
</tr>
<tr>
<td>DHCP auto-configuration for inside clients.</td>
<td>Enabled on outside interface if you use DHCP to obtain the outside interface IPv4 address.</td>
<td>Explicit, but indirectly.</td>
</tr>
<tr>
<td>(Auto-configuration supplies clients with addresses for WINS and DNS servers.)</td>
<td>If you use static addressing, DHCP auto-configuration is disabled.</td>
<td></td>
</tr>
</tbody>
</table>
| Data interface configuration.               | • ASA 5506-X, ISA 3000—All data interfaces (such as GigabitEthernet1/2) except the outside interface are enabled and part of the inside bridge group. You can plug end points or switches into these ports and obtain addresses from the DHCP server for the inside interface. These interfaces are named inside_1, inside_2, and so forth.  
• All other models—The outside and inside interfaces are the only ones configured and enabled. All other data interfaces are disabled. | Default.                                    |
| Outside physical interface and IP address.  | The default outside port based on the device model. See Default Configuration Prior to Initial Setup, on page 30.                                                                                               | Interface is Default.                        |
|                                            | The IP address is obtained by DHCP, or it is a static address as entered (IPv4, IPv6, or both).                                                                                                             | Addressing is Explicit.                     |
### Configuration Basics

The following topics explain the basic methods for configuring the device.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Configuration</th>
<th>Explicit, implied, or default configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static routes.</td>
<td>If you configure a static IPv4 or IPv6 address for the outside interface, a static default route is configured for IPv4/IPv6 as appropriate, pointing to the gateway you defined for that address type. If you select DHCP, the default route is obtained from the DHCP server. Network objects are also created for the gateway and the &quot;any&quot; address, that is, 0.0.0.0/0 for IPv4, ::/0 for IPv6.</td>
<td>Implied.</td>
</tr>
<tr>
<td>Security zones.</td>
<td><strong>inside_zone</strong>, containing the inside interface. For models that have an inside bridge group, the zone contains all members of the inside bridge group interface. <strong>outside_zone</strong>, containing the outside interface. (You can edit these zones to add other interfaces, or create your own zones.)</td>
<td>Implied.</td>
</tr>
<tr>
<td>Access control policy.</td>
<td>A rule trusting all traffic from the inside_zone to the outside_zone. This allows without inspection all traffic from users inside your network to get outside, and all return traffic for those connections. For models that have an inside bridge group, a second rule trusting all traffic between the interfaces in the inside_zone. This allows without inspection all traffic between users on your inside network. The default action for any other traffic is to block it. This prevents any traffic initiated from outside to enter your network.</td>
<td>Implied.</td>
</tr>
<tr>
<td>NAT</td>
<td>(Models that do not have an inside bridge group.) An interface dynamic PAT rule translates the source address for any IPv4 traffic destined to the outside interface to a unique port on the outside interface's IP address. (Models that have an inside bridge group.) For each member of the inside bridge group, an interface dynamic PAT rule translates the source address for any IPv4 traffic destined to the outside interface to a unique port on the outside interface's IP address. These appear in the NAT rule table and you can edit them later if desired. There are additional hidden PAT rules to enable HTTPS access through the inside interfaces, and routing through the data interfaces for the management address. These do not appear in the NAT table, but you will see them if you use the <code>show nat</code> command in the CLI.</td>
<td>Implied.</td>
</tr>
</tbody>
</table>
Configuring the Device

When you initially log into Firepower Device Manager, you are guided through a setup wizard to help you configure basic settings. Once you complete the wizard, use the following method to configure other features and to manage the device configuration.

If you have trouble distinguishing items visually, select a different color scheme in the user profile. Select Profile from the user icon drop-down menu in the upper right of the page.

Procedure

Step 1
Click Device to get to the Device Summary.

The dashboard shows a visual status for the device, including enabled interfaces and whether key settings are configured (colored green) or still need to be configured. For more information, see Viewing Interface and Management Status, on page 39.

Above the status image is a summary of the device model, software version, VDB (System and Vulnerability Database) version, and the last time intrusion rules were updated.

Below the image are groups for the various features you can configure, with summaries of the configurations in each group, and actions you can take to manage the system configuration.

Step 2
Click the links in each group to configure the settings or perform the actions.

Following is a summary of the groups:

- **Interface**—You should have at least two data interfaces configured in addition to the management interface. See Interfaces, on page 133.

- **Routing**—The routing configuration. You must define a default route. Other routes might be necessary depending on your configuration. See Routing, on page 155.

- **Updates**—Geolocation, intrusion rule, and vulnerability database updates, and system software upgrades. Set up a regular update schedule to ensure that you have the latest database updates if you use those features. You can also go to this page if you need to download an update before the regularly schedule update occurs. See Updating System Databases and Feeds, on page 403.

- **System Settings**—This group includes a variety of settings. Some are basic settings that you would configure when you initially set up the device and then rarely change. See System Settings, on page 391.

- **Smart License**—Shows the current state of the system licenses. You must install the appropriate licenses to use the system. Some features require additional licenses. See Licensing the System, on page 79.

- **Backup and Restore**—Back up the system configuration or restore a previous backup. See Backing Up and Restoring the System, on page 408.

- **Troubleshoot**—Generate a troubleshooting file at the request of the Cisco Technical Assistance Center. See Creating a Troubleshooting File, on page 423.

- **Site-to-Site VPN**—The site-to-site virtual private network (VPN) connections between this device and remote devices. See Managing Site-to-Site VPNs, on page 327.
Remote Access VPN—The remote access virtual private network (VPN) configuration that allows outside clients to connect to your inside network. See Configuring Remote Access VPN, on page 356.

Advanced Configuration—Use FlexConfig and Smart CLI to configure features that you otherwise cannot configure using Firepower Device Manager. See Advanced Configuration, on page 431.

Step 3 Click the Deploy button in the menu to deploy your changes.

Changes are not active on the device until you deploy them. See Deploying Your Changes, on page 37.

What to do next
Click Policies in the main menu and configure the security policy for the system. You can also click Objects to configure the objects needed in those policies.

Configuring Security Policies
Use the security policies to implement your organization’s acceptable use policy and to protect your network from intrusions and other threats.

Procedure

Step 1 Click Policies.

The Security Policies page shows the general flow of a connection through the system, and the order in which security policies are applied.

Step 2 Click the name of a policy and configure it.

You might not need to configure each policy type, although you must always have an access control policy. Following is a summary of the policies:

• SSL Decryption—If you want to inspect encrypted connections (such as HTTPS) for intrusions, malware, and so forth, you must decrypt the connections. Use the SSL decryption policy to determine which connections need to be decrypted. The system re-encrypts the connection after inspecting it. See Configuring SSL Decryption Policies, on page 171.

• Identity—If you want to correlate network activity to individual users, or control network access based on user or user group membership, use the identity policy to determine the user associated with a given source IP address. See Configuring Identity Policies, on page 188.

• Security Intelligence—Use the Security Intelligence policy to quickly drop connections from or to blacklisted IP addresses or URLs. By blacklisting known bad sites, you do not need to account for them in your access control policy. Cisco provides regularly updated feeds of known bad addresses and URLs so that the Security Intelligence blacklist updates dynamically. Using feeds, you do not need to edit the policy to add or remove items in the blacklist. See Configuring Security Intelligence, on page 199.
• **NAT** (Network Address Translation)—Use the NAT policy to convert internal IP addresses to externally routeable addresses. See *Configure NAT*, on page 246.

• **Access Control**—Use the access control policy to determine which connections are allowed on the network. You can filter by security zone, IP address, protocol, port, application, URL, user or user group. You also apply intrusion and file (malware) policies using access control rules. Use this policy to implement URL filtering. See *Configuring the Access Control Policy*, on page 210.

• **Intrusion**—Use the intrusion policies to inspect for known threats. Although you apply intrusion policies using access control rules, you can edit the intrusion policies to selectively enable or disable specific intrusion rules. See *Managing Intrusion Policies*, on page 230.

**Step 3**

Click the **Deploy** button in the menu to deploy your changes.

Changes are not active on the device until you deploy them. See *Deploying Your Changes*, on page 37.

---

**Deploying Your Changes**

When you update a policy or setting, the change is not immediately applied to the device. There is a two step process for making configuration changes:

1. Make your changes.
2. Deploy your changes.

This process gives you the opportunity to make a group of related changes without forcing you to run a device in a “partially configured” manner. In most cases, the deployment includes just your changes. However, if necessary, the system will reapply the entire configuration, which might be disruptive to your network. In addition, some changes require inspection engines to restart, with traffic dropping during the restart. Thus, consider deploying changes when potential disruptions will have the least impact.

---

**Note**

If the deployment job fails, the system must roll back any partial changes to the previous configuration. Rollback includes clearing the data plane configuration and redeploying the previous version. This will disrupt traffic until the rollback completes.

---

**Caution**

The Firepower Threat Defense device using the Firepower Device Manager drops traffic when the inspection engines are busy because of a software resource issue, or down because a configuration requires the engines to restart during configuration deployment. For detailed information on changes that require a restart, see *Configuration Changes that Restart Inspection Engines*, on page 38.
**Procedure**

**Step 1**
Click the **Deploy Changes** icon in the upper right of the web page.

The icon is highlighted with a dot when there are undeployed changes.

The Deployment Summary page opens. The window shows a list of previous deployments with summary information on the changes (“modified objects”), when the deployment was initiated and completed, and the status of each deployment.

If the deployment requires that inspection engines be restarted, the page includes a message that provides detail on what changed that requires a restart. If momentary traffic loss at this time would be unacceptable, close the dialog box and wait until a better time to deploy changes.

If the icon is not highlighted, you can still click it to see the results of previous deployment jobs.

**Step 2**
Click **Deploy Now**.

---

**Configuration Changes that Restart Inspection Engines**

Any of the following configurations or actions restart inspection engines when you deploy configuration changes.

**Caution**

When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations requires inspection engines to restart, which interrupts traffic inspection and drops traffic.

**Deployment**

Some changes require that inspection engines be restarted, which will result in momentary traffic loss. Following are the changes that require inspection engine restart:

- SSL decryption policy is enabled or disabled.
- The MTU changed on one or more physical interfaces (but not subinterfaces).
- You add or remove a file policy on an access control rule.
- The rule database was updated.
- The VDB was updated.

In addition, some packets might be dropped during deployment if the Snort process is busy, with the total CPU utilization exceeding 60%. You can check the current CPU utilization for Snort using the `show asp inspect-dp snort` command.
System Database Updates

If you download an update to the Rules database or VDB, you must deploy the update for it to become active. This deployment might restart inspection engines. When you manually download an update, or schedule an update, you can indicate whether the system should automatically deploy changes after the download is complete. If you do not have the system automatically deploy the update, the update is applied the next time you deploy changes, at which time inspection engines might restart.

System Updates

Installing a system update or patch that does not reboot the system and includes a binary change requires inspection engines to restart. Binary changes can include changes to inspection engines, a preprocessor, the vulnerability database (VDB), or a shared object rule. Note also that a patch that does not include a binary change can sometimes require a Snort restart.

Viewing Interface and Management Status

The Device Summary includes a graphical view of your device and select settings for the management address. To open the Device Summary, click Device.

Elements on this graphic change color based on the status of the element. Mousing over elements sometimes provides additional information. Use this graphic to monitor the following items.

Note

The interface portion of the graphic, including interface status information, is also available on the Interfaces page and the Monitoring > System dashboard.

Interface Status

Mouse over a port to see its IP addresses, and enabled and link statuses. The IP addresses can be statically assigned or obtained using DHCP. Mousing over a Bridge Virtual Interface (BVI) also shows the list of member interfaces.

Interface ports use the following color coding:

- Green—The interface is configured, enabled, and the link is up.
- Gray—The interface is not enabled.
- Orange/Red—The interface is configured and enabled, but the link is down. If the interface is wired, this is an error condition that needs correction. If the interface is not wired, this is the expected status.

Inside, Outside Network Connections

The graphic indicates which port is connected to the outside (or upstream) and inside networks, under the following conditions.

- Inside Network—The port for the inside network is shown for the interface named “inside” only. If there are additional inside networks, they are not shown. If you do not name any interface “inside,” no port is marked as the inside port.
- Outside Network—The port for the outside network is shown for the interface named “outside” only. As with the inside network, this name is required, or no port is marked as the outside port.
Management Setting Status

The graphic shows whether the gateway, DNS servers, NTP servers, and Smart Licensing are configured for the management address, and whether those settings are functioning correctly.

Green indicates that the feature is configured and functioning correctly, gray indicates that it is not configured or not functioning correctly. For example, the DNS box is gray if the servers cannot be reached. Mouse over the elements to see more information.

If you find problems, correct them as follows:

- Management port and gateway—Select **System Settings > Management Interface**.
- DNS servers—Select **System Settings > DNS Server**.
- NTP servers—Select **System Settings > NTP**. Also see *Troubleshooting NTP, on page 417*.
- Smart License—Click the **View Configuration** link in the Smart License group.

Viewing System Task Status

System tasks include actions that occur without your direct involvement, such as retrieving and applying various database updates. You can view a list of these tasks and their status to verify that these system tasks are completing successfully.

**Procedure**

**Step 1**
Click the **Task List** button in the main menu.

The task list opens, displaying the status and details of system tasks.

**Step 2**
Evaluate the task status.

If you find a persistent problem, you might need to fix the device configuration. For example, a persistent failure to obtain database updates could indicate that there is no path to the Internet for the device's management IP address. You might need to contact the Cisco Technical Assistance Center (TAC) for some issues as indicted in the task descriptions.

You can do the following with the task list:

- Click the **Success** or **Failures** buttons to filter the list based on these statuses.
- Click the delete icon (_erase) for a task to remove it from the list.
- Click **Remove All Completed Tasks** to empty the list of all tasks that are not in progress.
Using the CLI Console to Monitor and Test the Configuration

FTD devices include a command line interface (CLI) that you can use for monitoring and troubleshooting. Although you can open an SSH session to get access to all of the system commands, you can also open a CLI Console in Firepower Device Manager to use read-only commands, such as the various `show` commands and `ping`, `traceroute`, and `packet-tracer`.

You can keep the CLI Console open as you move from page to page, configure, and deploy features. For example, after deploying a new static route, you could use `ping` in the CLI Console to verify that the target network is reachable.

The CLI Console uses the base FTD CLI. You cannot enter the diagnostic CLI, expert mode, or FXOS CLI (on models that use FXOS) using the CLI Console. Use SSH if you need to enter those other CLI modes.

Notes:

- Although `ping` is supported in CLI Console, the `ping system` command is not supported.
- The system can process at most 2 concurrent commands. Thus, if another user is issuing commands (for example, using the REST API), you might need to wait for other commands to complete before entering a command. If this is a persistent problem, use an SSH session instead of the CLI Console.
- Commands return information based on the deployed configuration. If you make a configuration change in FDM, but do not deploy it, you will not see the results of your change in the command output. For example, if you create a new static route but do not deploy it, that route will not appear in `show route` output.

Procedure

**Step 1**
Click the **CLI Console** button in the upper right of the web page.

**Step 2**
Type the commands at the prompt and press **Enter**.

Some commands take longer to produce output than others, please be patient. If you get a message that the command execution timed out, please try again. You will also get a time out error if you enter a command that requires interactive responses, such as `show perfstats`. If the problem persists, you might need to use an SSH client instead of the CLI Console.

Following are some tips on how to use the window.

- Press the **Tab** key to automatically complete a command after partially typing it. Also, Tab will list out the parameters available at that point in the command. Tab works down to three levels of keyword. After three levels, you need to use the command reference for more information.
- You can stop command execution by pressing **Ctrl+C**.
- To move the window, click and hold anywhere in the header, then drag the window to the desired location.
- Click the **Expand** (확장) or **Collapse** (축소) button to make the window bigger or smaller.
• Click the **Undock Into Separate Window** button to detach the window from the web page into its own browser window. To dock it again, click the **Dock to Main Window** button.

• Click and drag to highlight text, then press Ctrl+C to copy output to the clipboard.

• Click the **Clear CLI** button to erase all output.

• Click the **Copy Last Output** button to copy the output from the last command you entered to the clipboard.

**Step 3**

When you are finished, simply close the console window. Do not use the `exit` command.

Although the credentials you use to log into Firepower Device Manager validate your access to the CLI, you are never actually logged into the CLI when using the console.
Use Cases for Firepower Threat Defense

The following topics explain some common tasks you might want to accomplish with Firepower Threat Defense using Firepower Device Manager. These use cases assume that you completed the device configuration wizard and that you retained this initial configuration. Even if you modified the initial configuration, you should be able to use these examples to understand how to use the product.

- How to Configure the Device in Firepower Device Manager, on page 43
- How to Gain Insight Into Your Network Traffic, on page 48
- How to Block Threats, on page 55
- How to Block Malware, on page 61
- How to Implement an Acceptable Use Policy (URL Filtering), on page 63
- How to Control Application Usage, on page 68
- How to Add a Subnet, on page 72
- More Examples, on page 77

How to Configure the Device in Firepower Device Manager

After you complete the setup wizard, you should have a functioning device with a few basic policies in place:

- (Except for ASA 5506-X and ISA 3000.) An outside and an inside interface. No other data interfaces are configured.

- (ASA 5506-X, ISA 3000 only.) An outside interface, and an inside bridge group that includes all other data interfaces.

- Security zones for the inside and outside interfaces.

- An access rule trusting all inside to outside traffic.

- An interface NAT rule that translates all inside to outside traffic to unique ports on the IP address of the outside interface.

- A DHCP server running on the inside interface or bridge group.

The following steps provide an overview of additional features you might want to configure. Please click the help button (?) on a page to get detailed information about each step.
Procedure

**Step 1** Choose **Device**, then click **View Configuration** in the **Smart License** group.

Click **Enable** for each of the optional licenses you want to use: Threat, Malware, URL. Read the explanation of each license if you are unsure of whether you need it.

If you have not registered, you can do so from this page. Click **Request Register** and follow the instructions. Please register before the evaluation license expires.

For example, an enabled Threat license should look like the following:

![Threat License Example](image)

**Step 2** If you wired other interfaces, choose **Device**, then click the link in the **Interfaces** summary.

- Because the ASA 5506-X and ISA 3000 comes pre-configured with a bridge group containing all non-outside data interfaces, there is no need to configure these interfaces. If you want to break apart the bridge group, you can edit it to remove the interfaces you want to treat separately. Then you can configure those interfaces as hosting separate networks.

  For other models, you can create a bridge group for the other interfaces, or configure separate networks, or some combination of both.

Click the edit icon (✓) for each interface to define the IP address and other settings.

The following example configures an interface to be used as a “demilitarized zone” (DMZ), where you place publically-accessible assets such as your web server. Click **Save** when you are finished.
Step 3  If you configured new interfaces, choose **Objects**, then select **Security Zones** from the table of contents.

Edit or create new zones as appropriate. Each interface must belong to a zone, because you configure policies based on security zones, not interfaces. You cannot put the interfaces in zones when configuring them, so you must always edit the zone objects after creating new interfaces or changing the purpose of existing interfaces.

The following example shows how to create a new dmz-zone for the dmz interface.

Step 4  If you want internal clients to use DHCP to obtain an IP address from the device, choose **Device**, then **System Settings > DHCP Server**. Select the **DHCP Servers** tab.
There is already a DHCP server configured for the inside interface, but you can edit the address pool or even delete it. If you configured other inside interfaces, it is very typical to set up a DHCP server on those interfaces. Click + to configure the server and address pool for each inside interface.

You can also fine-tune the WINS and DNS lists supplied to clients on the Configuration tab.

The following example shows how to set up a DHCP server on the inside2 interface with the address pool 192.168.4.50-192.168.4.240.

**Step 5** Choose Device, then click View Configuration (or Create First Static Route) in the Routing group and configure a default route.

The default route normally points to the upstream or ISP router that resides off the outside interface. A default IPv4 route is for any-ipv4 (0.0.0.0/0), whereas a default IPv6 route is for any-ipv6 (::/0). Create routes for each IP version you use. If you use DHCP to obtain an address for the outside interface, you might already have the default routes that you need.

The routes you define on this page are for the data interfaces only. They do not impact the management interface. Set the management gateway on System Settings > Management Interface.

The following example shows a default route for IPv4. In this example, isp-gateway is a network object that identifies the IP address of the ISP gateway (you must obtain the address from your ISP). You can create this object by clicking Create New Network at the bottom of the Gateway drop-down list.
Step 6

Choose **Policies** and configure the security policies for the network.

The device setup wizard enables traffic flow between the inside-zone and outside-zone, and interface NAT for all interfaces when going to the outside interface. Even if you configure new interfaces, if you add them to the inside-zone object, the access control rule automatically applies to them.

However, if you have multiple inside interfaces, you need an access control rule to allow traffic flow from inside-zone to inside-zone. If you add other security zones, you need rules to allow traffic to and from those zones. These would be your minimum changes.

In addition, you can configure other policies to provide additional services, and fine-tune NAT and access rules to get the results that your organization requires. You can configure the following policies:

- **SSL Decryption**—If you want to inspect encrypted connections (such as HTTPS) for intrusions, malware, and so forth, you must decrypt the connections. Use the SSL decryption policy to determine which connections need to be decrypted. The system re-encrypts the connection after inspecting it.

- **Identity**—If you want to correlate network activity to individual users, or control network access based on user or user group membership, use the identity policy to determine the user associated with a given source IP address.

- **Security Intelligence**—Use the Security Intelligence policy to quickly drop connections from or to blacklisted IP addresses or URLs. By blacklisting known bad sites, you do not need to account for them in your access control policy. Cisco provides regularly updated feeds of known bad addresses and URLs so that the Security Intelligence blacklist updates dynamically. Using feeds, you do not need to edit the policy to add or remove items in the blacklist.

- **NAT** (Network Address Translation)—Use the NAT policy to convert internal IP addresses to externally routeable addresses.

- **Access Control**—Use the access control policy to determine which connections are allowed on the network. You can filter by security zone, IP address, protocol, port, application, URL, user or user group. You also apply intrusion and file (malware) policies using access control rules. Use this policy to implement URL filtering.

- **Intrusion**—Use the intrusion policies to inspect for known threats. Although you apply intrusion policies using access control rules, you can edit the intrusion policies to selectively enable or disable specific intrusion rules.

The following example shows how to allow traffic between the inside-zone and dmz-zone in the access control policy. In this example, no options are set on any of the other tabs except for **Logging**, where **At End of Connection** is selected.

Step 7

Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.
b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

---

**How to Gain Insight Into Your Network Traffic**

After completing initial device setup, you have an access control policy that allows all inside traffic access to the Internet or other upstream network, and a default action to block all other traffic. Before you create additional access control rules, you might find it beneficial to gain insight into the traffic that is actually occurring on your network.

You can use the monitoring capabilities of Firepower Device Manager to analyze network traffic. Firepower Device Manager reporting helps you answer the following questions:

- What is my network being used for?
- Who is using the network the most?
- Where are my users going?
- What devices are they using?
- What access control rules (policies) are being hit the most?

The initial access rule can provide some insight into traffic, including policies, destinations, and security zones. But to obtain user information, you need to configure an identity policy that requires users to authenticate (identify) themselves. To obtain information on applications used on the network, you need to make some additional adjustments.

The following procedure explains how to set up the Firepower Threat Defense device to monitor traffic and provides an overview of the end-to-end process of configuring and monitoring policies.

**Note**

This procedure does not provide insight into the web site categories and reputations of sites visited by users, so you cannot see meaningful information in the URL categories dashboard. You must implement category-based URL filtering, and enable the URL license, to obtain category and reputation data. If you just want to obtain this information, you can add a new access control rule that allows access to an acceptable category, such as Financial Services, and make it the first rule in the access control policy. For details on implementing URL filtering, see **How to Implement an Acceptable Use Policy (URL Filtering)**, on page 63.

**Procedure**

**Step 1**

To gain insight into user behavior, you need to configure an identity policy to ensure that the user associated with a connection is identified.
By enabling the identity policy, you can collect information about who is using the network, and what resources they are using. This information is available in the User monitoring dashboard. User information is also available for connection events shown in Event Viewer.

Users are authenticated only when they use a web browser for HTTP connections.

If a user fails to authenticate, the user is not prevented from making web connections. This just means that you do not have user identity information for the connections. If you want, you can create an access control rule to drop traffic for Failed Authentication users.

a) Click **Policies** in the main menu, then click **Identity**.

The identity policy is initially disabled. The identity policy uses your Active Directory server to authenticate users and associate them with the IP address of the workstation they are using. Subsequently, the system will identify traffic for that IP address as being the user's traffic.

b) Click **Enable Identity Policy**.

This action opens the Identity Policy Configuration dialog box.

c) Click in **Realm Server** to open the drop-down list, then select **Create New Identity Realm**.

If you already created your realm server object, simply select it and skip the steps for configuring the server.

d) Fill in the following fields, then click **OK**.

  - **Name**—A name for the directory realm.
  
  - **Type**—The type of directory server. Active Directory is the only supported type, and you cannot change this field.
  
  - **Directory Username, Directory Password**—The distinguished username and password for a user with appropriate rights to the user information you want to retrieve. For Active Directory, the user does not need elevated privileges. You can specify any user in the domain. The username must be fully qualified; for example, Administrator@example.com (not simply Administrator).

    **Note** The system generates ldap-login-dn and ldap-login-password from this information. For example, Administrator@example.com is translated as cn=adminisntrator,cn=users,dc=example,dc=com. Note that cn=users is always part of this translation, so you must configure the user you specify here under the common name “users” folder.

  - **Base DN**—The directory tree for searching or querying user and group information, that is, the common parent for users and groups. For example, dc=example,dc=com. For information on finding the base DN, see **Determining the Directory Base DN**, on page 120.

  - **AD Primary Domain**—The fully qualified Active Directory domain name that the device should join. For example, example.com.

  - **Hostname/IP Address**—The hostname or IP address of the directory server. If you use an encrypted connection to the server, you must enter the fully-qualified domain name, not the IP address.

  - **Port**—The port number used for communications with the server. The default is 389. Use port 636 if you select LDAPS as the encryption method.

  - **Encryption**—To use an encrypted connection for downloading user and group information, select the desired method, **STARTTLS** or **LDAPS**. The default is **None**, which means that user and group information is downloaded in clear text.
- **STARTTLS** negotiates the encryption method, and uses the strongest method supported by the directory server. Use port 389. This option is not supported if you use the realm for remote access VPN.

- **LDAPS** requires LDAP over SSL. Use port 636.

- **Trusted CA Certificate**—If you select an encryption method, upload a Certificate Authority (CA) certificate to enable a trusted connection between the system and the directory server. If you are using a certificate to authenticate, the name of the server in the certificate must match the server Hostname / IP Address. For example, if you use 10.10.10.250 as the IP address but ad.example.com in the certificate, the connection fails.

**Example:**

For example, the following image shows how to create an unencrypted connection for the ad.example.com server. The primary domain is example.com, and the directory username is Administrator@ad.example.com. All user and group information is under the Distinguished Name (DN) ou=user,dc=example,dc=com.

<table>
<thead>
<tr>
<th>Name</th>

<td>Please select a certificate</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Encryption</th>
<th>Trusted CA certificate</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Please select a certificate</td>
</tr>
</tbody>
</table>

e) In the Identity Policy Configuration dialog box, **Realm Server** list, select the realm server you just created.

f) In the Identity Policy Configuration dialog box, configure the Active Authentication captive portal settings.
When an identity rule requires active authentication for a user, the user is redirected to the captive portal port on the interface through which they are connected and then they are prompted to authenticate.

- **Server Certificate**—Select the internal certificate to present to users during active authentication. You can select the predefined self-signed DefaultInternalCertificate, or you can click **Create New Internal Certificate** and upload a certificate that your browsers already trust.

  Users will have to accept the certificate if you do not upload a certificate that their browsers already trust.

- **Port**—The captive portal port. The default is 885 (TCP). If you configure a different port, it must be in the range 1025-65535.

**Example:**

The Identity Policy Configuration dialog box should now look like the following.

![Identity Policy Configuration](image)

- **Realm Server**
  - AD

- **ACTIVE AUTHENTICATION**
  - **Server Certificate**
    - DefaultInternalCertificate
  - **Port**
    - 885
      - e.g. 885 or 1025-65535

- **g)** Click **Save**.

  Now, create a rule to require active authentication.

- **h)** Click the **Create Identity Rule** button, or the + button.

- **i)** Fill in the identity rule properties.

  Assuming you want to require everyone to authenticate, you could use the following settings:

  - **Name**—Anything you choose, for example, Require_Authentication.

  - **User Authentication**—**Active** should already be selected; keep it.
• **Type**—Select **HTTP Negotiate**. This allows the browser and directory server to negotiate the strongest authentication protocol, in order, NTLM, then HTTP basic.

  **Note** For the HTTP Basic, HTTP Response Page, and NTLM authentication methods, the user is redirected to the captive portal using the IP address of the interface. However, for HTTP Negotiate, the user is redirected using the fully-qualified DNS name `firewall-hostname.AD-domain-name`. If you want to use HTTP Negotiate, you must also update your DNS server to map this name to the IP addresses of all inside interfaces where you are requiring active authentication. Otherwise, the redirection cannot complete, and users cannot authenticate. If you cannot, or do not want to, update the DNS server, select one of the other authentication methods.

• **Source/Destination**—Leave all fields to default to Any.

You can constrain the policy as you see fit to a more limited set of traffic. However, active authentication will only be attempted for HTTP traffic, so it does not matter that non-HTTP traffic matches the source/destination criteria. For more details about identity policy properties, see [Configure Identity Rules, on page 190](#).

![Add Identity Rule](image)

j) Click **OK** to add the rule.

If you look in the upper right of the window, you can see that the **Deploy** icon button now has a dot, which indicates that there are undeployed changes. Making changes in the user interface is not sufficient for getting the changes configured on the device, you must deploy changes. Thus, you can make a set of related changes before you deploy them, so that you do not face the potential problems of having a partially-configured set of changes running on the device. You will deploy changes later in this procedure.

**Step 2** Change the action on the Inside_Outside_Rule access control rule to **Allow**.

The Inside_Outside_Rule access rule is created as a trust rule. However, trusted traffic is not inspected, so the system cannot learn about some of the characteristics of trusted traffic, such as application, when the traffic matching criteria does not include application or other conditions besides zone, IP address, and port. If you change the rule to allow rather than trust traffic, the system fully inspects the traffic.

**Note** (ASA 5506-X, ISA 3000.) Also consider changing the Inside_Inside_Rule from Trust to Allow. This rule covers traffic going between the inside interfaces.
a) Click **Access Control** on the **Policies** page.
b) Hover over the **Actions** cell on the right side of the Inside_Outside_Rule row to expose the edit and delete icons, and click the edit icon (تعديل) to open the rule.
c) Select **Allow** for the **Action**.

d) Click **OK** to save the change.

**Step 3**
Enable logging on the access control policy default action.

Dashboards contain information about connections only if the connection matches an access control rule that enables connection logging. The Inside_Outside_Rule enables logging, but the default action has logging disabled. Thus, dashboards show information for the Inside_Outside_Rule only, and do not reflect connections that do not match any rules.

a) Click anywhere in the default action at the bottom of the access control policy page.

b) Select **Select Log Action > At Beginning and End of Connection**.
c) Click **OK**.

**Step 4**
Set an update schedule for the vulnerability database (VDB).

Cisco regularly releases updates to the VDB, which includes the application detectors that can identify the application used in a connection. You should update the VDB on a regular basis. You can either manually download updates, or you can set up a regular schedule. The following procedure shows how to set up a schedule. By default, VDB updates are disabled, so you need to take action to get VDB updates.

a) Click **Device**.
b) Click **View Configuration** in the Updates group.

c) Click **Configure** in the VDB group.

d) Define the update schedule.
Choose a time and frequency that will not be disruptive to your network. Also, please understand that the system will do an automatic deployment after downloading the update. This is necessary to activate the new detectors. Thus, any configuration changes that you have made and saved but have not yet deployed will also be deployed.

For example, the following schedule updates the VDB once a week on Sunday at 12:00 AM (using the 24-hour clock notation).

```
Set recurring VDB Update

Frequency
Weekly

Days of Week Time
Sundays at 00 : 00
(-07:00) America/Los_Angeles
```

e) Click **Save**.

**Step 5** Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button and wait for deployment to finish.

The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

**What to do next**

At this point, the monitoring dashboards and events should start showing information about users and applications. You can evaluate this information for undesirable patterns and develop new access rules to constrain unacceptable use.
If you want to start collecting information about intrusions and malware, you need to enable intrusion and file policies on one or more access rule. You also need to enable the licenses for those features.

If you want to start collecting information about URL categories, you must implement URL filtering.

How to Block Threats

You can implement next generation Intrusion Prevention System (IPS) filtering by adding intrusion policies to your access control rules. Intrusion policies analyze network traffic, comparing the traffic contents against known threats. If a connection matches a threat you are monitoring, the system drops the connection, thus preventing the attack.

All other traffic handling occurs before network traffic is examined for intrusions. By associating an intrusion policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy.

You can configure intrusion policies on rules that allow traffic only. Inspection is not performed on rules set to trust or block traffic. In addition, you can configure an intrusion policy as part of the default action if the default action is allow.

Cisco delivers several intrusion policies with the Firepower System. These policies are designed by the Cisco Talos Intelligence Group (Talos), who set the intrusion and preprocessor rule states and advanced settings.

Besides inspecting traffic that you allow for potential intrusions, you can use the Security Intelligence policy to preemptively block all traffic to or from known bad IP addresses, or to known bad URLs.

Procedure

Step 1

If you have not already done so, enable the Threat license.

You must enable the Threat license to use intrusion policies and Security Intelligence. If you are currently using the evaluation license, you are enabling an evaluation version of the license. If you have registered the device, you must purchase the required license and add it to your Smart Software Manager account on Cisco.com.

a) Click Device.

b) Click View Configuration in the Smart License group.

The system registers the license with your account, or activates the evaluation license, as appropriate. The group should indicate that the license is enabled, and the button changes to a Disable button.
Step 2  
Select an intrusion policy for one or more access rules. 
Determine which rules cover traffic that should be scanned for threats. For this example, we will add intrusion inspection to the Inside_Outside_Rule. For ASA 5506-X models, you might also want to add it to the Inside_Inside_Rule.

a) Click Policies in the main menu.

Ensure that the Access Control policy is displayed.

b) Hover over the Actions cell on the right side of the Inside_Outside_Rule row to expose the edit and delete icons, and click the edit icon (_udp) to open the rule.

c) If you have not already done so, select Allow for the Action.

d) Click the Intrusion Policy tab.

e) Click the Intrusion Policy toggle to enable it, then select the intrusion policy.

The policies are listed from least to most secure. The Balanced Security and Connectivity policy is appropriate for most networks. It provides a good intrusion defense without being overly aggressive, which has the potential of dropping traffic that you might not want to be dropped. If you determine that too much traffic is getting dropped, you can ease up on intrusion inspection by selecting the Connectivity over Security policy.

If you need to be aggressive about security, try the Security over Connectivity policy. The Maximum Detection policy offers even more emphasis on network infrastructure security with the potential for even greater operational impact.
f) Click **OK** to save the change.

**Step 3**

Set an update schedule for the intrusion rule database.

Cisco regularly releases updates to the intrusion rule database, which is used by intrusion policies to determine whether connections should be dropped. You should update the rule database on a regular basis. You can either manually download updates, or you can set up a regular schedule. The following procedure shows how to set up a schedule. By default, database updates are disabled, so you need to take action to get updated rules.

a) Click **Device**.

b) Click **View Configuration** in the Updates group.

c) Click **Configure** in the Rule group.
d) Define the update schedule.

Choose a time and frequency that will not be disruptive to your network. Also, please understand that the system will do an automatic deployment after downloading the update. This is necessary to activate the new rules. Thus, any configuration changes that you have made and saved but have not yet deployed will also be deployed.

For example, the following schedule updates the rule database once a week on Monday at 12:00 AM (using the 24-hour clock notation).

![Set recurring Rule Update](image)

Step 4 Configure the Security Intelligence policy to preemptively drop connections with known bad hosts and sites.

By using Security Intelligence to block connections with hosts or sites that are known to be threats, you save your system the time needed to do deep packet inspection to identify threats in each connection. Security Intelligence provides an early block of undesirable traffic, leaving more system time to handle the traffic you really care about.

a) Click **Device**, then click **View Configuration** in the **Updates** group.
b) Click **Update Now** in the Security Intelligence Feeds group.
c) Also, click **Configure** and set a recurring update for the feeds. The default, **Hourly**, is appropriate for most networks but you can decrease the frequency if necessary.
d) Click **Policies**, then click the **Security Intelligence** policy.
e) Click **Enable Security Intelligence** if you have not already enabled the policy.
f) On the **Network** tab, click + under **Blacklist**, and select all of the feeds on the **Network Feeds** tab. You can click the **i** button next to a feed to read a description of each feed.
If you see a message that there are no feeds yet, please try again later. The feeds download has not yet completed. If this problem persists, ensure that there is a path between the management IP address and the Internet.

**g)** Click **OK** to add the selected feeds.

If you know of additional bad IP addresses, you can click **+ > Network Objects** and add the objects that contain the addresses. You can click **Create New Network Object** at the bottom of the list to add them now.

**h)** Click the **URL** tab, then click **+ > URL Feeds** under **Blacklist**, and select all of the URL feeds. Click **OK** to add them to the blacklist.

Similar to the network list, you can add your own URL objects to the blacklist to block additional sites that are not in the feeds. Click **+ > URL Objects**. You can add new objects by clicking **Create New URL Object** at the end of the list.
i) Click the gear icon, and enable **Connection Events Logging**, to enable the policy to generate Security Intelligence events for matched connections. Click **OK** to save your changes.

If you do not enable connection logging, you will have no data to use to evaluate whether the policy is performing to expectations. If you have an external syslog server defined, you can select it now so that the events are also sent to that server.

j) As needed, you can add network or URL objects to the **Do Not Block** list on each tab to create exceptions to the blacklist.

The **Do Not Block** lists are not real white lists. They are exception lists. If an address or URL in the exception list also appears in the blacklist, the connection for the address or URL is allowed to pass on to the access control policy. This way, you can block a feed, but if you later find that a desirable address or site is being blocked, you can use the exception list to override that block without needing to remove the feed entirely. Keep in mind that these connections are subsequently evaluated by access control, and if configured, an intrusion policy. Thus, if any connections do contain threats, they can be identified and blocked during intrusion inspection.

Use the Access and SI Rules dashboard, and the Security Intelligence view in the Event Viewer, to determine what traffic is actually being dropped by the policy, and whether you need to add addresses or URLs to the **Do Not Block** lists.

**Step 5** Commit your changes.
a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

   Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

---

**What to do next**

At this point, the monitoring dashboards and events should start showing information about attackers, targets, and threats, if any intrusions are identified. You can evaluate this information to determine if your network needs more security precautions, or if you need to reduce the level of intrusion policy you are using.

For Security Intelligence, you can see policy hits on the Access and SI Rules dashboard. You can also see Security Intelligence events in the Event Viewer. Security Intelligence blocks are not reflected in intrusion threat information, because the traffic is blocked before it can be inspected.

---

**How to Block Malware**

Users are continually at risk of obtaining malicious software, or *malware*, from Internet sites or other communication methods, such as e-mail. Even trusted web sites can be hijacked to serve malware to unsuspecting users. Web pages can contain objects coming from different sources. These objects can include images, executables, Javascript, advertisements, and so forth. Compromised web sites often incorporate objects hosted on external sources. Real security means looking at each object individually, not just the initial request.

Use file policies to detect malware using Advanced Malware Protection for Firepower (AMP for Firepower). You can also use file policies to perform file control, which allows control over all files of a specific type regardless of whether the files contain malware.

AMP for Firepower uses the AMP cloud to retrieve dispositions for possible malware detected in network traffic. The management interface must have a path to the Internet to reach the AMP cloud and perform malware lookups. When the device detects an eligible file, it uses the file's SHA-256 hash value to query the AMP cloud for the file's disposition. The possible disposition can be **clean**, **malware**, or **unknown** (no clear verdict). If the AMP cloud is unreachable, the disposition is **unknown**.

By associating a file policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect any files in the connection.

You can configure file policies on rules that **allow** traffic only. Inspection is not performed on rules set to **trust** or **block** traffic.

**Procedure**

**Step 1**

If you have not already done so, enable the **Malware** license.

You must enable the Malware license to use file policies for malware control. If you are currently using the evaluation license, you are enabling an evaluation version of the license. If you have registered the device, you must purchase the required license and add it to your Smart Software Manager account on Cisco.com.
a) Click **Device**.
b) Click **View Configuration** in the Smart License group.

c) Click **Enable** in the **Malware** group.

The system registers the license with your account, or activates the evaluation license, as appropriate. The group should indicate that the license is enabled, and the button changes to a **Disable** button.

---

**Step 2** Select a file policy for one or more access rules.

Determine which rules cover traffic that should be scanned for malware. For this example, we will add file inspection to the **Inside_Outside_Rule**. For ASA 5506-X models, you might also want to add it to the **Inside_Inside_Rule**.

a) Click **Policies** in the main menu.

Ensure that the **Access Control** policy is displayed.

b) Hover over the **Actions** cell on the right side of the **Inside_Outside_Rule** row to expose the edit and delete icons, and click the edit icon (▲) to open the rule.

c) If you have not already done so, select **Allow** for the **Action**.

d) Click the **File Policy** tab.

e) Click the file policy you want to use.

Your main choice is between **Block Malware All**, which drops any files that are considered malware, or **Cloud Lookup All**, which queries the AMP cloud to determine the file's disposition, but does no blocking. If you want to first see how files are being evaluated, use cloud lookup. You can switch to the blocking policy later if you are satisfied with how files are being evaluated.

There are other policies available that block malware. These policies are coupled with file control, blocking the upload of Microsoft Office, or Office and PDF, documents. That is, these policies prevent users from sending these file types to other networks in addition to blocking malware. You can select these policies if they fit your needs.

For this example, select **Block Malware All**.
f) Click the **Logging** tab and verify that **Log Files** under File Events is selected.

By default, file logging is enabled whenever you select a file policy. You must enable file logging to get file and malware information in events and dashboards.

**FILE EVENTS**

![File Events](image)

 Include **Log Files**

---

g) Click **OK** to save the change.

**Step 3** Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

![Deploy Changes](image)

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be **Deployed**.

---

**What to do next**

At this point, the monitoring dashboards and events should start showing information about file types and file and malware events, if any files or malware are transmitted. You can evaluate this information to determine if your network needs more security precautions related to file transmissions.

---

**How to Implement an Acceptable Use Policy (URL Filtering)**

You might have an acceptable use policy for your network. Acceptable use policies differentiate between network activity that is appropriate in your organization and activity that is considered inappropriate. These
policies are typically focused on Internet usage, and are geared towards maintaining productivity, avoiding legal liabilities (for example, maintaining a non-hostile workplace), and in general controlling web traffic.

You can use URL filtering to define an acceptable use policy with access policies. You can filter on broad categories, such as Gambling, so that you do not need to identify every individual web site that should be blocked. For category matches, you can also specify the relative reputation of sites to allow or block. If a user attempts to browse to any URL with that category and reputation combination, the session is blocked.

Using category and reputation data also simplifies policy creation and administration. It grants you assurance that the system will control web traffic as expected. Finally, because Cisco's threat intelligence is continually updated with new URLs, as well as new categories and risks for existing URLs, you can ensure that the system uses up-to-date information to filter requested URLs. Malicious sites that represent security threats such as malware, spam, botnets, and phishing may appear and disappear faster than you can update and deploy new policies.

The following procedure explains how to implement an acceptable use policy using URL filtering. For purposes of this example, we will block sites of any reputation in several categories, risky Social Networking sites, and an unclassified site, badsite.example.com.

**Procedure**

**Step 1**

If you have not already done so, enable the URL license.

You must enable the URL license to use URL category and reputation information, or to see the information in dashboards and events. If you are currently using the evaluation license, you are enabling an evaluation version of the license. If you have registered the device, you must purchase the required license and add it to your Smart Software Manager account on Cisco.com.

a) Click **Device**.
b) Click **View Configuration** in the Smart License group.

c) Click **Enable** in the **URL License** group.

The system registers the license with your account, or activates the evaluation license, as appropriate. The group should indicate that the license is enabled, and the button changes to a Disable button.

**Step 2**

Create a URL filtering access control rule.

You might want to first see the categories for sites your users are visiting before making a blocking rule. If that is the case, you can create a rule with the Allow action for an acceptable category, such as Financial Services. Because all web connections must be inspected to determine if the URL belongs to this category, you would get category information even for non-Financial Services sites.
But there are probably URL categories that you already know you want to block. A blocking policy also forces inspection, so you get category information on connections to unblocked categories, not just the blocked categories.

a) Click **Policies** in the main menu.

   Ensure that the **Access Control** policy is displayed.

b) Click + to add a new rule.

c) Configure the order, title, and action.

   • **Order**—The default is to add new rules to the end of the access control policy. However, you must place this rule ahead of (above) any rule that would match the same Source/Destination and other criteria, or the rule will never be matched (a connection matches one rule only, and that is the first rule it matches in the table). For this rule, we will use the same Source/Destination as the Inside_Outside_Rule created during initial device configuration. You might have created other rules as well. To maximize access control efficiency, it is best to have specific rules early, to ensure the quickest decision on whether a connection is allowed or dropped. For the purposes of this example, select 1 as the rule order.

   • **Title**—Give the rule a meaningful name, such as Block_Web_Sites.

   • **Action**—Select Block.

d) On the **Source/Destination** tab, click + for **Source > Zones**, select inside_zone, then click **OK** in the zones dialog box.

   Adding any of the criteria works the same way. Clicking + opens a little dialog box, where you click the items you want to add. You can click multiple items, and clicking a selected item de-selects it; the check marks indicate the selected items. But nothing is added to the policy until you click the **OK** button; simply selecting the items is not sufficient.

e) Using the same technique, select **outside_zone** for **Destination > Zones**.
f) Click the URLs tab.

g) Click the + for Categories, and select the categories you want to fully or partially block.

For purposes of this example, select Adult and Pornography, Bot Nets, Confirmed SPAM Sources, and Social Network. There are additional categories that you would most likely want to block.

h) To implement reputation-sensitive blocking for the Social Network category, click Reputation: Risk Any for that category, deselect Any, then move the slider to Benign sites with security risks. Click away from the slider to close it.

The left of the reputation slider indicates sites that will be allowed, the right side are sites that will be blocked. In this case, only Social Networking sites with reputations in the Suspicious Sites and High Risk ranges will be blocked. Thus, your users should be able to get to commonly-used Social Networking sites, where there are fewer risks.

Using reputation, you can selectively block sites within a category you otherwise want to allow.

i) Click the + next to the URLs list to the left of the categories list.

j) At the bottom of the popup dialog box, click the Create New URL link.

k) Enter badsite.example.com for both the name and URL, then click OK to create the object.

You can name the object the same as the URL or give the object a different name. For the URL, do not include the protocol portion of the URL, just add the server name.
l) Select the new object, then click **OK**.

Adding new objects while editing policies simply adds the object to the list. The new object is not automatically selected.

m) Click the **Logging** tab and select **Select Log Action > At Beginning and End of Connection**.

You must enable logging to get category and reputation information into the web category dashboard and connection events.

n) Click **OK** to save the rule.

**Step 3**

(Optional.) Set preferences for URL filtering.

When you enable the URL license, the system automatically enables updates to the web category database. The system checks for updates every 30 minutes, although the data is typically updated once per day. You can turn off these updates if for some reason you do not want them.

You can also elect to send URLs that are not categorized to Cisco for analysis. Thus, if the installed URL database does not have a categorization for a site, Cisco CSI might have one. Cisco CSI returns the category and reputation, and your category-based rules can then be applied correctly to the URL request. Selecting this option is important for lower-end systems, which install a smaller URL database due to memory limitations.

a) Click **Device**.

b) Click **System Settings > Traffic Settings > URL Filtering Preferences**.

c) Select **Query Cisco CSI for Unknown URLs**.
d) Click **Save**.

**Step 4**

Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

---

**What to do next**

At this point, the monitoring dashboards and events should start showing information about URL categories and reputations, and which connections were dropped. You can evaluate this information to determine if your URL filtering is dropping just those sites that are objectionable, or if you need to ease up on the reputation setting for certain categories.

Consider informing users beforehand that you will be blocking access to web sites based on their categorization and reputation.

---

**How to Control Application Usage**

The Web has become the ubiquitous platform for application delivery in the enterprise, whether that is browser based application platforms, or rich media applications that use web protocols as the transport in and out of enterprise networks.

Firepower Threat Defense inspects connections to determine the application being used. This makes it possible to write access control rules targeted at applications, rather than just targeting specific TCP/UDP ports. Thus, you can selectively block or allow web-based applications even though they use the same port.

Although you can select specific applications to allow or block, you can also write rules based on type, category, tag, risk, or business relevance. For example, you could create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is blocked.

Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule blocking high risk applications can automatically apply to new applications without you having to update the rule manually.

In this use case, we will block any application that belongs to the **anonymizer/proxy** category.

---

**Before you begin**

This use case assumes that you completed the use case *How to Gain Insight Into Your Network Traffic*, on page 48. That use case explains how to collect application usage information, which you can analyze in the Applications dashboard. Understanding what applications are actually being used can help you design effective application-based rules. The use case also explains how to schedule VDB updates, which will not be repeated here. Ensure that you update the VDB regularly so that applications can be correctly identified.
Procedure

**Step 1** Create the application-based access control rule.

a) Click **Policies** in the main menu. Ensure that the **Access Control** policy is displayed.

b) Click + to add a new rule.

c) Configure the order, title, and action.

- **Order**—The default is to add new rules to the end of the access control policy. However, you must place this rule ahead of (above) any rule that would match the same Source/Destination and other criteria, or the rule will never be matched (a connection matches one rule only, and that is the first rule it matches in the table). For this rule, we will use the same Source/Destination as the Inside_Outside_Rule created during initial device configuration. You might have created other rules as well. To maximize access control efficiency, it is best to have specific rules early, to ensure the quickest decision on whether a connection is allowed or dropped. For the purposes of this example, select 1 as the rule order.

- **Title**—Give the rule a meaningful name, such as Block_Anonymizers.

- **Action**—Select Block.

d) On the **Source/Destination** tab, click + for **Source > Zones**, select inside_zone, then click OK in the zones dialog box.

e) Using the same technique, select **outside_zone** for **Destination > Zones**.
f) Click the Applications tab.

g) Click the + for Applications, and then click the Advanced Filter link at the bottom of the popup dialog box.

Although you can create application filter objects beforehand and select them on the Application Filters list here, you can also specify criteria directly in the access control rule, and optionally save the criteria as a filter object. Unless you are writing a rule for a single application, it is easier to use the Advanced Filter dialog box to find applications and construct appropriate criteria.

As you select criteria, the Applications list at the bottom of the dialog box updates to show exactly which applications match the criteria. The rule you are writing applies to these applications.

**Look at this list carefully.** For example, you might be tempted to block all very high risk applications. However, as of this writing, Facebook and TFPT are classified as very high risk. Most organizations would not want to block those applications. Take the time to experiment with various filter criteria to see which applications match your selections. Keep in mind that these lists can change with every VDB update.

For purposes of this example, select anonymizers/proxies from the Categories list.
h) Click **Add** in the Advanced Filters dialog box.
The filter is added and shown on the Applications tab.

i) Click the **Logging** tab and select **Select Log Action > At Beginning and End of Connection**.
You must enable logging to get information about any connections blocked by this rule.

j) Click **OK** to save the rule.

**Step 2**  
Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.
Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

**Step 3**

Click **Monitoring** and evaluate the results.

You might now see dropped connections on the Applications widget on the **Network Overview** dashboard. Use the **All/Denied/Allowed** drop-down options to focus just on dropped applications.

You can also find information about the applications on the **Web Applications** dashboard. The **Applications** dashboards show protocol-related results. If someone tries to use these applications, you should be able to correlate the application with the user attempting the connection, assuming that you enable identity policies and require authentication.

---

**How to Add a Subnet**

If you have an available interface on your device, you can wire it to a switch (or another router) to provide services to another subnet.

There are many potential reasons you would add a subnet. For this use case, we will address the following typical scenario.

- The subnet is an inside network using the private network 192.168.2.0/24.
- The interface for the network has the static address 192.168.2.1. In this example, the physical interface is devoted to the network. Another option is to use an already-wired interface and create a subinterface for the new network.
- The device will provide addresses to workstations on the network using DHCP, using 192.168.2.2-192.168.2.254 as the address pool.
- Network access to other inside networks, and to the outside network, will be allowed. Traffic going to the outside network will use NAT to obtain a public address.

---

**Note**

This example assumes the unused interface is not part of a bridge group. If it is currently a bridge group member, you must first remove it from the bridge group before following this procedure.

---

**Before you begin**

Physically connect the network cable to the interface and to the switch for the new subnet.

**Procedure**

**Step 1**

Configure the interface.

a) Click **Device**, then click the link in the **Interfaces** summary.

b) Hover over the **Actions** cell on the right side of the row for the interface you wired, and click the edit icon.

---
c) Configure the basic interface properties.
   - **Name**—A unique name for the interface. For this example, *inside_2*.
   - **Status**—Click the status toggle to enable the interface.
   - **IPv4 Address** tab—Select **Static** for **Type**, then enter **192.168.2.1/24**.

![Edit Physical Interface]

   d) Click **Save**.
   
   The interface list shows the updated interface status and the configured IP address.

   ![GigabitEthernet1/3 inside_2 192.168.2.1 STATIC]

**Step 2** Configure the DHCP server for the interface.

a) Click **Device**.

b) Click **System Settings > DHCP Server**.

c) Click the **DHCP Servers** tab.

   The table lists any existing DHCP servers. If you are using the default configuration, the list includes one for the inside interface.

d) Click **+** above the table.

e) Configure the server properties.

   - **Enable DHCP Server**—Click this toggle to enable the server.

   - **Interface**—Select the interface on which you are providing DHCP services. In this example, select *inside_2*.

   - **Address Pool**—The addresses the server can supply to devices on the network. Enter 192.168.2.2-192.168.2.254. Make sure you do not include the network address (.0), the interface address (.1), or the broadcast address (.255). Also, if you need static addresses for any devices on the network, exclude those addresses from the pool. The pool must be a single continuous series of addresses, so choose static addresses from the beginning or ending of the range.
Step 3  
Add the interface to the inside security zone.

To write policies on an interface, the interface must belong to a security zone. You write policies for the security zones. Thus, as you add and remove interfaces in the zones, you automatically change the policies applied to the interface.

a) Click Objects in the main menu.
b) Select Security Zones from the objects table of contents.
c) Hover over the Actions cell on the right side of the row for the inside_zone object, and click the edit icon ( ).
d) Click + under Interfaces, select the inside_2 interface, and click OK in the interfaces list.

e) Click Save.

Step 4  
Create an access control rule that allows traffic between the inside networks.
Traffic is not automatically allowed between any interfaces. You must create access control rules to allow the traffic that you want. The only exception is if you allow traffic in the access control rule's default action. For the purposes of this example, we will assume you retained the block default action that the device setup wizard configures. Thus, you need to create a rule that will allow traffic between the inside interfaces. If you have already created a rule like this, skip this step.

a) Click **Policies** in the main menu.
   Ensure that the **Access Control** policy is displayed.

b) Click + to add a new rule.

c) Configure the order, title, and action.

   • **Order**—The default is to add new rules to the end of the access control policy. However, you must place this rule ahead of (above) any rule that would match the same Source/Destination and other criteria, or the rule will never be matched (a connection matches one rule only, and that is the first rule it matches in the table). For this rule, we will use unique Source/Destination criteria, so adding the rule to the end of the list is acceptable.

   • **Title**—Give the rule a meaningful name, such as Allow_Inside_Inside.

   • **Action**—Select Allow.

d) On the **Source/Destination** tab, click + for **Source > Zones**, select inside_zone, then click OK in the zones dialog box.

e) Using the same technique, select inside_zone for **Destination > Zones**.
   A security zone must contain at least two interfaces to select the same zone for source and destination.

f) (Optional.) Configure intrusion and malware inspection.
Although the inside interfaces are in a trusted zone, it is typical for users to connect laptops to the network. Thus, a user might unknowingly bring a threat inside your network from an outside network or a Wi-Fi hot spot. Thus, you might want to scan for intrusions and malware in traffic that goes between your inside networks.

Consider doing the following.

- Click the **Intrusion Policy** tab, enable the intrusion policy, and use the slider to select the Balanced Security and Connectivity policy.

- Click the **File Policy** tab, then select the Block Malware All policy.

g) Click the **Logging** tab and select **Select Log Action > At Beginning and End of Connection**. You must enable logging to get information about any connections that match this rule. Logging adds statistics to the dashboard as well as showing events in the event viewer.

h) Click **OK** to save the rule.

**Step 5** Verify that required policies are defined for the new subnet.

By adding the interface to the inside_zone security zone, any existing policies for inside_zone automatically apply to the new subnet. However, take the time to inspect your policies and ensure that no additional policies are needed.

If you completed the initial device configuration, the following policies should already apply.

- **Access Control**—The Inside_Outside_Rule should allow all traffic between the new subnet and the outside network. If you followed the previous use cases, the policy also provides intrusion and malware inspection. You must have a rule that allows some traffic between the new network and the outside network, or users cannot access the Internet or other external networks.

- **NAT**—The InsideOutsideNATrule applies to any interface going to the outside interface, and applies interface PAT. If you kept this rule, traffic from the new network going to the outside will have the IP address translated to a unique port on the outside interface's IP address. If you do not have a rule that applies to all interfaces, or the inside_zone interfaces, when going to the outside interface, you might need to create one now.

- **Identity**—There is no default identity policy. However, if you followed previous use cases, you might have an identity policy that already requires authentication for the new network. If you do not have an identity policy that applies, create one now if you want to have user-based information for the new network.

**Step 6** Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.
What to do next

Verify that workstations on the new subnet are getting IP addresses using DHCP, and that they can reach other inside networks and the outside network. Use the monitoring dashboards and the event viewer to evaluate network usage.

More Examples

In addition to the examples in the Use Case chapter, there are example configurations in some of the chapters that explain specific services. You might find the following examples of interest.

**Network Address Translation (NAT)**

**NAT for IPv4 addresses**

- Providing Access to an Inside Web Server (Static Auto NAT), on page 287
- Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation), on page 290
- Different Translation Depending on the Destination (Dynamic Manual PAT), on page 296
- Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT), on page 302
- DNS Reply Modification, DNS Server on Outside, on page 314
- DNS Reply Modification, DNS Server on Host Network, on page 317
- Exempting Site-to-Site VPN Traffic from NAT, on page 340

**NAT for IPv6 addresses**

Licensing the System

The following topics explain how to license the Firepower Threat Defense device.

- Smart Licensing for the Firepower System, on page 79
- Managing Smart Licenses, on page 82

Smart Licensing for the Firepower System

Cisco Smart Licensing lets you purchase and manage a pool of licenses centrally. Unlike product authorization key (PAK) licenses, smart licenses are not tied to a specific serial number or license key. Smart licensing lets you assess your license usage and needs at a glance.

In addition, Smart Licensing does not prevent you from using product features that you have not yet purchased. You can start using a license immediately, as long as you are registered with the Cisco Smart Software Manager, and purchase the license later. This allows you to deploy and use a feature, and avoid delays due to purchase order approval.

Cisco Smart Software Manager

When you purchase one or more licenses for the Firepower Threat Defense device, you manage them in the Cisco Smart Software Manager: https://software.cisco.com/#SmartLicensing-Inventory. The Cisco Smart Software Manager lets you create a master account for your organization.

By default, your licenses are assigned to the Default Virtual Account under your master account. As the account administrator, you can create additional virtual accounts; for example, for regions, departments, or subsidiaries. Multiple virtual accounts help you manage large numbers of licenses and appliances.

Licenses and appliances are managed per virtual account; only that virtual account’s appliances can use the licenses assigned to the account. If you need additional licenses, you can transfer an unused license from another virtual account. You can also transfer appliances between virtual accounts.

When you register a device with Cisco Smart Software Manager, you create a Product Instance Registration Token in the manager, and then enter it in Firepower Device Manager. A registered device becomes associated with a virtual account based on the token that is used.

For more information about the Cisco Smart Software Manager, see the online help for the manager.
Periodic Communication with the License Authority

When you use a Product Instance Registration Token to register a Firepower Threat Defense device, the device registers with the Cisco License Authority. The License Authority issues an ID certificate for communication between the device and the License Authority. This certificate is valid for one year, although it will be renewed every six months. If an ID certificate expires (usually in nine months or a year with no communication), the device reverts to a de-registered state and licensed feature usage is suspended.

The device communicates with the License Authority on a periodic basis. If you make changes in the Cisco Smart Software Manager, you can refresh the authorization on the device so the changes immediately take effect. You also can wait for the device to communicate as scheduled. Normal license communication occurs every 30 days, but with the grace period, your device will operate for up to 90 days without calling home. You must contact the License Authority before 90 days have passed.

Smart License Types

The following table explains the licenses available for the Firepower Threat Defense device.

Your purchase of a Firepower Threat Defense device automatically includes a Base license. All additional licenses are optional.

<table>
<thead>
<tr>
<th>License</th>
<th>Duration</th>
<th>Granted Capabilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base (automatically included)</td>
<td>Perpetual</td>
<td>All features not covered by the optional term licenses. You must also specify whether to <strong>Allow export-controlled functionality on the products registered with this token</strong>. You can select this option only if your country meets export-control standards. This option controls your use of advanced encryption and the features that require advanced encryption.</td>
</tr>
</tbody>
</table>
### Impact of Expired or Disabled Optional Licenses

If an optional license expires, you can continue using features that require the license. However, the license is marked out of compliance and you need to purchase the license and add it to your account to bring the license back into compliance.

If you disable an optional license, the system reacts as follows:

<table>
<thead>
<tr>
<th>License</th>
<th>Duration</th>
<th>Granted Capabilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Threat</td>
<td>Term-based</td>
<td><strong>Intrusion detection and prevention</strong>—Intrusion policies analyze network traffic for intrusions and exploits and, optionally, drop offending packets. <strong>File control</strong>—File policies detect and, optionally, block users from uploading (sending) or downloading (receiving) files of specific types. AMP for Firepower, which requires a Malware license, allows you to inspect and block files that contain malware. You must have the Threat license to use any type of File policy. <strong>Security Intelligence filtering</strong>—Drop selected traffic before the traffic is subjected to analysis by access control rules. Dynamic feeds allow you to immediately drop connections based on the latest intelligence.</td>
</tr>
<tr>
<td>Malware</td>
<td>Term-based</td>
<td>File policies that check for malware, which use Cisco Advanced Malware Protection (AMP) with AMP for Firepower (network-based Advanced Malware Protection) and Cisco Threat Grid. File policies can detect and block malware in files transmitted over your network.</td>
</tr>
<tr>
<td>URL Filtering</td>
<td>Term-based</td>
<td>Category and reputation-based URL filtering. You can perform URL filtering on individual URLs without this license.</td>
</tr>
<tr>
<td>RA VPN: • AnyConnect Plus • AnyConnect Apex • AnyConnect VPN Only</td>
<td>Term-based or perpetual based on license type.</td>
<td>Remote access VPN configuration. Your base license must allow export-controlled functionality to configure RA VPN. You select whether you meet export requirements when you register the device. Firepower Device Manager can use any valid AnyConnect license. The available features do not differ based on license type. If you have not already purchased one, see Licensing Requirements for Remote Access VPN, on page 355. Also see Cisco AnyConnect Ordering Guide, <a href="http://www.cisco.com/c/dam/en/us/products/collateral/security/anyconnect-og.pdf">http://www.cisco.com/c/dam/en/us/products/collateral/security/anyconnect-og.pdf</a>.</td>
</tr>
</tbody>
</table>
• **Malware license**—The system stops querying the AMP cloud, and also stops acknowledging retrospective events sent from the AMP cloud. You cannot re-deploy existing access control policies if they include file policies that apply malware inspection. Note that for a very brief time after a Malware license is disabled, the system can use existing cached file dispositions. After the time window expires, the system assigns a disposition of Unavailable to those files.

• **Threat**—The system no longer applies intrusion or file-control policies. For Security Intelligence policies, the system no longer applies the policy and stops downloading feed updates. You cannot re-deploy existing policies that require the license.

• **URL Filtering**—Access control rules with URL category conditions immediately stop filtering URLs, and the system no longer downloads updates to URL data. You cannot re-deploy existing access control policies if they include rules with category and reputation-based URL conditions.

• **RA VPN**—You cannot edit the remote access VPN configuration, but you can remove it. Users can still connect using the RA VPN configuration. However, if you change the device registration so that the system is no longer export compliant, the remote access VPN configuration stops immediately and no remote users can connect through the VPN.

### Managing Smart Licenses

Use the Smart License page to view the current license status for the system. The system must be licensed.

The page shows you whether you are using the 90-day evaluation license, or if you have registered with the Cisco Smart Software Manager. Once registered, you can see the status of the connection to the Cisco Smart Software Manager as well as the status for each type of license.

Usage Authorization identifies the Smart License Agent status:

• **Authorized (“Connected,” “Sufficient Licenses”)**—The device has contacted and registered successfully with the License Authority, which has authorized the license entitlements for the appliance. The device is now In-Compliance.

• **Out-of-Compliance**—There is no available license entitlement for the device. Licensed features continue to work. However, you must either purchase or free up additional entitlements to become In-Compliance.

• **Authorization Expired**—The device has not communicated with the Licensing Authority in 90 or more days. Licensed features continue to work. In this state, the Smart License Agent retries its authorization requests. If a retry succeeds, the agent enters either an Out-of-Compliance or Authorized state, and begins a new Authorization Period. Try manually synchronizing the device.

---

**Note**

Click the i button next to the Smart License status to view the virtual account, export-controlled features, and get a link to open the Cisco Smart Software Manager. Export-Controlled Features control software that is subject to national security, foreign policy, and anti-terrorism laws and regulations.

The following procedure provides an overview of how to manage licenses for the system.
Procedure

Step 1
Click **Device**, then click **View Configuration** in the Smart License summary.

Step 2
Register the device.

You must register with the Cisco Smart Software Manager before you can assign the optional licenses. Register before the end of the evaluation period.

See **Registering the Device**, on page 83.

**Note**
When you register, you elect whether to send usage data to Cisco. You can change your election by clicking the **Go To Cisco Success Network** link next to the gear icon.

Step 3
Request and manage the optional feature licenses.

You must register the optional licenses to use the features controlled by the license. See **Enabling or Disabling Optional Licenses**, on page 84.

Step 4
Maintain system licensing.

You can do the following tasks:

- Synchronizing with the Cisco Smart Software Manager, on page 85
- Unregistering the Device, on page 85

---

**Registering the Device**

Your purchase of a Firepower Threat Defense device automatically includes a Base license. The Base license covers all features not covered by the optional licenses. It is a perpetual license.

During initial system setup, you are prompted to register the device with Cisco Smart Software Manager. If you instead elected to use the 90-day evaluation license, you must register the device before the end of the evaluation period.

When you register the device, your virtual account allocates the license to the device. Registering the device also registers any optional licenses that you have enabled.

**Procedure**

Step 1
Click **Device**, then click **View Configuration** in the Smart License summary.

Step 2
Click **Request Register** and follow the instructions.

a) Click the link to open the Cisco Smart Software Manager and log into your account, or create a new one if necessary.

b) Generate a new token.

When you create the token, you specify the amount of time the token is valid for use. The recommended expiration period is 30 days. This period defines the expiration date of the token itself, and has no impact on the device that you register using the token. If the token expires before you can use it, you can simply generate a new token.
You must also specify whether to **Allow export-controlled functionality on the products registered with this token**. You can select this option only if your country meets export-control standards. This option controls your use of advanced encryption and the features that require advanced encryption.

c) Copy and paste the token into the edit box on the Smart License Registration dialog box.

d) Decide whether to send usage data to Cisco.

Read the information in the Cisco Success Network step, click the Sample Data link to view the actual data that is collected, then decide whether to leave the **Enable Cisco Success Network** option selected. Even if you do not enable the connection, you are registered with the Cisco Cloud Services server so that you can enable cloud services as you need them.

e) Click **Request Register**.

---

## Enabling or Disabling Optional Licenses

You can enable (register) or disable (release) optional licenses. You must enable a license to use the features controlled by the license.

If you no longer want to use the features covered by an optional term license, you can disable the license. Disabling the license releases it in your Cisco Smart Software Manager account, so that you can apply it to another device.

You can also enable evaluation versions of these licenses when running in evaluation mode. In evaluation mode, the licenses are not registered with Cisco Smart Software Manager until you register the device. However, you cannot enable the RA VPN license in evaluation mode.

### Before you begin

Before disabling a license, ensure that you are not using it. Rewrite or delete any policies that require the license.

### Procedure

**Step 1**

Click **Device**, then click **View Configuration** in the Smart License summary.

**Step 2**

Click the **Enable/Disable** control for each optional license as desired.

- **Enable**—Registers the license with your Cisco Smart Software Manager account and enables the controlled features. You can now configure and deploy policies controlled by the license.

- **Disable**—Unregisters the license with your Cisco Smart Software Manager account and disables the controlled features. You cannot configure the features in new policies, nor can you deploy policies that use the feature.

**Step 3**

If you enabled the **RA VPN** license, select the type of license you have available in your account.

You can use any of the AnyConnect licenses: **Plus**, **Apex**, or **VPN Only**. You can select **Plus and Apex** if you have both licenses and you want to use them both.
Synchronizing with the Cisco Smart Software Manager

The system periodically synchronizes license information with Cisco Smart Software Manager. Normal license communication occurs every 30 days, but with the grace period, your appliance will operate for up to 90 days without calling home.

However, if you make changes in the Cisco Smart Software Manager, you can refresh the authorization on the device so the changes immediately take effect.

Synchronization gets the current status of licenses, and renews authorization and the ID certificate.

Procedure

Step 1: Click Device, then click View Configuration in the Smart License summary.
Step 2: Select Resync Connection from the gear drop-down list.

Unregistering the Device

If you no longer want to use the device, you can unregister it from the Cisco Smart Software Manager. When you unregister, the base license and all optional licenses associated with the device are freed in your virtual account. Optional licenses are available to be assigned to other devices.

After unregistering the device, the current configuration and policies on the device continue to work as-is, but you cannot make or deploy any changes.

Procedure

Step 1: Click Device, then click View Configuration in the Smart License summary.
Step 2: Select Unregister Device from the gear drop-down list.
Step 3: Read the warning and click Unregister if you really want to unregister the device.
Unregistering the Device
Monitoring the Device

The system includes dashboards and an Event Viewer that you can use to monitor the device and traffic that is passing through the device.

- Enable Logging to Obtain Traffic Statistics, on page 87
- Monitoring Traffic and System Dashboards, on page 90
- Monitoring Additional Statistics Using the CommandLine, on page 92
- Viewing Events, on page 93

Enable Logging to Obtain Traffic Statistics

You can monitor a wide range of traffic statistics using the monitoring dashboards and the Event Viewer. However, you must enable logging to tell the system which statistics to collect. Logging generates various types of events that provide insight into the connections going through the system.

The following topics explain more about events and the information they provide, with special emphasis on connection logging.

Event Types

The system can generate the following types of events. You must generate these events to see related statistics in the monitoring dashboards.

Connection Events

You can generate events for connections as users generate traffic that passes through the system. Enable connection logging on access rules to generate these events. You can also enable logging on Security Intelligence policies and SSL decryption rules to generate connection events.

Connection events include a wide variety of information about a connection, including source and destination IP addresses and ports, URLs and applications used, and the number of bytes or packets transmitted. The information also includes the action taken (for example, allowing or blocking the connection), and the policies applied to the connection.

Intrusion Events

The system examines the packets that traverse your network for malicious activity that could affect the availability, integrity, and confidentiality of a host and its data. When the system identifies a possible intrusion, it generates an intrusion event, which is a record of the date, time, type of exploit, and contextual information.
information about the source of the attack and its target. Intrusion events are generated for any intrusion rule set to block or alert, regardless of the logging configuration of the invoking access control rule.

**File Events**

File events represent files that the system detected, and optionally blocked, in network traffic based on your file policies. You must enable file logging on the access rule that applies the file policy to generate these events.

When the system generates a file event, the system also logs the end of the associated connection regardless of the logging configuration of the invoking access control rule.

**Malware Events**

The system can detect malware in network traffic as part of your overall access control configuration. AMP for Firepower can generate a malware event, containing the disposition of the resulting event, and contextual data about how, where, and when the malware was detected. You must enable file logging on the access rule that applies the file policy to generate these events.

The disposition of a file can change, for example, from clean to malware or from malware to clean. If AMP for Firepower queries the AMP cloud about a file, and the cloud determines the disposition has changed within a week of the query, the system generates retrospective malware events.

**Security Intelligence Events**

Security Intelligence events are a type of connection event generated by the Security Intelligence policy for each connection blacklisted (blocked) or monitored by the policy. All Security Intelligence events have a populated Security Intelligence Category field.

For each of these events, there is a corresponding “regular” connection event. Because the Security Intelligence policy is evaluated before many other security policies, including access control, when a connection is blocked by Security Intelligence, the resulting event does not contain the information that the system would have gathered from subsequent evaluation, for example, user identity.

### Configurable Connection Logging

You should log connections according to the security and compliance needs of your organization. If your goal is to limit the number of events you generate and improve performance, only enable logging for the connections critical to your analysis. However, if you want a broad view of your network traffic for profiling purposes, you can enable logging for additional connections.

Because the system can log a connection for multiple reasons, disabling logging in one place does not ensure that matching connections will not be logged.

You can configure connection logging in the following places:

- **Access control rules and default action**—Logging at the end of a connection provides the most information about the connection. You can also log the beginning of the connection, but these events have incomplete information. Connection logging is disabled by default, so you must enable it for each rule (and the default action) that targets traffic that you want to track.

- **Security Intelligence policy**—You can enable logging to generate Security Intelligence connection events for each blacklisted connection. When the system logs a connection event as the result of Security Intelligence filtering, it also logs a matching Security Intelligence event, which is a special kind of connection event that you can view and analyze separately.
• SSL Decryption rules and default action—You can configure logging at the end of a connection. For blocked connections, the system immediately ends the session and generates an event. For monitored connections and connections that you pass to access control rules, the system generates an event when the session ends.

**Automatic Connection Logging**

The system automatically saves the following end-of-connection events, regardless of any other logging configurations.

• The system automatically logs connections associated with intrusion events, unless the connection is handled by the access control policy's default action. You must enable logging on the default action to get intrusion events for matching traffic.

• The system automatically logs connections associated with file and malware events. This is for connection events only: you can optionally disable the generation of file and malware events.

**Tips for Connection Logging**

Keep the following tips in mind when considering your logging configuration and the evaluation of related statistics:

• When you allow traffic with an access control rule, you can use an associated intrusion or file policy (or both) to further inspect traffic and block intrusions, prohibited files, and malware before the traffic can reach its final destination. Note, however, that by default file and intrusion inspection is disabled for encrypted payloads. If the intrusion or file policies find reason to block a connection, the system immediately logs an end-of-connection event regardless of your connection log settings. Logging allowed connections provides the most statistical information on the traffic in your network.

• A trusted connection is one that is handled by a Trust access control rule or the default action in an access control policy. However, trusted connections are not inspected for discovery data, intrusions, or prohibited files and malware. Therefore, connection events for trusted connections contain limited information.

• For access control rules and access control policy default actions that block traffic, the system logs beginning-of-connection events. Matching traffic is denied without further inspection.

• Logging blocked TCP connections during a Denial of Service (DoS) attack can affect system performance and overwhelm the database with multiple similar events. Before you enable logging for a Block rule, consider whether the rule monitors traffic on an Internet-facing interface or other interface vulnerable to DoS attack.

**Sending Events to an External Syslog Server**

Besides viewing events through Firepower Device Manager, which has a limited capacity to store events, you can selectively configure rules and policies to send events to an external syslog server. You can then use the features and additional storage of your selected syslog server platform to view and analyze event data.

To send events to an external syslog server, edit each rule, default action, or policy that enables connection logging and select a syslog server object in the log settings. To send intrusion events to a syslog server, configure the server in the intrusion policy settings.
For more information, see the help for each rule and policy type and also see Configuring Syslog Servers, on page 115.

Monitoring Traffic and System Dashboards

The system includes several dashboards that you can use to analyze the traffic going through the device and the results of your security policy. Use the information to evaluate the overall efficacy of your configuration and to identify and resolve network problems.

**Note**

The data used in traffic-related dashboards is collected from access control rules that enable connection or file logging, and other security policies that allow logging. The dashboards do not reflect traffic that matches rules for which no logging is enabled. Ensure that you configure your rules to log the information that matters to you. In addition, user information is available only if you configure identity rules to collect user identity. And finally, intrusion, file, malware, and URL category information is available only if you have a license for those features and configure rules that use the features.

**Procedure**

**Step 1**

Click **Monitoring** in the main menu to open the Dashboards page.

You can select predefined time ranges, such as the last hour or week, or define a custom time range with specific start and end times, to control the data shown in the dashboard graphs and tables.

Traffic-related dashboards include the following types of display:

- **Top 5 bar graphs**—These are shown in the **Network Overview** dashboard, and in the per-item summary dashboards you see if you click on an item in a dashboard table. You can toggle the information between a count of **Transactions** or **Data Usage** (total bytes sent and received). You can also toggle the display to show all transactions, allowed transactions, or denied transactions. Click the **View More** link to see the table associated with the graph.

- **Tables**—Tables show items of a particular type (for example, applications or URL categories) with that item's total transactions, allowed transactions, blocked transactions, data usage, and bytes sent and received. You can toggle the numbers between raw **Values** and **Percentages**, and show the top 10, 100, or 1000 entries. If the item is a link, click it to see a summary dashboard with more detailed information.

**Step 2**

Click the **Dashboard** links in the table of contents to see dashboards for the following data:

- **Network Overview**—Shows summary information about the traffic in the network, including the access rules (policies) matched, users initiating traffic, applications used in connections, intrusion threats (signatures) matched, URL categories for URLs accessed, and the most frequent destinations for connections.

- **Users**—Shows the top users of your network. You must configure identity policies to see user information. If there is no user identity, the source IP address is included. You might see the following special entities:
  - **Failed Authentication**—The user was prompted to authenticate, but failed to enter a valid username/password pair within the maximum number of allowed attempts. Failure to authenticate
does not itself prevent the user from accessing the network, but you can write an access rule to limit network access for these users.

- **Guest**—Guest users are like Failed Authentication users, except that your identity rule is configured to call these users Guest. Guest users were prompted to authenticate and failed to do so within the maximum number of attempts.

- **No Authentication Required**—The user was not prompted to authentication, because the user's connections matched identity rules that specified no authentication.

- **Unknown**—There is no user mapping for the IP address, and there is no record of failed authentication yet. Typically, this means that no HTTP traffic has yet been seen from that address.

- **Applications**—Shows the top applications, such as HTTP, that are being used in the network. The information is available only for connections that are inspected. Connections are inspected if they match an “allow” rule, or a block rule that uses criteria other than zone, address, and port. Thus, application information is not available if the connection is trusted or blocked prior to hitting any rule that requires inspection.

- **Web Applications**—Shows the top web applications, such as Google, that are being used in the network. The conditions for collecting web application information are the same as those for the Application dashboard.

- **URL Categories**—Shows the top categories of websites, such as Gambling or Educational Institutions, that are being used in the network based on the categorization of web sites visited. You must have at least one access control rule that uses URL category as a traffic matching criteria to get this information. The information will be available for traffic that matches the rule, or for traffic that has to be inspected to determine if it matches the rule. You will not see category (or reputation) information for connections that match rules that come before the first web-category access control rule.

- **Access And SI Rules**—Shows the top access rules and Security Intelligence rule-equivalents matched by network traffic.

- **Zones**—Shows the top security zone pairs for traffic entering and then exiting the device.

- **Destinations**—Shows the top destinations for network traffic.

- **Attackers**—Shows the top attackers, which are the source of connections that trigger intrusion events. You must configure intrusion policies on access rules to see this information.

- **Targets**—Shows the top targets of intrusion events, which are the victims of an attack. You must configure intrusion policies on access rules to see this information.

- **Threats**—Shows the top intrusion rules that have been triggered. You must configure intrusion policies on access rules to see this information.

- **File Logs**—Shows the top file types seen in network traffic. You must configure file policies on access rules to see this information.

- **Malware**—Shows the top Malware action and disposition combinations. You can drill down to see information on the associated file types. You must configure file policies on access rules to see this information.

  - Possible actions are: Malware Cloud Lookup, Block, Archive Block (Encrypted), Detect, Custom Detection, Cloud Lookup Timeout, Malware Whitelist, Malware Block, Archive Block (Depth Exceeded), Custom Detection Block, TID block, Archive Block (Failed to Inspect).
Monitoring Additional Statistics Using the Command Line

The Firepower Device Manager dashboards provide a wide variety of statistics related to the traffic going through the device and general system usage. However, you can get additional information on areas not covered by the dashboards using the CLI Console or by logging into the device CLI (see Logging Into the Command Line Interface (CLI), on page 12).

The CLI includes a variety of show commands to provide these statistics. You can also use the CLI for general troubleshooting, including commands such as ping and traceroute. Most show commands have companion clear commands to reset statistics to 0. (You cannot clear statistics from the CLI Console.)

For example, you might find the following commands generally useful.

- **show nat** displays hit counts for your NAT rules.
- **show xlate** displays the actual NAT translations that are active.
- **show conn** provides information about current connections going through the device.
- **show dhcpd** provides information about the DHCP servers you configure on the interfaces.
- **show interface** provides usage statistics for each interface.
Viewing Events

You can view events that are generated from your security policies that enable logging. Events are also generated for intrusion and file policies that are triggered.

The event viewer table shows the events generated in real time. As new events are generated, older events are rolled out of the table.

Before you begin

Whether events of particular types are generated depends on the following in addition to connections that match the related policy:

- Connection events—An access rule must enable connection logging. You can also enable connection logging in the Security Intelligence policy and in SSL decryption rules.
- Intrusion events—An access rule must apply an intrusion policy.
- File and Malware events—An access rule must apply a file policy and enable file logging.
- Security Intelligence events—You must enable and configure the Security Intelligence policy, and enable logging.

Procedure

Step 1  Click Monitoring in the main menu.

Step 2  Select Events from the table of contents.

The event viewer organizes events on tabs based on event types. For more information, see Event Types, on page 87.

Step 3  Click the tab that shows the type of event you want to view.

You can do the following with the event list:

- Click Pause to stop the addition of new events so that you can more easily find and analyze an event. Click Resume to allow new events to appear.
- Select a different refresh rate (5, 10, 20, or 60 seconds) to control how fast new events are shown.
- Create a custom view that includes the columns you want. To create a custom view, either click the + button in the tab bar, or click Add/Remove Columns. You cannot change the pre-set tabs, so adding or removing columns creates a new view. For more information, see Configuring Custom Views, on page 94.
- To change the width of a column, click and drag the column heading divider to the desired width.
- Mouse over an event and click View Details to see complete information on an event. For a description of the various fields in an event, see Event Field Descriptions, on page 96.

Step 4  If necessary, apply a filter to the table to help you locate the desired events based on various event attributes.

To create a new filter, either manually type in the filter by selecting atomic elements from the drop-down list and entering the filter value, or build a filter by clicking a cell in the events table that includes a value on
which you want to filter. You can click multiple cells in the same column to create an OR condition among the values, or click cells in different columns to create an AND condition among the columns. If you build the filter by clicking cells, you can also edit the resulting filter to fine-tune it. For detailed information about creating filter rules, see Filtering Events, on page 95.

Once you build the filter, do any of the following:

- To apply the filter and update the table to show only those events that match the filter, click the Filter button.
- To clear an entire filter that you have applied and return the table to a non-filtered state, click Reset Filters in the Filter box.
- To clear one of the atomic elements of a filter, mouse over the element and click the X for the element. Then, click the Filter button.

### Configuring Custom Views

You can create your own custom views so that you can easily see the columns you want when viewing events. You can also edit or delete custom views, although you cannot edit or delete the pre-defined views.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Select Monitoring &gt; Events.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Do one of the following:</td>
</tr>
<tr>
<td></td>
<td>- To create a new view based on an existing custom (or pre-defined) view, click the tab for the view, then click the + button to the left of the tabs.</td>
</tr>
<tr>
<td></td>
<td>- To edit an existing custom view, click the tab for the view.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To delete a custom view, simply click the X button in the view’s tab. You cannot undo a delete.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Click the Add/Remove Columns link above the events table on the right, and select or deselect columns until the selected list includes only those columns to include in the view. Click and drag columns between the available (but not used) and selected lists. You can also click and drag columns in the selected list to change the left-to-right order of the columns in the table. For a description of the columns, see Event Field Descriptions, on page 96. When finished, click OK to save your column changes.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>If you change column selection while viewing a pre-defined view, a new view is created.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>If necessary, change column widths by clicking and dragging the column separators.</td>
</tr>
</tbody>
</table>
Filtering Events

You can create complex filters to limit the events table to the events that currently interest you. You can use the following techniques, alone or in combination, to build a filter:

Clicking columns

The easiest way to build a filter is to click on cells in the events table that contain the values on which you intend to filter. Clicking a cell updates the Filter field with a correctly-formulated rule for that value and field combination. However, using this technique requires that the existing list of events contains the desired values.

You cannot filter on all columns. If you can filter on the contents of a cell, it is underlined when you mouse over it.

Selecting atomic elements

You can also build a filter by clicking in the Filter field and selecting the desired atomic element from the drop-down list, then typing in the match value. These elements include event fields that are not shown as columns in the events table. They also include operators to define the relationship between the value you type in and the events to display. Whereas clicking columns always results in an “equals (=)” filter, when you select an element, you can also select “greater than (>)” or “less than (<)” for numeric fields.

Regardless of how you add an element to the Filter field, you can type into the field to adjust the operator or value. Click Filter to apply the filter to the table.

Operators for Event Filters

You can use the following operators in an event filter:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equals. The event matches the specified value. You cannot use wildcards.</td>
</tr>
<tr>
<td>!=</td>
<td>Not equals. The event does not match the specified value. You must type in the ! (exclamation point) to build a not-equals expression.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than. The event contains a value that is greater than the specified value. This operator is available for numeric values only, such as port and IP address.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less than. The event contains a value that is less than the specified value. This operator is available for numeric values only.</td>
</tr>
</tbody>
</table>

Rules for Complex Event Filters

When building a complex filter that contains more than one atomic element, keep the following rules in mind:

- Elements of the same type have an OR relationship between all values for that type. For example, including Initiator IP=10.100.10.10 and Initiator IP=10.100.10.11 matches events that have either of these addresses as the traffic source.

- Elements of different types have an AND relationship. For example, including Initiator IP=10.100.10.10 and Destination Port/ICMP Type=80 matches events that have this source address AND destination port only. Events from 10.100.10.10 to a different destination port are not shown.

- Numeric elements, including IPv4 and IPv6 addresses, can specify ranges. For example, you could specify Destination Port=50-80 to capture all traffic for ports within this range. Use a hyphen to separate the start and end numbers. Ranges are not allowed for all numeric fields, for example, you cannot specify an IP address range in the Source element.
Event Field Descriptions

Events can contain the following information. You can see this information when you view event details. You can also add columns to the Event Viewer table to show the information that most interests you.

Following is a complete list of the available fields. Not every field applies to every type of event. Keep in mind that the information available for any individual event can vary depending on how, why, and when the system logged the connection.

**Action**

For connection or security intelligence events, the action associated with the access control rule or default action that logged the connection:

**Allow**

Explicitly allowed connections.

**Trust**

Trusted connections. TCP connections detected by a trust rule on the first packet only generate an end-of-connection event. The system generates the event one hour after the final session packet.

**Block**

Blocked connections. The **Block** action can be associated with Allow access rules under the following conditions:

- Connections where an exploit was blocked by an intrusion policy.
- Connections where a file was blocked by a file policy.
- Connections blacklisted by Security Intelligence.
- Connections blocked by an SSL policy.

**Default Action**

The connection was handled by the default action.

For file or malware events, the file rule action associated with the rule action for the rule the file matched, and any associated file rule action options.

**Allowed Connection**

Whether the system allowed the traffic flow for the event.

**Application**

The application detected in the connection.

**Application Business Relevance**

The business relevance associated with the application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of application detected in the connection has an associated business relevance; this field displays the lowest (least relevant) of those.
Application Categories, Application Tag
Criteria that characterize the application to help you understand the application's function.

Application Risk
The risk associated with the application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of application detected in the connection has an associated risk; this field displays the highest of those.

Block Type
The type of block specified in the access control rule matching the traffic flow in the event: block or interactive block.

Client Application, Client Version
The client application and version of that client detected in the connection.

Client Business Relevance
The business relevance associated with the client traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of client detected in the connection has an associated business relevance; this field displays the lowest (least relevant) of those.

Client Category, Client Tag
Criteria that characterize the application to help you understand the application's function.

Client Risk
The risk associated with the client traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of client detected in the connection has an associated risk; this field displays the highest of those.

Connection
The unique ID for the traffic flow, internally generated.

Connection Blocktype Indicator
The type of block specified in the access control rule matching the traffic flow in the event: block or interactive block.

Connection Bytes
The total bytes for the connection.

Connection Time
The time for the beginning of the connection.

Connection Timestamp
The time the connection was detected.

Denied Connection
Whether the system denied the traffic flow for the event.

Destination Country and Continent
The country and continent of the receiving host.

Destination IP
The IP address used by the receiving host in an intrusion, file, or malware event.
**Destination Port/ICMP Code; Destination Port; Destination Icode**

The port or ICMP code used by the session responder.

**Direction**

The direction of transmission for a file.

**Disposition**

The file's disposition:

- **Malware**
  Indicates that the AMP cloud categorized the file as malware or the file's threat score exceeded the malware threshold defined in the file policy. Local malware analysis can also mark files as malware.

- **Clean**
  Indicates that the AMP cloud categorized the file as clean, or that a user added the file to the clean list.

- **Unknown**
  Indicates that the system queried the AMP cloud, but the file has not been assigned a disposition; in other words, the AMP cloud has not categorized the file.

- **Unavailable**
  Indicates that the system could not query the AMP cloud. You may see a small percentage of events with this disposition; this is expected behavior.

- **N/A**
  Indicates that a Detect Files or Block Files rule handled the file and the system did not query the AMP cloud.

**Egress Interface, Egress Security Zone**

The interface and zone through which the connection exited the device.

**Event, Event Type**

The type of event.

**Event Seconds, Event Microseconds**

The time, in seconds or microseconds, when the event was detected.

**File Category**

The general categories of file type, for example: Office Documents, Archive, Multimedia, Executables, PDF files, Encoded, Graphics, or System Files.

**File Event Timestamp**

The time and date the file or malware file was created.

**File Name**

The name of the file.

**File Rule Action**

The action associated with file policy rule that detected the file, and any associated file rule action options.
**File SHA-256**
The SHA-256 hash value of the file.

**File Size (KB)**
The size of the file, in kilobytes. File size can be blank in cases where the system blocked the file before it was completely received.

**File Type**
The type of file, for example, HTML or MSEXE.

**File/Malware Policy**
The file policy associated with the generation of the event.

**Filelog Blocktype Indicator**
The type of block specified in the file rule matching the traffic flow in the event: block or interactive block.

**Firewall Policy Rule, Firewall Rule**
The access control rule or default action that handled the connection.

**First Packet**
The date and time the first packet of the session was seen.

**HTTP Referrer**
The HTTP referrer, which represents the referrer of a requested URL for HTTP traffic detected in the connection (such as a website that provided a link to, or imported a link from, another URL).

**HTTP Response**
The HTTP status code sent in response to a client's HTTP request over a connection.

**IDS Classification**
The classification where the rule that generated the event belongs.

**Ingress Interface, Ingress Security Zone**
The interface and zone through which the connection entered the device.

**Initiator Bytes, Initiator Packets**
The total number of bytes or packets transmitted by the session initiator.

**Initiator Country and Continent**
The country and continent of the host that initiated the session. Available only if the initiator IP address is routable.

**Initiator IP**
The host IP address (and hostname, if DNS resolution is enabled) that initiated the session in a connection or Security Intelligence event.

**Inline Result**
Whether the system dropped or would have dropped the packet that triggered an intrusion event if operating in inline mode. Blank indicates that the triggered rule was not set to Drop and Generate Events.
Intrusion Policy
The intrusion policy where the rule that generated the event was enabled.

IPS Blocktype Indicator
The action of the intrusion rule matching the traffic flow in the event.

Last Packet
The date and time the last packet of the session was seen.

MPLS Label
The Multiprotocol Label Switching label associated with the packet that triggered this intrusion event.

Malware Blocktype Indicator
The type of block specified in the file rule matching the traffic flow in the event: block or interactive block.

Message
For intrusion events, the explanatory text for the event. For malware or file events, any additional information associated with the malware event.

NetBIOS Domain
The NetBIOS domain used in the session.

Original Client Country and Continent
The country and continent of the original client host that initiated the session. Available only if the original client IP address is routable.

Original Client IP
The original IP address of the client that initiated an HTTP connection. This address is derived from the X-Forwarded-For (XFF) or True-Client-IP HTTP header fields or their equivalent.

Policy, Policy Revision
The access control policy, and its revision, that includes the access (firewall) rule associated with the event.

Priority
The event priority as determined by the Cisco Talos Intelligence Group (Talos): high, medium, or low.

Protocol
The transport protocol used in the connection.

Reason
The reason or reasons the connection was logged, in the situations explained in the following table. This field is otherwise empty.

<table>
<thead>
<tr>
<th>Reason</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Block</td>
<td>The connection contained a file or malware file that the system prevented from being transmitted. A reason of File Block is always paired with an action of Block.</td>
</tr>
<tr>
<td>Reason</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>File Monitor</td>
<td>The system detected a particular type of file in the connection.</td>
</tr>
<tr>
<td>File Resume Allow</td>
<td>File transmission was originally blocked by a Block Files or Block Malware file rule. After a new access control policy allowing the file was deployed, the HTTP session automatically resumed.</td>
</tr>
<tr>
<td>File Resume Block</td>
<td>File transmission was originally allowed by a Detect Files or Malware Cloud Lookup file rule. After a new access control policy blocking the file was deployed, the HTTP session automatically stopped.</td>
</tr>
<tr>
<td>Intrusion Block</td>
<td>The system blocked or would have blocked an exploit (intrusion policy violation) detected in the connection. A reason of Intrusion Block is paired with an action of Block for blocked exploits and Allow for would-have-blocked exploits.</td>
</tr>
<tr>
<td>Intrusion Monitor</td>
<td>The system detected, but did not block, an exploit detected in the connection. This occurs when the state of the triggered intrusion rule is set to Generate Events.</td>
</tr>
<tr>
<td>IP Block</td>
<td>The system denied the connection without inspection, based on the IP address and Security Intelligence data. A reason of IP Block is always paired with an action of Block.</td>
</tr>
<tr>
<td>SSL Block</td>
<td>The system blocked an encrypted connection based on the SSL inspection configuration. A reason of SSL Block is always paired with an action of Block.</td>
</tr>
<tr>
<td>URL Block</td>
<td>The system denied the connection without inspection, based on the URL and Security Intelligence data. A reason of URL Block is always paired with an action of Block.</td>
</tr>
</tbody>
</table>

**Receive Times**

The date and time the event was generated.

**Referenced Host**

If the protocol in the connection is HTTP or HTTPS, this field displays the hostname that the respective protocol was using.

**Responder Bytes, Responder Packets**

The total number of bytes or packets transmitted by the session responder.

**Responder Country and Continent**

The country and continent of the host that responded to the session. Available only if the responder IP address is routable.

**Responder IP**

The host IP address (and hostname, if DNS resolution is enabled) of the session responder in a connection or Security Intelligence event.
SI Category ID (Security Intelligence Category)

The name of the object that contained the blacklisted item, such as a network or URL object name, or the name of a feed category.

Signature

The signature ID for a file/malware event.

Source Country and Continent

The country and continent of the sending host. Available only if the source IP address is routable.

Source IP

The IP address used by the sending host in an intrusion, file, or malware event.

Source Port/ICMP Type; Source Port; Source Port Ictype

The port or ICMP type used by the session initiator.

SSL Actual Action

The actual action that the system applied to the connection. This can differ from the expected action. For example, a connection might match a rule that applies decryption, but could not be decrypted for some reason.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block/Block with reset</td>
<td>Represents blocked encrypted connections.</td>
</tr>
<tr>
<td>Decrypt (Resign)</td>
<td>Represents an outgoing connection decrypted using a re-signed server certificate.</td>
</tr>
<tr>
<td>Decrypt (Replace Key)</td>
<td>Represents an outgoing connection decrypted using a self-signed server certificate with a substituted public key.</td>
</tr>
<tr>
<td>Decrypt (Known Key)</td>
<td>Represents an incoming connection decrypted using a known private key.</td>
</tr>
<tr>
<td>Default Action</td>
<td>Indicates the connection was handled by the default action.</td>
</tr>
<tr>
<td>Do not Decrypt</td>
<td>Represents a connection the system did not decrypt.</td>
</tr>
</tbody>
</table>

SSL Certificate Fingerprint

The SHA hash value used to authenticate the certificate.

SSL Certificate Status

This applies only if you configured a Certificate Status SSL rule condition. If encrypted traffic matches an SSL rule, this field displays one or more of the following server certificate status values:

• Self Signed
• Valid
• Invalid Signature
• Invalid Issuer
• Expired
- Unknown
- Not Valid Yet
- Revoked

If undecryptable traffic matches an SSL rule, this field displays Not Checked.

**SSL Cipher Suite**
- The cipher suite used in the connection.

**SSL Expected Action**
- The action specified in the SSL rule the connection matched.

**SSL Flow Flags**
- The first ten debugging level flags for an encrypted connection.

**SSL Flow Messages**
- The SSL/TLS messages exchanged between client and server during the SSL handshake, such as HELLO_REQUEST and CLIENT HELLO. See [http://tools.ietf.org/html/rfc5246](http://tools.ietf.org/html/rfc5246) for more information about the messages exchanged in TLS connections.

**SSL Policy**
- The name of the SSL Decryption policy applied to the connection.

**SSL Rule**
- The name of the SSL Decryption rule applied to the connection.

**SSL Session ID**
- The hexadecimal Session ID negotiated between the client and server during the SSL handshake.

**SSL Ticket ID**
- A hexadecimal hash value of the session ticket information sent during the SSL handshake.

**SSL URL Category**
- The URL category of the destination web server as determined during SSL decryption processing.

**SSL Version**
- The SSL/TLS version used in the connection.

**TCP Flags**
- The TCP flags detected in the connection.

**Total Packets**
- The total number of packets transmitted in the connection, which is **Initiator Packets + Responder Packets**.

**URL, URL Category, URL Reputation, URL Reputation Score**
- The URL requested by the monitored host during the session and its associated category, reputation, and reputation score, if available.
If the system identifies or blocks an SSL application, the requested URL is in encrypted traffic, so the system identifies the traffic based on an SSL certificate. For SSL applications, therefore, the URL indicates the common name contained in the certificate.

**User**

The user associated with the initiator IP address.

**VLAN**

The innermost VLAN ID associated with the packet that triggered the event.

**Web App Business Relevance**

The business relevance associated with the web application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of web application detected in the connection has an associated business relevance; this field displays the lowest (least relevant) of those.

**Web App Categories, Web App Tag**

Criteria that characterize the web application to help you understand the web application’s function.

**Web App Risk**

The risk associated with the web application traffic detected in the connection: Very High, High, Medium, Low, or Very Low. Each type of web application detected in the connection has an associated risk; this field displays the highest of those.

**Web Application**

The web application, which represents the content or requested URL for HTTP traffic detected in the connection.

If the web application does not match the URL for the event, the traffic is probably referred traffic, such as advertisement traffic. If the system detects referred traffic, it stores the referring application (if available) and lists that application as the web application.
CHAPTER 5

Objects

Objects are reusable containers that define criteria that you want to use in policies or other settings. For example, network objects define host and subnet addresses.

Objects let you define criteria so that you can easily reuse the same criteria in different policies. When you update an object, all policies that use the object are automatically updated.

• Object Types, on page 105
• Managing Objects, on page 107

Object Types

You can create the following types of object. In most cases, if a policy or setting allows an object, you must use an object.

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Main Use</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AnyConnect Client Profile</td>
<td>Remote access VPN.</td>
<td>AnyConnect client profiles are downloaded to clients along with the AnyConnect client software. These profiles define many client-related options, such as auto connect on startup and auto reconnect, and whether the end user is allowed to change the option from the AnyConnect client preferences and advanced settings. See Configure and Upload Client Profiles, on page 357.</td>
</tr>
<tr>
<td>Application Filter</td>
<td>Access control rules.</td>
<td>An application filter object defines the applications used in an IP connection, or a filter that defines applications by type, category, tag, risk, or business relevance. You can use these objects in policies to control traffic instead of using port specifications. See Configuring Application Filter Objects, on page 111.</td>
</tr>
<tr>
<td>Certificates</td>
<td>Identity policies.</td>
<td>Digital certificates provide digital identification for authentication. Certificates are used for SSL (Secure Socket Layer), TLS (Transport Layer Security), and DTLS (Datagram TLS) connections, such as HTTPS and LDAPS. See Configuring Certificates, on page 126.</td>
</tr>
<tr>
<td>Object Type</td>
<td>Main Use</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Geolocation</td>
<td>Security policies.</td>
<td>A geolocation object defines countries and continents that host the device that is the source or destination of traffic. You can use these objects in policies to control traffic instead of using IP addresses. See Configuring Geolocation Objects, on page 114.</td>
</tr>
<tr>
<td>Identity Realm</td>
<td>Identity policies.</td>
<td>An identity realm is a directory server plus other attributes required to provide authentication services. The directory server contains information about the users and user groups who are allowed access to your network. See Configuring AD Identity Realms, on page 116.</td>
</tr>
<tr>
<td>IKE Policy</td>
<td>VPN.</td>
<td>Internet Key Exchange (IKE) Policy objects define the IKE proposal used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). There are separate objects for IKEv1 and IKEv2. See Configuring the Global IKE Policy, on page 331.</td>
</tr>
<tr>
<td>IPsec Proposal</td>
<td>VPN.</td>
<td>IPsec Proposal objects configure the IPsec proposal used during IKE Phase 2 negotiations. The IPsec proposal defines the combination of security protocols and algorithms that secure traffic in an IPsec tunnel. There are separate objects for IKEv1 and IKEv2. See Configuring IPsec Proposals, on page 335.</td>
</tr>
<tr>
<td>Network</td>
<td>Security policies and a wide variety of device settings.</td>
<td>Network groups and network objects (collectively referred to as network objects) define the addresses of hosts or networks. See Configuring Network Objects and Groups, on page 108.</td>
</tr>
<tr>
<td>Port</td>
<td>Security policies.</td>
<td>Port groups and port objects (collectively referred to as port objects) define the protocols, ports, or ICMP services for traffic. See Configuring Port Objects and Groups, on page 109.</td>
</tr>
<tr>
<td>Secret Keys</td>
<td>Smart CLI and FlexConfig policies.</td>
<td>Secret key objects define passwords or other authentication strings that you want to encrypt and hide. See Configuring Secret Key Objects, on page 449.</td>
</tr>
<tr>
<td>Security Zone</td>
<td>Security policies.</td>
<td>A security zone is a grouping of interfaces. Zones divide the network into segments to help you manage and classify traffic. See Configuring Security Zones, on page 110.</td>
</tr>
</tbody>
</table>
### Managing Objects

You can configure objects directly through the Objects page, or you can configure them while editing policies. Either method yields the same results, a new or updated object, so use the technique that suits your needs at the time.

The following procedure explains how you can create and manage your objects directly through the Objects page.

#### Procedure

**Step 1** Select Objects.

The Objects page has a table of contents listing the available types of objects. When you select an object type, you see a list of existing objects, and you can create new ones from here. You can also see the object contents and type.

**Step 2** Select the object type from the table of contents and do any of the following:

- To create an object, click the + button. The content of the objects differ based on type; see the configuration topic for each object type for specific information.
- To create a group object, click the Add Group (add) button. Group objects include more than one item.
- To edit an object, click the edit icon (edit) for the object. You cannot edit the contents of a pre-defined object.

---

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Main Use</th>
<th>Description</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syslog Servers</td>
<td>Access control rules, Diagnostic logging, Security Intelligence policies, SSL decryption rules, Intrusion policies.</td>
<td>A syslog server object identifies a server that can receive connection-oriented or diagnostic system log (syslog) messages. See Configuring Syslog Servers, on page 115.</td>
<td></td>
</tr>
<tr>
<td>URL</td>
<td>Access control rules, Security Intelligence policies.</td>
<td>URL objects and groups (collectively referred to as URL objects) define the URL or IP addresses of web requests. See Configuring URL Objects and Groups, on page 113.</td>
<td></td>
</tr>
</tbody>
</table>
• To delete an object, click the delete icon (🗑) for the object. You cannot delete an object if it is currently being used in a policy or another object, or if it is a pre-defined object.

---

**Configuring Network Objects and Groups**

Use network group and network objects (collectively referred to as network objects) to define the addresses of hosts or networks. You can then use the objects in security policies for purposes of defining traffic matching criteria, or in settings to define the addresses of servers or other resources.

A network object defines a single host or network address, whereas a network group object can define more than one address.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create network objects while editing an address property by clicking the Create New Network link shown in the object list.

**Procedure**

**Step 1** Select **Objects**, then select **Network** from the table of contents.

**Step 2** Do one of the following:

• To create an object, click the + button.

• To create a group, click the **Add Group** (.addButton) button.

• To edit an object or group, click the edit icon (editIcon) for the object.

To delete an unreferenced object, click the trash can icon (trashIcon) for the object.

**Step 3** Enter a Name for the object and optionally, a description, and define the object contents.

We recommend that you do not use an IP address alone for the name so that you can easily tell object names from object contents or standalone IP addresses. If you want to use an IP address in the name, prefix it with something meaningful, such as host-192.168.1.2 or network-192.168.1.0. If you use an IP address as the name, the system adds a vertical bar as a prefix, for example, |192.168.1.2. FDM does not show the bar in the object selectors, but you will see this naming standard if you examine the running configuration using the `show running-config` command in the CLI.

**Step 4** Configure the contents of the object.

**Network Objects**

Select the object **Type** and configure the contents:

• **Network**—Enter a network address using one of the following formats:
  
  • IPv4 network including subnet mask, for example, 10.100.10.0/24 or 10.100.10.0/255.255.255.0.
  
  • IPv6 network including prefix, for example, 2001:DB8:0:CD30::/60.

• **Host**—Enter a host IP address using one of the following formats:
  
  • IPv4 host address, for example, 10.100.10.10.
• IPv6 host address, for example, 2001:DB8::0DB8:800:200C:417A or 2001:DB8:0:0:0DB8:800:200C:417A.

Network Groups
Click the + button to select network objects to add to the group. You can also create new objects.

Step 5  
Click OK to save your changes.

Configuring Port Objects and Groups
Use port group and port objects (collectively referred to as port objects) to define the protocols, ports, or ICMP services for traffic. You can then use the objects in security policies for purposes of defining traffic matching criteria, for example, to use access rules to allow traffic to specific TCP ports.

A port object defines a single protocol, TCP/UDP port or port range, or ICMP service, whereas a port group object can define more than one service.

The system includes several pre-defined objects for common services. You can use these objects in your policies. However, you cannot edit or delete system-defined objects.

Note
When creating port group objects, ensure that the combination of objects makes sense. For example, you cannot have a mixture of protocols in an object if you use it to specify both source and destination ports in an access rule. Exercise care when editing an object that is already being used, or you could invalid (and disable) policies that use the object.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create port objects while editing a service property by clicking the Create New Port link shown in the object list.

Procedure

Step 1  
Select Objects, then select Ports from the table of contents.

Step 2
Do one of the following:

• To create an object, click the + button.
• To create a group, click the Add Group ( ) button.
• To edit an object or group, click the edit icon ( ) for the object.

To delete an unreferenced object, click the trash can icon ( ) for the object.

Step 3
Enter a name for the object and optionally, a description, and define the object contents.

Port Objects
Select the Protocol, then configure the protocol as follows:
• **TCP, UDP**—Enter the single port or port range number, for example, 80 (for HTTP) or 1-65535 (to cover all ports).

• **ICMP, IPv6-ICMP**—Select the ICMP Type and optionally, the **Code**. Select Any for the type to apply to all ICMP messages. For information on the types and codes, see the following pages:
  - **ICMP**—http://www.iana.org/assignments/icmp-parameters/icmp-parameters.xml
  - **ICMPv6**—http://www.iana.org/assignments/icmpv6-parameters/icmpv6-parameters.xml

• **Other**—Select the desired protocol.

### Port Groups
Click the + button to select port objects to add to the group. You can also create new objects.

**Step 4** Click **OK** to save your changes.

## Configuring Security Zones

A security zone is a grouping of interfaces. Zones divide the network into segments to help you manage and classify traffic. You can define multiple zones, but a given interface can be in one zone only.

The system creates the following zones during initial configuration. You can edit these zones to add or remove interfaces, or you can delete the zones if you no longer use them.

• **inside_zone**—Includes the inside interface. If the inside interface is a bridge group, this zone includes all the bridge group member interfaces instead of the inside Bridge Virtual Interface (BVI). This zone is intended to represent internal networks.

• **outside_zone**—Includes the outside interface. This zone is intended to represent networks external to your control, such as the Internet.

Typically, you would group interfaces by the role they play in your network. For example, you would place the interface that connects to the Internet in the **outside_zone** security zone, and all of the interfaces for your internal networks in the **inside_zone** security zone. Then, you could apply access control rules to traffic coming from the outside zone and going to the inside zone.

Before creating zones, consider the access rules and other policies you want to apply to your networks. For example, you do not need to put all internal interfaces into the same zone. If you have 4 internal networks, and you want to treat one differently than the other three, you can create two zones rather than one. If you have an interface that should allow outside access to a public web server, you might want to use a separate zone for the interface.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create security zones while editing a security zone property by clicking the **Create New Security Zone** link shown in the object list.

### Procedure

**Step 1** Select Objects, then select **Security Zones** from the table of contents.

**Step 2** Do one of the following:
• To create an object, click the + button.

• To edit an object, click the edit icon (📝) for the object.

To delete an unreferenced object, click the trash can icon (🗑️) for the object.

Step 3
Enter a Name for the object and optionally, a description.

Step 4
In the Interfaces list, click + and select the interfaces to add to the zone.

The list shows all named interfaces that are not currently in a zone. You must configure an interface and give it a name before you can add it to a zone.

If all named interfaces are already in zones, the list is empty. If you are trying to move an interface to a different zone, you must first remove it from its current zone.

Note You cannot add a bridge group interface (BVI) to a zone. Instead, add the member interfaces. You can put the members into different zones.

Step 5
Click OK to save your changes.

Configuring Application Filter Objects

An application filter object defines the applications used in an IP connection, or a filter that defines applications by type, category, tag, risk, or business relevance. You can use these objects in policies to control traffic instead of using port specifications.

Although you can specify individual applications, application filters simplify policy creation and administration. For example, you could create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is blocked.

You can select applications and application filters directly in a policy without using application filter objects. However, an object is convenient if you want to create several policies for the same group of applications or filters. The system includes several pre-defined application filters, which you cannot edit or delete.

Note
Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule blocking high risk applications can automatically apply to new applications without you having to update the rule manually.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create application filter objects while editing an access control rule by clicking the Save As Filter link after adding application criteria to the Applications tab.

Before you begin
When editing a filter, if a selected application was removed by a VDB update, “(Deprecated)” appears after the application name. You must remove these applications from the filter, or subsequent deployments and system software upgrades will be blocked.
**Procedure**

**Step 1**
Select **Objects**, then select **Application Filters** from the table of contents.

**Step 2**
Do one of the following:

- To create an object, click the + button.
- To edit an object, click the edit icon (📝) for the object.

To delete an unreferenced object, click the trash can icon (🗑️) for the object.

**Step 3**
Enter a Name for the object and optionally, a description.

**Step 4**
In the **Applications** list, click **Add +** and select the applications and filters to add to the object.

The initial list shows applications in a continually scrolling list. Click **Advanced Filter** to see the filter options and to get an easier view for selecting applications. Click **Add** when you have made your selections. You can repeat the process to add additional applications or filters.

**Note**

Multiple selections within a single filter criteria have an OR relationship. For example, Risk is High OR Very High. The relationship between filters is AND, so Risk is High OR Very High, AND Business Relevance is Low OR Very Low. As you select filters, the list of applications in the display updates to show only those that meet the criteria. You can use these filters to help you find applications that you want to add individually, or to verify that you are selecting the desired filters to add to the rule.

**Risks**

The likelihood that the application is used for purposes that might be against your organization's security policy, from very low to very high.

**Business Relevance**

The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally, from very low to very high.

**Types**

The type of application:

- **Application Protocol**—Application protocols such as HTTP and SSH, which represent communications between hosts.
- **Client Protocol**—Clients such as web browsers and email clients, which represent software running on the host.
- **Web Application**—Web applications such as MPEG video and Facebook, which represent the content or requested URL for HTTP traffic.

**Categories**

A general classification for the application that describes its most essential function.

**Tags**

Additional information about the application, similar to category.
For encrypted traffic, the system can identify and filter traffic using only the applications tagged **SSL Protocol**. Applications without this tag can only be detected in unencrypted or decrypted traffic. Also, the system assigns the **decrypted traffic** tag to applications that the system can detect in decrypted traffic only, not encrypted or unencrypted.

**Applications List (bottom of the display)**

This list updates as you select filters from the options above the list, so you can see the applications that currently match the filter. Use this list to verify that your filter is targeting the desired applications when you intend to add filter criteria to the rule. If your intention is to add specific applications, select them from this list.

**Step 5** Click **OK** to save your changes.

---

**Configuring URL Objects and Groups**

Use URL objects and groups (collectively referred to as URL objects) to define the URL or IP addresses of web requests. You can use these objects to implement manual URL filtering in access control policies, or blocking in Security Intelligence policies.

A URL object defines a single URL or IP address, whereas a URL group object can define more than one URL or address.

When creating URL objects, keep the following points in mind:

- If you do not include a path (that is, there is no / character in the URL), the match is based on the server’s hostname only. The hostname is considered a match if it comes after the :// separator, or after any dot in the hostname. For example, ign.com matches ign.com and www.ign.com, but it does not match verisign.com.

- If you include one or more / character, the entire URL string is used for a substring match, including the server name, path, and any query parameters. However, we recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites, as servers can be reorganized and pages moved to new paths. Substring matching can also lead to unexpected matches, where the string you include in the URL object also matches paths on unintended servers or strings within query parameters.

- The system disregards the encryption protocol (HTTP vs HTTPS). In other words, if you block a website, both HTTP and HTTPS traffic to that website is blocked, unless you use an application condition to target a specific protocol. When creating a URL object, you do not need to specify the protocol when creating an object. For example, use example.com rather than http://example.com.

- If you plan to use a URL object to match HTTPS traffic in an access control rule, create the object using the subject common name in the public key certificate used to encrypt the traffic. Also, the system disregards subdomains within the subject common name, so do not include subdomain information. For example, use example.com rather than www.example.com.

However, please understand that the subject common name in the certificate might be completely unrelated to a website’s domain name. For example, the subject common name in the certificate for youtube.com is *.google.com (this of course might change at any time). You will get more consistent results if you use the SSL Decryption policy to decrypt HTTPS traffic so that URL filtering rules work on decrypted traffic.
URL objects will not match HTTPS traffic if the browser resumes a TLS session because the certificate information is no longer available. Thus, even if you carefully configure the URL object, you might get inconsistent results for HTTPS connections.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create URL objects while editing a URL property by clicking the Create New URL link shown in the object list.

**Procedure**

**Step 1** Select Objects, then select URL from the table of contents.

**Step 2** Do one of the following:
- To create an object, click the + button.
- To create a group, click the Add Group (✓) button.
- To edit an object or group, click the edit icon (✓) for the object.

To delete an unreferenced object, click the trash can icon (✓) for the object.

**Step 3** Enter a Name for the object and optionally, a description.

**Step 4** Define the object contents.

**URL Objects**

Enter a URL or IP address in the URL box. You cannot use wildcards in the URL.

**URL Groups**

Click the + button to select URL objects to add to the group. You can also create new objects.

**Step 5** Click OK to save your changes.

---

### Configuring Geolocation Objects

A geolocation object defines countries and continents that host the device that is the source or destination of traffic. You can use these objects in policies to control traffic instead of using IP addresses. For example, using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

You can typically select geographical locations directly in a policy without using geolocation objects. However, an object is convenient if you want to create several policies for the same group of countries and continents.

---

**Note**

To ensure that you are using up-to-date geographical location data to filter your traffic, Cisco strongly recommends that you regularly update the geolocation database (GeoDB).
The following procedure explains how you can create and edit objects directly through the Objects page. You can also create geolocation objects while editing a network property by clicking the Create New Geolocation link shown in the object list.

**Procedure**

**Step 1** Select **Objects**, then select **Geolocation** from the table of contents.

**Step 2** Do one of the following:

- To create an object, click the + button.
- To edit an object, click the edit icon (📝) for the object.

To delete an unreferenced object, click the trash can icon (🗑️) for the object.

**Step 3** Enter a Name for the object and optionally, a description.

**Step 4** In the **Continents/Countries** list, click **Add +** and select the continents and countries to add to the object.

Selecting a continent selects all countries within the continent.

**Step 5** Click **OK** to save your changes.

### Configuring Syslog Servers

A syslog server object identifies a server that can receive connection-oriented or diagnostic system log (syslog) messages. If you have a syslog server set up for log collection and analysis, create objects to define them and use the objects in the related policies.

You can send the following types of events to the syslog server:

- Connection events. Configure the syslog server object on the following types of policy: access control rules and default action, SSL decryption rules and default action, Security Intelligence policy.
- Intrusion events. Configure the syslog server object on the intrusion policy.
- Diagnostic events. See Configuring Diagnostic Logging, on page 393.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create syslog server objects while editing a syslog server property by clicking the Add Syslog Server link shown in the object list.

**Procedure**

**Step 1** Select **Objects**, then select **Syslog Servers** from the table of contents.

**Step 2** Do one of the following:

- To create an object, click the + button.
- To edit an object, click the edit icon (📝) for the object.
To delete an unreferenced object, click the trash can icon (eń) for the object.

**Step 3** Configure the syslog server properties:

- **Device Interface**—Select the interface through which the syslog server is reached. If the server is accessible through a bridge group member interface, select the bridge group interface (BVI) instead.
  
  **Note** The Snort process does not use this interface for intrusion events. Snort always sends intrusion syslog messages out the virtual management interface. If you use this syslog server for intrusion policies, ensure that the syslog server is also reachable from the management IP address.

- **IP Address**—Enter the IP address of the syslog server.

- **Port**—Enter the UDP port that the server uses for receiving syslog messages. The default is 514. If you change the default, the port must be in the range 1025 to 65535.

**Step 4** Click OK to save your changes.

---

**Configuring AD Identity Realms**

An identity realm is a directory server plus other attributes required to provide authentication services. The directory server contains information about the users and user groups who are allowed access to your network.

For Active Directory, a realm is equivalent to an Active Directory domain.

Realms are used in the following policies:

- **Identity**—The realm provides user identity and group membership information, which you can then use in access control rules. The system downloads updated information about all users and groups every day in the last hour of the day (UTC). The directory server must be reachable from the management interface.

- **Remote access VPN**—The realm provides authentication services, which determine whether a connection is allowed. The directory server must be reachable from the RA VPN outside interface.

Work with your directory administrator to get the values required to configure the directory server properties.

**Note** If the directory server is not on an attached network or available through the default route, create a static route for the server. Select **Device > Routing > View Configuration** to create static routes.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create identity realm objects while editing a realm property by clicking the **Create New Identity Realm** link shown in the object list.

**Before you begin**

Ensure that time settings are consistent among the directory servers, Firepower Threat Defense device, and clients. A time shift among these devices can prevent successful user authentication. “Consistent” means that you can use different time zones, but the time should be the same relative to those zones; for example, 10 AM PST = 1 PM EST.
Procedure

Step 1
Select Objects, then select Identity Realm from the table of contents.

Step 2
Do one of the following:
- To create a realm, click the + button. You can create at most one realm.
- To edit a realm, click the edit icon (blue) for the realm.

You cannot delete a realm once you create it. To stop using the realm, disable the configured feature that uses it.

Step 3
Configure the basic realm properties.
- Name—A name for the directory realm.
- Type—The type of directory server. Active Directory is the only supported type, and you cannot change this field.
- Directory Username, Directory Password—The distinguished username and password for a user with appropriate rights to the user information you want to retrieve. For Active Directory, the user does not need elevated privileges. You can specify any user in the domain. The username must be fully qualified; for example, Administrator@example.com (not simply Administrator).

Note
The system generates ldap-login-dn and ldap-login-password from this information. For example, Administrator@example.com is translated as cn=administrator,cn=users,dc=example,dc=com. Note that cn=users is always part of this translation, so you must configure the user you specify here under the common name “users” folder.

- Base DN—The directory tree for searching or querying user and group information, that is, the common parent for users and groups. For example, cn=users,dc=example,dc=com. For information on finding the base DN, see Determining the Directory Base DN, on page 120.
- AD Primary Domain—The fully qualified Active Directory domain name that the device should join. For example, example.com.

Step 4
Configure the directory server properties.
- Hostname/IP Address—The hostname or IP address of the directory server. If you use an encrypted connection to the server, you must enter the fully-qualified domain name, not the IP address.
- Port—The port number used for communications with the server. The default is 389. Use port 636 if you select LDAPS as the encryption method.
- Encryption—To use an encrypted connection for downloading user and group information, select the desired method, STARTTLS or LDAPS. The default is None, which means that user and group information is downloaded in clear text.

  - STARTTLS negotiates the encryption method, and uses the strongest method supported by the directory server. Use port 389. This option is not supported if you use the realm for remote access VPN.
  - LDAPS requires LDAP over SSL. Use port 636.
• **Trusted CA Certificate**—If you select an encryption method, upload a Certificate Authority (CA) certificate to enable a trusted connection between the system and the directory server. If you are using a certificate to authenticate, the name of the server in the certificate must match the server Hostname/IP Address. For example, if you use 10.10.10.250 as the IP address but ad.example.com in the certificate, the connection fails.

**Step 5**  
Click the **Test** button to verify the system can contact the server.

The system uses separate processes and interfaces to access the server, so you might get errors indicating that the connection works for one type of use but not another, for example, available for Identity policies but not for remote access VPN. If the server cannot be reached, verify that you have the right IP address and hostname, that the DNS server has an entry for the hostname, and so forth. You might need to configure a static route for the server. For more information, see **Troubleshooting Directory Server Connections, on page 118**.

**Step 6**  
Click **OK**.

---

**Troubleshooting Directory Server Connections**

The system uses different processes to communicate with your directory server depending on the feature. Thus, a connection for identity policies might work, whereas one for remote access VPN fails.

These processes use different interfaces to communicate with the directory server. You must ensure connectivity from these interfaces.

- Management interface, for: identity policies.
- Data interface, for: remote access VPN (outside interface).

When you configure the identity realm, use the **Test** button to verify that the connection can work. Failure messages should indicate the feature that is having connection problems. The following are the general issues you might encounter, based on authentication attributes and routing/interface configuration.

**Directory user authentication issues.**

If the problem is that the system could not log into the directory server because of the username or password, ensure that the name and password are correct and valid on the directory server. For Active Directory, the user does not need elevated privileges. You can specify any user in the domain. The username must be fully qualified; for example, Administrator@example.com (not simply Administrator).

Also, the system generates ldap-login-dn and ldap-login-password from the username and password information. For example, Administrator@example.com is translated as cn=administrator,cn=users,dc=example,dc=com. Note that cn=users is always part of this translation, so you must configure the user you specify here under the common name “users” folder.

**The directory server is accessible through a data interface.**

If the directory server is on a network that is either directly connected to a data interface (such as a GigabitEthernet interface), or routeable from a directly-connected network, you must ensure that there is a route between the virtual management interface and the directory server.

- Using **data-interfaces** as the management gateway should make routing successful.
- If you have an explicit gateway on the management interface, that gateway router needs to have a route to the directory server.
• You do not need to configure an IP address on the diagnostic interface, which is the physical interface used by the virtual management interface. However, if you do configure an address, do not also configure a static route (such as a default route) that would redirect traffic to the directory server to the diagnostic interface.

• If there is a router between the directly-connected network and the network that hosts the directory server, configure a static route for the directory server (Device > Routing).

• Verify that the data interface has the correct IP address and subnet mask.

The directory server is accessible through the Management physical interface.

If the directory server is on the network that is either directly connected to the Management physical interface (such as Management0/0) or routeable from that network, you must do the following:

• Configure an IPv4 address for the Management interface (with the logical name diagnostic) on Device > Interfaces. The IP address must be on the same subnet as the virtual management address (Device > System Settings > Management Interface).

• If there is a router between the directory server and the Management interface, configure a route for the directory server on Device > Routing for the diagnostic interface.

• Verify that the diagnostic and management interfaces have the correct IP address and subnet mask.

The directory server is on an external network.

If the directory server is on a network on the other side of the outside (uplink) interface, you might need to configure a site-to-site VPN connection. For the detailed procedure, see How to Use a Directory Server on an Outside Network with Remote Access VPN, on page 372.

Limitations on Number of Users

Firepower Device Manager can download information on up to 2000 users from the directory server.

If your directory server includes more than 2000 user accounts, you will not see all possible names when selecting users in an access rule or when viewing user-based dashboard information. You can write rules on only those names that were downloaded.

The limit also applies to the names associated with groups. If a group has more than 2000 members, only the 2000 names that were downloaded can be matched against the group membership.

If you have more than 2000 users, consider using Firepower Management Center (the remote manager) instead of Firepower Device Manager. Firepower Management Center supports significantly more users.

Supported Directory Servers

You can use Microsoft Active Directory (AD) on Windows Server 2008 and 2012.

Note the following about your server configuration:

• If you want to perform user control on user groups or on users within groups, you must configure user groups on the directory server. The system cannot perform user group control if the server organizes the users in basic object hierarchy.

• The directory server must use the field names listed in the following table in order for the system to retrieve user metadata from the servers for that field.
Determining the Directory Base DN

When you configure directory properties, you need to specify the common base distinguished name (DN) for users and groups. The base is defined in your directory server, and differs from network to network. You must enter the correct bases for identity policies to work. If the base is wrong, the system cannot determine user or group names, and thus identity-based policies will be inoperable.

Tip
To get the correct bases, consult the administrator who is responsible for the directory servers.

For active directory, you can determine the correct bases by logging into the Active Directory server as domain administrator, and using the `dsquery` command at a command prompt as follows to determine the bases:

**User search base**

Enter the `dsquery user` command with a known username (partial or complete) to determine the base distinguished name. For example, the following command uses the partial name “John*” to return information for all users that start with “John.”

```
C:\Users\Administrator>dsquery user -name "John*"
"CN=John Doe,CN=Users,DC=csc-lab,DC=example,DC=com"
```

The base DN would be “DC=csc-lab,DC=example,DC=com.”

**Group search base**

Enter the `dsquery group` command with a known group name to determine the base distinguished name. For example, the following command uses the group name Employees to return the distinguished name:

```
C:\>dsquery group -name "Employees"
"CN=Employees,CN=Users,DC=csc-lab,DC=example,DC=com"
```

The group base DN would be “DC=csc-lab,DC=example,DC=com.”

Cisco Firepower Threat Defense Configuration Guide for Firepower Device Manager, Version 6.2.3
You can also use the ADSI Edit program to browse the Active Directory structure (Start > Run > adsiedit.msc). In ADSI Edit, right click any object, such as an organizational unit (OU), group, or user, and choose Properties to view the distinguished name. You can then copy the string of DC values as the base.

To verify that you have the correct base:

1. Click the Test Connection button in the directory properties to verify connectivity. Resolve any problems, and save the directory properties.

2. Commit changes to the device.

3. Create an access rule, select the Users tab, and try to add known user and group names from the directory. You should see auto-complete suggestions as you type for matching users and groups in the realm that contains the directory. If these suggestions appear in a drop-down list, then the system was able to query the directory successfully. If you see no suggestions, and you are certain the string you typed should appear in a user or group name, you need to correct the corresponding search base.
Certificates

Digital certificates provide digital identification for authentication. Certificates are used for SSL (Secure Socket Layer), TLS (Transport Layer Security), and DTLS (Datagram TLS) connections, such as HTTPS and LDAPS. The following topics explain how to create and manage certificates.

- About Certificates, on page 123
- Configuring Certificates, on page 126

About Certificates

Digital certificates provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. A digital certificate also includes a copy of the public key for the user or device. Certificates are used for SSL (Secure Socket Layer), TLS (Transport Layer Security), and DTLS (Datagram TLS) connections, such as HTTPS and LDAPS.

You can create the following types of certificate:

- Internal certificates—Internal identity certificates are certificates for specific systems or hosts. You can generate these yourself using the OpenSSL toolkit or get them from a Certificate Authority. You can also generate a self-signed certificate.

- Internal Certificate Authority (CA) certificates—Internal CA certificates are certificates that the system can use to sign other certificates. These certificates differ from internal identity certificates with respect to the basic constraints extension and the CA flag, which are enabled for CA certificates but disabled for identity certificates. You can generate these yourself using the OpenSSL toolkit or get them from a Certificate Authority. You can also generate a self-signed internal CA certificate. If you configure self-signed internal CA certificates, the CA runs on the device itself.

- Trusted Certificate Authority (CA) certificates—A trusted CA certificate is used to sign other certificates. It is self-signed and called a root certificate. A certificate that is issued by another CA certificate is called a subordinate certificate.

Certificate Authorities (CAs) are trusted authorities that “sign” certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security. A CA can be a trusted third party, such as VeriSign, or a private (in-house) CA that you establish within your organization. CAs are responsible for managing certificate requests and issuing digital certificates. For more information, see Public Key Cryptography, on page 124.
Public Key Cryptography

In public key cryptography, such as the RSA encryption system, each user has a key pair containing both a public and a private key. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other.

In simple terms, a signature is formed when data is encrypted with a private key. The signature is attached to the data and sent to the receiver. The receiver applies the public key of the sender to the data. If the signature sent with the data matches the result of applying the public key to the data, the validity of the message is established.

This process relies on the receiver having a copy of the public key of the sender and a high degree of certainty that this key belongs to the sender, not to someone pretending to be the sender.

Obtaining the public key of a sender is normally handled externally or through an operation performed at installation. For example, most web browsers are configured with the root certificates of several CAs by default.

You can learn more about digital certificates and public key cryptography through openssl.org, Wikipedia, or other sources. Having a firm understanding of SSL/TLS cryptography will help you establish secure connections to your device.

Certificate Types Used by Feature

You need to create the right type of certificate for each feature. The following features require certificates.

Identity Policies (Captive Portal)—Internal Certificate

(Optional.) Captive portal is used in identity policies. Users must accept this certificate when authenticating to the device for purposes of identifying themselves and getting their IP address associated with their usernames. If you do not supply a certificate, the device uses an automatically generated certificate.

Identity Realms (Identity Policies and Remote Access VPN)—Trusted CA Certificate

(Optional.) If you use an encrypted connection for your directory server, the certificate must be accepted to perform authentication with the directory server. Users must authenticate when prompted by identity and remote access VPN policies. A certificate is not needed if you do not use encryption for the directory server.

Remote Access VPN—Internal Certificate

(Required.) The internal certificate is for the outside interface, which establishes the device identity for AnyConnect clients when they make a connection to the device. Clients must accept this certificate.

SSL Decryption Policy—Internal, Internal CA, and Trusted CA Certificates

(Required.) The SSL decryption policy uses certificates for the following purposes:

- Internal certificates are used for known key decryption rules.
- Internal CA certificates are used for decrypt re-sign rules when creating the session between the client and FTD device.
- Trusted CA certificates are used indirectly for decrypt re-sign rules when creating the session between the FTD device and server. Unlike the other certificates, you do not directly configure these certificates in the SSL decryption policy; they simply need to be uploaded to the system. The system includes a large number of trusted CA certificates, so you might not need to upload any additional certificates.
Example: Generating an Internal Certificate using OpenSSL

The following example uses OpenSSL commands to generate an internal server certificate. You can obtain OpenSSL from openssl.org. Consult OpenSSL documentation for specific information. The commands used in this example might change, and you might have other options available that you might want to use.

This procedure is meant to give you an idea of how to obtain a certificate to upload to FTD.

Note

The OpenSSL commands shown here are examples only. Adjust the parameters to fit your security requirements.

Procedure

Step 1
Generate a key.

```
openssl genrsa -out server.key 4096
```

Step 2
Generate a certificate signing request (CSR).

```
openssl req -new -key server.key -out server.csr
```

Step 3
Generate a self-signed certificate with the key and CSR.

```
openssl x509 -req -days 365 -in server.csr -signkey server.key -out server.crt
```

Because Firepower Device Manager does not support encrypted keys, try to skip the challenge password by just pressing return when generating a self signed certificate.

Step 4
Upload the files into the appropriate fields when creating an internal certificate object in Firepower Device Manager.

You can also copy/paste the file contents. The sample commands create the following files:

- server.crt—Upload or paste the contents into the Server Certificate field.
- server.key—Upload or paste the contents into the Certificate Key field. If you provided a password when generating the key, you can decrypt it using the following command. The output is sent to stdout, where you can copy it.

```
openssl rsa -in server.key -check
```
Configuring Certificates

FTD supports X509 certificates in PEM or DER format. Use OpenSSL to generate certificates if needed, obtain them from a trusted Certificate Authority, or create self-signed certificates.

For more information on certificates, see About Certificates, on page 123.

For information on which type is used for each feature, see Certificate Types Used by Feature, on page 124.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create certificate objects while editing a certificate property by clicking the Create New Certificate link shown in the object list.

Procedure

Step 1
Select Objects, then select Certificates from the table of contents.

The system comes with the following pre-defined certificates, which you can use as is or replace.

- DefaultInternalCertificate
- NGFW-Default-InternalCA

The system also includes many trusted CA certificates from third party Certificate Authorities. These are used by SSL decryption policies for Decrypt Re-Sign actions.

Step 2
Do one of the following:

- To create a new certificate object, use the command for the type of certificate from the + menu.
- To view or edit a certificate, click either the edit icon ( ) or the view icon ( ) for the certificate.
- To delete an unreferenced certificate, click the trash can icon ( ) for the certificate.

For detailed information on creating or editing certificates, see the following topics:

- Uploading Internal and Internal CA Certificates, on page 126
- Generating Self-Signed Internal and Internal CA Certificates, on page 128
- Uploading Trusted CA Certificates, on page 129

Uploading Internal and Internal CA Certificates

Internal identity certificates are certificates for specific systems or hosts.

Internal CA certificates are certificates that the system can use to sign other certificates. These certificates differ from internal identity certificates with respect to the basic constraints extension and the CA flag, which are enabled for CA certificates but disabled for identity certificates.
You can generate these certificates yourself using the OpenSSL toolkit or get them from a Certificate Authority, and then upload them using the following procedure. For an example of generating a key, see Example: Generating an Internal Certificate using OpenSSL, on page 125.

You can also generate a self-signed internal identity and internal CA certificates. If you configure self-signed internal CA certificates, the CA runs on the device itself. For information on creating self-signed certificates, see Generating Self-Signed Internal and Internal CA Certificates, on page 128.

For information on the features that use these certificates, see Certificate Types Used by Feature, on page 124.

### Procedure

**Step 1**
Select **Objects**, then select **Certificates** from the table of contents.

**Step 2**
Do one of the following:

- **Add Internal Certificate**

- **Add Internal CA Certificate**

**Step 3**
Enter a **Name** for the certificate.

The name is used in the configuration as an object name only, it does not become part of the certificate itself.

**Step 4**
Click **Upload Certificate** (or **Replace Certificate** when editing) and select the certificate file (for example, *.crt). Allowed file extensions are .pem, .cert, .cer, .crt, and .der. Alternatively, paste in the certificate.

The certificate must be an X509 certificate in PEM or DER format.

The certificate you paste must include the BEGIN CERTIFICATE and END CERTIFICATE lines. For example:

```
-----BEGIN CERTIFICATE-----
MIICMTCCAzoGCCqoU3DgYDQgMCIiNVRk79nMjzw/SFZ9YgdMLDUGJ1bYgkjN7mVrkjyLQxxTYsem
r8iTK66iyTRbuS4iPeyEKKnF5FglCqKWEdmthN9kBhOsPs1A8e60r5mImeDrtw+
```

**Step 5**
Click **Upload Key** (or **Replace Key** when editing) and select the certificate file (for example, *.key). The file extension must be .key. Alternatively, paste in the key for the certificate.

The key cannot be encrypted.

For example:

```
-----BEGIN RSA PRIVATE KEY-----
MIICQAIBAAKBgQChJr79nMjzw/SFZ9YgdMLDUGJ1bYgkjN7mVrkjyLQxxTYsem
r8iTK66iyTRbuS4iPeyEKKnF5FglCqKWEdmthN9kBhOsPs1A8e60r5mImeDrtw+
```
Step 6  Click OK.

---

Generating Self-Signed Internal and Internal CA Certificates

Internal identity certificates are certificates for specific systems or hosts.

Internal CA certificates are certificates that the system can use to sign other certificates. These certificates differ from internal identity certificates with respect to the basic constraints extension and the CA flag, which are enabled for CA certificates but disabled for identity certificates.

You can generate a self-signed internal identity and internal CA certificates, that is, the certificates are signed by the device itself. If you configure self-signed internal CA certificates, the CA runs on the device. The system generates both the certificate and the key.

You can also create these certificates using OpenSSL, or obtain them from a trusted CA, and upload them. For more information, see Uploading Internal and Internal CA Certificates, on page 126.

For information on the features that use these certificates, see Certificate Types Used by Feature, on page 124.

Note

New self-signed certificates are generated with a 5-year validity term. Be sure to replace certificates before they expire.

Procedure

Step 1  Select Objects, then select Certificates from the table of contents.

Step 2  Do one of the following:

• Click + > Add Internal Certificate, then click Self-Signed Certificate.

• Click + > Add Internal CA Certificate, then click Self-Signed Certificate.

Note

To edit or view a certificate, click the information icon (i). The dialog box shows the certificate subject, issuer, and valid time range. Click Replace Certificate to upload a new certificate and key. When replacing a certificate, you cannot redo the self-signed characteristics explained in the following steps. Instead, you must paste or upload a new certificate as described in Uploading Internal and Internal CA Certificates, on page 126. The remaining steps apply to new self-signed certificates only.

Step 3  Enter a Name for the certificate.
The name is used in the configuration as an object name only, it does not become part of the certificate itself.

**Step 4** Configure at least one of the following for the certificate subject and issuer information.

- **Country** (C)—The two-character ISO 3166 country code to include in the certificate. For example, the country code for the United States is US. Select the country code from the drop-down list.
- **State or Province** (ST)—The state or province to include in the certificate.
- **Locality or City** (L)—The locality to include in the certificate, such as the name of the city.
- **Organization** (O)—The organization or company name to include in the certificate.
- **Organizational Unit (Department)** (OU)—The name of the organization unit (for example, a department name) to include in the certificate.
- **Common Name** (CN)—The X.500 common name to include in the certificate. This could be the name of the device, web site, or another text string. This element is usually required for successful connections. For example, you must include a CN in the internal certificate used for remote access VPN.

**Step 5** Click Save.

---

### Uploading Trusted CA Certificates

A trusted Certificate Authority (CA) certificate is used to sign other certificates. It is self-signed and called a root certificate. A certificate that is issued by another CA certificate is called a subordinate certificate.

For information on the features that use these certificates, see Certificate Types Used by Feature, on page 124.

Obtain a trusted CA certificate from an external Certificate Authority, or create one using your own internal CA, for example, with OpenSSL tools. Then, use the following procedure to upload the certificate.

**Procedure**

**Step 1** Select Objects, then select Certificates from the table of contents.

**Step 2** Do one of the following:

- Click + > Add Trusted CA Certificate.

- To edit a certificate, click the edit icon (☐) for the certificate.

**Step 3** Enter a Name for the certificate.

The name is used in the configuration as an object name only, it does not become part of the certificate itself.

**Step 4** Click Upload Certificate (or Replace Certificate when editing) and select the trusted CA certificate file (for example *.pem). Allowed file extensions are .pem, .cert, .cer, .crt, and .der. Alternatively, paste in the trusted CA certificate.

The name of the server in the certificate must match the server Hostname / IP Address. For example, if you use 10.10.10.250 as the IP address but ad.example.com in the certificate, the connection fails.

The certificate must be an X509 certificate in PEM or DER format.
The certificate you paste must include the BEGIN CERTIFICATE and END CERTIFICATE lines. For example:

```
-----BEGIN CERTIFICATE-----
MIIFgTCCA2mgAwIBAgIJAANvdClnabFGYMA0GCSqGSIb3DQEBCwUAMFowCzAJBgNV
BAYTa1VMTQswCQYDVQQIDAUNEPMA0GA1UDEwBw FitzgeraldGVzdGluMRIwIAYDVQQK

**Step 5** Click OK.
PART 1

The Basics

• Interfaces, on page 133
• Routing, on page 155
CHAPTER 7

Interfaces

The following topics explain how to configure the interfaces on your FTD device.

- About FTD Interfaces, on page 133
- Guidelines and Limitations for Interfaces, on page 136
- Configure a Physical Interface, on page 138
- Configure Bridge Groups, on page 141
- Configure VLAN Subinterfaces and 802.1Q Trunking, on page 145
- Configure Advanced Interface Options, on page 148
- Add Interfaces to Firepower Threat Defense Virtual, on page 151
- Monitoring Interfaces, on page 152
- Examples for Interfaces, on page 153

About FTD Interfaces

The FTD includes data interfaces as well as a management/diagnostic interface.

When you attach a cable to an interface connection (physically or virtually), you need to configure the interface. At minimum, you need to name the interface and enable it for it to pass traffic. If the interface is a member of a bridge group, this is sufficient. For non-bridge group members, you also need to give the interface an IP address. If you intend to create VLAN subinterfaces rather than a single physical interface on a given port, you would typically configure the IP addresses on the subinterface, not on the physical interface. VLAN subinterfaces let you divide a physical interface into multiple logical interfaces that are tagged with different VLAN IDs, which is useful when you connect to a trunk port on a switch.

The interface list shows the available interfaces, their names, addresses, and states. You can change the state of an interface, on or off, directly in the list of interfaces. The list shows the interface characteristics based on your configuration. Use the open/close arrow on a bridge group interface to view the member interfaces, which also appear by themselves in the list. For information on how these interfaces map to virtual interfaces and network adapters, see How VMware Network Adapters and Interfaces Map to Firepower Threat Defense Physical Interfaces, on page 21.

The following topics explain the limitations of configuring interfaces through Firepower Device Manager as well as other interface management concepts.

Interface Modes

You can configure one of the following modes for each interface:
Routed

Each Layer 3 routed interface requires an IP address on a unique subnet. You would typically attach these interfaces to switches, a port on another router, or to an ISP/WAN gateway.

BridgeGroupMember

A bridge group is a group of interfaces that the FTD bridges instead of routes. All interfaces are on the same network. The bridge group is represented by a Bridge Virtual Interface (BVI) that has an IP address on the bridge network.

You can route between routed interfaces and BVIs, if you name the BVI. In this case, the BVI acts as the gateway between member interfaces and routed interfaces. If you do not name the BVI, traffic on the bridge group member interfaces cannot leave the bridge group. Normally, you would name the interface so that you can route member interfaces to the internet.

One use for a bridge group in routed mode is to use extra interfaces on the Firepower Threat Defense device instead of an external switch. You can attach endpoints directly to bridge group member interfaces. You can also attach switches to add more endpoints to the same network as the BVI.

Management/Diagnostic Interface

The physical port labeled Management (or for Firepower Threat Defense Virtual, the Management0/0 virtual interface) actually has two separate interfaces associated with it.

- Management virtual interface—This IP address is used for system communication. This is the address the system uses for Smart Licensing and to retrieve database updates. You can open management sessions to it (Firepower Device Manager and CLI). You must configure a management address, which is defined on System Settings > Management Interface.

- Diagnostic physical interface—The physical Management port is actually named Diagnostic. You can use this interface to send syslog messages to an external syslog server. Configuring an IP address for the Diagnostic physical interface is optional. The only reason to configure the interface is if you want to use it for syslog. This interface appears, and is configurable, on the Device > Interfaces page. The Diagnostic physical interface only allows management traffic, and does not allow through traffic.

(Hardware devices.) The recommended way to configure Management/Diagnostic is to not wire the physical port to a network. Instead, configure the Management IP address only, and configure it to use the data interfaces as the gateway for obtaining updates from the Internet. Then, open the inside interfaces to HTTPS/SSH traffic (by default, HTTPS is enabled) and open Firepower Device Manager using the inside IP address (see Configuring the Management Access List, on page 391).

For Firepower Threat Defense Virtual, the recommended configuration is to attach Management0/0 to the same network as the inside interface, and use the inside interface as the gateway. Do not configure a separate address for Diagnostic.

Recommendations for Configuring a Separate Management Network

(Hardware devices.) If you want to use a separate management network, wire the physical Management/Diagnostic interface to a switch or router.

For Firepower Threat Defense Virtual, attach Management0/0 to a separate network from any of the data interfaces. If you are still using the default IP addresses, you will need to change either the management IP address or the inside interface IP address, as they are on the same subnet.

Then, configure the following:
Limitations for Management/Diagnostic Interface Configuration for a Separate Management Network

If you wire the physical Management interface, or for Firepower Threat Defense Virtual, you attach Management0/0 to a separate network, ensure that you follow these limitations:

- If you want a DHCP server on the management network, configure it on the Management interface (Device > System Settings > Management Interface). You cannot configure a DHCP server on the Diagnostic (physical) interface.
- If there is another DHCP server on the management network, disable it or the DHCP server running on Management. As a rule, a given subnet should have no more than one DHCP server.
- If you configure addresses for both Management and Diagnostic, ensure that they are on the same subnet.
- (Hardware devices only.) You can use the data interfaces as the management gateway even if you configure an IP address for Diagnostic. But Diagnostic will not use the data interfaces as a gateway. If you need a path from Diagnostic to other networks, another router on the management network needs to route the traffic originating from the Diagnostic IP address. If necessary, configure static routes for the Diagnostic interface (select Device > Routing).

Security Zones

Each interface can be assigned to a single security zone. You then apply your security policy based on zones. For example, you can assign the inside interface to the inside zone; and the outside interface to the outside zone. You can configure your access control policy to enable traffic to go from inside to outside, but not from outside to inside, for example.

For bridge groups, you add member interfaces to the zones, you cannot add the Bridge Virtual Interface (BVI). You do not include the Diagnostic/Management interface in a zone. Zones apply to data interfaces only.

You can create security zones on the Objects page.

IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network. For a bridge group, you configure the global address on the Bridge Virtual Interface (BVI), not on each member interface. You cannot specify any of the following as a global address.
• Internally reserved IPv6 addresses: fd00::/56 (from=fd00:: to=fd00:0000:0000:00ff:ffff:ffff:ffff:ffff)
• An unspecified address, such as ::/128
• The loopback address, ::1/128
• Multicast addresses, ff00::/8
• Link-local addresses, fe80::/10

• Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the Network Discovery functions such as address resolution and neighbor discovery. In a bridge group, enabling IPv6 on the BVI automatically configures link-local addresses for each bridge group member interface. Each interface must have its own address because the link-local address is only available on a segment, and is tied to the interface MAC address.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

**Auto-MDI/MDIX Feature**

For RJ-45 interfaces, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

**Guidelines and Limitations for Interfaces**

The following topics cover some of the limitations for interfaces.

**Limitations for Interface Configuration**

When you use Firepower Device Manager to configure the device, there are several limitations to interface configuration. If you need any of the following features, you must use Firepower Management Center to configure the device.

• Routed firewall mode only is supported. You cannot configure transparent firewall mode interfaces.

• You cannot configure passive or ERSPAN interfaces.

• You cannot configure interfaces to be inline (in an inline set), or inline tap, for IPS-only processing. IPS-only mode interfaces bypass many firewall checks and only support IPS security policy. In comparison, Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow
states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this firewall mode traffic according to your security policy.

- You cannot configure EtherChannel or redundant interfaces.
- You can only add one bridge group.
- You cannot configure PPPoE for IPv4. If the Internet interface is connected to a DSL, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address, you must use Firepower Management Center to configure these settings.
- For the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X, and the Firepower 2100 series, you can install an optional network interface module. Modules are only discovered during bootstrap (that is, initial installation or reimage, or when switching between local/remove management). Firepower Device Manager sets the correct defaults for speed and duplex for these interfaces. If you replace an optional module with one that changes the speed/duplex options for the interfaces, without changing the total number of interfaces available, reboot the device so that the system recognizes the correct speed/duplex values for the replaced interfaces. From an SSH or Console session with the device, enter the reboot command. Then, in Firepower Device Manager, edit each physical interface that had capability changes and select valid speed and duplex options, as the system does not automatically correct your original settings. Deploy your changes right away to ensure correct system behavior.

---

**Note**

Replacing a module with one that changes the total number of interfaces, or removing interfaces that were referred to by other objects, can result in unexpected problems. If you need to make this kind of change, please first remove all references to the interfaces you will remove, such as security zone membership, VPN connections, and so forth. We also suggest you do a backup prior to making the change.

- For Firepower Threat Defense Virtual devices, you cannot add or remove interfaces without reinitializing the device as described in Add Interfaces to Firepower Threat Defense Virtual, on page 151. However, if you simply replace interfaces with ones that have different speed/duplex capabilities, reboot the device so that the system recognizes the new speed/duplex values. From the CLI console, enter the reboot command. Then, in Firepower Device Manager, edit each interface that had capability changes and select valid speed and duplex options, as the system does not automatically correct your original settings. Deploy your changes right away to ensure correct system behavior.

---

**Maximum Number of VLAN Subinterfaces by Device Model**

The device model limits the maximum number of VLAN subinterfaces that you can configure. Note that you can configure subinterfaces on data interfaces only, you cannot configure them on the management interface. The following table explains the limits for each device model.

<table>
<thead>
<tr>
<th>Model</th>
<th>Maximum VLAN Subinterfaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firepower 2100</td>
<td>1024</td>
</tr>
<tr>
<td>Firepower Threat Defense Virtual</td>
<td>50</td>
</tr>
</tbody>
</table>
Configure a Physical Interface

At minimum, you must enable a physical interface to use it. You would also typically name it and configure IP addressing. You would not configure IP addressing if you intend to create VLAN subinterfaces, or if you intend to add the interface to a bridge group.

You can disable an interface to temporarily prevent transmission on the connected network. You do not need to remove the interface's configuration.

**Procedure**

**Step 1**
Click **Device**, then click the link in the **Interfaces** summary.

The interface list shows the available interfaces, their names, addresses, and states.

**Step 2**
Click the edit icon (🔗) for the physical interface you want to edit.

**Step 3**
Set the following:

<table>
<thead>
<tr>
<th>Model</th>
<th>Maximum VLAN Subinterfaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASA 5506-X</td>
<td>30</td>
</tr>
<tr>
<td>ASA 5506W-X</td>
<td>50</td>
</tr>
<tr>
<td>ASA 5506H-X</td>
<td>100</td>
</tr>
<tr>
<td>ASA 5515-X</td>
<td>100</td>
</tr>
<tr>
<td>ASA 5516-X</td>
<td>100</td>
</tr>
<tr>
<td>ASA 5525-X</td>
<td>200</td>
</tr>
<tr>
<td>ASA 5545-X</td>
<td>300</td>
</tr>
<tr>
<td>ASA 5555-X</td>
<td>500</td>
</tr>
<tr>
<td>ISA 3000</td>
<td>25</td>
</tr>
</tbody>
</table>
### Configure a Physical Interface

**a)** Set the **Interface Name**.

Set the name for the interface, up to 48 characters. Alphabetic characters must be lower case. For example, `inside` or `outside`. Without a name, the rest of the interface configuration is ignored. Unless you configure subinterfaces, the interface should have a name.

**Note**  
If you change the name, the change is automatically reflected everywhere you used the old name, including security zones, syslog server objects, and DHCP server definitions. However, you cannot remove the name until you first remove all configurations that use the name, because you typically cannot use an unnamed interface for any policy or setting.

**b)** Set the **Status** slider to the enabled setting (on).

If you intend to configure subinterfaces for this physical interface, you are probably done. Click **Save** and continue with Configure VLAN Subinterfaces and 802.1Q Trunking, on page 145. Otherwise, continue.

**Note**  
Even when configuring subinterfaces, it is valid to name the interface and supply IP addresses. This is not the typical setup, but if you know that is what you need, you can configure it.

**c)** (Optional) Set the **Description**.

The description can be up to 200 characters on a single line, without carriage returns.
Step 4  Click the IPv4 Address tab and configure the IPv4 address.

Select one of the following options from the Type field:

- **Dynamic (DHCP)**—Choose this option if the address should be obtained from the DHCP server on the network. Change the following options if necessary:
  - **Route Metric**—If you obtain the default route from the DHCP server, the administrative distance to the learned route, between 1 and 255. The default is 1.
  - **Obtain Default Route**—Whether to get the default route from the DHCP server. You would normally select this option, which is the default.

- **Static**—Choose this option if you want to assign an address that should not change. Type in the interface's IP address and the subnet mask for the network attached to the interface. For example, if you attach the 10.100.10.0/24 network, you could enter 10.100.10.1/24. Ensure that the address is not already used on the network.

  **Note** If there is a DHCP server configured for the interface, you are shown the configuration. You can edit or delete the DHCP address pool. If you change the interface IP address to a different subnet, you must either delete the DHCP server, or configure an address pool on the new subnet, before you can save the interface changes. See Configuring DHCP Server, on page 394.

Step 5  (Optional.) Click the IPv6 Address tab and configure the IPv6 address.

- **State**—To enable IPv6 processing and to automatically configure the link-local address when you do not configure the global address, select Enabled. The link local address is generated based on the interface MAC addresses (Modified EUI-64 format).

  **Note** Disabling IPv6 does not disable IPv6 processing on an interface that is configured with an explicit IPv6 address or that is enabled for autoconfiguration.

- **Address Auto Configuration**—Select this option to have the address automatically configured. IPv6 stateless autoconfiguration will generate a global IPv6 address only if the link on which the device resides has a router configured to provide IPv6 services, including the advertisement of an IPv6 global prefix for use on the link. If IPv6 routing services are not available on the link, you will get a link-local IPv6 address only, which you cannot access outside of the device's immediate network link. The link local address is based on the Modified EUI-64 interface ID.

Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the FTD device does send Router Advertisement messages in this case. Select Suppress RA to suppress messages and conform to the RFC.

- **Static Address/PREFIX**—If you do not use stateless autoconfiguration, enter the full static global IPv6 address and network prefix. For example, 2001:0DB8::BA98:0:3210/48. For more information on IPv6 addressing, see IPv6 Addressing, on page 135.

  If you want to use the address as link local only, select the Link - Local option. Link local addresses are not accessible outside the local network. You cannot configure a link-local address on a bridge group interface.

  **Note** A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:fee6:a82. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.
• **Suppress RA**—Whether to suppress router advertisements. The Firepower Threat Defense device can participate in router advertisements so that neighboring devices can dynamically learn a default router address. By default, router advertisement messages (ICMPv6 Type 134) are periodically sent out each IPv6 configured interface.

Router advertisements are also sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You might want to suppress these messages on any interface for which you do not want the FTD device to supply the IPv6 prefix (for example, the outside interface).

**Step 6** (Optional.) Configure Advanced Options, on page 149.

The advanced settings have defaults that are appropriate for most networks. Edit them only if you are resolving network issues.

**Step 7** Click **OK**.

---

**What to do next**

• Add the interfaces to the appropriate security zones. See Configuring Security Zones, on page 110.

---

**Configure Bridge Groups**

A bridge group is a virtual interface that groups one or more interfaces. The main reason to group interfaces is to create a group of switched interfaces. Thus, you can attach workstations or other endpoint devices directly to the interfaces included in the bridge group. You do not need to connect them through a separate physical switch, although you can also attach a switch to a bridge group member.

The group members do not have IP addresses. Instead, all member interfaces share the IP address of the Bridge Virtual Interface (BVI). If you enable IPv6 on the BVI, member interfaces are automatically assigned unique link-local addresses.

You enable and disable the member interfaces individually. Thus, you can disable any unused interfaces without needing to remove them from the bridge group. The bridge group itself is always enabled.

You typically configure a DHCP server on the bridge group interface (BVI), which provides IP addresses for any endpoints connected through member interfaces. However, you can configure static addresses on the endpoints connected to the member interfaces if you prefer. All endpoints within the bridge group must have IP addresses on the same subnet as the bridge group IP address.

**Guidelines and Limitations**

• You can add one bridge group.

• You cannot configure bridge groups on Firepower 2100 series or Firepower Threat Defense Virtual devices.

• For all ASA 5506-X models, on a new version 6.2+ system, or a reimaged 6.2+ system, the device comes pre-configured with bridge group BVI1, named **inside**, which includes all data interfaces except for the **outside** interface. Thus, the device is pre-configured with one port used for linking to the Internet or other upstream network, and all other ports enabled and available for direct connections to endpoints.
ISA 3000 models also come with this default configuration. If you want to use an inside interface for a new subnet, you must first remove the needed interfaces from BVII.

**Before you begin**

Configure the interfaces that will be members of the bridge group. Specifically, each member interface must meet the following requirements:

- The interface must have a name.
- The interface cannot have any IPv4 or IPv6 addresses defined for it, either static or served through DHCP. If you need to remove the address from an interface that you are currently using, you might also need to remove other configurations for the interface, such as static routes, DHCP server, or NAT rules, that depend on the interface having an address.
- You must remove the interface from its security zone (if it is in a zone), and delete any NAT rules for the interface, before you can add it to a bridge group.

**Procedure**

**Step 1** Click **Device**, then click the link in the **Interfaces** summary.

The interface list shows the available interfaces, their names, addresses, and states. If there is already a bridge group, it is a folder. Click the open/close arrow to view the member interfaces. Member interfaces also appear separately in the list.

**Step 2** Do one of the following:

- Click the edit icon (✓) for the BVII bridge group.
- Select **Add Bridge Group Interface** from the gear drop-down list to create a new group.

  **Note** You can have a single bridge group. If you already have a bridge group defined, you should edit that group instead of trying to create a new one. If you need to create a new bridge group, you must first delete the existing bridge group.

- Click the delete icon (✗) for the bridge group if you no longer need it. When you delete a bridge group, its members become standard routed interfaces, and any NAT rules or security zone membership are retained. You can edit the interfaces to give them IP addresses. If you want to add them to a new bridge group, first you need to remove the NAT rules and remove the interface from its security zone.

**Step 3** Configure the following:
a) (Optional) Set the **Interface Name**.

Set the name for the bridge group, up to 48 characters. Alphabetic characters must be lower case. For example, **inside** or **outside**. Set the name if you want this BVI to participate in routing between it and other named interfaces.

**Note** If you change the name, the change is automatically reflected everywhere you used the old name, including security zones, syslog server objects, and DHCP server definitions. However, you cannot remove the name until you first remove all configurations that use the name, because you typically cannot use an unnamed interface for any policy or setting.

b) (Optional) Set the **Description**.

The description can be up to 200 characters on a single line, without carriage returns.

c) Edit the **Bridge Group Members** list.

You can add up to 64 interfaces or subinterfaces to a single bridge group.

- Add an interface—Click the plus icon (➕), click one or more interfaces, and then click **OK**.
- Remove an interface—Mouse over an interface and click the x on the right side.

**Step 4** Click the **IPv4 Address** tab and configure the IPv4 address.

Select one of the following options from the **Type** field:

- **Static**—Choose this option if you want to assign an address that should not change. Type in the bridge group's IP address and the subnet mask. All attached endpoints will be on this network. For models with a pre-configured bridge group, the default for the BVII “inside” network is 192.168.1.1/24 (i.e. 255.255.255.0). Ensure that the address is not already used on the network.
If there is a DHCP server configured for the interface, you are shown the configuration. You can edit or delete the DHCP address pool. If you change the interface IP address to a different subnet, you must either delete the DHCP server, or configure an address pool on the new subnet, before you can save the interface changes. See Configuring DHCP Server, on page 394.

- **Dynamic (DHCP)**—Choose this option if the address should be obtained from the DHCP server on the network. This is not the typical option for bridge groups, but you can configure it if needed. Change the following options if necessary:
  - **Route Metric**—If you obtain the default route from the DHCP server, the administrative distance to the learned route, between 1 and 255. The default is 1.
  - **Obtain Default Route**—Whether to get the default route from the DHCP server. You would normally select this option, which is the default.

**Step 5**  
(Optional.) Click the **IPv6 Address** tab and configure the IPv6 address.

- **State**—To enable IPv6 processing and to automatically configure the link-local address when you do not configure the global address, select **Enabled**. The link local address is generated based on the interface MAC addresses (Modified EUI-64 format).

  **Note**  
  Disabling IPv6 does not disable IPv6 processing on an interface that is configured with an explicit IPv6 address or that is enabled for autoconfiguration.

- **Static Address/Prefix**—If you do not use stateless autoconfiguration, enter the full static global IPv6 address and network prefix. For example, 2001:0DB8::BA98:0:3210/48. For more information on IPv6 addressing, see IPv6 Addressing, on page 135.

  If you want to use the address as link local only, select the **Link - Local** option. Link local addresses are not accessible outside the local network. You cannot configure a link-local address on a bridge group interface.

  **Note**  
  A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:fee6:6a82. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

- **Suppress RA**—Whether to suppress router advertisements. The Firepower Threat Defense device can participate in router advertisements so that neighboring devices can dynamically learn a default router address. By default, router advertisement messages (ICMPv6 Type 134) are periodically sent out each IPv6 configured interface.

  Router advertisements are also sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

  You might want to suppress these messages on any interface for which you do not want the FTD device to supply the IPv6 prefix (for example, the outside interface).

**Step 6**  
(Optional.) Configure Advanced Options, on page 149.

You configure most advanced options on bridge group member interfaces, but some are available for the bridge group interface.
The advanced settings have defaults that are appropriate for most networks. Edit them only if you are resolving network issues.

**Step 7**

Click **OK**.

---

**What to do next**

- Ensure that all member interfaces that you intend to use are enabled.
- Configure a DHCP server for the bridge group. See Configuring DHCP Server, on page 394.
- Add the member interfaces to the appropriate security zones. See Configuring Security Zones, on page 110.
- Ensure that policies, such as identity, NAT, and access, supply the required services for the bridge group and member interfaces.

---

**Configure VLAN Subinterfaces and 802.1Q Trunking**

VLAN subinterfaces let you divide a physical interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs allow you to keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or devices.

Create subinterfaces if you attach the physical interface to a trunk port on a switch. Create a subinterface for each VLAN that can appear on the switch trunk port. If you attach the physical interface to an access port on the switch, there is no point in creating a subinterface.

**Guidelines and Limitations**

- Preventing untagged packets on the physical interface—If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. Because the physical interface must be enabled for the subinterface to pass traffic, ensure that the physical interface does not pass traffic by not naming the interface. If you want to let the physical interface pass untagged packets, you can name the interface as usual.
- You cannot configure IP addresses on bridge group member interfaces, although you can modify advanced settings as needed.
- All subinterfaces on the same parent interface must be either bridge group members or routed interfaces; you cannot mix and match.
- The FTD does not support the Dynamic Trunking Protocol (DTP), so you must configure the connected switch port to trunk unconditionally.
- You might want to assign unique MAC addresses to subinterfaces defined on the FTD, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the FTD.
Procedure

**Step 1**
Click **Device**, then click the link in the **Interfaces** summary.

The interface list shows the available interfaces, their names, addresses, and states.

**Step 2**
Do one of the following:

- Select **Add Subinterface** from the gear drop-down list to create a new subinterface.
- Click the edit icon (.modify) for the subinterface you want to edit.

If you no longer need a subinterface, click the delete icon (.delete) for the subinterface to delete it.

**Step 3**
Set the **Status** slider to the enabled setting (on).

**Step 4**
Configure the parent interface, name, and description:

a) Choose the **Parent Interface**.

The parent interface is the physical interface to which you want to add the subinterface. You cannot change the parent interface after you create the subinterface.

b) Set the **Subinterface Name**, up to 48 characters.

Alphabetic characters must be lower case. For example, *inside* or *outside*. Without a name, the rest of the interface configuration is ignored.

*Note*  
If you change the name, the change is automatically reflected everywhere you used the old name, including security zones, syslog server objects, and DHCP server definitions. However, you cannot remove the name until you first remove all configurations that use the name, because you typically cannot use an unnamed interface for any policy or setting.

c) (Optional) Set a **Description**.

The description can be up to 200 characters on a single line, without carriage returns.

d) Set the **VLAN ID**.

Enter the VLAN ID between 1 and 4094 that will be used to tag the packets on this subinterface.

e) Set the **Subinterface ID**.

Enter the subinterface ID as an integer between 1 and 4294967295. This ID is appended to the interface ID; for example Ethernet1/1.100. You can match the VLAN ID for convenience, but it is not required. You cannot change the ID after you create the subinterface.

**Step 5**
Click the **IPv4 Address** tab and configure the IPv4 address.

Select one of the following options from the **Type** field:

- **Dynamic** (DHCP)—Choose this option if the address should be obtained from the DHCP server on the network. Change the following options if necessary:
  - **Route Metric**—If you obtain the default route from the DHCP server, the administrative distance to the learned route, between 1 and 255. The default is 1.
  - **Obtain Default Route**—Whether to get the default route from the DHCP server. You would normally select this option, which is the default.
• **Static**—Choose this option if you want to assign an address that should not change. Type in the interface's IP address and the subnet mask for the network attached to the interface. For example, if you attach the 10.100.10.0/24 network, you could enter 10.100.10.1/24. Ensure that the address is not already used on the network.

**Note** If there is a DHCP server configured for the interface, you are shown the configuration. You can edit or delete the DHCP address pool. If you change the interface IP address to a different subnet, you must either delete the DHCP server, or configure an address pool on the new subnet, before you can save the interface changes. See Configuring DHCP Server, on page 394.

**Step 6** (Optional.) Click the **IPv6 Address** tab and configure the IPv6 address.

• **State**—To enable IPv6 processing and to automatically configure the link-local address when you do not configure the global address, select **Enabled**. The link local address is generated based on the interface MAC addresses (Modified EUI-64 format).

**Note** Disabling IPv6 does not disable IPv6 processing on an interface that is configured with an explicit IPv6 address or that is enabled for autoconfiguration.

• **Address Auto Configuration**—Select this option to have the address automatically configured. IPv6 stateless autoconfiguration will generate a global IPv6 address only if the link on which the device resides has a router configured to provide IPv6 services, including the advertisement of an IPv6 global prefix for use on the link. If IPv6 routing services are not available on the link, you will get a link-local IPv6 address only, which you cannot access outside of the device's immediate network link. The link local address is based on the Modified EUI-64 interface ID.

Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the FTD device does send Router Advertisement messages in this case. Select **Suppress RA** to suppress messages and conform to the RFC.

• **Static Address/Prefix**—If you do not use stateless autoconfiguration, enter the full static global IPv6 address and network prefix. For example, 2001:0DB8::BA98:0:3210/48. For more information on IPv6 addressing, see IPv6 Addressing, on page 135.

If you want to use the address as link local only, select the **Link - Local** option. Link local addresses are not accessible outside the local network. You cannot configure a link-local address on a bridge group interface.

**Note** A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

• **Suppress RA**—Whether to suppress router advertisements. The Firepower Threat Defense device can participate in router advertisements so that neighboring devices can dynamically learn a default router address. By default, router advertisement messages (ICMPv6 Type 134) are periodically sent out each IPv6 configured interface.

Router advertisements are also sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You might want to suppress these messages on any interface for which you do not want the FTD device to supply the IPv6 prefix (for example, the outside interface).
Step 7  (Optional.) Configure Advanced Options, on page 149.

The advanced settings have defaults that are appropriate for most networks. Edit them only if you are resolving network issues.

Step 8  Click OK.

What to do next

- Add the subinterfaces to the appropriate security zones. See Configuring Security Zones, on page 110.

**Configure Advanced Interface Options**

Advanced options include setting the MTU, hardware settings, management only, MAC address, and other settings.

**About the MTU**

The MTU specifies the maximum frame payload size that the Firepower Threat Defense device can transmit on a given Ethernet interface. The MTU value is the frame size without Ethernet headers, VLAN tagging, or other overhead. For example, when you set the MTU to 1500, the expected frame size is 1518 bytes including the headers, or 1522 when using VLAN. Do not set the MTU value higher to accommodate these headers.

**Path MTU Discovery**

The Firepower Threat Defense device supports Path MTU Discovery (as defined in RFC 1191), which lets all devices in a network path between two hosts coordinate the MTU so they can standardize on the lowest MTU in the path.

**MTU and Fragmentation**

For IPv4, if an outgoing IP packet is larger than the specified MTU, it is fragmented into 2 or more frames. Fragments are reassembled at the destination (and sometimes at intermediate hops), and fragmentation can cause performance degradation. For IPv6, packets are typically not allowed to be fragmented at all. Therefore, your IP packets should fit within the MTU size to avoid fragmentation.

For UDP or ICMP, the application should take the MTU into account to avoid fragmentation.

**Note**

The Firepower Threat Defense device can receive frames larger than the configured MTU as long as there is room in memory.

**MTU and Jumbo Frames**

A larger MTU lets you send larger packets. Larger packets might be more efficient for your network. See the following guidelines:
• Matching MTUs on the traffic path—We recommend that you set the MTU on all FTD interfaces and other device interfaces along the traffic path to be the same. Matching MTUs prevents intermediate devices from fragmenting the packets.

• Accommodating jumbo frames—A jumbo frame is an Ethernet packet larger than the standard maximum of 1522 bytes (including Layer 2 header and VLAN header), up to 9216 bytes. You can set the MTU up to 9198 bytes to accommodate jumbo frames. The maximum is 9000 for Firepower Threat Defense Virtual.

  **Note**  
  Increasing the MTU assigns more memory for jumbo frames, which might limit the maximum usage of other features, such as access rules. If you increase the MTU above the default 1500 on ASA 5500-X series devices or Firepower Threat Defense Virtual, you must reboot the system. You do not need to reboot Firepower models, where jumbo frame support is always enabled.

---

**Configure Advanced Options**

Advanced interface options have default settings that are appropriate for most networks. Configure them only if you are resolving networking problems.

The following procedure assumes the interface is already defined. You can also edit these settings while initially editing or creating the interface.

**Limitations**

• For bridge groups, you configure most of these options on the member interfaces. Except for DAD attempts, these options are not available for the Bridge Virtual Interface (BVI).

• You cannot set MTU, duplex, or speed for the Management interface on a Firepower 2100 device.

**Procedure**

**Step 1**
Click **Device**, then click the link in the **Interfaces** summary.

The interface list shows the available interfaces, their names, addresses, and states.

**Step 2**
Click the edit icon ( 📐 ) for the interface you want to edit.

**Step 3**
Click **Advanced Options**.

**Step 4**
To make a data interface management only, select **Management Only**.

A management only interface does not allow through traffic, so there is very little value in setting a data interface as management only. You cannot change this setting for the Management/Diagnostic interface, which is always management only.

**Step 5**
Change the **MTU** (maximum transmission unit) to the desired value.

The default MTU is 1500 bytes. You can specify a value from 64 - 9198 (or 9000 for Firepower Threat Defense Virtual). Set a high value if you typically see jumbo frames on your network.
Note: If you increase MTU above 1500 on ASA 5500-X series devices, ISA 3000 series devices, or Firepower Threat Defense Virtual, you must reboot the device. Log into the CLI and use the `reboot` command. You do not need to reboot Firepower models, where jumbo frame support is always enabled.

**Step 6** (Physical interface only.) Modify the speed and duplex settings.

The default is that the interface negotiates the best duplex and speed with the interface at the other end of the wire, but you can force a specific duplex or speed if necessary. The options listed are only those supported by the interface. Before setting these options for interfaces on a network module, please read Limitations for Interface Configuration, on page 136.

- **Duplex**—Choose **Auto, Half, Full, or Default**. Auto is the default when the interface supports it. For example, you cannot select Auto for the SFP interfaces on a Firepower 2100 series device.
  
  Select **Default** to indicate that Firepower Device Manager should not attempt to configure the setting. Any existing configuration is left unchanged.

- **Speed**—Choose **Auto** to have the interface negotiate the speed (this is the default), or pick a specific speed: 10, 100, 1000, 10000 Mbps. You can also select these special options:
  
  - **No Negotiate**—For fiber interfaces, sets the speed to 1000 Mbps and does not negotiate link parameters. This is the default configured setting on these interfaces.
  
  - **Default**—Indicates that Firepower Device Manager should not attempt to configure the setting. Any existing configuration is left unchanged.

The type of interface limits the options you can select. For example, the SFP+ interfaces on a Firepower 2100 series device support 1000 (1 Gbps) and 10000 (10 Gbps) only, and the SFP interfaces support 1000 (1 Gbps) only, whereas GigabitEthernet ports do not support 10000 (10 Gbps). SPF interfaces on other devices might require **No Negotiate**. Consult the hardware documentation for information on what the interfaces support.

**Step 7** Modify the **IPv6 Configuration** settings.

- **Enable DHCP for IPv6 address configuration**—Whether to set the Managed Address Configuration flag in the IPv6 router advertisement packet. This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

- **Enable DHCP for IPv6 non-address configuration**—Whether to set the Other Address Configuration flag in the IPv6 router advertisement packet. This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address.

- **DAD Attempts**—How often the interface performs Duplicate Address Detection (DAD), from 0 - 600. The default is 1. During the stateless autoconfiguration process, DAD verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used. The interface uses neighbor solicitation messages to perform Duplicate Address Detection. Set the value to 0 to disable duplicate address detection (DAD) processing.

**Step 8** Click OK.
Add Interfaces to Firepower Threat Defense Virtual

When you deploy the FTDv, you assign interfaces to the virtual machine. Then, from within FDM, you configure those interfaces using the same methods you would use for a hardware device.

However, you cannot add more virtual interfaces to the virtual machine and then have FDM automatically recognize them. If you need more physical-interface equivalents for the FTDv, you basically have to start over. You can either deploy a new virtual machine, or you can use the following procedure.

Caution
Adding interfaces to a virtual machine requires that you completely wipe out the FTDv configuration. The only part of the configuration that remains intact is the management address and gateway settings.

Before you begin
Do the following in FDM:

- Examine the FTDv configuration, and make notes on settings that you will want to replicate in the new virtual machine.
- Choose Devices > Smart License > View Configuration, and disable all feature licenses.

Procedure

1. Power off the FTDv.
2. Using the virtual machine software, add the interfaces to the FTDv.
   For VMware, virtual appliances use e1000 (1 Gbit/s) interfaces by default. You can also use vmxnet3 or ixgbe (10 Gbit/s) interfaces.
3. Power on the FTDv.
4. Open the FTDv console, delete the local manager, then enable the local manager.

Deleting the local manager, then enabling it, resets the device configuration and gets the system to recognize the new interfaces. The management interface configuration does not get reset. The following SSH session shows the commands.

```
> show managers
Managed locally.

> configure manager delete
If you enabled any feature licenses, you must disable them in Firepower Device Manager before deleting the local manager.
Otherwise, those licenses remain assigned to the device in Cisco Smart Software Manager.
Do you want to continue[yes/no] yes
DHCP Server Disabled

> show managers
No managers configured.

> configure manager local
```
Step 5  Open a browser session to Firepower Device Manager, complete the device setup wizard, and configure the device. See Complete the Initial Configuration Using the Setup Wizard, on page 24.

Monitoring Interfaces

You can view some basic information about interfaces in the following areas:

- **Device.** Use the port graphic to monitor the current state of the interfaces. Mouse over a port to see its IP addresses and enabled and link statuses. The IP addresses can be statically assigned or obtained using DHCP.

  Interface ports use the following color coding:
  - Green—The interface is configured, enabled, and the link is up.
  - Gray—The interface is not enabled.
  - Orange/Red—The interface is configured and enabled, but the link is down. If the interface is wired, this is an error condition that needs correction. If the interface is not wired, this is the expected status.

- **Monitoring > System.** The **Throughput** dashboard shows information on traffic flowing through the system. You can view information on all interfaces, or you can select a specific interface to examine.

- **Monitoring > Zones.** This dashboard shows statistics based on security zones, which are composed of interfaces. You can drill into this information for more detail.

Monitoring Interfaces in the CLI

You can also open the CLI console or log into the device CLI and use the following commands to get more detailed information about interface-related behavior and statistics.

- `show interface` displays interface statistics and configuration information. This command has many keywords you can use to get to the information you need. Use `?` as a keyword to see the available options.

- `show ipv6 interface` displays IPv6 configuration information about the interfaces.

- `show bridge-group` displays information about Bridge Virtual Interfaces (BVI), including member information and IP addresses.

- `show conn` displays information about the connections currently established through the interfaces.

- `show traffic` displays statistics about traffic flowing through each interface.

- `show ipv6 traffic` displays statistics about IPv6 traffic flowing through the device.

- `show dhcpd` displays statistics and other information about DHCP usage on the interfaces, particularly about the DHCP servers configured on interfaces.
Examples for Interfaces

The use case chapter includes the following interface-related examples:

- How to Configure the Device in Firepower Device Manager, on page 43
- How to Add a Subnet, on page 72
Routing

The system uses a routing table to determine the egress interface for packets entering the system. The following topics explain routing basics and how to configure routing on the device.

- Routing Overview, on page 155
- Static Routes, on page 160
- Monitoring Routing, on page 162

Routing Overview

The following topics describe how routing behaves within the FTD device. Routing is the act of moving information across a network from a source to a destination. Along the way, at least one intermediate node is typically encountered. Routing involves two basic activities: determining optimal routing paths and transporting packets through a network.

Route Types

There are two main types of route: static or dynamic.

Static routes are those that you define explicitly. These are stable, normally high-priority routes, that you would use to ensure traffic to the route destination is always sent out the correct interface. For example, you would create a default static route to cover all traffic not already covered by any other route, that is, 0.0.0.0/0 for IPv4 or ::/0 for IPv6. Another example would be a static route to an internal syslog server that you always want to use.

Dynamic routes are those learned through the operation of a routing protocol, such as OSPF, BGP, EIGRP, IS-IS, or RIP. You do not define the routes directly. Instead, you configure the routing protocol, and the system then communicates with neighbor routers, transmitting routing updates to them and receiving routing updates in turn.

Dynamic routing protocols adjust the routing table to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the system recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Static routing is simple and serves the purpose of basic routing. It works well in environments where network traffic is relatively predictable and where network design is relatively simple. However, because static routes cannot change unless you edit them, they cannot react to changes in the network.
Unless you have a small network, you would typically combine static routes with one or more dynamic routing protocols. You would define at least one static route, as the default route for any traffic that does not match an explicit route.

**Note**
You can use Smart CLI to configure the following routing protocols: OSPF. Use FlexConfig to configure other routing protocols that are supported in ASA software.

### The Routing Table and Route Selection

When NAT translations (xlates) and rules do not determine the egress interface, the system uses the routing table to determine the path for a packet.

Routes in the routing table include a metric called “administrative distance” that provides a relative priority to a given route. If a packet matches more than one route entry, the one with the lowest distance is used. Directly connected networks (those defined on an interface) have the distance 0, so they are always preferred. Static routes have a default distance of 1, but you can create them with any distance between 1-254.

Routes that identify a specific destination take precedence over the default route (the route whose destination is 0.0.0.0/0 or ::/0).

### How the Routing Table Is Populated

The FTD routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the dynamic routing protocols. Because the FTD can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner. When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

For example, if the RIP and OSPF processes discovered the following routes:

- RIP: 192.168.32.0/24
- OSPF: 192.168.32.0/19

Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

- If the FTD learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.
If the FTD learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower default administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the Firepower Threat Defense device uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. The following table shows the default administrative distance values for the routing protocols supported by the Firepower Threat Defense device.

<table>
<thead>
<tr>
<th>Route Source</th>
<th>Default Administrative Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected interface</td>
<td>0</td>
</tr>
<tr>
<td>Static route</td>
<td>1</td>
</tr>
<tr>
<td>EIGRP Summary Route</td>
<td>5</td>
</tr>
<tr>
<td>External BGP</td>
<td>20</td>
</tr>
<tr>
<td>Internal EIGRP</td>
<td>90</td>
</tr>
<tr>
<td>OSPF</td>
<td>110</td>
</tr>
<tr>
<td>IS-IS</td>
<td>115</td>
</tr>
<tr>
<td>RIP</td>
<td>120</td>
</tr>
<tr>
<td>EIGRP external route</td>
<td>170</td>
</tr>
<tr>
<td>Internal and local BGP</td>
<td>200</td>
</tr>
<tr>
<td>Unknown</td>
<td>255</td>
</tr>
</tbody>
</table>

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the Firepower Threat Defense device receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the Firepower Threat Defense device chooses the OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.
In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the Firepower Threat Defense device would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the Firepower Threat Defense device on which the command was entered. The administrative distance is not advertised in routing updates. Administrative distance does not affect the routing process. The routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the routing table.

**Backup Dynamic and Floating Static Routes**

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the Firepower Threat Defense device. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

**How Forwarding Decisions Are Made**

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.

- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.

- If the destination matches more than one entry in the routing table, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

For example, a packet destined for 192.168.32.1 arrives on an interface with the following routes in the routing table:

- 192.168.32.0/24 gateway 10.1.1.2
- 192.168.32.0/19 gateway 10.1.1.3

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but 192.168.32.0/24 has the longest prefix within the routing table (24 bits versus 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.

**Note**

Existing connections continue to use their established interfaces even if a new similar connection would result in different behavior due to a change in routes.
Routing Table for Management Traffic

As a standard security practice, it is often necessary to segregate and isolate Management traffic from data traffic. To achieve this isolation, the FTD uses a separate routing table for management-only traffic vs. data traffic. Separate routing tables means that you can create separate default routes for data and management as well.

Through-the-device traffic always uses the data routing table.

From-the-device traffic, depending on the type, uses either the management routing table or the data routing table by default. If a match is not found in the default routing table, it checks the other routing table.

Management table from-the-device traffic includes features that open a remote file using HTTP, SCP, TFTP, and so on.

Data table from-the-device traffic includes all other features like ping, DNS, DHCP, and so on.

If you need from-the-box traffic to go out an interface that isn't in its default routing table, then you might need to specify that interface when you configure it, rather than relying on the fall back to the other table. The FTD checks the correct routing table for routes for that interface. For example, if you need a ping to go out a management-only interface, then specify the interface in the ping function. Otherwise, if there is a default route in the data routing table, then it will match the default route and never fall back to the management routing table.

The management routing table supports dynamic routing separate from the data interface routing table. A given dynamic routing process must run on either the management-only interface or the data interface; you cannot mix both types.

Management-only interfaces include any Management x/x (named "diagnostic") interfaces as well as any interfaces that you have configured to be management-only.

Note
This routing table does not affect the special FTD Management logical interface that it uses to communicate with the FMC; that interface has its own routing table. The Diagnostic logical interface, on the other hand, uses the management-only routing table described in this section.

Note
This routing table does not affect the special FTD Management virtual interface that it uses to communicate with the licensing server or for database updates; that interface has its own routing table. The Diagnostic physical interface, on the other hand, uses the management-only routing table described in this section.

Equal-Cost Multi-Path (ECMP) Routing

The Firepower Threat Defense device supports Equal-Cost Multi-Path (ECMP) routing.

You can have up to 3 equal cost static or dynamic routes per interface. For example, you can configure multiple default routes on the outside interface that specify different gateways.

```plaintext
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.3
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.4
```
In this case, traffic is load-balanced on the outside interface between 10.1.1.2, 10.1.1.3, and 10.1.1.4. Traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses, incoming interface, protocol, source and destination ports.

ECMP is not supported across multiple interfaces, so you cannot define a route to the same destination on a different interface. The following route is disallowed when configured with any of the routes above:

```
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.1
```

### Static Routes

You can create static routes to provide basic routing for your network.

### About Static and Default Routes

To route traffic to a non-connected host or network, you must define a route to the host or network, either using static or dynamic routing. Generally, you must configure at least one static route: a default route for all traffic that is not routed by other means to a default network gateway, typically the next hop router.

### Default Route

The simplest option is to configure a default static route to send all traffic to an upstream router, relying on the router to route the traffic for you. A default route identifies the gateway IP address to which the FTD device sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 (IPv4) or ::/0 (IPv6) as the destination IP address.

You should always define a default route.

Because the FTD uses separate routing tables for data traffic and for management traffic, you can optionally configure a default route for data traffic and another default route for management traffic. Note that from-the-device traffic uses either the management or data routing table by default depending on the type (see **Routing Table for Management Traffic, on page 159**), but will fall back to the other routing table if a route is not found. Default routes will always match traffic, and will prevent a fall back to the other routing table. In this case, you must specify the interface you want to use for egress traffic if that interface is not in the default routing table.

### Static Routes

You might want to use static routes in the following cases:

- Your networks use an unsupported router discovery protocol.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.
- In some cases, a default route is not enough. The default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the FTD device.
- You are using a feature that does not support dynamic routing protocols.
Guidelines for Static Routing

**Bridge Groups**

- In routed mode, you must specify the BVI as the gateway; you cannot specify the member interface.
- For traffic that originates on the Firepower Threat Defense device (such as syslog or SNMP) that is destined through a bridge group member interface for a non-directly connected network, you need to configure either a default route or static routes so the Firepower Threat Defense device knows out of which bridge group member interface to send traffic. If you have servers that cannot all be reached through a single default route, then you must configure static routes.

Configuring Static Routes

Define static routes to tell the system where to send packets that are not bound for networks that are directly connected to the interfaces on the system.

You need at least one static route, the default route, for network 0.0.0.0/0. This route defines where to send packets whose egress interface cannot be determined by existing NAT xlates (translations) or static NAT rules, or other static routes.

You might need other static routes if the default gateway cannot be used to get to all networks. For example, the default route is usually an upstream router on the outside interface. If there are additional inside networks that are not directly connected to the device, and they cannot be accessed through the default gateway, you need static routes for each of those inside networks.

You cannot define static routes for the networks that are directly connected to system interfaces. The system automatically creates these routes.

**Procedure**

**Step 1**
Click Device, then click the link in the Routing summary.

**Step 2**
On the Static Routing page, do one of the following:
- To add a new route, click +.
- Click the edit icon (-pencil) for the route you want to edit.

If you no longer need a route, click the trash can icon for the route to delete it.

**Step 3**
Configure the route properties

**Name**
A display name for the route.

**Description**
An optional description of the purpose for the route.

**Interface**
Select the interface through which you want to send traffic. The gateway address needs to be accessible through this interface.
For bridge groups, you configure the route for the bridge group interface (BVI), not for the member interfaces.

**Protocol**
Select whether the route is for an **IPv4** or **IPv6** address.

**Networks**
Select the network objects that identify the destination networks or hosts that should use the gateway in this route.

To define a default route, use the pre-defined any-ipv4 or any-ipv6 network objects, or create an object for the 0.0.0.0/0 (IPv4) or ::/0 (IPv6) network.

**Gateway**
Select the host network object that identifies the IP address for the gateway. Traffic is sent to this address. You cannot use the same gateway for routes on more than one interface.

**Metric**
The administrative distance for the route, between 1 and 254. The default for static routes is 1. If there are additional routers between the interface and the gateway, enter the number of hops as the administrative distance.

Administrative distance is a parameter used to compare routes. The lower the number, the higher precedence the route is given. Connected routes (networks directly connected to an interface on the device) always take precedence over static routes.

**Step 4** Click **OK**.

---

**Monitoring Routing**

To monitor and troubleshoot routing, open the CLI console or log into the device CLI and use the following commands.

- **show route** displays the routing table for the data interfaces, including routes for directly-connected networks.
- **show ipv6 route** displays the IPv6 routing table for the data interfaces, including routes for directly-connected networks.
- **show network** displays the configuration for the virtual management interface, including the management gateway. Routing through the virtual interface is not handled by the data interface routing table, unless you specify data-interfaces as the management gateway.
- **show network-static-routes** displays static routes configured for the virtual management interface using the **configure network static-routes** command. Normally, there will not be any static routes, as the management gateway suffices for management routing in most cases. These routes are not available to traffic on the data interfaces. This command is not available in the CLI console.
PART II

Security Policies

• SSL Decryption, on page 165
• Identity Policies, on page 187
• Security Intelligence, on page 197
• Access Control, on page 201
• Intrusion Policies, on page 223
• Network Address Translation (NAT), on page 235
SSL Decryption

Some protocols, such as HTTPS, use Secure Sockets Layer (SSL) or its follow-on version, Transport Layer Security (TLS), to encrypt traffic for secure transmissions. Because the system cannot inspect encrypted connections, you must decrypt them if you want to apply access rules that consider higher-layer traffic characteristics to make access decisions.

- About SSL Decryption, on page 165
- License Requirements for SSL Decryption, on page 168
- Guidelines for SSL Decryption, on page 169
- How to Implement and Maintain the SSL Decryption Policy, on page 169
- Configuring SSL Decryption Policies, on page 171
- Example: Blocking Older SSL/TLS Versions from the Network, on page 182
- Monitoring and Troubleshooting SSL Decryption, on page 184

About SSL Decryption

Normally, connections go through the access control policy to determine if they are allowed or blocked. However, if you enable the SSL decryption policy, encrypted connections are first sent through the SSL decryption policy to determine if they should be decrypted or blocked. Any unblocked connections, whether or not decrypted, then go through the access control policy for a final allow/block decision.

Note

You must enable the SSL decryption policy in order to implement active authentication rules in the identity policy. If you enable SSL decryption to enable identity policies, but do not otherwise want to implement SSL decryption, select Do Not Decrypt for the default action and do not create additional SSL decryption rules. The identity policy automatically generates whatever rules it needs.

The following topics explain encrypted traffic flow management and decryption in more detail.

Why Implement SSL Decryption?

Encrypted traffic, such as HTTPS connections, cannot be inspected.

Many connections are legitimately encrypted, such as connections to banks and other financial institutions. Many web sites use encryption to protect privacy or sensitive data. For example, your connection to Firepower Device Manager is encrypted.
However, users can also hide undesirable traffic within encrypted connections.

By implementing SSL decryption, you can decrypt connections, inspect them to ensure they do not contain threats or other undesirable traffic, and then re-encrypt them before allowing the connection to proceed. (The decrypted traffic goes through your access control policy and matches rules based on inspected characteristics of the decrypted connection, not on the encrypted characteristics.) This balances your need to apply access control policies with the user’s need to protect sensitive information.

You can also configure SSL decryption rules to block encrypted traffic of types you know you do not want on your network.

Keep in mind that decrypting and then re-encrypting traffic adds a processing load on the device, which will reduce overall system performance.

**Actions You Can Apply to Encrypted Traffic**

When configuring SSL decryption rules, you can apply the actions described in the following topics. These actions are also available for the default action, which applies to any traffic that does not match an explicit rule.

---

**Note**

Any traffic that passes through the SSL decryption policy must then pass through the access control policy. Except for traffic you drop in the SSL decryption policy, the ultimate allow or drop decision rests with the access control policy.

---

**Decrypt Re-Sign**

If you elect to decrypt and re-sign traffic, the system acts as a man-in-the-middle.

For example, the user types in https://www.cisco.com in a browser. The traffic reaches the FTD device, the device then negotiates with the user using the CA certificate specified in the rule and builds an SSL tunnel between the user and the FTD device. At the same time the device connects to https://www.cisco.com and creates an SSL tunnel between the server and the FTD device.

Thus, the user sees the CA certificate configured for the SSL decryption rule instead of the certificate from www.cisco.com. The user must trust the certificate to complete the connection. The FTD device then performs decryption/re-encryption in both directions for traffic between the user and destination server.
If the client does not trust the CA used to re-sign the server certificate, it warns the user that the certificate should not be trusted. To prevent this, import the CA certificate into the client trusted CA store. Alternatively, if your organization has a private PKI, you can issue an intermediate CA certificate signed by the root CA which is automatically trusted by all clients in the organization, then upload that CA certificate to the device.

If you configure a rule with the Decrypt Re-Sign action, the rule matches traffic based on the referenced internal CA certificate’s signature algorithm type, in addition to any configured rule conditions. Because you can select a single re-sign certificate for the SSL decryption policy, this can limit traffic matching for resign rules.

For example, outgoing traffic encrypted with an elliptic curve (EC) algorithm matches a Decrypt Re-Sign rule only if the re-sign certificate is an EC-based CA certificate. Similarly, traffic encrypted with an RSA algorithm matches Decrypt Re-Sign rules only if the global re-sign certificate is RSA; outgoing traffic encrypted with an EC algorithm does not match the rule, even if all other configured rule conditions match.

**Decrypt Known Key**

If you own the destination server, you can implement decryption with a known key. In this case, when the user opens a connection to https://www.cisco.com, the user sees the actual certificate for www.cisco.com, even though it is the FTD device that is presenting the certificate.

Your organization must be the owner of the domain and certificate. For the example of cisco.com the only possible way to have the end user see Cisco’s certificate would be if you actually own the domain cisco.com (i.e. you are Cisco Systems) and have ownership of the cisco.com certificate signed by a public CA. You can only decrypt with known keys for sites that your organization owns.

The main purpose of decrypting with a known key is to decrypt traffic heading to your HTTPS server to protect your servers from external attacks. For inspecting client side traffic to external HTTPS sites, you must use decrypt re-sign as you do not own the servers.

**Note**

To use known key decryption, you must upload the server’s certificate and key as an internal identity certificate, and then add it to the list of known-key certificates in the SSL decryption policy settings. Then, you can write the rule for known-key decryption with the server’s address as the destination address. For information on adding the certificate to the SSL decryption policy, see Configure Certificates for Known Key and Re-Sign Decryption, on page 180.

**Do Not Decrypt**

If you elect to bypass decryption for certain types of traffic, no processing is done on the traffic. The encrypted traffic proceeds to the access control policy, where it is allowed or dropped based on the access control rule it matches.
Block

You can simply block encrypted traffic that matches an SSL decryption rule. Blocking in the SSL decryption policy prevents the connection from reaching the access control policy.

When you block an HTTPS connection, the user does not see the system default block response page. Instead, the user sees the browser’s default page for a secure connection failure. The error message does not indicate the site was blocked due to policy. Instead, errors might indicate that there are no common encryption algorithms. It will not be obvious from this message that you blocked the connection on purpose.

Automatically Generated SSL Decryption Rules

Whether you enable the SSL decryption policy, the system automatically generates Decrypt Re-sign rules for each identity policy rule that implements active authentication. This is required to enable active authentication for HTTPS connections.

When you enable the SSL decryption policy, you see these rules under the Identity Policy Active Authentication Rules heading. These rules are grouped at the top of the SSL decryption policy. The rules are read only. You can change them only by altering your identity policy.

Handling Undecryptable Traffic

There are several characteristics that make a connection undecryptable. If a connection has any of the following characteristics, the default action is applied to the connection regardless of any rule the connection would otherwise match. If you select Block as your default action (rather than Do Not Decrypt), you might run into issues, including excessive drops of legitimate traffic.

- Compressed session—Data compression was applied to the connection.
- SSLv2 session—The minimum supported SSL version is SSLv3.
- Unknown cipher suite—The system does not recognize the cipher suite for the connection.
- Unsupported cipher suite—The system does not support decryption based on the detected cipher suite.
- Session not cached—The SSL session has session reuse enabled, the client and server reestablished the session with the session identifier, and the system did not cache that session identifier.
- Handshake errors—An error occurred during the SSL handshake negotiation.
- Decryption errors—An error occurred during the decryption operation.

License Requirements for SSL Decryption

You do not need a special license to use the SSL decryption policy.

However, you do need the URL Filtering license to create rules that use URL categories and reputations as match criteria. For information on configuring licenses, see Enabling or Disabling Optional Licenses, on page 84.
Guidelines for SSL Decryption

Keep the following in mind when configuring and monitoring SSL decryption policies:

- The SSL Decryption policy is bypassed for any connections that match access control rules set to trust or block if those rules:
  - Use security zone, network, geolocation, and port only as the traffic matching criteria.
  - Come before any other rules that require inspection, such as rules that match connections based on application or URL, or allow rules that apply intrusion or file inspection.

- When using URL category matching, note that there are cases where the login page for a site is in a different category than the site itself. For example, Gmail is in the “Web based email” category, whereas the login page is in the “Internet Portals” category. To get connections to these sites decrypted, you must include both categories in the rule.

- If a Vulnerability Database (VDB) update removes (deprecates) applications, you must make changes to any SSL decryption rules or application filters that use the application that was deleted. You cannot deploy changes until you fix these rules. In addition, you cannot install system software updates before fixing the issue. On the Application Filters object page, or the Application tab of the rule, these applications say “(Deprecated)” after the application name.

How to Implement and Maintain the SSL Decryption Policy

You can use SSL decryption policies to turn encrypted traffic into plain text traffic, so that you can then apply URL filtering, intrusion and malware control, and other services that require deep packet inspection. If your policies allow the traffic, the traffic is re-encrypted before it leaves the device.

The SSL decryption policy applies to encrypted traffic only. No unencrypted connections are evaluated against SSL decryption rules.

Unlike some other security policies, you need to monitor and actively maintain the SSL decryption policy, because certificates can expire or even be changed on destination servers. Additionally, changes in client software might alter your ability to decrypt certain connections, because the decrypt re-sign action is indistinguishable from a man-in-the-middle attack.

The following procedure explains the end-to-end process of implementing and maintaining the SSL decryption policy.

Procedure

Step 1
If you will implement Decrypt Re-sign rules, create the required internal CA certificate.

You must use an internal Certificate Authority (CA) certificate. You have the following options. Because users must trust the certificate, either upload a certificate client browsers are already configured to trust, or ensure that the certificate you upload is added to the browser trust stores.

- Create a self-signed internal CA certificate, which is signed by the device itself. See Generating Self-Signed Internal and Internal CA Certificates, on page 128.
How to Implement and Maintain the SSL Decryption Policy

• Upload an internal CA certificate and key signed by an external trusted CA or by a CA inside your organization. See Uploading Internal and Internal CA Certificates, on page 126.

Step 2 If you will implement Decrypt Known Key rules, collect the certificate and key from each of the internal servers.

You can use Decrypt Known Key only with servers that you control, because you must obtain the certificate and key from the server. Upload these certificates and keys as internal certificates (not internal CA certificates). See Uploading Internal and Internal CA Certificates, on page 126.

Step 3 Enable the SSL Decryption Policy, on page 172.

When you enable the policy, you also configure some basic settings.

Step 4 Configure the Default SSL Decryption Action, on page 173.

If in doubt, select Do Not Decrypt as the default action. Your access control policy can still drop traffic that matches the default SSL decryption rule if appropriate.

Step 5 Configure SSL Decryption Rules, on page 174.

Identify traffic to decrypt and the type of decryption to apply.

Step 6 If you configure known key decryption, edit the SSL decryption policy settings to include those certificates. See Configure Certificates for Known Key and Re-Sign Decryption, on page 180.

Step 7 If necessary, download the CA certificate used for Decrypt Re-sign rules and upload it to the browser on client workstations.

For information on downloading the certificate and distributing it to clients, see Downloading the CA Certificate for Decrypt Re-Sign Rules, on page 181.

Step 8 Periodically, update re-sign and known key certificates.

 • Re-sign certificate—Update this certificate before it expires. If you generate the certificate through Firepower Device Manager, it is valid for 5 years. To check the validity period for a certificate, select Objects > Certificates, find the certificate in the list, and click the information icon (i) for it in the Actions column. The information dialog box shows the validity period and some other characteristics. You can also upload a replacement certificate from this page.

 • Known-key certificate—For any known-key decryption rules, you need to ensure that you have uploaded the destination server’s current certificate and key. Whenever the certificate and key changes on supported servers, you must also upload the new certificate and key (as an internal certificate) and update the SSL decryption settings to use the new certificate.

Step 9 Upload missing trusted CA certificates for external servers.

The system includes a wide range of trusted CA root and intermediate certificates issued by third parties. These are needed when negotiating the connection between FTD and the destination servers for decrypt re-sign rules.

Upload all certificates within a root CA’s chain of trust to the list of trusted CA certificates, including the root CA certificate and all intermediate CA certificates. Otherwise, it is more difficult to detect trusted certificates issued by intermediate CAs. Upload certificates on the Objects > Certificates page. See Uploading Trusted CA Certificates, on page 129.
Configuring SSL Decryption Policies

You can use SSL decryption policies to turn encrypted traffic into plain text traffic, so that you can then apply URL filtering, intrusion and malware control, and other services that require deep packet inspection. If your policies allow the traffic, the traffic is re-encrypted before it leaves the device.

The SSL decryption policy applies to encrypted traffic only. No unencrypted connections are evaluated against SSL decryption rules.

VPN tunnels are decrypted before the SSL decryption policy is evaluated, so the policy never applies to the tunnel itself. However, any encrypted connections within the tunnel are subject to evaluation by the SSL decryption policy.

The following procedure explains how to configure the SSL decryption policy. For an explanation of the end-to-end process of creating and managing SSL decryption, see How to Implement and Maintain the SSL Decryption Policy, on page 169.

Before you begin

The SSL decryption rules table contains two sections:

- **Identity Policy Active Authentication Rules**—If you enable the identity policy and create rules that use active authentication, the system automatically creates the SSL decryption rules needed to make those policies work. These rules are always evaluated before the SSL decryption rules you create yourself. You can alter these rules only indirectly, by making changes to the identity policy.

- **SSL Native Rules**—These are rules that you have configured. You can add rules to this section only.

Procedure

**Step 1**  Select **Policies > SSL Decryption**.

If you have not yet enabled the policy, click **Enable SSL Decryption** and configure policy settings, as described in Enable the SSL Decryption Policy, on page 172.

**Step 2**  Configure the default action for the policy.

The safest choice is **Do Not Decrypt**. For more information, see Configure the Default SSL Decryption Action, on page 173.

**Step 3**  Manage the SSL decryption policy.

After you configure SSL decryption settings, this page lists all rules in order. Rules are matched against traffic from top to bottom with the first match determining the action to apply. You can do the following from this page:

- **To disable the policy**, click the **SSL Decryption Policy** toggle. You can re-enable it by clicking **Enable SSL Decryption**.
To edit policy settings, including the list of certificates used in the policy, click the SSL Decryption Settings button (✓). You can also download the certificate used with decrypt re-sign rules so that you can distribute it to clients. See the following topics:

- Configure Certificates for Known Key and Re-Sign Decryption, on page 180
- Downloading the CA Certificate for Decrypt Re-Sign Rules, on page 181

To configure rules:

- To create a new rule, click the + button. See Configure SSL Decryption Rules, on page 174.

- To edit an existing rule, click the edit icon (✓) for the rule (in the Actions column). You can also selectively edit a rule property by clicking on the property in the table.

- To delete a rule you no longer need, click the delete icon (✗) for the rule (in the Actions column).

- To move a rule, edit it and select the new location from the Order drop-down list.

---

Enable the SSL Decryption Policy

Before you can configure SSL decryption rules, you must enable the policy and configure some basic settings. The following procedure explains how to enable the policy directly. You can also enable it when you enable identity policies. Identity policies require that you enable the SSL decryption policy.

Before you begin

If you upgraded from a release that did not have SSL decryption policies, but you had configured the identity policy with active authentication rules, the SSL decryption policy is already enabled. Ensure that you select the Decrypt Re-Sign certificate you want to use, and optionally enable pre-defined rules.

Procedure

**Step 1** Select Policies > SSL Decryption.

**Step 2** Click **Enable SSL Decryption** to configure the policy settings.

- If this is the first time you enabled the policy, the SSL Decryption Configuration dialog box opens. Proceed with the next steps.

- If you have already configured the policy once and then disabled it, the policy is simply enabled again with your previous settings and rules. You can click the SSL Decryption Settings button (✓) and configure settings as described in Configure Certificates for Known Key and Re-Sign Decryption, on page 180.

**Step 3** In Decrypt Re-Sign Certificate, select the internal CA certificate to use for rules that implement decryption with re-signed certificates.

You can use the pre-defined NGFW-Default-InternalCA certificate, or one that you created or uploaded. If the certificate does not yet exist, click Create Internal CA to create it.
If you have not already installed the certificate in client browsers, click the download button ![download button](image) to obtain a copy. See the documentation for each browser for information on how to install the certificate. Also see Downloading the CA Certificate for Decrypt Re-Sign Rules, on page 181.

**Step 4**
Select the initial SSL decryption rules.

The system includes the following pre-defined rule that you might find useful:

- **Sensitive_Data**—This rule does not decrypt traffic that matches web sites in the Financial Services or Health and Medicine URL categories, which include banks, healthcare services, and so forth. You must enable the URL license to implement this rule.

**Step 5**
Click **Enable**.

---

**Configure the Default SSL Decryption Action**

If an encrypted connection does not match a specific SSL decryption rule, it is handled by the default action for the SSL decryption policy.

**Procedure**

**Step 1**
Select **Policies > SSL Decryption**.

**Step 2**
Click anywhere in the **Default Action** field.

**Step 3**
Select the action to apply to matching traffic.

- **Do Not Decrypt**—Allow the encrypted connection. The access control policy then evaluates the encrypted connection and drops or allows it based on access control rules.

- **Block**—Drop the connection immediately. The connection is not passed on to the access control policy.

**Step 4**
(Optional.) Configure logging for the default action.

You must enable logging for traffic that matches the default action to be included in dashboard data or Event Viewer. Select from these options:

- **At End of Connection**—Generate an event at the conclusion of the connection.

- **Send Connection Events To**—If you want to send a copy of the events to an external syslog server, select the server object that defines the syslog server. If the required object does not already exist, click **Create New Syslog Server** and create it. (To disable logging to a syslog server, select **Any** from the server list.)

  Because event storage on the device is limited, sending events to an external syslog server can provide more long term storage and enhance your event analysis.

- **No Logging**—Do not generate any events.

**Step 5**
Click **Save**.
Configure SSL Decryption Rules

Use SSL decryption rules to determine how to handle encrypted connections. Rules in the SSL decryption policy are evaluated from top to bottom. The rule applied to traffic is the first one where all the traffic criteria are matched.

You can create and edit rules in the SSL Native Rules section only.

Note

Traffic for your VPN connections (both site-to-site and remote access) is decrypted before the SSL decryption policy evaluates connections. Thus, SSL decryption rules are never applied to VPN connections, and you do not need to consider VPN connections when creating these rules. However, any use of encrypted connections within a VPN tunnel are evaluated. For example, an HTTPS connection to an internal server through an RA VPN connection is evaluated by SSL decryption rules, even though the RA VPN tunnel itself is not (because it is decrypted already).

Before you begin

If you are creating a decrypt known-key rule, ensure that you upload the certificate and key for the destination server (as an internal certificate) and also edit the SSL decryption policy settings to use the certificate. Known-key rules typically specify the destination server in the destination network criteria of the rule. For more information, see Configure Certificates for Known Key and Re-Sign Decryption, on page 180.

Procedure

Step 1
Select Policies > SSL Decryption.

If you have not configured any SSL decryption rules (other than the ones automatically generated for active authentication identity rules), you can add pre-defined rules by clicking Add Pre-Defined Rules. You are prompted to select the rules that you want.

Step 2
Do any of the following:

• To create a new rule, click the + button.
• To edit an existing rule, click the edit icon (EDIT) for the rule.

To delete a rule you no longer need, click the delete icon (DELETE) for the rule.

Step 3
In Order, select where you want to insert the rule in the ordered list of rules.

You can insert rules into the SSL Native Rules section only. The Identity Policy Active Authentication Rules are automatically generated from your identity policy and are read-only.

Rules are applied on a first-match basis, so you must ensure that rules with highly specific traffic matching criteria appear above policies that have more general criteria that would otherwise apply to the matching traffic.

The default is to add the rule to the end of the list. If you want to change a rule's location later, edit this option.

Step 4
In Title, enter a name for the rule.

The name cannot contain spaces. You can use alphanumeric characters and these special characters: + . _ -
**Step 5**

Select the action to apply to matching traffic.

For a detailed discussion of each option, see the following:

- Decrypt Re-Sign, on page 166
- Decrypt Known Key, on page 167
- Do Not Decrypt, on page 167
- Block, on page 168

**Step 6**

Define the traffic matching criteria using any combination of the following tabs:

- **Source/Destination**—The security zones (interfaces) through which the traffic passes, the IP addresses or the country or continent (geographical location) for the IP address, or the TCP ports used in the traffic. The default is any zone, address, geographical location, and TCP port. See Source/Destination Criteria for SSL Decryption Rules, on page 176.
- **Application**—The application, or a filter that defines applications by type, category, tag, risk, or business relevance. The default is any encrypted application. See Application Criteria for SSL Decryption Rules, on page 177.
- **URL**—The URL category of a web request. The default is that the URL category and reputation are not considered for matching purposes. See URL Criteria for SSL Decryption Rules, on page 178.
- **Users**—The user or user group. Your identity policies determine whether user and group information is available for traffic matching. You must configure identity policies to use this criteria. See User Criteria for SSL Decryption Rules, on page 178.
- **Advanced**—The characteristics derived from the certificates used in the connection, such as SSL/TLS version and certificate status. See Advanced Criteria for SSL Decryption Rules, on page 179.

To modify a condition, you click the + button within that condition, select the desired object or element, and click OK in the popup dialog box. If the criterion requires an object, you can click Create New Object if the object you require does not exist. Click the x for an object or element to remove it from the policy.

When adding conditions to SSL decryption rules, consider the following tips:

- You can configure multiple conditions per rule. Traffic must match all the conditions in the rule for the rule to apply to traffic. For example, you can use a single rule to decrypt traffic based on URL category.
- For each condition in a rule, you can add up to 50 criteria. Traffic that matches any of a condition's criteria satisfies the condition. For example, you can use a single rule to apply application control for up to 50 applications or application filters. Thus, there is an OR relationship among the items in a single condition, but an AND relationship between condition types (for example, between source/destination and application).
- Matching URL category requires the URL Filtering license.

**Step 7**

(Optional.) Configure logging for the rule.

You must enable logging for traffic that matches the rule to be included in dashboard data or Event Viewer. Select from these options:

- **At End of Connection**—Generate an event at the conclusion of the connection.
- **Send Connection Events To**—If you want to send a copy of the events to an external syslog server, select the server object that defines the syslog server. If the required object does not already exist, click Create New Syslog Server and create it. (To disable logging to a syslog server, select Any from the server list.)
Because event storage on the device is limited, sending events to an external syslog server can provide more long term storage and enhance your event analysis.

- **No Logging**—Do not generate any events.

**Step 8**  
Click OK.

---

### Source/Destination Criteria for SSL Decryption Rules

The Source/Destination criteria of an SSL decryption rule define the security zones (interfaces) through which the traffic passes, the IP addresses or the country or continent (geographical location) for the IP address, or the TCP ports used in the traffic. The default is any zone, address, geographical location, and any TCP port. TCP is the only protocol matched to SSL decryption rules.

To modify a condition, you click the + button within that condition, select the desired object or element, and click OK. If the criterion requires an object, you can click **Create New Object** if the object you require does not exist. Click the x for an object or element to remove it from the policy.

You can use the following criteria to identify the source and destination to match in the rule.

#### Source Zones, Destination Zones

The security zone objects that define the interfaces through which the traffic passes. You can define one, both, or neither criteria: any criteria not specified applies to traffic on any interface.

- To match traffic leaving the device from an interface in the zone, add that zone to the **Destination Zones**.
- To match traffic entering the device from an interface in the zone, add that zone to the **Source Zones**.
- If you add both source and destination zone conditions to a rule, matching traffic must originate from one of the specified source zones and egress through one of the destination zones.

Use this criteria when the rule should apply based on where the traffic enters or exits the device. For example, if you want to ensure that all traffic going from outside hosts to inside hosts gets decrypted, you would select your outside zone as the **Source Zones** and your inside zone as the **Destination Zones**.

#### Source Networks, Destination Networks

The network objects or geographical locations that define the network addresses or locations of the traffic.

- To match traffic from an IP address or geographical location, configure the **Source Networks**.
- To match traffic to an IP address or geographical location, configure the **Destination Networks**.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

When you add this criteria, you select from the following tabs:

- **Network**—Select the network objects or groups that define the source or destination IP addresses for the traffic you want to control.
For Decrypt Known-Key rules, select an object with the IP address of the destination server that uses the certificate and key you uploaded.

- **Geolocation**—Select the geographical location to control traffic based on its source or destination country or continent. Selecting a continent selects all countries within the continent. Besides selecting geographical location directly in the rule, you can also select a geolocation object that you created to define the location. Using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

### Source Ports, Destination Ports/Protocols

The port objects that define the protocols used in the traffic. You can specify TCP protocol and ports only for SSL decryption rules.

- To match traffic from a TCP port, configure the Source Ports.
- To match traffic to a TCP port, configure the Destination Ports/Protocols.
- To match traffic both originating from specific TCP ports and destined for specific TCP ports, configure both. For example, you could target traffic from port TCP/80 to port TCP/8080.

### Application Criteria for SSL Decryption Rules

The Application criteria of an SSL decryption rule defines the application used in an IP connection, or a filter that defines applications by type, category, tag, risk, or business relevance. The default is any application that has the SSL Protocol tag. You cannot match SSL decryption rules to any non-encrypted application.

Although you can specify individual applications in the rule, application filters simplify policy creation and administration. For example, you could create an SSL decryption rule that decrypts or blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is decrypted or blocked.

In addition, Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule for high risk applications can automatically apply to new applications without you having to update the rule manually.

You can specify applications and filters directly in the rule, or create application filter objects that define those characteristics. The specifications are equivalent, although using objects can make it easier to stay within the 50-items-per-criteria system limit if you are creating a complex rule.

To modify the application and filters list, you click the + button within the condition, select the desired applications or application filter objects, which are listed on separate tabs, and click OK in the popup dialog box. On either tab, you can click Advanced Filter to select filter criteria or to help you search for specific applications. Click the x for an application, filter, or object to remove it from the policy. Click the Save As Filter link to save the combined criteria that is not already an object as a new application filter object.

For more information about the application criteria and how to configure advanced filters and select applications, see Configuring Application Filter Objects, on page 111.

Consider the following tips when using application criteria in SSL decryption rules.

- The system can identify unencrypted applications that become encrypted using StartTLS. This includes such applications as SMTPS, POP3S, FTPS, TelnetS, and IMAPS. In addition, it can identify certain
encrypted applications based on the Server Name Indication in the TLS ClientHello message, or the server certificate subject distinguished name value.

- The system can identify the application only after the server certificate exchange. If traffic exchanged during the SSL handshake matches all other conditions in an SSL rule containing an application condition but the identification is not complete, the SSL policy allows the packet to pass. This behavior allows the handshake to complete so that applications can be identified. After the system completes its identification, the system applies the SSL rule action to the remaining session traffic that matches its application condition.

- If a selected application was removed by a VDB update, “(Deprecated)” appears after the application name. You must remove these applications from the filter, or subsequent deployments and system software upgrades will be blocked.

**URL Criteria for SSL Decryption Rules**

The URL criteria of an SSL decryption rule defines the category to which the URL in a web request belongs. You can also specify the relative reputation of sites to decrypt, block, or allow without decryption. The default is to not match connections based on URL categories.

For example, you could block all encrypted Gambling sites, or decrypt high risk Social Networking sites. If a user attempts to browse to any URL with that category and reputation combination, the session is blocked or decrypted. For more information on URL category matching, see Filtering URLs by Category and Reputation, on page 203.

**Categories Tab**

Click +, select the desired categories, and click OK. Click the x for a category to remove it from the policy.

The default is to apply the rule to all URLs in each selected category regardless of reputation. To limit the rule based on reputation, click the down arrow for each category, deselect the Any checkbox, and then use the Reputation slider to choose the reputation level. The left of the reputation slider indicates sites that will be allowed without decryption, the right side are sites that will be decrypted or blocked. How reputation is used depends on the rule action:

- If the rule decrypts or blocks connections, selecting a reputation level also selects all reputations more severe than that level. For example, if you configure a rule to decrypt or block Suspicious sites (level 2), it also automatically decrypts or blocks High risk (level 1) sites.

- If the rule allows connections without decryption (do not decrypt), selecting a reputation level also selects all reputations less severe than that level. For example, if you configure a rule to not decrypt Benign sites (level 4), it also automatically does not decrypt Well known (level 5) sites.

**User Criteria for SSL Decryption Rules**

The User criteria of an SSL decryption rule defines the user or user group for an IP connection. You must configure identity policies and the associated directory server to include user or user group criteria in a rule.

Your identity policies determine whether user identity is collected for a particular connection. If identity is established, the IP address of the host is associated with the identified user. Thus, traffic whose source IP address is mapped to a user is considered to be from that user. IP packets themselves do not include user identity information, so this IP-address-to-user mapping is the best approximation available.
Because you can add a maximum of 50 users or groups to a rule, selecting groups usually makes more sense than selecting individual users. For example, you could create a rule that decrypts traffic to the Engineering group that comes from the outside network, and create a separate rule that does not decrypt outgoing traffic from that group. Then, to make the rule apply to new engineers, you only need to add the engineer to the Engineering group in the directory server.

To modify the users list, you click the + button within the condition and select the desired users or user groups using one of the following techniques. Click the x for a user or group to remove it from the policy.

- **Users and Groups** tab—Select the desired users or user groups. Groups are available only if you configure groups in the directory server. If you select a group, the rule applies to any member of the group, including subgroups. If you want to treat a sub-group differently, you need to create a separate access rule for the sub-group and place it above the rule for the parent group in the access control policy.

- **Special Entities** tab—Select from the following:
  - **Failed Authentication**—The user was prompted to authenticate, but failed to enter a valid username/password pair within the maximum number of allowed attempts. Failure to authenticate does not itself prevent the user from accessing the network, but you can write an access rule to limit network access for these users.
  - **Guest**—Guest users are like Failed Authentication users, except that your identity rule is configured to call these users Guest. Guest users were prompted to authenticate and failed to do so within the maximum number of attempts.
  - **No Authentication Required**—The user was not prompted to authentication, because the user's connections matched identity rules that specified no authentication.
  - **Unknown**—There is no user mapping for the IP address, and there is no record of failed authentication yet. Typically, this means that no HTTP traffic has yet been seen from that address.

### Advanced Criteria for SSL Decryption Rules

The Advanced traffic matching criteria relate to characteristics derived from the certificates used in the connection. You can configure any or all of the following options.

**Certificate Properties**

Traffic matches the certificate properties option of the rule if it matches any of the selected properties.

You can configure the following:

**Certificate Status**

Whether the certificate is **Valid** or **Invalid**. Select **Any** (the default) if you do not care about certificate status.

A certificate is considered valid if all of the following conditions are met, otherwise it is invalid:

- The policy trusts the CA that issued the certificate.
- The certificate’s signature can be properly validated against the certificate’s content.
- The issuer CA certificate is stored in the policy’s list of trusted CA certificates.
- None of the policy’s trusted CAs revoked the certificate.
- The current date is between the certificate Valid From and Valid To dates.
Self-Signed

Whether the server certificate contains the same subject and issuer distinguished name. Select one of the following:

- **Self-Signing** — The server certificate is self-signed.
- **CA-Signing** — The server certificate is signed by a Certificate Authority. That is, the issuer and subject are not the same.
- **Any** — Do not consider whether the certificate is self-signed as a match criteria.

Supported Version

The SSL/TLS version to match. The rule applies to traffic that uses the any of the selected versions only. The default is all versions. Select from: **SSLv3.0**, **TLSv1.0**, **TLSv1.1**, **TLSv1.2**.

For example, if you wanted to permit TLSv1.2 connections only, you could create a block rule for the non-TLSv1.2 versions.

Traffic that uses any version not listed, such as SSL v2.0, is handled by the default action for the SSL decryption policy.

Configure Certificates for Known Key and Re-Sign Decryption

If you implement decryption, either by re-signing or using known keys, you need to identify the certificates that the SSL decryption rules can use. Ensure that all certificates are valid and unexpired.

Especially for known-key decryption, you need to ensure that the system has the current certificate and key for each destination server whose connections you are decrypting. With a decrypt known-key rule, you use the actual certificate and key from the destination server for decryption. Thus, you must ensure that the FTD device has the current certificate and key at all times, or decryption will be unsuccessful.

Upload a new internal certificate and key whenever you change the certificate or key on the destination server in a known key rule. Upload them as an internal certificate (not an internal CA certificate). You can upload the certificate during the following procedure, or go to the Objects > Certificates page and upload it there.

**Procedure**

**Step 1** Select **Policies > SSL Decryption**.

**Step 2** Click the **SSL Decryption Settings** button (🔗).

**Step 3** In **Decrypt Re-Sign Certificate**, select the internal CA certificate to use for rules that implement decryption with re-signed certificates.

You can use the pre-defined NGFW-Default-InternalCA certificate, or one that you created or uploaded. If the certificate does not yet exist, click **Create Internal CA** to create it.

If you have not already installed the certificate in client browsers, click the download button (🔗) to obtain a copy. See the documentation for each browser for information on how to install the certificate. Also see **Downloading the CA Certificate for Decrypt Re-Sign Rules, on page 181**.

**Step 4** For each rule that decrypts using a known key, upload the internal certificate and key for the destination server.

a) Click + under **Decrypt Known-Key Certificates**.
b) Select the internal identity certificate, or click **Create New Internal Certificate** to upload it now.
c) Click **OK**.

**Step 5**
Click **Save**.

---

**Downloading the CA Certificate for Decrypt Re-Sign Rules**

If you decide to decrypt traffic, users must have the internal CA certificate that is used in the encryption process defined as a Trusted Root Certificate Authority in their applications that use TLS/SSL. Typically if you generate a certificate, or sometimes even if you import one, the certificate is not already defined as trusted in these applications. By default in most web browsers, when users send HTTPS requests, they will see a warning message from the client application informing them that there is a problem with the web site’s security certificate. Usually, the error message says that the web site’s security certificate was not issued by a trusted certificate authority or the web site was certified by an unknown authority, but the warning might also suggest there is a possible man-in-the-middle attack in progress. Some other client applications do not show this warning message to users nor allow users to accept the unrecognized certificate. You have the following options for providing users with the required certificate:

**Inform users to accept the root certificate**

You can inform the users in your organization what the new policies are at the company and tell them to accept the root certificate supplied by the organization as a trusted source. Users should accept the certificate and save it in the Trusted Root Certificate Authority storage area so that they are not prompted again the next time they access the site.

**Note**
The user needs to accept and trust the CA certificate that created the replacement certificate. If they instead simply trust the replacement server certificate, they will continue to see warnings for each different HTTPS site that they visit.

**Add the root certificate to client devices**

You can add the root certificate to all client devices on the network as a trusted root certificate authority. This way, the client applications automatically accept transactions with the root certificate.

You can either make the certificate available to users by E-mailing it or placing it on a shared site, or you could incorporate the certificate into your corporate workstation image and use your application update facilities to distribute it automatically to users.

The following procedure explains how to download the internal CA certificate and install it on Windows clients.

**Procedure**

**Step 1**
Download the certificate from Firepower Device Manager.

a) Select **Policies > SSL Decryption**.
b) Click the **SSL Decryption Settings** button (🔗).
c) Click the **Download** button (⬇️).
d) Select a download location, optionally change the file name (but not the extension), and click Save.

You can now cancel out of the SSL Decryption Settings dialog box.

**Step 2**

Install the certificate in the Trusted Root Certificate Authority storage area in web browsers on client systems, or make it available for clients to install themselves.

The process differs depending on the operating system and type of browser. For example, you can use the following process for Internet Explorer and Chrome running on Windows. (For Firefox, install through the Tools > Options > Advanced page.)

a) From the Start menu, select Control Panel > Internet Options.
b) Select the Content tab.
c) Click the Certificates button to open the Certificates dialog box.
d) Select the Trusted Root Certificate Authorities tab.
e) Click Import, and follow the wizard to locate and select the downloaded file (<uuid>_internalCA.crt) and add it to the Trusted Root Certificate Authorities store.
f) Click Finish.

Messages should indicate that the import was successful. You might see an intermediate dialog box warning you that Windows could not validate the certificate if you generated a self-signed certificate rather than obtaining one from a well-known third-party Certificate Authority.

You can now close out the Certificate and Internet Options dialog boxes.

---

**Example: Blocking Older SSL/TLS Versions from the Network**

Some organizations are required to prevent the use of older versions of SSL or TLS either by government regulation or company policy. You can use the SSL Decryption policy to block traffic that uses an SSL/TLS version that you prohibit. Consider placing this rule at the top of the SSL Decryption policy to ensure that you catch the prohibited traffic immediately.

The following example blocks all SSL 3.0 and TLS 1.0 connections.

**Before you begin**

This procedure assumes you have already enabled the SSL Decryption policy as explained in Enable the SSL Decryption Policy, on page 172.

**Procedure**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Select Policies &gt; SSL Decryption.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click the + button to create a new rule.</td>
</tr>
<tr>
<td>Step 3</td>
<td>In Order, select 1 to place the rule at the top of the policy, or select the number most suitable for your network. The default is to add the rule at the end of the policy.</td>
</tr>
<tr>
<td>Step 4</td>
<td>In Title, enter a name for the rule, for example, Block_SSL3.0_and_TLS1.0.</td>
</tr>
<tr>
<td>Step 5</td>
<td>In Action, select Block. This will immediately drop any traffic that matches the rule.</td>
</tr>
</tbody>
</table>
**Step 6** Leave the default values for all options on the following tabs: **Source/Destination**, **Applications**, **URLs**, **Users**.

**Step 7** Click the **Advanced** tab and under **Supported Versions**, leave SSL 3.0 and TLS 1.0 selected, but uncheck TLS 1.1 and TLS 1.2.

The policy should look like the following:

![Add SSL Decryption Rule](image)

**Step 8** (Optional) Click the **Logging** tab and select **At End of Connection** if you want to dashboards and events to reflect blocked connections. You can also select an external syslog server if you are using one.

**Step 9** Click **OK**.

You can now deploy the policy. Once deployed, any SSL 3.0 or TLS 1.0 connection that goes through the system will be dropped.

**Note** SSL 2.0 connections are handled by the default action for the policy. If you want to ensure these are also dropped, change the default action to Block.

---

**What to do next**

If you implement this rule, we have the following recommendations:

- For any type of decrypt rule, leave the default settings on the Advanced tab, where all SSL/TLS options are selected. By applying to all versions, the handshake process is simplified. However, your initial block rule will still prevent SSL 3.0 and TLS 1.0 connections.

- We normally recommend that you use Do Not Decrypt as the default action for the policy. However, because SSL 2.0 connections are always handled by the default action, you might want to use Block instead. However, if you want to apply Do Not Decrypt as the default action for all decryptable traffic, create a Do Not Decrypt rule at the end of the policy where you accept all default values for traffic matching criteria. This rule would match any supported TLS connection that does not match an earlier rule in the table, and act as the default for those TLS versions.
Monitoring and Troubleshooting SSL Decryption

The following topics explain how to monitor and troubleshoot SSL decryption policies.

Monitoring SSL Decryption

You can view information about decryption in the dashboards and events for traffic that matches rules (or the default action) for which you enabled logging.

SSL Decryption Dashboard

To evaluate overall decryption statistics, view the Monitoring > SSL Decryption dashboard. The dashboard shows the following information:

- Percentage of encrypted versus plain text traffic.
- How much encrypted traffic is decrypted per SSL rules.

Events

In addition to the dashboard, the event viewer (Monitoring > Events) includes SSL information for encrypted traffic. Following are some tips in evaluating events:

- For connections that were dropped because they matched an SSL rule (or default action) that blocked matching traffic, the Action should be “Block,” and the Reason should indicate “SSL Block.”
- The SSL Actual Action field indicates the actual action that the system applied to the connection. This can differ from the SSL Expected Action, which indicates the action defined on the matching rule. For example, a connection might match a rule that applies decryption, but could not be decrypted for some reason.

Handling Web Sites Where Decrypt Re-sign Works for a Browser but not an App (SSL or Certificate Authority Pinning)

Some apps for smart phones and other devices use a technique called SSL (or Certificate Authority) pinning. The SSL pinning technique embeds the hash of the original server certificate inside the app itself. As a result, when the app receives the resized certificate from the Firepower Threat Defense device, the hash validation fails and the connection is aborted.

The primary symptom is that users cannot connect to the web site using the site’s app, but they can connect using the web browser, even when using the browser on the same device where the app fails. For example, users cannot use the Facebook iOS or Android app, but they can point Safari or Chrome at https://www.facebook.com and make a successful connection.

Because SSL pinning is specifically used to avoid man-in-the-middle attacks, there is no workaround. You must choose between the following options:

- Support app users, in which case you cannot decrypt any traffic to the site. Create a Do Not Decrypt rule for the site’s application (on the Application tab for the SSL Decryption rule) and ensure that the rule comes before any Decrypt Re-sign rule that would apply to the connections.
• Force users to use browsers only. If you must decrypt traffic to the site, you will need to inform users that they cannot use the site’s app when connecting through your network, that they must use their browsers only.

More Details

If a site works in a browser but not in an app on the same device, you are almost certainly looking at an instance of SSL pinning. However, if you want to delve deeper, you can use connection events to identify SSL pinning in addition to the browser test.

There are two ways an app might deal with hash validation failures:

• Group 1 apps, such as Facebook, send an SSL ALERT Message as soon as it receives the SH, CERT, SHD message from the server. The Alert is usually an “Unknown CA (48)” alert indicating SSL Pinning. A TCP Reset is sent following the Alert message. You should see the following symptoms in the event details:
  • SSL Flow Flags include ALERT_SEEN.
  • SSL Flow Flags do not include APP_DATA_C2S or APP_DATA_S2C.
  • SSL Flow Messages typically are: CLIENT_HELLO, SERVER_HELLO, SERVER_CERTIFICATE, SERVER_KEY_EXCHANGE, SERVER_HELLO_DONE.

• Group 2 apps, such as Dropbox, do not send any alerts. Instead they wait until the handshake is done and then send a TCP Reset. You should see the following symptoms in the event:
  • SSL Flow Flags do not include ALERT_SEEN, APP_DATA_C2S, or APP_DATA_S2C.
  • SSL Flow Messages typically are: CLIENT_HELLO, SERVER_HELLO, SERVER_CERTIFICATE, SERVER_KEY_EXCHANGE, SERVER_HELLO_DONE, CLIENT_KEY_EXCHANGE, CLIENT_CHANGE_CIPHER_SPEC, CLIENT_FINISHED, SERVER_CHANGE_CIPHER_SPEC, SERVER_FINISHED.
Handling Web Sites Where Decrypt Re-sign Works for a Browser but not an App (SSL or Certificate Authority Pinning)
Identity Policies

You can use identity policies to collect user identity information from connections. You can then view usage based on user identity in the dashboards, and configure access control based on user or user group.

- Identity Policy Overview, on page 187
- Configuring Identity Policies, on page 188
- Enabling Transparent User Authentication, on page 193
- Monitoring Identity Policies, on page 196
- Examples for Identity Policies, on page 196

Identity Policy Overview

You can use identity policies to detect the user who is associated with a connection. By identifying the user, you can correlate threat, endpoint, and network intelligence with user identity information. By linking network behavior, traffic, and events directly to individual users, the system can help you identify the source of policy breaches, attacks, or network vulnerabilities.

For example, you can identify who owns the host targeted by an intrusion event, and who initiated an internal attack or port scan. You can also identify high bandwidth users and users who are accessing undesirable web sites or applications.

User detection goes beyond collecting data for analysis. You can also write access rules based on username or user group name, selectively allowing or blocking access to resources based on user identity.

Establishing User Identity through Active Authentication

Authentication is the act of confirming the identity of a user.

With active authentication, when an HTTP traffic flow comes from an IP address for which the system has no user-identity mapping, you can decide whether to authenticate the user who initiated the traffic flow against the directory configured for the system. If the user successfully authenticates, the IP address is considered to have the identity of the authenticated user.

Failure to authenticate does not prevent network access for the user. Your access rules ultimately decide what access to provide these users.
Dealing with Unknown Users

When you configure the directory server for the identity policy, the system downloads user and group membership information from the directory server. This information is refreshed every 24 hours at midnight, or whenever you edit and save the directory configuration (even if you do not make any changes).

If a user succeeds in authenticating when prompted by an active authentication identity rule, but the user’s name is not in the downloaded user identity information, the user is marked as Unknown. You will not see the user’s ID in identity-related dashboards, nor will the user match group rules.

However, any access control rules for the Unknown user will apply. For example, if you block connections for Unknown users, these users are blocked even though they succeeded in authenticating (meaning that the directory server recognizes the user and the password is valid).

Thus, when you make changes to the directory server, such as adding or deleting users, or changing group membership, these changes are not reflected in policy enforcement until the system downloads the updates from the directory.

If you do not want to wait until the daily midnight update, you can force an update by editing the directory realm information (from Objects > Identity Realm, then edit the realm). Click Save, then deploy changes. The system will immediately download the updates.

Note

You can check whether new or deleted user information is on the system by going to Policies > Access Control, clicking the Add Rule (+) button, and looking at the list of users on the Users tab. If you cannot find a new user, or you can find a deleted user, then the system has old information.

Configuring Identity Policies

You can use identity policies to collect user identity information from connections. You can then view usage based on user identity in the dashboards, and configure access control based on user or user group.

The following is an overview of how to configure the elements required to obtain user identity through identity policies.

Procedure

Step 1
Select Policies > Identity.

If you have not yet defined an identity policy, click Enable Identity Policy and configure settings as described in Configure Identity Policy Settings, on page 189.

Step 2
Manage the identity policy.

After you configure identity settings, this page lists all rules in order. Rules are matched against traffic from top to bottom with the first match determining the action to apply. You can do the following from this page:

• To enable or disable the identity policy, click the Identity Policy toggle.

• To change the identity policy settings, click the Identity Policy Configuration button ( ).

• To move a rule, edit it and select the new location from the Order drop-down list.
• To configure rules:
  • To create a new rule, click the + button.
  • To edit an existing rule, click the edit icon ( ) for the rule (in the Actions column). You can also selectively edit a rule property by clicking on the property in the table.
  • To delete a rule you no longer need, click the delete icon ( ) for the rule (in the Actions column).

For more information on creating and editing identity rules, see Configure Identity Rules, on page 190.

---

**Configure Identity Policy Settings**

For identity policies to work, you must configure the directory realm and server that contains the user accounts for your network. You must also configure captive portal, which is used for actively authenticating users when they made web requests that go through the device.

**Before you begin**

Ensure that time settings are consistent among the directory servers, Firepower Threat Defense device, and clients. A time shift among these devices can prevent successful user authentication. "Consistent" means that you can use different time zones, but the time should be the same relative to those zones; for example, 10 AM PST = 1 PM EST.

**Procedure**

**Step 1**
Select Policies > Identity.

**Step 2**
Do one of the following:
  • If you have not configured the identity policy yet, click Enable Identity Policy to configure the identity policy settings.
  • Click the Identity Policy Configuration button ( ).

**Step 3**
Select the Realm Server.
If you have not configured the realm server yet, click Configure New Identity Realm from the drop-down list. For more information, see Configuring AD Identity Realms, on page 116.

**Step 4**
Configure the Active Authentication options.
When an identity rule requires active authentication for a user, the user is redirected to the captive portal port on the interface through which they are connected and then they are prompted to authenticate.

**Server Certificate**
Select the internal certificate to present to users during active authentication. If you have not already created the required certificate, click Create New Internal Certificate from the bottom of the drop-down list.

Users will have to accept the certificate if you do not upload a certificate that their browsers already trust.
Port
The captive portal port. The default is 885 (TCP). If you configure a different port, it must be in the range 1025-65535.

Note For the HTTP Basic, HTTP Response Page, and NTLM authentication methods, the user is redirected to the captive portal using the IP address of the interface. However, for HTTP Negotiate, the user is redirected using the fully-qualified DNS name firewall-hostname.AD-domain-name. If you want to use HTTP Negotiate, you must also update your DNS server to map this name to the IP addresses of all inside interfaces where you are requiring active authentication. Otherwise, the redirection cannot complete, and users cannot authenticate.

Step 5 In Decrypt Re-Sign Certificate, select the internal CA certificate to use for rules that implement decryption with re-signed certificates.

You can use the pre-defined NGFW-Default-InternalCA certificate, or one that you created or uploaded. If the certificate does not yet exist, click Create Internal CA to create it.

If you have not already installed the certificate in client browsers, click the download button to obtain a copy. See the documentation for each browser for information on how to install the certificate. Also see Downloading the CA Certificate for Decrypt Re-Sign Rules, on page 181.

Note You are prompted for SSL Decryption settings only if you have not already configured the SSL decryption policy. To change these settings after enabling the identity policy, edit the SSL decryption policy settings.

Step 6 Click Save.

Configure Identity Rules
Identity rules determine whether user identity information should be collected for matching traffic. You can configure No Authentication if you do not want to get user identity information for matching traffic.

Keep in mind that regardless of your rule configuration, active authentication is performed on HTTP traffic only. Thus, you do not need to create rules to exclude non-HTTP traffic from active authentication. You can simply apply an active authentication rule to all sources and destinations if you want to get user identity information for all HTTP traffic.

Note Also keep in mind that a failure to authentication has no impact on network access. Identity policies collect user identity information only. You must use access rules if you want to prevent users who failed to authenticate from accessing the network.

Procedure

Step 1 Select Policies &gt; Identity.
Step 2 Do any of the following:
  • To create a new rule, click the + button.
• To edit an existing rule, click the edit icon (ейчас) for the rule.

To delete a rule you no longer need, click the delete icon (пометить как исходящий) for the rule.

Step 3 In Order, select where you want to insert the rule in the ordered list of rules.

Rules are applied on a first-match basis, so you must ensure that rules with highly specific traffic matching criteria appear above policies that have more general criteria that would otherwise apply to the matching traffic.

The default is to add the rule to the end of the list. If you want to change a rule's location later, edit this option.

Step 4 Select the type of User Authentication.

You must select the AD identity realm that includes the user accounts for passive and active authentication rules.

• Active—Use active authentication to determine user identity. Active authentication is applied to HTTP traffic only. If any other type of traffic matches an identity policy that requires or allows active authentication, then active authentication will not be attempted.

• No Auth—Do not obtain user identity. Identity-based access rules will not be applied to this traffic. These users are marked as No Authentication Required.

Step 5 (Active Authentication only.) Select the authentication method (Type) supported by your directory server.

• HTTP Basic—Authenticate users using an unencrypted HTTP Basic Authentication (BA) connection. Users log in to the network using their browser's default authentication popup window. This is the default.

• NTLM—Authenticate users using an NT LAN Manager (NTLM) connection. This selection is only available when you select an AD realm. Users log in to the network using their browser's default authentication popup window, although you can configure IE and Firefox browsers to transparently authenticate using their Windows domain login (see Enabling Transparent User Authentication, on page 193).

• HTTP Negotiate—Allow the device to negotiate the method between the user agent (the application the user is using to initiate the traffic flow) and the Active Directory server. Negotiation results in the strongest commonly supported method being used, in order, NTLM, then basic. Users log in to the network using their browser's default authentication popup window.

• HTTP Response Page—Prompt users to authenticate using a system-provided webpage. This is a form of HTTP Basic authentication.

Note For the HTTP Basic, HTTP Response Page, and NTLM authentication methods, the user is redirected to the captive portal using the IP address of the interface. However, for HTTP Negotiate, the user is redirected using the fully-qualified DNS name firewall-hostname.AD-domain-name. If you want to use HTTP Negotiate, you must also update your DNS server to map this name to the IP addresses of all inside interfaces where you are requiring active authentication. Otherwise, the redirection cannot complete, and users cannot authenticate.

Step 6 (Active authentication only.) Select Fall Back as Guest > On/Off to determine whether users who fail active authentication are labeled as Guest users.

Users get 3 chances to successfully authenticate. If they fail, your selection for this option determines how the user is marked. You can write access rules based on these values.

• Fall Back as Guest > On—Users are marked as Guest.

• Fall Back as Guest > Off—Users are marked as Failed Authentication.
Step 7

Define the traffic matching criteria on the **Source/Destination** tab.

Keep in mind that active authentication will be attempted with HTTP traffic only. Therefore, there is no need to configure No Auth rules for non-HTTP traffic, and there is no point in creating Active Authentication rules for any non-HTTP traffic.

The Source/Destination criteria of an identity rule define the security zones (interfaces) through which the traffic passes, the IP addresses or the country or continent (geographical location) for the IP address, or the protocols and ports used in the traffic. The default is any zone, address, geographical location, protocol, and port.

To modify a condition, you click the + button within that condition, select the desired object or element, and click **OK** in the popup dialog box. If the criterion requires an object, you can click **Create New Object** if the object you require does not exist. Click the x for an object or element to remove it from the policy.

You can configure the following traffic matching criteria.

**Source Zones, Destination Zones**

The security zone objects that define the interfaces through which the traffic passes. You can define one, both, or neither criteria: any criteria not specified applies to traffic on any interface.

- To match traffic leaving the device from an interface in the zone, add that zone to the **Destination Zones**.
- To match traffic entering the device from an interface in the zone, add that zone to the **Source Zones**.
- If you add both source and destination zone conditions to a rule, matching traffic must originate from one of the specified source zones and egress through one of the destination zones.

Use this criteria when the rule should apply based on where the traffic enters or exits the device. For example, if you want to ensure that user identity is collected from all traffic originating from inside networks, select an inside zone as the **Source Zones** while leaving the destination zone empty.

**Source Networks, Destination Networks**

The network objects or geographical locations that define the network addresses or locations of the traffic.

- To match traffic from an IP address or geographical location, configure the **Source Networks**.
- To match traffic to an IP address or geographical location, configure the **Destination Networks**.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

When you add this criteria, you select from the following tabs:

- **Network**—Select the network objects or groups that define the source or destination IP addresses for the traffic you want to control.
- **Geolocation**—Select the geographical location to control traffic based on its source or destination country or continent. Selecting a continent selects all countries within the continent. Besides selecting geographical location directly in the rule, you can also select a geolocation object that you created to define the location. Using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

Note To ensure you are using up-to-date geographical location data to filter your traffic, Cisco strongly recommends that you regularly update the geolocation database (GeoDB).
**Source Ports, Destination Ports/Protocols**

The port objects that define the protocols used in the traffic. For TCP/UDP, this can include ports.

- To match traffic from a protocol or port, configure the **Source Ports**. Source ports can be TCP/UDP only.

- To match traffic to a protocol or port, configure the **Destination Ports/Protocols**.

- To match traffic both originating from specific TCP/UDP ports and destined for specific TCP/UDP ports, configure both. If you add both source and destination ports to a condition, you can only add ports that share a single transport protocol, TCP or UDP. For example, you could target traffic from port TCP/80 to port TCP/8080.

**Step 8**  
Click **OK**.

---

**Enabling Transparent User Authentication**

If you configure the identity policy to allow for active authentication, you can use the following authentication methods to acquire user identity:

**HTTP Basic**

With HTTP basic authentication, users are always prompted to authenticate with their directory username and password. The password is transmitted in clear text. For that reason, basic authentication is not considered a secure form of authentication.

Basic is the default authentication mechanism.

**HTTP Response Page**

This is a type of HTTP basic authentication, where the user is presented with a login browser page.

**NTLM, HTTP Negotiate (Integrated Windows Authentication for Active Directory)**

With integrated Windows authentication, you take advantage of the fact that users log into a domain to use their workstation. The browser tries to use this domain login when accessing a server, including the Firepower Threat Defense captive portal during active authentication. The password is not transmitted. If authentication is successful, the user is transparently authenticated; the user is unaware that any authentication challenge was made or satisfied.

If the browser cannot satisfy an authentication request using the domain login credentials, the user is prompted for username and password, which is the same user experience as basic authentication. Thus, if you configure integrated Windows authentication, it can reduce the need for users to supply credentials when accessing the network or servers in the same domain.

Note that HTTP Negotiate picks the strongest method supported by both the Active directory server and the user agent. If negotiation selects HTTP Basic as the authentication method, you will not get transparent authentication. The order of strength is NTLM, then basic. Negotiation must select NTLM for transparent authentication to be possible.

You must configure client browsers to support integrated Windows authentication to enable transparent authentication. The following sections explain the general requirements and basic configuration of integrated Windows authentication for some commonly used browsers that support it. Users should consult the help for their browser (or other user agent) for more detailed information, because the techniques can change between software releases.
Requirements for Transparent Authentication

Users must configure their browser or user agent to implement transparent authentication. They can do this individually, or you can configure it for them and push the configuration to client workstations using your software distribution tools. If you decide to have users do it themselves, ensure that you provide the specific configuration parameters that work for your network.

Regardless of browser or user agent, you must implement the following general configuration:

• Add the Firepower Threat Defense interface through which users connect to the network to the Trusted Sites list. You can use the IP address or if available, the fully-qualified domain name (for example, inside.example.com). You can also use wildcards or partial addresses to create a generalized trusted site. For example, you can typically cover all internal sites using *.example.com or simply example.com, trusting all servers in your network (use your own domain name). If you add the specific address of the interface, you might need to add several addresses to the trusted sites to account for all user access points to the network.

• Integrated Windows authentication does not work through a proxy server. Therefore, you must either not use a proxy, or you must add the Firepower Threat Defense interface to the addresses excluded from going through the proxy. If you decide that you must use a proxy, users will be prompted for authentication even if you use NTLM.

Tip

Configuring transparent authentication is not a requirement, but a convenience to end users. If you do not configure transparent authentication, users are presented with a login challenge for all authentication methods.

Configuring Internet Explorer for Transparent Authentication

To configure Internet Explorer for NTLM transparent authentication:

Procedure

Step 1 Select Tools > Internet Options.

Step 2 Select the Security tab, select the Local Intranet zone, then do the following:

a) Click the Sites button to open the list of trusted sites.

b) Ensure that at least one of the following options is selected:

• Automatically detect intranet network. If you select this option, all other options are disabled.

• Include all sites that bypass the proxy.

Tip

Not all browsers support integrated Windows authentication, such as Chrome and Safari (based on the versions available when this was written). Users will be prompted for username and password. Consult the browser’s documentation to determine if support is available in the version you use.
c) Click **Advanced** to open the Local Intranet Sites dialog box, then paste the URL you want to trust into the **Add Site** box and click **Add**.

Repeat the process if you have more than one URL. Use wildcards to specify a partial URL, such as `http://*.example.com` or simply `*.example.com`.

Close the dialog boxes to return to the Internet Options dialog box.

d) With **Local Intranet** still selected, click **Custom Level** to open the Security Settings dialog box. Find the **User Authentication > Logon** setting and select **Automatic logon only in Intranet zone**. Click **OK**.

**Step 3**

In the Internet Options dialog box, click the **Connections** tab, then click **LAN Settings**.

If **Use a proxy server for your LAN** is selected, you need to ensure that the Firepower Threat Defense interface bypasses the proxy. Do any of the following as appropriate:

- Select **Bypass proxy server for local addresses**.
- Click **Advanced** and enter the address into the **Do not use proxy server for addresses beginning with** box. You can use wildcards, for example, `*.example.com`.

---

**Configuring Firefox for Transparent Authentication**

To configure Firefox for NTLM transparent authentication:

**Procedure**

**Step 1**

Open **about:config**. Use the filter bar to help you locate the preferences that you need to modify.

**Step 2**

To support NTLM, modify the following preferences (filter on `network.automatic`):

- **network.automatic-ntlm-auth.trusted-uris** — Double-click the preference, enter the URL, and click **OK**. You can enter multiple URLs by separating them with commas; including the protocol is optional. For example:

  ```
  http://host.example.com, http://hostname, myhost.example.com
  ```

  You can also use partial URLs. Firefox matches the end of the string, not a random substring. Thus, you could include your entire internal network by specifying just your domain name. For example:

  ```
  example.com
  ```

- **network.automatic-ntlm-auth.allow-proxies** — Ensure that the value is **true**, which is the default. Double-click to change the value if it is currently false.

**Step 3**

Check the HTTP proxy settings. You can find these by selecting **Tools > Options**, then click the **Network** tab in the Options dialog box. Click the **Settings** button in the Connection group.

- If **No Proxy** is selected, there is nothing to configure.
• If Use System Proxy Settings is selected, you need to modify the `network.proxy.no_proxies_on` property in about:config to add the trusted URIs you included in `network.automatic-ntlm-auth.trusted-uris`.

• If Manual Proxy Configuration is selected, update the No Proxy For list to include these trusted URIs.

• If one of the other options is selected, ensure that the properties used for those configurations exclude the same trusted URIs.

---

**Monitoring Identity Policies**

If identity policies that require authentication are working correctly, you should see user information on the Monitoring > Users dashboard and other dashboards that include user information.

In addition, events shown in Monitoring > Events should include user information.

If you do not see any user information, verify that the directory server is functioning correctly. Use the Test button in the directory server configuration dialog box to verify connectivity.

If the directory server is functioning and usable, verify that the traffic matching criteria on the identity rules that require active authentication are written in a way that will match your users. For example, ensure that the source zone contains the interfaces through which your user traffic will enter the device. The active authentication identity rules match HTTP traffic only, so users must be sending that type of traffic through the device.

**Examples for Identity Policies**

The use case chapter includes an example of implementing identity policies. Please see How to Gain Insight Into Your Network Traffic, on page 48.
Security Intelligence

The Security Intelligence policy gives you an early opportunity to drop unwanted traffic based on source/destination IP address or destination URL. The following topics explain how to implement Security Intelligence.

- About Security Intelligence, on page 197
- License Requirements for Security Intelligence, on page 199
- Configuring Security Intelligence, on page 199
- Monitoring Security Intelligence, on page 200
- Examples for Security Intelligence, on page 200

About Security Intelligence

The Security Intelligence policy gives you an early opportunity to drop unwanted traffic based on source/destination IP address or destination URL. The system drops this blacklisted traffic before evaluating it with the access control policy, thus reducing the amount of system resources used.

You can blacklist traffic based on the following:

- Cisco Talos Intelligence Group (Talos) feeds—Talos provides access to regularly updated security intelligence feeds. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations. The system downloads feed updates regularly, and thus new threat intelligence is available without requiring you to redeploy the configuration.

  **Note**
  
  Talos feeds are updated by default every hour. You can change the update frequency, and even update the feeds on demand, from the Device > Updates page.

- Network and URL objects—If you know of specific IP addresses or URLs you want to block, you can create objects for them and add them to the blacklist (or the exception list, also known as the whitelist).

You create separate blacklists for IP addresses (networks) and URLs.
Making Exceptions to the Blacklists

For each blacklist, you can create an associated exception list, which is also known as a whitelist. The only purpose of the exception list is to exempt IP addresses or URLs that appear in the blacklist. That is, if you find an address or URL you need to use, and you know to be safe, is in a feed configured on the blacklist, you can exempt that network/URL without completely removing the category from the blacklist.

Exempted or whitelisted traffic is subsequently evaluated by the access control policy. The ultimate decision on whether the connections are allowed or dropped is based on the access control rule the connections match. The access rule also determines whether intrusion or malware inspection is applied to the connection.

Security Intelligence Feed Categories

The following table describes the categories available in the Cisco Talos Intelligence Group (Talos) feeds. These categories are available for both network and URL blacklisting.

Table 5: Talos Feed Categories

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attackers</td>
<td>Active scanners and blacklisted hosts known for outbound malicious activity.</td>
</tr>
<tr>
<td>bogon</td>
<td>Bogon networks and unallocated IP addresses.</td>
</tr>
<tr>
<td>bots</td>
<td>Sites that host binary malware droppers.</td>
</tr>
<tr>
<td>CnC</td>
<td>Sites that host command-and-control servers for botnets.</td>
</tr>
<tr>
<td>dga</td>
<td>Malware algorithms used to generate a large number of domain names acting as</td>
</tr>
<tr>
<td></td>
<td>rendezvous points with their command-and-control servers.</td>
</tr>
<tr>
<td>exploitkit</td>
<td>Software kits designed to identify software vulnerabilities in clients.</td>
</tr>
<tr>
<td>malware</td>
<td>Sites that host malware binaries or exploit kits.</td>
</tr>
<tr>
<td>open_proxy</td>
<td>Open proxies that allow anonymous web browsing.</td>
</tr>
<tr>
<td>open_relay</td>
<td>Open mail relays that are known to be used for spam.</td>
</tr>
<tr>
<td>phishing</td>
<td>Sites that host phishing pages.</td>
</tr>
<tr>
<td>response</td>
<td>IP addresses and URLs that are actively participating in malicious or</td>

<tr>
<td></td>
<td>suspicious activity.</td>
</tr>
<tr>
<td>spam</td>
<td>Mail hosts that are known for sending spam.</td>
</tr>
<tr>
<td>suspicious</td>
<td>Files that appear to be suspicious and have characteristics that resemble</td>
</tr>
<tr>
<td></td>
<td>known malware.</td>
</tr>
<tr>
<td>tor_exit_node</td>
<td>Tor exit nodes.</td>
</tr>
</tbody>
</table>
License Requirements for Security Intelligence

You must enable the Threat license to use Security Intelligence. See Enabling or Disabling Optional Licenses, on page 84.

Configuring Security Intelligence

The Security Intelligence policy gives you an early opportunity to drop unwanted traffic based on source/destination IP address or destination URL. Any allowed connections are still evaluated by access control policies and might eventually be dropped. You must enable the Threat license to use Security Intelligence.

Procedure

Step 1  Select Policies > Security Intelligence.
Step 2  If the policy is not enabled, click the Enable Security Intelligence button.

You can disable the policy at any time by clicking the Security Intelligence toggle to Off. Your configuration is preserved, so that when you enable the policy again you do not need to reconfigure it.

Step 3  Configure Security Intelligence.

There are separate blacklists for Networks (IP addresses) and URLs.

a)  Click the Network or URL tab to display the blacklist you want to configure.
b)  In the Blacklist, click + to select the objects or feeds whose connections you want to drop immediately.

The object selector organizes the objects and feeds on separate tabs by type. If the object you want does not yet exist, click the Create New Object link at the bottom of the list and create it now. For a description of the Cisco Talos Intelligence Group (Talos) feeds, click the i button next to the feed. See also Security Intelligence Feed Categories, on page 198.

Note  Security Intelligence ignores IP address blocks using a /0 netmask. This includes the any-ipv4 and any-ipv6 network objects. Do not select these objects for network blacklisting.

c)  In the Do Not Block list, click + and select any exceptions to the blacklist.

The only reason to configure this list is to make exceptions for IP addresses or URLs that are in the blacklist. Exempted connections are subsequently evaluated by your access control policy, and might be dropped anyway.
d)  Repeat the process to configure the other blacklist.

Step 4  (Optional.) Click the Edit Logging Settings button ( ) to configure logging.

If you enable logging, any matches to blacklist entries are logged. Matches to exception entries are not logged, although you get log messages if exempted connections match access control rules with logging enabled.

Configure the following settings:

•  Connection Events Logging—Click the toggle to enable or disable logging.
• **Syslog**—If you want to send a copy of the events to an external syslog server, select this option and select the server object that defines the syslog server. If the required object does not already exist, click **Add Syslog Server** and create it.

Because event storage on the device is limited, sending events to an external syslog server can provide more long term storage and enhance your event analysis.

---

**Monitoring Security Intelligence**

If you enable logging for the Security Intelligence policy, the system generates Security Intelligence events for each blacklisted connection. There are matching connection events for these connections.

Statistics for dropped blacklisted connections appear in the various dashboards available on the Monitoring page.

The **Monitoring > Access and SI Rules** dashboard shows the top access rules and Security Intelligence rule-equivalents that are matching traffic.

In addition, you can select **Monitoring > Events**, then the **Security Intelligence** view, to see the Security Intelligence events, as well as the related connection events on the **Connection** tab.

- The SI Category ID field in an event indicates the object matched in the blacklist, such as a network or URL object or feed.
- The Reason field in a connection event explains why the action shown in the event was applied. For example, a Block action paired with reasons such as IP Block or URL Block indicates that a connection was blacklisted and dropped by Security Intelligence.

**Examples for Security Intelligence**

The use case chapter includes an example of implementing Security Intelligence policies. Please see **How to Block Threats**, on page 55.
CHAPTER 12

Access Control

The following topics explain access control rules. These rules control which traffic is allowed to pass through the device, and apply advanced services to the traffic, such as intrusion inspection.

- Access Control Overview, on page 201
- License Requirements for Access Control, on page 209
- Guidelines and Limitations for Access Control Policies, on page 209
- Configuring the Access Control Policy, on page 210
- Monitoring Access Control Policies, on page 220
- Examples for Access Control, on page 221

Access Control Overview

The following topics explain access control policies.

Access Control Rules and the Default Action

Use the access control policy to allow or block access to network resources. The policy consists of a set of ordered rules, which are evaluated from top to bottom. The rule applied to traffic is the first one where all the traffic criteria are matched.

You can control access based on:

- Traditional network characteristics such as source and destination IP addresses, protocol, ports, and interfaces (in the form of security zones).

- The application that is being used. You can control access based on the specific application, or you can create rules that cover categories of applications, applications tagged with a particular characteristic, the type of application (client, server, web), or the application's risk or business relevance rating.

- The destination URL of a web request, including the generalized category of the URL. You can refine category matches based on the public reputation of the target site.

- The user who is making the request, or the user groups to which the user belongs.

For unencrypted traffic that you allow, you can apply IPS inspection to check for threats and block traffic that appears to be an attack. You can also use file policies to check for prohibited files or malware.
Any traffic that does not match an access rule is handled by the access control Default Action. If you allow traffic by default, you can apply intrusion inspection to the traffic. However, you cannot perform file or malware inspection on traffic handled by the default action.

Application Filtering

You can use access control rules to filter traffic based on the application used in the connection. The system can recognize a wide variety of applications, so that you do not need to figure out how to block one web application without blocking all web applications.

For some popular applications, you can filter on different aspects of the application. For example, you could create a rule that blocks Facebook Games without blocking all of Facebook.

You can also create rules based on general application characteristics, blocking or allowing entire groups of applications by selecting risk or business relevance, type, category, or tag. However, as you select categories in an application filter, look over the list of matching applications to ensure you are not including unintended applications. For a detailed explanation of the possible groupings, see Application Criteria, on page 214.

Application Control for Encrypted and Decrypted Traffic

If an application uses encryption, the system might not be able to identify the application.

The system can detect application traffic encrypted with StartTLS, including SMTPS, POPS, FTPS, TelnetS, and IMAPS. In addition, it can identify certain encrypted applications based on the Server Name Indication in the TLS ClientHello message, or the subject distinguished name value from the server certificate.

Use the application filters dialog box to determine if your application requires decryption by selecting the following Tags, then examining the list of applications.

- **SSL Protocol**—You do not need to decrypt traffic tagged as SSL Protocol. The system can recognize this traffic and apply your access control action. Access control rules for the listed applications should match to expected connections.

- **Decrypted Traffic**—The system can recognize this traffic only if you first decrypt the traffic. Configure SSL decryption rules for this traffic.

Best Practices for Application Filtering

Please keep the following recommendations in mind when designing your application filtering access control rules.

- To handle traffic referred by a web server, such as advertisement traffic, match the referred application rather than the referring application.

- Avoid combining application and URL criteria in the same rule, especially for encrypted traffic.

- If you write a rule for traffic that is tagged Decrypted Traffic, ensure that you have an SSL Decryption rule that will decrypt the matching traffic. These applications can be identified in decrypted connections only.

- The system can detect multiple types of Skype application traffic. To control Skype traffic, choose the Skype tag from the Application Filters list rather than selecting individual applications. This ensures that the system can detect and control all Skype traffic the same way.
To control access to Zoho mail, select both the Zoho and Zoho Mail applications.

URL Filtering

You can use access control rules to filter traffic based on the URL used in an HTTP or HTTPS connection. Note that URL filtering for HTTP is more straight-forward than it is for HTTPS, because HTTPS is encrypted.

You can use the following techniques to implement URL filtering:

- Category and reputation-based URL filtering—With a URL Filtering license, you can control access to web sites based on the URL’s general classification (category) and risk level (reputation). This is by far the easiest and most effective way to block unwanted sites.

- Manual URL filtering—With any license, you can manually specify individual URLs, and groups of URLs, to achieve granular, custom control over web traffic. The main purpose of manual filtering is to create exceptions to category-based block rules, but you can use manual rules for other purposes.

The following topics provide more information on URL filtering.

Filtering URLs by Category and Reputation

With a URL Filtering license, you can control access to web sites based on the category and reputation of the requested URLs:

- Category—A general classification for the URL. For example, ebay.com belongs to the Auctions category, and monster.com belongs to the Job Search category. A URL can belong to more than one category.

- Reputation—How likely the URL is to be used for purposes that might be against your organization’s security policy. Reputations range from High Risk (level 1) to Well Known (level 5).

URL categories and reputations help you quickly configure URL filtering. For example, you can use access control to block high risk URLs in the Abused Drugs category.

Using category and reputation data also simplifies policy creation and administration. Sites that represent security threats, or that serve undesirable content, might appear and disappear faster than you can update and deploy new policies. As Cisco updates the URL database with new sites, changed classifications, and changed reputations, your rules automatically adjust to the new information. You do not need to edit your rules to account for new sites.

If you enable regular URL database updates, you can ensure that the system uses up-to-date information for URL filtering. You can also enable communications with Cisco Collective Security Intelligence (CSI) to obtain the latest threat intelligence for URLs with unknown category and reputation. For more information, see Configuring URL Filtering Preferences, on page 399.

Note

To see URL category and reputation information in events and application details, you must create at least one rule with a URL condition.

Looking Up the Category and Reputation for a URL

You can check on the category and reputation for a particular URL by using the following site. You can use this information to help you check the behavior of your category and reputation based URL filtering rules.
Manual URL Filtering

You can supplement or selectively override category and reputation-based URL filtering by manually filtering individual URLs or groups of URLs. You can perform this type of URL filtering without a special license.

For example, you might use access control to block a category of websites that are not appropriate for your organization. However, if the category contains a website that is appropriate, and to which you want to provide access, you can create a manual Allow rule for that site and place it before the Block rule for the category.

To configure manual URL filtering, you create a URL object with the destination URL. How this URL is interpreted is based on the following rules:

- If you do not include a path (that is, there is no / character in the URL), the match is based on the server’s hostname only. The hostname is considered a match if it comes after the :// separator, or after any dot in the hostname. For example, ign.com matches ign.com and www.ign.com, but it does not match verisign.com.

- If you include one or more / character, the entire URL string is used for a substring match, including the server name, path, and any query parameters. However, we recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites, as servers can be reorganized and pages moved to new paths. Substring matching can also lead to unexpected matches, where the string you include in the URL object also matches paths on unintended servers or strings within query parameters.

- The system disregards the encryption protocol (HTTP vs HTTPS). In other words, if you block a website, both HTTP and HTTPS traffic to that website is blocked, unless you use an application condition to target a specific protocol. When creating a URL object, you do not need to specify the protocol when creating an object. For example, use example.com rather than http://example.com.

- If you plan to use a URL object to match HTTPS traffic in an access control rule, create the object using the subject common name in the public key certificate used to encrypt the traffic. Also, the system disregards subdomains within the subject common name, so do not include subdomain information. For example, use example.com rather than www.example.com.

However, please understand that the subject common name in the certificate might be completely unrelated to a website’s domain name. For example, the subject common name in the certificate for youtube.com is *.google.com (this of course might change at any time). You will get more consistent results if you use the SSL Decryption policy to decrypt HTTPS traffic so that URL filtering rules work on decrypted traffic.

Note

URL objects will not match HTTPS traffic if the browser resumes a TLS session because the certificate information is no longer available. Thus, even if you carefully configure the URL object, you might get inconsistent results for HTTPS connections.

Filtering HTTPS Traffic

Because HTTPS traffic is encrypted, performing URL filtering directly on HTTPS traffic is not as straight-forward as it is on HTTP traffic. For that reason, you should consider using SSL Decryption policies to decrypt all HTTPS traffic that you intend to filter. That way, the URL filtering access control policies work on decrypted traffic, and you get the same results you would get for regular HTTP traffic.
However, if you do intend to allow some HTTPS traffic to pass undecrypted into the access control policy, you need to understand that rules match HTTPS traffic differently than they do for HTTP traffic. To filter encrypted traffic, the system determines the requested URL based on information passed during the SSL handshake: the subject common name in the public key certificate used to encrypt the traffic. There might be little or no relationship between the web site hostname in the URL and the subject common name.

HTTPS filtering, unlike HTTP filtering, disregards subdomains within the subject common name. Do not include subdomain information when manually filtering HTTPS URLs. For example, use example.com rather than www.example.com. Also, review the content of the certificates used by the site to ensure you have the right domain, the one used in the subject common name, and that this name will not conflict with your other rules (for example, the name for a site you want to block might overlap with one you want to allow). For example, the subject common name in the certificate for youtube.com is *.google.com (this of course might change at any time).

URL objects will not match HTTPS traffic if the browser resumes a TLS session because the certificate information is no longer available. Thus, even if you carefully configure the URL object, you might get inconsistent results for HTTPS connections.

Controlling Traffic by Encryption Protocol

The system disregards the encryption protocol (HTTP vs HTTPS) when performing URL filtering. This occurs for both manual and reputation-based URL conditions. In other words, URL filtering treats traffic to the following web sites identically:

- http://example.com
- https://example.com

To configure a rule that matches only HTTP or HTTPS traffic, but not both, either specify the TCP port in the Destination condition or add an application condition to the rule. For example, you could allow HTTPS access to a site while disallowing HTTP access by constructing two access control rules, each with an TCP port or application, and URL, condition.

The first rule allows HTTPS traffic to the website:

Action: Allow
TCP port or Application: HTTPS (TCP port 443)
URL: example.com

The second rule blocks HTTP access to the same website:

Action: Block
TCP port or Application: HTTP (TCP port 80)
URL: example.com

Comparing URL and Application Filtering

URL and application filtering have similarities. But you should use them for very distinct purposes:

- URL filtering is best used to block or allow access to an entire web server. For example, if you do not want to allow any type of gambling on your network, you can create a URL filtering rule to block the Gambling category. With this rule, users cannot get to any pages on any web server within the category.
Application filtering is useful for blocking specific applications regardless of the hosting site, or for blocking specific features of an otherwise allowable web site. For example, you could block just the Facebook Games application without blocking all of Facebook.

Because combining application and URL criteria can lead to unexpected results, especially for encrypted traffic, it is a good policy to create separate rules for URL and application criteria. If you do need to combine application and URL criteria in a single rule, you should place these rules after straightforward application-only or URL-only rules, unless the application+URL rule is acting as an exception to a more general application-only or URL-only rule. Because URL filtering block rules are more broad than application filtering, you should place them above application-only rules.

If you do combine application and URL criteria, you might need to monitor your network more carefully to ensure that you are not allowing access to unwanted sites and applications.

**Best Practices for Effective URL Filtering**

Please keep the following recommendations in mind when designing your URL filtering access control rules.

- Use category and reputation blocking whenever possible. This ensures that new sites get blocked automatically as they are added to the categories, and that blocking based on reputation is adjusted if a site becomes more (or less) reputable.

- When using URL category matching, note that there are cases where the login page for a site is in a different category than the site itself. For example, Gmail is in the Web-based Email category, whereas the login page is in the Internet Portals category. If you have different rules with different actions for the categories, you might get unintended results.

- Use URL objects to target entire web sites and to make exceptions to category blocking rules. That is, to allow specific sites that would otherwise get blocked in a category rule.

- If you want to manually block a web server (using a URL object), it is much more effective to do so in the Security Intelligence policy. The Security Intelligence policy drops connections before the access control rules are evaluated, so you get a faster, more efficient, block.

- For the most effective filtering of HTTPS connections, implement SSL decryption rules to decrypt traffic for which you are writing an access control rule. Any decrypted HTTPS connections are filtered as HTTP connections in the access control policy, so you avoid all of the limitations for HTTPS filtering.

- Place URL blocking rules before any application filtering rules, because URL filtering blocks entire web servers, whereas application filtering targets specific application usage regardless of the web server.

**What the User Sees When You Block Web Sites**

When you block web sites with URL filtering rules, what the user sees differs based on whether the site is encrypted.

- HTTP connections—The user sees a system default block response page instead of the normal browser page for timed out or reset connections. This page should make it clear that you blocked the connection on purpose.

- HTTPS (encrypted) connections—The user does not see the system default block response page. Instead, the user sees the browser’s default page for a secure connection failure. The error message does not indicate the site was blocked due to policy. Instead, errors might indicate that there are no common encryption algorithms. It will not be obvious from this message that you blocked the connection on purpose.
In addition, web sites might be blocked by other access control rules that are not explicitly URL filtering rules, or even by the default action. For example, if you block entire networks or geolocations, any web sites on that network or in that geographic location are also blocked. Users blocked by these rules may, or may not, get a response page as described in the limitations below.

If you implement URL filtering, consider explaining to end users what they might see when a site is intentionally blocked, and what types of site you are blocking. Otherwise, they might spend a good deal of time troubleshooting blocked connections.

**Limitations of HTTP Response Pages**

HTTP response pages do not always appear when the system blocks web traffic.

- The system does not display a response page when web traffic is blocked as a result of a promoted access control rule (an early-placed blocking rule with only simple network conditions).

- The system does not display a response page when web traffic is blocked before the system identifies the requested URL.

- The system does not display a response page for encrypted connections blocked by access control rules.

**Intrusion, File, and Malware Inspection**

Intrusion and file policies work together as the last line of defense before traffic is allowed to its destination:

- Intrusion policies govern the system's intrusion prevention capabilities.

- File policies govern the system's file control and AMP for Firepower capabilities.

All other traffic handling occurs before network traffic is examined for intrusions, prohibited files, and malware. By associating an intrusion or file policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy, a file policy, or both.

You can configure intrusion and file policies on rules that allow traffic only. Inspection is not performed on rules set to trust or block traffic. In addition, if the default action for the access control policy is allow, you can configure an intrusion policy but not a file policy.

For any single connection handled by an access control rule, file inspection occurs before intrusion inspection. That is, the system does not inspect files blocked by a file policy for intrusions. Within file inspection, simple blocking by type takes precedence over malware inspection and blocking. Until a file is detected and blocked in a session, packets from the session may be subject to intrusion inspection.

---

**Note**

By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured. Inspection works with unencrypted traffic only.
Best Practices for Access Control Rule Order

Rules are applied on a first-match basis, so you must ensure that rules with highly specific traffic matching criteria appear above policies that have more general criteria that would otherwise apply to the matching traffic. Consider the following recommendations:

- Specific rules should come before general rules, especially when the specific rules are exceptions to general rules.
- Any rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number) should come as early as possible. We recommend they come before any rule that requires inspection, such as those with application or URL criteria, because Layer-3/4 criteria can be evaluated quickly and without inspection. Of course, any exceptions to these rules must be placed above them.
- Whenever possible, put specific drop rules near the top of the policy. This ensures the earliest possible decision on undesirable traffic.
- Any rules that include both application and URL criteria should come after straight-forward application-only or URL-only rules, unless the application+URL rule is acting as an exception to a more general application-only or URL-only rule. Combining application and URL criteria can lead to unexpected results, especially for encrypted traffic, so we recommend that you create separate rules for URL and application filtering whenever possible.

NAT and Access Rules

Access rules always use the real IP addresses when determining an access rule match, even if you configure NAT. For example, if you configure NAT for an inside server, 10.1.1.5, so that it has a publicly routable IP address on the outside, 209.165.201.5, then the access rule to allow the outside traffic to access the inside server needs to reference the server’s real IP address (10.1.1.5), and not the mapped address (209.165.201.5).

How Other Security Policies Impact Access Control

Other security policies can affect how access control rules function and match connections. As you configure your access rules, keep the following in mind:

- **SSL Decryption** policy—The SSL decryption rules are evaluated before access control. Thus, if an encrypted connection matches an SSL decryption rule that applies some type of decryption, it is the plain text (decrypted) connection that is evaluated by the access control policy. The access rules do not see the encrypted version of the connection. Additionally, any connections that match SSL decryption rules that drop traffic are never seen by the access control policy. Finally, any encrypted connection that matches a Do Not Decrypt rule is evaluated in its encrypted state.
- **Identity** policy—Connections are matched to users (and thus, user groups) only if there is a user mapping for the source IP address. Access rules that key on user or group membership can match only those connections for which user identity was successfully collected by your identity policy.
- **Security Intelligence** policy—Any connection that is blacklisted and dropped is never seen by the access control policy.
- **VPN** (site-to-site or remote access)—VPN traffic is always evaluated against the access control policy, and connections are allowed or dropped based on the matching rule. However, the VPN tunnel itself is decrypted before the access control policy is evaluated. The access control policy evaluates the connections that are embedded within the VPN tunnel, not the tunnel itself.
License Requirements for Access Control

You do not need a special license to use the access control policy. However, you do need the following licenses for specific features within the access control policy. For information on configuring licenses, see Enabling or Disabling Optional Licenses, on page 84.

- **URL Filtering** license—To create rules that use URL categories and reputations as match criteria.
- **Threat** license—To configure an intrusion policy on an access rule or the default action. You also need this license use a file policy.
- **Malware** license—To configure a file policy on an access rule for malware control.

Guidelines and Limitations for Access Control Policies

Following are some additional limitations for access control. Please consider them when evaluating whether you are getting the expected results from your rules.

- Firepower Device Manager can download information on up to 2000 users from the directory server. If your directory server includes more than 2000 user accounts, you will not see all possible names when selecting users in an access rule or when viewing user-based dashboard information. You can write rules on only those names that were downloaded.

  The 2000 limit also applies to the names associated with groups. If a group has more than 2000 members, only the 2000 names that were downloaded can be matched against the group membership.

- If a Vulnerability Database (VDB) update removes (deprecates) applications, you must make changes to any access control rules or application filters that use the application that was deleted. You cannot deploy changes until you fix these rules. In addition, you cannot install system software updates before fixing the issue. On the Application Filters object page, or the Application tab of the rule, these applications say “(Deprecated)” after the application name.

- If you edit a rule that is actively in use, the changes do not apply to established connections that are no longer being inspected by Snort. The new rule is used to match against future connections. In addition, if Snort is actively inspecting a connection, it can apply the changed matching or action criteria to an existing connection. If you need to ensure that your changes apply to all current connections, you can log into the device CLI and use the `clear conn` command to end established connections, on the assumption that the sources for the connections will then attempt to reestablish the connection and thus be matched appropriately against the new rule.

- It takes 3 to 5 packets for the system to identify the application or URL in a connection. Thus, the correct access control rule might not be matched immediately for a given connection. However, once the application/URL is known, the connection is handled based on the matching rule. For encrypted connections, this happens after the server certificate exchange in the SSL handshake.

- The system applies the default policy action to packets that do not have a payload in a connection where an application is identified.

- Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. For example, the system can more efficiently match traffic for all interfaces if you simply leave the security zone criteria blank, rather than if you create zones that contain all interfaces.
When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

- Due to memory limitations, some device models perform most URL filtering with a smaller, less granular, set of categories and reputations. For example, even if a parent URL's subsites have different URL categories and reputations, some devices may only store the parent URL's data. For web traffic handled by these devices, the system may perform cloud lookups to determine category and reputation for sites not in the local database. Lower-memory devices include the following ASA models: 5506-X, 5506H-X, 5506W-X, 5508-X, 5512-X, 5515-X, 5516-X, and 5525-X.

## Configuring the Access Control Policy

Use the access control policy to control access to network resources. The policy consists of a set of ordered rules, which are evaluated from top to bottom. The rule applied to traffic is the first one where all the traffic criteria are matched. If no rules match the traffic, the default action shown at the bottom of the page is applied.

To configure the access control policy, select **Policies > Access Control**.

The access control table lists all rules in order. For each rule:

- Click the > button next to the rule number in the left-most column to open the rule diagram. The diagram can help you visualize how the rule controls traffic. Click the button again to close the diagram.

- Most cells allow inline editing. For example, you can click the action to select a different one, or click a source network object to add or change the source criteria.

- To move a rule, hover over the rule until you get the move icon (ꡒ), then click, drag, and drop the rule to the new location. You can also move a rule by editing it and selecting the new location in the **Order** list. It is critical that you put the rules in the order that you want them processed. Specific rules should be near the top, especially for rules that define exceptions to more general rules.

- The right-most column contains the action buttons for a rule; mouse over the cell to see the buttons. You can edit (✎) or delete (🗑) a rule.

The following topics explain how to configure the policy.

## Configuring the Default Action

If a connection does not match a specific access rule, it is handled by the default action for the access control policy.

**Procedure**

1. **Step 1** Select **Policies > Access Control**.
2. **Step 2** Click anywhere in the **Default Action** field.
3. **Step 3** Select the action to apply to matching traffic.
   - **Trust**—Allow traffic without further inspection of any kind.
   - **Allow**—Allow the traffic subject to the intrusion policy.
**Configuring Access Control Rules**

Use access control rules to control access to network resources. Rules in the access control policy are evaluated from top to bottom. The rule applied to traffic is the first one where all the traffic criteria are matched.

**Procedure**

**Step 1** Select **Policies > Access Control**.

**Step 2** Do any of the following:

- To create a new rule, click the + button.
- To edit an existing rule, click the edit icon (Edit) for the rule.

To delete a rule you no longer need, click the delete icon (Trash) for the rule.

**Step 3** In **Order**, select where you want to insert the rule in the ordered list of rules.

Rules are applied on a first-match basis, so you must ensure that rules with highly specific traffic matching criteria appear above policies that have more general criteria that would otherwise apply to the matching traffic.

The default is to add the rule to the end of the list. If you want to change a rule's location later, edit this option.

**Step 4** In **Title**, enter a name for the rule.

The name cannot contain spaces. You can use alphanumeric characters and these special characters: +._-.

**Step 5** Select the action to apply to matching traffic.

- **Trust**—Allow traffic without further inspection of any kind.
- **Allow**—Allow the traffic subject to the intrusion and other inspection settings in the policy.
- **Block**—Drop the traffic unconditionally. The traffic is not inspected.

**Step 6** Define the traffic matching criteria using any combination of the following tabs:

- **Source/Destination**—The security zones (interfaces) through which the traffic passes, the IP addresses or the country or continent (geographical location) for the IP address, or the protocols and ports used in the traffic. The default is any zone, address, geographical location, protocol, and port. See **Source/Destination Criteria**, on page 212.
**Application**—The application, or a filter that defines applications by type, category, tag, risk, or business relevance. The default is any application. See Application Criteria, on page 214.

**URL**—The URL or URL category of a web request. The default is any URL. See URL Criteria, on page 215.

**Users**—The user or user group. Your identity policies determine whether user and group information is available for traffic matching. You must configure identity policies to use this criteria. See User Criteria, on page 216.

To modify a condition, you click the + button within that condition, select the desired object or element, and click OK in the popup dialog box. If the criterion requires an object, you can click Create New Object if the object you require does not exist. Click the x for an object or element to remove it from the policy.

When adding conditions to access control rules, consider the following tips:

- You can configure multiple conditions per rule. Traffic must match all the conditions in the rule for the rule to apply to traffic. For example, you can use a single rule to perform URL filtering for specific hosts or networks.

- For each condition in a rule, you can add up to 50 criteria. Traffic that matches any of a condition's criteria satisfies the condition. For example, you can use a single rule to apply application control for up to 50 applications or application filters. Thus, there is an OR relationship among the items in a single condition, but an AND relationship between condition types (for example, between source/destination and application).

- Some features require that you enable the appropriate license.

**Step 7** (Optional.) For policies that use the Allow action, you can configure further inspection on unencrypted traffic. Click one of the following links:

- **Intrusion Policy**—Select Intrusion Policy > On and select the intrusion inspection policy to inspect traffic for intrusions and exploits. See Intrusion Policy Settings, on page 217.

- **File Policy**—Select the file policy to inspect traffic for files that contain malware and for files that should be blocked. See File Policy Settings, on page 218.

**Step 8** (Optional.) Configure logging for the rule.

By default, connection events are not generated for traffic that matches a rule, although file events are generated by default if you select a file policy. You can change this behavior. You must enable logging for traffic that matches the policy to be included in dashboard data or Event Viewer. See Logging Settings, on page 219.

Intrusion events are always generated for intrusion rules set to drop or alert regardless of the logging configuration on the matching access rule.

**Step 9** Click OK.

### Source/Destination Criteria

The Source/Destination criteria of an access rule define the security zones (interfaces) through which the traffic passes, the IP addresses or the country or continent (geographical location) for the IP address, or the protocols and ports used in the traffic. The default is any zone, address, geographical location, protocol, and port.
To modify a condition, you click the + button within that condition, select the desired object or element, and click OK. If the criterion requires an object, you can click Create New Object if the object you require does not exist. Click the x for an object or element to remove it from the policy.

You can use the following criteria to identify the source and destination to match in the rule.

**Source Zones, Destination Zones**

The security zone objects that define the interfaces through which the traffic passes. You can define one, both, or neither criteria: any criteria not specified applies to traffic on any interface.

- To match traffic leaving the device from an interface in the zone, add that zone to the Destination Zones.
- To match traffic entering the device from an interface in the zone, add that zone to the Source Zones.
- If you add both source and destination zone conditions to a rule, matching traffic must originate from one of the specified source zones and egress through one of the destination zones.

Use this criteria when the rule should apply based on where the traffic enters or exits the device. For example, if you want to ensure that all traffic going to inside hosts gets intrusion inspection, you would select your inside zone as the Destination Zones while leaving the source zone empty. To implement intrusion filtering in the rule, the rule action must be Allow, and you must select an intrusion policy in the rule.

**Source Networks, Destination Networks**

The network objects or geographical locations that define the network addresses or locations of the traffic.

- To match traffic from an IP address or geographical location, configure the Source Networks.
- To match traffic to an IP address or geographical location, configure the Destination Networks.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

When you add this criteria, you select from the following tabs:

- **Network**—Select the network objects or groups that define the source or destination IP addresses for the traffic you want to control.

- **Geolocation**—Select the geographical location to control traffic based on its source or destination country or continent. Selecting a continent selects all countries within the continent. Besides selecting geographical location directly in the rule, you can also select a geolocation object that you created to define the location. Using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

---

**Note**

To ensure that you are using up-to-date geographical location data to filter your traffic, Cisco strongly recommends that you regularly update the geolocation database (GeoDB).
**Source Ports, Destination Ports/Protocols**

The port objects that define the protocols used in the traffic. For TCP/UDP, this can include ports. For ICMP, it can include codes and types.

- To match traffic from a protocol or port, configure the **Source Ports**. Source ports can be TCP/UDP only.

- To match traffic to a protocol or port, configure the **Destination Ports/Protocols**. If you add only destination ports to a condition, you can add ports that use different transport protocols. ICMP and other non-TCP/UDP specifications are allowed in destination ports only; they are not allowed in source ports.

- To match traffic both originating from specific TCP/UDP ports and destined for specific TCP/UDP ports, configure both. If you add both source and destination ports to a condition, you can only add ports that share a single transport protocol, TCP or UDP. For example, you could target traffic from port TCP/80 to port TCP/8080.

**Application Criteria**

The **Application criteria** of an access rule defines the application used in an IP connection, or a filter that defines applications by type, category, tag, risk, or business relevance. The default is any application.

Although you can specify individual applications in the rule, application filters simplify policy creation and administration. For example, you could create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is blocked.

In addition, Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule blocking high risk applications can automatically apply to new applications without you having to update the rule manually.

You can specify applications and filters directly in the rule, or create application filter objects that define those characteristics. The specifications are equivalent, although using objects can make it easier to stay within the 50-items-per-criteria system limit if you are creating a complex rule.

To modify the application and filters list, you click the + button within the condition, select the desired applications or application filter objects, which are listed on separate tabs, and click OK in the popup dialog box. On either tab, you can click **Advanced Filter** to select filter criteria or to help you search for specific applications. Click the x for an application, filter, or object to remove it from the policy. Click the **Save As Filter** link to save the combined criteria that is not already an object as a new application filter object.

---

**Note**

If a selected application was removed by a VDB update, “(Deprecated)” appears after the application name. You must remove these applications from the filter, or subsequent deployments and system software upgrades will be blocked.

You can use the following **Advanced Filter** criteria to identify the application or filter to match in the rule. These are the same elements used in application filter objects.
Multiple selections within a single filter criteria have an OR relationship. For example, Risk is High OR Very High. The relationship between filters is AND, so Risk is High OR Very High, AND Business Relevance is Low OR Very Low. As you select filters, the list of applications in the display updates to show only those that meet the criteria. You can use these filters to help you find applications that you want to add individually, or to verify that you are selecting the desired filters to add to the rule.

**Risks**

The likelihood that the application is used for purposes that might be against your organization's security policy, from very low to very high.

**Business Relevance**

The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally, from very low to very high.

**Types**

The type of application:

- **Application Protocol**—Application protocols such as HTTP and SSH, which represent communications between hosts.

- **Client Protocol**—Clients such as web browsers and email clients, which represent software running on the host.

- **Web Application**—Web applications such as MPEG video and Facebook, which represent the content or requested URL for HTTP traffic.

**Categories**

A general classification for the application that describes its most essential function.

**Tags**

Additional information about the application, similar to category.

For encrypted traffic, the system can identify and filter traffic using only the applications tagged **SSL Protocol**. Applications without this tag can only be detected in unencrypted or decrypted traffic. Also, the system assigns the **decrypted traffic** tag to applications that the system can detect in decrypted traffic only, not encrypted or unencrypted.

**Applications List (bottom of the display)**

This list updates as you select filters from the options above the list, so you can see the applications that currently match the filter. Use this list to verify that your filter is targeting the desired applications when you intend to add filter criteria to the rule. If your intention is to add specific applications, select them from this list.

**URL Criteria**

The URL criteria of an access rule defines the URL used in a web request, or the category to which the requested URL belongs. For category matches, you can also specify the relative reputation of sites to allow or block. The default is to allow all URLs.
URL categories and reputations allow you to quickly create URL conditions for access control rules. For example, you could block all Gambling sites, or high risk Social Networking sites. If a user attempts to browse to any URL with that category and reputation combination, the session is blocked.

Using category and reputation data also simplifies policy creation and administration. It grants you assurance that the system will control web traffic as expected. Finally, because Cisco's threat intelligence is continually updated with new URLs, as well as new categories and risks for existing URLs, you can ensure that the system uses up-to-date information to filter requested URLs. Malicious sites that represent security threats such as malware, spam, botnets, and phishing may appear and disappear faster than you can update and deploy new policies.

To modify the URL list, you click the + button within the condition and select the desired categories or URLs using one of the following techniques. Click the x for a category or object to remove it from the policy.

**URL Tab**

Click +, select URL objects or groups, and click OK. You can click Create New URL if the object you require does not exist.

**Note**

Before configuring URL objects to target specific sites, carefully read the information on manual URL filtering.

**Categories Tab**

Click +, select the desired categories, and click OK.

The default is to apply the rule to all URLs in each selected category regardless of reputation. To limit the rule based on reputation, click the down arrow for each category, deselect the Any checkbox, and then use the Reputation slider to choose the reputation level. The left of the reputation slider indicates sites that will be allowed, the right side are sites that will be blocked. How reputation is used depends on the rule action:

- If the rule blocks or monitors web access, selecting a reputation level also selects all reputations more severe than that level. For example, if you configure a rule to block or monitor Suspicious sites (level 2), it also automatically blocks or monitors High risk (level 1) sites.

- If the rule allows web access, selecting a reputation level also selects all reputations less severe than that level. For example, if you configure a rule to allow Benign sites (level 4), it also automatically allows Well known (level 5) sites.

**User Criteria**

The User criteria of an access rule defines the user or user group for an IP connection. You must configure identity policies and the associated directory server to include user or user group criteria in an access rule.

Your identity policies determine whether user identity is collected for a particular connection. If identity is established, the IP address of the host is associated with the identified user. Thus, traffic whose source IP address is mapped to a user is considered to be from that user. IP packets themselves do not include user identity information, so this IP-address-to-user mapping is the best approximation available.

Because you can add a maximum of 50 users or groups to a rule, selecting groups usually makes more sense than selecting individual users. For example, you could create a rule allowing the Engineering group access to a development network, and create a subsequent rule that denies all other access to the network. Then, to...
make the rule apply to new engineers, you only need to add the engineer to the Engineering group in the directory server.

To modify the users list, you click the + button within the condition and select the desired identities using one of the following techniques. Click the x for an identity to remove it from the policy.

- **Users and Groups** tab—Select the desired users or user groups. Groups are available only if you configure groups in the directory server. If you select a group, the rule applies to any member of the group, including subgroups. If you want to treat a sub-group differently, you need to create a separate access rule for the sub-group and place it above the rule for the parent group in the access control policy.

- **Special Entities** tab—Select from the following:
  - **Failed Authentication**—The user was prompted to authenticate, but failed to enter a valid username/password pair within the maximum number of allowed attempts. Failure to authenticate does not itself prevent the user from accessing the network, but you can write an access rule to limit network access for these users.
  - **Guest**—Guest users are like Failed Authentication users, except that your identity rule is configured to call these users Guest. Guest users were prompted to authenticate and failed to do so within the maximum number of attempts.
  - **No Authentication Required**—The user was not prompted to authentication, because the user's connections matched identity rules that specified no authentication.
  - **Unknown**—There is no user mapping for the IP address, and there is no record of failed authentication yet. Typically, this means that no HTTP traffic has yet been seen from that address.

### Intrusion Policy Settings

Cisco delivers several intrusion policies with the Firepower System. These policies are designed by the Cisco Talos Intelligence Group (Talos), who set the intrusion and preprocessor rule states and advanced settings. You cannot modify these policies. However, you can change the action to take for a given rule, as described in Changing Intrusion Rule Actions, on page 231.

For access control rules that allow traffic, you can select one of the following intrusion policies to inspect traffic for intrusions and exploits. An intrusion policy examines decoded packets for attacks based on patterns, and can block or alter malicious traffic.

To enable intrusion inspection, select **Intrusion Policy > On** and select the desired policy. The policies are listed from least to most secure.

- **Connectivity over Security**—This policy is built for organizations where connectivity (being able to get to all resources) takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled. Select this policy if you want to apply some intrusion protection but you are fairly confident in the security of your network.

- **Balanced Security and Connectivity**—This policy is designed to balance overall network performance with network infrastructure security. This policy is appropriate for most networks. Select this policy for most situations where you want to apply intrusion prevention.

- **Security over Connectivity**—This policy is built for organizations where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic. Select this policy when security is paramount or for traffic that is high risk.
• **Maximum Detection**—This policy is built for organizations where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policy, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known in-the-wild exploits. If you select this policy, carefully evaluate whether too much legitimate traffic is being dropped.

**File Policy Settings**

Use file policies to detect malicious software, or **malware**, using Advanced Malware Protection for Firepower (AMP for Firepower). You can also use file policies to perform file control, which allows control over all files of a specific type regardless of whether the files contain malware.

AMP for Firepower uses the AMP cloud to retrieve dispositions for possible malware detected in network traffic, and to obtain local malware analysis and file pre-classification updates. The management interface must have a path to the Internet to reach the AMP cloud and perform malware lookups. When the device detects an eligible file, it uses the file's SHA-256 hash value to query the AMP cloud for the file's disposition. The possible dispositions are:

- **Malware**—The AMP cloud categorized the file as malware. An archive file (e.g. a zip file) is marked as malware if any file within it is malware.
- **Clean**—The AMP cloud categorized the file as clean, containing no malware. An archive file is marked as clean if all files within it are clean.
- **Unknown**—The AMP cloud has not assigned a disposition to the file yet. An archive file is marked as unknown if any file within it is unknown.
- **Unavailable**—The system could not query the AMP cloud to determine the file's disposition. You may see a small percentage of events with this disposition; this is expected behavior. If you see a number of "unavailable" events in succession, ensure that the Internet connection for the management address is functioning correctly.

**Available File Policies**

You can select one of the following file policies:

- **None**—Do not evaluate transmitted files for malware and do no file-specific blocking. Select this option for rules where file transmissions are trusted or where they are unlikely (or impossible), or for rules where you are confident your application or URL filtering adequately protects your network.
- **Block Malware All**—Query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.
- **Cloud Lookup All**—Query the AMP cloud to obtain and log the disposition of files traversing your network while still allowing their transmission.
- **Block Office Document and PDF Upload, Block Malware Others**—Block users from uploading Microsoft Office documents and PDFs. Additionally, query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.
- **Block Office Documents Upload, Block Malware Others**—Block users from uploading Microsoft Office documents. Additionally, query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.
Logging Settings

The logging settings for an access rule determine whether connection events are issued for traffic that matches the rule. You must enable logging to see events related to the rule in the Event Viewer. You must also enable logging for matching traffic to be reflected in the various dashboards you can use to monitor the system.

You should log connections according to the security and compliance needs of your organization. If your goal is to limit the number of events you generate and improve performance, only enable logging for the connections critical to your analysis. However, if you want a broad view of your network traffic for profiling purposes, you can enable logging for additional connections.

---

**Caution**

Logging blocked TCP connections during a Denial of Service (DoS) attack can affect system performance and overwhelm the database with multiple similar events. Before you enable logging for a Block rule, consider whether the rule is for an Internet-facing interface or other interface vulnerable to DoS attack.

---

You can configure the following logging actions.

**Select Log Action**

You can select one of the following actions:

- **Log at Beginning and End of Connection**—Issue events at the start and end of a connection. Because end-of-connection events contain everything that start-of-connection events contain, plus all of the information that could be gleaned during the connection, Cisco recommends that you do not select this option for traffic that you are allowing. Logging both events can impact system performance. However, this is the only option allowed for blocked traffic.

- **Log at End of Connection**—Select this option if you want to enable connection logging at the end of the connection, which is recommended for allowed or trusted traffic.

- **No Logging at Connection**—Select this option to disable logging for the rule. This is the default.

---

**Note**

When an intrusion policy invoked by an access control rule detects an intrusion and generates an intrusion event, the system automatically logs the end of the connection where the intrusion occurred, regardless of the logging configuration of the rule. For connections where an intrusion was blocked, the action for the connection in the connection log is **Block**, with a reason of **Intrusion Block**, even though to perform intrusion inspection you must use an Allow rule.

---

**File Events**

Select **Log Files** if you want to enable logging of prohibited files or malware events. You must select a file policy in the rule to configure this option. The option is enabled by default if you select a file policy for the rule. Cisco recommends you leave this option enabled.

When the system detects a prohibited file, it automatically logs one of the following types of event:

- **File events**, which represent detected or blocked files, including malware files.

- **Malware events**, which represent detected or blocked malware files only.

- **Retrospective malware events**, which are generated when the malware disposition for a previously detected file changes.
For connections where a file was blocked, the action for the connection in the connection log is **Block**
even though to perform file and malware inspection you must use an Allow rule. The connection's Reason
is either **File Monitor** (a file type or malware was detected), or **Malware Block** or **File Block** (a file
was blocked).

**Send Connection Events To**

If you want to send a copy of the events to an external syslog server, select the server object that defines
the syslog server. If the required object does not already exist, click **Create New Syslog Server** and
create it. (To disable logging to a syslog server, select **Any** from the server list.)

Because event storage on the device is limited, sending events to an external syslog server can provide
more long term storage and enhance your event analysis.

**Monitoring Access Control Policies**

The following topics explain how you can monitor the access control policy.

**Monitoring Access Control Statistics in the Dashboards**

Most of the data on the **Monitoring** dashboards are directly related to your access control policy. See **Monitoring
Traffic and System Dashboards,** on page 90.

- **Monitoring > Access And SI Rules** shows the most-hit access rules and Security Intelligence
  rule-equivalents and related statistics.

- You can find general statistics on the **Network Overview**, **Destinations**, and **Zones**, dashboards.

- You can find URL filtering results on the **URL Categories** and **Destinations** dashboards. You must
  have at least one URL filtering policy to see any information on the **URL Categories** dashboard.

- You can find application filtering results on the **Applications** and **Web Applications** dashboards.

- You can find user-based statistics on the **Users** dashboard. You must implement identity policies to
  collect user information.

- You can find intrusion policy statistics on the **Attackers** and **Targets** dashboards. You must apply an
  intrusion policy to at least one access control rule to see any information on these dashboards.

- You can find file policy and malware filtering statistics on the **File Logs** and **Malware** dashboards. You
  must apply a file policy to at least one access control rule to see any information on these dashboards.

- **Monitoring > Events** also shows events for connections and data related to the access control rules.

**Monitoring Access Control Policies in the CLI**

You can also open the CLI console or log into the device CLI and use the following commands to get more
detailed information about access control policies and statistics.

- **show access-control-config** displays summary information about the access control rules along with
  per-rule hit counts.

- **show access-list** displays the access control lists (ACLs) that were generated from the access control
  rules. The ACLs provide an initial filter and attempt to provide quick decisions whenever possible, so
that connections that should be dropped do not need to be inspected (and thus consume resources unnecessarily). This information includes hit counts.

- **show snort statistics** displays information about the Snort inspection engine, which is the main inspector. Snort implements application filtering, URL filtering, intrusion protection, and file and malware filtering.

- **show conn** displays information about the connections currently established through the interfaces.

- **show traffic** displays statistics about traffic flowing through each interface.

- **show ipv6 traffic** displays statistics about IPv6 traffic flowing through the device.

### Examples for Access Control

The use case chapter includes several examples of implementing access control rules. Please see the following examples:

- **How to Gain Insight Into Your Network Traffic**, on page 48. This example shows some basic ideas for collecting overall connection and user information.

- **How to Block Threats**, on page 55. This example shows how to apply intrusion policies.

- **How to Block Malware**, on page 61. This example shows how to apply file policies.

- **How to Implement an Acceptable Use Policy (URL Filtering)**, on page 63. This example shows how to perform URL filtering.

- **How to Control Application Usage**, on page 68. This example shows how to perform application filtering.

- **How to Add a Subnet**, on page 72. This example shows how to integrate a new subnet into your overall network, including the access rules needed to allow traffic flow.
CHAPTER 13

Intrusion Policies

The following topics explain intrusion policies and the closely associated network analysis policies (NAP). Intrusion policies include rules that check traffic for threats and block traffic that appears to be an attack. Network analysis policies control traffic preprocessing, which prepares traffic to be further inspected by normalizing traffic and identifying protocol anomalies.

Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet must complement each other.

- About Intrusion and Network Analysis Policies, on page 223
- License Requirements for Intrusion Policies, on page 230
- Managing Intrusion Policies, on page 230
- Monitoring Intrusion Policies, on page 233
- Examples for Intrusion Policies, on page 233

About Intrusion and Network Analysis Policies

Network analysis and intrusion policies work together to detect and prevent intrusion threats.

- A network analysis policy (NAP) governs how traffic is decoded and preprocessed so that it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.

- An intrusion policy uses intrusion and preprocessor rules, which are collectively known as intrusion rules, to examine the decoded packets for attacks based on patterns. The rules can either prevent (drop) the threatening traffic and generate an event, or simply detect (alert) it and generate an event only.

As the system analyzes traffic, the network analysis decoding and preprocessing phase occurs before and separately from the intrusion prevention phase. Together, network analysis and intrusion policies provide broad and deep packet inspection. They can help you detect, alert on, and protect against network traffic that could threaten the availability, integrity, and confidentiality of hosts and their data.

System-Defined Network Analysis and Intrusion Policies

The system includes several pairs of same-named network analysis and intrusion policies that complement and work with each other. For example there are both NAP and intrusion policies named “Balanced Security and Connectivity,” which are meant to be used together. The system-provided policies are configured by the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets the intrusion and preprocessor rule states and provides the initial configurations for preprocessors and other advanced settings.
As new vulnerabilities become known, Talos releases intrusion rule updates. These rule updates can modify any system-provided network analysis or intrusion policy, and can provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default policy settings. Rule updates might also delete rules from system-provided policies and provide new rule categories, as well as modify the default variable set.

You can manually update the rules database, or configure a regular update schedule. You must deploy an update for it to take effect. For more information on updating system databases, see Updating System Databases, on page 404.

The following are the system-provided policies:

**Balanced Security and Connectivity network analysis and intrusion policies**

These policies are built for both speed and detection. Used together, they serve as a good starting point for most networks and deployment types. The system uses the Balanced Security and Connectivity network analysis policy as the default.

**Connectivity Over Security network analysis and intrusion policies**

These policies are built for networks where connectivity, the ability to get to all resources, takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled.

**Security Over Connectivity network analysis and intrusion policies**

These policies are built for networks where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic.

**Maximum Detection network analysis and intrusion policies**

These policies are built for networks where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policies, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known-in-the-wild exploits.

### Intrusion and Preprocessor Rules

An intrusion rule is a specified set of keywords and arguments that the system uses to detect attempts to exploit vulnerabilities in your network. As the system analyzes network traffic, it compares packets against the conditions specified in each rule, and triggers the rule if the data packet meets all the conditions specified in the rule.

The system includes the following types of rules created by Cisco Talos Intelligence Group (Talos):

- Intrusion rules, which are subdivided into shared object rules and standard text rules
- Preprocessor rules, which are rules associated with preprocessors and packet decoder detection options in the network analysis policy. Most preprocessor rules are disabled by default.

The following topics explain intrusion rules in more depth.

### Intrusion Rule Attributes

When you select Policies > Intrusion, you see a list of all the intrusion rules available for identifying threats. Above the table, you can click the name of the intrusion policy to see the rules for each policy.
The list of rules for each policy show only those rules set to alert or drop, and those rules you explicitly disabled. Rules that are disabled by default are not shown. Although there are over 30,000 rules, you will see only a subset of all possible rules. But even for the smallest enabled rule set, scrolling through the list will take time. Rules are revealed as you scroll.

Following are the attributes that define each rule:

> **Signature Description**

Click the > button in the left column to open the signature description. The description is the actual code used by the Snort inspection engine to match traffic against the rule. Explaining the code is out of scope for this document, but it is explained in detail in *Firepower Management Center Configuration Guide*; select the book for your software version from [http://www.cisco.com/c/en/us/support/security/defense-center/products-installation-and-configuration-guides-list.html](http://www.cisco.com/c/en/us/support/security/defense-center/products-installation-and-configuration-guides-list.html). Look for information on intrusion rule editing.

The signatures contain variables for certain items. For more information, see *Default Intrusion Variable Set, on page 226*.

**GID**

Generator Identifier (ID). This number indicates which system component evaluates the rule and generates events. A 1 indicates a standard text intrusion rule, a 3 indicates a shared object intrusion rule. (The difference in these rule types is not meaningful for a Firepower Device Manager user.) These are the main rules of interest when configuring an intrusion policy. For information on the other GIDs, see *Generator Identifiers, on page 227*.

**SID**

Snort Identifier (ID), also called signature ID. Snort IDs lower than 1000000 were created by the Cisco Talos Intelligence Group (Talos).

**Action**

The state of this rule in the selected intrusion policy. For each rule, “(Default)” is added to the action that is the default action for the rule within this policy. To return a rule to its default setting, you select this action. Possible actions are:

- **Alert**—Create an event when this rule matches traffic, but do not drop the connection.
- **Drop**—Create an event when this rule matches traffic, and also drop the connection.
- **Disabled**—Do not match traffic against this rule. No events are generated.

**Status**

If you change the default action for a rule, this column shows “Overridden.” Otherwise, the column is empty.

**Message**

This is the name of the rule, which also appears in events triggered by the rule. The message typically identifies the threat that the signature matches. You can search the Internet for more information on each threat.
Default Intrusion Variable Set

The intrusion rule signatures contain variables for certain items. Following are the default values for the variables, with $HOME_NET and $EXTERNAL_NET being the most commonly used variables. Note that the protocol is specified separately from port numbers, so port variables are numbers only.

- $AIM_SERVERS = 20 addresses of networks or hosts: 64.12.24.0/23, 64.12.28.0/23, 64.12.31.136, 64.12.46.140, 64.12.161.0/24, 64.12.163.0/24, 64.12.186.85, 64.12.200.0/24, 205.188.1.132, 205.188.3.0/24, 205.188.5.0/24, 205.188.7.0/24, 205.188.9.0/24, 205.188.11.228, 205.188.11.253, 205.188.11.254, 205.188.153.0/24, 205.188.179.0/24, 205.188.210.203, 205.188.248.0/24.
- $DNS_SERVERS = $HOME_NET (meaning any IP address).
- $EXTERNAL_NET = any IP address.
- $FILE_DATA_PORTS = $HTTP_PORTS, 143, 110.
- $FTP_PORTS = 21, 2100, 3535.
- $GTP_PORTS = 3386, 2123, 2152.
- $HOME_NET = any IP address.
- $HTTP_PORTS = 144 ports numbered: 36, 80-90, 311, 383, 443, 555, 591, 631, 666, 801, 808, 818, 901, 972, 1158, 1212, 1220, 1414, 1422, 1533, 1741, 1830, 1942, 2231, 2301, 2381, 2578, 2809, 2980, 3029, 3037, 3057, 3128, 3443, 3507, 3702, 4000, 4343, 4848, 5000, 5117, 5222, 5250, 5450, 5600, 5814, 6080, 6173, 6767, 6988, 7000, 7001, 7005, 7071, 7080, 7144, 7145, 7510, 7770, 7777-7779, 8000, 8001, 8008, 8014, 8015, 8020, 8028, 8040, 8060, 8080-8082, 8085, 8088, 8118, 8123, 8161, 8180-8182, 8222, 8243, 8280, 8300, 8333, 8344, 8400, 8443, 8500, 8509, 8787, 8800, 8888, 8899, 8983, 9000, 9002, 9060, 9080, 9090, 9091, 9111, 9290, 9443, 9447, 9710, 9788, 9999, 10000, 11371, 12601, 13014, 15489, 19980, 23472, 29991, 33300, 34412, 34443, 34444, 40007, 41080, 44449, 50000, 50002, 51423, 53331, 55252, 55555, 56712.
- $SHTTP_SERVERS = $HOME_NET (meaning any IP address).
- $ORACLE_PORTS = any
- $SHELLCODE_PORTS = 180.
- $SIP_PORTS = 5060, 5061, 5600
- $SIP_SERVERS = $HOME_NET (meaning any IP address).
- $SMTP_SERVERS = $HOME_NET (meaning any IP address).
- $SNMP_SERVERS = $HOME_NET (meaning any IP address).
- $SSH_PORTS = 22.
- $SSH_SERVERS = $HOME_NET (meaning any IP address).
- $TELNET_SERVERS = $HOME_NET (meaning any IP address).
Generator Identifiers

The generator identifier (GID) identifies the subsystem that evaluates an intrusion rule and generates events. Standard text intrusion rules have a generator ID of 1, and shared object intrusion rules have a generator ID of 3. There are also several sets of rules for various preprocessors. The following table explains the GIDs.

**Table 6: Generator IDs**

<table>
<thead>
<tr>
<th>ID</th>
<th>Component</th>
</tr>

**Network Analysis Policies**

Network analysis policies control traffic preprocessing. Preprocessors prepare traffic to be further inspected by normalizing traffic and identifying protocol anomalies. Network analysis-related preprocessing occurs after Security Intelligence blacklisting and SSL decryption, but before access control and intrusion or file inspection.

By default, the system uses the Balanced Security and Connectivity network analysis policy to preprocess all traffic handled by the access control policy. However, the system applies different network analysis policies based on which intrusion policies you select in the access control rules.

The system attempts to match the intrusion and network analysis policies, so that you receive optimal processing. However, network analysis policy (NAP) rules do not have the same traffic matching criteria that are available in access control rules, so you can get mismatched policies if you do not follow the recommended guidelines.

**How the System Selects Network Analysis Policies using NAP Rules**

You cannot directly assign network analysis policies. Instead, the system automatically generates NAP rules based on the intrusion policies you assign in access control rules.

NAP rules are based on security zone and network specifications only. Thus, for each access control rule that includes an intrusion policy, the system creates a NAP rule that applies the same-named network analysis policy to the same source/destination security zone and network. Ports, URLs, users, and application criteria are ignored.

This is a critical difference: although you can apply different intrusion policies based on layer 4 or 7 criteria, such as ports, applications, or URLs, those higher layer conditions have no impact on network analysis policy selection.

The system orders NAP rules in the same order as the access control rules. The system uses the first matching NAP rule to determine the network analysis policy to apply.
Thus, if you have multiple access control rules that allow traffic for the same source/destination zone and network object combination, but that differ in other traffic matching criteria, the system generates multiple NAP rules that overlap, and the second and subsequent duplicate rules will never be matched to traffic. If you apply different intrusion policies to these “overlapping” rules, at least some of the traffic will get mismatched intrusion and network analysis policies.

For example, consider the following rules:

1. Access rule 1
   - Action: Allow
   - Source zone: inside_zone
   - Source network: any
   - Destination zone: outside_zone
   - Destination network: any
   - URL category: Social Network
   - Intrusion policy: Security over Connectivity

2. Access rule 2
   - Action: Allow
   - Source zone: inside_zone
   - Source network: any
   - Destination zone: outside_zone
   - Destination network: any
   - Intrusion policy: Balanced Security and Connectivity

In this case, there will be two NAP rules:

1. NAP Rule 1
   - Source zone: inside_zone
   - Source network: any
   - Destination zone: outside_zone
   - Destination network: any
   - Network analysis policy: Security over Connectivity

2. NAP Rule 2
   - Source zone: inside_zone
   - Source network: any
   - Destination zone: outside_zone
   - Destination network: any
   - Network analysis policy: Balanced Security and Connectivity

Because both NAP rules have the same match criteria, the system will apply the Security over Connectivity network analysis policy to any traffic that matches either access control rule 1 or 2. However, most traffic will match access control rule 2, and use the Balanced intrusion policy. Thus, any traffic that matches access control rule 2 will get mismatched NAP and intrusion policies.
If you use a single intrusion policy in the access control policy, the system simply sets the same-named network analysis policy as the default policy and generates no NAP rules. Otherwise, the system sets the Balanced policy as the default network analysis policy. The default policy applies when no other NAP rule applies, which would typically be for zone and network combinations for which you have assigned no intrusion policies.

Note

Best Practices for Applying Intrusion Policies to Optimize NAP Processing

Consider the following recommendations when deciding how to assign intrusion policies to ensure that you get the matching network analysis policy:

- If you always use the same intrusion policy, the same-named network analysis policy is set as the default, and you will always get matched intrusion and network analysis policies.

- If you decide you need to use different intrusion policies for certain traffic, always use the same intrusion policy for the same combination of source/destination security zone and network object. This will ensure that the NAP rules assign the same-named network analysis policy for all associated access control rules.

For example, if you decide you need to use the Security over Connectivity policy for some inside_zone to outside_zone traffic for network_one, assign the Security over Connectivity policy to each access control rule that has the same source/destination zone and network specification.

License Requirements for Intrusion Policies

You must enable the Threat license to apply intrusion policies in access control rules. For information on configuring licenses, see Enabling or Disabling Optional Licenses, on page 84.

No extra license is needed for network analysis policies.

Managing Intrusion Policies

With Firepower Device Manager, you can apply any of the pre-defined intrusion policies. Each of these policies includes the same list of intrusion rules (also known as signatures), but they differ in the actions taken for each rule. For example, a rule might be active in one policy, but disabled in another policy.

If you find that a particular rule is giving you too many false positives, where the rule is blocking traffic that you do not want blocked, you can disable the rule without needing to switch to a less-secure intrusion policy. You could alternatively change it to alert on matches without dropping traffic.

However, if a rule is disabled by default in the intrusion policy, you cannot change it to drop or alert on matching traffic. You can change the action only on enabled policies or on policies that you previously disabled.

Use the intrusion related dashboards, and the Event Viewer (both on the Monitoring page), to evaluate how intrusion rules are impacting traffic. Keep in mind that you will see intrusion events and intrusion data only for traffic that matches intrusion rules set to alert or drop; disabled rules are not evaluated.

The following topics explain intrusion policies and rule tuning in more detail.
Applying Intrusion Policies in Access Control Rules

To apply intrusion policies to network traffic, you select the policy within an access control rule that allows traffic. You do not directly assign intrusion policies.

You can assign different intrusion policies to provide variable intrusion protection based on the relative risks of the networks you are protecting. For example, you might use the more stringent Security over Connectivity policy for traffic between your inside network and external networks. On the other hand, you might apply the more lenient Connectivity over Security policy for traffic between inside networks.

You can also simplify your configuration by using the same policy for all networks. For example, the Balanced Security and Connectivity policy is designed to provide good protection without excessively impacting connectivity.

If you do decide to use different policies for different networks, you will get the best results if you apply the same policy in all rules that use the same source/destination security zone and network object match criteria. For more information, see Best Practices for Applying Intrusion Policies to Optimize NAP Processing, on page 230.

Procedure

**Step 1** Select **Policies > Access Control**.

**Step 2** Either create a new rule, or edit an existing rule, that allows traffic.

If the default action is allow, you can also specify an intrusion policy in the default action.

**Step 3** Click the **Intrusion Policy** tab.

**Step 4** Select **Intrusion Policy > On** and select the intrusion inspection policy to use on matching traffic.

Changing Intrusion Rule Actions

Each pre-defined intrusion policy has the same rules. The difference is the action taken for each rule can be different from policy to policy.

Within a given policy, you can change the default action for a rule only if it is enabled, that is, set to alert or drop. By changing the default action, you can disable rules that are giving you too many false positives, or you can change whether the rule alerts on or drops matching traffic.

**Note**

If you change an action from the default, the next time the intrusion rules database is updated, the system resets the rule default to the action you selected. At that point, your selection becomes the new default, and the status no longer shows the action as Overridden.

Procedure

**Step 1** Select **Policies > Intrusion**.

**Step 2** Click the tab for the intrusion policy whose rule actions you want to change.
The pre-defined policies are:

- Connectivity over Security
- Balanced Security and Connectivity
- Security over Connectivity
- Maximum Detection

**Step 3** Find the rule whose action you want to change.

The rules are sorted with the overridden ones listed first, and sorted by action within the group of overridden rules. Otherwise, the rules are sorted by GID, then SID.

The list of rules for each policy show only those rules set to alert or drop, and those rules you explicitly disabled. Rules that are disabled by default are not shown.

Use the search box to locate the rule you want to change. Ideally, you can get the Snort identifier (SID) and generator identifier (GID) from an event or from Cisco Technical Support, if you are working with them on an issue.

For detailed information about the elements of each rule, see Intrusion Rule Attributes, on page 224.

To search the list:

a) Click in the Search box to open the search attributes dialog box.

b) Enter a combination of Generator ID (GID), Snort ID (SID), or rule Action, and click Search.

For example, you could select **Action = Drop** to see all the rules in the policy that will drop matching connections. The text beside the search box indicates how many rules match your criteria, for example, “8937 of 9416 rules found.”

To clear a search criteria, click the x for the criteria in the search box.

**Step 4** Click the **Action** column for the rule and select the required action:

- **Alert**—Create an event when this rule matches traffic, but do not drop the connection.
- **Drop**—Create an event when this rule matches traffic, and also drop the connection.
- **Disabled**—Do not match traffic against this rule. No events are generated.

The default action for the rule is indicated by “(Default)” added to the action. If you change the default, the status column indicates “Overridden” for that rule.

---

**Configuring Syslog for Intrusion Events**

You can configure an external syslog server for intrusion policies to send intrusion events to your syslog server. You must configure the syslog server on the intrusion policy to get intrusion events sent to the server. Configuring a syslog server on an access rule sends connection events only to the syslog server, not intrusion events.
Procedure

Step 1  Select Policies > Intrusion.
Step 2  Click the Edit Logging Settings button ( ) to configure syslog.
Step 3  Click in the Send Connection Events To field and select the server object that defines the syslog server. If the required object does not already exist, click Create New Syslog Server and create it.
Step 4  Click OK.

Monitoring Intrusion Policies

You can find intrusion policy statistics on the Attackers and Targets dashboards on the Monitoring page. You must apply an intrusion policy to at least one access control rule to see any information on these dashboards. See Monitoring Traffic and System Dashboards, on page 90.

To see intrusion events, select Monitoring > Events, then click the Intrusion tab. You can hover over an event and click the View Details link to get more information. From the details page, you can click the View IPS Rule to go to the rule in the relevant intrusion policy, where you can change the rule action. This can help you reduce the impact of false positives, where a rule is blocking too many good connections, by changing the action from drop to alert. Conversely, you can change an alert rule into a drop rule if you are seeing a lot of attack traffic for a rule.

Examples for Intrusion Policies

The use case chapter includes the following examples of implementing intrusion policies.

- How to Block Threats, on page 55
Network Address Translation (NAT)

The following topics explain Network Address Translation (NAT) and how to configure it.

- Why Use NAT?, on page 235
- NAT Basics, on page 236
- Guidelines for NAT, on page 242
- Configure NAT, on page 246
- Translating IPv6 Networks, on page 272
- Monitoring NAT, on page 286
- Examples for NAT, on page 287

Why Use NAT?

Each computer and device within an IP network is assigned a unique IP address that identifies the host. Because of a shortage of public IPv4 addresses, most of these IP addresses are private, not routable anywhere outside of the private company network. RFC 1918 defines the private IP addresses you can use internally that should not be advertised:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into legal, routable addresses that can be used on the public Internet. In this way, NAT conserves public addresses because it can be configured to advertise at a minimum only one public address for the entire network to the outside world.

Other functions of NAT include:

- Security—Keeping internal IP addresses hidden discourages direct attacks.
- IP routing solutions—Overlapping IP addresses are not a problem when you use NAT.
- Flexibility—You can change internal IP addressing schemes without affecting the public addresses available externally; for example, for a server accessible to the Internet, you can maintain a fixed IP address for Internet use, but internally, you can change the server address.
• Translating between IPv4 and IPv6 (Routed mode only) — If you want to connect an IPv6 network to an IPv4 network, NAT lets you translate between the two types of addresses.

**Note**
NAT is not required. If you do not configure NAT for a given set of traffic, that traffic will not be translated, but will have all of the security policies applied as normal.

**NAT Basics**

The following topics explain some of the basics of NAT.

**NAT Terminology**

This document uses the following terminology:

- **Real address/host/network/interface** — The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the “real” network. Note that you can translate any network connected to the device, not just an inside network. Therefore if you configure NAT to translate outside addresses, “real” can refer to the outside network when it accesses the inside network.

- **Mapped address/host/network/interface** — The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the “mapped” network.

**Note**
During address translation, IP addresses configured for the device interfaces are not translated.

- **Bidirectional initiation** — Static NAT allows connections to be initiated bidirectionally, meaning both to the host and from the host.

- **Source and destination NAT** — For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address.

**NAT Types**

You can implement NAT using the following methods:

- **Dynamic NAT** — A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See Dynamic NAT, on page 247.

- **Dynamic Port Address Translation (PAT)** — A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See Dynamic PAT, on page 252.
• Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See Static NAT, on page 256.

• Identity NAT—A real address is statically translated to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See Identity NAT, on page 265.

### NAT in Routed Mode

The following figure shows a typical NAT example in routed mode, with a private network on the inside.

*Figure 7: NAT Example: Routed Mode*

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is translated to a mapped address, 209.165.201.10.

2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the Firepower Threat Defense device receives the packet because the Firepower Threat Defense device performs proxy ARP to claim the packet.

3. The Firepower Threat Defense device then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

### Auto NAT and Manual NAT

You can implement address translation in two ways: *auto NAT* and *manual NAT*.

We recommend using auto NAT unless you need the extra features that manual NAT provides. It is easier to configure auto NAT, and it might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, you might see a failure in the translation of indirect addresses that do not belong to either of the objects used in the rule.)
**Auto NAT**

All NAT rules that are configured as a parameter of a network object are considered to be *auto NAT* rules. This is a quick and easy way to configure NAT for a network object. You cannot create these rules for a group object, however.

Although these rules are configured as part of the object itself, you cannot see the NAT configuration in the object definition through the object manager.

When a packet enters an interface, both the source and destination IP addresses are checked against the auto NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use manual NAT for that kind of functionality, where you can identify the source and destination address in a single rule.

**Manual NAT**

Manual NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

---

**Note**

For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then you must specify the source ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

**Comparing Auto NAT and Manual NAT**

The main differences between these two NAT types are:

- **How you define the real address.**
  - Auto NAT—The NAT rule becomes a parameter for a network object. The network object IP address serves as the original (real) address.
  - Manual NAT—you identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that manual NAT is more scalable.

- **How source and destination NAT is implemented.**
  - Auto NAT—Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
• Manual NAT—A single rule translates both the source and destination. A packet matches one rule only, and further rules are not checked. Even if you do not configure the optional destination address, a matching packet still matches one manual NAT rule only. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.

• Order of NAT Rules.
  • Auto NAT—Automatically ordered in the NAT table.
  • Manual NAT—Manually ordered in the NAT table (before or after auto NAT rules).

**NAT Rule Order**

Auto NAT and manual NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3, until a match is found. For example, if a match is found in section 1, sections 2 and 3 are not evaluated. The following table shows the order of rules within each section.

*Table 7: NAT Rule Table*

<table>
<thead>
<tr>
<th>Table Section</th>
<th>Rule Type</th>
<th>Order of Rules within the Section</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section 1</td>
<td>Manual NAT</td>
<td>Applied on a first match basis, in the order they appear in the configuration. Because the first match is applied, you must ensure that specific rules come before more general rules, or the specific rules might not be applied as desired. By default, manual NAT rules are added to section 1.</td>
</tr>
<tr>
<td>Section 2</td>
<td>Auto NAT</td>
<td>If a match in section 1 is not found, section 2 rules are applied in the following order:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1. Static rules.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. Dynamic rules.</td>
</tr>
</tbody>
</table>

**Within each rule type, the following ordering guidelines are used:**

1. Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses.

2. For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0.

3. If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.
<table>
<thead>
<tr>
<th>Table Section</th>
<th>Rule Type</th>
<th>Order of Rules within the Section</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section 3</td>
<td>Manual NAT</td>
<td>If a match is still not found, section 3 rules are applied on a first match basis, in the order they appear in the configuration. This section should contain your most general rules. You must also ensure that any specific rules in this section come before general rules that would otherwise apply.</td>
</tr>
</tbody>
</table>

For section 2 rules, for example, you have the following IP addresses defined within network objects:

- 192.168.1.0/24 (static)
- 192.168.1.0/24 (dynamic)
- 10.1.1.0/24 (static)
- 192.168.1.1/32 (static)
- 172.16.1.0/24 (dynamic) (object def)
- 172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:

- 192.168.1.1/32 (static)
- 10.1.1.0/24 (static)
- 192.168.1.0/24 (static)
- 172.16.1.0/24 (dynamic) (object abc)
- 172.16.1.0/24 (dynamic) (object def)
- 192.168.1.0/24 (dynamic)

### NAT Interfaces

Except for bridge group member interfaces, you can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside.
However, the concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. This could result in many similar rules where only one interface is different. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

Configuring Routing for NAT

The FTD device needs to be the destination for any packets sent to the translated (mapped) address. When sending packets, the device uses the destination interface if you specify one, or a routing table lookup if you do not, to determine the egress interface. For identity NAT, you have the option to use a route lookup even if you specify a destination interface.

The type of routing configuration needed depends on the type of mapped address, as explained in the following topics.

Addresses on the Same Network as the Mapped Interface

If you use addresses on the same network as the destination (mapped) interface, the Firepower Threat Defense device uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the Firepower Threat Defense device does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

Addresses on a Unique Network

If you need more addresses than are available on the destination (mapped) interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the Firepower Threat Defense device.
The Same Address as the Real Address (Identity NAT)

The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.

Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for “any” IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches “any” address). The Firepower Threat Defense device will then proxy ARP for the address, even though the packet is not actually destined for the Firepower Threat Defense device. (Note that this problem occurs even if you have a manual NAT rule; although the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the “source” address). If the Firepower Threat Defense device ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the Firepower Threat Defense device.

Guidelines for NAT

The following topics provide detailed guidelines for implementing NAT.

Interface Guidelines

NAT is supported for standard routed physical or subinterfaces.

However, configuring NAT on bridge group member interfaces (interfaces that are part of a Bridge Virtual Interface, or BVI) has the following restrictions:

- When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself.
- When doing NAT between bridge group member interfaces, you must specify the source and destination interfaces. You cannot specify “any” as the interface.
- You cannot configure interface PAT when the destination interface is a bridge group member interface, because there is no IP address attached to the interface.
- You cannot translate between IPv4 and IPv6 networks (NAT64/46) when the source and destination interfaces are members of the same bridge group. Static NAT/PAT 44/66, dynamic NAT44/66, and dynamic PAT44 are the only allowed methods; dynamic PAT66 is not supported.

IPv6 NAT Guidelines

NAT supports IPv6 with the following guidelines and restrictions.

- For standard routed mode interfaces, you can also translate between IPv4 and IPv6.
- You cannot translate between IPv4 and IPv6 for interfaces that are members of the same bridge group. You can translate between two IPv6 or two IPv4 networks only. This restriction does not apply between a bridge group member and a standard routed interface.
IPv6 NAT Best Practices

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- **NAT66 (IPv6-to-IPv6)**—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only).

- **NAT46 (IPv4-to-IPv6)**—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address.

- **NAT64 (IPv6-to-IPv4)**—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

NAT Support for Inspected Protocols

Some application layer protocols that open secondary connections, or that embedded IP addresses in packets, are inspected to provide the following services:

- **Pinhole creation**—Some application protocols open secondary TCP or UDP connections either on standard or negotiated ports. Inspection opens pinholes for these secondary ports so that you do not need to create access control rules to allow them.

- **NAT rewrite**—Protocols such as FTP embed IP addresses and ports for the secondary connections in packet data as part of the protocol. If there is NAT translation involved for either of the endpoints, the inspection engines rewrite the packet data to reflect the NAT translation of the embedded addresses and ports. The secondary connections would not work without NAT rewrite.

- **Protocol enforcement**—Some inspections enforce some degree of conformance to the RFCs for the inspected protocol.

The following table lists the inspected protocols that apply NAT rewrite and their NAT limitations. Keep these limitations in mind when writing NAT rules that include these protocols. Inspected protocols not listed here do not apply NAT rewrite. These inspections include GTP, HTTP, IMAP, POP, SMTP, SSH, and SSL.
NAT rewrite is supported on the listed ports only. If you use these protocols on non-standard ports, do not use NAT on the connections.

## Additional Guidelines for NAT

- For interfaces that are members of a bridge group, you write NAT rules for the member interfaces. You cannot write NAT rules for the Bridge Virtual Interface (BVI) itself.

- (Auto NAT only.) You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address.

- If a VPN is defined on an interface, inbound ESP traffic on the interface is not subject to the NAT rules. The system allows the ESP traffic for established VPN tunnels only, dropping traffic not associated with an existing tunnel. This restriction applies to ESP and UDP ports 500 and 4500.

- If you define a site-to-site VPN on a device that is behind a device that is applying dynamic PAT, so that UDP ports 500 and 4500 are not the ones actually used, you must initiate the connection from the device that is behind the PAT device. The responder cannot initiate the security association (SA) because it does not know the correct port numbers.

- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the `clear xlate` command in the device CLI. However, clearing the translation table disconnects all current connections that use translations.

### Note

If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the `clear xlate` command. This safeguard ensures that the same address is not assigned to multiple hosts.

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.

- (Manual NAT only.) When using `any` as the source address in a NAT rule, the definition of “any” traffic (IPv4 vs. IPv6) depends on the rule. Before the Firepower Threat Defense device performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the Firepower Threat Defense device can determine the value of `any` in a NAT rule. For example, if you configure a rule from “any” to an IPv6 server, and that server was mapped from an IPv4 address, then `any` means “any IPv6 traffic.” If you configure a rule from “any” to “any,” and you map the source to the interface IPv4 address, then `any` means “any IPv4 traffic” because the mapped interface address implies that the destination is also IPv4.

- You can use the same mapped object or group in multiple NAT rules.
• The mapped IP address pool cannot include:
  • The mapped interface IP address. If you specify “any” interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), specify the interface name instead of the interface address.
  • The failover interface IP address.
  • (Dynamic NAT.) The standby interface IP address when VPN is enabled.

• Avoid using overlapping addresses in static and dynamic NAT policies. For example, with overlapping addresses, a PPTP connection can fail to get established if the secondary connection for PPTP hits the static instead of dynamic xlate.

• You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.

• If you specify a destination interface in a rule, then that interface is used as the egress interface rather than looking up the route in the routing table. However, for identity NAT, you have the option to use a route lookup instead.

• NAT applies to through traffic only. Traffic generated by the system is not subject to NAT.

Configure NAT

Network address translation can be very complex. We recommend that you keep your rules as simple as possible to avoid translation problems and difficult troubleshooting situations. Careful planning before you implement NAT is critical. The following procedure provides the basic approach.

Procedure

Step 1
Select Policies > NAT.

Step 2
Decide what kinds of rules you need.
You can create dynamic NAT, dynamic PAT, static NAT, and identity NAT rules. For an overview, see NAT Types, on page 236.

Step 3
Decide which rules should be implemented as manual or auto NAT.
For a comparison of these two implementation options, see Auto NAT and Manual NAT, on page 237.

Step 4
Create the rules as explained in the following sections.
  • Dynamic NAT, on page 247
  • Dynamic PAT, on page 252
  • Static NAT, on page 256
  • Identity NAT, on page 265

Step 5
Manage the NAT policy and rules.
You can do the following to manage the policy and its rules.

- To edit a rule, click the edit icon (📝) for the rule.
- To delete a rule, click the delete icon (🗑️) for the rule.

### Dynamic NAT

The following topics explain dynamic NAT and how to configure it.

#### About Dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, NAT assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

**Note**

For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

The following figure shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

*Figure 9: Dynamic NAT*

The following figure shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the packet is dropped.
Dynamic NAT Disadvantages and Advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

  Use PAT or a PAT fall-back method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.

- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

Configure Dynamic Auto NAT

Use dynamic auto NAT rules to translate addresses to different IP addresses that are routable on the destination network.

Before you begin

Select Objects and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- Original Address—This must be a network object (not a group), and it can be a host or subnet.
• **Translated Address**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

**Procedure**

**Step 1** Select **Policies > NAT**.

**Step 2** Do one of the following:

- To create a new rule, click the + button.
- To edit an existing rule, click the edit icon (ckeck) for the rule.

(To delete a rule you no longer need, click the trash can icon for the rule.)

**Step 3** Configure the basic rule options:

- **Title**—Enter a name for the rule.
- **Create Rule For**—Select **Auto NAT**.
- **Type**—Select **Dynamic**.

**Step 4** Configure the following packet translation options:

- **Source Interface, Destination Interface**—(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. **Source** is the real interface, the one through which the traffic enters the device. **Destination** is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.
- **Original Address**—The network object that contains the addresses you are translating.
- **Translated Address**—The network object or group that contains the mapped addresses.

**Step 5** (Optional.) Click the **Advanced Options** link and select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 307.
- **Fallthrough to Interface NAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group.

**Step 6** Click **OK**.

**Configure Dynamic Manual NAT**

Use dynamic manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic NAT translates addresses to different IP addresses that are routable on the destination network.
Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source Address**—This can be a network object or group, and it can contain a host or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.

- **Translated Source Address**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

You can also create network objects for the **Original Destination Address** and **Translated Destination Address** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

**Procedure**

**Step 1** Select **Policies > NAT**.

**Step 2** Do one of the following:

- To create a new rule, click the + button.

- To edit an existing rule, click the edit icon (охранник) for the rule.

(To delete a rule you no longer need, click the trash can icon for the rule.)

**Step 3** Configure the basic rule options:

- **Title**—Enter a name for the rule.

- **Create Rule For**—Select **Manual NAT**.

- **Rule Placement**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule you select.

- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.

**Step 4** Configure the following interface options:

- **Source Interface, Destination Interface**—(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. **Source** is the real interface, the one through which the traffic enters the device. **Destination** is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5** Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.
Configure Dynamic Manual NAT

Security Policies

• **Original Source Address**—The network object or group that contains the addresses you are translating.

• **Original Destination Address**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Interface** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6**

Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

• **Translated Source Address**—The network object or group that contains the mapped addresses.

• **Translated Destination Address**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination Address**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7** (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

**Step 8** (Optional.) Click the **Advanced Options** link and select the desired options:

• **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 307.

• **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group.
Step 9 Click OK.

Dynamic PAT

The following topics describe dynamic PAT.

About Dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port. If available, the real source port number is used for the mapped port. However, if the real port is not available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool that can be used.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

The following figure shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

*Figure 11: Dynamic PAT*

For the duration of the translation, a remote host on the destination network can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

After the connection expires, the port translation also expires.

*Note* We recommend that you use different PAT pools for each interface. If you use the same pool for multiple interfaces, especially if you use it for "any" interface, the pool can be quickly exhausted, with no ports available for new translations.

Dynamic PAT Disadvantages and Advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the Firepower Threat Defense device interface IP address as the PAT address. However, you cannot use interface PAT for the IPv6 addresses on the interface.

You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply between a bridge group member and a standard routed interface.
Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. For more information, see NAT Support for Inspected Protocols, on page 243.

Dynamic PAT might also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack.

Configure Dynamic Auto PAT

Use dynamic auto PAT rules to translate addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address, either the destination interface's address or another address.

Before you begin

Select Objects and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Address**—This must be a network object (not a group), and it can be a host or subnet.
- **Translated Address**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface IPv4 address, you do not need a network object. You cannot use interface PAT for IPv6.
  - **Single PAT address**—Create a network object containing a single host.

Procedure

**Step 1**
Select Policies > NAT.

**Step 2**
Do one of the following:

- To create a new rule, click the + button.
- To edit an existing rule, click the edit icon (📝) for the rule.

(To delete a rule you no longer need, click the trash can icon for the rule.)

**Step 3**
Configure the basic rule options:

- **Title**—Enter a name for the rule.
- **Create Rule For**—Select Auto NAT.
- **Type**—Select Dynamic.

**Step 4**
Configure the following packet translation options:

- **Source Interface, Destination Interface**—(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. Source is the real interface, the one through which the traffic enters the device. Destination is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.
- **Original Address**—The network object that contains the addresses you are translating.
- **Translated Address**—One of the following:
Configure Dynamic Manual PAT

Use dynamic manual PAT rules when auto PAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic PAT translates addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address, either the destination interface's address or another address.

Before you begin

Select Objects and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source Address**—This can be a network object or group, and it can contain a host or subnet. If you want to translate all original source traffic, you can skip this step and specify Any in the rule.

- **Translated Source Address**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface IPv4 address, you do not need a network object. You cannot use interface PAT for IPv6.
  - **Single PAT address**—Create a network object containing a single host.

You can also create network objects for the **Original Destination Address** and **Translated Destination Address** if you are configuring a static translation for those addresses in the rule.

For dynamic PAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

1. **Select Policies > NAT.**
2. **Do one of the following:**

   - (Interface PAT.) To use the IPv4 address of the destination interface, select **Interface**. You must also select a specific destination interface, which cannot be a bridge group member interface. You cannot use interface PAT for IPv6.
   - To use a single address other than the destination interface address, select the host network object you created for this purpose.

   **Step 5** (Optional.) Click the **Advanced Options** link and select the desired options:

      - **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. You cannot select this option if you already configured interface PAT as the translated address. You also cannot use this option with IPv6 networks.

   **Step 6** Click **OK**.
- To create a new rule, click the + button.
- To edit an existing rule, click the edit icon (✏️) for the rule.

(To delete a rule you no longer need, click the trash can icon for the rule.)

**Step 3**  Configure the basic rule options:

- **Title**—Enter a name for the rule.
- **Create Rule For**—Select **Manual NAT**.
- **Rule Placement**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule you select.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.

**Step 4**  Configure the following interface options:

- **Source Interface, Destination Interface**—(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. Source is the real interface, the one through which the traffic enters the device. Destination is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5**  Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source Address**—The network object or group that contains the addresses you are translating.
- **Original Destination Address**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Interface** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6**  Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source Address**—One of the following:
• (Interface PAT.) To use the IPv4 address of the destination interface, select Interface. You must also select a specific destination interface, which cannot be a bridge group member interface. You cannot use interface PAT for IPv6.

• To use a single address other than the destination interface address, select the host network object you created for this purpose.

• Translated Destination Address—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for Original Destination, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: Original Destination Port, Translated Destination Port.

Dynamic NAT does not support port translation, so leave the Original Source Port and Translated Source Port fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 (Optional.) Click the Advanced Options link and select the desired options:

• Fallthrough to Interface PAT (Destination Interface)—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. You cannot select this option if you already configured interface PAT as the translated address. You also cannot use this option with IPv6 networks.

Step 9 Click OK.

Static NAT

The following topics explain static NAT and how to implement it.

About Static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

The following figure shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.
Static NAT with Port Translation

Static NAT with port translation lets you specify a real and mapped protocol and port. When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

The following figure shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

Figure 13: Typical Static NAT with Port Translation Scenario

Static NAT-with-port-translation rules limit access to the destination IP address for the specified port only. If you try to access the destination IP address on a different port not covered by a NAT rule, then the connection is blocked. In addition, for manual NAT, traffic that does not match the source IP address of the NAT rule will be dropped if it matches the destination IP address, regardless of the destination port. Therefore, you must add additional rules for all other traffic allowed to the destination IP address. For example, you can configure a static NAT rule for the IP address, without port specification, and place it after the port translation rule.

Note

For applications that require application inspection for secondary channels (for example, FTP and VoIP), NAT automatically translates the secondary ports.

Following are some other uses of static NAT with port translation.

Static NAT with Identity Port Translation

You can simplify external access to internal resources. For example, if you have three separate servers that provide services on different ports (such as FTP, HTTP, and SMTP), you can give external users a single IP address to access those services. You can then configure static NAT with identity port translation to map the single external IP address to the correct IP addresses of the real servers based on the port they
are trying to access. You do not need to change the port, because the servers are using the standard ones (21, 80, and 25 respectively).

**Static NAT with Port Translation for Non-Standard Ports**

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

**Static Interface NAT with Port Translation**

You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the device's outside interface to an inside host, then you can map the inside host IP address/port 23 to the outside interface address/port 23.

**One-to-Many Static NAT**

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

The following figure shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/first mapped IP is technically the only bidirectional translation.

*Figure 14: One-to-Many Static NAT*

For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server.
**Other Mapping Scenarios (Not Recommended)**

NAT has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated to the real host, but all traffic from the real host uses only the first mapped address for the source.

The following figure shows a typical few-to-many static NAT scenario.
For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

Note

Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

The following figure shows a typical many-to-few static NAT scenario.

**Configure Static Auto NAT**

Use static auto NAT rules to translate addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

**Before you begin**

Select **Objects** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Address**—This must be a network object (not a group), and it can be a host or subnet.
- **Translated Address**—You have the following options to specify the translated address:
• **Destination Interface**—To use the destination interface IPv4 address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number. You cannot use interface PAT for IPv6.

• **Address**—Create a network object or group containing hosts or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Select Policies &gt; NAT.</th>
</tr>
</thead>
</table>
| Step 2 | Do one of the following:  
  - To create a new rule, click the + button.  
  - To edit an existing rule, click the edit icon (📝) for the rule.  
  (To delete a rule you no longer need, click the trash can icon for the rule.) |
| Step 3 | Configure the basic rule options:  
  - **Title**—Enter a name for the rule.  
  - **Create Rule For**—Select **Auto NAT**.  
  - **Type**—Select **Static**. |
| Step 4 | Configure the following packet translation options:  
  - **Source Interface, Destination Interface**—(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. **Source** is the real interface, the one through which the traffic enters the device. **Destination** is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.  
  - **Original Address**—The network object that contains the addresses you are translating.  
  - **Translated Address**—One of the following:  
    - To use a set group of addresses, select the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.  
    - (Static interface NAT with port translation.) To use the address of the destination interface, select **Interface**. You must also select a specific destination interface, which cannot be a bridge group member interface. You cannot use interface PAT for IPv6. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.  
    - (Optional.) **Original Port, Translated Port**—If you need to translate a TCP or UDP port, select the port objects that define the original and translated ports. The objects must be for the same protocol. Click the Create New Object link if the objects do not already exist. For example, you can translate TCP/80 to TCP/8080 if necessary. |
| Step 5 | (Optional.) Click the Advanced Options link and select the desired options: |
Configure Static Manual NAT

Use static manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Static NAT translates addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select Objects and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source Address**—This can be a network object or group, and it can contain a host or subnet. If you want to translate all original source traffic, you can skip this step and specify Any in the rule.

- **Translated Source Address**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface IPv4 address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number. You cannot use interface PAT for IPv6.
  - **Address**—Create a network object or group containing hosts or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

You can also create network objects for the **Original Destination Address** and **Translated Destination Address** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports.

Step 6  Click OK.
Procedure

**Step 1** Select Policies > NAT.

**Step 2** Do one of the following:
- To create a new rule, click the + button.
- To edit an existing rule, click the edit icon (✏️) for the rule.

(To delete a rule you no longer need, click the trash can icon for the rule.)

**Step 3** Configure the basic rule options:
- **Title**—Enter a name for the rule.
- **Create Rule For**—Select Manual NAT.
- **Rule Placement**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule you select.
- **Type**—Select Static. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.

**Step 4** Configure the following interface options:
- **Source Interface, Destination Interface**—(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. **Source** is the real interface, the one through which the traffic enters the device. **Destination** is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5** Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source Address**—The network object or group that contains the addresses you are translating.
- **Original Destination Address**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select Interface to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.
Step 6  Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source Address**—One of the following:
  - To use a set group of addresses, select the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the IPv4 address of the destination interface, select Interface. You must also select a specific destination interface, which cannot be a bridge group member interface. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number. You cannot use interface PAT for IPv6.

- **Translated Destination Address**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7  (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port, Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port, Translated Destination Port**—Defines a port translation for the destination address.

Step 8  (Optional.) Click the **Advanced Options** link and select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 307. This option is not available if you are doing port translation.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Step 9  Click **OK**.
Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate an address to itself.

The following figure shows a typical identity NAT scenario.

Figure 18: Identity NAT

The following topics explain how to configure identity NAT.

Configure Identity Auto NAT

Use static identity auto NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select Objects and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Address**—This must be a network object (not a group), and it can be a host or subnet.

- **Translated Address**—A network object or group with the exact same contents as the original source object. You can use the same object.

Procedure

- **Step 1** Select Policies > NAT.

- **Step 2** Do one of the following:
  - To create a new rule, click the + button.
  - To edit an existing rule, click the edit icon (✎) for the rule.

  (To delete a rule you no longer need, click the trash can icon for the rule.)

- **Step 3** Configure the basic rule options:
  - **Title**—Enter a name for the rule.
  - **Create Rule For**—Select Auto NAT.
  - **Type**—Select Static.

- **Step 4** Configure the following packet translation options:
Configure Identity Manual NAT

Use static identity manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Use static identity NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select Objects and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

• **Original Source Address**—This can be a network object or group, and it can contain a host or subnet. If you want to translate all original source traffic, you can skip this step and specify Any in the rule.

• **Translated Source Address**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

You can also create network objects for the **Original Destination Address** and **Translated Destination Address** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports. You can use the same object for identity NAT.
Procedure

**Step 1**
Select Policies > NAT.

**Step 2**
Do one of the following:

- To create a new rule, click the + button.
- To edit an existing rule, click the edit icon (📝) for the rule.

(To delete a rule you no longer need, click the trash can icon for the rule.)

**Step 3**
Configure the basic rule options:

- **Title**—Enter a name for the rule.
- **Create Rule For**—Select Manual NAT.
- **Rule Placement**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule you select.
- **Type**—Select Static. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.

**Step 4**
Configure the following interface options:

- **Source Interface, Destination Interface**—(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. **Source** is the real interface, the one through which the traffic enters the device. **Destination** is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5**
Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.

- **Original Source Address**—The network object or group that contains the addresses you are translating.

- **Original Destination Address**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Interface** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.
Step 6  Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source Address**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.
- **Translated Destination Address**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination Address**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7  (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port, Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port, Translated Destination Port**—Defines a port translation for the destination address.

Step 8  (Optional.) Click the **Advanced Options** link and select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform route lookup for Destination interface**—If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Step 9  Click **OK**.

---

**NAT Rule Properties for Firepower Threat Defense**

Use Network Address Translation (NAT) rules to translate IP addresses to other IP addresses. You would typically use NAT rules to convert private addresses to publically routable addresses. The translation can be from one address to another, or you can use Port Address Translation (PAT) to translate many addresses to one, using port numbers to distinguish among the source addresses.

NAT rules include the following basic properties. The properties are the same for auto NAT and manual NAT rules except where indicated.

**Title**

Enter a name for the rule. The name cannot include spaces.
Create Rule For

Whether the translation rule is Auto NAT or Manual NAT. Auto NAT is simpler than manual NAT, but manual NAT allows you to create separate translations for a source address based on the destination address.

Status

Whether you want the rule to be active or disabled.

Placement (Manual NAT only.)

Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule you select.

Type

Whether the translation rule is Dynamic or Static. Dynamic translation automatically chooses the mapped address from a pool of addresses, or an address/port combination when implementing PAT. Use static translation if you want to precisely define the mapped address/port.

The following topics describe the remaining NAT rules properties.

Packet Translation Properties for Auto NAT

Use the Packet Translation options to define the source addresses and the mapped translated addresses. The following properties apply to auto NAT only.

Source Interface, Destination Interface

(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. Source is the real interface, the one through which the traffic enters the device. Destination is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

Original Address (Always required.)

The network object that contains the source addresses you are translating. This must be a network object (not a group), and it can be a host or subnet.

Translated Address (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- Dynamic NAT—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

- Dynamic PAT—One of the following:
  - (Interface PAT.) To use the IPv4 address of the destination interface, select Interface. You must also select a specific destination interface, which cannot be a bridge group member interface. You cannot use interface PAT for IPv6.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose.

- Static NAT—One of the following:
• To use a set group of addresses, select the network object or group that contains the mapped addresses. The object or group can contain hosts or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

• (Static interface NAT with port translation.) To use the address of the destination interface, select Interface. You must also select a specific destination interface, which cannot be a bridge group member interface. This configures static interface NAT with port translation: the source address/port is translated to the interface’s address and the same port number. You cannot use interface PAT for IPv6.

• Identity NAT—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Port, Translated Port (Static NAT only.)

If you need to translate a TCP or UDP port, select the port objects that define the original and translated ports. The objects must be for the same protocol. For example, you can translate TCP/80 to TCP/8080 if necessary.

Packet Translation Properties for Manual NAT

Use the Packet Translation options to define the source addresses and the mapped translated addresses. The following properties apply to manual NAT only. All are optional except as indicated.

Source Interface, Destination Interface

(Required for bridge group member interfaces.) The interfaces where this NAT rule applies. Source is the real interface, the one through which the traffic enters the device. Destination is the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

Original Source Address (Always required.)

The network object or group that contains the addresses you are translating. This can be a network object or group, and it can contain a host or subnet. If you want to translate all original source traffic, you can specify Any in the rule.

Translated Source Address (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

• Dynamic NAT—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

• Dynamic PAT—One of the following:
  • (Interface PAT.) To use the address of the destination interface, select Interface. You must also select a specific destination interface, which cannot be a bridge group member interface. You cannot use interface PAT for IPv6.
  • To use a single address other than the destination interface address, select the host network object you created for this purpose.

• Static NAT—One of the following:
To use a set group of addresses, select the network object or group that contains the mapped addresses. The object or group can contain hosts or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

(Static interface NAT with port translation.) To use the address of the destination interface, select Interface. You must also select a specific destination interface, which cannot be a bridge group member interface. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number. You cannot use interface PAT for IPv6.

Identity NAT—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Destination Address
The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select Interface to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Translated Destination Address
The network object or group that contains the destination addresses used in the translated packet. If you selected an object for Original Destination, you can set up identity NAT (that is, no translation) by selecting the same object.

Original Source Port, Translated Source Port, Original Destination Port, Translated Destination Port
The port objects that define the source and destination services for the original and translated packets. You can translate the ports, or select the same object to make the rule sensitive to the service without translating the ports. Keep the following rules in mind when configuring services:

- (Dynamic NAT or PAT.) You cannot do translation on the Original Source Port and Translated Source Port. You can do translation on the destination port only.

- NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same object for both the real and mapped ports.

Advanced NAT Properties
When you configure NAT, you can configure properties that provide specialized services in the Advanced options. All of these properties are optional: configure them only if you need the service.

Translate DNS replies that match this rule
Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and
AAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 307. This option is not available if you are doing port translation in a static NAT rule.

**Fallthrough to Interface PAT (Destination Interface) (Dynamic NAT only.)**

Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. You cannot select this option if you already configured interface PAT as the translated address. You cannot use this option with IPv6 networks.

**Do not proxy ARP on Destination Interface (Static NAT only.)**

Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

**Perform Route Lookup for Destination Interface (Static Identity NAT only. Routed mode only.)**

If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

---

**Translating IPv6 Networks**

In cases where you need to pass traffic between IPv6-only and IPv4-only networks, you need to use NAT to convert between the address types. Even with two IPv6 networks, you might want to hide internal addresses from the outside network.

You can use the following translation types with IPv6 networks:

- **NAT64, NAT46**—Translates IPv6 packets into IPv4 and vice versa. You need to define two policies, one for the IPv6 to IPv4 translation, and one for the IPv4 to IPv6 translation. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

  **Note**  
  NAT46 supports static mappings only.

  **Note**  
  NAT64 and NAT 46 are possible on standard routed interfaces only. NAT66 is possible on both routed and bridge group member interfaces.

- **NAT66**—Translates IPv6 packets to a different IPv6 address. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.
NAT64/46: Translating IPv6 Addresses to IPv4

When traffic goes from an IPv6 network to an IPv4-only network, you need to convert the IPv6 address to IPv4, and return traffic from IPv4 to IPv6. You need to define two address pools, an IPv4 address pool to bind IPv6 addresses in the IPv4 network, and an IPv6 address pool to bind IPv4 addresses in the IPv6 network.

- The IPv4 address pool for the NAT64 rule is normally small and typically might not have enough addresses to map one-to-one with the IPv6 client addresses. Dynamic PAT might more easily meet the possible large number of IPv6 client addresses compared to dynamic or static NAT.
- The IPv6 address pool for the NAT46 rule can be equal to or larger than the number of IPv4 addresses to be mapped. This allows each IPv4 address to be mapped to a different IPv6 address. NAT46 supports static mappings only, so you cannot use dynamic PAT.

You need to define two policies, one for the source IPv6 network, and one for the destination IPv4 network. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet

Following is a straight-forward example where you have an inside IPv6-only network, and you want to convert to IPv4 for traffic sent to the Internet. This example assumes you do not need DNS translation, so you can perform both the NAT64 and NAT46 translations in a single manual NAT rule.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network.

Procedure

Step 1  Create a network object for the inside IPv6 network.
   a)  Choose **Objects**.
   b)  Select **Network** from the table of contents and click +.
   c)  Define the inside IPv6 network.
Name the network object (for example, inside_v6), select **Network**, and enter the network address, 2001:db8::/96.

![Add Network Object](image)

d) Click **OK**.

**Step 2** Create the manual NAT rule to translate the IPv6 network to IPv4 and back again.

a) Select **Policies > NAT**.
b) Click the + button.
c) Configure the following properties:

- **Title** = PAT64Rule (or another name of your choosing).
- **Create Rule For** = Manual NAT.
- **Placement** = Before Auto NAT Rules
- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Packet Source Address** = inside_v6 network object.
- **Translated Packet Source Address** = Interface. This option uses the IPv4 address of the destination interface as the PAT address.
- **Original Packet Destination Address** = inside_v6 network object.
- **Translated Packet Destination Address** = any-ipv4 network object.
d) Click OK.

With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface. Conversely, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method.

NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet and DNS Translation

Following is a typical example where you have an inside IPv6-only network, but there are some IPv4-only services on the outside Internet that internal users need.
In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network. You enable DNS rewrite on the NAT46 rule, so that replies from the external DNS server can be converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

Following is a typical sequence for a web request where a client at 2001:DB8::100 on the internal IPv6 network tries to open www.example.com.

1. The client’s computer sends a DNS request to the DNS server at 2001:DB8::D1A5:CA81. The NAT rules make the following translations to the source and destination in the DNS request:
   - 2001:DB8::100 to a unique port on 209.165.201.1 (The NAT64 interface PAT rule.)
   - 2001:DB8::D1A5:CA81 to 209.165.202.129 (The NAT46 rule. D1A5:CA81 is the IPv6 equivalent of 209.165.202.129.)

2. The DNS server responds with an A record indicating that www.example.com is at 209.165.200.225. The NAT46 rule, with DNS rewrite enabled, converts the A record to the IPv6-equivalent AAAA record, and translates 209.165.200.225 to 2001:db8:D1A5:C8E1 in the AAAA record. In addition, the source and destination addresses in the DNS response are untranslated:
   - 209.165.202.129 to 2001:DB8::D1A5:CA81
   - 209.165.201.1 to 2001:db8::100

3. The IPv6 client now has the IP address of the web server, and makes an HTTP request to www.example.com at 2001:db8:D1A5:C8E1. (D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225.) The source and destination of the HTTP request are translated:
   - 2001:DB8::100 to a unique port on 209.156.101.54 (The NAT64 interface PAT rule.)
   - 2001:db8:D1A5:C8E1 to 209.165.200.225 (The NAT46 rule.)
The following procedure explains how to configure this example.

**Procedure**

**Step 1** Create the network objects that define the inside IPv6 and outside IPv4 networks.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click +.

c) Define the inside IPv6 network.

   Name the network object (for example, `inside_v6`), select **Network**, and enter the network address, `2001:db8::/96`.

   ![Add Network Object](Image)

   - **Name**: `inside_v6`
   - **Network**: `2001:db8::/96`

   d) Click **OK**.

   e) Click + and define the outside IPv4 network.

   Name the network object (for example, `outside_v4_any`), select **Network**, and enter the network address `0.0.0.0/0`. 
Step 2 Configure the NAT64 dynamic PAT rule for the inside IPv6 network.

a) Select Policies > NAT.
b) Click the + button.
c) Configure the following properties:

- **Title** = PAT64Rule (or another name of your choosing).
- **Create Rule For** = Auto NAT.
- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Address** = inside_v6 network object.
- **Translated Address** = **Interface**. This option uses the IPv4 address of the destination interface as the PAT address.
d) Click **OK**.

With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface.

**Step 3**  Configure the static NAT46 rule for the outside IPv4 network.

a) Click the **+** button.

b) Configure the following properties:

  - **Title** = NAT46Rule (or another name of your choosing).
  - **Create Rule For** = Auto NAT.
  - **Type** = Static.
  - **Source Interface** = outside.
  - **Destination Interface** = inside.
  - **Original Address** = outside_v4_any network object.
  - **Translated Address** = inside_v6 network object.
  - On the **Advanced Options** tab, select **Translate DNS replies that match this rule**.
c) Click OK.

With this rule, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method. In addition, DNS responses are converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

**NAT66: Translating IPv6 Addresses to Different IPv6 Addresses**

When going from an IPv6 network to another IPv6 network, you can translate the addresses to different IPv6 addresses on the outside network. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Because you are not translating between different address types, you need a single rule for NAT66 translations. You can easily model these rules using auto NAT. However, if you do not want to allow returning traffic, you can make the static NAT rule unidirectional using manual NAT only.

**NAT66 Example, Static Translation between Networks**

You can configure a static translation between IPv6 address pools using auto NAT. The following example explains how to convert inside addresses on the 2001:db8:122:2091::/96 network to outside addresses on the 2001:db8:122:2999::/96 network.
This example assumes that the inside interface is not a bridge group interface (BVI) but a standard routed interface. If the inside interface is a BVI, you need to duplicate the rules for each member interface.

**Procedure**

**Step 1**

Create the network objects that define the inside IPv6 and outside IPv6 NAT networks.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click `+`.

c) Define the inside IPv6 network.

   Name the network object (for example, inside_v6), select **Network**, and enter the network address, 2001:db8:122:2091::/96.
d) Click **OK**.

e) Click + and define the outside IPv6 NAT network.

Name the network object (for example, `outside_nat_v6`), select **Network**, and enter the network address 2001:db8:122:2999::/96.

---

**Step 2**  Configure the static NAT rule for the inside IPv6 network.

a) Select **Policies > NAT**.

b) Click the + button.

c) Configure the following properties:

   - **Title** = NAT66Rule (or another name of your choosing).
   - **Create Rule For** = Auto NAT.
• **Type** = Static.
• **Source Interface** = inside.
• **Destination Interface** = outside.
• **Original Address** = inside_v6 network object.
• **Translated Address** = outside_nat_v6 network object.

![Add NAT Rule](image)

- Click **OK**.

  With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a static NAT66 translation to an address on the 2001:db8:122:2999::/96 network.

### NAT66 Example, Simple IPv6 Interface PAT

A simple approach for implementing NAT66 is to dynamically assign internal addresses to different ports on the outside interface IPv6 address.

However, you cannot configure interface PAT using the IPv6 address of an interface using Firepower Device Manager. Instead, use a single free address on the same network as a dynamic PAT pool.
This example assumes that the inside interface is not a bridge group interface (BVI) but a standard routed interface. If the inside interface is a BVI, you need to duplicate the rules for each member interface.

**Procedure**

**Step 1** Create the network objects that define the inside IPv6 network and the IPv6 PAT address.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click +.

c) Define the inside IPv6 network.

Name the network object (for example, inside_v6), select **Network**, and enter the network address, 2001:db8:122:2091::/96.
d) Click OK.
e) Click + and define the outside IPv6 PAT address.

Name the network object (for example, ipv6_pat), select **Host**, and enter the host address 2001:db8:122:201b::2.

---

**Step 2**

Configure the dynamic PAT rule for the inside IPv6 network.

a) Select **Policies > NAT**.

b) Click the + button.

c) Configure the following properties:

- **Title** = PAT66Rule (or another name of your choosing).
- **Create Rule For** = Auto NAT.
• **Type** = Dynamic.

• **Source Interface** = inside.

• **Destination Interface** = outside.

• **Original Address** = inside_v6 network object.

• **Translated Address** = ipv6_pat network object.

d) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a dynamic PAT66 translation to a port on 2001:db8:122:201b::2.

---

**Monitoring NAT**

To monitor and troubleshoot NAT connections, open the CLI console or log into the device CLI and use the following commands.

• **show nat** displays the NAT rules and per-rule hit counts. There are additional keywords to show other aspects of NAT.

• **show xlate** displays the actual NAT translations that are currently active.
• **clear xlate** lets you remove an active NAT translation. You might need to remove active translations if you alter NAT rules, because existing connections continue to use the old translation slot until the connection ends. Clearing a translation allows the system to build a new translation for a client on the client's next connection attempt based on your new rules. (You cannot use this command in the CLI console.)

### Examples for NAT

The following topics provide examples for configuring NAT on Threat Defense devices.

#### Providing Access to an Inside Web Server (Static Auto NAT)

The following example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address.

**Note**

This example assumes that the inside interface is not a bridge group interface (BVI) but a standard routed interface. If the inside interface is a BVI, select the specific bridge group member interface to which the web server is attached, for example, inside1_3.

---

![Figure 19: Static NAT for an Inside Web Server](image)
Procedure

**Step 1**
Create the network objects that define the server’s private and public host addresses.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click +.

c) Define the web server’s private address.

   Name the network object (for example, WebServerPrivate), select **Host**, and enter the real host IP address, 10.1.2.27.

   ![New Network Object](image)

   - **Name**: WebServerPrivate
   - **Type**: Network, Host
   - **Host**: 10.1.2.27

   d) Click **OK**.

   e) Click + and define the public address.

   Name the network object (for example, WebServerPublic), select **Host**, and enter the host address 209.165.201.10.
f) Click OK.

**Step 2**

Configure static NAT for the object.

a) Select **Policies > NAT**.

b) Click the + button.

c) Configure the following properties:

- **Title** = WebServer (or another name of your choosing).
- **Create Rule For** = Auto NAT.
- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Address** = WebServerPrivate network object.
- **Translated Address** = WebServerPublic network object.
d) Click OK.

Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation)

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports.

Note
This example assumes that the inside interface is a standard routed interface attached to a switch, with the servers attached to the switch. If your inside interface is a bridge group interface (BVI), and the servers are attached to separate bridge group member interfaces, select the specific member interface to which each server is attached for the corresponding rule. For example, the rules might have inside1_2, inside1_3, and inside1_4 for the source interface rather than inside.
**Procedure**

**Step 1** Create a network object for the FTP server.

a) Choose **Objects**.
b) Select **Network** from the table of contents and click +.
c) Name the network object (for example, FTPserver), select **Host**, and enter the real IP address for the FTP server, 10.1.2.27.
d) Click **OK**.

**Step 2**  
Create a network object for the HTTP server.

a) Click **+**.

b) Name the network object (for example, HTTPserver), select **Host**, and enter the host address 10.1.2.28.

c) Click **OK**.

**Step 3**  
Create a network object for the SMTP server.

a) Click **+**.

b) Name the network object (for example, SMTPserver), select **Host**, and enter the host address 10.1.2.29.
c) Click OK.

**Step 4**  Create a network object for the public IP address used for the three servers.

a) Click +.

b) Name the network object (for example, ServerPublicIP), select Host, and enter the host address 209.165.201.3.

c) Click OK.

**Step 5**  Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

a) Select Policies > NAT.

b) Click the + button.

c) Configure the following properties:
• **Title** = FTPServer (or another name of your choosing).

• **Create Rule For** = Auto NAT.

• **Type** = Static.

• **Source Interface** = inside.

• **Destination Interface** = outside.

• **Original Address** = FTPserver network object.

• **Translated Address** = ServerPublicIP network object.

• **Original Port** = FTP port object.

• **Translated Port** = FTP port object.

[d) Click **OK**.

**Step 6**

Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click the **+** button.

b) Configure the following properties:

• **Title** = HTTPServer (or another name of your choosing).

• **Create Rule For** = Auto NAT.

• **Type** = Static.

• **Source Interface** = inside.

• **Destination Interface** = outside.
Security Policies

Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation)

- **Original Address** = HTTPserver network object.
- **Translated Address** = ServerPublicIP network object.
- **Original Port** = HTTP port object.
- **Translated Port** = HTTP port object.

c) Click **OK**.

**Step 7** Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click the + button.

b) Configure the following properties:

- **Title** = SMTPServer (or another name of your choosing).
- **Create Rule For** = Auto NAT.
- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Address** = SMTPserver network object.
- **Translated Address** = ServerPublicIP network object.
- **Original Port** = SMTP port object.
- **Translated Port** = SMTP port object.
Different Translation Depending on the Destination (Dynamic Manual PAT)

The following figure shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:port. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:port.

Note

This example assumes that the inside interface is a standard routed interface attached to a switch, with the servers attached to the switch. If your inside interface is a bridge group interface (BVI), and the servers are attached to separate bridge group member interfaces, select the specific member interface to which each server is attached for the corresponding rule. For example, the rules might have inside1_2 and inside1_3 for the source interface rather than inside.

c) Click OK.
Procedure

**Step 1**
Create a network object for the inside network.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click +.

c) Name the network object (for example, myInsideNetwork), select **Network**, and enter the real network address, 10.1.2.0/24.
d) Click OK.

**Step 2**
Create a network object for the DMZ network 1.

a) Click +.

b) Name the network object (for example, DMZnetwork1), select **Network**, and enter the network address 209.165.201.0/27 (subnet mask of 255.255.255.224).

![New Network Object](image)

C) Click OK.

**Step 3**
Create a network object for the PAT address for DMZ network 1.

a) Click +.

b) Name the network object (for example, PATaddress1), select **Host**, and enter the host address 209.165.202.129.

![New Network Object](image)

C) Click OK.
**Step 4** Create a network object for the DMZ network 2.

a) Click +.

b) Name the network object (for example, DMZnetwork2), select **Network**, and enter the network address 209.165.200.224/27 (subnet mask of 255.255.255.224).

c) Click **OK**.

**Step 5** Create a network object for the PAT address for DMZ network 2.

a) Click +.

b) Name the network object (for example, PATaddress2), select **Host**, and enter the host address 209.165.202.130.
c) Click OK.

**Step 6**  Configure dynamic manual PAT for DMZ network 1.

a) Select **Policies > NAT**.

b) Click the + button.

c) Configure the following properties:

- **Title** = DMZNetwork1 (or another name of your choosing).
- **Create Rule For** = Manual NAT.
- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source Address** = myInsideNetwork network object.
- **Translated Source Address** = PATaddress1 network object.
- **Original Destination Address** = DMZnetwork1 network object.
- **Translated Destination Address** = DMZnetwork1 network object.

**Note** Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.
Step 7

Configure dynamic manual PAT for DMZ network 2.

a) Click the + button.

b) Configure the following properties:
   - **Title** = DMZNetwork2 (or another name of your choosing).
   - **Create Rule For** = Manual NAT.
   - **Type** = Dynamic.
   - **Source Interface** = inside.
   - **Destination Interface** = dmz.
   - **Original Source Address** = myInsideNetwork network object.
   - **Translated Source Address** = PATaddress2 network object.
   - **Original Destination Address** = DMZnetwork2 network object.
   - **Translated Destination Address** = DMZnetwork2 network object.
c) Click **OK**.

---

**Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT)**

The following figure shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129:<port>. When the host accesses the same server for web services, the real address is translated to 209.165.202.130:<port>.

---

**Note**

This example assumes that the inside interface is a standard routed interface attached to a switch, with the server attached to the switch. If your inside interface is a bridge group interface (BVI), and the server is attached to a bridge group member interface, select the specific member interface to which the server is attached. For example, the rule might have inside1_2 for the source interface rather than inside.
Procedure

Step 1  Create a network object for the inside network.
   a) Choose Objects.
   b) Select Network from the table of contents and click +.
   c) Name the network object (for example, myInsideNetwork), select Network, and enter the real network address, 10.1.2.0/24.
d) Click OK.

**Step 2**
Create a network object for the Telnet/Web server.

a) Click +.
b) Name the network object (for example, TelnetWebServer), select **Host**, and enter the host address 209.165.201.11.

c) Click OK.

**Step 3**
Create a network object for the PAT address when using Telnet.

a) Click +.
b) Name the network object (for example, PATaddress1), select **Host**, and enter the host address 209.165.202.129.

c) Click OK.
**Step 4**  
Create a network object for the PAT address when using HTTP.

a) Click +.
b) Name the network object (for example, PATaddress2), select Host, and enter the host address 209.165.202.130.
c) Click OK.

**Step 5**  
Configure dynamic manual PAT for Telnet access.

a) Select Policies > NAT.
b) Click the + button.
c) Configure the following properties:
   • Title = TelnetServer (or another name of your choosing).
   • Create Rule For = Manual NAT.
   • Type = Dynamic.
   • Source Interface = inside.
   • Destination Interface = dmz.
   • Original Source Address = myInsideNetwork network object.
   • Translated Source Address = PATaddress1 network object.
   • Original Destination Address = TelnetWebServer network object.
   • Translated Destination Address = TelnetWebServer network object.
   • Original Destination Port = TELNET port object.
   • Translated Destination Port = TELNET port object.

**Note** Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.
d) Click OK.

**Step 6**
Configure dynamic manual PAT for web access.

a) Click the + button.

b) Configure the following properties:
   - **Title** = WebServer (or another name of your choosing).
   - **Create Rule For** = Manual NAT.
   - **Type** = Dynamic.
   - **Source Interface** = inside.
   - **Destination Interface** = dmz.
   - **Original Source Address** = myInsideNetwork network object.
   - **Translated Source Address** = PATaddress2 network object.
   - **Original Destination Address** = TelnetWebServer network object.
   - **Translated Destination Address** = TelnetWebServer network object.
   - **Original Destination Port** = HTTP port object.
   - **Translated Destination Port** = HTTP port object.
### Rewriting DNS Queries and Responses Using NAT

You might need to configure the Firepower Threat Defense device to modify DNS replies by replacing the address in the reply with an address that matches the NAT configuration. You can configure DNS modification when you configure each translation rule. DNS modification is also known as DNS doctoring.

This feature rewrites the address in DNS queries and replies that match a NAT rule (for example, the A record for IPv4, the AAAA record for IPv6, or the PTR record for reverse DNS queries). For DNS replies traversing from a mapped interface to any other interface, the record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the record is rewritten from the real value to the mapped value.

Following are the main circumstances when you would need to configure DNS rewrite on a NAT rule.

- The rule is NAT64 or NAT46, and the DNS server is on the outside network. You need DNS rewrite to convert between DNS A records (for IPv4) and AAAA records (for IPv6).
- The DNS server is on the outside, clients are on the inside, and some of the fully-qualified domain names that the clients use resolve to other inside hosts.
- The DNS server is on the inside and responds with private IP addresses, clients are on the outside, and the clients access fully-qualified domain names that point to servers that are hosted on the inside.

---

c) Click **OK**.
DNS Rewrite Limitations

Following are some limitations with DNS rewrite:

- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A or AAAA
  record, and the PAT rule to use is ambiguous.

- If you configure a manual NAT rule, you cannot configure DNS modification if you specify the destination
  address as well as the source address. These kinds of rules can potentially have a different translation
  for a single address when going to A vs. B. Therefore, the can not accurately match the IP address inside
  the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which
  source/destination address combination was in the packet that prompted the DNS request.

- DNS rewrite is actually done on the xlate entry, not the NAT rule. Thus, if there is no xlate for a dynamic
  rule, rewrite cannot be done correctly. The same problem does not occur for static NAT.

- DNS rewrite does not rewrite DNS Dynamic Update messages (opcode 5).

The following topics provide examples of DNS rewrite in NAT rules.

DNS 64 Reply Modification

The following figure shows an FTP server and DNS server on the outside IPv4 network. The system has a
static translation for the outside server. In this case, when an inside IPv6 user requests the address for
ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1, where
D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225) you need to configure DNS reply modification for
the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule
for the inside IPv6 hosts.
This example assumes that the inside interface is not a bridge group interface (BVI) but a standard routed interface. If the inside interface is a BVI, you need to duplicate the rules for each member interface.

**Procedure**

**Step 1** Create the network objects for the FTP server, DNS server, inside network, and PAT pool.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click +.

c) Define the real FTP server address.

Name the network object (for example, ftp_server), select **Host**, and enter the real host IP address, 209.165.200.225.
d) Click **OK**.

e) Click + and define the DNS server's real address.

Name the network object (for example, dns_server), select **Host**, and enter the host address 209.165.201.15.

f) Click **OK**.

g) Click + and define the inside IPv6 network.

Name the network object (for example, inside_v6), select **Network**, and enter the network address, 2001:DB8::/96.
h) Click OK.
i) Click + and define the IPv4 PAT address for the inside IPv6 network.
Name the network object (for example, ipv4_pat), select Host, and enter the host address, 209.165.200.230.

j) Click OK.

Step 2 Configure the static NAT rule with DNS modification for the FTP server.
a) Select Policies > NAT.
b) Click the + button.
c) Configure the following properties:
   • Title = FTPServer (or another name of your choosing).
• **Create Rule For** = Auto NAT.
• **Type** = Static.
• **Source Interface** = outside.
• **Destination Interface** = inside.
• **Original Address** = ftp_server network object.
• **Translated Address** = inside_v6 network object. Because the IPv4 embedded address method is used when converting IPv4 to IPv6 addresses, 209.165.200.225 is converted to the IPv6 equivalent D1A5:C8E1 and the network prefix is added to get the full address, 2001:DB8::D1A5:C8E1.

  • On the **Advanced Options** tab, select **Translate DNS replies that match this rule**.

![Add NAT Rule](image)

d) Click **OK**.

**Step 3** Configure the static NAT rule for the DNS server.

a) Select **Policies > NAT**.

b) Click the + button.

c) Configure the following properties:

  • **Title** = DNSServer (or another name of your choosing).
  • **Create Rule For** = Auto NAT.
  • **Type** = Static.
  • **Source Interface** = outside.
**Destination Interface** = inside.

**Original Address** = dns_server network object.

**Translated Address** = inside_v6 network object. Because the IPv4 embedded address method is used when converting IPv4 to IPv6 addresses, 209.165.201.15 is converted to the IPv6 equivalent D1A5:C90F and the network prefix is added to get the full address, 2001:DB8::D1A5:C90F.

---

**Step 4** Configure the dynamic PAT rule for the inside IPv6 network.

a) Select **Policies > NAT**.

b) Click the **+** button.

c) Configure the following properties:

- **Title** = PAT64Rule (or another name of your choosing).
- **Create Rule For** = Auto NAT.
- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Address** = inside_v6 network object.
- **Translated Address** = ipv4_pat network object.

d) Click **OK**.
d) Click OK.

**DNS Reply Modification, DNS Server on Outside**

The following figure shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure NAT to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network.

In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The system refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.
This example assumes that the inside interface is not a bridge group interface (BVI) but a standard routed interface. If the inside interface is a BVI, you need to duplicate the rules for each member interface.

Procedure

**Step 1**
Create the network objects for the FTP server.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click +.

c) Define the real FTP server address.

   Name the network object (for example, ftp_server), select **Host**, and enter the real host IP address, 10.1.3.14.
d) Click **OK**.
e) Click + and define the FTP server's translated address.

Name the network object (for example, `ftp_server_outside`), select **Host**, and enter the host address `209.165.201.10`.

---

**Step 2**

Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Policies > NAT**.
b) Click the + button.
c) Configure the following properties:

• **Title** = FTPServer (or another name of your choosing).
• **Create Rule For** = Auto NAT.
• **Type** = Static.
• **Source Interface** = inside.
• **Destination Interface** = outside.
• **Original Address** = ftp_server network object.
• **Translated Address** = ftp_server_outside network object.
• On the **Advanced Options** tab, select **Translate DNS replies that match this rule**.

d) Click **OK**.

**DNS Reply Modification, DNS Server on Host Network**

The following figure shows an FTP server and DNS server on the outside. The system has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.
This example assumes that the inside interface is not a bridge group interface (BVI) but a standard routed interface. If the inside interface is a BVI, you need to duplicate the rules for each member interface.

**Procedure**

**Step 1** Create the network objects for the FTP server.

a) Choose **Objects**.

b) Select **Network** from the table of contents and click +.

c) Define the real FTP server address.

   Name the network object (for example, ftp_server), select **Host**, and enter the real host IP address, 209.165.201.10.
d) Click **OK**.

e) Click + and define the FTP server's translated address.

Name the network object (for example, ftp_server_translated), select **Host**, and enter the host address 10.1.2.56.

---

**Step 2**

Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Policies > NAT**.

b) Click the + button.

c) Configure the following properties:

- **Title** = FTPServer (or another name of your choosing).
- **Create Rule For** = Auto NAT.
• Type = Static.
• Source Interface = outside.
• Destination Interface = inside.
• Original Address = ftp_server network object.
• Translated Address = ftp_server_translated network object.
• On the Advanced Options tab, select Translate DNS replies that match this rule.

d) Click OK.
PART III

Virtual Private Networks (VPN)

- Site-to-Site VPN, on page 323
- Remote Access VPN, on page 353
Site-to-Site VPN

A virtual private network (VPN) is a network connection that establishes a secure tunnel between remote peers using a public source, such as the Internet or other network. VPNs use tunnels to encapsulate data packets within normal IP packets for forwarding over IP-based networks. They use encryption to ensure privacy and authentication to ensure the integrity of data.

- VPN Basics, on page 323
- Managing Site-to-Site VPNs, on page 327
- Monitoring Site-to-Site VPN, on page 340
- Examples for Site-to-Site VPN, on page 340

VPN Basics

Tunneling makes it possible to use a public TCP/IP network, such as the Internet, to create secure connections between remote users and private corporate networks. Each secure connection is called a tunnel.

IPsec-based VPN technologies use the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and IPsec tunneling standards to build and manage tunnels. ISAKMP and IPsec accomplish the following:

- Negotiate tunnel parameters.
- Establish tunnels.
- Authenticate users and data.
- Manage security keys.
- Encrypt and decrypt data.
- Manage data transfer across the tunnel.
- Manage data transfer inbound and outbound as a tunnel endpoint or router.

A device in a VPN functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.

After the site-to-site VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. A connection consists of the IP addresses...
and hostnames of the two gateways, the subnets behind them, and the method the two gateways use to authenticate to each other.

**Internet Key Exchange (IKE)**

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and to automatically establish IPsec security associations (SAs).

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection.

An IKE policy is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters protect subsequent IKE negotiations. For IKE version 1 (IKEv1), IKE policies contain a single set of algorithms and a modulus group. Unlike IKEv1, in an IKEv2 policy, you can select multiple algorithms and modulus groups from which peers can choose during the Phase 1 negotiation. It is possible to create a single IKE policy, although you might want different policies to give higher priority to your most desired options. For site-to-site VPNs, you can create a single IKE policy.

To define an IKE policy, specify:

- A unique priority (1 to 65,543, with 1 the highest priority).
- An encryption method for the IKE negotiation, to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method (called integrity algorithm in IKEv2) to ensure the identity of the sender, and to ensure that the message has not been modified in transit.
- For IKEv2, a separate pseudorandom function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The options are the same as those used for the hash algorithm.
- A Diffie-Hellman group to determine the strength of the encryption-key-determination algorithm. The device uses this algorithm to derive the encryption and hash keys.
- An authentication method, to ensure the identity of the peers.
- A limit to the time the device uses an encryption key before replacing it.

When IKE negotiation begins, the peer that starts the negotiation sends all of its enabled policies to the remote peer, and the remote peer searches for a match with its own policies, in priority order. A match between IKE policies exists if they have the same encryption, hash (integrity and PRF for IKEv2), authentication, and Diffie-Hellman values, and an SA lifetime less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter lifetime, obtained from the remote peer, applies. By default, a simple IKE policy that uses DES is the only enabled policy. You can enable other IKE policies at higher priorities to negotiate stronger encryption standards, but the DES policy should ensure a successful negotiation.

**How Secure Should a VPN Connection Be?**

Because a VPN tunnel typically traverses a public network, most likely the Internet, you need to encrypt the connection to protect the traffic. You define the encryption and other security techniques to apply using IKE policies and IPsec proposals.
If your device license allows you to apply strong encryption, there is a wide range of encryption and hash algorithms, and Diffie-Hellman groups, from which to choose. However, as a general rule, the stronger the encryption that you apply to the tunnel, the worse the system performance. Find a balance between security and performance that provides sufficient protection without compromising efficiency.

We cannot provide specific guidance on which options to choose. If you operate within a larger corporation or other organization, there might already be defined standards that you need to meet. If not, take the time to research the options.

The following topics explain the available options.

**Deciding Which Encryption Algorithm to Use**

When deciding which encryption algorithms to use for the IKE policy or IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN.

For IKEv2, you can configure multiple encryption algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

For IPsec proposals, the algorithm is used by the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and anti-replay services. ESP is IP protocol type 50. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-.

If your device license qualifies for strong encryption, you can choose from the following encryption algorithms. If you are not qualified for strong encryption, you can select DES only.

- **AES-GCM**—(IKEv2 only.) Advanced Encryption Standard in Galois/Counter Mode is a block cipher mode of operation providing confidentiality and data-origin authentication, and provides greater security than AES. AES-GCM offers three different key strengths: 128-, 192-, and 256-bit keys. A longer key provides higher security but a reduction in performance. GCM is a mode of AES that is required to support NSA Suite B. NSA Suite B is a set of cryptographic algorithms that devices must support to meet federal standards for cryptographic strength.

- **AES-GMAC**—(IKEv2 IPsec proposals only.) Advanced Encryption Standard Galois Message Authentication Code is a block cipher mode of operation providing only data-origin authentication. It is a variant of AES-GCM that allows data authentication without encrypting the data. AES-GMAC offers three different key strengths: 128-, 192-, and 256-bit keys.

- **AES**—Advanced Encryption Standard is a symmetric cipher algorithm that provides greater security than DES and is computationally more efficient than 3DES. AES offers three different key strengths: 128-, 192-, and 256-bit keys. A longer key provides higher security but a reduction in performance.

- **3DES**—Triple DES, which encrypts three times using 56-bit keys, is more secure than DES because it processes each block of data three times with a different key. However, it uses more system resources and is slower than DES.

- **DES**—Data Encryption Standard, which encrypts using 56-bit keys, is a symmetric secret-key block algorithm. If your license account does not meet the requirements for export controls, this is your only option. It is faster than 3DES and uses less system resources, but it is also less secure. If you do not need strong data confidentiality, and if system resources or speed is a concern, choose DES.

- **Null**—A null encryption algorithm provides authentication without encryption. This is typically used for testing purposes only.
Deciding Which Hash Algorithms to Use

In IKE policies, the hash algorithm creates a message digest, which is used to ensure message integrity. In IKEv2, the hash algorithm is separated into two options, one for the integrity algorithm, and one for the pseudo-random function (PRF).

In IPsec proposals, the hash algorithm is used by the Encapsulating Security Protocol (ESP) for authentication. In IKEv2 IPsec Proposals, this is called the integrity hash. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-., and there is also an -HMAC suffix (which stands for “hash method authentication code”).

For IKEv2, you can configure multiple hash algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

You can choose from the following hash algorithms.

- **SHA (Secure Hash Algorithm)**—Standard SHA (SHA1) produces a 160-bit digest. SHA is more resistant to brute-force attacks than MD5. However, it is also more resource intensive than MD5. For implementations that require the highest level of security, use the SHA hash algorithm.

  The following SHA-2 options, which are even more secure, are available for IKEv2 configurations. Choose one of these if you want to implement the NSA Suite B cryptography specification.

  - **SHA256**—Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
  - **SHA384**—Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
  - **SHA512**—Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

- **MD5 (Message Digest 5)**—Produces a 128-bit digest. MD5 uses less processing time for an overall faster performance than SHA, but it is considered to be weaker than SHA.

- **Null or None (NULL, ESP-NONE)**—(IPsec Proposals only.) A null Hash Algorithm; this is typically used for testing purposes only. However, you should choose the null integrity algorithm if you select one of the AES-GCM/GMAC options as the encryption algorithm. Even if you choose a non-null option, the integrity hash is ignored for these encryption standards.

Deciding Which Diffie-Hellman Modulus Group to Use

You can use the following Diffie-Hellman key derivation algorithms to generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus provides higher security, but requires more processing time. You must have a matching modulus group on both peers.

If you select AES encryption, to support the large key sizes required by AES, you should use Diffie-Hellman (DH) Group 5 or higher. IKEv1 policies do not support all of the groups listed below.

To implement the NSA Suite B cryptography specification, use IKEv2 and select one of the elliptic curve Diffie-Hellman (ECDH) options: 19, 20, or 21. Elliptic curve options and groups that use 2048-bit modulus are less exposed to attacks such as Logjam.

For IKEv2, you can configure multiple groups. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

- **1**—Diffie-Hellman Group 1: 768-bit modulus. DH group 1 is considered insecure, please do not use it.
- **2**—Diffie-Hellman Group 2: 1024-bit modular exponential (MODP) group. This option is no longer considered good protection.
- 5—Diffie-Hellman Group 5: 1536-bit MODP group. Formerly considered good protection for 128-bit keys, this option is no longer considered good protection.
- 19—Diffie-Hellman Group 19: National Institute of Standards and Technology (NIST) 256-bit elliptic curve modulo a prime (ECP) group.
- 24—Diffie-Hellman Group 24: 2048-bit MODP group with 256-bit prime order subgroup. This option is no longer recommended.

VPN Topologies

You can configure only point-to-point VPN connections using Firepower Device Manager. Although all connections are point-to-point, you can link into larger hub-and-spoke or meshed VPNs by defining each of the tunnels in which your device participates.

The following diagram displays a typical point-to-point VPN topology. In a point-to-point VPN topology, two endpoints communicate directly with each other. You configure the two endpoints as peer devices, and either device can start the secured connection.

Managing Site-to-Site VPNs

A virtual private network (VPN) is a network connection that establishes a secure tunnel between remote peers using a public source, such as the Internet or other network. VPNs use tunnels to encapsulate data packets within normal IP packets for forwarding over IP-based networks. They use encryption to ensure privacy and authentication to ensure the integrity of data.

You can create VPN connections to peer devices. All connections are point-to-point, but you can link the device into larger hub-and-spoke or meshed VPNs by configuring all relevant connections.
VPN connections use encryption to secure network privacy. The encryption algorithms that you can use depend on whether your base license allows strong encryption. This is controlled by whether you selected the option to allow export-controlled functionality on the device when you registered with Cisco Smart License Manager. If you are using the evaluation license, or you did not enable export-controlled functionality, you cannot use strong encryption.

**Procedure**

**Step 1**
Click **Device**, then click **View Configuration** in the Site-to-Site VPN group. This opens the Site-to-Site VPN page, which lists all of the connections that you have configured.

**Step 2**
Do any of the following.

- To create a new Site-to-Site VPN connection, click the + button. See Configuring a Site-to-Site VPN Connection, on page 328.
  
  If there are no connections yet, you can also click the **Create Site-to-Site Connection** button.

- To edit an existing connection, click the edit icon (редактирование) for the connection. See Configuring a Site-to-Site VPN Connection, on page 328.

- To copy a summary of the connection configuration to the clipboard, click the copy icon (копировать) for the connection. You can paste this information in a document and send it to the administrator for the remote device to help configure that end of the connection.

- To delete a connection that you no longer need, click the delete icon (удалить) for the connection.

---

**Configuring a Site-to-Site VPN Connection**

You can create a point-to-point VPN connection to link your device to another device, assuming that you have the cooperation and permission of the remote device owner. Although all connections are point-to-point, you can link into larger hub-and-spoke or meshed VPNs by defining each of the tunnels in which your device participates.

**Note**

You can create a single VPN connection per local network/remote network combination. However, you can create multiple connections for a local network if the remote network is unique in each connection profile.

**Procedure**

**Step 1**
Click **Device**, then click **View Configuration** in the Site-to-Site VPN group.

**Step 2**
Do any of the following:
To create a new Site-to-Site VPN connection, click the + button.

If there are no connections yet, you can also click the Create Site-to-Site Connection button.

To edit an existing connection, click the edit icon (-pencil) for the connection.

To delete a connection that you no longer need, click the delete icon (-trash) for the connection.

---

**Step 3** Define the endpoints of the point-to-point VPN connection.

- **Connection Profile Name**—The name for this connection, up to 64 characters without spaces. For example, MainOffice. You cannot use an IP address as the name.

- **Local Site**—These options define the local endpoint.
  - **Local VPN Access Interface**—Select the interface to which the remote peer can connect. This is typically the outside interface. The interface cannot be a member of a bridge group.
  - **Local Network**—Click + and select the network objects that identify the local networks that should participate in the VPN connection. Users on these networks will be able to reach the remote networks through the connection.

  **Note** You can use IPv4 or IPv6 addresses for these networks, but you must have a matching address type on each side of the connection. For example, the VPN connection for a local IPv4 network must have at least one remote IPv4 network. You can combine IPv4 and IPv6 on both sides of a single connection. The protected networks for the endpoints cannot overlap.

- **Remote Site**—These options define the remote endpoint.
  - **Remote IP Address**—Enter the IP address of the remote VPN peer's interface that will host the VPN connection.
  - **Remote Network**—Click + and select the network objects that identify the remote networks that should participate in the VPN connection. Users on these networks will be able to reach the local networks through the connection.

---

**Step 4** Click Next.

**Step 5** Define the privacy configuration for the VPN.

- **IKE Version 2, IKE Version 1**—Choose the IKE versions to use during Internet Key Exchange (IKE) negotiations. Select either or both options as appropriate. When the device attempts to negotiate a connection with the other peer, it uses whichever versions you allow and that the other peer accepts. If you allow both versions, the device automatically falls back to the other version if negotiations are unsuccessful with the initially chosen version. IKEv2 is always tried first if it is configured. Both peers must support IKEv2 to use it in a negotiation.

- **IKE Policy**—Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). This is a global policy: the objects you enable are applied to all VPNs. Click *Edit* to examine the current globally-enabled policies per IKE version, and to enable and create new policies. For more information, see Configuring the Global IKE Policy, on page 331.
- **IPsec Proposal**—The IPsec proposal defines the combination of security protocols and algorithms that secure traffic in an IPsec tunnel. Click Edit and select the proposals for each IKE version. Select all proposals that you want to allow. Click Set Default to simply select the system defaults, which differ based on your export compliance. The system negotiates with the peer, starting from the strongest to the weakest proposal, until a match is agreed upon. For more information, see Configuring IPsec Proposals, on page 335.

- **(IKEv2) Local Preshared Key, Remote Peer Preshared Key**—The keys defined on this device and on the remote device for the VPN connection. These keys can be different in IKEv2. The key can be 1-127 alphanumeric characters.

- **(IKEv1) Preshared Key**—The key that is defined on both the local and remote device. The key can be 1-127 alphanumeric characters.

- **NAT Exempt**—Whether to exempt the VPN traffic from NAT policies on the local VPN access interface. If you do not want NAT rules to apply to the local network, select the interface that hosts the local network. This option works only if the local network resides behind a single routed interface (not a bridge group member). If the local network is behind more than one routed interface, or one or more bridge group members, you must manually create the NAT exempt rules. For information on manually creating the required rules, see Exempting Site-to-Site VPN Traffic from NAT, on page 340.

- **Diffie-Helman Group for Perfect Forward Secrecy**—Whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. To enable Perfect Forward Secrecy, select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list. If you enable both IKEv1 and IKEv2, the options are limited to those supported by IKEv1. For an explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use, on page 326.

**Step 6**
Click Next.

**Step 7**
Review the summary and click Finish.

The summary information is copied to the clipboard. You can paste the information in a document and use it to help you configure the remote peer, or to send it to the party responsible for configuring the peer.

After you deploy the configuration, log into the device CLI and use the `show ipsec sa` command to verify that the endpoints establish a security association. See Verifying Site-to-Site VPN Connections, on page 337.

---

### What to do next

By default, VPN-terminated traffic bypasses the access control policy, including any advanced inspections defined in that policy, such as URL filtering, intrusion protection, or file policies. If you want VPN traffic to be evaluated and inspected by the access control policy, use FlexConfig to configure the `no sysopt connection permit-vpn` command. You can then configure access control rules to allow traffic between the address pool and the inside networks from the outside to inside interfaces. The system decrypts the VPN traffic before evaluating it with the access control policy, so you can apply intrusion prevention, URL filtering, and so forth.
Configuring the Global IKE Policy

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs).

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters are used to protect subsequent IKE negotiations.

IKE policy objects define the IKE proposals for these negotiations. The objects that you enable are the ones used when the peers negotiate a VPN connection: you cannot specify different IKE policies per connection. The relative priority of each object determines which of these policies are tried first, with the lower number being higher priority. The connection is not established if the negotiation fails to find a policy that both peers can support.

To define the global IKE policy, you select which objects to enable for each IKE version. If the pre-defined objects do not satisfy your requirements, create new policies to enforce your security policy.

The following procedure explains how to configure the global policy through the Objects page. You can also enable, disable, and create policies when editing a VPN connection by clicking Edit for the IKE Policy settings.

Procedure

**Step 1**
Select Objects, then select IKE Policies from the table of contents.

Policies for IKEv1 and IKEv2 are shown in separate lists.

**Step 2**
Enable the IKE policies you want to allow for each IKE version.

a) Select IKEv1 or IKEv2 above the object table to show the policies for that version.

b) Click the State toggle to enable the appropriate objects and to disable objects that do not meet your requirements.

   If some of your security requirements are not reflected in the existing objects, define new ones to implement your requirements. For details, see the following topics:
   - Configuring IKEv1 Policies, on page 332
   - Configuring IKEv2 Policies, on page 333

c) Verify that the relative priorities match your requirements.

   If you need to change the priority of a policy, edit it. If the policy is a pre-defined system policy, you need to create your own version of the policy to change the priority.

   The priority is relative, and not absolute. For example, priority 80 is higher than 160. If 80 is the highest priority object that you enable, that becomes your first-choice policy. If you then enable a policy with priority 25, that becomes your first-choice policy.

d) If you use both IKE versions, repeat the process for the other version.
Configuring IKEv1 Policies

Internet Key Exchange (IKE) version 1 policy objects contain the parameters required for IKEv1 policies when defining VPN connections. IKE is a key management protocol that facilitates the management of IPsec-based communications. It is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs).

There are several pre-defined IKEv1 policies. If any suit your needs, simply enable them by clicking the State toggle. You can also create new policies to implement other combinations of security settings. You cannot edit or delete system-defined objects.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create IKEv1 Policy objects while editing the IKEv1 settings in a VPN connection by clicking the Create New IKE Policy link shown in the object list.

Procedure

**Step 1** Select Objects, then select IKE Policies from the table of contents.

**Step 2** Select IKEv1 above the object table to show IKEv1 policies.

**Step 3** If any of the system-defined policies meet your requirements, click the State toggle to enable them.

Also use the State toggle to disable unwanted policies. The relative priority determines which of these policies are tried first, with the lower number being higher priority.

**Step 4** Do one of the following:

- To create an object, click the + button.

- To edit an object, click the edit icon (Edit) for the object.

To delete an unreferenced object, click the trash can icon (Trash) for the object.

**Step 5** Configure the IKEv1 properties.

- **Priority**—The relative priority of the IKE policy, from 1 to 65,535. The priority determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your highest priority policy, it tries to use the parameters defined in the next lowest priority. The lower the number, the higher the priority.

- **Name**—The name of the object, up to 128 characters.

- **State**—Whether the IKE policy is enabled or disabled. Click the toggle to change the state. Only enabled policies are used during IKE negotiations.

- **Authentication**—The method of authentication to use between the two peers.

  - **Preshared Key**—Use the preshared key that is defined on each device. These keys allow for a secret key to be shared between two peers and to be used by IKE during the authentication phase. If the peer is not configured with the same preshared key, the IKE SA cannot be established.

- **Encryption**—The encryption algorithm used to establish the Phase 1 security association (SA) for protecting Phase 2 negotiations. For an explanation of the options, see Deciding Which Encryption Algorithm to Use, on page 325.
• **Diffie-Hellman Group**—The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. For an explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use, on page 326.

• **Hash**—The hash algorithm for creating a message digest, which is used to ensure message integrity. For an explanation of the options, see Deciding Which Hash Algorithms to Use, on page 326.

• **Lifetime**—The lifetime of the security association (SA), in seconds, from 120 to 2147483647 or blank. When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. As a general rule, the shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes. The default is 86400. To specify an unlimited lifetime, enter no value (leave the field blank).

**Step 6** Click **OK** to save your changes.

---

### Configuring IKEv2 Policies

Internet Key Exchange (IKE) version 2 policy objects contain the parameters required for IKEv2 policies when defining VPN connections. IKE is a key management protocol that facilitates the management of IPsec-based communications. It is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs).

There are several pre-defined IKEv2 policies. If any suit your needs, simply enable them by clicking the **State** toggle. You can also create new policies to implement other combinations of security settings. You cannot edit or delete system-defined objects.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create IKEv2 Policy objects while editing the IKEv2 settings in a VPN connection by clicking the **Create New IKE Policy** link shown in the object list.

#### Procedure

**Step 1** Select **Objects**, then select **IKE Policies** from the table of contents.

**Step 2** Select **IKEv2** above the object table to show IKEv2 policies.

**Step 3** If any of the system-defined policies meet your requirements, click the **State** toggle to enable them.

Also use the **State** toggle to disable unwanted policies. The relative priority determines which of these policies are tried first, with the lower number being higher priority.

**Step 4** Do one of the following:

- To create an object, click the **+** button.

- To edit an object, click the edit icon (liği) for the object.

To delete an unreferenced object, click the trash can icon (wę) for the object.

**Step 5** Configure the IKEv2 properties.
• Priority—The relative priority of the IKE policy, from 1 to 65,535. The priority determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your highest priority policy, it tries to use the parameters defined in the next lowest priority. The lower the number, the higher the priority.

• Name—The name of the object, up to 128 characters.

• State—Whether the IKE policy is enabled or disabled. Click the toggle to change the state. Only enabled policies are used during IKE negotiations.

• Encryption—The encryption algorithm used to establish the Phase 1 security association (SA) for protecting Phase 2 negotiations. Select all algorithms that you want to allow, although you cannot include both mixed-mode (AES-GCM) and normal mode options in the same policy. (Normal mode requires that you select an integrity hash, whereas mixed mode prohibits a separate integrity hash selection.) The system negotiates with the peer, starting from the strongest to the weakest algorithm, until a match is agreed upon. For an explanation of the options, see Deciding Which Encryption Algorithm to Use, on page 325.

• Diffie-Hellman Group—The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select all algorithms that you want to allow. The system negotiates with the peer, starting from the strongest to the weakest group, until a match is agreed upon. For an explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use, on page 326.

• Integrity Hash—The integrity portion of the hash algorithm for creating a message digest, which is used to ensure message integrity. Select all algorithms that you want to allow. The system negotiates with the peer, starting from the strongest to the weakest algorithm, until a match is agreed upon. The integrity hash is not used with the AES-GCM encryption options. For an explanation of the options, see Deciding Which Hash Algorithms to Use, on page 326.

• Pseudo Random Function (PRF) Hash—The pseudo-random function (PRF) portion of the hash algorithm, which is used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. In IKEv1, the Integrity and PRF algorithms are not separated, but in IKEv2, you can specify different algorithms for these elements. Select all algorithms that you want to allow. The system negotiates with the peer, starting from the strongest to the weakest algorithm, until a match is agreed upon. For an explanation of the options, see Deciding Which Hash Algorithms to Use, on page 326.

• Lifetime—The lifetime of the security association (SA), in seconds, from 120 to 2147483647 or blank. When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. As a general rule, the shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes. The default is 86400. To specify an unlimited lifetime, enter no value (leave the field blank).

**Step 6** Click OK to save your changes.
Configuring IPsec Proposals

IPsec is one of the most secure methods for setting up a VPN. IPsec provides data encryption at the IP packet level, offering a robust security solution that is standards-based. With IPsec, data is transmitted over a public network through tunnels. A tunnel is a secure, logical communication path between two peers. Traffic that enters an IPsec tunnel is secured by a combination of security protocols and algorithms called a transform set. During the IPsec security association (SA) negotiation, peers search for a transform set that is the same at both peers.

There are separate IPsec proposal objects based on the IKE version, IKEv1, or IKEv2:

- When you create an IKEv1 IPsec proposal, you select the mode in which IPsec operates, and define the required encryption and authentication types. You can select single options for the algorithms. If you want to support multiple combinations in a VPN, create and select multiple IKEv1 IPsec Proposal objects.

- When you create an IKEv2 IPsec proposal, you can select all of the encryption and hash algorithms allowed in a VPN. The system orders the settings from the most secure to the least secure and negotiates with the peer until a match is found. This allows you to potentially send a single proposal to convey all the allowed combinations instead of the need to send each allowed combination individually as with IKEv1.

The Encapsulating Security Protocol (ESP) is used for both IKEv1 and IKEv2 IPsec proposals. It provides authentication, encryption, and antireplay services. ESP is IP protocol type 50.

Note

We recommend using both encryption and authentication on IPsec tunnels.

The following topics explain how to configure IPsec proposals for each IKE version.

Configuring IPsec Proposals for IKEv1

Use IKEv1 IPsec Proposal objects configure the IPsec proposal used during IKE Phase 2 negotiations. The IPsec proposal defines the combination of security protocols and algorithms that secure traffic in an IPsec tunnel.

There are several pre-defined IKEv1 IPsec proposals. You can also create new proposals to implement other combinations of security settings. You cannot edit or delete system-defined objects.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create IKEv1 IPsec Proposals objects while editing the IKEv1 IPsec settings in a VPN connection by clicking the Create New IPsec Proposal link shown in the object list.

Procedure

1. Select Object, then select IPsec Proposals from the table of contents.
2. Select IKEv1 above the object table to show IKEv1 IPsec proposals.
3. Do one of the following:
   - To create an object, click the + button.
   - To edit an object, click the edit icon for the object.
To delete an unreferenced object, click the trash can icon (определенная точка) for the object.

**Step 4** Configure the IKEv1 IPsec proposal properties.

- **Name**—The name of the object, up to 128 characters.
- **Mode**—The mode in which the IPSec tunnel operates.
  - **Tunnel** mode encapsulates the entire IP packet. The IPSec header is added between the original IP header and a new IP header. This is the default. Use tunnel mode when the firewall is protecting traffic to and from hosts positioned behind the firewall. Tunnel mode is the normal way regular IPSec is implemented between two firewalls (or other security gateways) that are connected over an untrusted network, such as the Internet.
  - **Transport** mode encapsulates only the upper-layer protocols of an IP packet. The IPSec header is inserted between the IP header and the upper-layer protocol header (such as TCP). Transport mode requires that both the source and destination hosts support IPSec, and can only be used when the destination peer of the tunnel is the final destination of the IP packet. Transport mode is generally used only when protecting a Layer 2 or Layer 3 tunneling protocol such as GRE, L2TP, and DLSW.
- **ESP Encryption**—The Encapsulating Security Protocol (ESP) encryption algorithm for this proposal. For an explanation of the options, see Deciding Which Encryption Algorithm to Use, on page 325.
- **ESP Hash**—The hash or integrity algorithm to use for authentication. For an explanation of the options, see Deciding Which Hash Algorithms to Use, on page 326.

**Step 5** Click **OK** to save your changes.

---

### Configuring IPsec Proposals for IKEv2

Use IKEv2 IPsec Proposal objects to configure the IPsec proposal used during IKE Phase 2 negotiations. The IPsec proposal defines the combination of security protocols and algorithms that secure traffic in an IPsec tunnel.

There are several pre-defined IKEv2 IPsec proposals. You can also create new proposals to implement other combinations of security settings. You cannot edit or delete system-defined objects.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create IKEv2 IPsec Proposals objects while editing the IKEv2 IPsec settings in a VPN connection by clicking the **Create New IPsec Proposal** link shown in the object list.

**Procedure**

**Step 1** Select **Objects**, then select **IPsec Proposals** from the table of contents.
**Step 2** Select **IKEv2** above the object table to show IKEv2 IPsec proposals.
**Step 3** Do one of the following:
  - To create an object, click the + button.
  - To edit an object, click the edit icon (определенная точка) for the object.
To delete an unreferenced object, click the trash can icon (Trash) for the object.

**Step 4** Configure the IKEv2 IPSec proposal properties.

- **Name**—The name of the object, up to 128 characters.

- **Encryption**—The Encapsulating Security Protocol (ESP) encryption algorithm for this proposal. Select all algorithms that you want to allow. The system negotiates with the peer, starting from the strongest to the weakest algorithm, until a match is agreed upon. For an explanation of the options, see *Deciding Which Encryption Algorithm to Use*, on page 325.

- **Integrity Hash**—The hash or integrity algorithm to use for authentication. Select all algorithms that you want to allow. The system negotiates with the peer, starting from the strongest to the weakest algorithm, until a match is agreed upon. For an explanation of the options, see *Deciding Which Hash Algorithms to Use*, on page 326.

**Note** You should choose the null integrity algorithm if you select one of the AES-GCM/GMAC options as the encryption algorithm. These encryption standards do not use the integrity hash even if you select a non-null option.

**Step 5** Click **OK** to save your changes.

---

### Verifying Site-to-Site VPN Connections

After you configure a site-to-site VPN connection, and deploy the configuration to the device, verify that the system establishes the security association with the remote device.

If the connection cannot be established, use the `ping interface interface_name remote_ip_address` command from the device CLI to ensure there is a path through the VPN interface to the remote device. If there is no connection through the configured interface, you can leave off the `interface interface_name` keyword and determine if connectivity is through a different interface. You might have selected the wrong interface for the connection: you must select the interface that faces the remote device, not the interface that faces the protected network.

If there is a network path, check the IKE versions and keys configured and supported by both endpoints, and adjust the VPN connection as needed. Ensure that no access control or NAT rules are blocking the connection.

#### Procedure

**Step 1** Log into the device CLI as explained in *Logging Into the Command Line Interface (CLI)*, on page 12.

**Step 2** Use the `show ipsec sa` command to verify that the IPSec security association is established.

You should see that the VPN connection is established between your device (the **local addr**) and the remote peer (**current_peer**). The packets (pkts) counts should increase as you send traffic through the connection. The access list should show the local and remote networks for the connection.

For example, the following output shows an IKEv2 connection.

```
> show ipsec sa
interface: site-a-outside
    Crypto map tag: s2sCryptoMap, seq num: 1, local addr: 192.168.2.15
```
Verifying Site-to-Site VPN Connections

The following output shows an IKEv1 connection.

```bash
> show ipsec sa
interface: site-a-outside
  Crypto map tag: s2sCryptoMap, seq num: 1, local addr: 192.168.2.15

```

Cisco Firepower Threat Defense Configuration Guide for Firepower Device Manager, Version 6.2.3
Step 3  Use the `show isakmp sa` command to verify the IKE security associations. You can use the command without the `sa` keyword (or use the `stats` keyword instead) to view IKE statistics. For example, the following output shows an IKEv2 security association.

```
> show isakmp sa

There are no IKEv1 SAs

IKEv2 SAs:

  Session-id:15317, Status:UP-ACTIVE, IKE count:1, CHILD count:1

  Tunnel-id  Local              Remote              Status   Role
      592216161  192.168.2.15/500  192.168.4.6/500     READY  INITIATOR
      Life/Active Time: 86400/12 sec

  Child sa: local selector 192.168.1.0/0 - 192.168.1.255/65535
                 remote selector 192.168.3.0/0 - 192.168.3.255/65535
       ESP spi in/out: 0x52d2f1e4/0xc2d22739c
```

The following output shows an IKEv1 security association.
> show isakmp sa

IKEv1 SAs:

Active SA: 1
Rekey SA: 0 (A tunnel will report 1 Active and 1 Rekey SA during rekey)
Total IKE SA: 1

1 IKE Peer: 192.168.4.6
Type : L2L Role : initiator
Rekey : no State : MM_ACTIVE

There are no IKEv2 SAs

---

Monitoring Site-to-Site VPN

To monitor and troubleshoot site-to-site VPN connections, open the CLI console or log into the device CLI and use the following commands.

- `show ipsec sa` displays the VPN sessions (security associations). You can reset these statistics using the `clear ipsec sa counters` command.
- `show ipsec keyword` displays IPsec operational data and statistics. Enter `show ipsec ?` to see the available keywords.
- `show isakmp` displays ISAKMP operational data and statistics.

Examples for Site-to-Site VPN

The following are examples of configuring site-to-site VPN.

Exempting Site-to-Site VPN Traffic from NAT

When you have a site-to-site VPN connection defined on an interface, and you also have NAT rules for that interface, you can optionally exempt the traffic on the VPN from the NAT rules. You might want to do this if the remote end of the VPN connection can handle your internal addresses.

When you create the VPN connection, you can select the NAT Exempt option to create the rules automatically. However, this works only if your local protected network is connected through a single routed interface (not a bridge group member). If instead, the local networks in the connection reside behind two or more routed interfaces, or one or more bridge group members, you need to manually configure the NAT exempt rules.

To exempt VPN traffic from NAT rules, you create an identity manual NAT rule for the local traffic when the destination is the remote network. Then, apply NAT to the traffic when the destination is anything else (for example, the Internet). If you have more than one interface for the local network, create rules for each interface. Also, consider the following suggestions:

- If there is more than one local network in the connection, create a network object group to hold the objects that define the networks.
• If you are including both IPv4 and IPv6 networks in the VPN, create separate identity NAT rules for each.

Consider the following example, which shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

Figure 23: Interface PAT and Identity NAT for Site-to-Site VPN

The following example explains the configuration for Firewall1 (Boulder). The example assumes that the inside interface is a bridge group, so you need to write the rules for each member interface. The process is the same if you have a single or multiple routed inside interfaces.

Note
This example assumes IPv4 only. If the VPN also includes IPv6 networks, create parallel rules for IPv6. Note that you cannot implement IPv6 interface PAT, so you need to create a host object with a unique IPv6 address to use for PAT.

Procedure

Step 1
Create the objects to define the various networks.
a) Choose Objects.
b) Select Network from the table of contents and click +.
c) Identify the Boulder inside network.
Name the network object (for example, boulder-network), select Network, and enter the network address, 10.1.1.0/24.

![Add Network Object](image)

- Click **OK**.
- Click + and define the inside San Jose network.

Name the network object (for example, sanjose-network), select Network, and enter the network address 10.2.2.0/24.

![Add Network Object](image)

- Click **OK**.

**Step 2** Configure manual identity NAT for the Boulder network when going over the VPN to San Jose on Firewall1 (Boulder).

a) Select **Policies > NAT**.

b) Click the + button.
c) Configure the following properties:

- **Title** = NAT Exempt 1_2 Boulder San Jose VPN (or another name of your choosing).
- **Create Rule For** = Manual NAT.
- **Placement** = Above a Specific Rule, and select the first rule in the Manual NAT Before Auto NAT section. You want to ensure that this rule comes before any general interface PAT rules for the destination interface. Otherwise, the rule might not be applied to the right traffic.
- **Type** = Static.
- **Source Interface** = inside1_2.
- **Destination Interface** = outside.
- **Original Source Address** = boulder-network network object.
- **Translated Source Address** = boulder-network network object.
- **Original Destination Address** = sanjose-network network object.
- **Translated Destination Address** = sanjose-network network object.

**Note** Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank. This rule configures identity NAT for both source and destination.
Step 3 Configure manual dynamic interface PAT when going to the Internet for the inside Boulder network on Firewall1 (Boulder).

**Note** There might already be dynamic interface PAT rules for the inside interfaces, covering any IPv4 traffic, as these are created by default during initial configuration. However, the configuration is shown here for completeness. Before completing these steps, check whether a rule already exists that covers the inside interface and network, and skip this step if it does.

a) Click the + button.
b) Configure the following properties:
   
   • **Title** = inside1_2 interface PAT (or another name of your choosing).
   
   • **Create Rule For** = Manual NAT.
   
   • **Placement** = **Below a Specific Rule**, and select the rule you created above for this interface in the Manual NAT Before Auto NAT section. Because this rule will apply to any destination address, the rule that uses sanjose-network as the destination must come before this rule, or the sanjose-network rule will never be matched. The default is to place new manual NAT rules at the end of the "NAT Rules Before Auto NAT" section, which is also sufficient.
• **Type** = Dynamic.

• **Source Interface** = inside1_2.

• **Destination Interface** = outside.

• **Original Source Address** = boulder-network network object.

• **Translated Source Address** = Interface. This option configures interface PAT using the destination interface.

• **Original Destination Address** = any.

• **Translated Destination Address** = any.

c) Click **OK**.

d) Repeat the process to create equivalent rules for each of the other inside interfaces.

**Step 4**  
Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.
Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

**Step 5**

If you are also managing Firewall2 (San Jose), you can configure similar rules for that device.

- The manual identity NAT rule would be for sanjose-network when the destination is boulder-network. Create new interface objects for the Firewall2 inside and outside networks.
- The manual dynamic interface PAT rule would be for sanjose-network when the destination is "any."

---

## How to Provide Internet Access on the Outside Interface for External Site-to-Site VPN Users (Hair Pinning)

In a site-to-site VPN, you might want users on the remote networks to access the Internet through your device. However, because the remote users are entering your device on the same interface that faces the Internet (the outside interface), you need to bounce Internet traffic right back out of the outside interface. This technique is sometimes called hairpinning.

The following graphic shows an example. There is a site-to-site VPN tunnel configured between 198.51.100.1 (on the main site, Site A) and 203.0.113.1 (the remote site, Site B). All user traffic from the remote site inside network, 192.168.2.0/24, goes through the VPN. Thus, when a user on that network wants to go to a server on the Internet, such as www.example.com, the connection first goes through the VPN, then gets routed back out to the Internet from the 198.51.100.1 interface.

![Example of site-to-site VPN tunnel](image)

The following procedure explains how to configure this service. You must configure both endpoints of the VPN tunnel.

**Procedure**

**Step 1**

(Site A, main site.) Configure the site-to-site VPN connection to remote Site B.

a) Click **Device**, then click **View Configuration** in the Site-to-Site VPN group.

b) Click + to add a new connection.

c) Define the endpoints as follows, and then click **Next**.
• **Connection Profile Name**—Give the connection a meaningful name, for example, Site-A-to-Site-B.

• **Local VPN Access Interface**—Select the outside interface.

• **Local Network**—Keep the default, Any.

• **Remote IP Address**—Enter the IP address of the remote peer’s outside interface. In this example, 203.0.113.1.

• **Remote Network**—Click +, then select the network object that defines the remote peer’s protected network. In this example, 192.168.2.0/24. You can click **Create New Network** to create the object now.

The following graphic shows how the first step should look.

![Connection Profile Name](image)

```
<table>
<thead>
<tr>
<th>Connection Profile Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Site-A-to-Site-B</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>LOCAL SITE</th>
<th>REMOTE SITE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local VPN Access Interface</td>
<td>Remote IP Address</td>
</tr>
<tr>
<td>outside</td>
<td>203.0.113.1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Local Network</th>
<th>Remote Network</th>
</tr>
</thead>
<tbody>
<tr>
<td>+ ANY</td>
<td>+ Site-B-Network</td>
</tr>
</tbody>
</table>
```

d) Define the privacy configuration, then click **Next**.

• **IKE Policy**—The IKE settings have no impact on hair pinning. Simply select the IKE versions, policies, and proposals that fit your security needs. Make note of the local and remote pre-shared keys you enter: you will need these when configuring the remote peer.

• **NAT Exempt**—Select the inside interface.

  **Additional Options**

  **NAT Exempt**

  ![NAT Exempt](image)

  **Diffie Helman Group for Perfect Forward Secrecy**—This setting has no impact on hair pinning. Configure it as you see fit.

e) Click **Finish**.

The connection summary is copied to the clipboard. You can paste it into a text file or other document to help you configure the remote peer.
Step 2  (Site A, main site.) Configure the NAT rule to translate all connections going out the outside interface to ports on the outside IP address (interface PAT).

When you complete the initial device configuration, the system creates a NAT rule named InsideOutsideNatRule. This rule applies interface PAT to IPv4 traffic from any interface that exits the device through the outside interface. Because the outside interface is included in “Any” source interface, the rule you need already exists, unless you edited it or deleted it.

The following procedure explains how to create the rule you need.

a) Click Policies > NAT.

b) Do one of the following:
   - To edit the InsideOutsideNatRule, mouse over the Action column and click the edit icon (محاولة).
   - To create a new rule, click +.

c) Configure a rule with the following properties:
   - **Title**—For a new rule, enter a meaningful name without spaces. For example, OutsideInterfacePAT.
   - **Create Rule For**—Manual NAT.
   - **Placement**—Before Auto NAT Rules (the default).
   - **Type**—Dynamic.
   - **Original Packet**—For **Source Address**, select Any or any-ipv4. For **Source Interface**, ensure that you select Any (which is the default). For all other Original Packet options, keep the default, Any.
   - **Translated Packet**—For **Destination Interface**, select outside. For **Translated Address**, select **Interface**. For all other Translated Packet options, keep the default, Any.

The following graphic shows the simple case where you select Any for the source address.
d) Click **OK**.

**Step 3**  
(Site A, main site.) Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

**Step 4**  
(Site B, remote site.) Log into the remote site’s device, and configure the site-to-site VPN connection to Site A.

Use the connection summary obtained from the Site A device configuration to help you configure the Site B side of the connection.

a) Click **Device**, then click **View Configuration** in the Site-to-Site VPN group.

b) Click + to add a new connection.

c) Define the endpoints as follows, and then click **Next**:

- **Connection Profile Name**—Give the connection a meaningful name, for example, Site-B-to-Site-A.
- **Local VPN Access Interface**—Select the outside interface.
• **Local Network**—Click +, then select the network object that defines the local protected network. In this example, 192.168.2.0/24. You can click **Create New Network** to create the object now.

• **Remote IP Address**—Enter the IP address of the main site’s outside interface. In this example, 198.51.100.1.

• **Remote Network**—Keep the default, Any. Ignore the warning; it is not relevant for this use case.

The following graphic shows how the first step should look.

![Diagram of settings](image)

- **IKE Policy**—The IKE settings have no impact on hair pinning. Configure the same or compatible options as those on Site A’s end of the VPN connection. You must configure the pre-shared keys correctly: switch the local and remote keys (for IKEv2) as configured on the Site A device. For IKEv1, there is just one key, which must be the same on both peers.

- **NAT Exempt**—Select the inside interface.

  ![Diagram of NAT Exempt options](image)

- **Diffie Helman Group for Perfect Forward Secrecy**—This setting has no impact on hair pinning. Match the setting used on Site A’s end of the VPN connection.

  ![Diagram of Diffie Helman Group](image)

de) Define the privacy configuration, then click **Next**.

  • **IKE Policy**—The IKE settings have no impact on hair pinning. Configure the same or compatible options as those on Site A’s end of the VPN connection. You must configure the pre-shared keys correctly: switch the local and remote keys (for IKEv2) as configured on the Site A device. For IKEv1, there is just one key, which must be the same on both peers.

  • **NAT Exempt**—Select the inside interface.

  ![Diagram of NAT Exempt options](image)

  • **Diffie Helman Group for Perfect Forward Secrecy**—This setting has no impact on hair pinning. Match the setting used on Site A’s end of the VPN connection.

c) Click **Finish**.

**Step 5** (Site B, remote site.) Delete all NAT rules for the protected network so that all traffic leaving the site must go through the VPN tunnel.
Performing NAT on this device is unnecessary because the Site A device will do the address translation. But please examine your specific situation. If you have multiple internal networks and not all of them are participating in this VPN connection, do not delete NAT rules that you need for those networks.

a) Click Policies > NAT.
b) Do one of the following:
   • To delete rules, mouse over the Action column and click the delete icon (🗑).
   • To edit rules so they no longer apply to the protected network, mouse over the Action column and click the edit icon (🛠).

**Step 6** (Site B, remote site.) Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button and wait for deployment to finish.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.
Remote Access VPN

Remote Access virtual private network (VPN) allows individual users to connect to your network from a remote location using a computer or other supported iOS or Android device connected to the Internet. This allows mobile workers to connect from their home networks or a public Wi-Fi network, for example.

The following topics explain how to configure remote access VPN for your network.

- Remote Access VPN Overview, on page 353
- Licensing Requirements for Remote Access VPN, on page 355
- Guidelines and Limitations for Remote Access VPN, on page 356
- Configuring Remote Access VPN, on page 356
- Monitoring Remote Access VPN, on page 364
- Troubleshooting Remote Access VPNs, on page 364
- Examples for Remote Access VPN, on page 367

Remote Access VPN Overview

You can use Firepower Device Manager to configure remote access VPN over SSL using the AnyConnect client software.

When the AnyConnect client negotiates an SSL VPN connection with the Firepower Threat Defense device, it connects using Transport Layer Security (TLS) or Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays. The client and Firepower Threat Defense device negotiate the TLS/DTLS version to use. DTLS is used if the client supports it.

Maximum Concurrent VPN Sessions By Device Model

There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

<table>
<thead>
<tr>
<th>Device Model</th>
<th>Maximum Concurrent Remote Access VPN Sessions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASA 5506-X, 5506H-X, 5506W-X</td>
<td>50</td>
</tr>
<tr>
<td>ASA 5508-X</td>
<td>100</td>
</tr>
</tbody>
</table>
## Maximum Concurrent Remote Access VPN Sessions

### Downloading the AnyConnect Client Software

Before you can configure a remote access VPN, you must download the AnyConnect software to your workstation. You will need to upload these packages when defining the VPN.

You should download the latest AnyConnect version, to ensure that you have the latest features, bug fixes, and security patches. Regularly update the packages on the Firepower Threat Defense device.

#### Note

You can upload one AnyConnect package per operating system: Windows, Mac, and Linux. You cannot upload multiple versions for a given OS type.

Obtain the AnyConnect software packages from software.cisco.com in the AnyConnect Secure Mobility Client category. You need to download the “Full Installation Package” versions of the clients.

### How Users Can Install the AnyConnect Software

To complete a VPN connection, your users must install the AnyConnect client software. You can use your existing software distribution methods to install the software directly. Or, you can have users install the AnyConnect client directly from the Firepower Threat Defense device.

Users must have Administrator rights on their workstations to install the software.

Once the AnyConnect client is installed, if you upload new AnyConnect versions to the system, the AnyConnect client will detect the new version on the next VPN connection the user makes. The system will automatically prompt the user to download and install the updated client software. This automation simplifies software distribution for you and your clients.
If you decide to have users initially install the software from the Firepower Threat Defense device, tell users to perform the following steps.

Note
Android and iOS users should download AnyConnect from the appropriate App Store.

Procedure

Step 1
Using a web browser, open https://ravpn-address, where ravpn-address is the IP address or hostname of the outside interface on which you are allowing VPN connections.

You identify this interface when you configure the remote access VPN. The system prompts the user to log in.

Step 2
Log into the site.

Users are authenticated using the directory server configured for the remote access VPN. Log in must be successful to continue.

If log in is successful, the system determines if the user already has the required version of the AnyConnect client. If the AnyConnect client is absent from the user’s computer, or is down-level, the system automatically starts installing the AnyConnect software.

When installation is finished, AnyConnect completes the remote access VPN connection.

Licensing Requirements for Remote Access VPN

Your base device license must meet export requirements before you can configure remote access VPN. When you register the device, you must do so with a Smart Software Manager account that is enabled for export-controlled features. You also cannot configure the feature using the evaluation license.

In addition, you need to purchase and enable a remote access VPN license, any of the following: AnyConnect Plus, AnyConnect Apex, or AnyConnect VPN Only. These licenses are treated the same for Firepower Threat Defense devices, even though they are designed to allow different feature sets when used with ASA Software-based headends.

To enable the license, select Device > Smart License > View Configuration, then select the appropriate license in the RA VPN License group. You need to have the license available in your Smart Software Manager account. For more information about enabling licenses, see Enabling or Disabling Optional Licenses, on page 84.

Guidelines and Limitations for Remote Access VPN

Please keep the following guidelines and limitations in mind when configuring RA VPN.

- You cannot configure both Firepower Device Manager access (HTTPS access in the management access list) and AnyConnect remote access SSL VPN on the same interface for the same TCP port. For example, if you configure remote access SSL VPN on the outside interface, you cannot also open the outside interface for HTTPS connections on port 443. Because you cannot configure the port used by these features in Firepower Device Manager, you cannot configure both features on the same interface.

- You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.

Configuring Remote Access VPN

To enable remote access VPN for your clients, you need to configure a number of separate items. The following procedure provides the end to end process.

Procedure

Step 1 Configure licenses.

You need to enable two licenses:

- When you register the device, you must do so with a Smart Software Manager account that is enabled for export-controlled features. The base license must meet export control requirements before you can configure remote access VPN. You also cannot configure the feature using the evaluation license. For the procedure to register the device, see Registering the Device, on page 83.

- A remote access VPN license. For details, see Licensing Requirements for Remote Access VPN, on page 355. To enable the license, see Enabling or Disabling Optional Licenses, on page 84.

Step 2 Configure Certificates.

Certificates are required to authenticate SSL connections between the clients and the device. You can use the pre-defined DefaultInternalCertificate for the VPN, or create your own.

If you use an encrypted connection for the directory realm used for authentication, you must upload a trusted CA certificate.

For more information on certificates and how to upload them, see Configuring Certificates, on page 126.

Step 3 (Optional.) Configure and Upload Client Profiles, on page 357.

Step 4 Configure the identity realm used for authenticating remote users. See Configuring AD Identity Realms, on page 116.

The identity realm defines the directory server that contains user accounts for your network.

Step 5 Configure a Remote Access VPN Connection, on page 358.

Step 6 (Optional.) Control Access to Resources by Remote Access VPN Group, on page 361.
If you do not want all of your remote access users to have the same access to all internal resources, you can apply access control rules to allow or prevent access based on user group membership.

**Step 7**  
Verify the Remote Access VPN Configuration, on page 362.  
If you encounter problems completing a connection, see Troubleshooting Remote Access VPNs, on page 364.

---

## Configure and Upload Client Profiles

AnyConnect client profiles are downloaded to clients along with the AnyConnect client software. These profiles define many client-related options, such as auto connect on startup and auto reconnect, and whether the end user is allowed to change the option from the AnyConnect client preferences and advanced settings.

If you configure a fully-qualified hostname (FQDN) for the outside interface when configuring the remote access VPN connection, the system creates a client profile for you. This profile enables the default settings. You need to create and upload client profiles only if you want non-default behavior. Note that client profiles are optional: if you do not upload one, AnyConnect clients will use default settings for all profile-controlled options.

---

**Note**

You must include the Firepower Threat Defense device’s outside interface in the VPN profile’s server list in order for the AnyConnect client to display all user controllable settings on the first connection. If you do not add the address or FQDN as a host entry in the profile, then filters do not apply for the session. For example, if you create a certificate match and the certificate properly matches the criteria, but you do not add the device as a host entry in that profile, the certificate match is ignored.

The following procedure explains how you can create and edit objects directly through the Objects page. You can also create AnyConnect client profile objects while editing a profile property by clicking the Create New AnyConnect Client Profile link shown in the object list.

### Before you begin

Before you can upload client profiles, you must do the following.

- Download and install the stand-alone AnyConnect “Profile Editor - Windows / Standalone installer (MSI).” The installation file is for Windows only, and has the file name anyconnect-profileeditor-win-<version>-k9.msi, where <version> is the AnyConnect version. For example, anyconnect-profileeditor-win-4.3.04027-k9.msi. You must also install Java JRE 1.6 (or higher) before installing the profile editor. Obtain the AnyConnect profile editor from software.cisco.com in the AnyConnect Secure Mobility Client category.

- Use the profile editor to create the profiles you need. You should specify the hostname or IP address of the outside interface in the profile. For detailed information, see the editor’s online help.

### Procedure

**Step 1** Select **Objects**, then select **AnyConnect Client Profile** from the table of contents.

**Step 2** Do one of the following:
Configure a Remote Access VPN Connection

You can create a remote access VPN connection to allow your users to connect to your inside networks when they are on external networks, such as their home network.

Before you begin

Before configuring the remote access (RA) VPN connection:

- Download the required AnyConnect software packages from software.cisco.com to your workstation.
- Optionally, use the AnyConnect Profile Editor to create a client profile. The system will create a default profile for you if you specify a fully-qualified domain name for the outside interface. Client profiles are optional, create one only if you want to customize features controlled by the profile.
- The outside interface, the one that terminates remote access VPN connections, cannot also have a management access list that allows HTTPS connections. Delete any HTTPS rules from the outside interface before configuring RA VPN. See Configuring the Management Access List, on page 391.

Procedure

Step 1 Click Device, then click Setup Connection Profile in the Remote Access VPN group.

You can configure one remote access VPN. If you have already configured it, clicking View Configuration opens your existing VPN; click the Edit button to make changes.

If you want to delete the configuration, click Clear Configuration.

Step 2 Define the AnyConnect client configuration.

- **Connection Profile Name**—The name for this connection, up to 50 characters without spaces. For example, MainOffice. You cannot use an IP address as the name.

  **Note** The name you enter here is what users will see in the connection list in the AnyConnect client. Choose a name that will make sense to your users.
• **AD Realm/Directory Server for User Authentication**—The directory realm that defines the directory server to use for client authentication. End users must be defined in this directory server to complete a VPN connection.

• **Fallback Local Identity Source**—If the primary source is an external server, you can select the LocalIdentitySource as a fallback in case the primary server is unavailable. If you use the local database as a fallback source, ensure that you define the same local usernames/passwords as the ones defined in the external server.

• **AnyConnect Packages**—The AnyConnect full installation software images that you will support on this VPN connection. For each package, the filename, including extensions, can be no more than 60 characters. You can upload separate packages for Windows, Mac, and Linux endpoints. Download the packages from software.cisco.com. If the endpoint does not already have the right package installed, the system prompts the user to download and install the package after the user authenticates.

Step 3  Click Next.

Step 4  Define the device identity and client addressing configuration.

• **Certificate of Device Identity**—Select the internal certificate used to establish the identity of the device. Clients must accept this certificate to complete a secure VPN connection. If you do not already have a certificate, click Create New Internal Certificate in the drop-down list. You must configure a certificate.

• **Outside Interface**—The interface to which users connect when making the remote access VPN connection. Although this is normally the outside (Internet-facing) interface, choose whichever interface is between the device and the end users you are supporting with this connection profile.

• **Fully-qualified Domain Name for the Outside Interface**—The name of the interface, for example, ravpn.example.com. If you specify a name, the system can create a client profile for you.

  **Note**  You are responsible for ensuring that the DNS servers used in the VPN and by clients can resolve this name to the outside interface's IP address. Add the FQDN to the relevant DNS servers.

• **IPv4, IPv6 Address Pools**—These options define the address pools for the remote endpoints. Clients are assigned an address from these pools based on the IP version they use to make the VPN connection. Select a network object that defines a subnet for each IP type you want to support. Select None (or leave blank) if you do not want to support that IP version. For example, you could define an IPv4 pool as 10.100.10.0/24. The address pool cannot be on the same subnet as the IP address for the outside interface.

• **Primary, Secondary DNS Servers**—The DNS servers clients should use for domain name resolution when connected to the VPN. Click the OpenDNS button to load these fields with the OpenDNS public DNS servers. Otherwise, enter the IP addresses of your DNS servers.

• **Domain Search Name**—Enter the domain name for your network, e.g. example.com. This domain is added to hostnames that are not fully-qualified, for example, serverA instead of serverA.example.com.

Step 5  Click Next.

Step 6  Define the connection settings to customize AnyConnect client behavior.

• **Banner Text for Authenticated Clients**—(Optional.) Enter any message you want to show to users at the beginning of their VPN session. For example, legal disclaimers and warnings about appropriate use. The banner can be up to 500 characters, but cannot contain semi-colons (;) or HTML tags.
Configure a Remote Access VPN Connection

- **Maximum Connection Time**—The maximum length of time, in minutes, that users are allowed to stay connected to the VPN without logging out and reconnecting, from 1-4473924 or blank. The default is unlimited (blank), but the idle timeout still applies.

- **Idle Timeout**—The length of time, in minutes, that the VPN connection can be idle before it is automatically closed, from 1-35791394. The default is 30 minutes.

- **Browser Proxy During VPN Sessions**—Whether proxies are used during a VPN session for Internet Explorer web browsers on Windows client devices. Select from the following options:
  - **No change in endpoint settings**—Allow the user to configure (or not configure) a browser proxy, and use the proxy if it is configured.
  - **Disable browser proxy**—Do not use the proxy defined for the browser, if any. No browser connections will go through the proxy.
  - **Auto detect settings**—Enables the use of automatic proxy server detection in the browser.
  - **Use custom settings**—Configures a proxy for the client browser. Enter the IP address and optionally, port, for the HTTP proxy server (the host and port combined cannot exceed 100 characters). You can also click Add Proxy Exception if you want to exempt requests to specific web servers from going through the proxy (specifying the port in the exception list is optional). The entire proxy exception list, combining all addresses and ports, cannot be longer than 255 characters.

- **Split Tunneling**—Enable split-tunneling to allow users access to their local networks or the Internet directly at the same time they are using a secure VPN tunnel. Keep split-tunneling disabled for a more secure VPN connection. If you enable split tunneling, you must also select the network objects that represent internal networks remote users will be accessing in the **Inside Networks** list. The networks list must contain the same IP types as the address pools you are supporting. For any networks outside the ones specified, the user’s ISP gateway is used for transmitting traffic.

- **NAT Exempt**—Enable NAT Exempt to exempt traffic to and from the remote access VPN endpoints from NAT translation. If you do not exempt VPN traffic from NAT, ensure that the existing NAT rules for the outside and inside interfaces do not apply to the RA VPN pool of addresses. NAT exempt rules are manual static identity NAT rules for a given source/destination interface and network combination, but they are not reflected in the NAT policy, they are hidden. If you enable NAT Exempt, you must also configure the following.
  - **Inside Interfaces**—Select the interfaces for the internal networks remote users will be accessing. NAT rules are created for these interfaces.
  - **Inside Networks**—Select the network objects that represent internal networks remote users will be accessing. The networks list must contain the same IP types as the address pools you are supporting.

- **AnyConnect Client Profiles**—(Optional.) If you configure a fully-qualified domain name for the outside interface, a default profile will be created for you. Alternatively, you can upload your own client profile. Create these profiles using the standalone AnyConnect Profile Editor, which you can download and install from software.cisco.com. If you do not select a client profile, the AnyConnect client uses default values for all options. The items in this list are AnyConnect Client Profile objects rather than the profiles themselves. You can create (and upload) new profiles by clicking **Create New AnyConnect Client Profile** in the drop-down list.

**Step 7**  Click Next.

**Step 8**  Review the summary.
First, verify that the summary is correct.

Then, click **Instructions** to see what end users need to do to initially install the AnyConnect software and test that they can complete a VPN connection. Click **Copy** to copy these instructions to the clipboard, and then distribute them to your users.

**Step 9**

Click **Finish**.

---

**Control Access to Resources by Remote Access VPN Group**

If you are familiar with configuring remote access VPN on an ASA, or on a FTD device using Firepower Management Center, then you might be used to controlling access to various resources in your network based on remote access VPN groups.

With Firepower Device Manager, you can configure a single connection profile with a single group policy. However, you can still control access based on user groups by implementing identity policies and user-group-based access control.

The following procedure explains the configuration.

**Before you begin**

This procedure assumes that you have already configured remote access VPN and the required identity realm. However, you can configure the identity and access control policies first, and then configure RA VPN.

This configuration requires that VPN traffic be subject to the access control policy. In the CLI, use the `show running-config` command to check that the `no sysopt connection permit-vpn` command appears. If it is not in the running configuration, use FlexConfig to configure the command.

**Procedure**

**Step 1**

Configure the required user groups in the directory server.

The directory server must have user groups, and those groups must contain the right users, based on the policies you want to deploy. For example, if you want to differentiate between Engineering and Marketing users, and allow group members access to different resources, you must have groups for those users defined in the directory server.

You cannot create user groups directly on the FTD device.

See the documentation for the directory server for information on creating user groups.

**Step 2**

Choose **Policies > Identity**, enable the identity policy, and create a rule to enforce active authentication for RA VPN users.

The identity policy uses the same realm as the RA VPN connection. At minimum, you must have an identity policy that requires active authentication for the IP addresses in the RA VPN address pool for the zone that contains the RA VPN outside interface.

If you have a blanket identity policy that requires active authentication for all addresses and all zones, you do not need any additional rules.

For the information on enabling the policy and creating rules, see **Configuring Identity Policies, on page 188**.
You must configure the identity rule because only names collected through identity policy authentication are available for user-based access control policies. Usernames obtained from RA VPN connections only cannot be used by access control policies.

**Step 3**
Click the **Deploy** button in the menu, then click the **Deploy Now** button, to deploy your changes.

The system needs to establish a connection to the directory server and download users and user groups. Deploying the configuration starts off this user/group download. If you do not deploy, then users and groups will not be selectable in access control rules.

**Step 4**
Choose **Policies > Access Control**, and create group-based access control rules.

You can now create access control rules to differentiate between the directory realm groups for RA VPN users. You can create very general rules, or specifically-targeted rules. For information on creating access control rules, see Configuring Access Control Rules, on page 211.

For example, rules targeted to specific RA VPN user groups might use the following criteria, based on the tabs in the Add/Edit Access Rule dialog box:

- **Source/Destination, Zones**—The **Source** zone should include the RA VPN outside interface. The **Destination** zone can include any relevant inside interfaces.

- **Source/Destination, Networks and Ports**—Select the RA VPN address pool network object as the **Source** network, and the network (and optionally port) objects that define the controlled resources as the **Destination** network/port. Instead of selecting a destination network/port, you can use the **Application** or **URL** tabs to define the destination resource if that is more appropriate for your requirements.

- **Users**—Select the specific directory groups on this tab. This is the criterion that provides group-based access control.

- **Applications, URLs**—You can use these criteria in addition to, or instead of, the destination network/ports criteria on the **Source/Destination** tab. For example, you can select a network object to limit the rule to a specific subnet, and then select applications to control access to those applications on the targeted network.

- **Intrusion Policy, File Policy**—Select the options that fit your requirements. These options control threats, they do not control access to specific resources.

- **Logging**—Select the option that fits your requirements. You must enable logging to see any results in the monitoring dashboards or connection events in Event Viewer.

---

**Verify the Remote Access VPN Configuration**

After you configure the remote access VPN, and deploy the configuration to the device, verify that you can make remote connections.

If you encounter problems, read through the troubleshooting topics to help isolate and correct the problems. See Troubleshooting Remote Access VPNs, on page 364.
Procedure

**Step 1**
From an external network, establish a VPN connection using the AnyConnect client.
Using a web browser, open [https://ravpn-address](https://ravpn-address), where `ravpn-address` is the IP address or hostname of the outside interface on which you are allowing VPN connections. If necessary, install the client software and complete the connection. See How Users Can Install the AnyConnect Software, on page 354.

**Step 2**
Log into the device CLI as explained in Logging Into the Command Line Interface (CLI), on page 12. Alternatively, open the CLI Console.

**Step 3**
Use the `show vpn-sessiondb` command to view summary information about current VPN sessions.
The statistics should show your active AnyConnect Client session, and information on cumulative sessions, the peak concurrent number of sessions, and inactive sessions. Following is sample output from the command.

```
> show vpn-sessiondb

VPN Session Summary
---------------------------------------------------------------------------
Active : Cumulative : Peak Concur : Inactive
---------------------------------------------------------------------------
AnyConnect Client : 1 : 49 : 3 : 0
SSL/TLS/DTLS : 1 : 49 : 3 : 0
Clientless VPN : 0 : 1 : 1
Browser : 0 : 1 : 1
---------------------------------------------------------------------------
Total Active and Inactive : 1 Total Cumulative : 50
Device Total VPN Capacity : 10000
Device Load : 0%
---------------------------------------------------------------------------

Tunnels Summary
---------------------------------------------------------------------------
Active : Cumulative : Peak Concurrent
---------------------------------------------------------------------------
Clientless : 0 : 1 : 1
AnyConnect-Parent : 1 : 49 : 3
SSL-Tunnel : 1 : 46 : 3
DTLS-Tunnel : 1 : 46 : 3
---------------------------------------------------------------------------
Totals : 3 : 142
---------------------------------------------------------------------------

IPv6 Usage Summary
---------------------------------------------------------------------------
Active : Cumulative : Peak Concurrent
---------------------------------------------------------------------------
AnyConnect SSL/TLS/DTLS :
Tunneled IPv6 : 1 : 20 : 2
---------------------------------------------------------------------------
```

**Step 4**
Use the `show vpn-sessiondb anyconnect` command to view detailed information about current AnyConnect VPN sessions.
Monitoring Remote Access VPN

To monitor and troubleshoot remote access VPN connections, open the CLI console or log into the device CLI and use the following commands.

- `show vpn-sessiondb anyconnect` displays information about VPN sessions. You can reset these statistics using the `clear vpn-sessiondb` command.

- `show webvpn keyword` displays information about the remote access VPN configuration, including statistics and the AnyConnect images installed. Enter `show webvpn ?` to see the available keywords.

- `show aaa-server` displays statistics about the directory server used with remote access VPN.

Troubleshooting Remote Access VPNs

Remote access VPN connection issues can originate in the client or in the Firepower Threat Defense device configuration. The following topics cover the main troubleshooting problems you might encounter.

Troubleshooting SSL Connection Problems

If the user cannot make the initial, non-AnyConnect, SSL connection to the outside IP address to download the AnyConnect client, do the following:

1. From the client workstation, verify that you can ping the IP address of the outside interface. If you cannot, determine why there is no route from the user’s workstation to the address.
2. From the client workstation, verify that you can ping the fully-qualified domain name (FQDN) of the outside interface, the one defined in the remote access (RA) VPN connection profile. If you can ping the IP address but not the FQDN, then you need to update the DNS servers used by the client and RA VPN connection profile to add the FQDN-to-IP-address mapping.

3. Verify that the user is accepting the certificate presented by the outside interface. The user should accept it permanently.

4. Examine the RA VPN connection configuration and verify that you selected the correct outside interface. A common mistake is to select an inside interface, the one facing the internal networks, rather than the outside interface, which faces the RA VPN users.

5. If SSL encryption is properly configured, use an external sniffer to verify whether the TCP three-way handshake is successful.

Troubleshooting AnyConnect Download and Installation Problems

If the user can make an SSL connection to the outside interface, but cannot download and install the AnyConnect package, consider the following:

- Ensure that you uploaded an AnyConnect package for the client’s operating system. For example, if the user’s workstation runs Linux, but you did not upload a Linux AnyConnect image, there is no package that can be installed.
- For Windows clients, the user must have Administrator rights to install software.
- For Windows clients, the workstation must enable ActiveX or install Java JRE 1.5 or higher, with JRE 7 recommended.
- For Safari browsers, Java must be enabled.
- Try different browsers, one might fail where another succeeds.

Troubleshooting AnyConnect Connection Problems

If the user was able to connect to the outside interface, download, and install the AnyConnect client, but could not then complete a connection using AnyConnect, consider the following:

- If authentication fails, verify that the user is entering the correct username and password, and that the username is defined correctly in the authentication server. The authentication server must also be available through one of the data interfaces.

  Note: If the authentication server is on an external network, you need to configure a site-to-site VPN connection to the external network, and include the remote access VPN interface address within the VPN. For details, see How to Use a Directory Server on an Outside Network with Remote Access VPN, on page 372.

- If you configured a fully-qualified domain name (FQDN) for the outside interface in the remote access (RA) VPN connection profile, verify that you can ping the FQDN from the client device. If you can ping the IP address but not the FQDN, then you need to update the DNS servers used by the client and RA VPN connection profile to add the FQDN-to-IP-address mapping. If you are using the default AnyConnect...
client profile that is generated when you specify an FQDN for the outside interface, the user will need to edit the server address to use the IP address until DNS is updated.

- Verify that the user is accepting the certificate presented by the outside interface. The user should accept it permanently.

- If the user’s AnyConnect client includes multiple connection profiles, that they are selecting the right one.

- If everything seems right on the client end, make an SSH connection to the Firepower Threat Defense device, and enter the `debug webvpn` command. Examine the messages issued during a connection attempt.

**Troubleshooting RA VPN Traffic Flow Problems**

If the user can make a secure remote access (RA) VPN connection, but cannot send and receive traffic, do the following:

1. Have the client disconnect, then reconnect. Sometimes this eliminates the problem.

2. In the AnyConnect client, check the traffic statistics to determine whether both the sent and received counters are increasing. If the received packet count stays at zero, the Firepower Threat Defense device is not returning any traffic. There is likely a problem in the Firepower Threat Defense configuration. Common problems include the following:
   - Access rules are blocking traffic. Check the access control policy for rules that prevent traffic between the inside networks and the RA VPN address pool. You might need to create an explicit Allow rule if your default action is to block traffic.
   - NAT rules are not being bypassed for the RA VPN traffic. Ensure that NAT exempt is configured for the RA VPN connection for every inside interface. Alternatively, ensure that the NAT rules do not prevent communication between the inside networks and interfaces and the RA VPN address pool and outside interface.
   - Routes are misconfigured. Ensure that all defined routes are valid and functioning correctly. For example, if you have a static IP address defined for the outside interface, ensure that the routing table includes a default route (for 0.0.0.0/0 and ::/0).
   - Ensure that the DNS server and domain name configured for the RA VPN are correct, and that the client system is using the correct ones. Verify that the DNS servers are reachable.
   - If you enable split tunneling in the RA VPN, check whether traffic to the specified inside networks is going through the tunnel, while all other traffic is bypassing the tunnel (so that the Firepower Threat Defense device does not see it).

3. Make an SSH connection to the Firepower Threat Defense device and verify that traffic is being sent and received for the remote access VPN. Use the following commands.

   - `show webvpn anyconnect`
   - `show vpn-sessiondb`
Examples for Remote Access VPN

The following are examples of configuring remote access VPN.

How to Provide Internet Access on the Outside Interface for Remote Access VPN Users (Hair Pinning)

In remote access VPN, you might want users on the remote networks to access the Internet through your device. However, because the remote users are entering your device on the same interface that faces the Internet (the outside interface), you need to bounce Internet traffic right back out of the outside interface. This technique is sometimes called hair pinning.

The following graphic shows an example. There is a remote access VPN configured on the outside interface, 198.51.100.1. You want to split the remote user’s VPN tunnel, so that Internet-bound traffic goes back out the outside interface, while traffic to your internal networks continue through the device. Thus, when a remote user wants to go to a server on the Internet, such as www.example.com, the connection first goes through the VPN, then gets routed back out to the Internet from the 198.51.100.1 interface.

The following procedure explains how to configure this service.

Before you begin

This example assumes that you have already registered the device, applied a remote access VPN license, and uploaded an AnyConnect client image. It also assumes that you have configured the identity realm, which is also used in Identity policies.

Procedure

Step 1
Configure the remote access VPN connection profile.

a) Click Device, then click Setup Connection Profile in the Remote Access VPN group. (Click View Configuration if you already configured a profile).

For existing connections, click Edit to modify the profile.

b) Configure the connection profile settings:

• Connection Profile Name—Enter a name, for example, Corporate-RAVPN.
• **AD Realm/Directory Server for User Authentication**—Select the identity realm used for authenticating remote users. If you have not already configured one, click **Create New Identity Realm** at the bottom of the drop-down list and create it now.

• **AnyConnect Packages**—Upload AnyConnect clients for each operating system you will support. Wait for the upload to complete before continuing.

The connection profile settings should look similar to the following:

![Connection Profile Settings](image)

- **Certificate of Device Identity**—Select the internal certificate used to establish the identity of the device. Clients must accept this certificate to complete a secure VPN connection. You can use the DefaultInternalCertificate if you do not have your own.

- **Outside Interface**—Select your outside interface, to which remote users will connect. This interface is normally named “outside.”

- **Fully-qualified Domain Name for the Outside Interface**—If you have a DNS name for the outside interface, enter it here. For example, corporate-vpn.example.com.

The device identity section of the page might look like the following:

![Device Identity Settings](image)
d) Continue down the page and configure the IPv4 Address Pool and optionally, the IPv6 Address Pool. Select an object that identifies a network. Remote access VPN users are assigned an address from this pool. For example, a network object that specifies 10.1.10.0/24. If the object does not already exist, click Create New Network at the bottom of the list. Also configure a pool for IPv6 if you support those addresses.

```
Certificate of Device Identity
DefaultInternalCertificate

Outside Interface
AnyConnect clients connect to this interface
outside

Fully-qualified Domain Name for the Outside Interface

```

corporate-vpn.example.com

e.g. ad.example.com

```
IPv4 Address Pool
Endpoints are provided an address from this pool

```
ravpn-pool

IPv6 Address Pool
Endpoints are provided an address from this pool

```
Please select

e) Scroll down the page and configure the DNS settings for remote connections.

Enter the IP addresses of the DNS servers you use, and your local domain name, for example, example.com. You can click OpenDNS to use the Open DNS servers.

```
Primary DNS IP Address

```
208.67.222.222

```
Secondary DNS IP Address

```
208.67.220.220

```
Domain Search Name

```
example.com
```
f) Click **Next**, scroll down, and configure the Corporate Resource options.

(You can also configure the banner, connection time and timeout, and proxy settings, but these are not directly related to hair pinning.)

The following settings are critical to making hair pinning possible in the remote access VPN.

- **Split Tunneling**—Disable this feature. You want all traffic to go to the VPN gateway, whereas split tunneling is a way to allow remote clients to directly access local or Internet sites outside of the VPN.

- **NAT Exempt**—Enable this feature. Select the inside interface, then select a network object that defines the internal networks. In this example, the object should specify 192.168.1.0/24. RA VPN traffic going to the internal network will not get address translation. However, because hair-pinned traffic is going out the outside interface, it will still be NAT’ed because the NAT exemption applies to the inside interface only.

![Split Tunneling and NAT Exempt settings](image)

- **Inside Interfaces**
The interfaces through which remote access VPN users can connect to the internal networks

![Inside Interfaces](image)

- **Inside Networks**
The internal networks remote access VPN users are allowed to use. The IP versions of the internal networks and address pools must match, either IPv4, IPv6, or both.

![Inside Networks](image)

![g) Optionally, select an AnyConnect Client Profile, then click Next.](image)

h) Review the RA VPN configuration, then click **Finish**.

**Step 2** Configure the NAT rule to translate all connections going out the outside interface to ports on the outside IP address (interface PAT).

When you complete the initial device configuration, the system creates a NAT rule named InsideOutsideNatRule. This rule applies interface PAT to IPv4 traffic from any interface that exits the device through the outside interface. Because the outside interface is included in “Any” source interface, the rule you need already exists, unless you edited it or deleted it.

The following procedure explains how to create the rule you need.

a) Click **Policies > NAT**.

b) Do one of the following:

   - To edit the InsideOutsideNatRule, mouse over the **Action** column and click the edit icon (🔗).
   - To create a new rule, click +.
c) Configure a rule with the following properties:

- **Title**—For a new rule, enter a meaningful name without spaces. For example, OutsideInterfacePAT.
- **Create Rule For**—Manual NAT.
- **Placement**—Before Auto NAT Rules (the default).
- **Type**—Dynamic.
- **Original Packet**—For Source Address, select either Any or any-ipv4. For Source Interface, ensure that you select Any (which is the default). For all other Original Packet options, keep the default, Any.
- **Translated Packet**—For Destination Interface, select outside. For Translated Address, select Interface. For all other Translated Packet options, keep the default, Any.

The following graphic shows the simple case where you select Any for the source address.

![Rule Configuration Graphic]

d) Click OK.

**Step 3** Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.
Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

How to Use a Directory Server on an Outside Network with Remote Access VPN

You can configure a remote access VPN to allow mobile workers and telecommuters to securely connect to your internal networks. Security of the connection depends on your directory server, which authenticates the user connection to ensure that only authorized users can gain entry.

If your directory server is on an outside network rather than an inside network, you need to configure a site-to-site VPN connection from the outside interface to the network that includes the directory server. **There is one trick to the site-to-site VPN configuration:** you must include the outside interface address of the remote access VPN device within the "inside" networks of the site-to-site VPN connection, and also in the remote networks for the device behind which the directory server resides. This will be explained further in the following procedure.

**Note**

If you use the data interfaces as a gateway for the virtual management interface, this configuration also enables usage of the directory for identity policies. If you do not use data-interfaces as the management gateway, ensure that there is a route from the management network to the inside network that participates in the site-to-site VPN connection.

This use case implements the following network scenario.

<table>
<thead>
<tr>
<th>Figure Callout</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Remote access host that makes a VPN connection to 192.168.4.6. Clients will get an address in the 172.18.1.0/24 address pool.</td>
</tr>
</tbody>
</table>
### Figure Callout

<table>
<thead>
<tr>
<th>Figure Callout</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Site A, which hosts the remote access VPN.</td>
</tr>
<tr>
<td>3</td>
<td>The site-to-site VPN tunnel between the outside interfaces of the Site A and Site B FTD devices.</td>
</tr>
<tr>
<td>4</td>
<td>Site B, which hosts the directory server.</td>
</tr>
<tr>
<td>5</td>
<td>The directory server, on the inside network of Site B.</td>
</tr>
</tbody>
</table>

### Before you begin

This use case assumes that you followed the device setup wizard to establish a normal baseline configuration. Specifically:

- There is an Inside_Outside_Rule access control rule that allows (or trusts) traffic going from the inside_zone to the outside_zone.
- The inside_zone and outside_zone security zones contain the inside and outside interfaces (respectively).
- There is an InsideOutsideNATRule that performs interface PAT for all traffic coming from inside interfaces going to the outside interface. On devices that use an inside bridge group by default, there might be several rules for interface PAT.
- There is a static IPv4 route for 0.0.0.0/0 that points to the outside interface. This example assumes that you are using static IP addresses for the outside interfaces, but you could also use DHCP and obtain the static route dynamically. For this example, we are assuming the following static routes:
  - Site A: outside interface, gateway is 192.168.4.254.
  - Site B: outside interface, gateway is 192.168.2.254.

### Procedure

**Step 1** Configure the site-to-site VPN connection on **Site B**, which hosts the directory server.

a) Click **Device**, then click **View Configuration** in the Site-to-Site VPN group.

b) Click the + button.

c) Configure the following options for **Endpoint Settings**.

- **Connection Profile Name**—Enter a name, for example, SiteA (to indicate that the connection is to Site A).
- **Local Site**—These options define the local endpoint.
  - **Local VPN Access Interface**—Select the outside interface (the one with the 192.168.2.1 address in the diagram).
  - **Local Network**—Click + and select the network object that identifies the local network that should participate in the VPN connection. Because the directory server is on this network, it can participate in the site-to-site VPN. Assuming that the object does not already exist, click **Create New Network** and configure an object for the 192.168.1.0/24 network. After saving the object, select it in the drop-down list and click **OK**.
Remote Site—These options define the remote endpoint.

- **Remote IP Address**—Enter 192.168.4.6, which is the IP address of the remote VPN peer's interface that will host the VPN connection.

- **Remote Network**—Click + and select the network objects that identify the remote networks that should participate in the VPN connection. Click **Create New Network**, configure the following objects, then select them in the list.

1. SiteAInside, Network, 192.168.3.0/24.
2. SiteAInterface, Host, 192.168.4.6. **This is key:** you must include the remote access VPN connection point address as part of the remote network for the site-to-site VPN connection so that the RA VPN hosted on that interface can use the directory server.

When you are finished, the endpoint settings should look like the following:

<table>
<thead>
<tr>
<th>Connection Profile Name</th>
<th>LOCAL SITE</th>
<th>REMOTE SITE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Local VPN Access Interface</td>
<td>Remote IP Address</td>
</tr>
<tr>
<td></td>
<td>outside</td>
<td>192.168.4.6</td>
</tr>
<tr>
<td>Local Network</td>
<td></td>
<td>Remote Network</td>
</tr>
<tr>
<td></td>
<td>+</td>
<td>SiteAInside</td>
</tr>
<tr>
<td></td>
<td>Network192.168.1.0</td>
<td>SiteAInterface</td>
</tr>
</tbody>
</table>

- d) Click **Next**.
- e) Define the privacy configuration for the VPN.

For this use case, we assume you qualify for export controlled features, which allows the use of strong encryption. Adjust these example settings to meet your needs and your license compliance.
• **IKE Version 2, IKE Version 1**—Keep the defaults, IKE Version 2 enabled, IKE Version 1 disabled.

• **IKE Policy**—Click **Edit** and enable **AES-GCM-NULL-SHA** and **AES-SHA-SHA**, and disable **DES-SHA-SHA**.

• **IPSec Proposal**—Click **Edit**. In the Select IPSec Proposals dialog box, click +, then click **Set Default** to choose the default AES-GCM proposals.

• **Local Preshared Key, Remote Peer Preshared Key**—Enter the keys defined on this device and on the remote device for the VPN connection. These keys can be different in IKEv2. The key can be 1-127 alphanumeric characters. **Remember these keys, because you must configure the same strings when creating the site-to-site VPN connection on the Site A device.**

The IKE policy should look like the following:

IKE Policy

IKE VERSION 2  
IKE VERSION 1  
IKE Policy  
Globally applied  
EDIT...  
IPSec Proposal  
Default set selected  
EDIT...  
Local Pre-shared Key  
REMOTEkees  
Remote Peer Pre-shared Key  
REMOTEkees

f) Configure the **Additional Options**.

• **NAT Exempt**—Select the interface that hosts the inside network, in this example, the **inside** interface. Typically, you do not want traffic within a site-to-site VPN tunnel to have their IP addresses translated. This option works only if the local network resides behind a single routed interface (not a bridge group member). If the local network is behind more than one routed interface, or one or more bridge group members, you must manually create the NAT exempt rules. For information on manually creating the required rules, see **Exempting Site-to-Site VPN Traffic from NAT**, on page 340.
- **Diffie-Helman Group for Perfect Forward Secrecy**—Select **Group 19**. This option determines whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. For an explanation of the options, see [Deciding Which Diffie-Hellman Modulus Group to Use](#), on page 326.

The options should look like the following.

### Additional Options

<table>
<thead>
<tr>
<th>NAT Exempt</th>
<th>Diffie-Hellman Group for Perfect Forward Secrecy</th>
</tr>
</thead>
<tbody>
<tr>
<td>inside</td>
<td>19</td>
</tr>
</tbody>
</table>

**g)** Click **Next**.

**h)** Review the summary and click **Finish**.

The summary information is copied to the clipboard. You can paste the information in a document and use it to help you configure the remote peer, or to send it to the party responsible for configuring the peer.

**i)** Click the **Deploy Changes** icon in the upper right of the web page.

**j)** Click the **Deploy Now** button and wait for deployment to complete successfully.

Now the Site B device is ready to host one end of the site-to-site VPN connection.

### Step 2
Log out of the Site B device and log into the Site A device.

### Step 3
Configure the site-to-site VPN connection on Site A, which will host the remote access VPN.

- **a)** Click **Device**, then click **View Configuration** in the Site-to-Site VPN group.
- **b)** Click the + button.
- **c)** Configure the following options for **Endpoint Settings**.

  - **Connection Profile Name**—Enter a name, for example, SiteB (to indicate that the connection is to Site B).

  - **Local Site**—These options define the local endpoint.

    - **Local VPN Access Interface**—Select the **outside** interface (the one with the 192.168.4.6 address in the diagram).

    - **Local Network**—Click + and select the network objects that identify the local networks that should participate in the VPN connection. Click **Create New Network**, configure the following objects, then select them in the list. **Note that you created the same objects in the Site B device, but you have to create them again in the Site A device.**

      1. SiteAInside, Network, 192.168.3.0/24.
2. **SiteAInterface, Host, 192.168.4.6.** This is key: you must include the remote access VPN connection point address as part of the inside network for the site-to-site VPN connection so that the RA VPN hosted on that interface can use the directory server on the remote network.

- **Remote Site**—These options define the remote endpoint.
  - **Remote IP Address**—Enter 192.168.2.1, which is the IP address of the remote VPN peer's interface that will host the VPN connection.
Remote Network—Click + and select the network object that identifies the remote network that should participate in the VPN connection, the one that includes the directory server. Click Create New Network and configure an object for the 192.168.1.0/24 network. After saving the object, select it in the drop-down list and click OK. Note that you created the same object in the Site B device, but you have to create it again in the Site A device.

When you are finished, the endpoint settings should look like the following. Notice that the local/remote networks are flipped compared to the Site B settings. This is how the two ends of a point-to-point connection should always look.

d) Click Next.
e) Define the privacy configuration for the VPN.

Configure the same IKE version, policy, and IPsec proposal, and the same preshared keys, as you did for the Site B connection, but make sure that you reverse the Local and Remote preshared keys.

The IKE policy should look like the following:

```
IKE Policy

IKE VERSION 2
IKE VERSION 1

IKE Policies are global, you cannot configure different policies per VPN. Any enabled IKE connections.

IKE Policy
Globally applied

IPSec Proposal
Default set selected

Local Pre-shared Key

Remote Peer Pre-shared Key
```

f) Configure the Additional Options.

- **NAT Exempt**—Select the interface that hosts the inside network, in this example, the inside interface. Typically, you do not want traffic within a site-to-site VPN tunnel to have their IP addresses translated. This option works only if the local network resides behind a single routed interface (not a bridge group member). If the local network is behind more than one routed interface, or one or more bridge group members, you must manually create the NAT exempt rules. For information on manually creating the required rules, see Exempting Site-to-Site VPN Traffic from NAT, on page 340.

- **Diffie-Helman Group for Perfect Forward Secrecy**—Select Group 19.

The options should look like the following.
g) Click Next.

h) Review the summary and click Finish.

i) Click the Deploy Changes icon in the upper right of the web page.

j) Click the Deploy Now button and wait for deployment to complete successfully.

Now the Site A device is ready to host the other end of the site-to-site VPN connection. Because Site B is already configured with compatible settings, the two devices should negotiate a VPN connection.

You can confirm the connection by logging into the device CLI and pinging the directory server. You can also use the show ipsec sa command to view the session information.

---

**Step 4** Configure the directory server on Site A. Click Test to verify that there is a connection.

a) Select Objects, then select Identity Realm from the table of contents.

b) Click the + button.

c) Configure the basic realm properties.

- **Name**—A name for the directory realm. For example, AD.

- **Type**—The type of directory server. Active Directory is the only supported type, and you cannot change this field.

- **Directory Username, Directory Password**—The distinguished username and password for a user with appropriate rights to the user information you want to retrieve. For Active Directory, the user does not need elevated privileges. You can specify any user in the domain. The username must be fully qualified; for example, Administrator@example.com (not simply Administrator).

  **Note** The system generates ldap-login-dn and ldap-login-password from this information. For example, Administrator@example.com is translated as cn=adminisntrator,cn=users,dc=example,dc=com. Note that cn=users is always part of this translation, so you must configure the user you specify here under the common name “users” folder.

- **Base DN**—The directory tree for searching or querying user and group information, that is, the common parent for users and groups. For example, cn=users,dc=example,dc=com. For information on finding the base DN, see Determining the Directory Base DN, on page 120.

- **AD Primary Domain**—The fully qualified Active Directory domain name that the device should join. For example, example.com.
d) Configure the directory server properties.

- **Hostname/IP Address**—The hostname or IP address of the directory server. If you use an encrypted connection to the server, you must enter the fully-qualified domain name, not the IP address. For this example, enter 192.168.1.175.

- **Port**—The port number used for communications with the server. The default is 389. Use port 636 if you select LDAPS as the encryption method. For this example, keep 389.

- **Encryption**—To use an encrypted connection for downloading user and group information. The default is None, which means that user and group information is downloaded in clear text. For RA VPN, you can use LDAPS, which is LDAP over SSL. Use port 636 if you select this option. RA VPN does not support STARTTLS. For this example, select None.

- **Trusted CA Certificate**—If you select an encryption method, upload a Certificate Authority (CA) certificate to enable a trusted connection between the system and the directory server. If you are using a certificate to authenticate, the name of the server in the certificate must match the server Hostname/IP Address. For example, if you use 192.168.1.175 as the IP address but ad.example.com in the certificate, the connection fails.

c) Click the **Test** button to verify the system can contact the server.

The system uses separate processes to access the server, so you might get errors indicating that the connection works for one type of use but not another, for example, available for Identity policies but not for remote access VPN. If the server cannot be reached, verify that you have the right IP address and host name, that the DNS server has an entry for the hostname, and so forth. Also, verify that the site-to-site VPN connection is working and that you included Site A's outside interface address in the VPN, and that
NAT is not translating traffic for the directory server. You might also need to configure a static route for the server.

f) Click **OK**.

**Step 5**

Click **Device > Smart License > View Configuration**, and enable the RA VPN license.

When enabling the RA VPN license, select the type of license you purchased: Plus, Apex (or both), or VPN Only. For more information, see [Licensing Requirements for Remote Access VPN](#) on page 355.

**RA VPN License**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PLUS</strong></td>
</tr>
</tbody>
</table>

Please select the license type that you purchased to enable remote access VPN. Note that Firepower Device Manager does not support any of the advanced features covered by the Apex license.

**Includes: RA-VPN**

**Step 6**

Configure the remote access VPN on Site A.

a) Click **Device**, then click **Setup Connection Profile** in the Remote Access VPN group.

b) Define the AnyConnect client configuration.

- **Connection Profile Name**—The name for this connection, up to 50 characters without spaces. For example, MainOffice. You cannot use an IP address as the name.

  **Note** The name you enter here is what users will see in the connection list in the AnyConnect client. Choose a name that will make sense to your users.

- **AD Realm/Directory Server for User Authentication**—Select the directory realm.

- **AnyConnect Packages**—The AnyConnect full installation software images that you will support on this VPN connection. For each package, the filename, including extensions, can be no more than 60 characters. You can upload separate packages for Windows, Mac, and Linux endpoints.

Download the packages from software.cisco.com (there is a link to the right location at the end of the page). If the endpoint does not already have the right package installed, the system prompts the user to download and install the package after the user authenticates.
c) Click Next.

d) Define the device identity and client addressing configuration.

- **Certificate of Device Identity**—Select DefaultInternalCertificate. This is the internal certificate used to establish the identity of the device. Clients must accept this certificate to complete a secure VPN connection. If you have a different certificate that you want to use, click **Create New Internal Certificate** in the drop-down list and upload it.

- **Outside Interface**—Select outside, the one with the 192.168.4.6 IP address. This is the interface to which users connect when making the remote access VPN connection.

- **Fully-qualified Domain Name for the Outside Interface**—The name of the interface, for example, ravpn.example.com. If you specify a name, the system can create a client profile for you. For this example, we will leave it blank.

  **Note**  
  You are responsible for ensuring that the DNS servers used in the VPN and by clients can resolve this name to the outside interface's IP address. Add the FQDN to the relevant DNS servers.

- **IPv4, IPv6 Address Pools**—These options define the address pools for the remote endpoints. For this example, select **Create New Network** in the IPv4 address pool and create an object for the 172.18.1.0/24 network, then select the object. Clients are assigned an address from this pool. Leave...
the IPv6 pool blank. The address pool cannot be on the same subnet as the IP address for the outside interface.

The object should look like the following:

Name
ra-vpn-pool

Description

Type
Network

Network
172.18.1.0/24

The pool specification should look like the following:

IPv4 Address Pool
Endpoints are provided an address from this pool
ra-vpn-pool

IPv6 Address Pool
Endpoints are provided an address from this pool

• **Primary, Secondary DNS Servers**—For this example, click the OpenDNS button to load these fields with the OpenDNS public DNS servers. RA VPN clients use these DNS servers clients for domain name resolution when connected to the VPN. Optionally, enter the IP addresses of your DNS servers.

• **Domain Search Name**—Enter the domain name for your network, e.g. example.com. This domain is added to hostnames that are not fully-qualified, for example, serverA instead of serverA.example.com.
e) Click Next.

f) Define the connection settings to customize AnyConnect client behavior.

Keep the default settings for all options, as they are appropriate for most networks.

Because **NAT Exempt** is selected, you need to configure the following options:

- **Inside Interfaces**—Select the *inside* interface. These are the interfaces for the internal networks remote users will be accessing. NAT rules are created for these interfaces.

- **Inside Networks**—Select the SiteAInside network object. These are the network objects that represent internal networks remote users will be accessing.

g) Click Next.

h) Review the summary.

First, verify that the summary is correct.
Then, click Instructions to see what end users need to do to initially install the AnyConnect software and test that they can complete a VPN connection. Click Copy to copy these instructions to the clipboard, and paste them in a text file or email.

i) Click Finish.

**Step 7** Click the Deploy Changes icon in the upper right of the web page.

**Step 8** Click the Deploy Now button and wait for deployment to complete successfully.

Now the Site A device is ready to accept RA VPN connections. Have an external user install the AnyConnect client and complete a VPN connection.

You can confirm the connection by logging into the device CLI and using the `show vpn-sessiondb anyconnect` command to view the session information.
PART IV

System Administration

- System Settings, on page 391
- System Management, on page 403
System Settings

The following topics explain how to configure the various system settings that are grouped together on the System Settings page. The settings cover overall system function.

- Configuring the Management Access List, on page 391
- Configuring Diagnostic Logging, on page 393
- Configuring DHCP Server, on page 394
- Configuring DNS, on page 396
- Configuring the Management Interface, on page 396
- Configuring the Device Hostname, on page 398
- Configuring Network Time Protocol (NTP), on page 398
- Configuring URL Filtering Preferences, on page 399
- Configuring Cloud Services, on page 399

Configuring the Management Access List

By default, you can reach the device's Firepower Device Manager web or CLI interfaces on the management address from any IP address. System access is protected by username/password only. However, you can configure an access list to allow connections from specific IP addresses or subnets only to provide another level of protection.

You can also open data interfaces to allow Firepower Device Manager or SSH connections to the CLI. You can then manage the device without using the management address. For example, you could allow management access to the outside interface, so that you can configure the device remotely. The username/password protects against unwanted connections. By default, HTTPS management access to data interfaces is enabled on the inside interface but it is disabled on the outside interface. For device models that have a default “inside” bridge group, this means that you can make Firepower Device Manager connections through any data interface within the bridge group to the bridge group IP address (default is 192.168.1.1). You can open a management connection only on the interface through which you enter the device.

Caution

If you constrain access to specific addresses, you can easily lock yourself out of the system. If you delete access for the IP address that you are currently using, and there is no entry for “any” address, you will lose access to the system when you deploy the policy. Be very careful if you decide to configure the access list.
Before you begin

You cannot configure both Firepower Device Manager access (HTTPS access) and AnyConnect remote access SSL VPN on the same interface for the same TCP port. For example, if you configure remote access SSL VPN on the outside interface, you cannot also open the outside interface for HTTPS connections on port 443. Because you cannot configure the port used by these features in Firepower Device Manager, you cannot configure both features on the same interface.

Procedure

Step 1
Click Device, then click the System Settings > Management Access link.

If you are already on the System Settings page, simply click Management Access in the table of contents.

Step 2
To create rules for the management address:

a) Select the Management Interface tab.

The list of rules defines which addresses are allowed access to the indicated port: 443 for Firepower Device Manager (the HTTPS web interface), 22 for the SSH CLI.

The rules are not an ordered list. If an IP address matches any rule for the requested port, the user is allowed to attempt logging into the device.

Note: To delete a rule, click the trash can icon (Trash) for the rule. If you delete all of the rules for a protocol, no one can access the device on that interface using the protocol.

b) Click + and fill in the following options:

- **Protocol**—Select whether the rule is for HTTPS (port 443) or SSH (port 22).

- **IP Address**—Select the network object that defines the IPv4 or IPv6 network or host that should be able to access the system. To specify "any" address, select any-ipv4 (0.0.0.0/0) and any-ipv6 (:/0).

c) Click OK.

Step 3
To create rules for data interfaces:

a) Select the Data Interfaces tab.

The list of rules defines which addresses are allowed access to the indicated port on the interface: 443 for Firepower Device Manager (the HTTPS web interface), 22 for the SSH CLI.

The rules are not an ordered list. If an IP address matches any rule for the requested port, the user is allowed to attempt logging into the device.

Note: To delete a rule, click the trash can icon (Trash) for the rule. If you delete all of the rules for a protocol, no one can access the device on that interface using the protocol.

b) Click + and fill in the following options:

- **Interface**—Select the interface on which you want to allow management access.

- **Protocols**—Select whether the rule is for HTTPS (port 443), SSH (port 22), or both. You cannot configure HTTPS rules for the outside interface if it is used in an remote access VPN connection profile.
• **Allowed Networks**—Select the network objects that define the IPv4 or IPv6 network or host that should be able to access the system. To specify "any" address, select `any-ipv4 (0.0.0.0/0)` and `any-ipv6 (::/0)`.

c) Click **OK**.

---

**Configuring Diagnostic Logging**

Diagnostic logging provides syslog messages for events that are not related to connections. You configure connection logging within individual access control rules. The following procedure explains how to configure the logging of diagnostic messages.

**Procedure**

**Step 1**
Click **Device**, then click the **System Settings > Logging Settings** link.

If you are already on the System Settings page, simply click **Logging Settings** in the table of contents.

**Step 2**
Click **Diagnostic Log Settings > On**.

Even if you configure the remaining fields on this page, diagnostic log messages are not generated unless you turn on this setting.

**Step 3**
Turn the slider to **On** for each of the locations where you want to see diagnostic log messages, and select a minimum severity level.

You can log messages to the following locations:

- **Console**—These messages appear when you log into the CLI on the Console port. You can also see these logs in an SSH session to other interfaces (including the management address) by using the `show console-output` command. In addition, you can see these messages in real time in the diagnostic CLI, enter `system support diagnostic-cli` from the main CLI.

- **Syslog**—These messages are sent to the external syslog servers that you specify. Click +, select the syslog server objects, and click **OK** in the popup dialog box. If the object for a server does not already exist, click **Add Syslog Server** to create it.

**Step 4**
Click **Save**.

---

**Severity Levels**

The following table lists the syslog message severity levels.

<table>
<thead>
<tr>
<th>Level Number</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>emergencies</td>
<td>System is unusable.</td>
</tr>
</tbody>
</table>
### Configuring DHCP Server

A DHCP server provides network configuration parameters, such as IP addresses, to DHCP clients. You can configure a DHCP server on an interface to provide configuration parameters to DHCP clients on the attached network.

An IPv4 DHCP client uses a broadcast rather than a multicast address to reach the server. The DHCP client listens for messages on UDP port 68; the DHCP server listens for messages on UDP port 67. The DHCP server does not support BOOTP requests.

DHCP clients must be on the same network as the interface on which the server is enabled. That is, there cannot be an intervening router between the server and client, although there can be a switch.

**Note**

Do not configure a DHCP server on a network that already has a DHCP server operating on it. The two servers will conflict and results will be unpredictable.

**Procedure**

**Step 1**
Click **Device**, then click the **System Settings > DHCP Server** link.

If you are already on the System Settings page, simply click **DHCP Server** in the table of contents.

The page has two tabs. Initially, the **Configuration** tab shows the global parameters.

The **DHCP Servers** tab shows the interfaces on which you have configured DHCP server, whether the server is enabled, and the address pool for the server.

**Step 2**
On the **Configuration** tab, configure auto-configuration and global settings.
DHCP auto configuration enables the DHCP Server to provide DHCP clients with DNS server, domain name, and WINS server information obtained from a DHCP client that is running on the specified interface. Typically, you would use auto-configuration if you are obtaining an address using DHCP on the outside interface, but you could choose any interface that obtains its address through DHCP. If you cannot use auto-configuration, you can manually define the required options.

a) Click **Enable Auto Configuration** > **On** (the slider should be on the right) if you want to use auto-configuration, and then select the interface that is obtaining its address through DHCP in **From Interface**.

b) If you do not enable auto-configuration, or if you want to override any of the automatically configured settings, configure the following global options. These settings will be sent to DHCP clients on all interfaces that host DHCP server.

- **Primary WINS IP Address, Secondary WINS IP Address**—The addresses of the Windows Internet Name Service (WINS) servers clients should use for NetBIOS name resolution.

- **Primary DNS IP Address, Secondary DNS IP Address**—The addresses of the Domain Name System (DNS) servers clients should use for domain name resolution. Click **Use OpenDNS** if you want to configure the OpenDNS public DNS servers. Clicking the button loads the appropriate IP addresses into the fields.

c) Click **Save**.

**Step 3** Click the **DHCP Servers** tab and configure the servers.

a) Do one of the following:

- To configure DHCP server for an interface that is not already listed, click +.

- To edit an existing DHCP server, click the edit icon (📝) for the server.

To delete a server, click the trash can icon (🗑️) for the server.

b) Configure the server properties:

- **Enable DHCP Server**—Whether to enable the server. You can configure a server but keep it disabled until you are ready to use it.

- **Interface**—Select the interface on which you will provide DHCP addresses to clients. The interface must have a static IP address; you cannot be using DHCP to obtain the interface address if you want to run a DHCP server on the interface. For bridge groups, you configure the DHCP server on the Bridge Virtual Interface (BVI), not the member interfaces, and the server operates on all member interfaces.

You cannot configure DHCP server on the Diagnostic interface, configure it on the Management interface instead, on the **Device > System Settings > Management Interface** page.

- **Address Pool**—The range of IP addresses from lowest to highest that the server is allowed to provide to clients that request an address. Specify the start and end address for the pool, separated by a hyphen. For example, 10.100.10.12-10.100.10.250.

The range of IP addresses must be on the same subnet as the selected interface and cannot include: the IP address of the interface itself, the broadcast address, or the subnet network address.

The size of the address pool is limited to 256 addresses per pool on the FTD device. If the address pool range is larger than 253 addresses, the netmask of the FTD interface cannot be a Class C address (for example, 255.255.255.0) and needs to be something larger, for example, 255.255.254.0.
c) Click OK.

## Configuring DNS

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. These servers are used by the management interface. You configure DNS servers during initial system setup, but you can change them using the following procedure.

You can also change the DNS configuration in the CLI using the `configure network dns servers` and `configure network dns searchdomains` commands.

If you have problems with DNS resolution, see Troubleshooting DNS for the Management Interface, on page 419.

### Procedure

**Step 1** Click Device, then click the System Settings > DNS Server link.

If you are already on the System Settings page, simply click DNS Server in the table of contents.

**Step 2** In Primary, Secondary, Tertiary DNS IP address, enter the IP addresses of up to three DNS servers in order of preference.

The primary DNS server is used unless it cannot be contacted, in which case the secondary is tried, and finally the tertiary.

Click Use OpenDNS if you want to configure the OpenDNS public DNS servers. Clicking the button loads the appropriate IP addresses into the fields.

**Step 3** In Domain Search Name, enter the domain name for your network, e.g. example.com.

This domain is added to hostnames that are not fully-qualified, for example, serverA instead of serverA.example.com.

**Step 4** Click Save.

## Configuring the Management Interface

The management interface is a virtual interface attached to the physical Management port. The physical port is named the Diagnostic interface, which you can configure on the Interfaces page with the other physical ports. On Firepower Threat Defense Virtual, this duality is maintained even though both interfaces are virtual.

The management interface has two uses:

- You can open web and SSH connections to the IP address and configure the device through the interface.
- The system obtains smart licensing and database updates through this IP address.
If you use the CLI setup wizard, you configure the management address and gateway for the device during initial system configuration. If you use the Firepower Device Manager setup wizard, the management address and gateway remain the defaults.

If necessary, you can change these addresses through Firepower Device Manager. You can also change the management address and gateway in the CLI using the `configure network ipv4 manual` and `configure network ipv6 manual` commands.

You can define static addresses, or obtain an address through DHCP if another device on the management network is acting as a DHCP server. By default, the management address is static, and a DHCP server runs on the port (except for Firepower Threat Defense Virtual, which does not have a DHCP server). Thus, you can plug a device directly into the management port and get a DHCP address for your workstation. This makes it easy to connect to and configure the device.

⚠️ **Caution**
If you change the address to which you are currently connected, you will lose access to Firepower Device Manager (or the CLI) when you save the changes, as they are applied immediately. You will need to reconnect to the device. Ensure that the new address is valid and available on the management network.

### Procedure

#### Step 1
Click **Device**, then click the **System Settings > Management Interface** link.

If you are already on the System Settings page, simply click **Management Interface** in the table of contents.

#### Step 2
Choose how you want to define the management gateway.

The gateway determines how the system can reach the Internet to obtain smart licenses, database updates (such as VDB, rule, Geolocation, URL), and to reach the management DNS and NTP servers. Choose from these options:

- **Use the Data Interfaces as the Gateway**—Select this option if you do not have a separate management network connected to the physical Management interface. Traffic is routed to the Internet based on the routing table, typically going through the outside interface. This is the default option. However, this option is not supported on Firepower Threat Defense Virtual devices.

- **Use Unique Gateways for the Management Interface**—Specify unique gateways (below) for IPv4 and IPv6 if you have a separate management network connected to the management interface.

#### Step 3
Configure the management address, subnet mask or IPv6 prefix, and gateway (if necessary) for IPv4, IPv6, or both.

You must configure at least one set of properties. Leave one set blank to disable that addressing method.

Select **Type > DHCP** to obtain the address and gateway through DHCP or IPv6 auto configuration. However, you cannot use DHCP if you are using the data interfaces as the gateway. In this case, you must use a static address.

#### Step 4
(Optional.) If you configure a static IPv4 address, configure a DHCP server on the port.

If you configure a DHCP server on the management port, directly-connected clients, or clients on the management network, can obtain their address from the DHCP pool. This option is not supported on Firepower Threat Defense Virtual devices.
a) Click **Enable DHCP Server > On**.
b) Enter the **Address Pool** for the server.

The address pool is the range of IP addresses from lowest to highest that the server is allowed to provide to clients that request an address. The range of IP addresses must be on the same subnet as the management address and cannot include: the IP address of the interface itself, the broadcast address, or the subnet network address. Specify the start and end address for the pool, separated by a hyphen. For example, 192.168.45.46-192.168.45.254.

**Step 5**
Click **Save**, read the warning, and click **OK**.

---

## Configuring the Device Hostname

You can change the device hostname.

You can also change the hostname in the CLI using the `configure network hostname` command.

⚠️ **Caution**
If you change the hostname when connected to the system using the hostname, you will lose access to Firepower Device Manager when you save the changes, as they are applied immediately. You will need to reconnect to the device.

---

**Procedure**

### Step 1
Click **Device**, then click the **System Settings > Hostname** link.

If you are already on the System Settings page, simply click **Hostname** in the table of contents

### Step 2
Enter a new hostname.

### Step 3
Click **Save**.

---

## Configuring Network Time Protocol (NTP)

You must configure Network Time Protocol (NTP) servers to define the time on the system. You configure NTP servers during initial system setup, but you can change them using the following procedure. If you have problems with the NTP connection, see **Troubleshooting NTP**, on page 417.

**Procedure**

### Step 1
Click **Device**, then click the **System Settings > NTP** link.

If you are already on the System Settings page, simply click **NTP** in the table of contents

### Step 2
In **NTP Time Server**, select whether you want to use your own or Cisco's time servers.
• **Default NTP Time Server**—If you select this option, the server list shows the server names that are used for NTP.

• **Manually Input**—If you select this option, enter the fully qualified domain name or IP address of the NTP server you want to use. For example, ntp1.example.com or 10.100.10.10. If you have more than one NTP server, click **Add Another NTP Time Server** and enter the address.

**Step 3**  
Click Save.

---

### Configuring URL Filtering Preferences

The system obtains the URL category and reputation database from Cisco Collective Security Intelligence (CSI). These preferences control database updates and how the system handles URLs with unknown category or reputation. You must enable the URL Filtering license to set these preferences.

**Procedure**

**Step 1**  
Click **Device**, then click the **System Settings > URL Filtering Preferences** link.

If you are already on the System Settings page, simply click **URL Filtering Preferences** in the table of contents

**Step 2**  
Configure the following options:

- **Enable Automatic Updates**—Allows the system to automatically check for and download updated URL data, which includes category and reputation information. The system checks for updates every 30 minutes, although the data is typically updated once per day. The default is to enable updates. If you deselect this option, and you are using category and reputation filtering, periodically enable it to get new URL data.

- **Query Cisco CSI for Unknown URLs**—Whether to check with Cisco CSI for updated information for URLs that do not have category and reputation data in the local URL filtering database. If the lookup returns this information within a reasonable time limit, it is used when selecting access rules based on URL conditions. Otherwise, the URL matches the Uncategorized category. Selecting this option is important for lower-end systems, which install a smaller URL database due to memory limitations.

**Step 3**  
Click Save.

---

### Configuring Cloud Services

Use the Cloud Services page to manage the cloud-based services used by the device from the device side. After you register for certain services, you need to manage them from the cloud.

You can click the **Cloud Services Portal** link at the top of the page to go to Cisco Cloud Services and manage your cloud-based services.

The following topics explain the cloud service options.
Configuring Cloud Management (Cisco Defense Orchestrator)

You can manage the device using the Cisco Defense Orchestrator cloud-based portal. Using Cisco Defense Orchestrator, you can approach device management using the following techniques:

- **Initial configuration download**—In this approach, you download the initial device configuration from Cisco Defense Orchestrator, but thereafter you configure the device locally using Firepower Device Manager.

**Note**

After configuring the device using Firepower Device Manager, if you decide you want to instead manage the device through the cloud, ensure that you duplicate your local changes in the cloud-based configuration.

- **Remote configuration management through the cloud**—In this approach, you use Cisco Defense Orchestrator to create and update the device configuration. When using this approach, do not make local changes to the configuration, because on each cloud deployment, the configuration defined in the cloud replaces the local configuration on the device. If you make a local change, be sure to repeat the configuration in the cloud-based configuration if you want to preserve the change.

For more information about how cloud management works, refer to the Cisco Defense Orchestrator portal (http://www.cisco.com/go/cdo) or ask the reseller or partner with whom you are working.

**Before you begin**

Obtain a registration key for Cisco Defense Orchestrator.

If you have already registered the device with Cisco Smart Software Manager (CSSM), we strongly recommend that you first unregister the device from the Smart Licensing page. You can re-register after you enable Cisco Defense Orchestrator using a token.

Also, ensure that the device has a route to the Internet.

**Procedure**

**Step 1**

Click Device, then click the System Settings > Cloud Services link.

If you are already on the System Settings page, simply click Cloud Services in the table of contents.

**Step 2**

Click Get Started in the Cisco Defense Orchestrator group.

**Step 3**

Paste the key in Registration Key and click Connect.

A registration request is sent to the cloud portal. If the key is valid, and there is a route to the Internet, the device should be successfully registered with the portal. You can then start using the portal to manage the device.

If you decide you no longer want to use cloud management, you can click the Disable button.
Connecting to the Cisco Success Network

When you register the device, you decide whether to enable the connection to the Cisco Success Network. See Registering the Device, on page 83.

By enabling Cisco Success Network, you are providing usage information and statistics to Cisco that are essential for Cisco to provide you with technical support. This information also allows Cisco to improve the product and to make you aware of unused available features so that you can maximize the value of the product in your network.

When you enable the connection, your device establishes a secure connection to the Cisco Cloud so that your device can participate in additional service offerings from Cisco such as technical support services, cloud management and monitoring services. Your device will establish and maintain this secure connection at all times.

You can turn off this connection at any time by disabling both Cisco Success Network and Cisco Defense Orchestrator. Disabling both will disconnect the device from the cloud. Disconnection does not impact the receipt of updates or the operation of the Smart Licensing capabilities, which continue to operate normally.

After you have registered the device, you can change the Cisco Success Network setting.

---

**Note**

When the system sends data to Cisco, the task list shows a Telemetry Job.

---

**Before you begin**

To enable Cisco Success Network the device must be enrolled with the cloud. To enroll the device either register the device with Cisco Smart Software Manager (on the Smart Licensing page), electing the Cisco Success Network option during registration, or enroll with Cisco Defense Orchestrator by entering a registration key.

---

**Procedure**

**Step 1**

Click **Device**, then click the **System Settings > Cloud Services** link.

If you are already on the System Settings page, simply click **Cloud Services** in the table of contents.

**Step 2**

Click the **Enable/Disable** control for the Cisco Success Network feature to change the setting as appropriate. You can click the **sample data** link to see the type of information that is sent to Cisco. When enabling the connection, read the disclosure and click **Accept**.
CHAPTER 18

System Management

The following topics explain how to perform system management tasks such as updating system databases and backing up and restoring the system.

• Installing Software Updates, on page 403
• Backing Up and Restoring the System, on page 408
• Rebooting the System, on page 412
• Troubleshooting the System, on page 412
• Uncommon Management Tasks, on page 424

Installing Software Updates

You can install updates to the system databases and to the system software. The following topics explain how to install these updates.

Updating System Databases and Feeds

The system uses several databases and Security Intelligence feeds to provide advanced services. Cisco provides updates to these databases and feeds so that your security policies use the latest information available.

Overview of System Database and Feed Updates

Firepower Threat Defense uses the following databases and feeds to provide advanced services.

Intrusion rules

As new vulnerabilities become known, the Cisco Talos Intelligence Group (Talos) releases intrusion rule updates that you can import. These updates affect intrusion rules, preprocessor rules, and the policies that use the rules.

Intrusion rule updates provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default intrusion policy settings. Rule updates may also delete rules, provide new rule categories and default variables, and modify default variable values.

For changes made by an intrusion rule update to take effect, you must redeploy the configuration. Intrusion rule updates may be large, so import rules during periods of low network use. On slow networks, an update attempt might fail, and you will need to retry.
**Geolocation database (GeoDB)**

The Cisco Geolocation Database (GeoDB) is a database of geographical data (such as country, city, coordinates) and connection-related data (such as Internet service provider, domain name, connection type) associated with routable IP addresses.

GeoDB updates provide updated information on physical locations, connection types, and so on that your system can associate with detected routable IP addresses. You can use geolocation data as a condition in access control rules.

The time needed to update the GeoDB depends on your appliance; the installation usually takes 30 to 40 minutes. Although a GeoDB update does not interrupt any other system functions (including the ongoing collection of geolocation information), the update does consume system resources while it completes. Consider this when planning your updates.

**Vulnerability database (VDB)**

The Cisco Vulnerability Database (VDB) is a database of known vulnerabilities to which hosts may be susceptible, as well as fingerprints for operating systems, clients, and applications. The Firepower System correlates the fingerprints with the vulnerabilities to help you determine whether a particular host increases your risk of network compromise. The Cisco Talos Intelligence Group (Talos) issues periodic updates to the VDB.

The time it takes to update vulnerability mappings depends on the number of hosts in your network map. You may want to schedule the update during low system usage times to minimize the impact of any system downtime. As a rule of thumb, divide the number of hosts on your network by 1000 to determine the approximate number of minutes to perform the update.

After you update the VDB, you must redeploy configurations before updated application detectors and operating system fingerprints can take effect.

**Cisco Talos Intelligence Group (Talos) Security Intelligence Feeds**

Talos provides access to regularly updated intelligence feeds for use in Security Intelligence policies. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations. These feeds contain addresses and URLs for known threats. When the system updates a feed, you do not have to redeploy. The new lists are used for evaluating subsequent connections.

**URL Category/Reputation Database**

The system obtains the URL category and reputation database from Cisco Collective Security Intelligence (CSI). If you configure URL filtering access control rules that filter on category and reputation, requested URLs are matched against the database. You can configure database updates and some other URL filtering preferences on **System Settings > URL Filtering Preferences**. You cannot manage URL category/reputation database updates the same way you manage updates for the other system databases.

**Updating System Databases**

You can manually retrieve and apply system database updates at your convenience. Updates are retrieved from the Cisco support site. Thus, there must be a path to the Internet from the system's management address.

You can also set up a regular schedule to retrieve and apply database updates. Because these updates can be large, schedule them for times of low network activity.
While a database update is in progress, you might find that the user interface is sluggish to respond to your actions.

**Before you begin**

To avoid any potential impact to pending changes, deploy the configuration to the device before manually updating these databases.

Please be aware that VDB and URL category updates can remove applications or categories. You need to update any access control or SSL decryption rules that use these deprecated items before you can deploy changes.

**Procedure**

**Step 1**

Click **Device**, then click **View Configuration** in the Updates summary.

This opens the Updates page. Information on the page shows the current version for each database and the last date and time each database was updated.

**Step 2**

To manually update a database, click **Update Now** in the section for that database.

Rule and VDB updates require a configuration deployment to make them active. You are asked whether you want to deploy now; click **Yes**. If you click **No**, remember to initiate a deployment job at your earliest convenience.

**Step 3**  
(Optional) To set up a regular database update schedule:

a) Click the **Configure** link in the section for the desired database. If there is already a schedule, click **Edit**.

   The update schedules for the databases are separate. You must define the schedules separately.

b) Set the update start time:

   • The frequency of the update (Daily, Weekly, or Monthly).
   
   • For weekly or monthly, the days of the week or month you want the update to occur.
   
   • The time you want the update to start. The time you specify is adjusted for Daylight Savings Time, so it will move an hour forward or backward whenever the time is adjusted in your area. You must edit the schedule at the time change if you want to keep this exact time throughout the year.

c) For Rule or VDB updates, select the **Automatically Deploy the Update** checkbox if you want the system to deploy the configuration whenever the database is updated.

   The update is not effective until it is deployed. The automatic deployment also deploys any other configuration changes that are not yet deployed.

d) Click **Save**.

**Note**  
If you want to remove a recurring schedule, click the **Edit** link to open the scheduling dialog box, then click the **Remove** button.
Updating Cisco Security Intelligence Feeds

Cisco Talos Intelligence Group (Talos) provides access to regularly updated Security Intelligence feeds. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations. When the system updates a feed, you do not have to redeploy. The new lists are used for evaluating subsequent connections.

If you want strict control over when the system updates a feed from the Internet, you can disable automatic updates for that feed. However, automatic updates ensure the most up-to-date, relevant data.

Procedure

Step 1
Click Device, then click View Configuration in the Updates summary.

This opens the Updates page. Information on the page shows the current version for the Security Intelligence Feeds and the last date and time the feeds were updated.

Step 2
To manually update the feeds, click Update Now in the Security Intelligence Feeds group.

Step 3
(Optional.) To configure a regular update frequency:

a) Click the Configure link in the section for Cisco Feeds. If there is already a schedule, click Edit.

b) Select the desired frequency.

The default is Hourly. You can also set a Daily update (specify the time of day) or Weekly update (select the days of the week and time of day). The time you specify is adjusted for Daylight Savings Time, so it will move an hour forward or backward whenever the time is adjusted in your area. You must edit the schedule at the time change if you want to keep this exact time throughout the year.

Click Delete to prevent automatic updates.

c) Click OK.

Upgrading Firepower Threat Defense Software

You can install Firepower Threat Defense software upgrades as they become available. The following procedure assumes that your system is already running Firepower Threat Defense version 6.2.0 or higher and that it is operating normally.

There are three types of upgrades: a hot fix, a minor upgrade, and a major upgrade. A hot fix upgrade might not require a reboot, while minor and major version upgrades do require a reboot. The system automatically reboots after installation if a reboot is required. Installing any update can disrupt traffic, so do the installation in off hours.

You cannot reimagine a device, or migrate from ASA software to Firepower Threat Defense software, using this procedure.

Note
Before installing an update, make sure that you deploy any pending changes. You should also run a backup and download the backup copy.
Before you begin

Check the task list and verify there are no tasks running. Please wait until all tasks, such as database updates, are completed before you install an upgrade. Also, check for any scheduled tasks. No schedule tasks should overlap with the upgrade task.

Prior to performing an update, ensure that no deprecated applications are present in application filters, access rules, or SSL decryption rules. These applications have "(Deprecated)" following the application name. While it is not possible to add deprecated applications to these objects, a subsequent VDB update can cause previously valid applications to become deprecated. If this happens, the upgrade will fail, leaving the device in an unusable state.

Log into Cisco.com and download the upgrade image.

• Ensure that you obtain the appropriate upgrade file, whose file type is REL.tar. Do not download the system software package or the boot image.

• Do not rename the upgrade file. The system considers renamed files to be invalid.

• You cannot downgrade or uninstall a patch.

Procedure

Step 1
Select Device, then click View Configuration in the Updates summary.

The System Upgrade section shows the currently running software version and any update that you have already uploaded.

Step 2
Upload the upgrade file.

• If you have not yet uploaded an upgrade file, click Browse and select the file.

• If there is already an uploaded file, but you want to upload a different one, click the Upload Another File link. You can upload one file only. If you upload a new file, it replaces the old file.

• To remove the file, click the delete icon (Trash).

Step 3
Click Install to start the installation process.

Information next to the icon indicates whether the device will reboot during installation. You are automatically logged out of the system. Installation might take 30 minutes or more.

Wait before logging into the system again. The Device Summary, or System monitoring dashboard, should show the new version.

Note Do not simply refresh the browser window. Instead, delete any path from the URL, and reconnect to the home page. This ensures that cached information gets refreshed with the latest code.

Step 4
(Optional.) Update the system databases.
If you do not have automatic update jobs configured for Geolocation, Rule, and Vulnerability (VDB) databases, this is a good time to update them.

---

**Reimaging the Device**

Reimaging a device involves wiping out the device configuration and installing a fresh software image. The intention of reimaging is to have a clean installation with a factory default configuration.

You would reimagine the device in these circumstances:

- You want to convert the system from ASA Software to Firepower Threat Defense Software. You cannot upgrade a device running an ASA image to one running a Firepower Threat Defense image.
- The device is running a pre-6.1.0 image, and you want to upgrade to 6.1 or a later image and configure the device using Firepower Device Manager. You cannot use Firepower Management Center to upgrade a pre-6.1 device and then switch to local management.
- The device is not functioning correctly and all attempts at fixing the configuration have failed.

For information on how to reimagine a device, see Reimage the Cisco ASA or Firepower Threat Defense Device or the Firepower Threat Defense Quick Start guide for your device model. These guides are available at http://www.cisco.com/c/en/us/support/security/firepower-ngfw/products-installation-guides-list.html.

---

**Backing Up and Restoring the System**

You can back up the system configuration so that you can restore the device if the configuration becomes corrupted due to subsequent mis-configuration or physical mishap.

You can restore a backup onto a replacement device only if the two devices are the same model and are running the same version of the software (including the build number, not just the same point release). Do not use the backup and restore process to copy configurations between appliances. A backup file contains information that uniquely identifies an appliance, so that it cannot be shared in this manner.

---

**Note**

The backup does not include the management IP address configuration. Thus, when you recover a backup file, the management address is not replaced from the backup copy. This ensures that any changes you made to the address are preserved, and also makes it possible to restore the configuration on a different device on a different network segment.

Backups include the configuration only, and not the system software. If you need to completely reimagine the device, you need to reinstall the software, then you can upload a backup and recover the configuration.

The configuration database is locked during backup. You cannot make configuration changes during a backup, although you can view policies, dashboards, and so forth. During a restore, the system is completely unavailable.

The table on the Backup and Restore page lists all existing backup copies that are available on the system, including the file name of the backup, the date and time it was created, and the file size. The type of backup (manual, scheduled, or recurring) is based on how you directed the system to create that backup copy.
Backup copies are created on the system itself. You must manually download backup copies and store them on secure servers to ensure that you have the backup copies you need for disaster recovery.

The following topics explain how to manage backup and restore operations.

**Backing Up the System Immediately**

You can start a backup whenever you want.

**Procedure**

**Step 1**
Click **Device**, then click **View Configuration** in the Backup and Restore summary.

This opens the Backup and Restore page. The table lists all existing backup copies that are available on the system.

**Step 2**
Click **Manual Backup > Back Up Now**.

**Step 3**
Enter a name for the backup and optionally a description.

If you decide you want to perform the backup at a future time rather than immediately, you can click **Schedule** instead.

**Step 4**
Click **Back Up Now**.

The system starts the backup process. When the backup is complete, the backup file will appear in the table. You can then download the backup copy to your system and store it elsewhere, if desired.

You can leave the Backup and Restore page after initiating the backup. However, the system will likely be sluggish, and you should consider pausing your work to allow the backup to complete.

In addition, the system will acquire locks on the configuration database during parts or all of the backup, which can prevent you from making changes for the duration of the backup process.

**Backing Up the System at a Scheduled Time**

You can set up a scheduled backup to back up the system at a specific future date and time. A scheduled backup is a one-time occurrence. If you want to create a backup schedule to regularly create backups, configure a recurring backup instead of a scheduled backup.

**Procedure**

**Step 1**
Click **Device**, then click **View Configuration** in the Backup and Restore summary.

If you want to delete the schedule for a future backup, edit the schedule and click **Remove**.
Step 2  Click Scheduled Backup > Schedule a Backup.
If you already have a scheduled backup, click Scheduled Backup > Edit.

Step 3  Enter a name for the backup and optionally a description.

Step 4  Select the date and time for the backup.

Step 5  Click Schedule.

When the selected date and time arrives, the system takes a backup. When completed, the backup copy is listed in the table of backups.

Setting Up a Recurring Backup Schedule

You can set up a recurring backup to back up the system on a regular schedule. For example, you could take a backup every Friday at midnight. A recurring backup schedule helps ensure that you always have a set of recent backups.

**Note**  If you want to delete a recurring schedule, edit the schedule and click Remove.

**Procedure**

Step 1  Click Device, then click View Configuration in the Backup and Restore summary.

Step 2  Click Recurring Backup > Configure.
If you already have a recurring backup configured, click Recurring Backup > Edit.

Step 3  Enter a name for the backup and optionally a description.

Step 4  Select the Frequency and the related schedule:
- **Daily**—Select the time of day. A backup is taken every day at the scheduled time.
- **Weekly**—Select the days of the week and the time of day. A backup is taken on each day you select at the scheduled time. For example, you could schedule backups for every Monday, Wednesday, and Friday at 23:00 hours (11 PM).
- **Monthly**—Select the days of the month and the time of day. A backup is taken on each day you select at the scheduled time. For example, you could schedule backups for the first (1), fifteenth (15), and twenty-eighth (28) days of the month at 23:00 hours (11 PM).

The time you specify is adjusted for Daylight Savings Time, so it will move an hour forward or backward whenever the time is adjusted in your area. You must edit the schedule at the time change if you want to keep this exact time throughout the year.

Step 5  Click Save.

When the selected dates and times arrive, the system takes a backup. When completed, the backup copy is listed in the table of backups.
The recurring schedule continues to take backups until you change or remove it.

---

**Restoring a Backup**

You can restore backups as needed so long as the device is running the same software version (including build number) as it was running when you took the backup. You can restore a backup onto a replacement device only if the two devices are the same model and are running the same version of the software (including build number).

If the backup copy you want to restore is not already on the device, you must upload the backup first before restoring it.

During a restore, the system is completely unavailable.

---

**Note**

The backup does not include the management IP address configuration. Thus, when you recover a backup file, the management address is not replaced from the backup copy. This ensures that any changes you made to the address are preserved, and also makes it possible to restore the configuration on a different device on a different network segment.

---

**Procedure**

**Step 1**

Click **Device**, then click **View Configuration** in the Backup and Restore summary.

This opens the Backup and Restore page. The table lists all existing backup copies that are available on the system.

**Step 2**

If the backup copy that you want to restore is not in the list of available backups, click **Upload > Browse** and upload the backup copy.

**Step 3**

Click the restore icon (ackle) for the file.

You are asked to confirm the restore. By default, the backup copy will be deleted after the restore, but you can select **Do not remove the backup after restoring** to keep it before proceeding with the restore.

The system will reboot after restore completes.

---

**Note**

After the system reboots, it automatically checks for Vulnerability Database (VDB), Geolocation, and Rules database updates, and downloads them if needed. Because these updates can be large, the initial attempt might fail. Please check the task list, and if a download failed, manually download an update as described in *Updating System Databases*, on page 404. The system also redeploys policies. Any subsequent deployment will fail until the update is successful.

---

**Managing Backup Files**

As you create new backups, the backup files are listed on the Backup and Restore page. Backup copies are not retained indefinitely: as disk space usage on the device reaches the maximum threshold, older backup
copies are deleted to make room for newer ones. Thus, you should regularly manage the backup files to ensure that you have the specific backup copies you most want to keep.

You can do the following to manage your backup copies:

- Download files to secure storage—To download a backup file to your workstation, click the download icon () for the file. You can then move the file to your secure file storage.

- Upload a backup file to the system—If you want to restore a backup copy that is no longer available on the device, click **Upload > Browse File** and upload it from your workstation. You can then restore it.

  **Note**
  Uploaded files may be renamed to match the original filename. Also, if there are more than 10 backup copies already on the system, the oldest one will be deleted to make room for the uploaded file. You cannot upload files that were created by an older software version.

- Restore a backup—To restore a backup copy, click the restore icon () for the file. The system is unavailable during restore, and will reboot after restore completes. You should deploy the configuration after the system is up and running.

- Delete a backup file—If you no longer want a particular backup, click the delete icon () for the file. You are asked to confirm the deletion. Once deleted, you cannot recover the backup file.

## Rebooting the System

If you believe the system is not performing correctly and other efforts to resolve the problem have failed, you can reboot the device. You must reboot the device through the CLI; you cannot reboot the device through Firepower Device Manager.

### Procedure

**Step 1**
Use an SSH client to open a connection to the management IP address and log into the device CLI with a username that has configuration CLI access. For example, the **admin** username.

**Step 2**
Enter the **reboot** command.

**Example:**

```
> reboot
```

## Troubleshooting the System

The following topics address some system-level troubleshooting tasks and capabilities. For information on troubleshooting a specific feature, such as access control, see the chapter for the feature.
Pinging Addresses to Test Connectivity

Ping is a simple command that lets you determine if a particular address is alive and responsive. This means that basic connectivity is working. However, other policies running on a device could prevent specific types of traffic from successfully getting through a device. You can use ping by opening the CLI console or by logging into the device CLI.

Because the system has multiple interfaces, you can control the interface used for pinging an address. You must ensure that you are using the right command, so that you are testing the connectivity that matters. For example, the system must be able to reach the Cisco license server through the virtual management interface, so you must use the ping system command to test the connection. If you use ping, you are testing whether an address can be reached through the data interfaces, which might not give you the same result.

The normal ping uses ICMP packets to test the connection. If your network prohibits ICMP, you can use a TCP ping instead (for data interface pings only).

Following are the main options for pinging network addresses.

Pinging an address through the virtual management interface

Use the ping system command.

`ping system host`

The host can be an IP address or fully-qualified domain name (FQDN), such as www.example.com. Unlike pings through the data interfaces, there is no default count for system pings. The ping continues until you stop it using Ctrl+c. For example:

```bash
> ping system www.cisco.com
PING origin-www.cisco.COM (72.163.4.161) 56(84) bytes of data.
64 bytes from www1.cisco.com (72.163.4.161): icmp_seq=1 ttl=242 time=10.6 ms
64 bytes from www1.cisco.com (72.163.4.161): icmp_seq=2 ttl=242 time=8.13 ms
64 bytes from www1.cisco.com (72.163.4.161): icmp_seq=3 ttl=242 time=8.51 ms
64 bytes from www1.cisco.com (72.163.4.161): icmp_seq=4 ttl=242 time=8.40 ms
--- origin-www.cisco.COM ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 3003ms
rtt min/avg/max/mdev = 8.139/8.927/10.650/1.003 ms
>
```

Pinging an address through a data interface using the routing table

Use the ping command. Without specifying an interface, you are testing whether the system can generically find a route to the host. Because this is how the system normally routes traffic, this is typically what you want to test.

`ping host`

Specify the IP address of the host. If you only know the FQDN, use the nslookup fqdn-name command to determine the IP address. For example:

```bash
> ping 171.69.38.1
Sending 5, 100-byte ICMP Echos to 171.69.38.1, timeout is 2 seconds:
!!!!!
```
You can specify the timeout, repeat count, packet size, and even the data pattern to send. Use the help indicator, ?, in the CLI to see the available options.

**Pinging an address through a specific data interface**

Use the `ping interface if_name` command if you want to test connectivity through a specific data interface. You can also specify the diagnostic interface using this command, but not the virtual management interface.

**ping interface if_name**

Specify the IP address of the host. If you only know the FQDN, use the `nslookup fqdn-name` command to determine the IP address. For example:

```
> ping interface inside 171.69.38.1
Sending 5, 100-byte ICMP Echos to 171.69.38.1, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

**Pinging an address through a data interface using TCP ping**

Use the `ping tcp` command. A TCP ping sends SYN packets and considers the ping successful if the destination sends a SYN-ACK packet.

**ping tcp [interface if_name] host port**

You must specify the host and TCP port. If you only know the FQDN, use the `nslookup fqdn-name` command to determine the IP address.

You can optionally specify the interface, which is the source interface of the ping, not the interface through which to send the pings. This type of ping always uses the routing table.

A TCP ping sends SYN packets and considers the ping successful if the destination sends a SYN-ACK packet. For example:

```
> ping tcp 10.0.0.1 21
Type escape sequence to abort.
No source specified. Pinging from identity interface.
Sending 5 TCP SYN requests to 10.0.0.1 port 21
from 10.0.0.10, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

You can also specify the timeout, repeat count, and the source address for the TCP ping. Use the help indicator, ?, in the CLI to see the available options.
Tracing Routes to Hosts

If you are having problems sending traffic to an IP address, you can trace the route to the host to determine if there is a problem on the network path. A traceroute works by sending UDP packets on an invalid port, or ICMPv6 echoes, to a destination. The routers along the way to the destination respond with an ICMP Time Exceeded Message, and report that error to traceroute. Each node receives three packets, so you get three chances per node to get an informative result. You can use traceroute by opening the CLI console or by logging into the device CLI.

There are separate commands for tracing a route through a data interface (traceroute) or through the virtual management interface (traceroute system). Ensure that you use the right command.

The following table describes the possible result per packet as displayed in the output.

<table>
<thead>
<tr>
<th>Output Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>No response was received for the probe within the timeout period.</td>
</tr>
<tr>
<td>nn msec</td>
<td>For each node, the round-trip time (in milliseconds) for the specified number of probes.</td>
</tr>
<tr>
<td>!N.</td>
<td>ICMP network unreachable.</td>
</tr>
<tr>
<td>!H</td>
<td>ICMP host unreachable.</td>
</tr>
<tr>
<td>!P</td>
<td>ICMP protocol unreachable.</td>
</tr>
<tr>
<td>!A</td>
<td>ICMP administratively prohibited.</td>
</tr>
<tr>
<td>?</td>
<td>Unknown ICMP error.</td>
</tr>
</tbody>
</table>

Tracing a route through the virtual management interface

Use the traceroute system command.

```
traceroute system destination
```

The host can be an IPv4/IPv6 address or fully-qualified domain name (FQDN), such as www.example.com. For example:

```bash
> traceroute system www.example.com
traceroute to www.example.com (172.163.4.161), 30 hops max, 60 byte packets
1  192.168.0.254 (192.168.0.254) 0.213 ms 0.310 ms 0.328 ms
2  10.88.127.1 (10.88.127.1) 0.677 ms 0.739 ms 0.899 ms
3  lab-gw1.example.com (10.89.128.25) 0.638 ms 0.856 ms 0.864 ms
4  04-bb-gw1.example.com (10.152.240.65) 1.169 ms 1.355 ms 1.409 ms
5  wan-gw1.example.com (10.152.240.33) 0.712 ms 0.722 ms 0.790 ms
6  wag-gw1.example.com (10.152.240.73) 13.868 ms 10.760 ms 11.187 ms
7  rbb-gw2.example.com (172.30.4.85) 7.202 ms 7.301 ms 7.101 ms
8  rbb-gw1.example.com (172.30.4.77) 8.162 ms 8.225 ms 8.373 ms
9  sbb-gw1.example.com (172.16.16.210) 7.396 ms 7.548 ms 7.653 ms
10 corp-gw2.example.com (172.16.16.58) 7.413 ms 7.310 ms 7.431 ms
11 dmzb-gw2.example.com (172.16.0.78) 7.835 ms 7.705 ms 7.702 ms
12 dmzdcc-gw2.example.com (172.16.0.190) 8.126 ms 8.193 ms 11.559 ms
13 dcz05n-gw1.example.com (172.16.2.106) 11.729 ms 11.728 ms 11.939 ms
```
Tracing a route through a data interface

Use the `traceroute` command.

```
traceroute destination
```

Specify the IP address of the host. If you only know the FQDN, use the `nslookup fqdn-name` command to determine the IP address. For example:

```
> traceroute 209.165.200.225
Tracing the route to 209.165.200.225
1 10.83.194.1 0 msec 10 msec 0 msec
2 10.83.193.65 0 msec 0 msec 0 msec
3 10.88.193.101 0 msec 10 msec 0 msec
4 10.88.193.97 0 msec 0 msec 10 msec
5 10.88.239.9 0 msec 10 msec 0 msec
6 10.88.238.65 10 msec 10 msec 0 msec
7 172.16.7.221 70 msec 70 msec 80 msec
8 209.165.200.225 70 msec 70 msec 70 msec
```

You can specify the timeout, time to live, number of packets per node, and even the IP address or interface to use as the source of the traceroute. Use the help indicator, `?`, in the CLI to see the available options.

### Making the Firepower Threat Defense Device Appear on Traceroutes

By default, the Firepower Threat Defense device does not appear on traceroutes as a hop. To make it appear, you need to decrement the time-to-live on packets that pass through the device, and increase the rate limit on ICMP unreachable messages. To accomplish this, you must create a FlexConfig object that configures the required service policy rule and other options.

If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as OSPF hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences. Keep these considerations in mind when defining your traffic class.

### Procedure

1. **Step 1** Click View Configuration in Device > Advanced Configuration.
2. **Step 2** Click FlexConfig > FlexConfig Objects in the Advanced Configuration table of contents.
3. **Step 3** Create the object to decrement TTL.
   a) Click the + button to create a new object.
b) Enter a name for the object. For example, **Decrement_TTL**.
c) In the **Template** editor, enter the following lines, including indentations.

```
icmp unreachable rate-limit 50 burst-size 1
policy-map global_policy
class class-default
  set connection decrement-ttl
```

d) In the **Negate Template** editor, enter the lines required to undo this configuration.

Just as you need to include the parent commands to enter the correct sub-mode for a command to enable it, you also need to include those commands in the negate template.

The negate template will be applied if you remove this object from the FlexConfig policy (after having deployed it successfully), and also during an unsuccessful deployment (to reset the configuration to its previous condition).

Thus, for this example, the negate template would be the following:

```
no icmp unreachable rate-limit 50 burst-size 1
policy-map global_policy
class class-default
  no set connection decrement-ttl
```

e) Click **OK** to save the object.

**Step 4** Add the objects to the FlexConfig policy.

Only those objects selected in the FlexConfig policy get deployed.

a) Click **FlexConfig Policy** in the table of contents.
b) Click + in the Group List.
c) Select the Decrement_TTL object and click **OK**.

The preview should update with the commands in the template. Verify you are seeing the expected commands.
d) Click **Save**.

You can now deploy the policy.

---

**Troubleshooting NTP**

The system relies on accurate and consistent time to function correctly and to ensure that events and other data points are handled accurately. You must configure at least one, but ideally three, Network Time Protocol (NTP) servers to ensure the system always has reliable time information.

The device summary connection diagram (click **Device** in the main menu) shows the status of the connection to the NTP server. If the status is yellow or orange, then there is an issue with the connection to the configured servers. If the connection problem persists (it is not just a momentary issue), try the following.

- First, ensure that you have at least three NTP servers configured on **Device > System Settings > NTP**. Although this is not a requirement, reliability is greatly enhanced if you have at least three NTP servers.
• Ensure that there is a network path between the management interface IP address (defined on Device > System Settings > Management Interface) and the NTP servers.
  
  • If the management interface gateway is the data interfaces, you can configure static routes to the NTP servers on Device > Routing if the default route is not adequate.
  
  • If you set an explicit management interface gateway, log into the device CLI and use the ping system command to test whether there is a network path to each NTP server.
  
• Log into the device CLI and check the status of the NTP servers with the following commands.
  
  • show ntp—This command shows basic information about the NTP servers and their availability. However, the connectivity status in Firepower Device Manager uses additional information to indicate the status, so there can be inconsistency in what this command shows and what the connectivity status diagram shows. You can also issue this command from the CLI console.
  
  • system support ntp—This command includes the output of show ntp plus the output of the standard NTP command ntpq, which is documented with the NTP protocol. Use this command if you need to confirm NTP synchronization.

Look for the section “Results of ‘ntpq -pn’.” For example, you might see something like the following:

```
Results of 'ntpq -pn'
remote : +216.229.0.50
refid : 129.7.1.66
st : 2
when : 704
poll : 1024
reach : 377
delay : 90.455
offset : 2.954
jitter : 2.473
```

In this example, the + before the NTP server address indicates that it is a potential candidate. An asterisk here, *, indicates the current time source peer.

The NTP daemon (NTPD) uses a sliding window of eight samples from each one of the peers and picks out one sample, then the clock selection determines the true chimers and the false tickers. NTPD then determines the round-trip distance (the offset of a candidate must not be over one-half the round trip delay). If connection delays, packet loss, or server issues cause one or all the candidates to be rejected, you would see long delays in the synchronization. The adjustment also occurs over a very long period of time: the clock offset and oscillator errors must be resolved by the clock discipline algorithm and this can take hours.

### Note

If the refid is .LOCL., this indicates the peer is an undisciplined local clock, that is, it is using its local clock only to set the time. Firepower Device Manager always marks the NTP connection yellow (not synchronized) if the selected peer is .LOCL. Normally, NTP does not select a .LOCL. candidate if a better one is available, which is why you should configure at least three servers.
Troubleshooting DNS for the Management Interface

You must configure at least one DNS server for use by the management interface. The server is needed for cloud connections to services such as smart licensing, database updates (such as GeoDB, rules, and VDB), and any other activity that needs domain name resolution.

Configuring a DNS server is rather trivial. You simply enter the IP addresses of the DNS servers you use when you initially configure the device. You can later change them on the Device > System Settings > DNS Server page.

However, the system can fail to resolve fully-qualified domain names (FQDN) due to network connectivity issues or problems with the DNS server itself. If you find the system cannot use your DNS servers, consider the following actions to identify and resolve the problem.

Procedure

**Step 1** Determine if you have a problem.

a) Use SSH to log into the device CLI.

b) Enter `ping system www.cisco.com`. If you get an “unknown host” message like the following, then the system could not resolve the domain name. If the ping is successful, then you are done: DNS is working. (Press Ctrl+C to stop the ping.)

   ```
   > ping system www.cisco.com
   ping: unknown host www.cisco.com
   ```

   **Note** It is critical that you include the `system` keyword in the `ping` command. The `system` keyword sends the ping through the management IP address, which is the only interface that uses the management DNS server. Pinging www.cisco.com is also a good option, because you need a route to that server for smart licensing and updates.

**Step 2** Verify the configuration for the management interface.

a) Click Device > System Settings > Management Interface, and verify the following. If you make changes, the changes are applied immediately on clicking Save. If you change the management address, you will need to reconnect and log back in.

   • The gateway IP address is correct for the management network. If you using the data interfaces as the gateway, subsequent steps will verify that configuration.

   • If you are not using the data interfaces as a gateway, verify that the management IP address/subnet mask and the gateway IP address are on the same subnet.

b) Click Device > System Settings > DNS Server and verify that the right DNS servers are configured.

   If you are deploying the device on your network edge, your service provider might have specific requirements about the DNS server you can use.

c) If you are using the data interfaces as the gateway, verify that you have the required routes.

   You need a default route for 0.0.0.0. You might need additional routes if the DNS server is not available through the gateway for the default route. There are two basic situations:
If you are using DHCP to obtain an address for the outside interface, and you selected the **Obtain Default Route using DHCP** option, the default route is not visible in Firepower Device Manager. From SSH, enter `show route` and verify that there is a route for 0.0.0.0. Because this is the default configuration for the outside interface, this is a likely situation that you might encounter. (Go to **Device > Interfaces** to view the configuration of the outside interface.)

If you are using a static IP address on the outside interface, or you are not obtaining the default route from DHCP, then open **Device > Routing**. Verify that the correct gateway is being used for the default route.

If the DNS server cannot be reached through the default route, you must define a static route to it on the **Routing** page. Note that you should not add routes for directly connected networks, that is, networks that are connected directly to any of the system’s data interfaces, as the system can route to those networks automatically.

Also verify that there are no static routes that are miss-directing traffic to the server out the wrong interface.

If the deployment button indicates that there are undeployed changes, deploy them now and wait for deployment to complete.

e) Retest **ping system www.cisco.com**. If you still have problems, continue with the next step.

**Step 3** In the SSH session, enter **nslookup www.cisco.com**.

- If **nslookup** indicates that it got a response from the DNS server, but the server could not find the name, it means that DNS is configured correctly, but the DNS server you are using does not have an address for the FQDN. The response would look similar to the following:

```
> nslookup www.cisco.com
Server: 10.163.47.11
Address: 10.163.47.11#53
** server can't find www.cisco.com: NXDOMAIN
```

**Resolution:** In this case, you need to configure a different DNS server, or get the one you have updated so it can resolve the FQDNs you need resolved. Work with your network administrator or ISP to get the IP address of a DNS server that will work for your network.

- If you get a “connection timed out” message, then the system cannot reach your DNS servers, or all of the DNS servers are currently down and not responding (which is less likely). Continue with the next step.

```
> nslookup www.cisco.com
; ; connection timed out; no servers could be reached
```

**Step 4** Use the **traceroute system DNS_server_ip_address** command to trace the route to the DNS server.

For example, if the DNS server is 10.100.10.1, enter:

```
> traceroute system 10.100.10.1
```
Following are the possible results:

- The traceroute completes and reaches the DNS server. In this case, there is in fact a route to the DNS server and the system can reach it. Thus, there is no routing problem. However, for some reason, DNS requests to this server are not getting a response.

  **Resolution:** There is a possibility that a router or firewall along the path is dropping UDP/53 traffic, which is the port used for DNS. You might try a DNS server along a different network path. This is a difficult problem to resolve, as you will need to determine which node is blocking traffic, and work with the system administrator to get the access rules changed.

- The traceroute cannot reach even one node, which would look like the following:

  ```
  > traceroute system 10.100.10.1
  traceroute to 10.100.10.1 (10.100.10.1), 30 hops max, 60 byte packets
  1 * * *
  2 * * *
  3 * * *
  (and so forth)
  ```

  **Resolution:** In this case, the routing problem is within your system. Try doing a `ping system` for the gateway IP address. Re-verify the configuration of the management interface as mentioned in earlier steps, and ensure that you have the required gateways and routes configured.

- The traceroute makes it through a few nodes before it can no longer resolve the route, which would look like the following:

  ```
  > traceroute system 10.100.10.1
  traceroute to 10.100.10.1 (10.100.10.1), 30 hops max, 60 byte packets
  1 192.168.0.254 (192.168.0.254) 0.475 ms 0.532 ms 0.542 ms
  2 10.88.127.1 (10.88.127.1) 0.803 ms 1.434 ms 1.443 ms
  3 site04-lab-gw1.example.com (10.89.128.25) 1.390 ms 1.399 ms 1.435 ms
  4 * * *
  5 * * *
  6 * * *
  ```

  **Resolution:** In this case, routing breaks down at the last node. You might need to work with the system administrator to get correct routes installed in that node. However, if there is intentionally no route to the DNS server through the node, you need to change your gateway, or create your own static route, to point to a router that can route traffic to the DNS server.

---

**Analyzing CPU and Memory Usage**

To view system-level information about CPU and memory usage, select **Monitoring > System** and look for the CPU and Memory bar graphs. These graphs show information collected through the CLI using the `show cpu system` and `show memory system` commands.

If you open the CLI console or log into the CLI, you can use additional versions of these commands to view other information. Typically, you would look at this information only if you are having persistent problems with usage, or at the direction of the Cisco Technical Assistance Center (TAC). Much of the detailed information is complex and requires TAC interpretation.

- **show cpu** displays data plane CPU utilization.
- **show cpu core** displays usage for each CPU core separately.
- **show cpu detailed** displays additional per-core and overall data plane CPU usage.
- **show memory** displays data plane memory usage.

Note

Some of the keywords (not mentioned above) require that you first set up profiling or other features using the `cpu` or `memory` commands. Use these features at the direction of TAC only.

**Viewing Logs**

The system logs information for a wide variety of actions. You can use the `system support view-files` command to open a system log. Use this command while working with the Cisco Technical Assistance Center (TAC) so that they can help you interpret the output and to select the appropriate log to view.

The command presents a menu for selecting a log. Use the following commands to navigate the wizard:

- To change to a sub-directory, type in the name of the directory and press Enter.
- To select a file to view, enter `s` at the prompt. You are then prompted for a file name. You must type the complete name, and capitalization matters. The file list shows you the size of the log, which you might consider before opening very large logs.
- Press the space bar when you see `--More--` to see the next page of log entries; press Enter to see just the next log entry. When you reach the end of the log, you are taken to the main menu. The `--More--` line shows you the size of the log and how much of it you have viewed. **Use Ctrl+C to close the log and exit the command if you do not want to page through the entire log.**
- Type `b` to go up one level in the structure to the menu.

If you want to leave the log open so you can see new messages as they are added, use the `tail-logs` command instead of `system support view-files`.

The following examples show how view the cisco/audit.log file, which tracks attempts to log into the system. The file listing starts with directories at the top, then a list of files in the current directory.

```bash
> system support view-files
--- View Logs ---

Directory: /ngfw/var/log
----------- sub-dirs -----------
cisco
mojo
removed_packages
setup
connector
```
sf
scripts
packages
removed_scripts
httpd

-----------files------------
2016-10-14 18:12:04.514783 | 5371 | SMART_STATUS_sda.log
2016-10-14 18:12:04.524783 | 353 | SMART_STATUS_sdb.log
2016-10-11 21:32:23.848733 | 326517 | action_queue.log
2016-10-06 16:00:56.620019 | 1018 | br1.down.log

Type the name of the file to view ([b] to go back, [Ctrl+C] to exit)

Creating a Troubleshooting File

Cisco Technical Assistance Center (TAC) personnel might ask you to submit system log information when you submit a problem report. This information assists them with diagnosing the problem. You do not need to submit a diagnostics file unless asked to do so.

The following procedure explains how to create and download the diagnostics file.

Procedure

Step 1

Click Device.
Step 2: Under Troubleshooting, click Request File to be Created or Re-Request File to be Created (if you have created one before).

The system starts generating the diagnostic file. You can go to other pages and return here to check status. When the file is ready, the date and time of the file creation is shown along with a download button.

Step 3: When the file is ready, click the download button.

The file is downloaded to your workstation using your browser's standard download method.

---

**Uncommon Management Tasks**

The following topics cover actions you would not perform often, if ever. All of these actions result in erasing your device configuration. Ensure that the device is not currently providing critical services to a production network before making these changes.

### Switching Between Local and Remote Management

You can configure and manage your device using the local Firepower Device Manager, which is hosted directly on the device, or remotely, using the Firepower Management Center multiple device manager. You might want to use the remote manager if you want to configure features not supported by Firepower Device Manager, or if you need the power and analysis capabilities available in Firepower Management Center.

You also must use Firepower Management Center if you want to run the device in transparent firewall mode.

You can switch between local and remote management without reinstalling the software. Before switching from remote to local management, verify that Firepower Device Manager meets all of your configuration requirements.

⚠️ **Caution**: Switching managers erases the device configuration and returns the system to the default configuration. However, management IP address and hostname are preserved.

### Before you begin

If you registered the device, especially if you enabled any feature licenses, you must unregister the device through Firepower Device Manager before switching to remote management. Unregistering the device frees the base license and all feature licenses. If you do not unregister the device, those licenses remain assigned to the device in Cisco Smart Software Manager. See Unregistering the Device, on page 85.

### Procedure

**Step 1**: Use an SSH client to open a connection to the management IP address and log into the device CLI with a username that has configuration CLI access. For example, the admin username.

It is important that you follow this process while connected to the management IP address. When using Firepower Device Manager, you have the option to manage the device through the IP address on a data
interface. However, you must use the Management physical port and management IP address to manage the device remotely.

If you cannot connect to the management IP address, address the following:

- Ensure that the Management physical port is wired to a functioning network.
- Ensure that the management IP address and gateway are configured for the management network. From Firepower Device Manager, configure the address and gateway on **Device > System Settings > Management Interface**. (In the CLI, use the `configure network ipv4/ipv6 manual` command.)

**Note** Ensure that you are using an external gateway for the management IP address. You cannot use the data interfaces as a gateway when using a remote manager.

### Step 2

To switch from local to remote management:

a) Verify you are currently in local management mode.

```
> show managers
Managed locally.
```

b) Configure the remote manager.

```
configure manager add {hostname | IPv4_address | IPv6_address | DONTRESOLVE} regkey [nat_id]
```

Where:

- `{hostname | IPv4_address | IPv6_address | DONTRESOLVE}` specifies the DNS host name or IP address (IPv4 or IPv6) of the Firepower Management Center that manages this device. If the Firepower Management Center is not directly addressable, use `DONTRESOLVE`. If you use `DONTRESOLVE`, `nat_id` is required.
- `regkey` is the unique alphanumeric registration key required to register a device to the Firepower Management Center.
- `nat_id` is an optional alphanumeric string used during the registration process between the Firepower Management Center and the device. It is required if the hostname is set to `DONTRESOLVE`.

For example, to use the manager at 192.168.0.123 with the registration key `secret`, enter the following:

```
> configure manager add 192.168.0.123 secret
If you enabled any feature licenses, you must disable them in Firepower Device Manager before switching to remote management.
Otherwise, those licenses remain assigned to the device in Cisco Smart Software Manager.
Do you want to continue [yes/no] yes
Manager successfully configured.
Please make note of reg_key as this will be required while adding Device in FMC.
```

```
> show managers
Host : 192.168.0.123
Registration Key : ****
Registration : pending
RPC Status : 
```

**Note** While registration is still pending, you can use `configure manager delete` to cancel the registration and then `configure manager local` to return to local management.
c) Log into the Firepower Management Center and add the device.
See the Firepower Management Center online help for details.

Step 3 To switch from remote management to local management:

a) Verify you are currently in remote management mode.

```
> show managers
Host : 192.168.0.123
Registration Key : ****
Registration : pending
RPC Status
```

b) Delete the remote manager and go into no manager mode.

You cannot go directly from remote management to local management. Use the `configure manager delete` command to remove the manager.

```
> configure manager delete
Deleting task list
Manager successfully deleted.
```

```
>
> show managers
No managers configured.
```

c) Configure the local manager.

`configure manager local`

For example:

```
> configure manager local
Deleting task list
```

```
> show managers
Managed locally.
```

You can now use a web browser to open the local manager at `https://management-IP-address`.

---

**Changing the Firewall Mode**

A Firepower Threat Defense firewall can run in routed or transparent mode. A routed mode firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a "bump in the wire," or a "stealth firewall," and is not seen as a router hop to connected devices.

The local Firepower Device Manager supports routed mode only. If, however, you need to run the device in transparent mode, you can change the firewall mode and start managing the device with Firepower Management Center. Conversely, you can convert a transparent mode device to routed mode, and then you have the option to configure it with the local manager (you can also manage routed mode devices using Firepower Management Center).
Regardless of local or remote management, you must use the device CLI to change the mode.

The following procedure explains how to change the mode when using the local manager, or when intending to use the local manager.

Caution
Changing firewall mode erases the device configuration and returns the system to the default configuration. However, management IP address and hostname are preserved.

Before you begin
If you are converting to transparent mode, install Firepower Management Center before changing the firewall mode.

If you enabled any feature licenses, you must disable them in Firepower Device Manager before deleting the local manager and switching to remote management. Otherwise, those licenses remain assigned to the device in Cisco Smart Software Manager. See Enabling or Disabling Optional Licenses, on page 84.

Procedure

Step 1
Use an SSH client to open a connection to the management IP address and log into the device CLI with a username that has configuration CLI access. For example, the admin username.

It is important that you follow this process while connected to the management IP address. When using Firepower Device Manager, you have the option to manage the device through the IP address on a data interface. However, you must use the Management physical port and management IP address to manage the device remotely.

If you cannot connect to the management IP address, address the following:

- Ensure that the Management physical port is wired to a functioning network.

- Ensure that the management IP address and gateway are configured for the management network. From Firepower Device Manager, configure the address and gateway on Device > System Settings > Management Interface. (In the CLI, use the configure network ipv4/ipv6 manual command.)

Note Ensure that you are using an external gateway for the management IP address. You cannot use the data interfaces as a gateway when using a remote manager.

Step 2
To change the mode from routed to transparent and use remote management:

a) Disable local management and enter no manager mode.

You cannot change the firewall mode while there is an active manager. Use the configure manager delete command to remove the manager.

> configure manager delete
If you enabled any feature licenses, you must disable them in Firepower Device Manager before deleting the local manager. Otherwise, those licenses remain assigned to the device in Cisco Smart Software Manager.
Do you want to continue[yes/no] yes
Deleting task list
Manager successfully deleted.
b) Change the firewall mode to transparent.

```
configure firewall transparent
```

**Example:**

```
> configure firewall transparent
This will destroy the current interface configurations,
are you sure that you want to proceed? [y/N] y
The firewall mode was changed successfully.
```

c) Configure the remote manager.

```
configure manager add {hostname | IPv4_address | IPv6_address | DONTRESOLVE} regkey [nat_id]
```

Where:

- `{hostname | IPv4_address | IPv6_address | DONTRESOLVE}` specifies the DNS host name or IP address (IPv4 or IPv6) of the Firepower Management Center that manages this device. If the Firepower Management Center is not directly addressable, use DONTRESOLVE. If you use DONTRESOLVE, `nat_id` is required.
- `regkey` is the unique alphanumeric registration key required to register a device to the Firepower Management Center.
- `nat_id` is an optional alphanumeric string used during the registration process between the Firepower Management Center and the device. It is required if the hostname is set to DONTRESOLVE.

For example, to use the manager at 192.168.0.123 with the registration key `secret`, enter the following:

```
> configure manager add 192.168.0.123 secret
Manager successfully configured.
Please make note of reg_key as this will be required while adding Device in FMC.
```

```
> show managers
Host : 192.168.0.123
Registration Key : ****
Registration : pending
RPC Status :
```

d) Log into the Firepower Management Center and add the device.

See the Firepower Management Center online help for details.

**Step 3** To change the mode from transparent to routed and convert to local management:

a) Deregister the device from the FMC.

b) Access the FTD device CLI, preferably from the console port.

Because changing the mode erases your configuration, the management IP address will revert to the default, so you might lose an SSH connection to the management IP address after changing modes.

c) Change the firewall mode to routed.
configure firewall routed

Example:

> configure firewall routed
This will destroy the current interface configurations, are you sure that you want to proceed? [y/N] y
The firewall mode was changed successfully.

d) Enable the local manager.

configure manager local

For example:

> configure manager local
Deleting task list
> show managers
Managed locally.

You can now use a web browser to open the local manager at https://management-IP-address.

Resetting the Configuration

You can reset the system configuration to the factory default if you want to start over. Although you cannot directly reset the configuration, deleting and adding the manager clears the configuration.

If your intention is to wipe away the configuration and then recover a backup, ensure that you have already download the backup copy you want to restore. You will need to upload it after resetting the system so that you can restore it.

Before you begin

If you enabled any feature licenses, you must disable them in Firepower Device Manager before deleting the local manager. Otherwise, those licenses remain assigned to the device in Cisco Smart Software Manager. See Enabling or Disabling Optional Licenses, on page 84.

Procedure

Step 1 Use an SSH client to open a connection to the management IP address and log into the device CLI with a username that has configuration CLI access. For example, the admin username.

Step 2 Use the configure manager delete command to remove the manager.

> configure manager delete
If you enabled any feature licenses, you must disable them in Firepower Device Manager before deleting the local manager. Otherwise, those licenses remain assigned to the device in Cisco Smart Software Manager.
Do you want to continue[yes/no] yes
Deleting task list
Manager successfully deleted.
>
> show managers
No managers configured.

**Step 3**  Configure the local manager.

```plaintext
configure manager local
```

For example:

```plaintext
> configure manager local
Deleting task list

> show managers
Managed locally.
```

You can now use a web browser to open the local manager at https://management-IP-address. By clearing the configuration, you will be prompted to complete the device setup wizard.
Advanced Configuration

Some device features are configured using ASA configuration commands. Although Firepower Device Manager can configure many command-based features, it does not support all of them. If you need to use some of these ASA features that are not otherwise supported in Firepower Device Manager, you can use Smart CLI or FlexConfig to manually configure the features.

The following topics explain this type of advanced configuration in more detail.

- About Smart CLI and FlexConfig, on page 431
- Guidelines and Limitations for Smart CLI and FlexConfig, on page 438
- Configuring Smart CLI Objects, on page 439
- Configuring the FlexConfig Policy, on page 440
- Troubleshooting the FlexConfig Policy, on page 450
- Examples for FlexConfig, on page 451

About Smart CLI and FlexConfig

Firepower Threat Defense uses ASA configuration commands to implement some features, but not all features. There is no unique set of Firepower Threat Defense configuration commands.

You can configure features using the CLI using the following methods:

- **Smart CLI**—(Preferred method.) A Smart CLI template is a pre-defined template for a particular feature. All of the commands needed for the feature are provided, and you simply need to select values for variables. The system validates your selection, so that you are more likely to configure a feature correctly. If a Smart CLI template exists for the feature you want, you must use this method.

- **FlexConfig**—The FlexConfig policy is a collection of FlexConfig objects. The FlexConfig objects are more free-form than Smart CLI templates, and the system does no CLI, variable, or data validation. You must know ASA configuration commands and follow the ASA configuration guides to create a valid sequence of commands.

The point of Smart CLI and FlexConfig is to allow you to configure features that are not directly supported through Firepower Device Manager policies and settings.
Recommended Usage for Smart CLI and FlexConfig

There are two main recommended uses for FlexConfig:

• You are migrating from ASA to FTD, and there are compatible features you are using (and need to continue using) that Firepower Device Manager does not directly support. In this case, use the `show running-config` command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Verify by comparing `show running-config` output on the two devices.

• You are using FTD but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

Before trying to recreate an ASA configuration, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control, which the ASA implements using separate features. Because many features are not configured using CLI commands, you will not see every policy represented within the output of `show running-config`.

At all times, keep in mind that there is not a one-to-one overlap between ASA and FTD. Do not attempt to completely recreate an ASA configuration on a FTD device. You must carefully test any feature that you configure using FlexConfig.

CLI Commands in Smart CLI and FlexConfig Objects

FTD uses ASA configuration commands to configure some features. Although not all ASA features are compatible with FTD, there are some features that can work on FTD but that you cannot configure in Firepower Device Manager policies. You can use Smart CLI and FlexConfig objects to specify the CLI required to configure these features.

If you decide to use Smart CLI or FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig does not validate CLI command syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference.
Determine the ASA Software Version and Current CLI Configuration

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the FTD device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from a FTD configuration. Many FTD policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and FTD configuration.

To view this information, either open the CLI Console in Firepower Device Manager or make an SSH connection to the device's management interface and issue the following commands:

- `show version system` and look for the Cisco Adaptive Security Appliance Software Version number.
- `show running-config` to view the current CLI configuration.
- `show running-config all` to include all the default commands in the current CLI configuration.

Prohibited CLI Commands

The purpose of Smart CLI and FlexConfig is to configure features that are available on ASA devices that you cannot configure on FTD devices using Firepower Device Manager.

Thus, you are prevented from configuring ASA features that have equivalents in Firepower Device Manager. The following table lists some of these prohibited command areas. This list contains many parent commands that enter configuration modes. The prohibition of the parent includes the prohibition of the children commands. It also includes the `no` version of the commands and their associated `clear` commands.

The FlexConfig object editor prevents you from including these commands in the object. This list does not apply to Smart CLI templates, as they include only those commands you can validly configure.

### Smart CLI Templates

The following table explains the Smart CLI templates based on the feature.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Templates</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routing: OSPFv2</td>
<td>OSPF</td>
<td>Use the OSPF template to configure the routing process, and the Interface template to configure per-interface OSPF behavior.</td>
</tr>
<tr>
<td></td>
<td>Interface</td>
<td></td>
</tr>
</tbody>
</table>

**Tips:**

- If you intend to redistribute routes from other routing processes, you should first configure those processes. For example, before configuring OSPF to redistribute EIGRP routes, first create and deploy the FlexConfig object that configures EIGRP.
- You can configure up to 2 OSPF processes.

### Guidelines and Limitations for Smart CLI and FlexConfig

Please keep the following in mind when configuring features through Smart CLI or FlexConfig.

- The commands defined in FlexConfig objects are deployed after all commands for features defined through Firepower Device Manager, including Smart CLI. Thus, you can depend on objects, interfaces, and so forth being configured before these commands are issued to the device. If you need to use a FlexConfig-deployed item in a Smart CLI template, create and deploy the FlexConfig before creating and deploying the Smart CLI template. For example, if you want to use the OSPF Smart CLI template to redistribute EIGRP routes, first use FlexConfig to configure EIGRP, then create the OSPF Smart CLI template.

- If you want to remove a feature or part of a feature that you configured through FlexConfig, but a Smart CLI template refers to that feature, you must first remove the commands in the Smart CLI template that use the feature. Then, deploy the configuration so that the Smart-CLI configured feature no longer refers to it. You can then remove the feature from FlexConfig and redeploy the configuration to finally eliminate it altogether.
Configuring Smart CLI Objects

Smart CLI objects define features that cannot be configured elsewhere in Firepower Device Manager. Smart CLI objects provide a level of guidance in configuring a feature. For a given feature (template), all possible commands are pre-loaded, and the variables you enter are validated. Thus, although you still use CLI commands to configure a feature, Smart CLI objects are not as free-form as FlexConfig objects.

Although Smart CLI templates do provide a level of guidance, you must still read the ASA configuration guides and command references to understand the command usage so that you pick values that work correctly for your network. Ideally, you already have an ASA configuration to work from, and you merely need to build the same sequence of commands in the Smart CLI object.

Smart CLI objects are grouped according to feature area.

Note

All Smart CLI objects that you define are deployed. Unlike FlexConfig, you cannot create several Smart CLI objects and then select which of them to deploy. Create Smart CLI objects only for those features you want to configure.

Procedure

Step 1
Click View Configuration in Device > Advanced Configuration.

Step 2
Click the appropriate feature area under Smart CLI in the Advanced Configuration table of contents.

Step 3
Do one of the following:

• To create an object, click the + button.

• To edit an object, click the edit icon ( Modiﬁ cations) for the object.

To delete an object, click the trash can icon ( ) for the object.

Step 4
Enter a Name for the object and optionally, a description.

Step 5
Select the CLI Template for the feature you are configuring.

The system loads the command template into the Template window. Initially, only the required commands are shown. These represent the minimum configuration required for the template.

Note

Some features require more than one template. For example, to configure OSPFv2, you need to create two Smart CLI objects, using the OSPF and the Interface templates. Note that you cannot use the OSPF template to configure OSPFv3.

Step 6
Fill in the variables and add commands as needed in the template.

Ideally, you are working with an existing configuration from an ASA or Firepower Threat Defense device (one that is managed by Firepower Management Center). With a configuration in hand, you simply need to make the template conform to it, changing variables such as IP addresses and interface names as appropriate for the location of this specific device in your network.

Following are some tips for filling in the template:
To select a value for a variable, click the variable and either type in the appropriate value, or select it from a list (in the case of enumerated values). Mousing over variables that require typing shows the valid values for the option, such as a range of numbers. In some cases, the recommended value is mentioned.

For example, in the OSPF template, the required command `router ospf process-id` shows “Process ID (1-65535)” on mouse-over, and when you click `process-id`, the field is highlighted. Simply type in the number you want.

When you select an option for a variable, if there are additional possible commands to configure the option, these are automatically exposed and disabled or enabled as appropriate. Watch for these additional commands.

Use the Show/Hide Disabled link above the template to control your view. Disabled commands will not be configured, but you must display them to configure them. To see the full template, click the Show Disabled link above the template. To see only those commands that will be configured, click the Hide Disabled link above the table.

To clear all of your edits since you last saved the object, click the Reset link above the template.

To enable an optional command, click the + button to the left of the line number.

To disable an optional command, click the - button to the left of the line number. If you edited the line, your edits are not deleted.

To duplicate a command, click the Options ... button and select Duplicate. You are allowed to duplicate commands only if it is valid to enter the command more than once.

To delete a duplicated command, click the Options ... button and select Delete. You cannot delete the commands that are a part of the base template.

**Step 7** Click OK.

---

**Configuring the FlexConfig Policy**

The FlexConfig Policy is simply a list of the FlexConfig objects that you want to deploy to the device configuration. Only those objects included in the policy are deployed, all others are simply defined and unused.

The commands defined in FlexConfig objects are deployed after all commands for features defined through Firepower Device Manager, including Smart CLI. Thus, you can depend on objects, interfaces, and so forth being configured before these commands are issued to the device. If you need to use a FlexConfig-deployed item in a Smart CLI template, create and deploy the FlexConfig before creating and deploying the Smart CLI template. For example, if you want to use the OSPF Smart CLI template to redistribute EIGRP routes, first use FlexConfig to configure EIGRP, then create the OSPF Smart CLI template.

---

**Note**

If there is a Smart CLI template for a feature, you cannot configure it using FlexConfig. You must use the Smart CLI object.

---

**Before you begin**

Create the FlexConfig objects. See the following topics:
Procedure

Step 1  Click View Configuration in Device > Advanced Configuration.
Step 2  Click FlexConfig > FlexConfig Policy in the Advanced Configuration table of contents.
Step 3  Manage the list of objects in the Group List.
   • To add an object, click the + button. If the object does not yet exist, click Create New FlexConfig Object to define it.
   • To delete an object, click the X button at the right of the object entry.

Note  We recommend that each object be completely self-contained and not depend on the configuration defined in any other FlexConfig object. This ensures that you can add or remove objects without affecting other objects. Although you can reposition the objects in the list, the order is not saved and it does not change the order in which the objects are deployed.

Step 4  Evaluate the proposed commands in the Preview pane.
   You can click the Expand button (and subsequently, Collapse) to widen the screen so you can see long commands more clearly.
   The preview evaluates variables and produces the exact commands that will be issued. Ensure that these commands are correct and valid. You are responsible for ensuring the commands will not result in errors or poor configurations that make the device unusable.
   Caution  The system does not validate the commands. It is possible for you to deploy invalid and even potentially destructive commands. Examine the preview very carefully before deploying changes.

Step 5  Click Save.

What to do next
After editing the FlexConfig policy, carefully examine the results of the next deployment. If there are errors, correct the CLI in the object. See Troubleshooting the FlexConfig Policy, on page 450.

Configuring FlexConfig Objects

A FlexConfig object contains the ASA commands required to configure a particular feature that you cannot otherwise configure using Firepower Device Manager. You are responsible for ensuring that you enter the right sequence of commands, without typos. The system does not validate the content of FlexConfig objects.

We recommend that you create separate objects for each general feature you intend to configure. For example, if you want to define banners and also configure the RIP routing protocol, use 2 separate objects. Isolating
features in separate objects makes it easier for you to pick and choose which to objects to deploy, and also makes troubleshooting more straight-forward.

---

**Note**

Do not include the `enable` and `configure terminal` commands. The system enters the right mode for configuration commands automatically.

---

## Procedure

**Step 1**  
Click **View Configuration** in **Device > Advanced Configuration**.

**Step 2**  
Click **FlexConfig > FlexConfig Objects** in the Advanced Configuration table of contents.

**Step 3**  
Do one of the following:

- To create an object, click the `+` button.
- To edit an object, click the edit icon (하겠습니다) for the object.

To delete an unreferenced object, click the trash can icon (삭제) for the object.

**Step 4**  
Enter a Name for the object and optionally, a description.

**Step 5**  
In the **Variables** section, create any variables that you want to use in the object body.

The only variables that you must create are those that point to objects defined within Firepower Device Manager, specifically, the Network, Port, and Secret Key variable types, or the Interface variable, which points to a named interface. For other variable types, you can simply type in the values into the object body.

For detailed information on creating and using variables, see **Creating Variables in a FlexConfig Object**, on page 443.

**Step 6**  
In the **Template** section, type in the ASA commands required to configure the feature.

You must enter commands in the right order for configuring the feature. Use the ASA CLI configuration guides to learn how to enter the commands. Ideally, you should have a pre-tested configuration file from an ASA or another FTD device that you can use as a reference.

You can also use Mustache notation to refer to and process variables. For detailed information, see **Referring to FlexConfig Variables and Retrieving Values**, on page 445.

Following are some tips for creating the object body:

- To add lines, put the cursor at the end of a line and press Enter.
- To use a variable, type the variable name between double-braces: `{variable_name}`. For variables that refer to objects, you must include the attribute whose value you are retrieving: `{variable_name.attribute}`. The available attributes differ based on object type. For complete information, see **Variable References: {{variable}}**, on page 445.
- Click the **Expand/Collapse** link above the template body to make the body larger or smaller.
- Click the **Reset** link to erase any changes you made since you last saved the object.
Step 7  In the **Negate Template** section, enter the commands needed to remove or reverse the commands configured in the object body.

The Negate section is very important and serves two purposes:

- It simplifies deployment. Before re-deploying the commands in the body, the system uses these commands to first erase or undo the configuration. This ensures a clean deployment.

- If you decide to remove the feature by removing the object from the FlexConfig Policy, the system uses these commands to remove the commands from the device.

If you do not supply the commands needed to negate or reverse the CLI in the object body, the deployment might need to clear the entire device configuration and redeploy all policies, not just the commands within the object. This will make deployment take longer and also disrupt traffic. Ensure that you have all, and only, those commands needed to undo the configuration defined in the object body. Although negate commands are typically the **no** or **clear** form of the commands in the template, if you are actually turning off a feature that was already enabled, the “negate” command is actually the positive form of the command, the one that enables the feature.

Use the ASA configuration guides and command reference to determine the appropriate commands. Sometimes, you can undo a configuration with a single command. For example, in an object that configures RIP, a simple `no router rip` command removes the entire `router rip` configuration, including subcommands.

Likewise, if you entered several `banner login` commands to create a multi-line banner, a single `no banner login` command negates the entire login banner.

If your template creates several nested objects, the negate template needs to remove the objects in reverse order, to first remove references to the objects before deleting the objects. For example, if you first create an ACL, then refer to it in a traffic class, then refer to the traffic class in a policy map, and finally enable the policy map using a service policy, the negate template must undo the configuration by first removing the service policy, then the policy map, then the traffic class, and finally the ACL.

Step 8  Click **OK**.

What to do next

Simply creating a FlexConfig object is not enough to get it deployed. You must add the object to the FlexConfig Policy. Only those objects in the FlexConfig policy get deployed. This makes it possible for you to refine your FlexConfig objects, and have some ready for special uses, without having all of them automatically deployed. See Configuring the FlexConfig Policy, on page 440.

Creating Variables in a FlexConfig Object

The variables you use inside a FlexConfig object are defined within the object itself. There is no separate list of variables. Thus, you cannot define a variable and then use it within separate FlexConfig objects.

Variables provide these main benefits:

- They make it possible to point to objects defined using Firepower Device Manager. This includes network, port, and secret key objects.

- They isolate values that might change from the object body. Thus, if you need to change a value, you simply edit the variable and you do not need to edit the object body. This can be especially helpful if you need to refer to the object in several command lines.
This procedure explains the process of adding variables to a FlexConfig object.

**Procedure**

**Step 1**
Edit or create a FlexConfig object from the Device > Advanced Configuration page.

See Configuring FlexConfig Objects, on page 441.

**Step 2**
Do one of the following in the Variables section:

- To add a variable, click the + button (or click Add Variable if there are none yet defined).

- To edit a variable, click the edit icon ( chỉnh sửa) for the variable.

To delete a variable, click the trash can ( xóa) icon for the variable. Make sure you remove any references to it from the template body.

**Step 3**
Enter a Name for the variable and optionally, a description.

**Step 4**
Select a data Type for the variable, then enter or select the value.

You can create the following types of variable. Choose a type that fits the data requirements of the commands in which you will use the variable.

- **String**—A text string. For example, hostnames, usernames, and so forth.

- **Numeric**—An integer number. Do not include commas, decimals, signs (such as negative), or hexadecimal notation. For non-integer numbers, use a string variable.

- **Boolean**—A logical true/false. Select either True or False.

- **Network**—A network object or group defined on the Objects page. Select the network object or group.

- **Port**—A TCP or UDP port object defined on the Objects page. Select the port object. You cannot select groups or objects for other protocols.

- **Interface**—A named interface defined on the Device > Interfaces page. Select the interface. You cannot select interfaces that have no names.

- **IP**—A single IPv4 or IPv6 IP address without netmask or prefix length.

- **Secret**—A secret key object defined for FlexConfig. Select the object. For information on creating secret key objects, see Configuring Secret Key Objects, on page 449.

**Step 5**
Click Add or Save in the Variable dialog box.

You can now use the variable within the body of the FlexConfig object. The way you refer to the variable differs based on variable type. For details on how to use these variables, see the following topics:

- **Variable References**: {{variable}}, on page 445

- **Sections**: {{#key}} {{/key}} and Inverse Sections: {{^key}} {{/key}}, on page 447

**Step 6**
Click OK in the FlexConfig Object dialog box.
Referring to FlexConfig Variables and Retrieving Values

FlexConfig uses Mustache as the template language, but support is limited to the features explained in the following sections. Use these features to refer to variables, retrieve their values, and process them.

Variable References: {{variable}}

To refer to a variable, which you define within a FlexConfig object, you use the following notation:

```
{{variable_name}}
```

This is sufficient for simple variables that are single values, which includes variables of the following types: Numeric, String, Boolean, and IP.

However, for variables that point to elements that are modeled as objects in the configuration database, you must use dot notation and include the name of the object attribute you want to retrieve. You can find these attribute names by examining the models in the API Explorer for the related object type. You must use the following notation to use variables of the following types: Secret, Network, Port, and Interface.

```
{{variable_name.attribute}}
```

For example, to retrieve the address from a network variable named net-object1 (which points to a network object, not a network group), you would use:

```
{{net-object1.value}}
```

If you are trying to retrieve an attribute value from an object within an object, you need to use a series of dotted attributes to drill down to the desired value. For example, the IP addresses for an interface are modeled as sub-objects, named ipv4 and ipv6, to the interface object. Thus, to retrieve the IPv4 address and subnet mask for an interface variable named int-inside (which points to the inside interface), you would use:

```
{{int-inside.ipv4.ipAddress.ipAddress}} {{int-inside.ipv4.ipAddress.netmask}}
```

To open API Explorer, change the last part of the URL in the browser to /#/api-explorer.

The following table lists the variable types, how to refer to them, and for objects, the name of the API model and the most likely references that you might use.
<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Reference Models</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean (simple variable) | **Variable:**
```
{{variable_name}}
```

**Section:**
```
{{#variable_name}}
commands
{{/variable_name}}
```

**Inverse Section:**
```
{{^variable_name}}
commands
{{/variable_name}}
```

A logical true/false. The main purpose for Boolean variables is for sections or inverse sections. You can edit the value of a Boolean variable to turn a section of commands on or off, for example, if you need to enable a feature periodically or under special circumstances only.

Some objects also have Boolean attributes in their models, which you can use to provide optional processing of a section.

| Interface (object variable: API model is Interface) | **Variable:**
```
{{variable_name.attribute}}
```

**Section:**
```
{{#variable_name.attribute}}
commands
{{/variable_name.attribute}}
```

**Inverse Section:**
```
{{^variable_name.attribute}}
commands
{{/variable_name.attribute}}
```

A named interface defined on the Device > Interfaces page. You cannot point to unnamed interfaces.

There is a wide variety of attributes available in the interface model. Also, the interface model includes sub-objects, for example, for IP addresses.

Following are some of the main attributes that you might find useful:

- `variable_name.name` returns the logical name of the interface.
- `variable_name.hardwareName` returns the interface port name, such as GigabitEthernet1/8.
- `variable_name.managementOnly` is a Boolean value. TRUE means that the interface is defined as management only. FALSE means the interface is for through-the-device traffic. You could use this option as a section key.
- `variable_name.ipv4.ipAddress.ipAddress` returns the IPv4 address for the interface.
- `variable_name.ipv4.ipAddress.netmask` returns the subnet mask for the IPv4 address for the interface.

| IP (simple variable) | **Variable:**
```
{{variable_name}}
```

A single IPv4 or IPv6 IP address without netmask or prefix length.
### Variable Type

<table>
<thead>
<tr>
<th>Description</th>
<th>Reference Models</th>
<th>Variable (Network Objects):</th>
</tr>
</thead>
<tbody>
<tr>
<td>A network object or group defined on the Objects page. You can use sections to process network groups. Following are the main attributes that you might find useful:</td>
<td>Variable (Network Objects):</td>
<td></td>
</tr>
<tr>
<td>Variable (Network Objects):</td>
<td>{{variable_name.attribute}}</td>
<td></td>
</tr>
<tr>
<td>Section (Group Objects):</td>
<td>{{variable_name.name}} returns the name of the network object or group.</td>
<td></td>
</tr>
<tr>
<td>{{variable_name.value}} returns the IP address contents of a network object (but not a network group). Ensure that you use a network object that has the right type of contents for a given command, for example, a host address rather than a subnet address.</td>
<td>{{variable_name.value}} returns the IP address contents of a network object (but not a network group). Ensure that you use a network object that has the right type of contents for a given command, for example, a host address rather than a subnet address.</td>
<td></td>
</tr>
<tr>
<td>{{variable_name.groups}} returns the list of network objects contained within a network group. Use this only with variables that point to network groups, and use it on a section tag to iteratively process the contents of the group. Use either {{value}} or {{name}} to retrieve the contents of each network object in turn.</td>
<td>{{variable_name.groups}} returns the list of network objects contained within a network group. Use this only with variables that point to network groups, and use it on a section tag to iteratively process the contents of the group. Use either {{value}} or {{name}} to retrieve the contents of each network object in turn.</td>
<td></td>
</tr>
</tbody>
</table>

### Numeric

<table>
<thead>
<tr>
<th>Description</th>
<th>Variable (Network Objects):</th>
</tr>
</thead>
<tbody>
<tr>
<td>A network object or group defined on the Objects page. You can use sections to process network groups. Following are the main attributes that you might find useful:</td>
<td>Numeric (simple variable)</td>
</tr>
<tr>
<td>Variable (Network Objects):</td>
<td>{{variable_name}}</td>
</tr>
<tr>
<td>An integer number. Do not include commas, decimals, signs (such as negative), or hexadecimal notation. For non-integer numbers, use a string variable.</td>
<td></td>
</tr>
</tbody>
</table>

### Port

<table>
<thead>
<tr>
<th>Description</th>
<th>Variable (Network Objects):</th>
</tr>
</thead>
<tbody>
<tr>
<td>A network object or group defined on the Objects page. You can use sections to process network groups. Following are the main attributes that you might find useful:</td>
<td>Port (object variable: API model is PortObject, tcpports or udpports)</td>
</tr>
<tr>
<td>Variable (Network Objects):</td>
<td>{{variable_name.attribute}}</td>
</tr>
<tr>
<td>An integer number. Do not include commas, decimals, signs (such as negative), or hexadecimal notation. For non-integer numbers, use a string variable.</td>
<td>A TCP or UDP port object defined on the Objects page. This must be a port object, not a port group. Following are the main attributes that you might find useful:</td>
</tr>
<tr>
<td>Section (Group Objects):</td>
<td>{{variable_name.port}} returns the port number. The protocol is not included.</td>
</tr>
<tr>
<td>{{variable_name.name}} returns the name of the port object.</td>
<td></td>
</tr>
</tbody>
</table>

### Secret

<table>
<thead>
<tr>
<th>Description</th>
<th>Variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>A secret key object defined for FlexConfig. The only reference you should make is to the password attribute, which returns the encrypted string.</td>
<td>Secret (object variable: API model is Secret)</td>
</tr>
<tr>
<td>Variable:</td>
<td>{{variable_name.password}}</td>
</tr>
<tr>
<td>A text string. For example, hostnames, usernames, and so forth.</td>
<td></td>
</tr>
</tbody>
</table>

### String

<table>
<thead>
<tr>
<th>Description</th>
<th>Variable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>A text string. For example, hostnames, usernames, and so forth.</td>
<td>String (simple variable)</td>
</tr>
<tr>
<td>Variable:</td>
<td>{{variable_name}}</td>
</tr>
</tbody>
</table>

### Sections {{#key}} {{/key}} and Inverse Sections {{^key}} {{/key}}

A section or an inverse section is a block of commands between the section start and end tags, which use a key as the processing criteria. How the section is processed depends on whether it is a regular or an inverse section:

- A regular section (or simply, a section) is processed if the key is TRUE or has non-empty contents. If the key is FALSE or the object has no content, the commands in the section are not configured. The section is bypassed.
The following is the syntax for a regular section.

```yaml
{{#key}}
  one or more commands
{{/key}}
```

- An inverse section is the opposite of a section. It is processed if the key is FALSE or the object has no contents. If the key is TRUE or the object has contents, the inverse section is bypassed.

The following is the syntax for an inverse section. The only difference is that a caret replaces the hash tag.

```yaml
{{^key}}
  one or more commands
{{/key}}
```

The following topics explain the main uses for sections and inverse sections.

### How to Process Multiple-Value Variables

The primary example of processing a multiple-value variable is a network variable that points to a network group. Because the group contains multiple objects (under the `objects` attribute), you can iteratively go through the values in the network group to configure the same command multiple times with different values.

For example, if you have a network group named `net-group` with the hosts 192.168.10.0, 192.168.20.0, and 192.168.30.0, you can use the following technique to configure a network command for each address for RIP routing. Note that you use the network object's `value` attribute alone, without specifying the entire `net-group.objects.value` reference, because the use of `net-group.objects` in the section start implies this usage. (You do not create a separate variable for the "value" attribute within the FlexConfig object.)

```yaml
router rip
{{net-group.objects}}
  network {{value}}
{{/net-group.objects}}
```

The system translates the section structure as:

```yaml
router rip
  network 192.168.10.0
  network 192.168.20.0
  network 192.168.30.0
```

### How to Perform Optional Processing Based on a Boolean Value or an Empty Object

If the content of the variable in the section start tag is TRUE, or an object is not empty, the section is processed. If a Boolean value is FALSE or empty (such as an empty object), the section is bypassed.

The main use here is for Boolean values. For example, you could create a Boolean variable, and put commands within a section covered by the variable. Then, if you need to enable or disable a section of the commands in the FlexConfig object, you merely need to change the value of the Boolean variable, you do not need to delete those lines from the code. This makes it easy to turn features on or off.

For example, you might want to be able to turn off SNMP traps if you use FlexConfig to enable SNMP. You could create a Boolean variable named `enable-traps`, and initially set it to TRUE. Then, if you need to turn
off traps, you simply edit the variable, change it to FALSE, save the object and then redeploy the configuration. The command sequence could look like the following:

```plaintext
snmp-server enable
snmp-server host inside 192.168.1.5
snmp-server community clearTextString
{{#enable-traps}}
   snmp-server enable traps all
{{/enable-traps}}
```

You can also do this type of processing based on Boolean values within an object. For example, you could check whether an interface is management-only before configuring some characteristic on it. In the following example, int-inside is an interface variable that points to the interface named inside. The FlexConfig configures the EIGRP-related interface options on the interface only if the interface is not set to management only. You would use an inverse section so that the commands are configured only if the Boolean value is FALSE.

```plaintext
router eigrp 2
   network 192.168.1.0 255.255.255.0
   {{^int-inside.managementOnly}}
      interface {{int-inside.hardwareName}}
      hello interval eigrp 2 60
      delay 200
   {{/int-inside.managementOnly}}
```

### Configuring Secret Key Objects

The point of a secret key object is to obscure passwords or sensitive strings. If you do not want to risk someone seeing a string used in a FlexConfig object or Smart CLI template, create a secret key object for the string.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Select <strong>Objects</strong>, then select <strong>Secret Keys</strong> from the table of contents.</td>
</tr>
</tbody>
</table>
| 2    | Do one of the following:  
|      | • To create an object, click the + button.  
|      | • To edit an object, click the edit icon (📝) for the object.  
|      | To delete an unreferenced object, click the trash can icon (Trash) for the object. |
| 3    | Enter a Name for the object and optionally, a description. |
| 4    | Enter the password or other secret string in both the **Password** and **Confirm Password** fields.  
|      | The system obscures the text as you type. |
| 5    | Click **OK**. |
What to do next

- If this is a new object, to use it in FlexConfig, edit a FlexConfig object, create a variable of the secret key type, and select the object. Then, refer to the variable within the object body. For more information, see Creating Variables in a FlexConfig Object, on page 443.

- If you are editing an existing object that is used in a FlexConfig object that is part of the FlexConfig policy, you need to deploy the configuration to update the device with the new string.

- In Smart CLI templates, if a command requires a secret key, you will see a list of these objects when editing the relevant property. Select the right key for the purpose.

Troubleshooting the FlexConfig Policy

After editing the FlexConfig policy, carefully examine the results of the next deployment. If you get a “Deployment has failed” message, look at the Status column in the Deployment Summary dialog box. The status for the failed job should include a See Details link.

If the deployment fails because of a FlexConfig problem, the details will mention the FlexConfig object with the bad command, and show the command that failed. Use this information to correct the object and try deployment again. The object name is a link, click it to open the edit dialog for the object.

For example, you might want to configure the maximum TCP segment size (TCP MSS). You can control this setting with the sysopt connection tcpmss command. When configured by Firepower Device Manager, the Firepower Threat Defense default for this option is 0, compared to the ASA default of 1380.

The ASA default is designed for optimal processing when running an IPv4 VPN on interfaces that use the default MTU of 1500. The system needs 120 bytes for the VPN headers. For IPv6, the system needs 140 bytes. The Firepower Threat Defense default of 0 simply allows the endpoints to negotiate the MSS, which is the ideal setting for normal traffic, especially if you use different MTUs across the interfaces on the device, including MTUs over 1500. Because TCP MSS is a global setting and not per-interface, you would change it only if a significant percentage of your traffic is over VPN and you are getting excessive fragmentation. In that case, you might set TCP MSS to MTU minus 120 (for IPv4) or 140 (for IPv6), and use the same MTU for all interfaces.

For purposes of illustration, suppose you want to set TCP MSS to 3 bytes. The command takes 48 bytes as the minimum value, so you will get a deployment error similar to the following:

```
1 sysopt connection tcpmss 3
```

The error is composed of these elements:

1. The deployment error message, which includes the name of the FlexConfig object that caused the error. The object name is linked to the edit dialog box so you can quickly open the object and correct the error. This is the first sentence of the message.

2. The text starting with “ERROR:” is the message returned from the device. This is exactly how an ASA would respond if you typed in the errant command, without the formatting of an SSH client. In this example, the error message is “ERROR: [3] is smaller than minimum allowed MSS of 48 by RFC
791.” The information following “Usage:” is additional information that is meant to help a user who is actually in the CLI, which you can ignore. If you were on an ASA using SSH, the interaction would look like the following:

asa3(config)# sysopt connection tcpmss 3
ERROR: <3> is smaller than minimum allowed MSS of 48 by RFC 791
Usage:
 [no] sysopt connection { permit-vpn | reclassify-vpn | preserve-vpn-flows | timewait | {tcpmss [minimum] <bytes>}
 [no] sysopt noproxyarp <if-name>
 [no] sysopt nodnsalias { inbound | outbound }
 [no] sysopt radius ignore-secret
 [no] sysopt traffic detailed-statistics
 [no] sysopt uauth allow-http-cache [DEPRECATED]
 show running-config [all] sysopt
 clear configure sysopt

3. The text in black is the actual line from the FlexConfig object that caused the error. You must fix this line. In this example, if you are trying to accommodate IPv4 VPN traffic on MTU 1500 interfaces (the common situation), you would change 3 to 1380.

In fixing this example, you can keep the CLI Console open and use show running-config all sysopt to see all of the sysopt command settings. Most of the sysopt commands have default settings appropriate for most uses, so they do not appear in the running configuration. The all keyword includes these default settings in the output.

Examples for FlexConfig

The following topics provide some examples for using FlexConfig to configure features.

How to Enable and Disable Global Default Inspections

Some protocols embed IP addressing information in the user data packet or open secondary channels on dynamically assigned ports. These protocols require the system to do a deep packet inspection so that NAT can be applied and secondary channels can be allowed. Several common inspection engines are enabled on the system by default, but you might need to enable others, or disable default inspections, depending on your network.

To see the list of currently enabled inspections, use the show running-config policy-map command, either in CLI Console or an SSH session. Following is what you would see on a system where no changes have been made to the inspection configuration. In this output, the list of inspect commands at the end of the output shows which protocol inspections are enabled. The preceding commands enable these inspections on the inspection_default traffic class (which is the normal protocols and, if applicable, port numbers, for the inspected protocol). This class is part of the global_policy policy map, which applies these inspections on all interfaces using a service-policy command that is not shown in the output. For example, ICMP inspection is done on all ICMP traffic that passes through the device.

> show running-config policy-map
! policy-map type inspect dns preset_dns_map
 parameters
 message-length maximum client auto
message-length maximum 512
no tcp-inspection
policy-map global_policy
class inspection_default
  inspect dns preset_dns_map
  inspect ftp
  inspect h323 h225
  inspect h323 ras
  inspect rsh
  inspect rtsp
  inspect sqlnet
  inspect skinny
  inspect sunrpc
  inspect xdmcp
  inspect sip
  inspect netbios
  inspect tftp
  inspect ip-options
  inspect icmp
  inspect icmp error

The following procedure shows you how to enable, or disable, inspections in this globally-applied default inspection class. For purposes of illustration, the example:

- Enables PPTP (Point-to-Point Tunneling Protocol). This protocol is used for tunneling a point-to-point connection between endpoints.
- Disables SIP (Session Initiation Protocol). You would typically disable SIP only if the inspection is causing problems in the network. However, if you disable SIP, you must ensure that your access control policies allow the SIP traffic (UDP/TCP 5060) and any dynamically allocated ports, and that you do not need NAT support for SIP connections. Adjust the access control and NAT policies accordingly through the standard pages, not through FlexConfig.

Before you begin

Good planning will help you use FlexConfig efficiently. In this example, we are changing two different and unrelated inspections, although we are making the changes in the same traffic class. But it is highly likely that if you need to alter these policies, you will do so independently.

Therefore, we recommend creating separate FlexConfig objects for each inspection in this example. That way, you can easily change your setting for one inspection without changing the other, and without needing to edit the FlexConfig object.

Procedure

**Step 1** Click View Configuration in Device > Advanced Configuration.

**Step 2** Click FlexConfig > FlexConfig Objects in the Advanced Configuration table of contents.
Step 3  Create the object to enable PPTP inspection.

a) Click the + button to create a new object.
b) Enter a name for the object. For example, **Enable_PPTP_Global_Inspection**.
c) In the Template editor, enter the following lines, including indentations.

```
policy-map global_policy
   class inspection_default
      inspect pptp
```

d) In the Negate Template editor, enter the lines required to undo this configuration.

Just as you need to include the parent commands to enter the correct sub-mode for a command to enable it, you also need to include those commands in the negate template.

The negate template will be applied if you remove this object from the FlexConfig policy (after having deployed it successfully), and also during an unsuccessful deployment (to reset the configuration to its previous condition).

Thus, for this example, the negate template would be the following:

```
policy-map global_policy
   class inspection_default
      no inspect pptp
```

The object should look like the following:
Because the inspection_default class has other inspection commands enabled, you do not want to negate the entire class. Similarly, the global_policy policy map includes these other inspections, and you do not want to negate the policy map either.

c) Click OK to save the object.

### Step 4
Create the object to disable SIP inspection.

a) Click the + button to create a new object.

b) Enter a name for the object. For example, Disable_SIP_Global_Inspection.

c) In the Template editor, enter the following lines, including indentations.

```
policy-map global_policy
  class inspection_default
    no inspect sip
```

d) In the Negate Template editor, enter the lines required to undo this configuration.

The “negate” command for a disabling “no” command is the command that enables the feature. Thus, the “negate” template is not just the commands to disable a feature, it is the commands to reverse whatever you do in the “positive” template. The point of the negate template is to undo your changes.

Thus, for this example, the negate template would be the following:

```
policy-map global_policy
  class inspection_default
    inspect sip
```

The object should look like the following:
Step 5

Add the objects to the FlexConfig policy.

Creating an object isn’t enough. Objects are deployed only if you add them to the FlexConfig policy (and save your changes). This allows you to experiment with objects (and leave them partially complete) without risking deployment failures on unfinished work. You can then easily turn features on or off simply by adding and removing objects: there is no need to recreate the object each time.

a) Click FlexConfig Policy in the table of contents.
b) Click + in the Group List.
c) Select the Enable_PPTP_Global_Inspection and Disable_SIP_Global_Inspection objects and click OK.

The group list should look like the following:
The preview should update with the commands in the template. Verify you are seeing the expected commands.

<table>
<thead>
<tr>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>6</td>
</tr>
</tbody>
</table>

d) Click **Save**.

You can now deploy the policy.

**Step 6**  Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

![Deploy Changes Icon]

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

**Step 7**  In CLI Console or an SSH session, use the **show running-config policy-map** command and verify that the running configuration has the correct changes.

In the following output, note that **inspect pptp** is added to the bottom of the inspection_default class, and that **inspect sip** is no longer in the class. This confirms that the changes defined in the FlexConfig object were successfully deployed.

```
> show running-config policy-map
! policy-map type inspect dns preset_dns_map
parameters
    message-length maximum client auto
    message-length maximum 512
no tcp-inspection
policy-map global_policy
class inspection_default
    inspect dns preset_dns_map
    inspect ftp
    inspect h323 h225
    inspect h323 ras
    inspect rsh
    inspect rtp
    inspect sqlnet
    inspect skinny
    inspect sunrpc
    inspect xdmcp
    inspect netbios
    inspect tftp
    inspect ip-options
```
How to Undo Your FlexConfig Changes

If you enter a correct negate template in a FlexConfig object, removing the changes made using that object is trivial. You simply delete the object from the FlexConfig policy, and upon the next deployment, the system uses your negate template to undo your changes.

You do not need to create a new object to undo your changes.

The following example shows how to re-enable global SIP inspection. The example reverts the change explained in How to Enable and Disable Global Default Inspections, on page 451, which disabled SIP inspection.

Before you begin

Verify that the FlexConfig object has the correct negate template. If it does not, edit the object to correct the negate template.

Procedure

Step 1  Click View Configuration in Device > Advanced Configuration.
Step 2  Click FlexConfig > FlexConfig Policy in the Advanced Configuration table of contents.
Step 3  Click the X on the right side of the Disable_SIP_Global_Inspection object’s entry in the FlexConfig policy to delete it from the policy.

The commands from the object are removed from the preview. The negate commands are not added to the preview, these will be executed behind the scenes.

Step 4  Click Save.
Step 5  Commit your changes.
  a)  Click the Deploy Changes icon in the upper right of the web page.

  b)  Click the Deploy Now button.

    Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be Deployed.

Step 6  In CLI Console or an SSH session, use the show running-config policy-map command and verify that the running configuration has the correct changes.
In the following output, note that inspect sip is added to the bottom of the inspection_default class. This confirms that the changes defined in the FlexConfig object were successfully deployed. (Order is not important in this class, so it does not matter that inspect sip is at the end and not in its original location.)

```bash
> show running-config policy-map
policy-map type inspect dns preset_dns_map
parameters
  message-length maximum client auto
  message-length maximum 512
  no tcp-inspection
policy-map global_policy
class inspection_default
  inspect dns preset_dns_map
  inspect ftp
  inspect h323 h225
  inspect h323 ras
  inspect rsh
  inspect rtsp
  inspect sqlnet
  inspect skinny
  inspect sunrpc
  inspect xdmcp
  inspect netbios
  inspect tftp
  inspect ip-options
  inspect icmp
  inspect icmp error
  inspect pptp
  inspect sip
```

---

**How to Enable Inspections for Unique Traffic Classes**

In this example, we will enable PPTP inspection for traffic between two endpoints on a specific interface. This targets the inspection to just those endpoints that have a point-to-point tunnel configured between them.

The CLI required to enable PPTP inspection between 2 endpoints involves the following:

1. An ACL with the source and destination set to the IP addresses of the endpoint hosts.
2. A traffic class that refers to this ACL.
3. A policy map that includes the traffic class, and that enables PPTP inspection on the traffic class.
4. A service policy that applies the policy map to the desired interface. This is the step that actually activates the policy and enables the inspection.

---

**Note**

**Procedure**

**Step 1**  
Click **View Configuration** in Device > Advanced Configuration.

**Step 2**  
Click **FlexConfig > FlexConfig Objects** in the Advanced Configuration table of contents.

**Step 3**  
Click the + button to create a new object.

**Step 4**  
Enter a name for the object. For example, **Enable_PPTP_Inspection_on_Interface**.

**Step 5**  
Add a variable for the inside interface.  
a) Click + above the Variables list.  
b) Enter a name for the variable, for example, **pptp-if**.  
c) For **Type**, select **Interface**.  
d) For **Value**, select the **inside** interface.

The dialog box should look like the following:

![Add New Variable](image)

- e) Click **Add**.

**Step 6**  
In the **Template** editor, enter the following lines, including indentations.

```plaintext
access-list MATCH_ACL permit ip host 192.168.1.55 host 198.51.100.1  
class-map MATCH_CMAP  
  match access-list MATCH_ACL  
policy-map PPTP_POLICY  
  class MATCH_CMAP  
  inspect pptp  
  service-policy PPTP_POLICY interface {{pptp-if.name}}
```

Note that to use the variable, you type the variable name between double braces. You also need to use dot notation to pick out the attribute you want to retrieve, because the object that defines an interface has many attributes. Because the interface name is held in the “name” attribute, entering `{{{pptp-if.name}}}` retrieves the value of the name attribute for the interface assigned to the variable. If you need to change the interface for PPTP inspection, you simply need to select a different interface in the variable definition.

**Step 7**  
In the **Negate Template** editor, enter the lines required to undo this configuration.

For this example, we will assume that the class map, policy map, and service policy exist for the sole purpose of applying PPTP inspection. Thus, in the negate template, we want to remove all of these.
If, however, you are actually adding PPTP inspection to an existing service policy on an interface, you would not negate the policy map or service policy. You would either negate the class from the policy map, or simply turn off inspection within the class within the policy map. You need to have a clear understanding of what you are implementing in other FlexConfig objects to ensure that your negate template does not have unintended consequences.

When deleting nested items, you need to do it in the reverse order in which you created them. Thus, you start by deleting the service policy, and end by deleting the access list. Otherwise, you would be trying to delete objects that are in use, and the system will return errors and not let you do that.

```plaintext
no service-policy PPTP_POLICY interface {{pptp-if.name}}
no policy-map PPTP_POLICY
no class-map MATCH_CMAP
no access-list MATCH_ACL permit ip host 192.168.1.55 host 198.51.100.1
```

The object should look like the following:

**Step 8**

Click **OK** to save the object.
**Step 9**

Add the objects to the FlexConfig policy.

a) Click **FlexConfig Policy** in the table of contents.

b) Click + in the Group List.

c) Select the **Enable_PPTP_Inspection_on_Interface** object and click **OK**.

The group list should look like the following:

```
FlexConfig Policy

Group List

Drag and drop to reorder

+ 1. Enable_PPTP_Inspection_on_Interface

```

The preview should update with the commands in the template. Verify you are seeing the expected commands, as shown in the following graphic. Notice that the interface variable resolves to the name “inside” in the preview. Pay special attention to variables: if they do not resolve correctly in the preview, they will not deploy correctly. Edit the FlexConfig object until you get the correct variable translation in the preview.

```
1 access-list MATCH_ACL permit ip host 192.168.1.55 host 192.51.100.1
2 class-map MATCH_CMAP
3 match access-list MATCH_ACL
4 policy-map PPTP_POLICY
5 class MATCH_CMAP
6 inspect pptp
7 service-policy PPTP_POLICY interface inside
```

d) Click **Save**.

You can now deploy the policy.

**Step 10**

Commit your changes.

a) Click the **Deploy Changes** icon in the upper right of the web page.

b) Click the **Deploy Now** button.

Wait for deployment to finish. The deployment summary should indicate that you have successfully deployed your changes, and the task status for the job should be **Deployed**.
**Step 11**

In CLI Console or an SSH session, use variations of the `show running-config` command and verify that the running configuration has the correct changes.

You can enter `show running-config` and examine the entire CLI configuration, or you can use the following commands to verify each part of this configuration:

- `show running-config access-list MATCH_ACL` to verify the ACL.
- `show running-config class` to verify the class map. This command will show all of the class maps.
- `show running-config policy-map PPTP_POLICY` to verify the class and policy map configuration.
- `show running-config service-policy` to verify that the policy map was applied to the interface. This will show all service policies.

The following output shows this sequence of commands, and you can see that configuration is correctly applied.

```
> show running-config access-list MATCH_ACL
access-list MATCH_ACL extended permit ip host 192.168.1.55 host 198.51.100.1

> show running-config class
! class-map MATCH_CMAP
 match access-list MATCH_ACL
 class-map inspection_default
 match default-inspection-traffic
!

> show running-config policy-map PPTP_POLICY
! policy-map PPTP_POLICY
 class MATCH_CMAP
 inspect pptp
!

> show running-config service-policy
service-policy global_policy global
service-policy PPTP_POLICY interface inside
```
