  EIGRP is a Cisco proprietary protocol that provides compatibility and seamless interoperation with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

- **Open Shortest Path First (OSPF)**
  
  OSPF is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

- **Routing Information Protocol (RIP)**
  
  RIP is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

- **Border Gateway Protocol (BGP)**
  
  BGP is an interautonomous system routing protocol. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP). Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).
Routing Table

The FTD uses separate routing tables for data traffic (through-the-device) and for management traffic (from-the-device). This section describes how the routing tables work. For information about the management routing table, see also Routing Table for Management Traffic, on page 945.

How the Routing Table Is Populated

The FTD routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the dynamic routing protocols. Because the FTD can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner. When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

• If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

  For example, if the RIP and OSPF processes discovered the following routes:

  • RIP: 192.168.32.0/24
  • OSPF: 192.168.32.0/19

  Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

• If the FTD learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

  Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

• If the FTD learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower default administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the Firepower Threat Defense device uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because the routing protocols have metrics based on algorithms that are different from the other protocols, it
is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. The following table shows the default administrative distance values for the routing protocols supported by the Firepower Threat Defense device.

**Table 79: Default Administrative Distance for Supported Routing Protocols**

<table>
<thead>
<tr>
<th>Route Source</th>
<th>Default Administrative Distance</th>
</tr>
</thead>

<td>200</td>
</tr>
<tr>
<td>Unknown</td>
<td>255</td>
</tr>
</tbody>
</table>

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the Firepower Threat Defense device receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the Firepower Threat Defense device chooses the OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the Firepower Threat Defense device would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the Firepower Threat Defense device on which the command was entered. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the routing table.

**Backup Dynamic and Floating Static Routes**

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table
maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the Firepower Threat Defense device. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

**How Forwarding Decisions Are Made**

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

For example, a packet destined for 192.168.32.1 arrives on an interface with the following routes in the routing table:

- 192.168.32.0/24 gateway 10.1.1.2
- 192.168.32.0/19 gateway 10.1.1.3

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but 192.168.32.0/24 has the longest prefix within the routing table (24 bits verses 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.

**Note**

Existing connections continue to use their established interfaces even if a new similar connection would result in different behavior due to a change in routes.

**Dynamic Routing and High Availability**

Dynamic routes are synchronized on the standby unit when the routing table changes on the active unit. This means that all additions, deletions, or changes on the active unit are immediately propagated to the standby unit. If the standby unit becomes active in an active/standby ready High Availability pair, it will already have an identical routing table as that of the former active unit because routes are synchronized as a part of the High Availability bulk synchronization and continuous replication processes.

**Dynamic Routing in Clustering**

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.
After the data node learn the routes from the control node, each node makes forwarding decisions independently. The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

**Routing Table for Management Traffic**

**Equal-Cost Multi-Path (ECMP) Routing**

The Firepower Threat Defense device supports Equal-Cost Multi-Path (ECMP) routing.

You can have up to 8 equal cost static or dynamic routes per interface. For example, you can configure multiple default routes on the outside interface that specify different gateways.

```
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.3
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.4
```
In this case, traffic is load-balanced on the outside interface between 10.1.1.2, 10.1.1.3, and 10.1.1.4. Traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses, incoming interface, protocol, source and destination ports.

**ECMP Across Multiple Interfaces Using Traffic Zones**

Use FlexConfig to configure traffic zones with the `zone` and `zone-member` commands.

If you configure traffic zones to contain a group of interfaces, you can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Similarly, your dynamic routing protocol can automatically configure equal cost routes. The Firepower Threat Defense device load-balances traffic across the interfaces with a more robust load balancing mechanism.

When a route is lost, the device seamlessly moves the flow to a different route.

**About Route Maps**

Route maps are used when redistributing routes into an OSPF, RIP, EIGRP or BGP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, and each has a permit or deny result. Evaluation of an ACL or a route map consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.

- They are generic mechanisms. Criteria matches and match interpretation are dictated by the way that they are applied and the feature that uses them. The same route map applied to different features might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs cannot verify. For example, a route map can verify if the type of route is internal.

- Each ACL ends with an implicit deny statement, by design convention. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Route maps that are applied to redistribution behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained a deny statement at the end.
Permit and Deny Clauses

Route maps can have permit and deny clauses. The deny clause rejects route matches from redistribution. You can use an ACL as the matching criterion in the route map. Because ACLs also have permit and deny clauses, the following rules apply when a packet matches the ACL:

- ACL permit + route map permit: routes are redistributed.
- ACL permit + route map deny: routes are not redistributed.
- ACL deny + route map permit or deny: the route map clause is not matched, and the next route-map clause is evaluated.

Match and Set Clause Values

Each route map clause has two types of values:
- A match value selects routes to which this clause should be applied.
- A set value modifies information that will be redistributed into the target protocol.

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeeds, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the set commands. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found that matches the route or until the end of the route map is reached.

A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several match entries are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a match entry refers to several objects in one entry, either of them should match (the logical OR algorithm is applied).
- If a match entry is not present, all routes match the clause.
- If a set entry is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

Note

Do not configure a set entry in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a match or set entry does perform an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).
Virtual Routing for Firepower Threat Defense

This chapter describes underlying concepts about virtual routers and on how virtual routing behaves within the Firepower Threat Defense.

- History for Virtual Routers in Firepower Threat Defense, on page 991

About Virtual Routers and Virtual Routing and Forwarding (VRF)

You can create multiple virtual routers to maintain separate routing tables for groups of interfaces. Because each virtual router has its own routing table, you can provide clean separation in the traffic flowing through the device.

Thus, you can provide support to two or more distinct customers over a common set of networking equipment. You can also use virtual routers to provide more separation for elements of your own network, for example, by isolating a development network from your general purpose corporate network.

Virtual routers implement the “light” version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP).

When you create a virtual router, you assign interfaces to the router. You can assign a given interface to one, and only one, virtual router. You would then define static routes, and configure routing protocols such as OSPF or BGP, for each virtual router. You would also configure separate routing processes over your entire network, so that routing tables on all participating devices are using the same per-virtual-router routing process and tables. Using virtual routers, you create logically-separated networks over the same physical network to ensure the privacy of the traffic that runs through each virtual router.

Because the routing tables are separate, you can use the same, or overlapping, address spaces across the virtual routers. For example, you could use the 192.168.1.0/24 address space for two separate virtual routers, supported by two separate physical interfaces.
Note that there are separate management and data routing tables per virtual router. For example, if you assign a management-only interface to a virtual router, then the routing table for that interface is separate from the data interfaces assigned to the virtual router.

**Applications of Virtual Routers**

You can use virtual routers to isolate network on shared resources and/or to isolate networks with common security policy. Thus, virtual routers help you to achieve:

- Traffic separation for customers through dedicated routing tables for each customer or for different departments.
- Common security policy management for different departments or networks.
- Shared internet access for different departments or network.

**Global and User-Defined Virtual Routers**

**Global Virtual Routers**

For a device with virtual routing capability, system creates a global virtual router by default. The system assigns all interfaces in your network to the global virtual router. A routed interface can belong to either a user-defined virtual router or a global virtual router. When you upgrade an FTD device to a version which has virtual router capability, all its existing routing configuration becomes part of the global virtual router.

**User-Defined Virtual Routers**

A user-defined virtual router is the one defined by you. You can create more than one virtual router on a device. However, anytime, an interface can be assigned to only one user-defined virtual router. While some of the device features are supported on user-defined virtual routers, few of the features are supported only on the global virtual routers.

**Supported Features and Monitoring Policies**

You can configure the following features on the global virtual router only:

- OSPFv3
- RIP
- EIGRP
- IS-IS
- BGPv6
- Multicast Routing
- Policy Based Routing (PBR)
- VPN

EIGRP, ISIS, and PBR are supported through Flex Config in FMC (see Predefined FlexConfig Objects, on page 1210). Configure only global virtual router interfaces for these features.
DHCP server auto-configuration uses WINS/DNS server that is learned from an interface. This interface can only be a global virtual router interface.

You can configure the following features separately for each user-defined virtual router:

- Static routes and their SLA monitors
- OSPFv2
- BGPv4
- Integrated Routing and Bridging (IRB)

Following features are used by the system when querying or communicating with the remote system (from-the-box traffic). These features use interfaces in the global virtual router only. That means, if you configure an interface for the feature, it must belong to the global virtual router. As a rule, anytime, if the system must look up a route to reach an external server for its own management purposes, it does the route lookup in the global virtual router.

- DNS server when used to resolve fully qualified names used in access control rules, or for resolving names for the ping command. If you specify any as the interface for a DNS server, the system considers interfaces in the global virtual router only.

- AAA server or identity realm when used with VPN. You can configure VPN on interfaces in the global virtual router only. Thus, the external AAA servers that are used for VPN, such as Active Directory, must be reachable through an interface in the global virtual router.

- Syslog server.
- SNMP.

**Configuring Policies to be Virtual-Router-Aware**

When you create a virtual router, the routing table for that virtual router is automatically separated from the global virtual router or any other virtual router. However, security policies are not automatically virtual-router-aware.

For example, if you write an access control rule that applies to “any” source or destination security zone, then the rule will apply to all interfaces across all virtual routers. This might in fact be exactly what you want. For example, all of your customers might want to block access to the same list of objectionable URL categories.

But, if you need to apply a policy to one of the virtual routers but not others, you need to create security zones that contain interfaces from that single virtual router only. Then, use the virtual-router-constrained security zones in the source and destination criteria of the security policy.

By using security zones whose memberships are constrained to the interfaces assigned to a single virtual router, you can write virtual-router-aware rules in the following policies:

- Access control policy.
- Intrusion and file policies.
- SSL decryption policy.
- Identity policy and user-to-IP address mappings. If you use overlapping address spaces in virtual routers, ensure that you create separate realms for each virtual router and apply them correctly in the identity policy rules.
If you use overlapping address spaces in your virtual routers, you should use security zones to ensure that the right policies get applied. For example, if you use the 192.168.1.0/24 address space in two separate virtual routers, an access control rule that simply specifies the 192.168.1.0/24 network will apply to traffic in both virtual routers. If that is not the desired outcome, you can limit the application of the rule by also specifying the source/destination security zones for just one of the virtual routers.

**Interconnecting Virtual Routers**

You can configure static routes to route traffic between virtual routers. For example, if you have the outside interface in the global virtual router, you can set up static default routes in each of the other virtual routers to send traffic to the outside interface. Then, any traffic that cannot be routed within a given virtual router gets sent to the global router for subsequent routing.

Static routes between virtual routers are known as route leaks, because you are leaking traffic to a different virtual router. When you are leaking routes, say, VR1 routes to VR2, you can initiate connections from VR2 to VR1 only. For traffic to flow from VR1 to VR2, you must configure the reverse route. When you create a static route to an interface in another virtual router, you do not need to specify a gateway address. Simply select the destination interface.

For inter-virtual-router routes, the system does destination interface look-up in the source virtual router. Then, it looks up the MAC address of the next hop in the destination virtual router. Thus, the destination virtual router must have either a dynamic (learned) or static route for the selected interface for the destination address.

Configuring NAT rules that use source and destination interfaces in different virtual routers can also allow traffic to route between virtual routers. If you do not select the option for NAT to do a route lookup, the rule will simply send traffic out the destination interface with a NATed address whenever destination translation happens. However, the destination virtual router should have a route for the translated destination IP address so that next-hop lookup can succeed.

Though NAT rule leaks traffic from one virtual router to another, to ensure correct routing, we recommend that you configure a static route leak between these virtual routers for the translated traffic. Without the route leak, sometimes the rule may not match the traffic you expect it to match, and the translation may not be applied.

Virtual routing does not support a cascading or chain of route leaks. For example, assume that your FTD has VR1, VR2, and VR3 virtual routers; VR3 is directly connected to a network - 10.1.1.0/24. Now, assume you configure a route leak in VR1 for network 10.1.1.0/24 through interface in VR2 and in VR2 define a route leak for 10.1.1.0/24 through VR3. This chain of route leaks will not allow traffic to hop from VR1 to VR2 and then exit from VR3. In case of route leaks, the route lookups first determine egress interface from input Virtual Router’s routing table and then looks at the output of Virtual Router’s routing table for next hop lookup. From both the lookups, egress interface should match. In our example, the egress interfaces will not be the same and hence the traffic does not pass through.

**Overlapping IP Addresses**

Virtual router creates multiple instances of routing tables that are independent, thereby, the same or overlapping IP addresses can be used without conflicts. FTD allows the same network to be part of two or more virtual routers. This involves multiple policies to be applied at the interface or at the virtual router level.

Other than few exceptions, the routing functions and most of the NGFW and IPS capability does not get impacted by the overlapping IP addresses. The following section describes the features that have limitations with overlapping IP addresses and the suggestions or recommendations to overcome them.
Limitations with Overlapping IP Addresses

When using an overlapping IP address in multiple virtual routers, to ensure proper application of the policy, you have to modify policies or rules for some of the features. Such features require you to use more specific interface either by splitting existing security zone or using new interface group as the need be.

Following features need modification for its proper functioning with an overlapping IP address:

- Network Map—Modify the network discovery policy to exclude some overlapping IP segments to ensure that there is no overlapping IP address being mapped.
- Identity Policy—The identity feed source cannot differentiate among virtual routers; to overcome this limitation, map overlapping address spaces or virtual routers in different realms.

For the following features, you need to apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments:

- Access Policy
- Prefilter Policy
- QoS/Rate Limit
- SSL Policy

Unsupported Features with Overlapping IP Addresses

- ISE SGT-based Rule in AC Policy—The static security group tag (SGT) to IP address mappings downloaded from Cisco Identity Services Engine (ISE) are not virtual-router-aware. Set up separate ISE systems per virtual router if you need to create different SGT mappings per virtual router. This is not necessary if you intend to map the same IP addresses to the same SGT number in each virtual router.
- Overlapping DHCP server pools are not supported across virtual routers.
- Events and Analytics—Many of the FMC analytics are dependent on network map and identity mappings which cannot differentiate if the same IP address belongs to two different end hosts. Hence, these analytics are not accurate when there are overlapping IP segments existing in same device but different virtual routers.

Maximum Number of Virtual Routers By Device Model

The maximum number of virtual routers you can create depends on the device model. The following table provides the maximum limits. You can double-check on your system by entering the `show vrf counters` command, which shows the maximum number of user-defined virtual routers for that platform not including the global virtual router. The numbers in the table below include user and global routers. For the Firepower 4100/9300, these numbers apply to native mode.

For platforms that support multi-instance capability, such as the Firepower 4100/9300, determine the maximum number of virtual routers per container instance by dividing the maximum virtual routers by the number of cores on the device, and then multiplying by the number of cores assigned to the instance, rounding down to the nearest whole number. For example, if the platform supports a maximum of 100 virtual routers, and it has 70 cores, then each core would support a maximum of 1.43 virtual routers (rounded). Thus, an instance assigned 6 cores would support 8.58 virtual routers, which rounds down to 8, and an instance assigned 10 cores would support 14.3 virtual routers (rounding down, 14).

## Guidelines and Limitations for Virtual Routers

### Firewall Mode Guidelines

Virtual routers are supported on routed firewall mode only.

### Device Guidelines

- Virtual routers are supported only on routed Firepower Threat Defense devices of version 6.6 and higher. Though Firepower Management Center release 6.6 supports FTD versions earlier than 6.6, you cannot enable virtual routers on such devices.
- Snort3 enabled devices do not support virtual router features. So, before proceeding to switch a Snort2 device that is enabled with a user-defined virtual router to a Snort3 engine, remove the device from the virtual router.

### Interface Guidelines

- You can assign an interface to only one virtual router.
- A virtual router can have any number of interfaces that are assigned to it.
- Only routed interfaces with logical names can be assigned to a user-defined virtual router.
- Named BVIs can also be assigned to a user-defined router and are supported by IRB in virtual routing.
- An interface assigned to a user-defined virtual router should not be configured to send SNMP traps to a server.
- Diagnostic and Management-only interfaces can also be assigned to a user-defined virtual router.
- If you want to change a virtual router interface to a non-routed mode, remove the interface from the virtual router, and then change its mode.
- You can assign an interface to a virtual router, either from a global virtual router or from another user-defined virtual router.
- If a route using the interface that is being moved or its virtual router is deleted, exist in source or destination virtual router table, remove the routes before the interface movement or virtual router deletion.
- As separate routing tables are maintained for each virtual router, when an interface is moved from one virtual router to another virtual router, be it global or user-defined, the system removes the IP address configured on the interface temporarily. All existing connections on the interface are terminated. Thus,
moving interfaces between virtual routers have drastic effect on the network traffic. Hence take precautionary measures before you move interfaces.

Global Virtual Router Guidelines

- The interfaces which are named and not part of other virtual routers, are part of the global virtual router.
- You cannot remove routed interfaces from global virtual router.
- You cannot modify global virtual router.
- Generally, after configuring interfaces, if you un-register and register back to same or another FMC, interface configuration is imported back from device. With virtual router support, there is a restriction—the IP address for only global virtual router interfaces is retained.

Additional Guidelines

- Security Intelligence Policy—The Security Intelligence policy is not virtual-router-aware. If you add an IP address, URL, or DNS name to the block list, it is blocked for all virtual routers. This limitation is applicable on the interface having security zones.
- NAT Rules—Do not mix interfaces in NAT rules. In virtual routing, if the specified source and destination interface objects (interface groups or security zones) have interfaces that belong to different virtual routers, the NAT rule diverts traffic from one virtual router through another virtual router. The NAT does the route lookup in the virtual router table for the inbound interface only. If necessary, define static routes in the source virtual router for the destination interface. If you leave the interface as any, the rule applies to all interfaces regardless of virtual router membership.
- DHCP Relay—Interconnecting virtual routers for DHCP relay is not supported. For example, if DHCP client is enabled on VR1 interface and DHCP relay server is enabled on VR2 interface, interconnecting VR1 and VR2 results in DHCP forwards within the virtual routers.
- Recreating a deleted virtual router—When you recreate a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to recreate a deleted virtual router successively, use a different name for the new virtual router.

Modifications to FMC Web Interface - Routing Page

Devices earlier to FTD 6.6 and few device models are not supported with virtual routing capability. The FMC web interface displays the same Routing page of FMC 6.5 or earlier version for such nonsupported devices. To know the supported devices and platform for virtual routing, see Maximum Number of Virtual Routers By Device Model.

You can configure virtual routers in the routing page of a supported device:

1. Navigate to Devices > Device Management and edit the virtual-router-aware device.
2. Click Routing to enter the virtual routers page.

For devices using virtual routing, the left pane of the Routing page displays the following:

- Manage Virtual Routers—allows you to create and manage virtual routers.
• List of virtual routing protocols—lists routing protocols that you can configure for the virtual routers.

• **General Settings**—allows you to configure BGP general settings that are applicable for all the virtual routers. Select the **Enable BGP** check box in order to define other BGP settings. To configure other BGP settings for a virtual router, navigate to **BGP** in the virtual routing protocols.

### Manage Virtual Routers Page

When you click **Manage Virtual Routers** on the Virtual Routers pane, the Manage Virtual Routers page appears. This page displays the existing virtual routers on the device and the associated interfaces. In this page, you can Add Virtual Router (➕) to the device. You can also Edit (✓) and Delete (🗑) user-defined virtual routers. You cannot edit or remove a global virtual router. You can only View (👁️) the details of a global virtual router.

### Create a Virtual Router

**Procedure**

**Step 1** Choose Devices > Device Management, and edit the FTD device.

**Step 2** Click Routing.

**Step 3** Click Manage Virtual Routers.

**Step 4** Click Add Virtual Router (➕).

**Step 5** In the Add Virtual Router box, enter a name and description for the virtual router.

**Note** If you are creating a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to create a deleted virtual router successively, use a different name for the new virtual router.

**Step 6** Click Ok.

The Routing page appears, displaying the newly created virtual router page.

### Configure a Virtual Router

<table>
<thead>
<tr>
<th>Smart License</th>
<th>Classic License</th>
<th>Supported Devices</th>
<th>Supported Domains</th>
<th>Access</th>
</tr>
</thead>
</table>

• **Configure a Virtual Router.**
Configure a Virtual Router

You can assign interfaces to a user-defined virtual router and configure the routing policies for the device. Though you cannot manually add or remove interfaces for a global virtual router, you can configure the routing policies for the device interfaces.

Before you begin

- To configure routing policies for a user-defined virtual router, add a router. See Create a Virtual Router, on page 957.
- All routing configuration settings of a non-VRF capable device are also available for a global virtual router. For information on the settings, see Routing Overview for Firepower Threat Defense.
- Only limited routing protocols are supported for a user-defined virtual router.

Procedure

<table>
<thead>
<tr>
<th>Any</th>
<th>N/A</th>
<th>FTD and FTDv</th>
<th>Any</th>
<th>Admin/Network Admin/Security Approver</th>
</tr>
</thead>
</table>

Step 1  
From the Devices > Device Management page, edit the virtual-router supported device. Navigate to Routing. For information on the modifications to the routing page, see Modifications to FMC Web Interface - Routing Page, on page 956.

Step 2  
From the drop-down list, select the desired virtual router.

Step 3  
In the Virtual Router Properties page, you can modify the description.

Step 4  
To add interfaces, select the interface under the Available Interfaces box, and then click Add.

Remember the following:

- Only interfaces with a logical name are listed under the Available Interfaces box. You can edit the interface and provide a logical name in Interfaces. Remember to save the changes for the settings to take effect.

- Only interfaces of global virtual routers are available for assigning. In other words, the Available Interfaces box lists only interfaces that are not assigned to any other user-defined virtual routers.

Step 5  
To save the settings, click Save.

Step 6  
To configure the routing policy for the virtual router, click the respective names to open the corresponding settings page:

- OSPF—Only OSPFv2 is supported on the user-defined virtual router. All other settings for OSPFv2 are as applicable as for a non-virtual-router-aware interface, except that Interface allows you to select only the interfaces of the virtual router that you are configuring. You can define the OSPFv3 and OSPFv2 routing policies for a global virtual router. For information on the OSPF settings, see OSPF for Firepower Threat Defense, on page 999.

- RIP—You can configure RIP routing policies only for a global virtual router. For information on RIP settings, see RIP for Firepower Threat Defense, on page 1043.

- BGP—This page displays the BGP general settings that you have configured in Settings:
• You cannot modify any of those general settings on this page, except for the router ID settings. You can override the router ID settings that were defined in the Settings page by editing them on this page.

• To configure other BGP IPv4 or IPv6 settings, you must enable the BGP option in BGP page under General Settings.

• Only BGP configuration with an IPv4 address family is supported for a user-defined virtual router.

For information on configuring BGP settings, see BGP for Firepower Threat Defense, on page 1027.

• **Static Route**—Use this setting to define where to send traffic for a specific destination network. You can also use this setting to create an inter-virtual router static route. You can create a leak of connected or static route by using the interfaces of user-defined or global virtual routers. **FMC prefixes** to an interface to indicate that it is belonging to another virtual router and can be used for a route leak. For the route leak to be successful, do not specify next hop gateway.

The Static Route table displays the virtual router whose interface is used for a route leak in the **Leaked from Virtual Router** column. If it is not a route leak, the column displays N/A.

Irrespective of which virtual router the static route belongs, a Null0 interface is listed along with the interfaces of the same virtual router to which the static route belongs.

For information on static route settings, see Static and Default Routes for Firepower Threat Defense, on page 993.

• **Multicast**—You can configure multicast routing policies only for a global virtual router. For information on multicast settings, see Multicast Routing for Firepower Threat Defense, on page 1049.

**Step 7**

To save the settings, click **Save**.

---

**What to do next**

• Modify a Virtual Router.

• Remove Virtual Routers.

---

**Modify a Virtual Router**

You can modify the description and other routing policies of a virtual router.

**Procedure**

**Step 1**  
Choose **Devices > Device Management**, and edit the FTD device.

**Step 2**  
Click **Routing**.

**Step 3**  
Click **Manage Virtual Routers**.

All virtual routers along with the assigned interfaces are displayed in the Virtual Routers page.

**Step 4**  
To modify a virtual router, click **Edit ( )** against the desired virtual router.
You cannot modify the general settings of the global virtual router. Hence, edit is not available for the global router; instead a View ( ) is provided to view the settings.

**Step 5** To save the changes, click **Save**.

---

**What to do next**

- Remove Virtual Routers.

---

### Remove Virtual Routers

**Before you begin**

- You cannot delete the Global virtual router. Hence, the delete option is not available for the Global virtual router.
- You can remove multiple virtual routers at a time.
- All the routing policies of the deleted virtual router are also deleted.
- All the interfaces of the deleted virtual router move to the global virtual router.
- If there are any restrictions on the movement of interfaces, such as overlapping IPs, route conflicts, and so on, you can remove the router only after resolving the conflicts.

**Procedure**

**Step 1** Choose Devices > Device Management, and edit the FTD device.

**Step 2** Click Routing.

**Step 3** Click Manage Virtual Routers.

All virtual routers along with the mapped interfaces are displayed in the Virtual Routers page.

**Step 4** To remove a virtual router, click Delete ( ) against the desired virtual router.

**Step 5** To remove multiple routers, holding the CTRL key, click the virtual routers that you want to delete. Right-click, and then click **Delete**.

**Step 6** To save the changes, click **Save**.

---

### Configuration Examples for Virtual Routers

#### How to Route to a Distant Server through Virtual Routers

In virtual routing, you can create multiple virtual routers to maintain separate routing tables for groups of interfaces, thereby achieve network separation. In some scenarios, you may need to access a server that is
reachable only through a separate virtual router. This example provides the procedure that interconnects virtual routers to reach to a host that is multiple hops away.

Consider an example, where a member of the sales department of a garment company wants to look up at the stock maintained by the warehousing department of its factory unit. In a virtual routing environment, you need to leak route between virtual routers where destination (warehousing department) is multiple hops away from sales department. This route leaking is done by adding multihop route leak, where, you configure a static route in Sales virtual router(source) to an interface in Warehouse virtual router (destination). As the destination network is multi-hop away, you also need to configure the Warehouse virtual router with the route to the destination network, namely 10.50.0.0/24.

*Figure 41: Interconnecting Two Virtual Routers - An Example*

**Before you begin**

This example assumes that you have already configured Sales_Router1 to route traffic from 10.20.0.1/30 interface to 10.50.0.5/24.

**Procedure**

**Step 1**

Configure the inside interface (Gi0/1) of the device to be assigned to Sales virtual router:

a) Choose **Devices > Device Management > Interfaces**.

b) Edit the Gi0/1 interface:

   - **Name**—For this example, VR-Sales.
   - Select the **Enabled** checkbox.
In IPv4, for IP Type, choose Use Static IP.

IP Address—Enter 10.30.0.1/24.

c) Click Ok.
d) Click Save.

**Step 2** Configure the inside interface (Gi0/2) of the device to be assigned to Warehouse virtual router:

a) Choose Devices > Device Management > Interfaces.
b) Edit the Gi0/2 interface:

- Name—For this example, VR-Warehouse.
- Select the Enabled checkbox.
- In IPv4, for IP Type, choose Use Static IP.
- IP Address—Leave it blank. The system does not allow you to configure interfaces with same IP address (10.30.0.1/24), as you are yet to create user-defined virtual routers.

c) Click Ok.
d) Click Save.

**Step 3** Create Sales and Warehouse virtual routers and assign their interfaces:

a) Choose Devices > Device Management, and edit the FTD device.
b) Choose Routing > Manage Virtual Routers.
c) Click Add Virtual Router and create Sales.
d) Click Add Virtual Router and create Warehouse.
e) Select Sales from virtual router drop-down, in Virtual Router Properties, add VR-Sales as Selected Interface and save.
f) Select Warehouse from virtual router drop-down, in Virtual Router Properties, add VR-Warehouse as Selected Interface and save.

**Step 4** Revisit the VR-Warehouse interface configuration:

a) Choose Devices > Device Management > Interfaces.
b) Click Edit against VR-Warehouse interface. Specify the IP Address as 10.30.0.1/24. The system now allows you to configure with same IP address of VR-Sales, because the interfaces are seperately assigned to two different virtual routers.
c) Click Ok.
d) Click Save.

**Step 5** Create network objects for the warehouse server—10.50.0.0/24, and for the warehouse gateway—10.40.0.2/30:

a) Choose Object > Object Management.
b) Choose Add Network > Add Object:

- Name—For this example, Warehouse-Server.
- Network—Click Network and enter 10.50.0.0/24.

c) Click Save.
d) Choose Add Network > Add Object:

- Name—For this example, Warehouse-Gateway.
**Step 6**

Define the route leak in Sales that points to the VR-Warehouse interface:

a) Choose **Devices > Device Management**, and edit the FTD device.

b) Choose **Routing**.

c) Choose Sales virtual router from the drop-down, and then click **Static Route**.

d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.

- **Network**—Select the Warehouse-Server object.

- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

```
Add Static Route Configuration

Type: IPv4  IPv6

Interface* VR-Warehouse

Available Network

 Gateway*

Metric: 1

Tunneled: [ ] (Used only for default Route)
Route Tracking: 
```

e) Click **Ok**.

f) Click **Save**.

**Step 7**

In the Warehouse virtual router, define the route that points to the Warehouse Router 2 gateway:

a) Choose Warehouse virtual router from the drop-down, and then click **Static Route**.

b) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.

- **Network**—Select the Warehouse-Server object.
How to Route to a Distant Server through Virtual Routers

**Gateway**—Select the Warehouse-Gateway object.

**Add Static Route Configuration**

<table>
<thead>
<tr>
<th>Type:</th>
<th>IPv4</th>
<th>IPv6</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
<td>VR-Warehouse</td>
<td></td>
</tr>
<tr>
<td>Available Network</td>
<td>Warehouse-Server</td>
<td></td>
</tr>
<tr>
<td>Selected Network</td>
<td>Warehouse-Server</td>
<td></td>
</tr>
</tbody>
</table>

- Ensure that egress virtual router has route to that destination.

  Gateway
  - Warehouse-Gateway
  - Metric: 1
  - Tunnels: (Used only for default route)
  - Route Tracking:

  c) Click **Ok**.
  d) Click **Save**.

**Step 8**
Configure access control rule that allows access to the warehouse server. For creating the access control rule, you need to create security zones. Use **Object > Object Management > Interface**. Choose **Add > Security Zone** and create security zones for VR-Sales and VR-Warehouse; for Warehouse-Server network object, create a Warehouse-Server interface group (Choose **Add > Interface Group**).

**Step 9**
Choose **Policies > Access Control** and configure an access control rule to allow traffic from the source interfaces in the Sales virtual router to the destination interfaces in the Warehouse virtual router for the destination Warehouse-Server network object.

For example, if the interfaces in Sales are in the Sales-Zone security zone, and those in Warehouse are in the Warehouse-Zone security zone, the access control rule would look similar to the following:
How to Provide Internet Access with Overlapping Address Spaces

When using virtual routers, you can have the same network address for interfaces that reside in separate routers. However, because the IP addresses routed in these separate virtual routers are the same, apply NAT/PAT rules for each interface with separate NAT/PAT pools to ensure that return traffic goes to the correct destination. This example provides the procedure to configure the virtual routers and NAT/PAT rules to manage the overlapping address spaces.

For example, interfaces vr1-inside and vr2-inside on FTD is defined to use the IP address 192.168.1.1/24, managing endpoints on their segment in the 192.168.1.0/24 network. To allow Internet access from two virtual routers that use the same address space, you need to apply NAT rules separately to the interfaces within each virtual router, ideally using separate NAT or PAT pools. You could use PAT to translate the source addresses in VR1 to 10.100.10.1, and for those in VR2, to 10.100.10.2. The following illustration shows this setup, where the Internet-facing outside interface is part of the global router. You must define the NAT/PAT rules with the source interface (vr1-inside and vr2-inside) explicitly selected—using “any” as the source interface makes it impossible for the system to identify the correct source because the same IP address could exist on two different interfaces.

![Diagram showing Internet access with overlapping address spaces](image)

**Note**

Even if you have some interfaces within virtual routers that does not use overlapping address spaces, define the NAT rule with the source interface to make troubleshooting easier, and to ensure a cleaner separation between traffic from the virtual routers that is Internet-bound.

**Procedure**

**Step 1**

Configure the inside interface of the device for VR1:

a) Choose **Devices > Device Management > Interfaces**.
b) Edit the interfaces that you want to assign to VR1:
   - **Name**—For this example, vr1-inside.
   - Select the **Enabled** checkbox.
   - In **IPV4**, for **IP Type**, choose **Use Static IP**.
   - **IP Address**—Enter 192.168.1.1/24.

c) Click **Ok**.
d) Click **Save**.

**Step 2**
Configure the inside interface of the device for VR2:

a) Choose **Devices > Device Management > Interfaces**.
b) Edit the interfaces that you want to assign to VR2:
   - **Name**—For this example, vr2-inside.
   - Select the **Enabled** checkbox.
   - In **IPV4**, for **IP Type**, choose **Use Static IP**.
   - **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address, as you are yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

**Step 3**
Configure VR1 and the static default route leak to the outside interface:

a) Choose **Devices > Device Management**, and edit the FTD device.
b) Choose **Routing > Manage Virtual Routers**, Click **Add Virtual Router** and create VR1.
c) For VR1, in **Virtual Router Properties**, assign vr1-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
   - **Interface**—Select the outside interface of the global router.
   - **Network**—Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR1.
   - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not provide a Gateway.
f) Click **Ok**.
g) Click **Save**.

**Step 4**
Configure VR2 and the static default route leak to the outside interface:

a) Choose **Devices > Device Management**, and edit the FTD device.
b) Choose **Routing > Manage Virtual Routers**. Click **Add Virtual Router** and create VR2.
c) For VR2, in **Virtual Router Properties**, assign vr2-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR2.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the Gateway.
f) Click **Ok**.
g) Click **Save**.

**Step 5** Configure IPv4 static default route, namely 172.16.1.2 on the outside interface of the global router:

a) Choose **Devices > Device Management**, and edit the FTD device.
b) Choose **Routing** and edit global router properties.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
   
   - **Interface**—Select the outside interface of the global router.
   - **Network**—Select the any-ipv4 object. This will be the default route for any IPv4 traffic.
   - **Gateway**—If already created, select the host name from the drop-down. If the object is not yet created, click **Add** and define the host object for the IP address of the gateway at the other end of the network link on the outside interface, in this example, 172.16.1.2. After you create the object, select it in the Gateway field.
e) Click **Ok**.

f) Click **Save**.

**Step 6**

Revisit the vr2-inside interface configuration:

a) Choose **Devices > Device Management > Interfaces**.

b) Click **Edit** against vr2-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with same IP address of vr1-inside, because the interfaces are separately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.

**Step 7**

Create the NAT rule to PAT inside to outside traffic of VR1 to 10.100.10.1.

a) Choose **Devices > NAT**.

b) Click **New Policy > Threat Defense NAT**.

c) Enter InsideOutsideNATRule as the NAT policy name, and select the FTD device. Click **Save**.

d) In InsideOutsideNATRule page, click **Add Rule** and define the following:

- **NAT Rule**—Select Manual NAT Rule.

- **Type**—Select Dynamic.

- **Insert**—Above, if any dynamic NAT rule exists.

- **Click Enabled**.

- In **Interface Objects**, select vr1-interface object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select outside as **Add to Destination**.
• In **Translation**, for **Original Source**, select any-ipv4. For **Translated Source**, click **Add** and define host object VR1-PAT-Pool with 10.100.10.1. Select VR1-PAT-Pool as shown in the figure below:

<table>
<thead>
<tr>
<th>NAT Rule</th>
<th>Translation PAT Pool Advanced</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manual NAT Rule</td>
<td>In Category</td>
</tr>

</tr>
<tr>
<td>Original Destination Port:</td>
<td>Translated Destination Port:</td>
</tr>
<tr>
<td>VR1-PAT-Pool</td>
<td>Address</td>
</tr>
</tbody>
</table>

e) Click **Ok**.
f) Click **Save**.

**Step 8** Add NAT rule to PAT inside to outside traffic of VR2 to 10.100.10.2.

a) Choose **Devices > NAT**.
b) Edit **InsideOutsideNATRule** to define the VR2 NAT rule:

• **NAT Rule**—Select Manual NAT Rule.
• **Type**—Select Dynamic.
• **Insert**—Above, if any dynamic NAT rule exists.
• Click **Enabled**.

• In **Interface Objects**, select vr2-interface object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select outside as **Add to Destination**.

• In **Translation**, for **Original Source**, select any-ipv4. For **Translated Source**, click **Add** and define host object VR2-PAT-Pool with 10.100.10.2. Select VR2-PAT-Pool as shown in the figure below:
c) Click Ok.
d) Click Save.

**Step 9**
To configure the access control policy that allows traffic from the vr1-inside and vr2-inside interfaces to the outside interface, you need to create security zones. Use **Object > Object Management > Interface**. Choose **Add > Security Zone** and create security zones for vr1-inside, vr2-inside, and outside interfaces.

**Step 10**
Choose **Policies > Access Control** and configure an access control rule to allow traffic from vr1-inside-zone and vr2-inside-zone to outside-zone.

Assuming that you create zones named after the interfaces, a basic rule that allows all traffic to flow to the Internet will look like the following. You can apply other parameters to this access control policy:
How to Allow RA VPN Access to Internal Networks in Virtual Routing

On virtual routing-enabled devices, RA VPN is supported only on global virtual router interfaces. This example provides the procedure that allows your AnyConnect client user to connect to user-defined virtual router networks.

In the following example, the RA VPN (AnyConnect client) user connects to the outside interface of FTD at 172.16.3.1, and is given an IP address within the pool of 192.168.80.0/24. The user can access the inside network of only the global virtual router. To allow traffic flow through the network of the user-defined virtual router VR1, namely 192.168.1.0/24, leak the route by configuring the static routes on global and VR1.
Before you begin

This example assumes that you have already configured the RA VPN, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

Procedure

**Step 1** Configure route leak from Global virtual router to the user-defined VR1:

a) Choose Devices > Device Management, and edit the FTD device.
b) Click Routing. By default, the Global routing properties page appears.
c) Click Static Route.
d) Click Add Route. In Add Static Route Configuration, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the Add Object option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

The route leak allows AnyConnect Clients assigned IP addresses in the VPN pool to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click Ok.
**Step 2** Configure the route leak from VR1 to the Global virtual router:

a) Choose **Devices > Device Management**, and edit the FTD device.
b) Click **Routing** and from the drop-down, select VR1.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

   - **Interface**—Select the outside interface of the global router.
   - **Network**—Select the global virtual router network object.
   - **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

![Add Static Route Configuration](image)

The configured static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections to AnyConnect Clients assigned IP addresses in the VPN pool.

e) Click **Ok**.

**What to do next**

If RA VPN address pool and the IP addresses in the user-defined virtual router overlap, you must also use static NAT rules on the IP addresses to enable proper routing. Alternatively, you can change your RA VPN address pool so that there is no overlap.
How to Secure Traffic from Networks in Multiple Virtual Routers over a Site-to-Site VPN

On virtual routing-enabled devices, Site-to-Site VPN is supported only on global virtual router interfaces. You cannot configure it on an interface that belongs to a user-defined virtual router. This example provides the procedure that allows you to secure the connections from or to networks hosted within user-defined virtual routers over the site-to-site VPN. You also need to update the site-to-site VPN connection to include the user-defined virtual routing networks.

Let us consider a scenario, where, a site-to-site VPN is configured between a branch office network to a company headquaters network; the FTD in the branch office having virtual routers. In this case, the site-to-site VPN is defined on the outside interface of the branch office at 172.16.3.1. This VPN includes the inside network 192.168.2.0/24 without extra configuration, because the inside interface is also part of the global virtual router. But, to provide site-to-site VPN services to the 192.168.1.0/24 network, which is part of the VR1 virtual router, you must leak the route by configuring the static routes on global and VR1, and add the VR1 network to the site-to-site VPN configuration.

Before you begin

This example assumes that you have already configured the site-to-site VPN between the 192.168.2.0/24 local network and the 172.16.20.0/24 external network, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

Procedure

Step 1

Configure route leak from the Global virtual router to the user-defined VR1:

a) Choose Devices > Device Management, and edit the FTD device.
b) Click Routing. By default, the Global routing properties page appears.
c) Click Static Route.
d) Click Add Route. In Add Static Route Configuration, specify the following:
   • Interface—Select the VR1 inside interface.
   • Network—Select the VR1 virtual router network object. You can create one using the Add Object option.
   • Gateway—Leave it blank. When leaking a route into another virtual router, do not select the gateway.
Step 2 Configure the route leak from VR1 to the Global virtual router:
   a) Choose Devices > Device Management, and edit the FTD device.
   b) Click Routing and from the drop-down, select VR1.
   c) Click Static Route.
   d) Click Add Route. In Add Static Route Configuration, specify the following:
      • Interface—Select the outside interface of the global router.
      • Network—Select the global virtual router network object.
      • Gateway—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

The route leak allows endpoints protected by the external (remote) end of the site-to-site VPN to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click Ok.
This static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections that will traverse the site-to-site VPN tunnel. For this example, the remote endpoint that is protecting the 172.16.20.0/24 network.

e) Click Ok.

**Step 3**  
Add the 192.168.1.0/24 network to the site-to-site VPN connection profile:

a) Choose Devices > VPN > Site To Site, and edit the VPN Topology.

b) In Endpoints, edit Node A endpoint.

c) In Edit Endpoint, in the Protected Networks field, click Add New Network Object.

d) Add the VR1 network object with 192.168.1.0 network:
e) Click **Ok** and save the configuration.

---

**How to Route Traffic between Two Overlapping Network Host in Virtual Routing**

You can configure hosts on the virtual routers that have same network address. If the hosts want to communicate, you can configure twice NAT. This example provides the procedure to configure the NAT rules to manage the overlapping network host.

In the following example, two hosts Host A and Host B belong to different virtual routers: VRG (interface vrg-inside), VRB (interface vrb-inside) respectively with the same subnet 10.1.1.0/24. For both the hosts to communicate, create a NAT policy where, VRG-Host interface object would use a mapped NAT address - 20.1.1.1, and VRB-Host interface object would use a mapped NAT address - 30.1.1.1. Thus, Host A uses 30.1.1.1 to communicate to Host B; Host B uses 20.1.1.1 to reach Host A.

**Before you begin**

This example assumes that you have already configured:
• vrg-inside and vrb-inside interfaces are associated with virtual routers: VRG and VRB respectively and vrg-inside and vrb-inside interfaces configured with same subnet address (say, 10.1.1.0/24).

• Interfaces zones VRG-Inf, VRB-Inf created with vrg-inside and vrb-inside interfaces respectively.

• Host A in VRG with vrg-inside as default gateway; Host B in VRB with vrb-inside as default gateway.

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Create the NAT rule to handle traffic from Host A to Host B. Choose Devices &gt; NAT.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click New Policy &gt; Threat Defense NAT.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Enter a NAT policy name, and select the FTD device. Click Save.</td>
</tr>
<tr>
<td>Step 4</td>
<td>In the NAT page, click Add Rule and define the following:</td>
</tr>
<tr>
<td></td>
<td>• NAT Rule—Select Manual NAT Rule.</td>
</tr>
<tr>
<td></td>
<td>• Type—Select Static.</td>
</tr>
<tr>
<td></td>
<td>• Insert—Select Above, if any NAT rule exists.</td>
</tr>
<tr>
<td></td>
<td>• Click Enabled.</td>
</tr>
<tr>
<td></td>
<td>• In Interface Objects, select VRG-Inf object and click Add to Source (If the object isn’t available, create one in Object &gt; Object Management &gt; Interface), and select VRB-Inf object and click Add to Destination.</td>
</tr>
<tr>
<td></td>
<td>• In Translation, select the following:</td>
</tr>
<tr>
<td></td>
<td>• Original Source, select vrg-inside.</td>
</tr>
<tr>
<td></td>
<td>• Translated Source, click Add and define object, VRG-Mapped-Host with 20.1.1.1. Select VRG-Mapped-Host.</td>
</tr>
<tr>
<td></td>
<td>• Translated Destination, select vrb-inside as shown in the following figure:</td>
</tr>
</tbody>
</table>
When you run the `show nat detail` command on the FTD device, you will see an output similar to this:

```
firepower(config-service-object-group)# show nat detail
Manual NAT Policies (Section 1)
1 (2001) to (3001) source static vrg-inside VRG-MAPPED-HOST destination static VRB-MAPPED-HOST
vrb-inside
translate_hits = 0, untranslate_hits = 0
Source - Origin: 10.1.1.1/24, Translated: 20.1.1.1/24
Destination - Origin: 30.1.1.1/24, Translated: 10.1.1.1/24
```

**Step 5**
Click **Ok**.

**Step 6**
Click **Save**.

The NAT rule looks like this:

When you deploy the configuration, a warning message appears:
How to Manage Overlapping Segments in Routed Firewall Mode with BVI Interfaces

You can deploy single FTD between multiple overlapping networks transparently and/or deploy the firewall between the hosts of same network. To achieve this deployment, configure BVI per virtual router. The procedure to configure the BVIs in virtual router is explained here.

BVI is a virtual interface within a router that acts like a normal routed interface. It does not support bridging, but represents the comparable bridge group to routed interfaces within the router. All the packets coming in or going out of these bridged interfaces, pass through the BVI interface. The interface number of the BVI is the number of the bridge group that the virtual interface represents.

In the following example, BVI-G is configured in VRG and Bridge Group 1 is the routed interface for interfaces G0/1 and G0/2. Similarly, BVI-B is configured in VRB and Bridge Group 2 is the routed interface for interfaces G0/3 and G0/4. Consider that both BVIs have the same IP subnet address, say 10.10.10.5/24. Because of virtual routers, the network is isolated on the shared resources.
Procedure

Step 1  Choose Devices > Device Management. Edit the required device.

Step 2  In Interfaces, choose Add Interfaces > Bridge Group Interface.

a) Enter the following details for BVI-G:

- **Name**—For this example, BVI-G.
- **Bridge Group ID**—For this example, 1.
- **Available Interface**—Select the interfaces.
- In IPV4, for **IP Type**, choose Use Static IP.
- **IP Address**—Enter 10.10.10.5/24.
b) Click **Ok**.

c) Click **Save**.

a) Enter the following details for BVI-B:

- **Name**—For this example, BVI-B.
- **Bridge Group ID**—For this example, 2.
- **Available Interface**—Select the sub interfaces.
- In IPV4, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave this field empty as the system does not allow two interfaces to have overlapping IP address. You can revisit the Bridge Group and provide the same IP address after aligning it under a virtual router.
b) Click **Ok**.
c) Click **Save**.

**Step 3**
Create virtual router, say VRG, and select BVI-G as its network:

a) Choose **Devices > Device Management**.
b) Edit the device, and choose **Routing > Manage Virtual Routers**.
c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.
d) In **Virtual Routing Properties**, select BVI-G and click **Add**.

d) In **Virtual Routing Properties**, select BVI-G and click **Add**.

c) Click **Save**.

**Step 4**
Create virtual router, say VRB, and select BVI-B as its network:

a) Choose **Devices > Device Management**.
b) Edit the device, and choose **Routing > Manage Virtual Routers**.
c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.
d) In **Virtual Routing Properties**, select **BVI-B** and click **Add**.

![Virtual Routing Properties](image)

e) Click **Save**.

**Step 5**

Revisit the BVI-B configuration:

a) Choose **Devices > Device Management > Interfaces**.

b) Click **Edit** against BVI-B interface. Specify the IP Address as 10.10.10.5/24. The system now allows you to configure with same IP address of BVI-G, because the interfaces are separately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.

If you want to enable inter-BVI communication, use an external router as default gateway. In overlapping BVI scenarios, as in this example, use twice NAT external router as gateway to establish inter-BVI traffic. When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself. When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.

---

**How to Configure User Authentication with Overlapping Networks**

In virtual routing, you can configure multiple virtual routers with overlapping IP and overlapping users. In the example, VRG, and VRB are the virtual routers with overlapping IP - 192.168.1.1/24. The users on two different domains are also on overlapping network IP 192.168.1.20. For VRG and VRB users to access the shared server 172.16.10.X, leak routes to the global virtual router. Use source NAT to handle the overlapping IP. For controlling the access from VRG and VRB users, you must set user authentication in FMC. FMC uses realms, Active Directories, Identity source, and Identity rules and policies for authenticating user identity. Because FTD does not have direct role in authenticating users, user access is managed only through the access control policy. For controlling traffic from the overlapping users, use Identity policy and rules to create access control policy.
Before you begin

This example assumes that you have:

- Two AD servers for the VRG and VRB users.
- ISE with the two AD servers added.

Procedure

Step 1 Configure the inside interface of the device for VRG:

a) Choose Devices > Device Management > Interfaces.

b) Edit the interfaces that you want to assign to VRG:

   - **Name**—For this example, VRG-inside.
   - Select the **Enabled** checkbox.
   - In **IPV4**, for **IP Type**, choose **Use Static IP**.
   - **IP Address**—Enter 192.168.1.1/24.

c) Click **Ok**.

d) Click **Save**.

Step 2 Configure the inside interface of the device for VRB:

a) Choose Devices > Device Management > Interfaces.

b) Edit the interfaces that you want to assign to VRB:

   - **Name**—For this example, VRB-inside.
   - Select the **Enabled** checkbox.
• In **IPV4**, for **IP Type**, choose **Use Static IP**.

• **IP Address**—Leave it blank. The system doesn’t allow you to configure interfaces with same IP address, as you’re yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

### Step 3
Configure VRG and the static default route leak to the inside interface of the Global router for the VRG users to access the common server 172.16.10.1:

a) Choose **Devices > Device Management**, and edit the FTD device.
b) Choose **Routing > Manage Virtual Routers**. Click **Add Virtual Router** and create VRG.
c) For VRG, in **Virtual Router Properties**, assign VRG-inside and save.

d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

  • **Interface**—Select the inside interface of the global router.
  
  • **Network**—Select the any-ipv4 object.
  
  • **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.
g) Click **Save**.

### Step 4
Configure VRB and the static default route leak to the inside interface of the Global router for the VRB users to access the shared server 172.16.10.x:

a) Choose **Devices > Device Management**, and edit the FTD device.
b) Choose **Routing > Manage Virtual Routers**. Click **Add Virtual Router** and create VRB.
For VRB, in **Virtual Router Properties**, assign VRB-inside and save.

c) Click **Static Route**.

d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

e) Click **Ok**.

f) Click **Save**.

g) Click **Save**.

**Step 5**

Revisit the VRB-inside interface configuration:

a) Choose **Devices > Device Management > Interfaces**.

b) Click **Edit** against VRB-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with the same IP address as that of VRG-inside, because the interfaces are seperately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.

**Step 6**

Add NAT rules for the source objects VRG and VRB. Click **Devices > NAT**.

**Step 7**

Click **New Policy > Threat Defense NAT**.

**Step 8**

Enter a NAT policy name, and select the FTD device. Click **Save**.

**Step 9**

In the NAT page, click **Add Rule** and define the following source NAT for VRG:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
• Click **Enabled**.

• In **Interface Objects**, select VRG-Inside object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select Global-Inside object and click **Add to Destination**.

• In **Translation**, select the following:
  - **Original Source**, select VRG-Users.
  - **Translated Source**, click **Add** and define object, VRG-NAT with 10.1.1.1. Select VRG-NAT as shown in the following figure:

Step 10  Click **Ok**.

Step 11  In the NAT page, click **Add Rule** and define the following source NAT for VRB:
  - **NAT Rule**—Select Manual NAT Rule.
  - **Type**—Select Static.
  - **Insert**—Select Above, if any NAT rule exists.
  - Click **Enabled**.
• In **Interface Objects**, select VRB-Inside object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select Global-Inside object and click **Add to Destination**.

• In **Translation**, select the following:
   - **Original Source**, select VRB-Users.
   - **Translated Source**, click **Add** and define object, VRB-NAT with 20.1.1.1. Select VRB-NAT as shown in the following figure:

![Add NAT Rule](image)

**Step 12** Click **Save**.

The NAT rule looks like this:
Step 13  Add the two unique AD servers in FMC one for each VRG and VRB users—choose System > Integration > Realms.

Step 14  Click New Realm and complete the fields. For detailed information on the fields, see Realm Fields, on page 2315.

Step 15  For controlling the access from VRG and VRB users, define 2 Active Directories, see Configure a Realm Directory, on page 2323.

Step 16  Add ISE in FMC—choose System > Integration > Identity Sources.

Step 17  Click Identity Services Engine and complete the fields. For detailed information on the fields, see How to Configure ISE/ISE-PIC for User Control Using a Realm, on page 2339.

Step 18  Create Identity policy, rules, and then define access control policy for controlling access of overlapping users from VRG and VRB.

History for Virtual Routers in Firepower Threat Defense

Static and Default Routes for Firepower Threat Defense

This chapter describes how to configure static and default routes on the FTD.

- About Static and Default Routes, on page 993
- Requirements and Prerequisites for Static Routes, on page 995
- Guidelines for Static and Default Routes, on page 996
- Add a Static Route, on page 996

About Static and Default Routes

To route traffic to a non-connected host or network, you must define a route to the host or network, either using static or dynamic routing. Generally, you must configure at least one static route: a default route for all traffic that is not routed by other means to a default network gateway, typically the next hop router.

Default Route

The simplest option is to configure a default static route to send all traffic to an upstream router, relying on the router to route the traffic for you. A default route identifies the gateway IP address to which the FTD device sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 (IPv4) or ::/0 (IPv6) as the destination IP address.

You should always define a default route.

Because the FTD uses separate routing tables for data traffic and for management traffic, you can optionally configure a default route for data traffic and another default route for management traffic. Note that from-the-device traffic uses either the management-only or data routing table by default depending on the type (see Routing Table for Management Traffic, on page 945), but will fall back to the other routing table if a route is not found. Default routes will always match traffic, and will prevent a fall back to the other routing table. In this case, you must specify the interface you want to use for egress traffic if that interface is not in the default routing table. The Diagnostic interface is included in the management-only table. The special Management interface uses a separate Linux routing table, and has its own default route. See the configure network commands.
Static Routes

You might want to use static routes in the following cases:

- Your networks use an unsupported router discovery protocol.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.
- In some cases, a default route is not enough. The default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the FTD device.
- You are using a feature that does not support dynamic routing protocols.
- Virtual routers use static routes to create route leaks. Route leaks enable flow of traffic from an interface of a virtual router to another interface in another virtual router. For more information, see Interconnecting Virtual Routers, on page 952.

Route to null0 Interface to Drop Unwanted Traffic

Access rules let you filter packets based on the information contained in their headers. A static route to the null0 interface is a complementary solution to access rules. You can use a null0 route to forward unwanted or undesirable traffic so the traffic is dropped. Static null0 routes have a favorable performance profile. You can also use static null0 routes to prevent routing loops. BGP can leverage the static null0 route for Remotely Triggered Black Hole routing.

Route Priorities

- Routes that identify a specific destination take precedence over the default route.
- When multiple routes exist to the same destination (either static or dynamic), then the administrative distance for the route determines priority. Static routes are set to 1, so they typically are the highest priority routes.
- When you have multiple static routes to the same destination with the same administrative distance, see Equal-Cost Multi-Path (ECMP) Routing, on page 945.
- For traffic emerging from a tunnel with the Tunneled option, this route overrides any other configured or learned default routes.

Transparent Firewall Mode and Bridge Group Routes

For traffic that originates on the Firepower Threat Defense device and is destined through a bridge group member interface for a non-directly connected network, you need to configure either a default route or static routes so the Firepower Threat Defense device knows out of which bridge group member interface to send traffic. Traffic that originates on the Firepower Threat Defense device might include communications to a syslog server or SNMP server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. For transparent mode, you cannot specify the BVI as the gateway.
interface; only member interfaces can be used. For bridge groups in routed mode, you must specify the BVI in a static route; you cannot specify a member interface. See #unique_1333 for more information.

**Static Route Tracking**

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the Firepower Threat Defense device goes down.

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. For example, you can define a default route to an ISP gateway and a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

The Firepower Threat Defense device implements static route tracking by associating a static route with a monitoring target host on the destination network that the Firepower Threat Defense device monitors using ICMP echo requests. If an echo reply is not received within a specified time period, the host is considered down, and the associated route is removed from the routing table. An untracked backup route with a higher metric is used in place of the removed route.

When selecting a monitoring target, you need to make sure that it can respond to ICMP echo requests. The target can be any network object that you choose, but you should consider using the following:

- The ISP gateway (for dual ISP support) address
- The next hop gateway address (if you are concerned about the availability of the gateway)
- A server on the target network, such as a syslog server, that the Firepower Threat Defense device needs to communicate with
- A persistent network object on the destination network

**Note**

A PC that may be shut down at night is not a good choice.

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interfaces with route tracking configured.

**Requirements and Prerequisites for Static Routes**

**Model Support**

FTD

**Supported Domains**

Any

**User Roles**

Admin
Guidelines for Static and Default Routes

Firewall Mode and Bridge Groups

- In transparent mode, static routes must use the bridge group member interface as the gateway; you cannot specify the BVI.
- In routed mode, you must specify the BVI as the gateway; you cannot specify the member interface.
- Static route tracking is not supported for bridge group member interfaces or on the BVI.

Supported Network Address

- Static route tracking is not supported for IPv6.
- ASA does not support CLASS E routing. Hence, CLASS E network is not routable as static routes.

Clustering and Multiple Context Mode

- In clustering, static route tracking is only supported on the primary unit.
- Static route tracking is not supported in multiple context mode.

Network Object Group

You cannot use a range of network objects or a network object group having a range of IP addresses while configuring a static route.

Add a Static Route

A static route defines where to send traffic for specific destination networks. You should at a minimum define a default route. A default route is simply a static route with 0.0.0.0/0 as the destination IP address.

Procedure

Step 1: Choose Devices > Device Management, and edit the FTD device.
Step 2: Click Routing.
Step 3: (For virtual-router-aware devices) From the virtual routers drop-down list, select the virtual router for which you are configuring a static route.
Step 4: Select Static Route.
Step 5: Click Add Routes.
Step 6: Click IPv4 or IPv6 depending on the type of static route that you are adding.
Step 7: Choose the Interface to which this static route applies.
For transparent mode, choose a bridge group member interface name. For routed mode with bridge groups, you can choose either the bridge group member interface for the BVI name. To “black hole” unwanted traffic, choose the Null0 interface.

For a device using virtual routing, you can select an interface that belongs to another virtual router. You can create such a static route if you want to leak traffic from this virtual router into the other virtual router. For more information, see Interconnecting Virtual Routers, on page 952.

**Step 8**

In the **Available Network** list, choose the destination network.

To define a default route, create an object with the address 0.0.0.0/0 and select it here.

**Note** Though you can create and choose a Network Object Group containing a range of IP addresses, FMC does not support using range of network objects while configuring a static route.

**Step 9**

In the **Gateway** or **IPv6 Gateway** field, enter or choose the gateway router which is the next hop for this route. You can provide an IP address or a Networks/Hosts object. When you are using static route configuration for virtual routers to leak routes, do not specify the next hop gateway.

**Step 10**

In the **Metric** field, enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1. The metric is a measurement of the “expense” of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. The metric is used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connected routes. The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static route takes precedence. Connected routes always take precedence over static or dynamically discovered routes.

**Step 11**

(Optional) For a default route, click the **Tunneled** checkbox to define a separate default route for VPN traffic.

You can define a separate default route for VPN traffic if you want your VPN traffic to use a different default route than your non VPN traffic. For example, traffic incoming from VPN connections can be easily directed towards internal networks, while traffic from internal networks can be directed towards the outside. When you create a default route with the tunneled option, all traffic from a tunnel terminating on the device that cannot be routed using learned or static routes, is sent to this route. You can configure only one default tunneled gateway per device. ECMP for tunneled traffic is not supported.

**Step 12**

(IPv4 static route only) To monitor route availability, enter or choose the name of an SLA (service level agreement) Monitor object that defines the monitoring policy, in the **Route Tracking** field.

See SLA Monitor Objects, on page 628.

**Step 13**

Click **Ok**.
CHAPTER 39

OSPF for Firepower Threat Defense

This chapter describes how to configure the FTD to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

- OSPF for Firepower Threat Defense, on page 999
- Requirements and Prerequisites for OSPF, on page 1002
- Guidelines for OSPF, on page 1002
- Configure OSPFv2, on page 1004
- Configure OSPFv3, on page 1016

About OSPF

OSPF is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. OSPF propagates link-state advertisements rather than routing table updates. Because only LSAs are exchanged instead of the entire routing tables, OSPF networks converge more quickly than RIP networks.

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include the following:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly, rather than gradually, as stale information is timed out.

- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The Firepower Threat Defense device calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The Firepower Threat Defense device can run two processes of OSPF protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses.
(NAT allows these interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The Firepower Threat Defense device supports the following OSPF features:

- Intra-area, inter-area, and external (Type I and Type II) routes.
- Virtual links.
- LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Configuring the Firepower Threat Defense device as a designated router or a designated backup router. The Firepower Threat Defense device also can be set up as an ABR.
- Stub areas and not-so-stubby areas.
- Area boundary router Type 3 LSA filtering.

OSPF supports MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (such as RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the ASA acting as an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other, which allows you to use NAT and OSPF together without advertising private networks.

**Note**

Only Type 3 LSAs can be filtered. If you configure the Firepower Threat Defense device as an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS, including public areas.

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either as default or Type 5 AS external LSAs. However, you need to configure static routes for the private networks protected by the Firepower Threat Defense device. Also, you should not mix public and private networks on the same Firepower Threat Defense device interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the Firepower Threat Defense device at the same time.
**OSPF Support for Fast Hello Packets**

The OSPF Support for Fast Hello Packets feature provides a way to configure the sending of hello packets in intervals less than one second. Such a configuration would result in faster convergence in an Open Shortest Path First (OSPF) network.

**Prerequisites for OSPF Support for Fast Hello Packets**

OSPF must be configured in the network already or configured at the same time as the OSPF Support for Fast Hello Packets feature.

**OSPF Hello Interval and Dead Interval**

OSPF hello packets are packets that an OSPF process sends to its OSPF neighbors to maintain connectivity with those neighbors. The hello packets are sent at a configurable interval (in seconds). The defaults are 10 seconds for an Ethernet link and 30 seconds for a non broadcast link. Hello packets include a list of all neighbors for which a hello packet has been received within the dead interval. The dead interval is also a configurable interval (in seconds), and defaults to four times the value of the hello interval. The value of all hello intervals must be the same within a network. Likewise, the value of all dead intervals must be the same within a network.

These two intervals work together to maintain connectivity by indicating that the link is operational. If a router does not receive a hello packet from a neighbor within the dead interval, it will declare that neighbor to be down.

**OSPF Fast Hello Packets**

OSPF fast hello packets refer to hello packets being sent at intervals of less than 1 second. To understand fast hello packets, you should already understand the relationship between OSPF hello packets and the dead interval. See OSPF Hello Interval and Dead Interval, on page 1001.

OSPF fast hello packets are achieved by using the ospf dead-interval command. The dead interval is set to 1 second, and the hello-multiplier value is set to the number of hello packets you want sent during that 1 second, thus providing subsecond or "fast" hello packets.

When fast hello packets are configured on the interface, the hello interval advertised in the hello packets that are sent out this interface is set to 0. The hello interval in the hello packets received over this interface is ignored.

The dead interval must be consistent on a segment, whether it is set to 1 second (for fast hello packets) or set to any other value. The hello multiplier need not be the same for the entire segment as long as at least one hello packet is sent within the dead interval.

**Benefits of OSPF Fast Hello Packets**

The benefit of the OSPF Fast Hello Packets feature is that your OSPF network will experience faster convergence time than it would without fast hello packets. This feature allows you to detect lost neighbors within 1 second. It is especially useful in LAN segments, where neighbor loss might not be detected by the Open System Interconnection (OSI) physical layer and data-link layer.
Implementation Differences Between OSPFv2 and OSPFv3

OSPFv3 is not backward compatible with OSPFv2. To use OSPF to route both IPv4 and IPv6 traffic, you must run both OSPFv2 and OSPFv3 at the same time. They coexist with each other, but do not interact with each other.

The additional features that OSPFv3 provides include the following:

- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Use of the IPv6 link-local address for neighbor discovery and other features.
- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Authentication support using the IPsec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

Requirements and Prerequisites for OSPF

**Model Support**

FTD

**Supported Domains**

Any

**User Roles**

Admin

Network Admin

Guidelines for OSPF

**Firewall Mode Guidelines**

OSPF supports routed firewall mode only. OSPF does not support transparent firewall mode.

**High Availability Guidelines**

OSPFv2 and OSPFv3 support Stateful High Availability.
IPv6 Guidelines

- OSPFv2 does not support IPv6.
- OSPFv3 supports IPv6.
- OSPFv3 uses IPv6 for authentication.
- The Firepower Threat Defense device installs OSPFv3 routes into the IPv6 RIB, provided it is the best route.

OSPFv3 Hello Packets and GRE

Typically, OSPF traffic does not pass through GRE tunnel. When OSPFv3 on IPv6 is encapsulated inside GRE, the IPv6 header validation for security check such as Multicast Destination fails. The packet is dropped due to the implicit security check validation, as this packet has destination IPv6 multicast.

You may define a pre-filter rule to bypass GRE traffic. However, with pre-filter rule, inner packets would not be interrogated by the inspection engine.

Clustering Guidelines

- OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment.
- In Spanned interface mode, dynamic routing is not supported on management-only interfaces.
- When a control role change occurs in the cluster, the following behavior occurs:
  - In spanned interface mode, the router process is active only on the control unit and is in a suspended state on the data units. Each cluster unit has the same router ID because the configuration has been synchronized from the control unit. As a result, a neighboring router does not notice any change in the router ID of the cluster during a role change.

Multiprotocol Label Switching (MPLS) and OSPF Guidelines

When a MPLS-configured router sends Link State (LS) update packets containing opaque Type-10 link-state advertisements (LSAs) that include an MPLS header, authentication fails and the appliance silently drops the update packets, rather than acknowledging them. Eventually the peer router will terminate the neighbor relationship because it has not received any acknowledgments.

Make sure that non-stop forwarding (NSF) is disabled on the appliance to ensure that the neighbor relationship remains stable:

- Navigate to the Non Stop Forwarding page in Firepower Management Center (Devices > Device Management (select the desired device) > Routing > OSPF > Advanced > Non Stop Forwarding).
  Ensure the Non Stop Forwarding Capability boxes are not checked.

Route Redistribution Guidelines

Redistribution of route maps with IPv4 or IPv6 prefix list on OSPFv2 or OSPFv3 is not supported. Use connected routes on OSPF for redistribution.
**Additional Guidelines**

- OSPFv2 and OSPFv3 support multiple instances on an interface.
- OSPFv3 supports encryption through ESP headers in a non-clustered environment.
- OSPFv3 supports Non-Payload Encryption.
- OSPFv2 supports Cisco NSF Graceful Restart and IETF NSF Graceful Restart mechanisms as defined in RFCs 4811, 4812 & 3623 respectively.
- OSPFv3 supports Graceful Restart mechanism as defined in RFC 5187.
- There is a limit to the number of intra area (type 1) routes that can be distributed. For these routes, a single type-1 LSA contains all prefixes. Because the system has a limit of 35 KB for packet size, 3000 routes result in a packet that exceeds the limit. Consider 2900 type 1 routes to be the maximum number supported.
- For a device using virtual routing, you can configure OSPFv2 and OSPFv3 for a global virtual router. However, you can configure only OSPFv2 for a user-defined virtual router.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.

**Configure OSPFv2**

This section describes the tasks involved in configuring an OSPFv2 routing process. For a device using virtual routing, you can configure OSPFv2 for global as well as for user-defined virtual routers.

**Configure OSPF Areas, Ranges, and Virtual Links**

You can configure several OSPF area parameters, which include setting authentication, defining stub areas, and assigning specific costs to the default summary route. You can enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area.

**Procedure**

**Step 1** Choose Devices > Device Management, and edit the FTD device.
**Step 2** Click Routing.
**Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
**Step 4** Click OSPF.
**Step 5** Select Process 1. You can enable up to two OSPF process instances for each context/virtual router. You must choose an OSPF process to be able to configure the Area parameters.
If the device is using virtual routing, the ID fields display the unique process IDs generated for the chosen virtual router.

**Step 6** Choose the OSPF role from the drop-down list, and enter a description for it in the next field. The options are Internal, ABR, ASBR, and ABR and ASBR. See About OSPF, on page 999 for a description of the OSPF roles.

**Step 7** Select Area > Add.

You can click Edit (✓), or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 8** Configure the following area options for each OSPF process:

- **OSPF Process**—Choose the process ID. For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.

- **Area ID**—Designation of the area for which routes are to be summarized.

- **Area Type**—Choose one of the following:
  - **Normal**—(Default) Standard OSPF area.
  - **Stub**—A stub area does not have any routers or areas beyond it. Stub areas prevent Autonomous System (AS) External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you can prevent summary LSAs (Types 3 and 4) from being flooded into the area by NOT checking the Summary Stub check box.
  - **NSSA**—Makes the area a not-so-stubby area (NSSA). NSSAs accept Type 7 LSAs. You can disable route redistribution by NOT checking the Redistribute check box and checking the Default Information Originate check box. You can prevent summary LSAs from being flooded into the area by NOT checking the Summary NSSA check box.

- **Metric Value**—The metric used for generating the default route. The default value is 10. Valid metric values range from 0 through 16777214.

- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

- **Available Network**—Choose one of the available networks and click Add, or click Add (✚) to add a new network object. See Network Objects, on page 564 for the procedure for adding networks.

- **Authentication**—Choose the OSPF authentication:
  - **None**—(Default) Disables OSPF area authentication.
  - **Password**—Provides a clear text password for area authentication, which is not recommended where security is a concern.
  - **MD5**—Allows MD5 authentication.

- **Default Cost**—The default cost for the OSPF area, which is used to determine the shortest paths to the destination. Valid values range from 0 through 65535. The default value is 1.

**Step 9** Click OK to save the area configuration.

**Step 10** Select Range > Add.
Choose one of the available networks and whether to advertise, or,

Click **Add (++)** to add a new network object. See *Network Objects, on page 564* for the procedure for adding networks.

**Step 11**
Click **OK** to save the range configuration.

**Step 12**
Select **Virtual Link**, click **Add**, and configure the following options for each OSPF process:

- **Peer Router**—Choose the IP address of the peer router. To add a new peer router, click **Add (++)**. See *Network Objects, on page 564* for the procedure for adding networks.

- **Hello Interval**—The time in seconds between the hello packets sent on an interface. The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. Valid values range from 1 through 65535. The default is 10.

  The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.

- **Transmit Delay**—The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 through 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

- **Retransmit Interval**—The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 through 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

- **Dead Interval**—The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The dead interval is an unsigned integer. The default is four times the hello interval, or 40 seconds. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 through 65535.

- **Authentication**—Choose the OSPF virtual link authentication from the following:

  - **None**—(Default) Disables virtual link area authentication.

  - **Area Authentication**—Enables area authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

  - **Password**—Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.

  - **MD5**—Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

  **Note**  
  Ensure to enter only numbers as the MD5 key ID.
• **Key Chain**—Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, see *Creating Key Chain Objects, on page 626*. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.

**Step 13**
Click **OK** to save the virtual link configuration.

**Step 14**
Click **Save** on the Routing page to save your changes.

---

**What to do next**
Continue with **Configure OSPF Redistribution**.

---

**Configure OSPF Redistribution**

The Firepower Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

**Procedure**

**Step 1**
Choose **Devices > Device Management**, and edit the FTD device.

**Step 2**
Click **Routing**.

**Step 3**
(For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

**Step 4**
Click **OSPF**.

**Step 5**
Select **Redistribution > Add**.

You can click **Edit (✓)**, or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 6**
Configure the following redistribution options for each OSPF process:

- **OSPF Process**—Choose the process ID. For a device using virtual routing, this drop-down list displays the unique process IDs generated for the selected virtual router.

- **Route Type**—Choose one of the following types:
  - **Static**—Redistributes static routes to the OSPF routing process.
  - **Connected**—Redistributes connected routes (routes established automatically by virtue of having the IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed as external to the device. You can select whether to use subnets under the Optional list.
  - **OSPF**—Redistributes routes from another OSPF routing process, for example, internal, external 1 and 2, NSSA external 1 and 2, or whether to use subnets. You can select these options under the Optional list.
  - **BGP**—Redistribute routes from the BGP routing process. Add the AS number and whether to use subnets.
• **RIP**—Redistributes routes from the RIP routing process. You can select whether to use subnets under the Optional list.

  **Note** As a user-defined virtual router does not support RIP, you cannot redistribute routes from RIP.

• **Metric Value**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.

• **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

• **Tag Value**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.

• **RouteMap**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add (✚)**. See Route Maps to add a new route map.

  **Step 7** Click **OK** to save the redistribution configuration.

  **Step 8** Click **Save** on the Routing page to save your changes.

---

**What to do next**

Continue with **Configure OSPF Inter-Area Filtering, on page 1008**.

---

**Configure OSPF Inter-Area Filtering**

ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.
Procedure

Step 1 Choose Devices > Device Management, and edit the FTD device.
Step 2 Click Routing.
Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
Step 4 Click OSPF.
Step 5 Select InterArea > Add.

You can click Edit ( ), or use the right-click menu to cut, copy, past, insert, and delete inter-areas.

Step 6 Configure the following inter-area filtering options for each OSPF process:

- **OSPF Process**—For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**—The area for which routes are to be summarized.
- **PrefixList**—The name of the prefix. To add a new prefix list object, see Step 5.
- **Traffic Direction**—Inbound or outbound. Choose Inbound to filter LSAs coming into an OSPF area, or Outbound to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

Step 7 Click Add ( ), and enter a name for the new prefix list, and whether to allow overrides.

You must configure a prefix list before you can configure a prefix rule.

Step 8 Click Add to configure prefix rules, and configure the following parameters:

- **Action**—Select Block or Allow for the redistribution access.
- **Sequence No**—The routing sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.
- **IP Address**—Specify the prefix number in the format of IP address/mask length.
- **Min Prefix Length**—(Optional) The minimum prefix length.
- **Max Prefix Length**—(Optional) The maximum prefix length.

Step 9 Click OK to save the inter-area filtering configuration.
Step 10 Click Save on the Routing page to save your changes.

What to do next

Continue with Configure OSPF Filter Rules, on page 1010.
**Configure OSPF Filter Rules**

You can configure ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restrict all other prefixes. You can apply this type of area filtering out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF area at the same time. OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

**Procedure**

**Step 1** Choose Devices > Device Management, and edit the FTD device.

**Step 2** Click Routing.

**Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

**Step 4** Click OSPF.

**Step 5** Select Filter Rule > Add.

You can click Edit, or use the right-click menu to cut, copy, paste, insert, and delete filter rules.

**Step 6** Configure the following filter rule options for each OSPF process:

- **OSPF Process**—For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.

- **Access List**—The access list for this OSPF process. To add a new standard access list object, click Add and see Configure Standard ACL Objects, on page 636.

- **Traffic Direction**—Choose In or Out for the traffic direction being filtered. Choose In to filter LSAs coming into an OSPF area, or Out to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

- **Interface**—The interface for this filter rule.

**Step 7** Click OK to save the filter rule configuration.

**Step 8** Click Save on the Routing page to save your changes.

**What to do next**

Continue with Configure OSPF Summary Addresses, on page 1010.

**Configure OSPF Summary Addresses**

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the Firepower Threat Defense device to advertise a single route for all the redistributed routes that are included for a specified network address and mask. This configuration decreases the size of the OSPF link-state database. Routes that match the specified IP address mask pair can be suppressed. The tag value can be used as a match value for controlling redistribution through route maps.
Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table. Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

**Procedure**

**Step 1** Choose Devices > Device Management, and edit the FTD device.

**Step 2** Click Routing.

**Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

**Step 4** Click OSPF.

**Step 5** Select Summary Address > Add.

You can click Edit to edit, or use the right-click menu to cut, copy, past, insert, and delete summary addresses.

**Step 6** Configure the following summary address options for each OSPF process:

- **OSPF Process** — For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.

- **Available Network** — The IP address of the summary address. Select one from the Available networks list and click Add, or to add a new network, click Add. See Network Objects, on page 564 for the procedure for adding networks.

- **Tag** — A 32-bit decimal value that is attached to each external route. This value is not used by OSPF itself, but may be used to communicate information between ASBRs.

- **Advertise** — Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

**Step 7** Click OK to save the summary address configuration.

**Step 8** Click Save on the Routing page to save your changes.

**What to do next**

Continue with Configure OSPF Interfaces and Neighbors, on page 1011.

**Configure OSPF Interfaces and Neighbors**

You can change some interface-specific OSPFv2 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval, the dead interval, and the authentication key. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.
You need to define static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv2 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

**Procedure**

**Step 1** Choose **Devices > Device Management**, and edit the FTD device.

**Step 2** Click **Routing**.

**Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

**Step 4** Click **OSPF**.

**Step 5** Select **Interface > Add**.

You can click **Edit (✓)**, or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 6** Configure the following Interface options for each OSPF process:

- **Interface**—The interface you are configuring.
  
  **Note** If the device is using virtual routing, this drop-down list displays only those interfaces that belong to the router.

- **Default Cost**—The cost of sending a packet through the interface. The default value is 10.

- **Priority**—Determines the designated router for a network. Valid values range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router. This setting does not apply to interfaces that are configured as point-to-point interfaces.

- **MTU Ignore**—OSPF checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency is not established.

- **Database Filter**—Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.

- **Hello Interval**—Specifies the interval, in seconds, between hello packets sent on an interface. Valid values range 1–8192 seconds. The default value is 10 seconds.

  The smaller the hello interval, the faster topological changes are detected, but more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface.

- **Transmit Delay**—Estimated time in seconds to send an LSA packet on the interface. Valid values range 1–65535 seconds. The default is 1 second.

  LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA
propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

• **Retransmit Interval** — Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

• **Dead Interval** — Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range 1–65535.

• **Hello Multiplier** — Specifies the number of Hello packets to be sent per second. Valid values are 3–20.

• **Point-to-Point** — Lets you transmit OSPF routes over VPN tunnels.

• **Authentication** — Choose the OSPF interface authentication from the following:
  - None — (Default) Disables interface authentication.
  - Area Authentication — Enables interface authentication using MD5. Click Add, and enter the key ID, key, confirm the key, and then click OK.
  - Password — Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - MD5 — Allows MD5 authentication. Click Add, and enter the key ID, key, confirm the key, and then click OK.

  **Note** Ensure to enter only numbers as the MD5 key ID.

• Key Chain — Allows key chain authentication. Click Add, and create the key chain, and then click Save. For detailed procedure, see [Creating Key Chain Objects, on page 626](#). Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.

• **Enter Password** — The password you configure if you choose Password as the type of authentication.

• **Confirm Password** — Confirm the password that you chose.

**Step 7** Select Neighbor > Add.

You can click Edit ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 8** Configure the following parameters for each OSPF process:

  - **OSPF Process** — Choose 1 or 2.

  - **Neighbor** — Choose one of the neighbors in the drop-down list, or click Add ( ) to add a new neighbor; enter the name, description, network, whether to allow overrides, and then click Save.

  - **Interface** — Choose the interface associated with the neighbor.

**Step 9** Click OK to save the neighbor configuration.
Step 10 Click Save on the Routing page to save your changes.

Configure OSPF Advanced Properties

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, an LSA timer, and graceful restarts.

Graceful Restarts

The Firepower Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv2 by using either using NSF Cisco (RFC 4811 and RFC 4812) or NSF IETF (RFC 3623).

Note

NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.

- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.

- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose Devices > Device Management, and edit the FTD device.
Step 2 Click Routing.
Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
Step 4 Click OSPF > Advanced Settings.
Step 5 Select General, and configure the following:

- **Router ID**—Choose Automatic or IP address for the router ID. If you choose IP address, enter the IP address in the IP Address field.

- **Ignore LSA MOSPF**—Suppresses syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.
• **RFC 1583 Compatible**—Configures RFC 1583 compatibility as the method used to calculate summary route costs. Routing loops can occur with RFC 1583 compatibility enabled. Disable it to prevent routing loops. All OSPF routers in an OSPF routing domain should have RFC compatibility set identically.

• **Adjacency Changes**—Defines the adjacency changes that cause syslog messages to be sent. By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.
  - **Log Adjacency Changes**—Causes the Firepower Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
  - **Log Adjacency Change Details**—Causes the Firepower Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

• **Administrative Route Distance**—Allows you to modify the settings that were used to configure administrative route distances for inter-area, intra-area, and external IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.

• **LSA Group Pacing**—Specifies the interval in seconds at which LSAs are collected into a group and refreshed, checksummed, or aged. Valid values range from 10 to 1800. The default value is 240.

• **Enable Default Information Originate**—Check the **Enable** check box to generate a default external route into an OSPF routing domain and configure the following options:
  - **Always advertise the default route**—Ensures that the default route is always advertised.
  - **Metric Value**—Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**—The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **RouteMap**—Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See **Route Maps** to add a new route map.

**Step 6**
Click **OK** to save the general configuration.

**Step 7**
Select **Non Stop Forwarding**, and configure Cisco NSF graceful restart for OSPFv2, for an NSF-capable or NSF-aware device:

**Note** There are two graceful restart mechanisms for OSPFv2, Cisco NSF and IETF NSF. Only one of these graceful restart mechanisms can be configured at a time for an OSPF instance. An NSF-aware device can be configured as both Cisco NSF helper and IETF NSF helper but a NSF-capable device can be configured in either Cisco NSF or IETF NSF mode at a time for an OSPF instance.

a) Check the **Enable Cisco Non Stop Forwarding Capability** check box.

b) (Optional) Check the **Cancel NSF restart when non-NSF-aware neighboring networking devices are detected** check box if required.

c) (Optional) Make sure the **Enable Cisco Non Stop Forwarding Helper** mode check box is unchecked to disable the helper mode on an NSF-aware device.

**Step 8**
Configure IETF NSF Graceful Restart for OSPFv2, for an NSF-capable or NSF-aware device:
a) Check the **Enable IETF Non Stop Forwarding Capability** check box.
b) In the **Length of graceful restart interval (seconds)** field, enter the restart interval in seconds. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.
c) (Optional) Make sure the **Enable IETF nonstop forwarding (NSF) for helper mode** check box is unchecked to disable the IETF NSF helper mode on an NSF-aware device.
d) **Enable Strict Link State advertisement checking**—When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.
e) **Enable IETF Non Stop Forwarding**—Enables non stop forwarding, which allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. OSPF uses extensions to the OSPF protocol to recover its state from neighboring OSPF devices. For the recovery to work, the neighbors must support the NSF protocol extensions and be willing to act as "helpers" to the device that is restarting. The neighbors must also continue forwarding data traffic to the device that is restarting while protocol state recovery takes place.

---

**Configure OSPFv3**

This section describes the tasks involved in configuring an OSPFv3 routing process. For a device using virtual routing, you can configure OSPFv3 only for its global virtual router and not for its user-defined virtual router.

**Configure OSPFv3 Areas, Route Summaries, and Virtual Links**

To enable OSPFv3, you need to create an OSPFv3 routing process, create an area for OSPFv3, enable an interface for OSPFv3, and then redistribute the route into the targeted OSPFv3 routing process.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose <strong>Devices &gt; Device Management</strong>, and edit the FTD device.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Select <strong>Routing &gt; OSPFv3</strong>.</td>
</tr>
<tr>
<td>Step 3</td>
<td>By default <strong>Enable Process</strong> 1 is selected. You can enable up to two OSPF process instances.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Chose the OSPFv3 role from the drop-down list, and enter a description for it. The options are Internal, ABR, ASBR, and ABR and ASBR. See About OSPF, on page 999 for descriptions of the OSPFv3 roles.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Select <strong>Area &gt; Add</strong>. You can click <strong>Edit (✓)</strong>, or use the right-click menu to cut, copy, past, insert, and delete areas.</td>
</tr>
</tbody>
</table>
| Step 6 | Select **General**, and configure the following options for each OSPF process:  
  • **Area ID**—The area for which routes are to be summarized.  
  • **Cost**—The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215. |
• **Type**—Specifies Normal, NSSA, or Stub. If you select Normal, there are no other parameters to configure. If you select Stub, you can choose to send summary LSAs in the area. If you select NSSA, you can configure the next three options:

  • **Allow Sending summary LSA into this area**—Allows the sending of summary LSAs into the area.
  
  • **Redistribute imports routes to normal and NSSA area**—Allows redistribution to import routes to normal and not to stubby areas.
  
  • **Defaults information originate**—Generates a default external route into an OSPFv3 routing domain.

• **Metric**—Metric used for generating the default route. The default value is 10. Valid metric values range from 0 to 16777214.

• **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

---

**Step 7**

Click **OK** to save the general configuration.

**Step 8**

Select **Route Summary > Add Route Summary**.

You can click **Edit (✓)**, or use the right-click menu to cut, copy, past, insert, and delete route summaries.

**Step 9**

Configure the following route summary options for each OSPF process:

  • **IPv6 Prefix/Length**—The IPv6 prefix. To add a new network object, click **Add (✚)**. See Network Objects, on page 564 for the procedure for adding networks.

  • **Cost**—The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.

  • **Advertise**—Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

**Step 10**

Click **OK** to save the route summary configuration.

**Step 11**

Select **Virtual Link**, click **Add Virtual Link**, and configure the following options for each OSPF process:

  • **Peer RouterID**—Choose the IP address of the peer router. To add a new network object, click **Add (✚)**. See Network Objects, on page 564 for the procedure for adding networks.

  • **TTL Security**—Enables TTL security check. The value for the hop-count is a number from 1 to 254. The default is 1.

  OSPF sends outgoing packets with an IP header Time to Live (TTL) value of 255 and discards incoming packets that have TTL values less than a configurable threshold. Because each device that forwards an IP packet decrements the TTL, packets received via a direct (one-hop) connection have a value of 255. Packets that cross two hops have a value of 254, and so on. The receive threshold is configured in terms of the maximum number of hops that a packet may have traveled.

  • **Dead Interval**—The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The default is four times the hello interval, or 40 seconds. Valid values range from 1 to 65535.
The dead interval is an unsigned integer. The value must be the same for all routers and access servers that are attached to a common network.

- **Hello Interval**—The time in seconds between the hello packets sent on an interface. Valid values range from 1 to 65535. The default is 10.

  The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.

- **Retransmit Interval**—The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 to 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

- **Transmit Delay**—The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 to 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

---

**Step 12**
Click **OK** to save the virtual link configuration.

**Step 13**
Click **Save** on the Router page to save your changes.

---

**What to do next**
Continue with **Configure OSPFv3 Redistribution**.

---

**Configure OSPFv3 Redistribution**

The Firepower Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

**Procedure**

**Step 1**
Choose **Devices > Device Management**, and edit the FTD device.

**Step 2**
Select **Routing > OSPF**.

**Step 3**
Select **Redistribution**, and click **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.
Configure the following redistribution options for each OSPF process:

- **Source Protocol**—The source protocol from which routes are being redistributed. The supported protocols are connected, OSPF, static, and BGP. If you choose OSPF, you must enter the Process ID in the **Process ID** field. If you choose BGP, you must add the AS number in the **AS Number** field.

- **Metric**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.

- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

- **Tag**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.

- **Route Map**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking Add (†). See *Route Maps, on page 631* for the procedure to add a new route map.

- **Process ID**—The OSPF process ID, either 1 or 2.

  **Note** The Process ID is enabled the OSPFv3 process is redistributing a route learned by another OSPFv3 process.

- **Match**—Enables OSPF routes to be redistributed into other routing domains:
  - **Internal** for routes that are internal to a specific autonomous system.
  - **External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 1 external routes.
  - **External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 2 external routes.
  - **NSSA External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 1 external routes.
  - **NSSA External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 2 external routes.

**Step 5** Click **OK** to save the redistribution configuration.

**Step 6** Click **Save** on the Routing page to save your changes.

**What to do next**

Continue with *Configure OSPFv3 Summary Prefixes, on page 1020.*
Configure OSPFv3 Summary Prefixes

You can configure the Firepower Threat Defense device to advertise routes that match a specified IPv6 prefix and mask pair.

Procedure

Step 1  Choose Devices > Device Management, and edit the FTD device.
Step 2  Select Routing > OSPFv3.
Step 3  Select Summary Prefix > Add.

You can click Edit (✓), or use the right-click menu to cut, copy, past, insert, and delete summary prefixes.

Step 4  Configure the following summary prefix options for each OSPF process:

- **IPv6 Prefix/Length**—The IPv6 prefix and prefix length label. Select one from the list or click Add (+) to add a new network object. See Network Objects, on page 564 for the procedure for adding networks.
- **Advertise**—Advertises routes that match the specified prefix and mask pair. Uncheck this check box to suppress routes that match the specified prefix and mask pair.
- **(Optional) Tag**—A value that you can use as a match value for controlling redistribution through route maps.

Step 5  Click OK to save the summary prefix configuration.
Step 6  Click Save on the Routing page to save your changes.

What to do next

Continue with Configure OSPFv3 Interfaces, Authentication, and Neighbors, on page 1020.

Configure OSPFv3 Interfaces, Authentication, and Neighbors

You can change certain interface-specific OSPFv3 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval and the dead interval. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

Procedure

Step 1  Choose Devices > Device Management, and edit the FTD device.
Step 2  Select Routing > OSPFv3.
Step 3  Select Interface > Add.

You can click Edit to edit, or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4  Configure the following interface options for each OSPFv3 process:
• **Interface**—The interface you are configuring.

• **Enable OSPFv3**—Enables OSPFv3.

• **OSPF Process**—Choose 1 or 2.

• **Area**—The area ID for this process.

• **Instance**—Specifies the area instance ID to be assigned to the interface. An interface can have only one OSPFv3 area. You can use the same area on multiple interfaces, and each interface can use a different area instance ID.

**Step 5**

Select **Properties**, and configuring the following options for each OSPFv3 process:

• **Filter Outgoing Link Status Advertisements**—Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.

• **Disable MTU mismatch detection**—Disables the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.

• **Flood Reduction**—Changes normal LSAs into Do Not Age LSAs, so that they don't get flooded every 3600 seconds across areas.

OSPF LSAs are refreshed every 3600 seconds. In large OSPF networks, this can lead to large amounts of unnecessary LSA flooding from area to area.

• **Point-to-Point Network**—Lets you transmit OSPF routes over VPN tunnels. When an interface is configured as point-to-point, non-broadcast, the following restrictions apply:
  
  • You can define only one neighbor for the interface.
  
  • You need to manually configure the neighbor.
  
  • You need to define a static route pointing to the crypto endpoint.
  
  • If OSPF over a tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
  
  • You should bind the crypto map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so that the OSPF adjacencies can be established over the VPN tunnel.

• **Broadcast**—Specifies that the interface is a broadcast interface. By default, this check box is checked for Ethernet interfaces. Uncheck this check box to designate the interface as a point-to-point, non-broadcast interface. Specifying an interface as point-to-point, nonbroadcast lets you transmit OSPF routes over VPN tunnels.

• **Cost**—Specifies the cost of sending a packet on the interface. Valid values for this setting range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, nonbroadcast interfaces.

When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.

• **Priority**—Determines the designated router for a network. Valid values range from 0 to 255.
• **Dead Interval**—Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535.

• **Poll Interval**—Time period in seconds between OSPF packets that the router will send before adjacency is established with a neighbor. Once the routing device detects an active neighbor, the hello packet interval changes from the time specified in the poll interval to the time specified in the hello interval. Valid values range from 1 to 65535 seconds.

• **Retransmit Interval**—Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

• **Transmit Delay**—Estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.

**Step 6** Click **OK** to save the properties configuration.

**Step 7** Select **Authentication**, and configure the following options for each OSPFv3 process:

- **Type**—Type of authentication. The available options are Area, Interface, and None. The None option indicates that no authentication is used.

- **Security Parameters Index**—A number from 256 to 4294967295. Configure this if you chose Interface as the type.

- **Authentication**—Type of authentication algorithm. Supported values are SHA-1 and MD5. Configure this if you chose Interface as the type.

- **Authentication Key**—When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.

- **Encrypt Authentication Key**—Enables encryption of the authentication key.

- **Include Encryption**—Enables encryption.

- **Encryption Algorithm**—Type of encryption algorithm. Supported value is DES. The NULL entry indicates no encryption. Configure this if you chose **Include Encryption**.

- **Encryption Key**—Enter the encryption key. Configure this if you chose **Include Encryption**.

- **Encrypt Key**—Enables the key to be encrypted.

**Step 8** Click **OK** to save the authentication configuration.

**Step 9** Select **Neighbor**, click **Add**, and configure the following options for each OSPFv3 process:

- **Link Local Address**—The IPv6 address of the static neighbor.

- **Cost**—Enables cost. Enter the cost in the **Cost** field, and check the **Filter Outgoing Link State Advertisements** if you want to advertise.

- **(Optional) Poll Interval**—Enables the poll interval. Enter the **Priority** level and the **Poll Interval** in seconds.

**Step 10** Click **Add** to add the neighbor.
Step 11  Click **OK** to save the Interface configuration.

---

**Configure OSPFv3 Advanced Properties**

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, passive OSPFv3 routing, LSA timers, and graceful restarts.

**Graceful Restarts**

The Firepower Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv3 using graceful-restart (RFC 5187).

---

**Note**  NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

---

**Procedure**

---

**Step 1**  Choose **Devices > Device Management**, and edit the FTD device.

**Step 2**  Select **Routing > OSPFv3 > Advanced**.

**Step 3**  For **Router ID**, choose **Automatic** or **IP address**. If you choose IP address, enter the IP address in the IP Address field.

**Step 4**  Check the **Ignore LSA MOSPF** check box if you want to suppress syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.

**Step 5**  Select **General**, and configure the following:

- **Adjacency Changes**—Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

- **Adjacency Changes**—Causes the Firepower Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
• **Include Details**—Causes the Firepower Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

• **Administrative Route Distances**—Allows you to modify the settings that were used to configure administrative route distances for inter-area, intra-area, and external IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.

• **Default Information Originate**—Check the Enable check box to generate a default external route into an OSPFv3 routing domain and configure the following options:
  
  • **Always Advertise**—Will always advertise the default route whether or not one exists.
  
  • **Metric**—Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  
  • **Metric Type**—The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  
  • **Route Map**—Choose the routing process that generates the default route if the route map is satisfied or click Add (+) to add a new one. See Route Maps, on page 631 to add a new route map.

**Step 6** Click OK to save the general configuration.

**Step 7** Select Passive Interface, select the interfaces on which you want to enable passive OSPFv3 routing from the Available Interfaces list, and click Add to move them to the Selected Interfaces list.

Passive routing assists in controlling the advertisement of OSPFv3 routing information and disables the sending and receiving of OSPFv3 routing updates on an interface.

**Step 8** Click OK to save the passive interface configuration.

**Step 9** Select Timer, and configure the following LSA pacing and SPF calculation timers:

• **Arrival**—Specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 6000,000 milliseconds. The default is 1000 milliseconds.

• **Flood Pacing**—Specifies the time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.

• **Group Pacing**—Specifies the interval in seconds at which LSAs are collected into a group and refreshed, checksummed, or aged. Valid values range from 10 to 1800. The default value is 240.

• **Retransmission Pacing**—Specifies the time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.

• **LSA Throttle**—Specifies the delay in milliseconds to generate the first occurrence of the LSA. The default value is 0 millisecond. The minimum specifies the minimum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds. The maximum specifies the maximum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.
For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

**Note**

- **SPF Throttle**—Specifies the delay in milliseconds to receive a change to the SPF calculation. The default value is 5000 milliseconds. The minimum specifies the delay in milliseconds between the first and second SPF calculations. The default value is 10000 milliseconds. The maximum specifies the maximum wait time in milliseconds for SPF calculations. The default value is 10000 milliseconds.

For SPF throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

**Step 10**
Click OK to save the LSA timer configuration.

**Step 11**
Select Non Stop Forwarding, and check the Enable graceful-restart helper check box. This is checked by default. Uncheck this to disable the graceful-restart helper mode on an NSF-aware device.

**Step 12**
Check the Enable link state advertisement check box to enable strict link state advertisement checking. When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.

**Step 13**
Check the Enable graceful-restart (Use when Spanned Cluster or Failover Configured) and enter the graceful-restart interval in seconds. The range is 1-1800. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.

**Step 14**
Click OK to save the graceful restart configuration.

**Step 15**
Click Save on the Routing page to save your changes.
Configure OSPFv3 Advanced Properties
BGP for Firepower Threat Defense

This section describes how to configure the FTD to route data, perform authentication, and redistribute routing information using the Border Gateway Protocol (BGP).

- About BGP, on page 1027
- Requirements and Prerequisites for BGP, on page 1030
- Guidelines for BGP, on page 1030
- Configure BGP, on page 1031

About BGP

BGP is an inter and intra autonomous system routing protocol. An autonomous system is a network or group of networks under a common administration and with common routing policies. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP).

Routing Table Changes

BGP neighbors exchange full routing information when the TCP connection between neighbors is first established. When changes to the routing table are detected, the BGP routers send to their neighbors only those routes that have changed. BGP routers do not send periodic routing updates, and BGP routing updates advertise only the optimal path to a destination network.

Note

AS loop detection is done by scanning the full AS path (as specified in the AS_PATH attribute), and checking that the AS number of the local system does not appear in the AS path. By default, EBGPs advertise the learned routes to the same peer to prevent additional CPU cycles on the ASA in performing loop checks and to avoid delays in the existing outgoing update tasks.

Routes learned via BGP have properties that are used to determine the best route to a destination, when multiple paths exist to a particular destination. These properties are referred to as BGP attributes and are used in the route selection process:

- Weight—This is a Cisco-defined attribute that is local to a router. The weight attribute is not advertised to neighboring routers. If the router learns about more than one route to the same destination, the route with the highest weight is preferred.
• Local preference—The local preference attribute is used to select an exit point from the local AS. Unlike the weight attribute, the local preference attribute is propagated throughout the local AS. If there are multiple exit points from the AS, the exit point with the highest local preference attribute is used as an exit point for a specific route.

• Multi-exit discriminator—The multi-exit discriminator (MED) or metric attribute is used as a suggestion to an external AS regarding the preferred route into the AS that is advertising the metric. It is referred to as a suggestion because the external AS that is receiving the MEDs may also be using other BGP attributes for route selection. The route with the lower MED metric is preferred.

• Origin—The origin attribute indicates how BGP learned about a particular route. The origin attribute can have one of three possible values and is used in route selection.
  • IGP—The route is interior to the originating AS. This value is set when the network router configuration command is used to inject the route into BGP.
  • EGP—The route is learned via the Exterior Border Gateway Protocol (EBGP).
  • Incomplete—The origin of the route is unknown or learned in some other way. An origin of incomplete occurs when a route is redistributed into BGP.

• AS_path—When a route advertisement passes through an autonomous system, the AS number is added to an ordered list of AS numbers that the route advertisement has traversed. Only the route with the shortest AS_path list is installed in the IP routing table.

• Next hop—The EBGP next-hop attribute is the IP address that is used to reach the advertising router. For EBGP peers, the next-hop address is the IP address of the connection between the peers. For IBGP, the EBGP next-hop address is carried into the local AS.

• Community—The community attribute provides a way of grouping destinations, called communities, to which routing decisions (such as acceptance, preference, and redistribution) can be applied. Route maps are used to set the community attribute. The predefined community attributes are as follows:
  • no-export—Do not advertise this route to EBGP peers.
  • no-advertise—Do not advertise this route to any peer.
  • internet—Advertise this route to the Internet community; all routers in the network belong to it.

**When to Use BGP**

Customer networks, such as universities and corporations, usually employ an Interior Gateway Protocol (IGP) such as OSPF for the exchange of routing information within their networks. Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

BGP can also be used for carrying routing information for IPv6 prefix over IPv6 networks.

**BGP Path Selection**

BGP may receive multiple advertisements for the same route from different sources. BGP selects only one path as the best path. When this path is selected, BGP puts the selected path in the IP routing table and
propagates the path to its neighbors. BGP uses the following criteria, in the order presented, to select a path for a destination:

- If the path specifies a next hop that is inaccessible, drop the update.
- Prefer the path with the largest weight.
- If the weights are the same, prefer the path with the largest local preference.
- If the local preferences are the same, prefer the path that was originated by BGP running on this router.
- If no route was originated, prefer the route that has the shortest AS_path.
- If all paths have the same AS_path length, prefer the path with the lowest origin type (where IGP is lower than EGP, and EGP is lower than incomplete).
- If the origin codes are the same, prefer the path with the lowest MED attribute.
- If the paths have the same MED, prefer the external path over the internal path.
- If the paths are still the same, prefer the path through the closest IGP neighbor.
- Determine if multiple paths require installation in the routing table for BGP Multipath, on page 1029.
- If both paths are external, prefer the path that was received first (the oldest one).
- Prefer the path with the lowest IP address, as specified by the BGP router ID.
- If the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster list length.
- Prefer the path that comes from the lowest neighbor address.

**BGP Multipath**

BGP Multipath allows installation into the IP routing table of multiple equal-cost BGP paths to the same destination prefix. Traffic to the destination prefix is then shared across all installed paths.

These paths are installed in the table together with the best path for load-sharing. BGP Multipath does not affect best-path selection. For example, a router still designates one of the paths as the best path, according to the algorithm, and advertises this best path to its BGP peers.

In order to be candidates for multipath, paths to the same destination need to have these characteristics equal to the best-path characteristics:

- Weight
- Local preference
- AS-PATH length
- Origin code
- Multi Exit Discriminator (MED)
- One of these:
  - Neighboring AS or sub-AS (before the addition of the BGP Multipaths)
  - AS-PATH (after the addition of the BGP Multipaths)
Some BGP Multipath features put additional requirements on multipath candidates:

- The path should be learned from an external or confederation-external neighbor (eBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric.

These are the additional requirements for internal BGP (iBGP) multipath candidates:

- The path should be learned from an internal neighbor (iBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric, unless the router is configured for unequal-cost iBGP multipath.

BGP inserts up to \( n \) most recently received paths from multipath candidates into the IP routing table, where \( n \) is the number of routes to install to the routing table, as specified when you configure BGP Multipath. The default value, when multipath is disabled, is 1.

For unequal-cost load balancing, you can also use BGP Link Bandwidth.

---

**Note**

The equivalent next-hop-self is performed on the best path that is selected among eBGP multipaths before it is forwarded to internal peers.

---

**Requirements and Prerequisites for BGP**

**Model Support**

FTD

**Supported Domains**

Any

**User Roles**

Admin

Network Admin

**Guidelines for BGP**

**Firewall Mode Guidelines**

Does not support transparent firewall mode. BGP is supported only in routed mode.

**IPv6 Guidelines**

Supports IPv6. Graceful restart is not supported for IPv6 address family.
Virtual Router Guidelines

BGP IPv4 is supported both on global and user-defined virtual routers. However, only BGP IPv6 configuration is supported on a global virtual router.

Additional Guidelines

- The system does not add route entry for the IP address received over PPPoE in the CP route table. BGP always looks into CP route table for initiating the TCP session, hence BGP does not form TCP session. Thus, BGP over PPPoE is not supported.

- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.

- The BGP table of the member unit is not synchronized with the control unit table. Only its routing table is synchronized with the control unit routing table.

Configure BGP

To configure BGP, see the following topics:

Configure BGP Basic Settings

You can set many basic settings for BGP.

For a device using virtual routing, the basic settings described in this section must be configured in the BGP page under General Settings. For more information, see Modifications to FMC Web Interface - Routing Page, on page 956.
**Procedure**

**Step 1**  Choose **Devices > Device Management**, and edit the FTD device.

**Step 2**  Select **Routing**.

**Step 3**  (For a virtual-router-aware device) Under **General Settings**, click **BGP**.

**Step 4**  Select the **Enable BGP** check box to enable the BGP routing process.

**Step 5**  In the **AS Number** field, enter the autonomous system (AS) number for the BGP process. The AS number internally includes multiple autonomous numbers. The AS number can be from 1 to 4294967295 or from 1.0 to 65535. 65535. The AS number is a uniquely assigned value, that identifies each network on the Internet.

**Step 6**  (Optional) Edit the various BGP settings, starting with **General**. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network. Click **Edit** (pencil) to edit the settings in the group:

a)  In the **Router ID** drop-down list, select Automatic or Manual from the drop-down list. If you choose Automatic, the highest-level IP address on the Firepower Threat Defense device is used as the router ID. To use a fixed router ID, choose Manual and enter an IPv4 address in the **IP Address** field. The default value is Automatic. For a virtual router-aware device, you can override the router ID settings in the **Virtual Routers > BGP** page.

b)  Enter the **Number of AS numbers in AS_PATH attribute**. An AS_PATH attribute is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Valid values are between 1 and 254. The default value is None.

c)  Check the **Log Neighbor Changes** check box to enable logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability. This is enabled by default.

d)  Check the **Use TCP Path MTU Discovery** check box to use the Path MTU determining technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation. This is enabled by default.

e)  Check the **Reset session upon Failover** check box to reset the external BGP session immediately upon link failure. This is enabled by default.

f)  Check the **Enforce that the first AS is peer’s AS for EBGP routes** check box to discard incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH attribute. This prevents a mis-configured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system. This is enabled by default.

g)  Check the **Use dot notation for AS number** check box to split the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 0-65553 are represented as decimal numbers and AS numbers larger than 65535 are represented using the dot notation. This is disabled by default.

h)  Click **OK**.

**Step 7**  (Optional) Edit the **Best Path Selection** section:

a)  Enter a value for **Default Local Preference** between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.

b)  Check the **Allow comparing MED from different neighbors** check box to allow the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. This is disabled by default.

c)  Check the **Compare Router ID for identical EBGP paths** check box to compare similar paths received from external BGP peers during the best path selection process and switch the best path to the route with the lowest router ID. This is disabled by default.
d) Check the **Pick the best MED path among paths advertised from the neighboring AS** check box to enable MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path. This is disabled by default.

e) Check the **Treat missing MED as the least preferred one** check box to consider the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred. This is disabled by default.

f) Click **OK**.

**Step 8** *(Optional) Edit the Neighbor Timers section:*

a) Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message in the **Keepalive interval** field. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.

b) Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Hold time** field. The default value is 180 seconds.

c) (Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Min Hold time** field. Specify a value from 0 to 65535.

d) Click **OK**.

**Step 9** *(Optional) Edit the Graceful Restart section:*

*Note* This section is available only when the Firepower Threat Defense device is in failover or spanned cluster mode. This is done so that there is no drop in packets in the traffic flow, when one of the devices in the failover setup fails.

a) Check the **Enable Graceful Restart** checkbox to enable FTD peers to avoid a routing flap following a switchover.

b) Specify the time duration that FTD peers will wait to delete stale routes before a BGP open message is received in the **Restart Time** field. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.

c) Enter the time duration that the FTD will wait before deleting stale routes after an end of record (EOR) message is received from the restarting FTD in the **Stalepath Time** field. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.

d) Click **OK**.

**Step 10** Click **Save**.

**Step 11** To view the BGP basic settings, from the virtual routers drop-down, select the desired router, and then click **BGP**.

This page displays the basic settings that are configured in the **Settings** page. You can edit the router ID settings on this page.

**Step 12** To edit the router ID settings, modify the IP address in the **IP Address** fields. The modified value overrides the router ID settings that were configured in the **BGP** page under **General Settings**.

**Configure BGP General Settings**

Configure Route maps, Administrative Route Distances, Synchronisation, Next-hop, and packet forwarding. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network.
## Configure BGP General Settings

**Procedure**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>On the <strong>Device Management</strong> page, click <strong>Routing</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>(For a virtual-router-aware device) From the virtual routers drop-down, select the virtual router for which you are configuring BGP.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Choose <strong>BGP &gt; IPv4</strong> or <strong>IPv6</strong>.</td>
</tr>
</tbody>
</table>

**Note** BGP configuration with IPv6 address family is not supported on a user-defined virtual router. Hence, if you select a user-defined virtual router, only **IPv4** settings are available.

| Step 4 | Click **General**. |
| Step 5 | In **General**, update the following sections: |

   a) In the **Settings** section, enter or select a **Route Map** object and enter a **Scanning Interval** for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60. Click **OK**.

   **Note** The **Route Map** field is applicable only to IPv4 settings

   b) In the **Routes and Synchronization** section, update the following as required, and click **OK**:

      - (Optional) **Generate Default Routes** — Select this option to configure default-information originate.

      - (Optional) **Summarize subnet routes into network-level routes** — Select this to configure automatic summarization of subnet routes into network-level routes. This check box is applicable only to IPv4 settings.

      - (Optional) **Advertise inactive routes** — Select this to advertise routes that are not installed in the routing information base (RIB).

      - (Optional) **Synchronise between BGP and IGP system** — Select this to enable synchronization between BGP and your Interior Gateway Protocol (IGP) system. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems.

      - (Optional) **Redistribute IBGP into IGP** — Select this to configure iBGP redistribution into an interior gateway protocol (IGP), such as OSPF.

   c) In the **Administrative Route Distances** section, update the following as required, and click **OK**:

      - **External** — Enter the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.

      - **Internal** — Enter administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.

      - **Local** — Enter administrative distance for local BGP routes. Local routes are those networks listed with a network router show command, often as back doors, for the router or for the networks that is being redistributed from another process. The range of values for this argument are from 1 to 255. The default value is 200.
d) In the **Next Hop** section, optionally select the **Enable address tracking** check box to enable BGP next hop address tracking and enter the **Delay Interval** between checks on updated next-hop routes installed in the routing table. Click **OK**.

**Note**  The **Next Hop** section is applicable only to IPv4 settings.

e) In the **Forward Packets over Multiple Paths** section, update the following as required and click **OK**:

- (Optional) **Number of Paths** — Specify the maximum number of Border Gateway Protocol routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

- (Optional) **IBGP Number of Paths** — Specify the maximum number of parallel internal Border Gateway Protocol (iBGP) routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

**Step 6**  Click **Save**.

---

## Configure BGP Neighbor Settings

A BGP router must connect with each of its peers before exchanging updates. These peers are called BGP neighbors. Use **Neighbor** to define BGP IPv4 or IPv6 neighbors and neighbor settings. If you have enabled virtual router on the device, you can define only BGP IPv4 neighbors for user-defined virtual router. However, for a global virtual router, you can define the BGP IPv6 as well.

### Procedure

**Step 1**  On the Device Management page, click **Routing**.

**Step 2**  (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

**Step 3**  Choose **BGP > IPv4 or IPv6**.

**Note**  BGP configuration with IPv6 address family is not supported on a user-defined virtual router. Hence, if you select a user-defined virtual router, only **IPv4** settings are available.

**Step 4**  Click **Neighbor**.

**Step 5**  Click **Add** to define BGP neighbors and neighbor settings.

**Step 6**  Enter the BGP neighbor **IP address**. This IP address is added to the BGP neighbor table.

**Step 7**  Choose the BGP neighbor **Interface**.

**Note**  The **Interface** field is only applicable to IPv6 settings. For a device using virtual routing, this field appears only for a global virtual router. Also, only the interfaces belonging to the router are listed in the drop-down.

**Step 8**  Enter the autonomous system to which the BGP neighbor belongs, in the **Remote AS** field.

**Step 9**  Select the **Enabled address** check box to enable communication with this BGP neighbor. Further neighbor settings will be configured only if the Enabled address check box is selected.

**Step 10**  (Optional) Select the **Shutdown administratively** check box to disable a neighbor or peer group.
Configure BGP Neighbor Settings

Step 11  (Optional) Select the **Configure graceful restart** check box to enable configuration of the BGP graceful restart capability for this neighbor. After selecting this option, you must use the Graceful Restart (failover / spanned mode) option to specify whether graceful restart should be enabled or disabled for this neighbor.

**Note**  The graceful restart fields are only applicable to IPv4 settings.

Step 12  (Optional) Select the **BFD Fallover** check box to enable configuration of the BFD support for BGP. This selection registers the BGP neighbor to receive forwarding path detection failure messages from BFD.

Step 13  (Optional) Enter a **Description** for the BGP neighbor.

Step 14  (Optional) In **Filtering Routes**, use access lists, route maps, prefix lists and AS path filters as required, to distribute BGP Neighbor information. Update the following sections:

a) Enter or Select the appropriate incoming or outgoing **Access List** to distribute BGP neighbor information.

**Note**  Access Lists are only applicable to IPv4 settings.

b) Enter or Select the appropriate incoming or outgoing **Route Maps** to apply a route map to incoming or outgoing routes.

c) Enter or Select the appropriate incoming or outgoing **Prefix List** to distribute BGP neighbor information.

d) Enter or Select the appropriate incoming or outgoing **AS path filter** to distribute BGP neighbor information.

e) Select the **Limit the number of prefixes allowed from the neighbor** to control the number of prefixes that can be received from a neighbor.

- Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.
- Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.

f) Select the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following

- Select **Terminate peering when prefix limit is exceeded** to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the **Restart interval** field.

- Select **Give only warning message when prefix limit is exceeded** to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.

g) Click **OK**.

Step 15  (Optional) In **Routes**, specify miscellaneous Neighbor route parameter. Proceed to update the following:

a) Enter the minimum interval (in seconds) between the sending of BGP routing updates in the **Advertisment Interval** field. Valid values are between 1 and 600.

b) Select the **Remove private AS numbers from outbound routing updates** to exclude the private AS numbers from being advertised on outbound routes.

c) Select the **Generate default routes** checkbox to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the **Route map** field.

d) To add conditionally advertised routes, click Add Row +. In the Add Advertised Route dialog box, do the following:

1. Add or select a route map in the **Advertise Map** field, that will be advertised if the conditions of the exist map or the non-exist map are met.
2. Select **Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.

3. Select **Non-Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.

4. Click **OK**.

**Step 16** In **Timers**, select the **Set Timers for the BGP Peer** check box to set the keepalive frequency, hold time and minimum hold time

- **Keepalive Interval**—Enter the frequency (in seconds) with which the FTD device sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.

- **Hold time**—Enter the interval (in seconds) after not receiving a keepalive message that the FTD device declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.

- **Min hold time**—(Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that the FTD device declares a peer dead. Valid values are between 0 and 65535. The default value is 0 seconds.

**Step 17** In **Advanced**, update the following:

a) (Optional) Select **Enable Authentication** to enable MD5 authentication on a TCP connection between two BGP peers.

1. Choose an encryption type from the **Enable Encryption** drop-down list.

2. Enter a password in the **Password** field. Reenter the password in the **Confirm** field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The string can contain any alphanumeric characters, including spaces.

   **Note** You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.

b) (Optional) Select the **Send Community attribute to this neighbor** check box to specify that communities attributes should be sent to the BGP neighbor

c) (Optional) Select the **Use FTD as next hop for this neighbor** check box to configure the router as the next-hop for a BGP speaking neighbor or peer group.

d) Select the **Disable Connection Verification** checkbox to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly connected to same network segment, connection verification will prevent the peering session from being established.

e) Select **Allow connections with neighbor that is not directly connected** to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the **TTL hops** field. Valid values are between 1 and 255. Alternately, select **Limited number of TTL hops to neighbor**, to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the **TTL hops** field. Valid values are between 1 and 254.
f) (Optional) Select the Use TCP MTU path discovery check box to enable a TCP transport session for a BGP session.
g) Choose the TCP connection mode from the TCP Transport Mode drop-down list. Options are Default, Active, or Passive.
h) (Optional) Enter a Weight for the BGP neighbor connection.
i) Select the BGP Version that the FTD device will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.

Step 18 Update Migration, only if AS migration is considered.

Note The AS migration customization should be removed after transition has been completed.

a) (Optional) Select the Customize the AS number for routes received from the neighbor check box to customize the AS_PATH attribute for routes received from an eBGP neighbor.
b) Enter the local autonomous system number in the Local AS number field. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.
c) (Optional) Select the Do not prepend local AS number to routes received from neighbor check box to prevent the local AS number from being prepended to any routes received from eBGP peer.
d) (Optional) Select the Replace real AS number with local AS number in routes received from neighbor check box to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.
e) (Optional) Select the Accept either real AS number or local AS number in routes received from neighbor check box to configure the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

Step 19 Click OK.

Step 20 Click Save.

---

**Configure BGP Aggregate Address Settings**

BGP neighbors store and exchange routing information and the amount of routing information increases as more BGP speakers are configured. Route aggregation is the process of combining the attributes of several different routes so that only a single route is advertised. Aggregate prefixes use the classless interdomain routing (CIDR) principle to combine contiguous networks into one classless set of IP addresses that can be summarized in routing tables. As a result fewer routes need to be advertised. Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

**Procedure**

**Step 1** When editing a Firepower Threat Defense device, click Routing.

**Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

**Step 3** Choose BGP > IPv4 or IPv6.

**Note** BGP configuration with IPv6 address family is not supported on a user-defined virtual router. Hence, if you select a user-defined virtual router, only IPv4 settings are available.
Step 4  Click Add Aggregate Address.

Step 5  Enter a value for the aggregate timer (in seconds) in the Aggregate Timer field. Valid values are 0 or any value between 6 and 60. The default value is 30.

Step 6  Click Add and update the Add Aggregate Address dialog:
   a) Network — Enter an IPv4 address or select the desired network/hosts objects.
   b) Attribute Map — (Optional) Enter or select the route map used to set the attribute of the aggregate route.
   c) Advertise Map — (Optional) Enter or select the route map used to select the routes to create AS_SET origin communities.
   d) Suppress Map — (Optional) Enter or select the route map used to select the routes to be suppressed.
   e) Generate AS set path Information — (Optional) Select the check box to enable generation of autonomous system set path information.
   f) Filter all routes from updates — (Optional) Select the check box to filter all more-specific routes from updates.
   g) Click OK.

What to do next
   • For BGPv4 settings, proceed to Configure BGPv4 Filtering Settings, on page 1039
   • For BGPv6 settings, proceed to Configure BGP Network Settings, on page 1040

Configure BGPv4 Filtering Settings

Filtering settings are used to filter routes or networks received in incoming BGP updates. Filtering is used to restrict routing information that the router learns or advertises.

Before you begin

Filtering is only applicable for a BGP IPv4 routing policy.

Procedure

Step 1  On the Device Management page, click Routing.

Step 2  (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3  Choose BGP > IPv4.

Step 4  Click Filtering.

Step 5  Click Add and update the Add Filter dialog:
   a) Access List — Select an access control list that defines which networks are to be received and which are to be suppressed in routing updates.
   b) Direction — (Optional) Select a direction that specifies if the filter should be applied to inbound updates or outbound updates.
   c) Protocol — (Optional) Select the routing process for which you want to filter: None, BGP, Connected, OSPF, RIP, or Static.
   d) Process ID — (Optional) Enter the process ID for the OSPF routing protocol.
Configure BGP Network Settings

Network settings are used to add networks that will be advertised by the BGP routing process and route maps that will be examined to filter the networks to be advertised.

Procedure

Step 1 On the Device Management page, click Routing.
Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
Step 3 Choose BGP > IPv4 or IPv6.

Note BGP configuration with IPv6 address family is not supported on a user-defined virtual router. Hence, if you select a user-defined virtual router, only IPv4 settings are available.

Step 4 Click Networks.
Step 5 Click Add and update the Add Networks dialog:
   a) Network — Enter the network to be advertised by the BGP routing processes.
   b) (Optional) Route Map— Enter or select a route map that should be examined to filter the networks to be advertised. If not specified, all networks are redistributed.
   c) Click OK.

Step 6 Click Save.

Configure BGP Redistribution Settings

Redistribution settings allow you to define the conditions for redistributing routes from another routing domain into BGP.

Procedure

Step 1 On the Device Management page, click Routing.
Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
Step 3 Choose BGP > IPv4 or IPv6.

Note BGP configuration with IPv6 address family is not supported on a user-defined virtual router. Hence, if you select a user-defined virtual router, only IPv4 settings are available.

Step 4 Click Redistribution.
Configure BGP Route Injection Settings

Route Injection settings allow you to define the routes to be conditionally injected into the BGP routing table.

**Procedure**

**Step 1** On the Device Management page, click **Routing**.

**Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

**Step 3** Choose **BGP > IPv4** or **IPv6**.

**Note** BGP configuration with IPv6 address family is not supported on a user-defined virtual router. Hence, if you select a user-defined virtual router, only **IPv4** settings are available.

**Step 4** Click **Route Injection**.

**Step 5** Click **Add** and update the **Add Route Injection** dialog:

a) **Inject Map** — Enter or select the route map that specifies the prefixes to inject into the local BGP routing table.

b) **Exist Map** — Enter or select the route map containing the prefixes that the BGP speaker will track.
c) **Injected routes will inherit the attributes of the aggregate route**— Select this to configure the injected route to inherit attributes of the aggregate route.

d) Click **OK**.

**Step 6** Click **Save**.
RIP for Firepower Threat Defense

This chapter describes how to configure the FTD to route data, perform authentication, and redistribute routing information, using the Routing Information Protocol (RIP). For a device using virtual routing, you can configure RIP only for its global virtual router and not for its user-defined virtual router.

- About RIP, on page 1043
- Requirements and Prerequisites for RIP, on page 1045
- Guidelines for RIP, on page 1045
- Configure RIP, on page 1046

About RIP

The Routing Information Protocol, or RIP, as it is more commonly called, is one of the most enduring of all routing protocols. RIP has four basic components: routing update process, RIP routing metrics, routing stability, and routing timers. Devices that support RIP send routing-update messages at regular intervals and when the network topology changes. These RIP packets include information about the networks that the devices can reach, as well as the number of routers or gateways that a packet must travel through to reach the destination address. RIP generates more traffic than OSPF, but is easier to configure.

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection. When RIP is enabled on an interface, the interface exchanges RIP broadcasts with neighboring devices to dynamically learn about and advertise routes.

The Firepower Threat Defense device supports both RIP Version 1 and RIP Version 2. RIP Version 1 does not send the subnet mask with the routing update. RIP Version 2 sends the subnet mask with the routing update and supports variable-length subnet masks. Additionally, RIP Version 2 supports neighbor authentication when routing updates are exchanged. This authentication ensures that the Firepower Threat Defense device receives reliable routing information from a trusted source.

RIP has advantages over static routes because the initial configuration is simple, and you do not need to update the configuration when the topology changes. The disadvantage to RIP is that there is more network and processing overhead than in static routing.

Routing Update Process

RIP sends routing-update messages at regular intervals and when the network topology changes. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop.
routers maintain only the best route (the route with the lowest metric value) to a destination. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates are sent independently of the regularly scheduled updates that RIP routers send.

**RIP Routing Metric**

RIP uses a single routing metric (hop count) to measure the distance between the source and a destination network. Each hop in a path from source to destination is assigned a hop count value, which is typically 1. When a router receives a routing update that contains a new or changed destination network entry, the router adds 1 to the metric value indicated in the update and enters the network in the routing table. The IP address of the sender is used as the next hop.

**RIP Stability Features**

RIP prevents routing loops from continuing indefinitely by implementing a limit on the number of hops allowed in a path from the source to a destination. The maximum number of hops in a path is 15. If a router receives a routing update that contains a new or changed entry, and if increasing the metric value by 1 causes the metric to be infinity (that is, 16), the network destination is considered unreachable. The downside of this stability feature is that it limits the maximum diameter of a RIP network to less than 16 hops.

RIP includes a number of other stability features that are common to many routing protocols. These features are designed to provide stability despite potentially rapid changes in network topology. For example, RIP implements the split horizon and hold-down mechanisms to prevent incorrect routing information from being propagated.

**RIP Timers**

RIP uses numerous timers to regulate its performance. Following are the timer stages for RIP:

- **Update**—The routing-update timer is the interval between periodic routing updates. This is how often the device sends routing updates. Generally, it is set to 30 seconds, with a small random amount of time added whenever the timer is reset. This is done to help prevent congestion, which could result from all routers simultaneously attempting to update their neighbors.

- **Invalid**—Each routing table entry has a route-timeout timer associated with it. This is the number of seconds since the device received the last valid update. When the route-timeout timer expires, the route is marked invalid but is retained in the table until the route-flush timer expires. Once this timer expires, the route goes into holddown. The default is 180 seconds (3 minutes).

- **Holddown**—The holddown period is the number of seconds the system waits before accepting any new updates for the route that is in holddown (that is, routes that have been marked invalid). The default is 180 seconds (3 minutes).

- **Flush**—The route-flush timer is the number of seconds since the system received the last valid update until the route is discarded and removed from the routing table. The default is 240 seconds (4 minutes).

As an example, when the interface on an adjacent router goes down, the system no longer receives routing updates from the adjacent router. At this time, the Invalid and Flush timers start increasing. In the first 180 seconds, nothing will happen. After 180 seconds, the invalid timer expires, making the route invalid, and the Holddown timer starts and holds the route for another 60 seconds. If there is still no update regarding the interface status on the adjacent router (that is, it is still down), then the route enters into the Flush state where in total the system has waited for 240 seconds from the last update (180 seconds for the Invalid timer and 60 seconds for the Holdown timer).
seconds for Holddown timer), and the system flushes the route. Even if the adjacent routers interface comes up immediately, the system does not accept a routing update until the Holddown timer completes the remaining 120 seconds.

Requirements and Prerequisites for RIP

Model Support
FTD

Supported Domains
Any

User Roles
Admin
Network Admin

Guidelines for RIP

IPv6 Guidelines
Does not support IPv6.

Additional Guidelines
The following information applies to RIP Version 2 only:

• If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.

• With RIP Version 2, the Firepower Threat Defense device transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.

• When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

Limitations

• The Firepower Threat Defense device cannot pass RIP updates between interfaces.

• RIP Version 1 does not support variable-length subnet masks.

• RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.

• RIP convergence is relatively slow compared to other routing protocols.

• You can only enable a single RIP process on the Firepower Threat Defense device.
Configure RIP

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection.

Procedure

Step 1 Choose Devices > Device Management, and edit the FTD device.

Step 2 Select Routing.

Step 3 Select RIP from the table of contents.

Step 4 Select the Enable RIP check box to configure the RIP settings.

Step 5 Select the RIP versions for sending and receiving RIP updates from the RIP Version drop-down list.

Step 6 (Optional) Select the Generate Default Route check box to generate a default route for distribution, based on the route map that you specify.

a) Specify a route map name to use for generating default routes, in the Route Map field. The default route 0.0.0.0/0 is generated for distribution over a certain interface, when the route map, specified in the Route Map field, is present.

Step 7 When Send and Receive Version 2 is the chosen RIP Version, the Enable Auto Summary option is available. When the Enable Auto Summary checkbox is checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.

Note RIP Version 1 always uses automatic summarization—you cannot disable it.

Step 8 Click Networks. Define one or more networks for RIP routing. Enter IP address(es), or enter or select the desired Network/Hosts objects. There is no limit to the number of networks you can add to the security appliance configuration. Any interface that belongs to a network defined by this command, will participate in the RIP routing process. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.

Note RIP only supports IPv4 objects.

Step 9 (Optional) Click Passive Interface. Use this option to specify passive interfaces on the appliance, and by extension the active interfaces. The device listens for RIP routing broadcasts on passive interfaces, using that information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive, receive and send updates.

Step 10 Click Redistribution to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process.

a) Click Add to specify redistribution routes.

b) Select the routing protocol to redistribute into the RIP routing process, in the Protocol drop-down list.

Note For the OSPF protocol, specify a process ID. Similarly, specify an AS path for BGP. When you choose the Connected option in the Protocol drop-down list, you can redistribute, directly connected networks into the RIP routing process.

c) (Optional) If you are redistributing OSPF routes into the RIP routing process, you can select specific types of OSPF routes to redistribute in the Match drop-down list. Ctrl-click to select multiple types:
Configure RIP

- Internal – Routes internal to the autonomous system (AS) are redistributed.
- External 1 – Type 1 routes external to the AS are redistributed.
- External 2 – Type 2 routes external to the AS are redistributed.
- NSSA External 1 – Type 1 routes external to a not-so-stubby area (NSSA) are redistributed.
- NSSA External 2 – Type 2 routes external to an NSSA are redistributed.

**Note** The default is match Internal, External 1, and External 2

d) Select the RIP metric type to apply to the redistributed routes in the **Metric** drop-down list. The two choices are:
   - Transparent – Use the current route metric
   - Specified Value – Assign a specific metric value. Enter a specific value from 0-16, in the **Metric Value** field.
   - None – No metric is specified. Do not use any metric value, to apply to redistributed routes.

e) (Optional) Enter the name of a route map that must be satisfied, in the **Route Map** field before the route can be redistributed into the RIP routing process. Routes are redistributed only if IP address matches an allow statement in the route map address list.

f) Click **OK**.

**Step 11** (Optional) Click **Filtering** to manage filters for the RIP policy. In this section, filters are used to prevent routing updates through an interface, control the advertising of routes in routing updates, control the processing of routing updates and filtering sources of routing updates.

a) Click **Add** to add RIP filters.
b) Select the type of traffic to be filtered - Inbound or Outbound in the **Traffic Direction** field.

**Note** If traffic direction is inbound, you can only define an Interface filter.

c) Specify whether the filter is based on an Interface or a Route, by selecting appropriate in the **Filter On** field. If you select Interface, enter or select the name of the interface on which routing updates are to be filtered. If you select Route, choose the route type:
   - Static – Only static routes are filtered.
   - Connected – Only connected routes are filtered.
   - OSPF – Only OSPFv2 routes discovered by the specified OSPF process are filtered. Enter the Process ID of the OSPF process to be filtered.
   - BGP – Only BGPv4 routes discovered by the specified BGP process are filtered. Enter the AS path of the BGP process to be filtered.

d) In the **Access List** field, enter or select the name of one or more access control lists (ACLs) that define the networks to be allowed or removed from RIP route advertisements.

e) Click **OK**.

**Step 12** (Optional) Click **Broadcast** to add or edit interface configurations. Using Broadcast, you can override the global RIP versions to send or receive per interface. You can also define the authentication parameters per interface if you want to implement authentication to ensure valid RIP updates.
a) Click **Add** to add interface configurations.

b) Enter or select an interface defined on this appliance in the **Interface** field.

c) In the Send option, select the appropriate boxes to specify sending updates using the RIP **Version 1, Version 2**, or both. These options let you override, for the specified interface, the global Send versions specified.

d) In the Receive option, select the appropriate boxes to specify accepting updates using the RIP **Version 1, Version 2**, or both. These options let you override, for the specified interface, the global Receive versions specified.

e) Select the **Authentication** used on this interface for RIP broadcasts.
   • None – No authentication
   • MD5 – Employ MD5
   • Clear Text – Employ clear-text authentication

If you choose MD5 or Clear Text, you must also provide the following authentication parameters.
   • Key ID – The ID of the authentication key. Valid values are from 0 to 255.
   • Key – The key used by the chosen authentication method. Can contain up to 16 characters
   • Confirm – Enter the authentication key again, to confirm

f) Click **OK**.
CHAPTER 42

Multicast Routing for Firepower Threat Defense

This chapter describes how to configure the Firepower Threat Defense device to use the multicast routing protocol. For a device using virtual routing, you can configure RIP only for its global virtual router and not for its user-defined virtual router.

- About Multicast Routing, on page 1049
- Requirements and Prerequisites for Multicast Routing, on page 1053
- Guidelines for Multicast Routing, on page 1053
- Configure IGMP Features, on page 1054
- Configure PIM Features, on page 1058
- Configure Multicast Routes, on page 1065
- Configure Multicast Boundary Filters, on page 1065

About Multicast Routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications that take advantage of multicast routing include videoconferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

Multicast routing protocols deliver source traffic to multiple receivers without adding any additional burden on the source or the receivers while using the least network bandwidth of any competing technology. Multicast packets are replicated in the network by Firepower Threat Defense device enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols, which results in the most efficient delivery of data to multiple receivers possible.

The Firepower Threat Defense device supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single Firepower Threat Defense device.

Note

The UDP and non-UDP transports are both supported for multicast routing. However, the non-UDP transport has no FastPath optimization.
IGMP Protocol

IP hosts use the Internet Group Management Protocol (IGMP) to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range of 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

Note
When you enable multicast routing on the Firepower Threat Defense device, IGMP Version 2 is automatically enabled on all interfaces.

Query Messages to Multicast Groups

The Firepower Threat Defense device sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the Firepower Threat Defense device. If the Firepower Threat Defense device discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packets for that group to the attached network, and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the Firepower Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

Stub Multicast Routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing. When configured for stub multicast routing, the Firepower Threat Defense device acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the Firepower Threat Defense device forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the Firepower Threat Defense device cannot be configured for PIM sparse or bidirectional mode. You must enable PIM on the interfaces participating in IGMP stub multicast routing.

The Firepower Threat Defense device supports both PIM-SM and bidirectional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees rooted at a single Rendezvous Point (RP) per multicast group and optionally creates shortest-path trees per multicast source.
PIM Multicast Routing

Bidirectional PIM is a variant of PIM-SM that builds bidirectional shared trees connecting multicast sources and receivers. Bidirectional trees are built using a Designated Forwarder (DF) election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point (RP), and therefore along the shared tree to receivers, without requiring source-specific state. The DF election takes place during RP discovery and provides a default route to the RP.

Note

If the Firepower Threat Defense device is the PIM RP, use the untranslated outside address of the Firepower Threat Defense device as the RP address.

PIM Source Specific Multicast Support

The Firepower Threat Defense device does not support PIM Source Specific Multicast (SSM) functionality and related configuration. However, the Firepower Threat Defense device allows SSM-related packets to pass through unless it is placed as a last-hop router.

SSM is classified as a data delivery mechanism for one-to-many applications such as IPTV. The SSM model uses a concept of "channels" denoted by an (S,G) pair, where S is a source address and G is an SSM destination address. Subscribing to a channel is achieved by using a group management protocol such as IGMPv3. SSM enables a receiving client, once it has learned about a particular multicast source, to receive multicast streams directly from the source rather than receiving it from a shared Rendezvous Point (RP). Access control mechanisms are introduced within SSM providing a security enhancement not available with current sparse or sparse-dense mode implementations.

PIM-SSM differs from PIM-SM in that it does not use an RP or shared trees. Instead, information on source addresses for a multicast group is provided by the receivers through the local receivership protocol (IGMPv3) and is used to directly build source-specific trees.

Multicast Bidirectional PIM

Multicast bidirectional PIM is useful for networks that have many sources and receivers talking to each other simultaneously and where each participant can become both the source and receiver of multicast traffic, such as in videoconferencing, Webex meetings, and group chat. When PIM bidirectional mode is used, the RP only creates the (*,G) entry for the shared tree. There is no (S,G) entry. This conserves resources on the RP because state tables for each (S,G) entry are not maintained.

In PIM sparse mode, traffic only flows down the shared tree. In PIM bidirectional mode, traffic flows up and down the shared tree.

PIM bidirectional mode also does not use the PIM register/register-stop mechanism to register sources to the RP. Each source can begin sending to the source at any time. When the multicast packets arrive at the RP, they are forwarded down the shared tree (if there are receivers) or dropped (when there are no receivers). However, there is no way for the RP to tell the source to stop sending multicast traffic.

Design-wise you must think about where to place the RP in your network because it should be somewhere in the middle between the sources and receivers in the network.

PIM bidirectional mode has no Reverse Path Forwarding (RPF) check. Instead it uses the concept of a Designated Forwarder (DF) to prevent loops. This DF is the only router on the segment that is allowed to
send multicast traffic to the RP. If there is only one router per segment that forwards multicast traffic, there will be no loops. The DF is chosen using the following mechanism:

- The router with the lowest metric to the RP is the DF.
- If the metric is equal, then the router with the highest IP address becomes the DF.

**PIM Bootstrap Router (BSR)**

PIM Bootstrap Router (BSR) is a dynamic Rendezvous Point (RP) selection model that uses candidate routers for RP function and for relaying the RP information for a group. The RP function includes RP discovery and provides a default route to the RP. It does this by configuring a set of devices as candidate BSRs (C-BSR) which participate in a BSR election process to choose a BSR amongst themselves. Once the BSR is chosen, devices that are configured as candidate Rendezvous Points (C-RP) start sending their group mapping to the elected BSR. The BSR then distributes the group-to-RP mapping information to all the other devices down the multicast tree through BSR messages that travel from PIM router to PIM router on a per-hop basis.

This feature provides a means of dynamically learning RPs, which is very essential in large complex networks where an RP can periodically go down and come up.

**PIM Bootstrap Router (BSR) Terminology**

The following terms are frequently referenced in the PIM BSR configuration:

- **Bootstrap Router (BSR)** — A BSR advertises Rendezvous Point (RP) information to other routers with PIM on a hop-by-hop basis. Among multiple Candidate-BSRs, a single BSR is chosen after an election process. The primary purpose of this Bootstrap router is to collect all Candidate-RP (C-RP) announcements in to a database called the RP-set and to periodically send this out to all other routers in the network as BSR messages (every 60 seconds).

- **Bootstrap Router (BSR) messages** — BSR messages are multicast to the All-PIM-Routers group with a TTL of 1. All PIM neighbors that receive these messages retransmit them (again with a TTL of 1) out of all interfaces except the one in which the messages were received. BSR messages contain the RP-set and the IP address of the currently active BSR. This is how C-RPs know where to unicast their C-RP messages.

- **Candidate Bootstrap Router (C-BSR)** — A device that is configured as a candidate-BSR participates in the BSR election mechanism. A C-BSR with highest priority is elected as the BSR. The highest IP address of the C-BSR is used as a tiebreaker. The BSR election process is preemptive, for example if a new C-BSR with a higher priority comes up, it triggers a new election process.

- **Candidate Rendezvous Point (C-RP)** — An RP acts as a meeting place for sources and receivers of multicast data. A device that is configured as a C-RP periodically advertises the multicast group mapping information directly to the elected BSR through unicast. These messages contain the Group-range, C-RP address, and a hold time. The IP address of the current BSR is learned from the periodic BSR messages that are received by all routers in the network. In this way, the BSR learns about possible RPs that are currently up and reachable.

---

**Note**

The Firepower Threat Defense device does not act as a C-RP, even though the C-RP is a mandatory requirement for BSR traffic. Only routers can act as a C-RP. So, for BSR testing functionality, you must add routers to the topology.
- BSR Election Mechanism — Each C-BSR originates Bootstrap messages (BSMs) that contain a BSR Priority field. Routers within the domain flood the BSMs throughout the domain. A C-BSR that hears about a higher-priority C-BSR than itself suppresses its sending of further BSMs for some period of time. The single remaining C-BSR becomes the elected BSR, and its BSMs inform all the other routers in the domain that it is the elected BSR.

**Multicast Group Concept**

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries—the hosts can be located anywhere on the Internet. Hosts that are interested in receiving data flowing to a particular group must join the group using IGMP. Hosts must be a member of the group to receive the data stream.

**Multicast Addresses**

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

**Clustering**

Multicast routing supports clustering. In Spanned EtherChannel clustering, the control unit sends all multicast routing packets and data packets until fast-path forwarding is established. After fast-path forwarding is established, data units may forward multicast data packets. All data flows are full flows. Stub forwarding flows are also supported. Because only one unit receives multicast packets in Spanned EtherChannel clustering, redirection to the control unit is common.

**Requirements and Prerequisites for Multicast Routing**

**Model Support**

FTD

**Supported Domains**

Any

**User Roles**

Admin

Network Admin

**Guidelines for Multicast Routing**

**Firewall Mode**

Supported only in routed firewall mode. Transparent firewall mode is not supported.
**IPv6**

Does not support IPv6.

**Multicast Group**

The range of addresses between 224.0.0.0 and 224.0.0.255 is reserved for the use of routing protocols and other topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Hence, Internet multicast routing from address range 224.0.0/24 is not supported; IGMP group is not created when enabling multicast routing for the reserved addressess.

**Clustering**

In clustering, for IGMP and PIM, this feature is only supported on the primary unit.

**Additional Guidelines**

- You must configure an access control or prefilter rule on the inbound security zone to allow traffic to the multicast host, such as 224.1.2.3. However, you cannot specify a destination security zone for the rule, or it cannot be applied to multicast connections during initial connection validation.

- You cannot disable an interface with PIM configured on it. If you have configured PIM on the interface (see Configure PIM Protocol, on page 1059), disabling the multicast routing and PIM does not remove the PIM configuration. You must remove (delete) the PIM configuration to disable the interface.

- PIM/IGMP Multicast routing is not supported on interfaces in a traffic zone.

- Do not configure FTD to simultaneously be a Rendezvous Point (RP) and a First Hop Router.

---

**Configure IGMP Features**

IP hosts use IGMP to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

This section describes how to configure optional IGMP settings on a per-interface basis.

**Procedure**

<tr>
<td>Step 5</td>
<td>Configure IGMP Join Groups, on page 1058.</td>
</tr>
</tbody>
</table>
Enable Multicast Routing

Enabling multicast routing on the Firepower Threat Defense device, enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

Note

Only the UDP transport layer is supported for multicast routing.

The following list shows the maximum number of entries for specific multicast tables. Once these limits are reached, any new entries are discarded.

- MFIB—30,000
- IGMP Groups—30,000
- PIM Routes—72,000

Procedure

Step 1
Choose Devices > Device Management, and edit the FTD device.

Step 2
Choose Routing > Multicast Routing > IGMP.

Step 3
Check the Enable Multicast Routing check box.

Checking this check box enables IP multicast routing on the Firepower Threat Defense device. Unchecking this check box disables IP multicast routing. By default, multicast is disabled. Enabling multicast routing enables multicast on all interfaces.

You can disable multicast on a per-interface basis. This is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the Firepower Threat Defense device from sending host query messages on that interface.

Configure IGMP Protocol

You can configure IGMP parameters per interface, such as the forward interface, query messages, and time intervals.

Procedure

Step 1
Choose Devices > Device Management, and edit the FTD device.

Step 2
Choose Routing > Multicast Routing > IGMP.

Step 3
On Protocol, click Add or Edit.

Use the Add IGMP parameters dialog box to add new IGMP parameters to the Firepower Threat Defense device. Use the Edit IGMP parameters dialog box to change existing parameters.
**Step 4** Configure the following options:

- **Interface**—From the drop-down list, select the interface for which you want to configure IGMP protocol.

- **Enable IGMP**—Check the check box to enable IGMP.

  **Note** Disabling IGMP on specific interfaces is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the Firepower Threat Defense device from sending host query messages on that interface.

- **Forward Interface**—From the drop-down list, select the specific interface from which you want to forward IGMP messages.

  This configures the Firepower Threat Defense device to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another interface.

- **Version**—Choose IGMP Version 1 or 2.

  By default, the Firepower Threat Defense device runs IGMP Version 2, which enables several additional features.

  **Note** All multicast routers on a subnet must support the same version of IGMP. The Firepower Threat Defense device does not automatically detect Version 1 routers and switch to Version 1. However, you can have a mix of IGMP Version 1 and 2 hosts on the subnet; the Firepower Threat Defense device running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

- **Query Interval**—The interval in seconds at which the designated router sends IGMP host-query messages. The range is 1 to 3600. The default is 125.

  **Note** If the Firepower Threat Defense device does not hear a query message on an interface for the specified timeout value, then the Firepower Threat Defense device becomes the designated router and starts sending the query messages.

- **Response Time**—The interval in seconds before the Firepower Threat Defense device deletes the group. The range is 1 to 25. The default is 10.

  If the Firepower Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

- **Group Limit**—The maximum number of hosts that can join on an interface. The range is 1 to 500. The default is 500.

  You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports exceeding the configured limits are not entered in the IGMP cache, and traffic for the excess membership reports is not forwarded.

- **Query Timeout**—The period of time in seconds before which the Firepower Threat Defense device takes over as the requester for the interface after the previous requester has stopped. The range is 60 to 300. The default is 255.

**Step 5** Click OK to save the IGMP protocol configuration.
Configure IGMP Access Groups

You can control access to multicast groups by using access control lists.

Procedure

**Step 1** Choose Devices > Device Management, and edit the FTD device.

**Step 2** Choose Routing > Multicast Routing > Access Group.

**Step 3** On Access Group, click Add or Edit.

Use the Add IGMP Access Group parameters dialog box to add new IGMP access groups to the Access Group table. Use the Edit IGMP Access Group parameters dialog box to change existing parameters.

**Step 4** Configure the following options:

a) From the Interface drop-down list, select the interface with which the access group is associated. You cannot change the associated interface when you are editing an existing access group.

b) Click one of the following:

- **Standard Access List**— From the Standard Access List drop-down list, select the standard ACL or click Add (➕) to create a new standard ACL. See Configure Standard ACL Objects, on page 636 for the procedure.

- **Extended Access List**— From the Extended Access List drop-down list, select the extended ACL or click Add (➕) to create a new extended ACL. See Configure Extended ACL Objects, on page 635 for the procedure.

**Step 5** Click OK to save the access group configuration.

Configure IGMP Static Groups

Sometimes a group member cannot report its membership in the group or there may be no members of a group on the network segment, but you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group. With this method, the Firepower Threat Defense device does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but this interface is not a member of the multicast group.

Procedure

**Step 1** Choose Devices > Device Management, and edit the FTD device.

**Step 2** Choose Routing > Multicast Routing > IGMP.

**Step 3** On Static Group, click Add or Edit.

Use the Add IGMP Static Group parameters dialog box to statically assign a multicast group to an interface. Use the Edit IGMP Static Group parameters dialog box to change existing static group assignments.
Configure IGMP Join Groups

You can configure an interface to be a member of a multicast group. Configuring the Firepower Threat Defense device to join a multicast group causes upstream routers to maintain multicast routing table information for that group and keep the paths for that group active.

Procedure

Step 1
Choose Devices > Device Management, and edit the FTD device.

Step 2
Choose Routing > Multicast Routing > IGMP.

Step 3
On Join Group, click Add or Edit.

Use the Add IGMP Join Group parameters dialog box to configure the Firepower Threat Defense device to be a member of a multicast group. Use the Edit IGMP Join Group parameters dialog box to change existing parameters.

Step 4
Configure the following options:

- From the Interface drop-down list, select the interface you want to be a member of a multicast group. If you are editing an existing entry, you cannot change the value.

- From the Join Group drop-down list, select the multicast group to which you want to assign the interface, or click Plus to create a new multicast group. See Creating Network Objects for the procedure.

Configure PIM Features

Routers use PIM to maintain forwarding tables to use for forwarding multicast diagrams. When you enable multicast routing on the Firepower Threat Defense device, PIM and IGMP are automatically enabled on all interfaces.
Note

PIM is not supported with PAT. The PIM protocol does not use ports, and PAT only works with protocols that use ports.

This section describes how to configure optional PIM settings.

Procedure

<table>

</tr>
</tbody>
</table>

**Configure PIM Protocol**

You can enable or disable PIM on a specific interface.

You can also configure the Designated Router (DR) priority. The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, choosing the DR is based on the DR priority. If multiple devices have the same DR priority, then the device with the highest IP address becomes the DR. By default, the Firepower Threat Defense device has a DR priority of 1.

Router query messages are used to choose the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the Firepower Threat Defense device sends PIM join or prune messages.

**Procedure**

**Step 1** Choose Devices > Device Management, and edit the FTD device.
**Step 2** Choose Routing > Multicast Routing > PIM.
**Step 3** On Protocol, click Add or Edit.

Use the Add PIM parameters dialog box to add new PIM parameters to the interface. Use the Edit PIM parameters dialog box to change existing parameters.

**Step 4** Configure the following options:
- **Interface**—From the drop-down list, select the interface for which you want to configure PIM protocol.
- **Enable PIM**—Check the check box to enable PIM.
• **DR Priority**—The value for the DR for the selected interface. The router with the highest DR priority on the subnet becomes the designated router. Valid values range from 0 to 4294967294. The default DR priority is 1. Setting this value to 0 makes the Firepower Threat Defense device interface ineligible to become the default router.

• **Hello Interval**—The interval in seconds at which the interface sends PIM hello messages. The range is 1 to 3600. The default is 30.

• **Join Prune Interval**—The interval in seconds at which the interface sends PIM join and prune advertisements. The range is 10 to 600. The default is 60.

**Step 5** Click **OK** to save the PIM protocol configuration.

### Configure PIM Neighbor Filters

You can define the routers that can become PIM neighbors. By filtering the routers that can become PIM neighbors, you can do the following:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

**Procedure**

**Step 1** Choose **Devices** > **Device Management**, and edit the FTD device.

**Step 2** Choose **Routing** > **Multicast Routing** > **PIM**.

**Step 3** On **Neighbor Filter**, click **Add** or **Edit**.

Use the **Add PIM Neighbor Filter** dialog box to add new PIM neighbor filters to the interface. Use the **Edit PIM Neighbor Filter** dialog box to change existing parameters.

**Step 4** Configure the following options:

- From the **Interface** drop-down list, select the interface to which you want to add a PIM neighbor filter.

- **Standard Access List**—From the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. See **Configure Standard ACL Objects**, on page 636 for the procedure.

**Note** Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the multicast group advertisements pass through the interface. Choosing **Block** prevents the specified multicast group advertisements from passing through the interface. When a multicast boundary is configured on an interface, all multicast traffic is prevented from passing through the interface unless permitted with a neighbor filter entry.

**Step 5** Click **OK** to save the PIM neighbor filter configuration.
Configure PIM Bidirectional Neighbor Filters

A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the Designated Forwarder (DF) election. If a PIM bidirectional neighbor filter is not configured for an interface, there are no restrictions. If a PIM bidirectional neighbor filter is configured, only those neighbors permitted by the ACL can participate in the DF election process.

Bidirectional PIM allows multicast routers to keep reduced state information. All of the multicast routers in a segment must be bidirectionally enabled to elect a DF.

When a PIM bidirectional neighbor filter is enabled, the routers that are permitted by the ACL are considered to be bidirectionally capable. Therefore, the following is true:

• If a permitted neighbor does not support bidirectional mode, then the DF election does not occur.
• If a denied neighbor supports bidirectional mode, then the DF election does not occur.
• If a denied neighbor does not support bidirectional mode, the DF election can occur.

Procedure

Step 1 Choose Devices > Device Management, and edit the FTD device.
Step 2 Choose Multicast Routing > PIM.
Step 3 On Bidirectional Neighbor Filter, click Add or Edit.

Use the Add PIM Bidirectional Neighbor Filter dialog box to create ACL entries for the PIM bidirectional neighbor filter ACL. Use the Edit PIM Bidirectional Neighbor Filter dialog box to change existing parameters.

Step 4 Configure the following options:

• From the Interface drop-down list, select the interface to which you want to configure the PIM bidirectional neighbor filter ACL entry.

• Standard Access List—From the Standard Access List drop-down list, select a standard ACL or click Add (†) to create a new standard ACL. See Configure Standard ACL Objects, on page 636 for the procedure.

Note Choosing Allow on the Add Standard Access List Entry dialog box lets the specified devices participate in the DR election process. Choosing Block prevents the specified devices from participating in the DR election process.

Step 5 Click OK to save the PIM bidirectional neighbor filter configuration.

Configure PIM Rendezvous Points

You can configure the Firepower Threat Defense device to serve as a RP to more than one group. The group range specified in the ACL determines the PIM RP group mapping. If an ACL is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4). See Multicast Bidirectional PIM, on page 1051 for more information about bidirectional PIM.
The following restrictions apply to RPs:

- You cannot use the same RP address twice.
- You cannot specify All Groups for more than one RP.

**Procedure**

**Step 1** Choose Devices > Device Management, and edit the FTD device.

**Step 2** Choose Routing > Multicast Routing > PIM.

**Step 3** On Rendezvous Points, click Add or Edit.

Use the Add Rendezvous Point dialog box to create a new entry to the Rendezvous Point table. Use the Edit Rendezvous Point dialog box to change existing parameters.

**Step 4** Configure the following options:

- From the Rendezvous Point IP address drop-down list, select the IP address that you want to add as an RP or click Add (➕) to create a new network object. See Creating Network Objects for the procedure.
- Check the Use bi-directional forwarding check box if the specified multicast groups are to operate in bidirectional mode. In bidirectional mode, if the Firepower Threat Defense device receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a prune message back to the source.
- Choose Use this RP for all Multicast Groups to use the specified RP for all multicast groups on the interface.
- Choose the Use this RP for all Multicast Groups as specified below to designate the multicast groups to use with the specified RP and then from the Standard Access List drop-down list, choose a standard ACL or click Add (➕) to create a new standard ACL. See Configure Standard ACL Objects, on page 636 for the procedure.

**Step 5** Click OK to save the rendezvous point configuration.

**Configure PIM Route Trees**

By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This method reduces delay, but requires more memory than the shared tree. You can configure whether or not the Firepower Threat Defense device should join the shortest-path tree or use the shared tree, either for all multicast groups or only for specific multicast addresses.

The shortest-path tree is used for any group that is not specified in the Multicast Groups table. The Multicast Groups table displays the multicast groups to use with the shared tree. The table entries are processed from the top down. You can create an entry that includes a range of multicast groups, but excludes specific groups within that range by placing deny rules for the specific groups at the top of the table and the permit rule for the range of multicast groups below the deny statements.
This behavior is known as Shortest Path Switchover (SPT). We recommend that you always use the Shared Tree option.

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Choose Devices &gt; Device Management, and edit the FTD device.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Choose Routing &gt; Multicast Routing &gt; PIM.</td>
</tr>
<tr>
<td>Step 3</td>
<td>On Route Tree, select the path for the route tree:</td>
</tr>
<tr>
<td></td>
<td>• Click Shortest Path to use the shortest-path tree for all multicast groups.</td>
</tr>
<tr>
<td></td>
<td>• Click Shared Tree to use the shared tree for all multicast groups.</td>
</tr>
<tr>
<td></td>
<td>• Click Shared tree for below mentioned group to designate the groups specified in the Multicast Groups table, and then from the Standard Access List drop-down list, select a standard ACL or click Add to create a new standard ACL. See Configure Standard ACL Objects, on page 636 for the procedure.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Click OK to save the route tree configuration.</td>
</tr>
</tbody>
</table>

### Configure PIM Request Filters

When the Firepower Threat Defense device is acting as an RP, you can restrict specific multicast sources from registering with it to prevent unauthorized sources from registering with the RP. You can define the multicast sources from which the Firepower Threat Defense device will accept PIM register messages.

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Choose Devices &gt; Device Management, and edit the FTD device.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Choose Routing &gt; Multicast Routing &gt; PIM.</td>
</tr>
<tr>
<td>Step 3</td>
<td>On Request Filter, define the multicast sources that are allowed to register with the Firepower Threat Defense device when it acts as an RP:</td>
</tr>
<tr>
<td></td>
<td>• From the Filter PIM register messages using: drop-down list select None, Access List, or Route Map.</td>
</tr>
<tr>
<td></td>
<td>• If you choose Access List from the drop-down list, select an extended ACL or click Add to create a new extended ACL. See Configure Extended ACL Objects, on page 635 for the procedure.</td>
</tr>
</tbody>
</table>

**Note**  
In the Add Extended Access List Entry dialog box, select Allow from the drop-down list to create a rule that allows the specified source of the specified multicast traffic to register with the Firepower Threat Defense device, or select Block to create a rule that prevents the specified source of the specified multicast traffic from registering with the Firepower Threat Defense device.
• If you choose Route Map, select a route map from the Route Map drop-down list, or click Add (++) to create a new route map. See Creating Network Objects for the procedure.

Step 4  Click OK to save the request filter configuration.

---

Configure the Firepower Threat Defense Device as a Candidate Bootstrap Router

You can configure the Firepower Threat Defense device as a candidate BSR.

Procedure

Step 1  Choose Devices > Device Management, and edit the FTD device.

Step 2  Choose Routing > Multicast Routing > PIM.

Step 3  On Bootstrap Router, check the Configure this FTD as a Candidate Bootstrap Router (C-BSR) check box to perform the C-BSR setup.

a) From the Interface drop-down list, select the interface on the Firepower Threat Defense device from which the BSR address is derived to make it a candidate.

This interface must be enabled with PIM.

b) In the Hash mask length field, enter the length of a mask (32 bits maximum) that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash (correspond) to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This fact allows you to get one RP for multiple groups. The range is 0 to 32.

c) In the Priority field, enter the priority of the candidate BSR. The BSR with the larger priority is preferred. If the priority values are the same, the router with the larger IP address is the BSR. The range is 0 to 255. The default value is 0.

Step 4  (Optional) Click Add (++) to select an interface on which no PIM BSR messages will be sent or received in the Configure this FTD as a Border Bootstrap Router (BSR) section.

• From the Interface drop-down list, select the interface on which no PIM BSR messages will be sent or received.

RP or BSR advertisements are filtered effectively isolating two domains of RP information exchange.

• Check the Enable Border BSR check box to enable BSR.

Step 5  Click OK to save the bootstrap router configuration.
Configure Multicast Routes

Configuring static multicast routes lets you separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the Firepower Threat Defense device expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

Procedure

Step 1  Choose Devices > Device Management, and edit the FTD device.
Step 2  Choose Routing > Multicast Routing > Multicast Routes > Add or Edit.

Use the Add Multicast Route Configuration dialog box to add a new multicast route to the Firepower Threat Defense device. Use the Edit Multicast Route Configuration dialog box to change an existing multicast route.

Step 3  From the Source Network drop-down box, select an existing network or click Add to add a new one. See Creating Network Objects for the procedure.
Step 4  To configure an interface to forward the route, click Interface and configure the following options:

- From the Source Interface drop-down list, select the incoming interface for the multicast route.
- From the Output Interface/Dense drop-down list, select the destination interface that the route is forwarded through.
- In the Distance field, enter the distance of the multicast route. The range is 0 to 255.

Step 5  To configure an RPF address to forward the route, click Address and configure the following options:

- In the RPF Address field, enter the IP address for the multicast route.
- In the Distance field, enter the distance of the multicast route. The range is 0 to 255.

Step 6  Click OK to save the multicast routes configuration.

Configure Multicast Boundary Filters

Address scoping defines domain boundary filters so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary filter on an interface for multicast group addresses. IANA has designated the multicast address range from 239.0.0.0 to 239.255.255.255 as the administratively scoped
addresses. This range of addresses can be reused in domains administered by different organizations. The addresses would be considered local, not globally unique.

A standard ACL defines the range of affected addresses. When a boundary filter is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary filter allows the same multicast group address to be reused in different administrative domains.

You can configure, examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL are removed. An Auto-RP group range announcement is permitted and passed by the boundary filter only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

Procedure

**Step 1** Choose **Devices > Device Management**, and edit the FTD device.

**Step 2** Choose **Routing > Multicast Routing > Multicast Boundary Filter**, and then click **Add** or **Edit**.

Use the **Add Multicast Boundary Filter** dialog box to add new multicast boundary filters to the Firepower Threat Defense device. Use the **Edit Multicast Boundary Filter** dialog box to change existing parameters.

You can configure a multicast boundary for administratively scoped multicast addresses. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains. When a multicast boundary is defined on an interface, only the multicast traffic permitted by the filter ACL passes through the interface.

**Step 3** From the **Interface** drop-down list, choose the interface for which you are configuring the multicast boundary filter ACL.

**Step 4** From the **Standard Access List** drop-down list, choose the standard ACL you want to use, or click **Add** (+) to create a new standard ACL. See **Configure Standard ACL Objects**, on page 636 for the procedure.

**Step 5** Check the **Remove any Auto-RP group range announcement from the Auto-RP packets that are denied by the boundary** check box to filter Auto-RP messages from sources denied by the boundary ACL. If this check box is not checked, all Auto-RP messages are passed.

**Step 6** Click **OK** to save the multicast boundary filter configuration.
PART X

Firepower Threat Defense VPN

• VPN Overview for Firepower Threat Defense, on page 1069
• Site-to-Site VPNs for Firepower Threat Defense, on page 1081
• Remote Access VPNs for Firepower Threat Defense, on page 1101

VPN Overview for Firepower Threat Defense

A virtual private network (VPN) connection establishes a secure tunnel between endpoints over a public network such as the Internet.

This chapter applies to Remote Access and Site-to-site VPNS on Firepower Threat Defense devices. It describes the Internet Protocol Security (IPsec), the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and SSL standards that are used to build site-to-site and remote access VPNS.

- VPN Types, on page 1069
- VPN Basics, on page 1070
- VPN Packet Flow, on page 1072
- VPN Licensing, on page 1072
- How Secure Should a VPN Connection Be?, on page 1072
- Removed or Deprecated Hash Algorithms, Encryption Algorithms, and Diffie-Hellman Modulus Groups, on page 1077
- VPN Topology Options, on page 1077

VPN Types

The Firepower Management Center supports the following types of VPN connections:

  Remote access VPNS are secure, encrypted connections, or tunnels, between remote users and your company’s private network. The connection consists of a VPN endpoint device, which is a workstation or mobile device with VPN client capabilities, and a VPN headend device, or secure gateway, at the edge of the corporate private network.

  Firepower Threat Defense devices can be configured to support Remote Access VPNS over SSL or IPsec IKEv2 by the Firepower Management Center. Functioning as secure gateways in this capacity, they authenticate remote users, authorize access, and encrypt data to provide secure connections to your network. No other types of appliances, managed by the Firepower Management Center, support Remote Access VPN connections.

  Firepower Threat Defense secure gateways support the AnyConnect Secure Mobility Client full tunnel client. This client is required to provide secure SSL IPsec IKEv2 connections for remote users. This client gives remote users the benefits of a client without the need for network administrators to install and configure clients on remote computers since it can be deployed to the client platform upon connectivity. It is the only client supported on endpoint devices.
Site-to-site VPNs on Firepower Threat Defense devices.

A site-to-site VPN connects networks in different geographic locations. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers that comply with all relevant standards. These peers can have any mix of inside and outside IPv4 and IPv6 addresses. Site-to-site tunnels are built using the Internet Protocol Security (IPsec) protocol suite and IKEv1 or IKEv2. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel.

VPN Basics

Tunneling makes it possible to use a public TCP/IP network, such as the Internet, to create secure connections between remote users and private corporate networks. Each secure connection is called a tunnel.

IPsec-based VPN technologies use the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and IPsec tunneling standards to build and manage tunnels. ISAKMP and IPsec accomplish the following:

- Negotiate tunnel parameters.
- Establish tunnels.
- Authenticate users and data.
- Manage security keys.
- Encrypt and decrypt data.
- Manage data transfer across the tunnel.
- Manage data transfer inbound and outbound as a tunnel endpoint or router.

A device in a VPN functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.

After the site-to-site VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. A connection consists of the IP addresses and hostnames of the two gateways, the subnets behind them, and the method the two gateways use to authenticate to each other.

Internet Key Exchange (IKE)

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and to automatically establish IPsec security associations (SAs).

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection.

An IKE policy is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters protect subsequent IKE negotiations. For IKE version 1 (IKEv1), IKE policies contain a single
set of algorithms and a modulus group. Unlike IKEv1, in an IKEv2 policy, you can select multiple algorithms and modulus groups from which peers can choose during the Phase 1 negotiation. It is possible to create a single IKE policy, although you might want different policies to give higher priority to your most desired options. For site-to-site VPNs, you can create a single IKE policy.

To define an IKE policy, specify:

- A unique priority (1 to 65,543, with 1 the highest priority).
- An encryption method for the IKE negotiation, to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method (called integrity algorithm in IKEv2) to ensure the identity of the sender, and to ensure that the message has not been modified in transit.
- For IKEv2, a separate pseudorandom function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The options are the same as those used for the hash algorithm.
- A Diffie-Hellman group to determine the strength of the encryption-key-determination algorithm. The device uses this algorithm to derive the encryption and hash keys.
- An authentication method, to ensure the identity of the peers.
- A limit to the time the device uses an encryption key before replacing it.

When IKE negotiation begins, the peer that starts the negotiation sends all of its policies to the remote peer, and the remote peer searches for a match with its own policies, in priority order. A match between IKE policies exists if they have the same encryption, hash (integrity and PRF for IKEv2), authentication, and Diffie-Hellman values, and an SA lifetime less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter lifetime—from the remote peer policy—Applies. By default, the Firepower Management Center deploys an IKEv1 policy at the lowest priority for all VPN endpoints to ensure a successful negotiation.

**IPsec**

IPsec is one of the most secure methods for setting up a VPN. IPsec provides data encryption at the IP packet level, offering a robust security solution that is standards-based. With IPsec, data is transmitted over a public network through tunnels. A tunnel is a secure, logical communication path between two peers. Traffic that enters an IPsec tunnel is secured by a combination of security protocols and algorithms.

An IPsec Proposal policy defines the settings required for IPsec tunnels. An IPsec proposal is a collection of one or more crypto-maps that are applied to the VPN interfaces on the devices. A crypto map combines all the components required to set up IPsec security associations, including:

- A proposal (or transform set) is a combination of security protocols and algorithms that secure traffic in an IPsec tunnel. During the IPsec security association (SA) negotiation, peers search for a proposal that is the same at both peers. When it is found, it is applied to create an SA that protects data flows in the access list for that crypto map, protecting the traffic in the VPN. There are separate IPsec proposals for IKEv1 and IKEv2. In IKEv1 proposals (or transform sets), for each parameter, you set one value. For IKEv2 proposals, you can configure multiple encryption and integration algorithms for a single proposal.

- A crypto map, combines all components required to set up IPsec security associations (SA), including IPsec rules, proposals, remote peers, and other parameters that are necessary to define an IPsec SA. When two peers try to establish an SA, they must each have at least one compatible crypto map entry.

Dynamic crypto map policies are used in site-to-site VPNs when an unknown remote peer tries to start an IPsec security association with the local hub. The hub cannot be the initiator of the security association.
negotiation. Dynamic crypto-policies allow remote peers to exchange IPsec traffic with a local hub even if the hub does not know the remote peer’s identity. A dynamic crypto map policy essentially creates a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer’s requirements.

Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply dynamic crypto map policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. Note that in a full mesh VPN topology, you can apply only static crypto map policies.

Note
Simultaneous IKEv2 dynamic crypto map is not supported for the same interface for both remote access and site-to-site VPNs on Firepower Threat Defense (FTD).

VPN Packet Flow

On a FTD device, by default no traffic is allowed to pass through access-control without explicit permission. VPN tunnel traffic as well, is not relayed to the endpoints until it has passed through Snort. Incoming tunnel packets are decrypted before being sent to the Snort process. Snort processes outgoing packets before encryption.

Access Control identifying the protected networks for each endpoint node of a VPN tunnel determines which traffic is allowed to pass through the FTD device and reach the endpoints. For Remote Access VPN traffic, a Group Policy filter or an Access Control rule must be configured to permit VPN traffic flow.

In addition, the system does not send tunnel traffic to the public source when the tunnel is down.

VPN Licensing

There is no specific licensing for enabling Firepower Threat Defense VPN, it is available by default.

The Firepower Management Center determines whether to allow or block the usage of strong crypto on a Firepower Threat Defense device based on attributes provided by the smart licensing server.

This is controlled by whether you selected the option to allow export-controlled functionality on the device when you registered with Cisco Smart License Manager. If you are using the evaluation license, or you did not enable export-controlled functionality, you cannot use strong encryption.

If you have created your VPN configurations with evaluation license, and upgrade your license from evaluation to smart license with export-controlled functionality, check and update your encryption algorithms for stronger encryption and for the VPNs to work properly. DES based encryptions are no longer supported.

How Secure Should a VPN Connection Be?

Because a VPN tunnel typically traverses a public network, most likely the Internet, you need to encrypt the connection to protect the traffic. You define the encryption and other security techniques to apply using IKE polices and IPsec proposals.

If your device license allows you to apply strong encryption, there is a wide range of encryption and hash algorithms, and Diffie-Hellman groups, from which to choose. However, as a general rule, the stronger the
encryption that you apply to the tunnel, the worse the system performance. Find a balance between security and performance that provides sufficient protection without compromising efficiency.

We cannot provide specific guidance on which options to choose. If you operate within a larger corporation or other organization, there might already be defined standards that you need to meet. If not, take the time to research the options.

The following topics explain the available options.

**Complying with Security Certification Requirements**

Many VPN settings have options that allow you to comply with various security certification standards. Review your certification requirements and the available options to plan your VPN configuration. See Security Certifications Compliance, on page 1391 for additional system information related to compliance.

**Deciding Which Encryption Algorithm to Use**

When deciding which encryption algorithms to use for the IKE policy or IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN.

For IKEv2, you can configure multiple encryption algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

For IPsec proposals, the algorithm is used by the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and anti-replay services. ESP is IP protocol type 50. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-.

If your device license qualifies for strong encryption, you can choose from the following encryption algorithms. If you are not qualified for strong encryption, you can select DES only.

- **AES-GCM**—(IKEv2 only.) Advanced Encryption Standard in Galois/Counter Mode is a block cipher mode of operation providing confidentiality and data-origin authentication, and provides greater security than AES. AES-GCM offers three different key strengths: 128-, 192-, and 256-bit keys. A longer key provides higher security but a reduction in performance. GCM is a mode of AES that is required to support NSA Suite B. NSA Suite B is a set of cryptographic algorithms that devices must support to meet federal standards for cryptographic strength.

- **AES**—Advanced Encryption Standard is a symmetric cipher algorithm that provides greater security than DES and is computationally more efficient than 3DES. AES offers three different key strengths: 128-, 192-, and 256-bit keys. A longer key provides higher security but a reduction in performance.

- **DES**—Data Encryption Standard, which encrypts using 56-bit keys, is a symmetric secret-key block algorithm. If your license account does not meet the requirements for export controls, this is your only option.
Deciding Which Hash Algorithms to Use

In IKE policies, the hash algorithm creates a message digest, which is used to ensure message integrity. In IKEv2, the hash algorithm is separated into two options, one for the integrity algorithm, and one for the pseudo-random function (PRF).

In IPSec proposals, the hash algorithm is used by the Encapsulating Security Protocol (ESP) for authentication. In IKEv2 IPSec Proposals, this is called the integrity hash. In IKEv1 IPSec proposals, the algorithm name is prefixed with ESP-, and there is also an -HMAC suffix (which stands for “hash method authentication code”).

For IKEv2, you can configure multiple hash algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

You can choose from the following hash algorithms.

- **SHA (Secure Hash Algorithm)**—Standard SHA (SHA1) produces a 160-bit digest.
  
  The following SHA-2 options, which are even more secure, are available for IKEv2 configurations. Choose one of these if you want to implement the NSA Suite B cryptography specification.
  
  - SHA256—Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
  - SHA384—Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
  - SHA512—Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

- **Null or None (NULL, ESP-NONE)**—(IPSec Proposals only.) A null Hash Algorithm; this is typically used for testing purposes only. However, you should choose the null integrity algorithm if you select one of the AES-GCM options as the encryption algorithm. Even if you choose a non-null option, the integrity hash is ignored for these encryption standards.

Deciding Which Diffie-Hellman Modulus Group to Use

You can use the following Diffie-Hellman key derivation algorithms to generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus provides higher security, but requires more processing time. You must have a matching modulus group on both peers.

If you select AES encryption, to support the large key sizes required by AES, you should use Diffie-Hellman (DH) Group 5 or higher. IKEv1 policies do not support all of the groups listed below.

To implement the NSA Suite B cryptography specification, use IKEv2 and select one of the elliptic curve Diffie-Hellman (ECDH) options: 19, 20, or 21. Elliptic curve options and groups that use 2048-bit modulus are less exposed to attacks such as Logjam.

For IKEv2, you can configure multiple groups. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

- **14**—Diffie-Hellman Group 14: 2048-bit modular exponential (MODP) group. Considered good protection for 192-bit keys.
• 15—Diffie-Hellman Group 15: 3072-bit MODP group.
• 16—Diffie-Hellman Group 16: 4096-bit MODP group.
• 19—Diffie-Hellman Group 19: National Institute of Standards and Technology (NIST) 256-bit elliptic curve modulo a prime (ECP) group.
• 20—Diffie-Hellman Group 20: NIST 384-bit ECP group.

Deciding Which Authentication Method to Use

Preshared keys and digital certificates are the methods of authentication available for VPNs. Site-to-site, IKEv1 and IKEv2 VPN connections can use both options.

Remote Access, which uses SSL and IPsec IKEv2 only, supports digital certificate authentication only.

Preshared keys allow for a secret key to be shared between two peers and used by IKE during the authentication phase. The same shared key must be configured at each peer or the IKE SA cannot be established.

Digital certificates use RSA key pairs to sign and encrypt IKE key management messages. Certificates provide non-repudiation of communication between two peers, meaning that it can be proved that the communication actually took place. When using this authentication method, you need a Public Key Infrastructure (PKI) defined where peers can obtain digital certificates from a Certification Authority (CA). CAs manage certificate requests and issue certificates to participating network devices providing centralized key management for all of the participating devices.

Preshared keys do not scale well, using a CA improves the manageability and scalability of your IPsec network. With a CA, you do not need to configure keys between all encrypting devices. Instead, each participating device is registered with the CA, and requests a certificate from the CA. Each device that has its own certificate and the public key of the CA can authenticate every other device within a given CA’s domain.

Pre-shared Keys

Preshared keys allow for a secret key to be shared between two peers. The key is used by IKE in the authentication phase. The same shared key must be configured on each peer, or the IKE SA cannot be established.

To configure the pre-shared keys, choose whether you will use a manual or automatically generated key, and then specify the key in the IKEv1/IKEv2 options. Then, when your configuration is deployed, the key is configured on all devices in the topology.

PKI Infrastructure and Digital Certificates

Public Key Infrastructure

A PKI provides centralized key management for participating network devices. It is a defined set of policies, procedures, and roles that support public key cryptography by generating, verifying, and revoking public key certificates commonly known as digital certificates.

In public key cryptography, each endpoint of a connection has a key pair consisting of both a public and a private key. The key pairs are used by the VPN endpoints to sign and encrypt messages. The keys act as
complements, and anything encrypted with one of the keys can be decrypted with the other, securing the data flowing over the connection.

Generate a general purpose RSA or ECDSA key pair, used for both signing and encryption, or you generate separate key pairs for each purpose. Separate signing and encryption keys help to reduce exposure of the keys. SSL uses a key for encryption but not signing, however, IKE uses a key for signing but not encryption. By using separate keys for each, exposure of the keys is minimized.

**Digital Certificates or Identify Certificates**

When you use Digital Certificates as the authentication method for VPN connections, peers are configured to obtain digital certificates from a Certificate Authority (CA). CAs are trusted authorities that “sign” certificates to verify their authenticity, thereby guaranteeing the identity of the device or user.

CA servers manage public CA certificate requests and issue certificates to participating network devices as part of a Public Key Infrastructure (PKI), this activity is called Certificate Enrollment. These digital certificates, also called identity certificates contain:

- The digital identification of the owner for authentication, such as name, serial number, company, department, or IP address.
- A public key needed to send and receive encrypted data to the certificate owner.
- The secure digital signature of a CA.

Certificates also provide non-repudiation of communication between two peers, meaning that it they prove that the communication actually took place.

**Certificate Enrollment**

Using a PKI improves the manageability and scalability of your VPN since you do not have to configure pre-shared keys between all the encrypting devices. Instead, you individually enroll each participating device with a CA server, which is explicitly trusted to validate identities and create an identity certificate for the device. When this has been accomplished, each participating peer sends their identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates. See Certificate Enrollment Objects, on page 619 for details on enrolling FTD devices.

**Certificate Authority Certificates**

In order to validate a peer’s certificate, each participating device must retrieve the CA's certificate from the server. A CA certificate is used to sign other certificates. It is self-signed and called a root certificate. This certificate contains the public key of the CA, used to decrypt and validate the CA's digital signature and the contents of the received peer's certificate. The CA certificate may be obtained by:

- Using the Simple Certificate Enrollment Protocol (SCEP) to retrieve the CA's certificate from the CA server
- Manually copying the CA's certificate from another participating device

**Trustpoints**

Once enrollment is complete, a trustpoint is created on the managed device. It is the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.
PKCS#12 File

A PKCS#12, or PFX, file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

Revocation Checking

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

Removed or Deprecated Hash Algorithms, Encryption Algorithms, and Diffie-Hellman Modulus Groups

Support has been removed for less secure ciphers. We recommend that you update your VPN configuration before you upgrade to FTD 6.70 to supported DH and encryption algorithms to ensure the VPN works correctly.

Update your IKE proposals and IPSec policies to match the ones supported in FTD 6.70 and then deploy the configuration changes.

The following less secure ciphers have been removed or deprecated in FTD 6.70 onwards:

- Diffie-Hellman GROUP 5 is deprecated for IKEv1 and removed for IKEv2
- Diffie-Hellman groups 2 and 24 have been removed.
- Encryption algorithms: 3DES, AES-GMAC, AES-GMAC-192, AES-GMAC-256 have been removed.

Note DES continues to be supported in evaluation mode or for users who do not satisfy export controls for strong encryption.

NULL is removed in IKEv2 policy, but supported in both IKEv1 and IKEv2 IPsec transform-sets.

VPN Topology Options

When you create a new VPN topology you must, at minimum, give it a unique name, specify a topology type, and select the IKE version. You can select from three types of topologies, each containing a group of VPN tunnels:

- Point-to-point (PTP) topologies establish a VPN tunnel between two endpoints.
- Hub and Spoke topologies establish a group of VPN tunnels connecting a hub endpoint to a group of spoke endpoints.
- Full Mesh topologies establish a group of VPN tunnels among a set of endpoints.
Define a pre-shared key for VPN authentication manually or automatically, there is no default key. When choosing automatic, the Firepower Management Center generates a pre-shared key and assigns it to all the nodes in the topology.

**Point-to-Point VPN Topology**

In a point-to-point VPN topology, two endpoints communicate directly with each other. You configure the two endpoints as peer devices, and either device can start the secured connection.

The following diagram displays a typical point-to-point VPN topology.

![Point-to-Point VPN Topology Diagram](image)

**Hub and Spoke VPN Topology**

In a Hub and Spoke VPN topology, a central endpoint (hub node) connects with multiple remote endpoints (spoke nodes). Each connection between the hub node and an individual spoke endpoint is a separate VPN tunnel. The hosts behind any of the spoke nodes can communicate with each other through the hub node.

The Hub and Spoke topology commonly represent a VPN that connects an organization’s main and branch office locations using secure connections over the Internet or other third-party network. These deployments provide all employees with controlled access to the organization’s network. Typically, the hub node is located at the main office. Spoke nodes are located at branch offices and start most of the traffic.

The following diagram displays a typical Hub and Spoke VPN topology.
In a Full Mesh VPN topology, all endpoints can communicate with every other endpoint by an individual VPN tunnel. This topology offers redundancy so that when one endpoint fails, the remaining endpoints can still communicate with each other. It commonly represents a VPN that connects a group of decentralized branch office locations. The number of VPN-enabled managed devices you deploy in this configuration depends on the level of redundancy you require.

The following diagram displays a typical Full Mesh VPN topology.
Implicit Topologies

In addition to the three main VPN topologies, other more complex topologies can be created as combinations of these topologies. They include:

- Partial mesh—A network in which some devices are organized in a full mesh topology, and other devices form either a hub-and-spoke or a point-to-point connection to some of the fully meshed devices. A partial mesh does not provide the level of redundancy of a full mesh topology, but it is less expensive to implement. Partial mesh topologies are used in peripheral networks that connect to a fully meshed backbone.

- Tiered hub-and-spoke—A network of hub-and-spoke topologies in which a device can behave as a hub in one or more topologies and a spoke in other topologies. Traffic is permitted from spoke groups to their most immediate hub.

- Joined hub-and-spoke—A combination of two topologies (hub-and-spoke, point-to-point, or full mesh) that connect to form a point-to-point tunnel. For example, a joined hub-and-spoke topology could comprise two hub-and-spoke topologies, with the hubs acting as peer devices in a point-to-point topology.
Site-to-Site VPNs for Firepower Threat Defense

About Firepower Threat Defense Site-to-site VPNs

Firepower Threat Defense site-to-site VPN supports the following features:

- Both IPsec IKEv1 & IKEv2 protocols are supported.
- Certificates and automatic or manual preshared keys for authentication.
- IPv4 & IPv6. All combinations of inside and outside are supported.
- IPsec IKEv2 Site-to-Site VPN topologies provide configuration settings to comply with Security Certifications.
- Static and Dynamic Interfaces.
- Support for both Firepower Management Center and FTD HA environments.
- VPN alerts when the tunnel goes down.
- Tunnel statistics available using the FTD Unified CLI.
- Support for IKEv1 and IKEv2 back-up peer configuration for point-to-point extranet and hub-and-spoke VPNs.
- Support for extranet device as hub in 'Hub and Spokes' deployments.
- Support for dynamic IP address for a managed endpoint pairing with extranet device in 'Point to Point' deployments.
• Support for dynamic IP address for extranet device as an endpoint.
• Support for hub as extranet in 'Hub and Spokes' deployments.

VPN Topology

To create a new site-to-site VPN topology you must, at minimum, give it a unique name, specify a topology type, choose the IKE version that is used for IPsec IKEv1 or IKEv2, or both. Also, determine your authentication method. Once configured, you deploy the topology to Firepower Threat Defense devices. The Firepower Management Center configures site-to-site VPNs on FTD devices only.

You can select from three types of topologies, containing one or more VPN tunnels:

• Point-to-point (PTP) deployments establish a VPN tunnel between two endpoints.
• Hub and Spoke deployments establish a group of VPN tunnels connecting a hub endpoint to a group of spoke nodes.
• Full Mesh deployments establish a group of VPN tunnels among a set of endpoints.

IPsec and IKE

In the Firepower Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

Authentication

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

Extranet Devices

Each topology type can include Extranet devices, devices that you do not manage in Firepower Management Center. These include:

• Cisco devices that Firepower Management Center supports, but for which your organization is not responsible. Such as spokes in networks managed by other organizations within your company, or a connection to a service provider or partner's network.
• Non-Cisco devices. You cannot use Firepower Management Center to create and deploy configurations to non-Cisco devices.

Add non-Cisco devices, or Cisco devices not managed by the Firepower Management Center, to a VPN topology as "Extranet" devices. Also specify the IP address of each remote device.

Firepower Threat Defense Site-to-site VPN Guidelines and Limitations

• A VPN connection can only be made across domains by using an extranet peer for the endpoint not in the current domain.
• A VPN topology cannot be moved between domains.
• Network objects with a 'range' option are not supported in VPN
• Firepower Threat Defense VPNs are only be backed up using the Firepower Management backup.
• The Firepower Threat Defense VPNs do not currently support PDF export and policy comparison.
• There is no per-tunnel or per-device edit option for Firepower Threat Defense VPNs, only the whole topology can be edited.
• Device interface address verification will not be performed for Transport mode when Crypto ACL is selected.
• All nodes in a topology must be configured with either Crypto ACL or Protected Network. A topology may not be configured with Crypto ACL on one node and Protected Network on another.
• There is no support for automatic mirror ACE generation. Mirror ACE generation for the peer is a manual process on either side.
• While using Crypto ACL, there is no support for tunnel health events for VPN topologies. With Crypto ACL, there is no support for Hub, Spoke, and Full Mesh topologies; only point to point VPN is supported.
• Whenever IKE ports 500/4500 are in use or when there are some PAT translations that are active, the Site-to-Site VPN cannot be configured on the same ports as it fails to start the service on those ports.
• Tunnel status is not updated in realtime, but at an interval of 5 minutes in the Firepower Management Center.
• The character " (double quote) is not supported as part of pre-shared keys. If you have used " in a pre-shared key, ensure that you change the character after you upgrade to Firepower Threat Defense 6.30.

Requirements and Prerequisites for Site-to-Site VPN

Model Support
FTD

Supported Domains
Leaf

User Roles
Admin
Managing Firepower Threat Defense Site-to-site VPNS

Procedure

**Step 1** For certificate authentication for your VPNs, you must prepare the devices by allocating trustpoints as described in Firepower Threat Defense Certificate-Based Authentication, on page 663.

**Step 2** Select Devices > VPN > Site To Site to manage your Firepower Threat Defense Site-to-site VPN configurations and deployments. Choose from the following:

- **Add**—To create a new VPN topology, click Add (➕) Add VPN > Firepower Threat Defense Device, and continue as instructed in Configuring Firepower Threat Defense Site-to-site VPNs, on page 1084:
  
  **Note** VPNs topologies can be created only on leaf domains.

- **Edit**—To modify the settings of an existing VPN topology, click Edit (🪪). Modifying is similar to configuring, continue as instructed above.
  
  **Note** You cannot edit the topology type after you initially save it. To change the topology type, delete the topology and create a new one.
  
  Two users should not edit the same topology simultaneously; however, the web interface does not prevent simultaneous editing.

- **Delete**—To delete a VPN deployment, click Delete (🗑️).

- **View VPN status**—This status applies to Firepower VPNs ONLY. Currently, no status is displayed for FTD VPNs. To determine the status of the FTD VPNs, see VPN Monitoring for Firepower Threat Defense, on page 1165.

- **Deploy**—Choose Deploy > Deployment; see Deploy Configuration Changes, on page 495.
  
  **Note** Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

Configuring Firepower Threat Defense Site-to-site VPNs

Procedure

**Step 1** Choose Devices > VPN > Site To Site. Then Add VPN > Firepower Threat Defense Device, or edit a listed VPN Topology.

**Step 2** Enter a unique Topology Name. We recommend naming your topology to indicate that it is a FTD VPN, and its topology type.

**Step 3** Click Policy Based (Crypto Map) to configure a site-to-site VPN.
**Step 4**  Choose the **Network Topology** for this VPN.

**Step 5**  Choose the IKE versions to use during IKE negotiations. **IKEv1** or **IKEv2**.

Default is IKEv2. Select either or both options as appropriate; select IKEv1 if any device in the topology does not support IKEv2. You can also configure backup peer for point-to-point extranet VPNs. For more information, see FTD VPN Endpoint Options, on page 1085.

**Step 6**  Required: Add Endpoints for this VPN deployment by clicking **Add** (➕) for each node in the topology.

Configure each endpoint field as described in FTD VPN Endpoint Options, on page 1085.

- For Point to point, configure **Node A** and **Node B**.
- For Hub and Spoke, configure a **Hub Node** and **Spoke Nodes**
- For Full Mesh, configure multiple **Nodes**

**Step 7**  (Optional) Specify non-default IKE options for this deployment as described in FTD VPN IKE Options, on page 1088.

**Step 8**  (Optional) Specify non-default IPsec options for this deployment as described in FTD VPN IPsec Options, on page 1090.

**Step 9**  (Optional) Specify non-default Advanced options for this deployment as described in FTD Advanced Site-to-site VPN Deployment Options, on page 1092.

**Step 10**  Click **Save**.

The endpoints are added to your configuration.

---

**What to do next**

Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

**Note**

Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

If you get an alert that your VPN tunnel is inactive even when the VPN session is up, follow the VPN troubleshooting instructions to verify and ensure that your VPN is active. For information, see VPN Monitoring for Firepower Threat Defense, on page 1165 and VPN Troubleshooting for Firepower Threat Defense, on page 1169.

---

**FTD VPN Endpoint Options**

**Navigation Path**

Devices > VPN > Site To Site. Then Add VPN > Firepower Threat Defense Device, or edit a listed VPN Topology. Open the **Endpoint** tab.
FTD VPN Endpoint Options

Fields

Device
Choose an endpoint node for your deployment:

• A FTD device managed by this Firepower Management Center.
• A FTD high availability container managed by this Firepower Management Center.
• An Extranet device, any device (Cisco or third-party) not managed by this Firepower Management Center.

Device Name
For Extranet devices only, provide a name for this device. We recommend naming it such that it is identifiable as an un-managed device.

Interface
If you chose a managed device as your endpoint, choose an interface on that managed device.

For 'Point to Point' deployments, you can also configure an endpoint with dynamic interface. Note that an endpoint with dynamic interface can pair only with an extranet device and cannot pair with an endpoint, which has a managed device.

You can configure device interfaces at Devices > Device Management > Add/Edit device > Interfaces.

IP Address
• If you choose an extranet device, a device not managed by the Firepower Management Center, specify an IP address for the endpoint.

For an extranet device, select Static and specify an IP address or select Dynamic to allow dynamic extranet devices.

If you have chosen point-to-point topology and only IKEv1, you can configure backup peer by entering the primary IP address and backup peer IP addresses separated by a comma.

• If you chose a managed device as an endpoint, choose a single IPv4 address or multiple IPv6 addresses from the drop-down list (these are the addresses already assigned to this interface on this managed device).

• All endpoints in a topology must have the same IP addressing scheme. IPv4 tunnels can carry IPv6 traffic and vice-versa. The Protected Networks define which addressing scheme the tunneled traffic will use.

• If the managed device is a high-availability container, choose from a list of interfaces.

This IP is Private
Check the check box if the endpoint resides behind a firewall with network address translation (NAT).

Note
Use this option only when the peer is managed by the same Firepower Management Center and do not use this option if peer is from extranet.
Public IP address

If you checked the This IP is Private check box, specify a public IP address for the firewall. If the endpoint is a responder, specify this value.

Connection Type

Specify the allowed negotiation as bidirectional, answer-only, or originate-only. Supported combinations for the connection type are:

Table 80: Connection Type Supported Combinations

<table>
<thead>
<tr>
<th>Central Node</th>
<th>Remote Node</th>
</tr>
</thead>
<tbody>
<tr>
<td>Answer-Only</td>
<td>Originate-Only</td>
</tr>
<tr>
<td>Answer-Only</td>
<td>Bi-Directional</td>
</tr>
<tr>
<td>Bi-Directional</td>
<td>Bi-Directional</td>
</tr>
</tbody>
</table>

Certificate Map

Choose a pre-configured certificate map object, or click Add to add a certificate map object that defines what information is necessary in the received client certificate for it to be valid for VPN connectivity. See FTD Certificate Map Objects, on page 653 for details.

Protected Networks

In the Hub and Spoke topology, for a dynamic crypto map, ensure that you do not select the protected network any for both the endpoints to avoid traffic drop.

Caution

Defines the networks that are protected by this VPN Endpoint. The networks may be marked by selecting the list of Subnet/IP Address that define the networks that are protected by this endpoint. Click Add to select from available Network Objects or add new Network Objects. See Creating Network Objects, on page 565. Access Control Lists will be generated from the choices made here.

- Subnet/IP Address (Network)—VPN endpoints cannot have the same IP address and protected networks in a VPN endpoint pair cannot overlap. If a list of protected networks for an endpoint contains one or more IPv4 or IPv6 entries, the other endpoint's protected network must have at least one entry of the same type (that is, IPv4 or IPv6). If it does not, then the other endpoint's IP address must be of the same type and must not overlap with the entries in the protected network. (Use /32 CIDR address blocks for IPv4 and /128 CIDR address blocks for IPv6.) If both of these checks fail, the endpoint pair is invalid.
Reverse Route Injection is enabled by default in Firepower Management Center. Subnet/IP Address (Network) remains the default selection.

When you have selected Protected Networks as Any and observe default route traffic being dropped, disable the Reverse Route Injection under VPN > Site to Site > edit a VPN > IPsec > Enable Reverse Route Injection. Deploy the configuration changes; this will remove set reverse-route (Reverse Route Injection) from the crypto map configuration and remove the VPN-advertised reverse route that causes the reverse tunnel traffic to be dropped.

* Access List (Extended)—An extended access lists provide the capability to control the type of traffic that will be accepted by this endpoint, like GRE or OSPF traffic. Traffic may be restricted either by address or port. Click Add (+) to add access control list objects.

Access Control List is supported only in the point to point topology.

Advanced Settings
Enable Dynamic Reverse Route Injection—Reverse Route Injection (RRI) is the ability for routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint. Dynamic RRI routes are created only upon the successful establishment of IPsec security associations (SA’s)

* Dynamic RRI is supported only on IKEv2, and not supported on IKEv1 or IKEv1 + IKEv2.
* Dynamic RRI is not supported on: originate-only peer, Full Mesh topology, and Extranet peer.
* In Point-to-Point, only one peer can have dynamic RRI enabled.
* Between Hub and Spoke, only one of the endpoints can have dynamic RRI enabled.
* Dynamic RRI cannot be combined with a dynamic crypto map.

FTD VPN IKE Options

For the versions of IKE you have chosen for this topology, specify the IKEv1/IKEv2 Settings.

Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

Navigation Path
Devices > VPN > Site To Site. Then Add VPN > Firepower Threat Defense Device, or edit a listed VPN Topology. Open the IKE tab.
**Fields**

**Policy**
Choose a predefined IKEv1 or IKEv2 policy object or create a new one to use. For details, see [FTD IKE Policies, on page 640](#).

**Authentication Type**
Site-to-site VPN supports two authentication methods, pre-shared key and certificate. For an explanation of the two methods, see [Deciding Which Authentication Method to Use, on page 1075](#).

---

**Note**
In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

- **Pre-shared Automatic Key**—The Management Center automatically defines the pre-shared key that is used for this VPN. Specify the **Pre-shared Key Length**, the number of characters in the key, 1-27.

  The character " (double quote) is not supported as part of pre-shared keys. If you have used " in a pre-shared key, ensure that you change the character after you upgrade to Firepower Threat Defense 6.30 or higher.

- **Pre-shared Manual Key**—Manually assign the pre-shared key that is used for this VPN. Specify the **Key** and then re-enter it in **Confirm Key** to confirm.

  When this option is chosen for IKEv2, the **Enforce hex-based pre-shared key only** check box appears, check if desired. If enforced, you must enter a valid hex value for the key, an even number of 2-256 characters, using numerals 0-9, or A-F.

- **Certificate**—When you use certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

  In the **Certificate** field, select a pre-configured certificate enrollment object. This enrollment object is used to generate a trustpoint with the same name on the managed device. The certificate enrollment object should be associated with and installed on the device, post which the enrollment process is complete, and then a trustpoint is created.

  A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate.

  Before you select this option, note the following:

  - **Ensure you have enrolled a certificate enrollment object on all the endpoints in the topology**—A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. Certificate Enrollment Objects are used to enroll your managed devices into your PKI infrastructure, and create trustpoints (CA objects) on devices that support VPN connections. For instructions on creating a certificate enrollment object, see [Adding Certificate Enrollment Objects, on page 621](#), and for instructions on enrolling the object on the endpoints see one of the following as applicable:

    - [Installing a Certificate Using Self-Signed Enrollment](#)
    - [Installing a Certificate Using SCEP Enrollment](#)
For a site-to-site VPN topology, ensure that the same certificate enrollment object is enrolled in all the endpoints in the topology. For further details, see the table below.

- Refer the following table to understand the enrollment requirement for different scenarios. Some of the scenarios require you to override the certificate enrollment object for specific devices. See Managing Object Overrides, on page 562 to understand how to override objects.

<table>
<thead>
<tr>
<th>Certificate Enrollment Types</th>
<th>Device identity certificate for all endpoints is from the same CA</th>
<th>Device identity certificate for all endpoints is from different CAs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manual</td>
<td>No override required</td>
<td>Override required</td>
</tr>
<tr>
<td>SCEP</td>
<td>No override required</td>
<td>Override required</td>
</tr>
<tr>
<td>PKCS</td>
<td>Override required</td>
<td>Override required</td>
</tr>
<tr>
<td>Self-signed</td>
<td>Not applicable</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

- Understand the VPN certificate limitations mentioned in Firepower Threat Defense VPN Certificate Guidelines and Limitations, on page 664.

If you use a Windows Certificate Authority (CA), the default Application Policies extension is IP security IKE intermediate. If you are using this default setting, you must select the Ignore IPsec Key Usage option in the Advanced Settings section on the Key tab in the PKI Certificate Enrollment dialog box for the object you select. Otherwise, the endpoints cannot complete the site-to-site VPN connection.

FTD VPN IPsec Options

- Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.
Crypto-Map Type

A crypto map combines all the components required to set up IPsec security associations (SA). When two peers try to establish an SA, they must each have at least one compatible crypto map entry. The proposals defined in the crypto map entry are used in the IPsec security negotiation to protect the data flows specified by that crypto map’s IPsec rules. Choose static or dynamic for this deployment's crypto-map:

- **Static**—Use a static crypto map in a point-to-point or full mesh VPN topology.

- **Dynamic**—Dynamic crypto-maps essentially create a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer’s requirements.

Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply dynamic crypto map policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. Note that in a full mesh VPN topology, you can apply only static crypto map policies.

IKEv2 Mode

For IPsec IKEv2 only, specify the encapsulation mode for applying ESP encryption and authentication to the tunnel. This determines what part of the original IP packet has ESP applied.

- **Tunnel mode**—(default) Encapsulation mode is set to tunnel mode. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), hiding the ultimate source and destination addresses and becoming the payload in a new IP packet.

  The major advantage of tunnel mode is that the end systems do not need to be modified to receive the benefits of IPsec. This mode allows a network device, such as a router, to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source router encrypts packets and forwards them along the IPsec tunnel. The destination router decrypts the original IP datagram and forwards it onto the destination system. Tunnel mode also protects against traffic analysis; with tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.

- **Transport preferred**—Encapsulation mode is set to transport mode with an option to fallback to tunnel mode if the peer does not support it. In Transport mode only the IP payload is encrypted, and the original IP headers are left intact. Therefore, the admin must select a protected network that matches the VPN interface IP address.

  This mode has the advantages of adding only a few bytes to each packet and allowing devices on the public network to see the final source and destination of the packet. With transport mode, you can enable special processing (for example, QoS) on the intermediate network based on the information in the IP header. However, the Layer 4 header is encrypted, which limits examination of the packet.

- **Transport required**—Encapsulation mode is set to transport mode only, falling back to tunnel mode is not allowed. If the endpoints cannot successfully negotiate transport mode, due to one endpoint not supporting it, the VPN connection is not made.

**Proposals**

Click **Edit** to specify the proposals for your chosen IKEv1 or IKEv2 method. Select from the available **IKEv1 IPsec Proposals** or **IKEv2 IPsec Proposals** objects, or create and then select a new one. See **Configure IKEv1 IPsec Proposal Objects**, on page 643 and **Configure IKEv2 IPsec Proposal Objects**, on page 644 for details.
Enable Security Association (SA) Strength Enforcement

Enabling this option ensures that the encryption algorithm used by the child IPsec SA is not stronger (in terms of the number of bits in the key) than the parent IKE SA.

Enable Reverse Route Injection

Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

Enable Perfect Forward Secrecy

Whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list.

Modulus Group

The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. For a full explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use, on page 1074.

Lifetime Duration

The number of seconds a security association exists before expiring. The default is 28,800 seconds.

Lifetime Size

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires. The default is 4,608,000 kilobytes. Infinite data is not allowed.

ESPv3 Settings

Validate incoming ICMP error messages

Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.

Enable 'Do Not Fragment' Policy

Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header.

Policy

• Copy DF bit—Maintains the DF bit.
• Clear DF bit—Ignores the DF bit.
• Set DF bit—Sets and uses the DF bit.

Enable Traffic Flow Confidentiality (TFC) Packets

Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the Burst, Payload Size, and Timeout parameters to generate random length packets at random intervals across the specified SA.

FTD Advanced Site-to-site VPN Deployment Options

The following sections describes the advanced options you can specify in your S2S VPN deployment. These settings apply to the entire topology, all tunnels, and all managed devices.
FTD VPN Advanced IKE Options

Advanced > IKE > ISAKAMP Settings

IKE Keepalive

Enable or disables IKE Keepalives. Or set to EnableInfinite specifying that the device never starts keepalive monitoring itself.

Threshold

Specifies the IKE keep alive confidence interval. This is the number of seconds allowing a peer to idle before beginning keepalive monitoring. The minimum and default is 10 seconds; the maximum is 3600 seconds.

Retry Interval

Specifies number of seconds to wait between IKE keep alive retries. The default is 2 seconds, the maximum is 10 seconds.

Identity Sent to Peers:

Choose the identity that the peers will use to identify themselves during IKE negotiations:

- **autoOrDN** (default)—Determines IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
- **ipAddress**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
- **hostname**—Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

---

**Note**

Enable or disable this option for all your VPN connections.

Enable Aggressive Mode

Available only in a hub-and-spoke VPN topology. Select this negotiation method for exchanging key information if the IP address is not known and DNS resolution might not be available on the devices. Negotiation is based on hostname and domain name.

Advanced > IKE > IVEv2 Security Association (SA) Settings

More session controls are available for IKE v2 that limit the number of open SAs. By default, there is no limit to the number of open SAs:

Cookie Challenge

Whether to send cookie challenges to peer devices in response to SA initiate packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:

- Custom:
- Never (default)
- Always

Threshold to Challenge Incoming Cookies

The percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%.
Number of SAs Allowed in Negotiation
Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check.

Maximum number of SAs Allowed
Limits the number of allowed IKEv2 connections. Default is unlimited.

Enable Notification on Tunnel Disconnect
Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. Sending this notification is disabled by default.

FTD VPN Advanced IPsec Options

Advanced > IPsec > IPsec Settings

Enable Fragmentation Before Encryption
This option lets traffic travel across NAT devices that do not support IP fragmentation. It does not impede the operation of NAT devices that do support IP fragmentation.

Path Maximum Transmission Unit Aging
Check to enable PMTU (Path Maximum Transmission Unit) Aging, the interval to Reset PMTU of an SA (Security Association)

Value Reset Interval
Enter the number of minutes at which the PMTU value of an SA (Security Association) is reset to its original value. Valid range is 10 to 30 minutes, default is unlimited.

FTD Advanced Site-to-site VPN Tunnel Options

Navigation Path
Devices > VPN > Site To Site, then select Add VPN > Firepower Threat Defense Device, or edit a listed VPN Topology. Open the Advanced tab, and select Tunnel in the navigation pane.

Tunnel Options
Only available for Hub and Spoke, and Full Mesh topologies. This section will not display for Point to Point configurations.

- Enable Spoke to Spoke Connectivity through Hub—Disabled by default. Choosing this field enables the devices on each end of the spokes to extend their connection through the hub node to the other device.

NAT Settings

- Keepalive Messages Traversal—Elect whether to enable NAT keepalive message traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there is a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow.

If you select this option, configure the Interval, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 5 to 3600 seconds. The default is 20 seconds.
Access Control for VPN Traffic

- **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** — Decrypted traffic is subjected to access control policy inspection by default. Enable this option to bypasses the ACL inspection; but VPN Filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

Enable or disable the option for all your VPN connections. If you disable this option, make sure that the traffic is allowed by the access control policy or pre-filter policy.

Certificate Map Settings

- **Use the certificate map configured in the Endpoints to determine the tunnel** — If this option is enabled (checked), the tunnel will be determined by matching the contents of the received certificate to the certificate map objects configured in the endpoint nodes.

- **Use the certificate OU field to determine the tunnel** — Indicates that if a node is not determined based on the configured mapping (the above option) if selected, then use the value of the organizational unit (OU) in the subject distinguished name (DN) of the received certificate to determine the tunnel.

- **Use the IKE identity to determine the tunnel** — Indicates that if a node is not determined based on a rule matching or taken from the OU (the above options) if selected, then the certificate-based IKE sessions are mapped to a tunnel based on the content of the phase1 IKE ID.

- **Use the peer IP address to determine the tunnel** — Indicates that if a tunnel is not determined based on a rule matching or taken from the OU or IKE ID methods (the above options) if selected, then use the established peer IP address.

About Virtual Tunnel Interfaces

Firepower Management Center supports a logical interface called Virtual Tunnel Interface (VTI). As an alternative to policy based VPN, a VPN tunnel can be created between peers with Virtual Tunnel Interfaces configured. This supports route-based VPN with IPsec profiles attached to the end of each tunnel. This allows dynamic or static routes to be used. Egressing traffic from the VTI is encrypted and sent to the peer, and the associated SA decrypts the ingress traffic to the VTI.

Using VTI does away with the requirement of configuring static crypto map access lists and mapping them to interfaces. You no longer have to track all remote subnets and include them in the crypto map access list. Deployments become easier, and having static VTI which supports route based VPN with dynamic routing protocol also satisfies many requirements of a virtual private cloud. FMC enables you to easily migrate from crypto-map based VPN configuration to VTI-based VPN.

You can configure route-based VPN in FMC, FTD Device REST API, and FDM by configuring a static Virtual Tunnel Interface. FMC supports a site-to-site VPN wizard with defaults to configure VTI or route-based VPN. Traffic is encrypted using static route or BGP.

You can create a routed security zone, add VTI interfaces to it, and define access control rules for the decrypted traffic control over the VTI tunnel.

VTI-based VPNs can be created between:

- Two FTD devices
- FTD and public cloud
• FTD and another FTD with service provider redundancy
• FTD and any other device with VTI interfaces configured

Guidelines and Limitations for Virtual Tunnel Interfaces

IPv6 Support
• IPv6 is not supported.

Limitations
• Only 20 unique IPSec profiles are supported.
• Only 100 VTIs are supported per physical interface.
• Dynamic VTI, OSPF, and QoS are not supported.
• Site-to-site VPN tunnels created with VTIs do not generate health alerts when the tunnel goes down. If you experience packet loss over a VPN with VTIs, check your VPN configuration.

General Configuration Guidelines
• VTIs are only configurable in IPsec mode.
• You can use dynamic or static routes for traffic using the tunnel interface.
• The MTU for VTIs is automatically set, according to the underlying physical interface.
• VTI supports IKE versions v1, v2, and uses IPsec for sending and receiving data between the tunnel's source and destination.
• If Network Address Translation has to be applied, the IKE and ESP packets will be encapsulated in the UDP header.
• IKE and IPsec security associations will be re-keyed continuously regardless of data traffic in the tunnel. This ensures that VTI tunnels are always up.
• Tunnel group name must match what the peer will send as its IKEv1 or IKEv2 identity.
• For IKEv1 in LAN-to-LAN tunnel groups, you can use names which are not IP addresses, if the tunnel authentication method is digital certificates and/or the peer is configured to use aggressive mode.
• VTI and crypto map configurations can co-exist on the same physical interface, provided the peer address configured in the crypto map and the tunnel destination for the VTI are different.
• By default, all traffic sent through a VTI is encrypted.
• There are no security level configurations for VTI interfaces.
• Access list can be applied on a VTI interface to control traffic through VTI.
Multi-instance
VTI is supported in multi-instance.

Firewall Mode
VTI is supported in routed mode only.

Add a VTI Interface

For configuring a route-based site-to-site VPN, you must create a Virtual Tunnel Interface on the devices at both the nodes of the VTI tunnel. To create a new VTI interface, perform the following steps:

Procedure

Step 1 Choose Devices > Device Management.
Step 2 Click the Edit icon next to the device on which you want to create a VTI interface.
Step 3 From the Add Interfaces drop-down menu, choose Virtual Tunnel Interface.
Step 4 In the Name field, enter a name for the new VTI.
Step 5 Keep the Enabled checkbox checked (default) to enable the interface once you finish creating it.
Step 6 (Optional) Enter a description for the new VTI.
Step 7 (Optional) In the Security Zone drop-down menu, select a security zone to add the VTI interface to that zone. If you want to do traffic inspection based on security zone, you can add the VTI to the security zone and configure an access control rule. To permit the VPN traffic over the tunnel, you need to add an AC rule with this security zone as the source zone.
Step 8 In the Tunnel ID field, enter a unique tunnel ID in the range of 0-10413.
Step 9 In the IP Address field, enter the IP address and subnet to use for the tunnel endpoint. The VTI IP addresses of both endpoints of a route-based VPN must be in the same subnet.

Note Cisco recommends you to use IP from 169.254.x.x/16 range excluding the FTD reserved range (169.254.1.x/24). Also, use /30 as net-mask to optimally use only two addresses for two ends of the VTI tunnel. For example, 169.254.100.1/30.

Step 10 In the Tunnel Source drop-down menu, select the tunnel source interface.
Step 11 Click OK.

Create a Route-based Site-to-Site VPN

You can configure a route-based site-to-site VPN between two nodes. You need virtual tunnel interfaces at both the nodes of the tunnel in order to configure a VTI-based VPN.

For more information on VTI, see About Virtual Tunnel Interfaces, on page 1095
Procedure

Step 1  Choose Devices > Site To Site.

Step 2  In the Add VPN drop-down menu, choose Firepower Threat Defense Device.

Step 3  In the Topology Name field, enter a name for the VPN topology that you are creating.

Step 4  Choose Route Based (VTI) as the topology type. Network topology is selected as Point to Point and IKE protocol version is selected as IKEv2 by default for the site-to-site configuration.

Step 5  Under Node A in the Endpoints tab, in the Device drop-down menu, select the name of the registered device (FTD) or Extranet to be used as the first endpoint of your VTI tunnel.

Step 6  For a registered device, you can specify the interface for Node A:

- In the Virtual Tunnel Interface drop-down menu, select the VTI interface, which you had created on FTD device that you have selected as Node A.

- If you want to create a new interface on Node A, click the + icon and fill the fields as described in Add a VTI Interface, on page 1097.

- If you want to edit the configuration of an existing VTI, select the VTI in the Virtual Tunnel Interface drop-down field and click Edit VTI.

  Note  The selected tunnel interface is the source interface for Node A and it becomes the tunnel destination for Node B.

Step 7  If your Node A device is behind a NAT device, check the Tunnel Source IP is Private checkbox. In the Tunnel Source Public IP Address field, enter the tunnel source public IP address.

Step 8  In the Connection Type drop-down menu, select Answer Only or Directional. If you have selected IKE protocol version as IKEv1, one of the nodes must be Answer Only.

Step 9  Under Additional Configuration, do the following:

- To route traffic to the VTI, click Routing Policy. FMC displays the Devices > Routing page. You can configure the Static or BGP routing for the VPN traffic.

- To permit VPN traffic, click AC Policy. FMC displays the access control policy page of the device. Proceed to add allow/block rule specifying the security zone of the VTI. If a backup VTI is being configured, ensure to include the backup tunnel to the same security zone as that of the primary VTI. No specific settings is required for the backup VTI in the AC policy page.

Step 10  For an extranet peer, specify the following parameters:

a)  In the Device Name, enter the name of the device.

b)  In the Endpoint IP address, enter the primary IP address.

c)  Click IKE tab and specify the pre-shared key provided on the extranet.

  Note  The AWS VPC has AES-SHA-SHA-LATEST as the default policy. Therefore, if the remote peer connects to AWS VPC, from the Policy drop-down list, select AES-SHA-SHA-LATEST to establish the VPN connection without the need to change the default value in AWS.

Step 11  Repeat the above procedure for Node B.
Additional Configurations for VTI

After you configure VTI interfaces and VTI tunnel on both the devices, you must configure a routing policy to route VTI traffic between the devices over the VTI tunnel. You must also configure an access control rule to allow encrypted traffic.

Routing Configuration for VTI

Static Route

Configure static routing on both the devices (both the ends) to route the traffic flow between the devices over the VTI tunnel.

If backup tunnel is configured for the VPN, configure a static route with a different metric to handle the failover of the traffic flow over the backup tunnel.

Ensure that you configure the following when you configure a static route:

- **Interface**—Select the VTI interface used in the VPN.
- **Selected Network**—Select the remote peer’s protected network (added as a network object).

For more information about static routing, see Add a Static Route, on page 996.

Border Gateway Protocol (BGP)

Configure BGP on both the devices to share routing information and to route traffic flow between the devices over the tunnel with the following settings:

- Under **General Settings > BGP**, enable BGP, provide the AS number of the local device, and add Router Id (if you choose Manual).
- Under **BGP**, enable IPv4 and configure neighbors on the Neighbor tab.
  - **IP Address**—Specify the remote peer’s VTI interface IP address as the neighbor’s IP address.
  - **Remote AS**—Specify the remote peer’s AS number.

For more information about BGP configuration, see Configure BGP, on page 1031.

AC Policy Rule

Add an access control rule to the access control policy on the device to allow encrypted traffic between the VTI tunnels with the following settings:

- Create the rule with the Allow action.
- Select the VTI security zone of the local device as the Source Zone and the VTI security zone of the remote peer as the Destination Zone.
- Select the VTI security zone of the remote peer as the Source Zone and the VTI security zone of the local device as the Destination Zone.

For more information about configuring an access control rule, see Create and Edit Access Control Rules, on page 1561.
If backup VTI is configured, ensure to include the backup tunnel to the same security zone as that of the primary VTI. No specific settings are required for the backup VTI in the AC policy page.

Firepower Threat Defense Remote Access VPN Overview

Firepower Threat Defense provides secure gateway capabilities that support remote access SSL and IPsec-IKEv2 VPNs. The full tunnel client, AnyConnect Secure Mobility Client, provides secure SSL and IPsec-IKEv2 connections to the security gateway for remote users. AnyConnect is the only client supported on endpoint devices for remote VPN connectivity to Firepower Threat Defense devices. The client gives remote users the benefits of an SSL or IPsec-IKEv2 VPN client without the need for network administrators to install and configure clients on remote computers. The AnyConnect mobile client for Windows, Mac, and Linux is deployed from the secure gateway upon connectivity. The AnyConnect apps for Apple iOS and Android devices are installed from the platform app store.

Use the Remote Access VPN Policy wizard in the Firepower Management Center to quickly and easily set up SSL and IPsec-IKEv2 remote access VPNs with basic capabilities. Then, enhance the policy configuration if desired and deploy it to your Firepower Threat Defense secure gateway devices.

You can configure the following settings using the remote access VPN policy:

- Two-Factor Authentication, on page 1151
- Secondary Authentication, on page 1155
- Manage Password Changes over VPN Sessions, on page 1145
- Send Accounting Records to the RADIUS Server, on page 1146
Remote Access VPN Features

The following section describes the features of Firepower Threat Defense remote access VPN:

• SSL and IPsec-IKEv2 remote access using the Cisco AnyConnect Secure Mobility Client.
• Firepower Management Center supports all combinations such as IPv6 over an IPv4 tunnel.
• Configuration support on both FMC and FDM. Device-specific overrides.
• Support for both Firepower Management Center and FTD HA environments.
• Support for multiple interfaces and multiple AAA servers.
• Rapid Threat Containment support using RADIUS CoA or RADIUS dynamic authorization.
• Support for DTLS v1.2 protocol with Cisco AnyConnect Secure Mobility Client version 4.7 or higher.
• AnyConnect client modules support for additional security services for RA VPN connections.
• VPN load balancing.

AAA

• Server authentication using self-signed or CA-signed identity certificates.
• AAA username and password-based remote authentication using RADIUS server or LDAP or AD.
• RADIUS group and user authorization attributes, and RADIUS accounting.
• Double authentication support using an additional AAA server for secondary authentication.
• NGFW Access Control integration using VPN Identity.
• LDAP or AD authorization attributes using Firepower Management Center web interface.
• Support for single sign-on using SAML 2.0.

VPN Tunneling

• Address assignment
• Split tunneling
AnyConnect Components

AnyConnect Secure Mobility Client Deployment

Your remote access VPN Policy can include the AnyConnect Client Image and an AnyConnect Client Profile for distribution to connecting endpoints. Or, the client software can be distributed using other methods. See the Deploy AnyConnect chapter in the appropriate version of the Cisco AnyConnect Secure Mobility Client Administrator Guide.

Without a previously installed client, remote users enter the IP address in their browser of an interface configured to accept SSL or IPsec-IKEv2 VPN connections. Unless the security appliance is configured to redirect http:// requests to https://, remote users must enter the URL in the form https://address. After the user enters the URL, the browser connects to that interface and displays the login screen.

After a user logs in, if the secure gateway identifies the user as requiring the VPN client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure connection, and either remains or uninstalls itself (depending on the security appliance configuration) when the connection stops. In the case of a previously installed client, after login, the Firepower Threat Defense security gateway examines the client version and upgrades it as necessary.

AnyConnect Secure Mobility Client Operation

When the client negotiates a connection with the security appliance, the client connects using Transport Layer Security (TLS), and optionally, Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

When an IPsec-IKEv2 VPN client initiates a connection to the secure gateway, negotiation consists of authenticating the device through Internet Key Exchange (IKE), followed by user authentication using IKE Extended Authentication (Xauth). The group profile is pushed to the VPN client and an IPsec security association (SA) is created to complete the VPN.

AnyConnect Client Profile and Editor

An AnyConnect client profile is a group of configuration parameters, stored in an XML file that the VPN client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.
You can configure a profile using the AnyConnect Profile Editor. This editor is a convenient GUI-based configuration tool that is available as part of the AnyConnect software package. It is an independent program that you run outside of the Firepower Management Center.

**Remote Access VPN Authentication**

**Remote Access VPN Server Authentication**

Firepower Threat Defense secure gateways always use certificates to identify and authenticate themselves to the VPN client endpoint. While setting up the remote access VPN configuration using the wizard, you can enroll the selected certificate on the targeted Firepower Threat Defense device. In the wizard, under **Access & Certificate** phase, select “Enroll the selected certificate object on the target devices” option. The certificate enrollment gets automatically initiated on the specified devices. As you complete the Remote Access VPN configuration, you can view the status of the enrolled certificate under the device certificate homepage. The status provides a clear standing as to whether the certificate enrollment was successful or not. Your Remote Access VPN configuration is now fully completed and ready for deployment.

Obtaining a certificate for the secure gateway, also known as PKI enrollment, is explained in Firepower Threat Defense Certificate-Based Authentication, on page 663. This chapter contains a full description of configuring, enrolling, and maintaining gateway certificates.

**Remote Access VPN Client AAA**

For both SSL and IPsec-IKEv2, remote user authentication is done using usernames and passwords only, certificates only, or both.

---

**Note**

If you are using client certificates in your deployment, they must be added to your client's platform independent of the Firepower Threat Defense or Firepower Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

AAA servers enable managed devices acting as secure gateways to determine who a user is (authentication), what the user is permitted to do (authorization), and what the user did (accounting). Some examples of the AAA servers are RADIUS, LDAP/AD, TACACS+, and Kerberos. For Remote Access VPN on Firepower Threat Defense devices, AD, LDAP, and RADIUS AAA servers are supported for authentication.

Refer to the section Understanding Policy Enforcement of Permissions and Attributes to understand more about remote access VPN authorization.

Before you add or edit the Remote Access VPN policy, you must configure the Realm and RADIUS server groups you want to specify. For more information, see Create a Realm, on page 2314 and RADIUS Server Groups, on page 656.

Without DNS configured, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames, it can only resolve IP addresses.

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Firepower Threat Defense secure gateway.
If users authenticate with RA VPN using Active Directory as the authentication source, users must log in using their username; the format `domain\username` or `username@domain` fails. (Active Directory refers to this username as the *logon name* or sometimes as *sAMAccountName*.) For more information, see [User Naming Attributes](https://msdn.microsoft.com/en-us/library/windows/desktop/aa379989.aspx) on MSDN.

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

Once authenticated via a VPN connection, the remote user takes on a *VPN Identity*. This VPN Identity is used by *identity policies* on the Firepower Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that the remote user blocked or allowed to access your network resources.

For more information, see the [About Identity Policies](https://support.cisco.com/s/article/About-Identity-Policies) on page 2373 and [Access Control Policies](https://support.cisco.com/s/article/Access-Control-Policies) on page 1535 sections.

## Understanding Policy Enforcement of Permissions and Attributes

The Firepower Threat Defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from an external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the Firepower Threat Defense device. If the Firepower Threat Defense device receives attributes from the external AAA server that conflict with those configured on the group policy, then attributes from the AAA server always take the precedence.

The Firepower Threat Defense device applies attributes in the following order:

1. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.

2. **Group policy configured on the Firepower Threat Defense device**—If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU=group-policy) for the user, the Firepower Threat Defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.

3. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy applied to the user before authentication.

### Related Topics
- Configure AAA Settings for Remote Access VPN, on page 1120

---

**Note**

The Firepower Threat Defense device does not support inheriting system default attributes from the default group policy, `DfltGrpPolicy`. The attributes on the group policy assigned to the connection profile are used for the user session, if they are not overridden by user attributes or the group policy from the AAA server as indicated above.
Understanding AAA Server Connectivity

LDAP, AD, and RADIUS AAA servers must be reachable from the Firepower Threat Defense device for your intended purposes: user-identity handling only, VPN authentication only, or both activities. AAA servers are used in remote access VPN for the following activities:

- **User-identity handling**—the servers must be reachable over the Management interface.
  
  On the Firepower Threat Defense device, the Management interface has a separate routing process and configuration from the regular interfaces used by VPN.

- **VPN authentication**—the servers must be reachable over one of the regular interfaces: the Diagnostic interface or a data interface.

  For regular interfaces, two routing tables are used. A management-only routing table for the Diagnostic interface as well as any other interfaces configured for management-only, and a data routing table used for data interfaces. When a route-lookup is done, the management-only routing table is checked first, and then the data routing table. The first match is chosen to reach the AAA server.

  
  **Note**  
  If you place a AAA server on a data interface, be sure the management-only routing policies do not match traffic destined for a data interface. For example, if you have a default route through the Diagnostic interface, then traffic will never fall back to the data routing table. Use the `show route management-only` and `show route` commands to verify routing determination.

For both activities on the same AAA servers, in addition to making the servers reachable over the Management interface for user-identity handling, do one of the following to provide VPN authentication access to the same AAA servers:

- Enable and configure the Diagnostic interface with an IP address on the same subnet as the Management interface, and then configure a route to the AAA server through this interface. The Diagnostic interface access will be used for VPN activity, the Management interface access for identity handling.

  **Note**  
  When configured this way, you cannot also have a data interface on the same subnet as the Diagnostic and Management interfaces. If you want the Management interface and a data interface on the same network, for example when using the device itself as a gateway, you will not be able to use this solution because the Diagnostic interface must remain disabled.

- Configure a route through a data interface to the AAA server. The data interface access will be used for VPN activity, the Management interface access for user-identity handling.

For more information about various interfaces, see Regular Firewall Interfaces for Firepower Threat Defense, on page 767.

After deployment, use the following CLI commands to monitor and troubleshoot AAA server connectivity from the Firepower Threat Defense device:

- `show aaa-server` to display AAA server statistics.

- `show route management-only` to view the management-only routing table entries.
• **show network** and **show network-static-routes** to view the Management interface default route and static routes.

• **show route** to view data traffic routing table entries.

• **ping system** and **traceroute system** to verify the path to the AAA server through the Management interface.

• **ping interface** *ifname* and **traceroute** *destination* to verify the path to the AAA server through the Diagnostic and data interfaces.

• **test aaa-server authentication** and **test aaa-server authorization** to test authentication and authorization on the AAA server.

• **clear aaa-server statistics** *groupname* or **clear aaa-server statistics protocol** *protocol* to clear AAA server statistics by group or protocol.

• **aaa-server** *groupname* **active** *host* *hostname* to activate a failed AAA server, or **aaa-server** *groupname* **fail** *host* *hostname* to fail a AAA server.

• **debug ldap level**,** debug aaa authentication**,** debug aaa authorization**, and **debug aaa accounting**.

### License Requirements for Remote Access VPN

**FTD License**

FTD remote access VPN requires Strong Encryption and one of the following licenses for AnyConnect:

- AnyConnect Plus
- AnyConnect Apex
- AnyConnect VPN Only

### Requirements and Prerequisites for Remote Access VPN

**Model Support**

FTD

**Supported Domains**

Any

**User Roles**

Admin
Guidelines and Limitations for Remote Access VPNS

Remote Access VPN Policy Configuration

- You can add a new remote access VPN policy only by using the wizard. You must proceed through the entire wizard to create a new policy; the policy will not be saved if you cancel before completing the wizard.

- Two users must not edit a remote access VPN policy at the same time; however, the web interface does not prevent simultaneous editing. If this occurs, the last saved configuration persists.

- Moving a Firepower Threat Defense device from one domain to another domain is not possible if a remote access VPN policy is assigned to that device.

- Firepower 9300 and 4100 series in cluster mode do not support remote access VPN configuration.

- Remote access VPN connectivity could fail if there is an FTD NAT rule is misconfigured.

- Whenever IKE ports 500/4500 or SSL port 443 is in use or when there are some PAT translations that are active, the AnyConnect IPSec-IKEv2 or SSL remote access VPN cannot be configured on the same port as it fails to start the service on those ports. These ports must not be used on the Firepower Threat Defense device before configuring Remote Access VPN.

- While configuring remote access VPNS using the wizard, you can create in-line certificate enrollment objects, but you cannot use them to install the identity certificate. Certificate enrollment objects are used for generating the identity certificate on the Firepower Threat Defense device being configured as the remote access VPN gateway. Install the identity certificate on the device before deploying the remote access VPN policy to the device. For more information about how to install the identity certificate based on the certificate enrollment object, see The Object Manager, on page 554.

- After you change the remote access VPN policy configurations, re-deploy the changes to the Firepower Threat Defense devices. The time it takes to deploy configuration changes depends on multiple factors such as complexity of the policies and rules, type and volume of configurations you send to the device, and memory and device model. Before deploying remote access VPN policy changes, review the Best Practices for Deploying Configuration Changes, on page 488.

- The ECMP zone interfaces cannot be used in Remote Access VPN (for both IPsec and SSL). Deployment of RA VPN configuration fails if all the RA VPN interfaces that belong to security zones or interface groups also belong to one or more ECMP zones. However, if some of the RA VPN interfaces belonging to the security zones or interface groups also belongs to one or more ECMP zones, deployment of the RA VPN configuration succeeds excluding those interfaces.

Concurrent VPN Sessions Capacity Planning (Hardware Models)

The maximum concurrent VPN sessions are governed by platform-specific limits and have no dependency on the license. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

<table>
<thead>
<tr>
<th>Device Model</th>
<th>Maximum Concurrent Remote Access VPN Sessions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firepower 2110</td>
<td>1500</td>
</tr>
</tbody>
</table>
### Maximum Concurrent Remote Access VPN Sessions

<table>
<thead>
<tr>
<th>Device Model</th>
<th>Maximum Concurrent Remote Access VPN Sessions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firepower 2120</td>
<td>3500</td>
</tr>
<tr>
<td>Firepower 2130</td>
<td>7500</td>
</tr>
<tr>
<td>Firepower 2140</td>
<td>10000</td>
</tr>
</tbody>
</table>

For capacity of other hardware models, contact your sales representative.

---

**Note**

The FTD device denies the VPN connections once the maximum session limit per platform is reached. The connection is denied with a syslog message. Refer the syslog messages %ASA-4-113029 and %ASA-4-113038 in the syslog messaging guide. For more information, see [http://www.cisco.com/c/en/us/td/docs/security/asa/syslog-guide/syslogs.html](http://www.cisco.com/c/en/us/td/docs/security/asa/syslog-guide/syslogs.html)

---

**Controlling Cipher Usage for VPN**

To prevent use of ciphers greater than DES, pre-deployment checks are available at the following locations in the Firepower Management Center:

**Devices > Platform Settings > SSL Settings**

**Devices > VPN > Remote Access > Advanced > IPsec**

For more information about SSL settings and IPsec, see Configure SSL Settings, on page 1357 and Configure Remote Access VPN IPsec/IKEv2 Parameters, on page 1137.

---

**Authentication, Authorization, and Accounting**

- Firepower Threat Defense device supports authentication of remote access VPN users using system-integrated authentication servers only; a local user database is not supported.

- Configure DNS on each device in the topology in to use remote access VPN. Without DNS, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames; it can only resolve IP addresses.

  You can configure DNS using the Platform Settings. For more information, see Configure DNS, on page 1347 and DNS Server Group Objects, on page 627.

---

**Client Certificates**

- If you are using client certificates in your deployment, they must be added to your client's platform independent of the Firepower Threat Defense or Firepower Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

---

**Unsupported Features of AnyConnect**

The only supported VPN client is the Cisco AnyConnect Secure Mobility Client. No other clients or native VPNs are supported. Clientless VPN is not supported for VPN connectivity; it is only used to deploy the AnyConnect client using a web browser.

The following AnyConnect features are not supported when connecting to an FTD secure gateway:
• Posture variants such as Hostscan and Endpoint Posture Assessment, and any Dynamic Access Policies based on the client posture.

• AnyConnect Customization and Localization support. The FTD device does not configure or deploy the files necessary to configure AnyConnect for these capabilities.

• Custom Attributes for the AnyConnect Client are not supported on the FTD. Hence all features that make use of Custom Attributes are not supported, such as Deferred Upgrade on desktop clients and Per-App VPN on mobile clients.

• Local authentication; VPN users cannot be configured on the FTD secure gateway.
  Local CA, the secure gateway cannot act as a Certificate Authority.

• TACACS, Kerberos (KCD Authentication and RSA SDI).

• Browser Proxy.

• VPN load balancing.

### Configuring a New Remote Access VPN Connection

This section provides instructions to configure a new remote access VPN policy with Firepower Threat Defense devices as VPN gateways and Cisco AnyConnect as the VPN client.

<table>
<thead>
<tr>
<th>Step</th>
<th>Do This</th>
<th>More Info</th>
</tr>
</thead>
</table>
| Step 1 | Review the guidelines and prerequisites. | Guidelines and Limitations for Remote Access VPNs, on page 1108  
Prerequisites for Configuring Remote Access VPN, on page 1111 |
| Step 2 | Create a new remote access VPN policy using the wizard. | Create a New Remote Access VPN Policy, on page 1111 |
| Step 3 | Update the access control policy deployed on the device. | Update the Access Control Policy on the Firepower Threat Defense Device, on page 1113 |
| Step 4 | (Optional) Configure a NAT exemption rule if NAT is configured on the device. | (Optional) Configure NAT Exemption, on page 1114 |
| Step 5 | Configure DNS. | Configure DNS, on page 1115 |
| Step 6 | Add an AnyConnect Client Profile. | Add an AnyConnect Client Profile XML File, on page 1115 |
| Step 7 | Deploy the remote access VPN policy. | Deploy Configuration Changes, on page 495 |
| Step 8 | (Optional) Verify the remote access VPN policy configuration. | Verify the Configuration, on page 1117 |
Prerequisites for Configuring Remote Access VPN

- Deploy Firepower Threat Defense devices and configure Firepower Management Center to manage the device with required licenses with export-controlled features enabled. For more information, see VPN Licensing, on page 1072.

- Configure the certificate enrollment object that is used to obtain the identity certificate for each Firepower Threat Defense device that act as a remote access VPN gateway.

- Configure the RADIUS server group object and any AD or LDAP realms being used by remote access VPN policies.

- Ensure that the AAA Server is reachable from the Firepower Threat Defense device for the remote access VPN configuration to work. Configure routing (at Devices > Device Management > Edit Device > Routing) to ensure connectivity to the AAA servers.

  For remote access VPN double authentication, ensure that both the primary and secondary authentication servers are reachable from the Firepower Threat Defense device for the double authentication configuration to work.

- Purchase and enable one of the following Cisco AnyConnect licenses: AnyConnect Plus, AnyConnect Apex, or AnyConnect VPN Only to enable the Firepower Threat Defense Remote Access VPN.

- Download the latest AnyConnect image files from Cisco Software Download Center.

  On your Firepower Management Center web interface, go to Objects > Object Management > VPN > AnyConnect File and add the new AnyConnect client image files.

- Create a security zone or interface group that contains the network interfaces that users will access for VPN connections. See Interface Objects: Interface Groups and Security Zones, on page 572.

- Download the AnyConnect Profile Editor from Cisco Software Download Center to create an AnyConnect client profile. You can use the standalone profile editor to create a new or modify an existing AnyConnect profile.

Create a New Remote Access VPN Policy

You can add a new remote access VPN Policy only by using the Remote Access VPN Policy wizard. The wizard guides you to quickly and easily set up remote access VPNs with basic capabilities. Further, you can enhance the policy configuration by specifying additional attributes as desired and deploy it to your Firepower Threat Defense secure gateway devices.

Before you begin

- Ensure that you complete all the prerequisites listed in Prerequisites for Configuring Remote Access VPN, on page 1111.

Procedure

Step 1  Choose Devices > VPN > Remote Access.
Step 2  Click (Add (\(\text{+}\)) Add to create a new Remote Access VPN Policy using a wizard that walks you through a basic policy configuration.

You must proceed through the entire wizard to create a new policy; the policy is not saved if you cancel before completing the wizard.

Step 3  Select the Target Devices and Protocols.

The Firepower Threat Defense devices selected here will function as your remote access VPN gateways for the VPN client users. You can select the devices from the list or add a new device.

You can select Firepower Threat Defense devices when you create a remote access VPN policy or change them later. See Setting Target Devices for a Remote Access VPN Policy, on page 1117.

You can select SSL or IPSec-IKEv2, or both the VPN protocols. Firepower Threat Defense supports both the protocols to establish secure connections over a public network through VPN tunnels.

Note  Firepower Threat Defense does not support IPSec tunnels with NULL encryption. If you have selected IPSec-IKEv2, make sure that you do not choose NULL encryption for IPSec IKEv2 proposal. See Configure IKEv2 IPsec Proposal Objects, on page 644.

For SSL settings, see Configure SSL Settings, on page 1357.

Step 4  Configure the Connection Profile and Group Policy settings.

A connection profile specifies a set of parameters that define how the remote users connect to the VPN device. The parameters include settings and attributes for authentication, address assignments to VPN clients, and group policies. Firepower Threat Defense device provides a default connection profile named DefaultWEBVPNGroup when you configure a remote access VPN policy.

For more information, see Configure Connection Profile Settings, on page 1118.

For information about configuring,

• AAA settings, see Configure AAA Settings for Remote Access VPN, on page 1120

• LDAP attribute maps, see Configuring LDAP Attribute Mapping, on page 1132

• SAML 2.0 single sign-on authentication, see Configuring a SAML Single Sign-on Authentication, on page 1158

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience for VPN users. You configure attributes such as user authorization profile, IP addresses, AnyConnect settings, VLAN mapping, and user session settings and so on using the group policy. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

For more information, see Configuring Group Policies, on page 1132.

Step 5  Select the AnyConnect Client Image that the VPN users will use to connect to the remote access VPN.

The Cisco AnyConnect Secure Mobility client provides secure SSL or IPSec (IKEv2) connections to the Firepower Threat Defense device for remote users with full VPN profiling to corporate resources. After the remote access VPN policy is deployed on the Firepower Threat Defense device, VPN users can enter the IP address of the configured device interface in their browser to download and install the AnyConnect client.

For information about configuring AnyConnect client profile and client modules, see Group Policy AnyConnect Options, on page 648.

Step 6  Select the Network Interface and Identity Certificate.
Interface objects segment your network to help you manage and classify traffic flow. A security zone object simply groups interfaces. These groups may span multiple devices; you can also configure multiple zones interface objects on a single device. There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

**Step 7**

View the Summary of the Remote Access VPN policy configuration.

The Summary page displays all the remote access VPN settings you have configured so far and provides links to the additional configurations that need to be performed before deploying the remote access VPN policy on the selected devices.

Click **Back** to make changes to the configuration, if required.

**Step 8**

Click **Finish** to complete the basic configuration for the remote access VPN policy.

When you have completed the remote access VPN policy using the wizard, it returns to the policy listing page. Set up DNS configuration, configure access control for VPN users, and enable NAT exemption (if necessary) to complete a basic RA VPN Policy configuration. Then, deploy the configuration and establish VPN connections.

---

**Update the Access Control Policy on the Firepower Threat Defense Device**

Before deploying the remote access VPN policy, you must update the access control policy on the targeted Firepower Threat Defense device with a rule that allows VPN traffic. The rule must allow all traffic coming in from the outside interface, with source as the defined VPN pool networks and destination as the corporate network.

If you have selected the **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** option on the Access Interface tab, you need not update the access control policy for remote access VPN.

Enable or disable the option for all your VPN connections. If you disable this option, make sure that the traffic is allowed by the access control policy or pre-filter policy.

For more information, see *Configure Access Interfaces for Remote Access VPN, on page 1127.*

**Before you begin**

Complete the remote access VPN policy configuration using the Remote Access VPN Policy wizard.

**Procedure**

**Step 1**

On your Firepower Management Center web interface, choose **Policies > Access Control.**

**Step 2**

Select the access control policy assigned to the target devices where the remote access VPN policy will be deployed and click **Edit.**

**Step 3**

Click **Add Rule** to add a new rule.
Step 4 Specify the Name for the rule and select Enabled.

Step 5 Select the Action, Allow or Trust.

Step 6 Select the following on the Zones tab:
   a) Select the outside zone from Available Zones and click Add to Source.
   b) Select the inside zone from Available Zones and click Add to Destination.

Step 7 Select the following on the Networks tab:
   a) Select the inside network (inside interface and/or a corporate network) from Available networks and click Add to Destination.
   b) Select the VPN address pool network from Available Networks and click Add to Source Networks.

Step 8 Configure other required access control rule settings and click Add.

Step 9 Save the rule and access control policy.

---

(Optional) Configure NAT Exemption

NAT exemption exempts addresses from translation and allows both translated and remote hosts to initiate connections with your protected hosts. Like identity NAT, you do not limit translation for a host on specific interfaces; you must use NAT exemption for connections through all interfaces. However, NAT exemption enables you to specify the real and destination addresses when determining the real addresses to translate (similar to policy NAT). Use static identity NAT to consider ports in the access list.

Before you begin

Check if NAT is configured on the targeted devices where remote access VPN policy is deployed. If NAT is enabled on the targeted devices, you must define a NAT policy to exempt VPN traffic.

Procedure

Step 1 On your Firepower Management Center web interface, click Devices > NAT.

Step 2 Select a NAT policy to update or click New Policy > Threat Defense NAT to create a NAT policy with a NAT rule to allow connections through all interfaces.

Step 3 Click Add Rule to add a NAT rule.

Step 4 On the Add NAT Rule window, select the following:
   a) Select the NAT Rule as Manual NAT Rule.
   b) Select the Type as Static.
   c) Click Interface Objects and select the Source and destination interface objects.

Note This interface object must be the same as the interface selected in the remote access VPN policy.

For more information, see Configure Access Interfaces for Remote Access VPN, on page 1127.

a) Click Translation and select the source and destination networks:

   • Original Source and Translated Source
   • Original Destination and Translated Destination
Step 5  On the Advanced tab, select **Do not proxy ARP on Destination Interface**.

*Do not proxy ARP on Destination Interface*—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router.

Step 6  Click **OK**.

**Configure DNS**

Configure DNS on each Firepower Threat Defense device in order to use remote access VPN. Without DNS, the devices cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames. It can only resolve IP addresses.

**Procedure**

Step 1  Configure DNS server details and domain-lookup interfaces using the Platform Settings. For more information, see *Configure DNS*, on page 1347 and *DNS Server Group Objects*, on page 627.

Step 2  Configure split-tunneling group policy to allow DNS traffic through remote access VPN tunnel if the DNS server is reachable through VNP network. For more information, see *Configure Group Policy Objects*, on page 645.

**Add an AnyConnect Client Profile XML File**

An AnyConnect client profile is a group of configuration parameters stored in an XML file that the client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.

You can create an AnyConnect client profile using the AnyConnect Profile Editor. This editor is a GUI-based configuration tool that is available as part of the AnyConnect software package. It is an independent program that you run outside of the Firepower Management Center. For more information about AnyConnect Profile Editor, see *Cisco AnyConnect Secure Mobility Client Administrator Guide*.

**Before you begin**

A Firepower Threat Defense remote access VPN policy requires an AnyConnect client profile to be assigned to the VPN clients. The client profile is attached to a group policy.

Download the AnyConnect Profile Editor from *Cisco Software Download Center*.

**Procedure**

Step 1  Choose **Devices > VPN > Remote Access**.
(Optional) Configure Split Tunneling

Split tunnel allows VPN connectivity to a remote network across a secure tunnel, and it also allows connectivity to a network outside VPN tunnel. You can configure split tunnel if you want to allow your VPN users to access an outside network while they are connected to a remote access VPN. To configure a split-tunnel list, you must create a Standard Access List or Extended Access List.

For more information, see Configuring Group Policies, on page 1132.

Procedure

Step 1 Choose Devices > VPN > Remote Access.
Step 2 Select a Remote Access policy and click Edit.
Step 3 Select a connection profile and click Edit.
Step 4 Click Add to add a group policy, or click Edit Group Policy > General > Split Tunneling.
Step 5 From the IPv4 Split Tunneling or IPv6 Split Tunneling list, select Exclude networks specified below; and then select the networks to be excluded from VPN traffic.
Step 6 If the split tunneling option is left as is, all traffic from the endpoint goes over the VPN connection.
Step 7 If you chose to add a new standard or extended access list, do the following:
   a) Specify the Name for the new access list and click Add.
   b) Select Allow from the Action drop-down.
   c) Select the network traffic to be allowed over the VPN tunnel and click Add.
Step 8 Click Save.

<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Open a web browser on a machine on the outside network.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enter the URL of an FTD device configured as a remote access VPN gateway.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enter the username and password when prompted, and click Logon. <strong>Note</strong> If AnyConnect is installed on the system, you will be connected to the VPN automatically.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>If AnyConnect is not installed, you will be prompted to download the AnyConnect client. Download AnyConnect if it is not installed already and connect to the VPN. The AnyConnect client installs itself. On successful authentication, you will be connected to the Firepower Threat Defense remote access VPN gateway. The applicable identity or QoS policy is enforced according to your remote access VPN policy configuration.</td>
</tr>
</tbody>
</table>

## Setting Target Devices for a Remote Access VPN Policy

You can add targeted devices while you create a new remote access VPN policy, or change them later.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Choose Devices &gt; VPN &gt; Remote Access.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Click Edit (✓) next to the remote access VPN policy that you want to edit.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Click Policy Assignment.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Do any of the following:</td>
</tr>
<tr>
<td></td>
<td>• To assign a device, high-availability pair, or device group to the policy, select it in the Available Devices list and click Add. You can also drag and drop the available devices to select.</td>
</tr>
<tr>
<td></td>
<td>• To remove a device assignment, click Delete (🗑) next to a device, high-availability pair, or device group in the Selected Devices list.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Click OK.</td>
</tr>
</tbody>
</table>

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Additional Remote Access VPN Configurations

Configure Connection Profile Settings

Remote Access VPN policy contains the connection profiles targeted for specific devices. These policies pertain to creating the tunnel itself, such as, how AAA is accomplished, and how addresses are assigned (DHCP or Address Pools) to VPN clients. They also include user attributes, which are identified in group policies configured on the Firepower Threat Defense device or obtained from an AAA server. A device also provides a default connection profile named DefaultWEBVPNGroup. The connection profile that is configured using the wizard appears in the list.

**Procedure**

1. **Step 1** Choose Devices > VPN > Remote Access.
2. **Step 2** Select an existing remote access VPN policy in the list and click the corresponding Edit icon.
3. **Step 3** Select a Connection Profile and click Edit.
   - The edit connection profile page is displayed.
4. **Step 4** (Optional) Add multiple connection profiles.
   - Configure Multiple Connection Profiles, on page 1118
5. **Step 5** Configure IP Addresses for VPN Clients.
   - Configure IP Addresses for VPN Clients, on page 1119
6. **Step 6** (Optional) Update AAA Settings for remote access VPNs.
   - Configure AAA Settings for Remote Access VPN, on page 1120
7. **Step 7** (Optional) Create or update Aliases.
   - Create or Update Aliases for a Connection Profile, on page 1126
8. **Step 8** Save the connection profile.

**Configure Multiple Connection Profiles**

If you decide to grant different rights to different groups of VPN users, then you can configure specific connection profiles or group policies for each of the user groups. For example, you might allow a finance group to access one part of a private network, a customer support group to access another part, and an MIS group to access other parts. In addition, you might allow specific users within MIS to access systems that other MIS users cannot access. Connection profiles and group policies provide the flexibility to do so securely.

You can configure only one connection profile when you create a VPN policy using the Remote Access Policy wizard. You can add more connection profiles later. A device also provides a default connection profile named DefaultWEBVPNGroup.

**Before you begin**

Ensure that you have configured remote access VPN using the Remote Access Policy wizard with a connection profile.
Procedure

Step 1
On your Firepower Management Center web interface, choose Devices > VPN > Remote Access. Existing remote access policies are listed.

Step 2
Select a remote access VPN policy and click Edit.

Step 3
Click Add and specify the following in the Add Connection Profile window:

a) **Connection Profile**—Provide a name that the remote users will use for VPN connections. The connection profile contains a set of parameters that define how the remote users connect to the VPN device.

b) **Client Address Assignment**—Assign IP Address for the remote clients from the local IP Address pools, DHCP servers, and AAA servers.

c) **AAA**—Configure the AAA servers to enable managed devices acting as secure VPN gateways to determine who a user is (authentication), what the user is permitted to do (authorization), and what the user did (accounting).

d) **Aliases**—Provide an alternate name or URL for the connection profile. Remote Access VPN administrators can enable or disable theAlias names and Alias URLs. VPN users can choose an Alias name when they connect to the Firepower Threat Defense device remote access VPN using the AnyConnect VPN client.

Step 4
Click Save.

Related Topics

- [Configure Connection Profile Settings](#), on page 1118

---

**Configure IP Addresses for VPN Clients**

Client address assignment provides a means of assigning IP addresses for the remote access VPN users.

You can configure to assign IP Address for remote VPN clients from the local IP Address pools, DHCP Servers, and AAA servers. The AAA servers are assigned first, followed by others. Configure the **Client Address Assignment** policy in the Advanced tab to define the assignment criteria. The IP pool(s) defined in this connection profile will only be used if no IP pools are defined in group policy associated with the connection profile, or the system default group policy DfltGrpPolicy.

**IPv4 Address Pools**—SSL VPN clients receive new IP addresses when they connect to the Firepower Threat Defense device. Address Pools define a range of addresses that remote clients can receive. Select an existing IP address pool. You can add a maximum of six pools for IPv4 and IPv6 addresses each.

---

**Note**

You can use the IP address from the existing IP pools in Firepower Management Center or create a new pool using the Add option. Also, you can create an IP pool in Firepower Management Center using the Objects > Object Management > Address Pools path. For more information, see Address Pools, on page 654.

---

Procedure

Step 1
On your Firepower Management Center web interface, choose Devices > VPN > Remote Access. Existing remote access policies are listed.

Step 2
Select a remote access VPN policy click Edit.

Step 3
Select the connection profile that you want to update and click Edit > Client Address Assignment.
Step 4  Select the following for Address Pools:
   a) Click Add to add IP addresses, and select IPv4 or IPv6 to add the corresponding address pool. Select the IP address pool from Available Pools and click Add.

   **Note**  If you share your remote access VPN policy among multiple Firepower Threat Defense devices, bear in mind that all devices share the same address pool unless you use device-level object overrides to replace the global definition with a unique address pool for each device. Unique address pools are required to avoid overlapping addresses in cases where the devices are not using NAT.

   b) Select the Add icon in the Address Pools window to add a new IPv4 or IPv6 address pool. When you choose the IPv4 pool, provide a starting and ending IP address. When you choose to include a new IPv6 address pool, enter Number of Addresses in the range 1-16384. Select the Allow Overrides option to avoid conflicts with IP address when objects are shared across many devices. For more information, see Address Pools, on page 654.

c) Click OK.

Step 5  Select the following for DHCP Servers:

**Note**  The DHCP server address can be configured only with IPv4 address.

   a) Specify the name and DHCP (Dynamic Host Configuration Protocol) server address as network objects. Click Add to choose the server from the object list. Click Delete to delete a DHCP server.

   b) Click Add in the New Objects page to add a new network object. Enter the new object name, description, network, and select the Allow Overrides option as applicable. For more information, see Creating Network Objects, on page 565 and Allowing Object Overrides, on page 562.

c) Click OK.

Step 6  Click Save.

**Related Topics**
Configure Connection Profile Settings, on page 1118

**Configure AAA Settings for Remote Access VPN**

**Procedure**

---

**Step 1**  Choose Devices > VPN > Remote Access.

**Step 2**  Select an existing remote access VPN policy in the list and click the corresponding Edit icon.

**Step 3**  Select a connection profile to update AAA settings, click Edit > AAA.

**Step 4**  Select the following for Authentication:

   • **Authentication Method**: Determines how a user is identified before being allowed access to the network and network services. It controls access by requiring valid user credentials, which are typically a username and password. It may also include the certificate from the client.

   When you select the Authentication Method as:

   • **AAA Only**: If you select the Authentication Server as RADIUS, by default, the Authorization Server has the same value. Select the Accounting Server from the drop-down list. Whenever you select AD and LDAP from the Authentication Server drop-down list, you must manually select the Authorization Server and Accounting Server respectively.
• **Client Certificate Only**: Each user is authenticated with a client certificate. The client certificate must be configured on VPN client endpoints. By default, the user name is derived from the client certificate fields CN and OU. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

If you select the Map specific field option, which includes the username from the client certificate, the Primary and Secondary fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

The primary and secondary fields pertaining to the **Map specific field** option contain these common values:

- C (Country)
- CN (Common Name)
- DNQ (DN Qualifier)
- EA (Email Address)
- GENQ (Generational Qualifier)
- GN (Given Name)
- I (Initial)
- L (Locality)
- N (Name)
- O (Organisation)
- OU (Organisational Unit)
- SER (Serial Number)
- SN (Surname)
- SP (State Province)
- T (Title)
- UID (User ID)
- UPN (User Principal Name)

• **Client Certificate & AAA**: Each user is authenticated with both a client certificate and AAA server. Select the required certificate and AAA configurations for authentication.

Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

• **SAML**: Each user is authenticated using the SAML single sign-on server. For more information, see Single Sign-on Authentication with SAML 2.0, on page 1157.
Authentication Server: Authentication is the way a user is identified before being allowed access to the network and network services. Authentication requires valid user credentials, a certificate, or both. You can use authentication alone, or with authorization and accounting.

Select (or add and select) an authentication server:

- **Realm**: Configure an LDAP or AD realm. See Create a Realm, on page 2314.
- **RADIUS Server Group**: Add a RADIUS server group object with RADIUS servers. See RADIUS Server Groups, on page 656.
- **Single Sign-On Server**: Create a single sign-on server object for SAML authentication. See Single Sign-on Server, on page 659.

Use secondary authentication: Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to AAA only and Client Certificate & AAA authentication methods.

Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the AnyConnect login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

Note: By default, secondary authentication is not required.

Authentication Server: Secondary authentication server to provide secondary username and password for VPN users.

Select the following under **Username for secondary authentication**:

- **Prompt**: Prompts the users to enter the username and password while logging on to VPN gateway.
- **Use primary authentication username**: The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.
- **Map username from client certificate**: Prefills the secondary username from the client certificate.
  - If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN** (Common Name) and **OU** (Organisational Unit) respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.

  See **Authentication Method** descriptions for more information about primary and secondary field mapping.

- **Prefill username from certificate on user login window**: Prefills the secondary username from the client certificate when the user connects via AnyConnect VPN client.
  - **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.
Step 5  Select the following for Authorization:

- **Authorization Server**: After authentication is complete, authorization controls the services and commands available to each authenticated user. Authorization works by assembling a set of attributes that describe what the user is authorized to perform, their actual capabilities, and restrictions. When you do not use authorization, authentication alone provides the same access to all authenticated users. Authorization requires authentication.

To know more about how remote access VPN authorization works, see [Understanding Policy Enforcement of Permissions and Attributes](#), on page 1105.

When a RADIUS Server is configured for user authorization in the connection profile, the Remote Access VPN system administrator can configure multiple authorization attributes for users or user-groups. The authorization attributes that are configured on the RADIUS server can be specific for a user or a user-group. Once users are authenticated, these specific authorization attributes are pushed to the Firepower Threat Defense device.

**Note**  The AAA server attributes obtained from the authorization server override the attribute values that may have been previously configured on the group policy or the connection profile.

- Check **Allow connection only if user exists in authorization database** if desired.

  When enabled, the system checks the username of the client must exist in the authorization database to allow a successful connection. If the username does not exist in the authorization database, then the connection is denied.

- When you select a realm as the Authorization Server, you must configure an LDAP attribute map. You can choose a single server for authentication and authorization or a different servers. Click **Configure LDAP Attribute Map** to add LDAP attribute maps for authorization.

  **Note**  Firepower Threat Defense does not support SAML Identity Provider as the Authorization server. If the Active Directory behind the SAML Identity Provider is reachable via FMC and FTD, you can configure authorization following these steps:

  - Add realm for the AD Server. See [Create a Realm](#), on page 2314.
  - Select the realm object as the Authorization Server in remote access VPN connection profile.
  - Configure LDAP attribute map for the selected realm.

  For information about configuring LDAP attribute maps, see [Configuring LDAP Attribute Mapping](#), on page 1132.

Step 6  Select the following for Accounting:

- **Accounting Server**: Accounting is used to track the services that users are accessing and the amount of network resources they are consuming. When AAA accounting is activated, the network access server reports user activity to the RADIUS server. Accounting information includes when sessions start and stop, usernames, the number of bytes that pass through the device for each session, the services used, and the duration of each session. This data can then be analyzed for network management, client billing, or auditing. You can use accounting alone or together with authentication and authorization.
Specify the RADIUS Server Group object that will be used to account for the Remote Access VPN session.

**Step 7** Select the following **Advanced Settings**:

- **Strip Realm from username**: Select to remove the realm from the username before passing the username on to the AAA server. For example, if you select this option and provide `domain\username`, the domain is stripped off from the username and sent to AAA server for authentication. By default this option is unchecked.

- **Strip Group from username**: Select to remove the group name from the username before passing the username on to the AAA server. By default this option is unchecked.

  **Note** A realm is an administrative domain. Enabling these options allows the authentication to be based on the username alone. You can enable any combination of these options. However, you must select both check boxes if your server cannot parse delimiters.

- **Password Management**: Enable managing the password for the Remote Access VPN users. Select to notify ahead of the password expiry or on the day the password expires.

**Step 8** Click **Save**.

**RADIUS Server Attributes for Firepower Threat Defense**

The Firepower Threat Defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from the external RADIUS server that are configured for authentication and/or authorization in the remote access VPN policy.

**Note** Firepower Threat Defense devices support attributes with vendor ID 3076.

The following user authorization attributes are sent to the Firepower Threat Defense device from the RADIUS server:

- RADIUS attributes 146 and 150 are sent from Firepower Threat Defense devices to the RADIUS server for authentication and authorization requests.
- All three (146, 150, and 151) attributes are sent from Firepower Threat Defense devices to the RADIUS server for accounting start, interim-update, and stop requests.

Create or Update Aliases for a Connection Profile

Aliases contain alternate names or URLs for a specific connection profile. Remote Access VPN administrators can enable or disable the Alias names and Alias URLs. VPN users can choose an Alias name when they connect to the Firepower Threat Defense device. Aliases names for all connections configured on this device can be turned on or off for display. You can also configure the list of Alias URLs, which your endpoints can select while initiating the Remote Access VPN connection. If users connect using the Alias URL, system will automatically log them using the connection profile that matches the Alias URL.

Procedure

**Step 1** Choose Devices > VPN > Remote Access.

**Step 2** From the list of available VPN policies, select the policy for which you want to modify the settings.

**Step 3** Select a Connection Profile and click Edit.

**Step 4** Click Aliases.

**Step 5** To add an Alias name, do the following:

a) Click Add under Alias Names.

b) Specify theAlias Name.

c) Select theEnabled check box in each window to enable the aliases.

d) Click OK.

**Step 6** To add an Alias URL, do the following:

a) Click Add under Alias URLs.

b) Select theAlias URL from the list or create a new URL object. For more information see Creating URL Objects, on page 571.

c) Select theEnabled check box in each window to enable the aliases.

d) Click OK.

• ClickEdit to edit the Alias name or the Alias URL.

---

### Configure Access Interfaces for Remote Access VPN

The **Access Interface** table lists the interface groups and security zones that contain the device interfaces. These are configured for remote access SSL or IPsec IKEv2 VPN connections. The table displays the name of each interface group or security-zone, the interface trustpoints used by the interface, and whether Datagram Transport Layer Security (DTLS) is enabled.

**Procedure**

1. **Step 1**  
Choose **Devices > VPN > Remote Access**.
2. **Step 2**  
Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
3. **Step 3**  
Click **Access Interface**.
4. **Step 4**  
To add an access interface, select **Add** and specify values for the following in the **Add Access Interface** window:
   a) **Access Interface**—Select the interface group or security zone to which the interface belongs. The interface group or security zone must be a Routed type. Other interface types are not supported for Remote Access VPN connectivity.
   b) Associate the **Protocol** object with the access interface by selecting the following options:
      - **Enable IPSec-IKEv2**—Select this option to enable IKEv2 settings.
      - **Enable SSL**—Select this option to enable SSL settings.
      - Select **Enable Datagram Transport Layer Security**.
        When selected, it enables Datagram Transport Layer Security (DTLS) on the interface and allows an AnyConnect VPN client to establish an SSL VPN connection using two simultaneous tunnels—an SSL tunnel and a DTLS tunnel.
        Enabling DTLS avoids the latency and bandwidth problems associated with certain SSL connections and improves the performance of real-time applications that are sensitive to packet delays.
        To configure SSL settings, and TLS and DTLS versions, see **About SSL Settings**, on page 1358.
        To configure SSL settings for the AnyConnect VPN client, see **Group Policy AnyConnect Options**, on page 648.
      - Select the **Configure Interface Specific Identity Certificate** check box and select **Interface Identity Certificate** from the drop-down list.
        If you do not select the Interface Identity Certificate, the **Trustpoint** will be used by default.
        If you do not select the Interface Identity Certificate or Trustpoint, the **SSL Global Identity Certificate** will be used by default.
c) Click OK to save the changes.

**Step 5** Select the following under Access Settings:

- Allow Users to select connection profile while logging in—If you have multiple connection profiles, selecting this option allows the user to select the correct connection profile during login. You must select this option for IPsec-IKEv2 VPNs.

**Step 6** Use the following options to configure SSL Settings:

- Web Access Port Number—The port to use for VPN sessions. The default port is 443.
- DTLS Port Number—The UDP port to use for DTLS connections. The default port is 443.
- SSL Global Identity Certificate—The selected SSL Global Identity Certificate will be used for all the associated interfaces if the Interface Specific Identity Certificate is not provided.

**Step 7** For IPsec-IKEv2 Settings, select the IKEv2 Identity Certificate from the list or add an identity certificate.

**Step 8** Under the Access Control for VPN Traffic section, select the following option if you want to bypass access control policy:

- Bypass Access Control policy for decrypted traffic (sysopt permit-vpn) — Decrypted traffic is subjected to Access Control Policy inspection by default. Enabling the Bypass Access Control policy for decrypted traffic option bypasses the ACL inspection, but VPN Filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

  **Note** If you select this option, you need not update the access control policy for remote access VPN as specified in Update the Access Control Policy on the Firepower Threat Defense Device, on page 1113.

**Step 9** Click Save to save the access interface changes.

### Configuring Remote Access VPN Advanced Options

#### Cisco AnyConnect Secure Mobility Client Image

**Cisco AnyConnect Secure Mobility Client Image**

The Cisco AnyConnect Secure Mobility client provides secure SSL or IPsec (IKEv2) connections to the Firepower Threat Defense device for remote users with full VPN profiling to corporate resources. Without a previously-installed client, remote users can enter the IP address of an interface configured to accept clientless VPN connections in their browser to download and install the AnyConnect client. The Firepower Threat Defense device downloads the client that matches the operating system of the remote computer. After downloading, the client installs and establishes a secure connection. In case of a previously installed client, when the user authenticates, the Firepower Threat Defense device, examines the version of the client, and upgrades the client if necessary.
The Remote Access VPN administrator associates any new or additional AnyConnect client images to the VPN policy. The administrator can unassociate the unsupported or end of life client packages that are no longer required.

The Firepower Management Center determines the type of operating system by using the file package name. If the user renamed the file without indicating the operating system information, the valid operating system type must be selected from the list box.

Download the AnyConnect client image file by visiting Cisco Software Download Center.

Related Topics
Adding a Cisco AnyConnect Mobility Client Image to the Firepower Management Center, on page 1129

Adding a Cisco AnyConnect Mobility Client Image to the Firepower Management Center

You can upload the Cisco AnyConnect Mobility client image to the Firepower Management Center by using the AnyConnect File object. For more information, see FTD File Objects, on page 652. For more information about the client image, see Cisco AnyConnect Secure Mobility Client Image, on page 1128.

Click Show re-order link to view a specific client image.

Note
To delete an already installed Cisco AnyConnect client image, click Delete in that row.

Procedure

Step 1 On the Firepower Management Center web interface, choose Devices > VPN > Remote Access, choose and edit a listed RA VPN policy, then choose the Advanced tab.

Step 2 Click Add in the Available AnyConnect Images portion of the AnyConnect Images dialog.

Step 3 Enter the Name, File Name, and Description for the available AnyConnect Image.

Step 4 Click Browse to navigate to the location for selecting the client image to be uploaded.

Step 5 Click Save to upload the image in the Firepower Management Center.

Once you upload the client image to the Firepower Management Center, the operating system displays platform information for the image that you uploaded to the Firepower Management Center.

Update AnyConnect Images for Remote Access VPN Clients

When new AnyConnect client updates are available in Cisco Software Download Center, you can download the packages manually and add them to the remote access VPN policy so that the new AnyConnect packages are upgraded on the VPN client systems according to their operating systems.

Before you begin

Instructions in this section help you update new AnyConnect client images to remote access VPN clients connecting to Firepower Threat Defense VPN gateway. Ensure that the following configurations are complete before updating your AnyConnect images:
• Download the latest AnyConnect image files from Cisco Software Download Center.

• On your Firepower Management Center web interface, go to Objects > Object Management > VPN > AnyConnect File and add the new AnyConnect client image files.

Procedure

**Step 1** On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.

**Step 2** Select an existing remote access policy in the list and click Edit.

**Step 3** Click Advanced > AnyConnect Client Image > Add.

**Step 4** Select a client image file from Available AnyConnect Images and click Add.

If the required AnyConnect client image is not listed, click Add to browse and upload an image.

**Step 5** Save the remote access VPN policy.

After the remote access VPN policy changes are deployed, the new AnyConnect client images are updated on the Firepower Threat Defense device that is configured as the remote access VPN gateway. When a new VPN user connects to the VPN gateway, the user will get the new AnyConnect client image to download depending on the operating system of the client system. For existing VPN users, the AnyConnect client image will be updated in their next VPN session.

**Related Topics**

Remote Access VPN Connection Profile Options

**Remote Access VPN Address Assignment Policy**

The Firepower Threat Defense device can use an IPv4 or IPv6 policy for assigning IP addresses to Remote Access VPN clients. If you configure more than one address assignment method, the Firepower Threat Defense device tries each of the options until it finds an IP address.

**IPv4 or IPv6 Policy**

You can use the IPv4 or IPv6 policy to address an IP address to Remote Access VPN clients. Firstly, you must try with the IPv4 policy and later followed by IPv6 policy.

• **Use Authorization Server**—Retrieves address from an external authorization server on a per-user basis. If you are using an authorization server that has IP address configured, we recommend using this method. Address assignment is supported by RADIUS-based authorization server only. It is not supported for AD/LDAP. This method is available for both IPv4 and IPv6 assignment policies.

• **Use DHCP**—Obtains IP addresses from a DHCP server configured in a connection profile. You can also define the range of IP addresses that the DHCP server can use by configuring DHCP network scope in the group policy. If you use DHCP, configure the server in the Objects > Object Management > Network pane. This method is available for IPv4 assignment policies.

  For more information about DHCP network scope configuration, see Group Policy General Options, on page 646.

• **Use an internal address pool**—Internally configured address pools are the easiest method of address pool assignment to configure. If you use this method, create the IP address pools in the Objects > Object Management > Address Pools pane and select the same in the connection profile. This method is available for both IPv4 and IPv6 assignment policies.
- **Reuse an IP address so many minutes after it is released**—Delays the reuse of an IP address after its return to the address pool. Adding a delay helps to prevent problems firewalls can experience when an IP address is reassigned quickly. By default, the delay is set to zero, meaning the Firepower Threat Defense device does not impose a delay in reusing the IP address. If you want to extend the delay, enter the number of minutes in the range 0 - 480 to delay the IP address reassignment. This configurable element is available for IPv4 assignment policies.

Configuring Group Policies

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

The group policy applied to a user is determined when the VPN tunnel is being established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

Note

There is no group policy attribute inheritance on the FTD. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

Procedure

Step 1 Choose Devices > VPN > Remote Access.
Step 2 Select an existing remote access VPN policy in the list and click the corresponding Edit icon.
Step 3 Click Advanced > Group Policies.
Step 4 Select one or more group policies to associate with this remote access VPN policy. These are above and beyond the default group policy assigned during the remote access VPN policy creation. Click Add.

Use the Refresh and Search utilities to locate the group policy. Add a new group policy object if necessary.

Step 5 Select group policies from the available group policy and click Add to select them.
Step 6 Click OK to complete the group policy selection.

Configure Group Policy Objects, on page 645

Configuring LDAP Attribute Mapping

An LDAP attribute name maps LDAP user or group Attribute name to a Cisco-understandable name. The attribute map equates attributes that exist in the Active Directory (AD) or LDAP server with Cisco attribute names. Any standard LDAP attribute can be mapped to a well-known vendor specific attribute (VSA). One or more LDAP attribute(s) can be mapped to one or more Cisco LDAP attributes. When the AD or LDAP server returns authentication to the FTD device during remote access VPN connection establishment, the FTD device can use the information to adjust how the AnyConnect VPN client completes the connection.

When you want to provide VPN users with different access permissions or VPN content, you can configure different VPN policies on the VPN server and assign these policy-sets to each user based on their credentials. You can achieve this in FTD by configuring LDAP authorization, with LDAP attribute maps. In order to use LDAP to assign a group policy to a user, you need to configure a map that maps an LDAP attribute, such as the Active Directory (AD) attribute memberOf, to the VPN-Group attribute that is understood by the VPN headend.

An LDAP attribute map consists of three components:
• **Name**—Specifies the name for the LDAP attribute map; the name is generated based on the selected realm.

• **Attribute Name Mapping** — Maps the LDAP user or group attribute name to Cisco-understandable name.

• **Attribute Value Mapping** — Maps value in the LDAP user or group attribute to the value of a Cisco attribute for the selected name mapping.

When a user connects to FTD remote access VPN, if the `memberOf` field matches the configured value, then group policy `VPN-Group` is applied to the user’s VPN Session.

The group policies used in an LDAP attribute map are added to the list of group policies in a remote access VPN configuration. When a group policy is removed from a remote access VPN configuration, the associated LDAP attribute mapping is also removed.

**Procedure**

**Step 1**  
Choose **Devices > VPN > Remote Access**.

**Step 2**  
Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

**Step 3**  
Click **Advanced > LDAP Attribute Mapping**.

**Step 4**  
Click **Add**.

**Step 5**  
On the Configure LDAP Attribute Map page, select a **Realm** to configure the attribute map.  

The name for the LDAP attribute map is generated based on the selected realm. If you change the realm, the LDAP attribute name is also changed.

**Step 6**  
Click **Add**.

You can configure multiple attribute maps. Each attribute map requires that you configure a name map and value maps.

**Note**  
Ensure that you follow these guidelines while creating an LDAP attribute map:

• You must configure one mapping for an LDAP attribute; multiple mappings with same LDAP attribute name is not allowed.

• Configuring a minimum of one Name map is mandatory to create an LDAP attribute map.

• Remove any LDAP attribute map if the attribute map is not associated with any connection profile in a remote access VPN configuration.

• Use the correct spelling and capitalization in the LDAP attribute map for both the Cisco and LDAP attribute names and values.

a) Specify the **LDAP Attribute Name** and then select the required **Cisco Attribute Name** from the list.

b) Click **Add Value Map** and Specify the **LDAP Attribute Value** and **Cisco Attribute Value**.

Repeat this step to add more value maps.

You can click the respective **Delete** icon to delete an LDAP attribute map, a name map, or a value map.

**Step 7**  
Click **OK** to complete LDAP attribute map configuration.
Step 8  Click Save to save the changes to the LDAP attribute mapping.

Configuring IPsec Settings for Remote Access VPNs

The IPsec settings are applicable only if you selected IPsec as the VPN protocol while configuring your remote access VPN policy. If not, you can enable IKEv2 using the Edit Access Interface dialog box. See Configure Access Interfaces for Remote Access VPN, on page 1127 for more information.

Procedure

Step 1  Choose Devices > VPN > Remote Access.
Step 2  From the list of available VPN policies, select the policy for which you want to modify the settings.
Step 3  Click Advanced.

The list of IPsec settings appears in a navigation pane on the left of the screen.

Step 4  Use the navigation pane to edit the following IPsec options:
   a) Crypto Maps—The Crypto Maps page lists the interface groups on which IKEv2 protocol is enabled. Crypto Maps are auto generated for the interfaces on which IKEv2 protocol is enabled. To edit a Crypto Map, see Configure Remote Access VPN Crypto Maps, on page 1134. You can add or remove interface groups to the selected VPN policy in Access Interface. See Configure Access Interfaces for Remote Access VPN, on page 1127 for more information.
   b) IKE Policy—The IKE Policy page lists all the IKE policy objects applicable for the selected VPN policy when AnyConnect endpoints connect using the IPsec protocol. See IKE Policies in Remote Access VPNs, on page 1136 for more information. To add a new IKE policy, see Configure IKEv2 Policy Objects , on page 641. FTD supports only AnyConnect IKEv2 clients. Third-party standard IKEv2 clients are not supported.
   c) IPsec/IKEv2 Parameters—The IPsec/IKEv2 Parameters page enables you to modify the IKEv2 session settings, IKEv2 Security Association settings, IPsec settings, and NAT Transparency settings. See Configure Remote Access VPN IPsec/IKEv2 Parameters, on page 1137 for more information.

Step 5  Click Save.

Configure Remote Access VPN Crypto Maps

Crypto maps are automatically generated for the interfaces on which IPsec-IKEv2 protocol has been enabled. You can add or remove interface groups to the selected VPN policy in Access Interface. See Configure Access Interfaces for Remote Access VPN, on page 1127 for more information.

Procedure

Step 1  Choose Devices > VPN > Remote Access.
Step 2  From the list of available VPN policies, select the policy for which you want to modify the settings.
Step 3 Click the Advanced > Crypto Maps, and select a row in the table and click Edit to edit the Crypto map options.

Step 4 Select IKEv2 IPsec Proposals and select the transform sets to specify which authentication and encryption algorithms will be used to secure the traffic in the tunnel.

Step 5 Select Enable Reverse Route Injection to enable static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

Step 6 Select Enable Client Services and specify the port number.

The Client Services Server provides HTTPS (SSL) access to allow the AnyConnect Downloader to receive software upgrades, profiles, localization and customization files, CSD, SCEP, and other file downloads required by the AnyConnect client. If you select this option, specify the client services port number. If you do not enable the Client Services Server, users will not be able to download any of these files that the AnyConnect client might need.

Note You can use the same port that you use for SSL VPN running on the same device. Even if you have an SSL VPN configured, you must select this option to enable file downloads over SSL for IPsec-IKEv2 clients.

Step 7 Select Enable Perfect Forward Secrecy and select the Modulus group.

Use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list.

Modulus group is the Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the modulus group that you want to allow in the remote access VPN configuration:

- 1—Diffie-Hellman Group 1 (768-bit modulus).
- 5—Diffie-Hellman Group 5 (1536-bit modulus, considered good protection for 128-bit keys, but group 14 is better). If you are using AES encryption, use this group (or higher).
- 14—Diffie-Hellman Group 14 (2048-bit modulus, considered good protection for 128-bit keys).
- 19—Diffie-Hellman Group 19 (256-bit elliptical curve field size).
- 20—Diffie-Hellman Group 20 (384-bit elliptical curve field size).
- 21—Diffie-Hellman Group 21 (521-bit elliptical curve field size).

Step 8 Specify the Lifetime Duration (seconds).

The lifetime of the security association (SA), in seconds. When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

You can specify a value from 120 to 2147483647 seconds. The default is 28800 seconds.
Step 9  Specify the **Lifetime Size (kbytes)**.

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires.

You can specify a value from 10 to 2147483647 kbytes. The default is 4,608,000 kilobytes. No specification allows infinite data.

Step 10  Select the following **ESPv3 Settings**:

- **Validate incoming ICMP error messages**—Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.

- **Enable 'Do Not Fragment' Policy**—Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header, and select one of the following from the **Policy** list:
  - Copy—Maintains the DF bit.
  - Clear—Ignores the DF bit.
  - Set—Sets and uses the DF bit.

- **Select Enable Traffic Flow Confidentiality (TFC) Packets**—Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.
  - Burst—Specify a value from 1 to 16 bytes.
  - Payload Size—Specify a value from 64 to 1024 bytes.
  - Timeout—Specify a value from 10 to 60 seconds.

Step 11  Click OK.

---

- Interface Objects: Interface Groups and Security Zones, on page 572

**IKE Policies in Remote Access VPNs**

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters are used to protect subsequent IKE negotiations.

**Note**

FTD supports only IKEv2 for remote access VPNs.

Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups in one policy. Since peers choose during the Phase 1 negotiation, this makes it possible to create a single IKE proposal, but
consider multiple, different proposals to give higher priority to your most desired options. For IKEv2, the policy object does not specify authentication, other policies must define the authentication requirements.

An IKE policy is required when you configure a remote access IPsec VPN.

**Configuring Remote Access VPN IKE Policies**

The IKE Policy table specifies all the IKE policy objects applicable for the selected VPN configuration when AnyConnect endpoints connect using the IPsec protocol. For more information, see IKE Policies in Remote Access VPNs, on page 1136.

---

**Note**

FTD supports only IKEv2 for remote access VPNS.

**Procedure**

**Step 1** Choose Devices > VPN > Remote Access.

**Step 2** From the list of available VPN policies, select the policy for which you want to modify the settings.

**Step 3** Click Advanced > IKE Policy.

**Step 4** Click Add to select from the available IKEv2 policies, or add a new IKEv2 policy and specify the following:

- **Name**—Name of the IKEv2 policy.
- **Description**—Optional description of the IKEv2 policy
- **Priority**—The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA).
- **Lifetime**—Lifetime of the security association (SA), in seconds
- **Integrity**—The Integrity Algorithms portion of the Hash Algorithm used in the IKEv2 policy.
- **Encryption**—The Encryption Algorithm used to establish the Phase 1 SA for protecting Phase 2 negotiations.
- **PRF Hash**—The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy.
  In IKEv2, you can specify different algorithms for these elements.
- **DH Group**—The Diffie-Hellman group used for encryption.

**Step 5** Click Save.

**Related Topics**

Remote Access VPN Access Interface Options

**Configure Remote Access VPN IPsec/IKEv2 Parameters**

**Procedure**
Step 1 Choose Devices > VPN > Remote Access.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click Advanced > IPsec > IPsec/IKEv2 Parameters.

Step 4 Select the following for IKEv2 Session Settings:

- **Identity Sent to Peers**—Choose the identity that the peers will use to identify themselves during IKE negotiations:
  - **Auto**—Determines the IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
  - **IP address**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
  - **Hostname**—Uses the fully qualified domain name (FQDN) of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

- **Enable Notification on Tunnel Disconnect**—Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. Sending this notification is disabled by default.

- **Do not allow device reboot until all sessions are terminated**—Check to enable waiting for all active sessions to voluntarily terminate before the system reboots. This is disabled by default.

Step 5 Select the following for IKEv2 Security Association (SA) Settings:

- **Cookie Challenge**—Whether to send cookie challenges to peer devices in response to SA initiated packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:
  - **Custom**—Specify **Threshold to Challenge Incoming Cookies**, the percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%. The default is 50%.
  - **Always**—Select to send cookie challenges to peer devices always.
  - **Never**—Select to never send cookie challenges to peer devices.

- **Number of SAs Allowed in Negotiation**—Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check. The default is 100%.

- **Maximum number of SAs Allowed**—Limits the number of allowed IKEv2 connections.

Step 6 Select the following for IPsec Settings:

- **Enable Fragmentation Before Encryption**—This option lets traffic travel across NAT devices that do not support IP fragmentation. It does not impede the operation of NAT devices that do support IP fragmentation.

- **Path Maximum Transmission Unit Aging**—Check to enable PMTU (Path Maximum Transmission Unit) Aging, the interval to Reset PMTU of an SA (Security Association).

- **Value Reset Interval**—Enter the number of minutes at which the PMTU value of an SA (Security Association) is reset to its original value. Valid range is 10 to 30 minutes, default is unlimited.
Step 7  
Select the following for NAT Settings:

- **Keepalive Messages Traversal**—Select whether to enable NAT keepalive message traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there is a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPSec flow. If you select this option, configure the interval, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 10 to 3600 seconds. The default is 20 seconds.

- **Interval**—Sets the NAT keepalive interval, from 10 to 3600 seconds. The default is 20 seconds.

Step 8  
Click **Save**.

---

**Configure AnyConnect Management VPN Tunnel**

A management VPN tunnel provides connectivity to the corporate network whenever a client system is powered up, without the VPN users having to connect to the VPN. This helps organizations keep their endpoints up-to-date with software patches and updates. Management tunnel disconnects when the user-initiated VPN tunnel is established.

This section provides information about configuring AnyConnect management VPN tunnel on FTD. Configuring an AnyConnect management tunnel on FTD using the FMC web interface requires the following settings:

- A **Connection profile** with certificate-based authentication and a group URL.

- **AnyConnect management VPN profile file**, configured a server with group URL and backup servers if required.

- A **Group policy** with the management VPN profile, split tunneling with explicitly included networks, client bypass protocol, and no banner.

For detailed instructions to configure an AnyConnect Management VPN tunnel, see Configuring AnyConnect Management VPN Tunnel on FTD, on page 1140.

**Requirements and Prerequisites for AnyConnect Management VPN Tunnel**

**Software and Configuration Requirements**

Ensure that you have the following before you configure the AnyConnect Management tunnel on using the FTD using the FMC web interface:

- Ensure that you are using FTD and FMC versions 6.7.0 or above.

- Download the AnyConnect VPN Webdeploy package 4.7 or above and upload it to FTD remote access VPN.

- Ensure that the certificate authentication is configured in the connection profile.

- Ensure that no banner is configured in the group policy.

- Check the split tunneling configuration in the management tunnel-group policy.
Certificate Requirements

- FTD must have a valid identity certificate for remote access VPN and the root certificate from the local certifying authority (CA) must be present on the FTD.
- Endpoints connecting to the management VPN tunnel must have a valid identity certificate.
- CA certificate for FTD's identity certificate must be installed on the endpoints and the CA certificate for the endpoints must be installed on the FTD.
- The identity certificate issued by the same local CA must be present in the Machine store.

Certificate Store (For Windows) and/or in System Keychain (For macOS).

Limitations of AnyConnect Management VPN Tunnel

- AnyConnect Management VPN Tunnel supports only certificate authentication, it does not support AAA-based authentication.
- Public or private proxy settings are not supported.
- AnyConnect client upgrade and AnyConnect module download are not supported when the management VPN tunnel is connected.

Configuring AnyConnect Management VPN Tunnel on FTD

Procedure

Step 1  Create a remote access VPN policy configuration using the wizard:
For information about configuring a remote access VPN, see Configuring a New Remote Access VPN Connection, on page 1110.

Step 2  Configure connection profile settings for management VPN tunnel:
Note  It is advisable to create a new connection profile to be used only for AnyConnect management VPN tunnel.

- a) Edit the remote access VPN policy you have created.
- b) Select and edit the connection profile that will be used for management VPN tunnel.
- c) Click AAA > Authentication Method and select Client Certificate Only. Configure the authorization and accounting settings as required.
- d) Click the Aliases tab of the connection profile.
- e) Click Add (+) under URL Aliases and URL Alias for the connection profile.
- f) Click Enabled to enable the URL.
- g) Click OK and then click Save to save the connection profile settings.

For more information about connection profile settings, see Configure Connection Profile Settings, on page 1118.

Step 3  Create a management tunnel profile using the AnyConnect profile editor:

- a) Download the AnyConnect VPN Management Tunnel Standalone Profile Editor from Cisco Software Download Center if you have not done already.
b) Create a management tunnel profile with the required settings for your VPN users and save the file.
c) Configure a server in the Server List with the group URL you have configured in the connection profile.

For information about creating a management profile using the Profile Editor, see the *Cisco AnyConnect Secure Mobility Client Administrator Guide*.

**Step 4**  
Create a management tunnel object:

a) On your Firepower Management Center web interface, navigate to Object > Object Management > VPN > AnyConnect File

b) Click Add AnyConnect File.

c) Specify the Name for the AnyConnect file.

d) Click Browse and select the management tunnel profile file you have saved.

e) Click the File Type drop-down and select AnyConnect Management VPN Profile.

f) Click Save.

Note You can also create the management tunnel object when you create or update AnyConnect settings for a group policy. See Group Policy AnyConnect Options, on page 648.

**Step 5**  
Associate a management profile with a group policy and configure group policy settings:

You must add the management VPN profile to the group policy associated with the connection profile used for the management tunnel VPN connection. When the user connects, the management VPN profile is downloaded along with the user VPN profile already mapped to the group policy, enabling the management VPN tunnel feature.

Caution No Banner: Check and ensure that no banner is configured in the group policy settings. You can check the banner settings under Group Policy > General Settings > Banner.

a) Edit the connect profile you have created for management VPN tunnel.

b) Click Edit Group Policy > AnyConnect > Management Profile.

c) Click the Management VPN Profile drop-down and select the management profile file object you have created.

Note You can also click + and add a new AnyConnect Management VPN Profile object.

d) Click Save.

**Step 6**  
Configure split tunneling in group policy:

a) Click Edit Group Policy > General > Split Tunneling.

b) From the IPv4 or IPv6 split tunneling drop-down, select Tunnel networks specified below.

c) Select the Split Tunnel Network List Type: Standard Access List or Extended Access List, and then select the required access list to allow the traffic over the management VPN tunnel.

d) Click Save to save the split tunnel settings.

**AnyConnect Custom Attribute**

AnyConnect Management VPN tunnel requires split include tunneling configuration by default. If you are configuring AnyConnect custom attribute in the group policy to deploy the management VPN tunnel with split tunneling to tunnel all, you can do so using FlexConfig because FMC 6.7 web interface does not support AnyConnect custom attribute.

The following is an example command for AnyConnect custom attribute:

```
webvpn
anyconnect-custom-attr ManagementTunnelAllAllowed description ManagementTunnelAllAllowed
```
Step 7  Deploy, verify, and monitor the remote access VPN policy:
   a) Deploy the management VPN tunnel configuration to FTD.
      
      **Note**  Client systems must connect to the FTD remote access VPN once to download the management tunnel VPN profile to the client machines.
   
   b) You can verify the AnyConnect management VPN tunnel at AnyConnect Secure Mobility Client > VPN > Statistics.
      You can also check the management VPN session details on the FTD command prompt using the show vpn-sessiondb anyconnect command.
   
   c) On your FMC web interface, click **Analysis** to view the management tunnel session information.

**Related Topics**

**Customizing Remote Access VPN AAA Settings**

This section provides information about customizing your AAA preferences for remote access VPNs. For more information, see Configure AAA Settings for Remote Access VPN, on page 1120.

**Authenticate VPN Users via Client Certificates**

You can configure remote access VPN authentication using client certificate when you create a new remote access VPN policy using the wizard or by editing the policy later.

**Before you begin**

Configure the certificate enrollment object that is used to obtain the identity certificate for each Firepower Threat Defense device that acts as a VPN gateway.

**Procedure**

---

**Step 1**  On your Firepower Management Center web interface, choose **Devices > VPN > Remote Access**.

**Step 2**  Select a remote access policy and click **Edit**; or click **Add** to create a new remote access VPN policy.

**Step 3**  For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.

**Step 4**  Click **AAA > Authentication Method > Client Certificate Only**.  
With this authentication method, the user is authenticated using a client certificate. You must configure the client certificate on VPN client endpoints. By default, the user name is derived from client certificate fields CN and OU respectively. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.
If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display the following default values, respectively: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields, that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

- Primary and Secondary fields pertaining to the **Map specific field** option contains these common values:
  - C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier)
  - EA (Email Address)
  - GENQ (Generational Qualifier)
  - GN (Given Name)
  - I (Initial)
  - L (Locality)
  - N (Name)
  - O (Organisation)
  - OU (Organisational Unit)
  - SER (Serial Number)
  - SN (Surname)
  - SP (State Province)
  - T (Title)
  - UID (User ID)
  - UPN (User Principal Name)

- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

For more information, see **Configure AAA Settings for Remote Access VPN**, on page 1120.

**Related Topics**

- **Configure Connection Profile Settings**, on page 1118
- **Adding Certificate Enrollment Objects**, on page 621

**Configure Remote Access VPN Login via Client Certificate and AAA Server**

When remote access VPN authentication is configured to use both client certificate and authentication server, VPN client authentication is done using both the client certificate validation and AAA server.
Configure Remote Access VPN Login via Client Certificate and AAA Server

Before you begin

- Configure the certificate enrollment object that is used to obtain the identity certificate for each Firepower Threat Defense device that acts as a VPN gateway.
- Configure the RADIUS server group object and any AD or LDAP realms being used by this remote access VPN policy.
- Ensure that the AAA Server is reachable from the Firepower Threat Defense device for the remote access VPN configuration to work.

Procedure

Step 1
On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.

Step 2
Select an existing remote access policy and click Edit; or click Add to create a new remote access VPN policy.

Step 3
For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click Edit.

Step 4
Click AAA > Authentication Method, Client Certificate & AAA.

- When you select the Authentication Method as:

  **Client Certificate & AAA**—Both types of authentication are done.

  - **AAA**—If you select the Authentication Server as RADIUS, by default, the Authorization Server has the same value. Select the Accounting Server from the drop-down list. Whenever you select AD and LDAP from the Authentication Server drop-down list, you must manually select the Authorization Server and Accounting Server respectively.

  - **Client Certificate**—User is authenticated using client certificate. Client certificate must be configured on VPN client endpoints. By default, user name is derived from client certificate fields CN & OU respectively. In case, user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

    If you select Map specific field option, which includes the username from the client certificate. The Primary and Secondary fields display default values: CN (Common Name) and OU (Organisational Unit) respectively. If you select the Use entire DN as username option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields, that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

    Primary and Secondary fields pertaining to the Map specific field option contains these common values:

    - C (Country)
    - CN (Common Name)
    - DNQ (DN Qualifier)
    - EA (Email Address)
    - GENQ (Generational Qualifier)
    - GN (Given Name)
    - I (Initial)
- L (Locality)
- N (Name)
- O (Organisation)
- OU (Organisational Unit)
- SER (Serial Number)
- SN (Surname)
- SP (State Province)
- T (Title)
- UID (User ID)
- UPN (User Principal Name)

- Whichever authentication method you choose, select or deselect Allow connection only if user exists in authorization database.

For more information, see Configure AAA Settings for Remote Access VPN, on page 1120.

**Related Topics**

- Configure Connection Profile Settings, on page 1118

**Manage Password Changes over VPN Sessions**

Password management allows a remote access VPN administrator to configure the notification settings for the remote access VPN users on their password expiry. Password management is available in AAA settings with authentication methods AAA Only and Client Certificate & AAA. For more information, see Configure AAA Settings for Remote Access VPN, on page 1120.

**Procedure**

**Step 1**
On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.

**Step 2**
Select a remote access policy and click Edit.

**Step 3**
Select the connection profile that includes AAA settings and click Edit.

**Step 4**
Select AAA > Advanced Settings > Password Management.

**Step 5**
Select Enable Password Management and select one of the following:

- Notify User - Notify user ahead of password expiry; specify the number of days in the box.
- Notify user on the day of password expiration - Notify user on the day their passwords expire.

**Step 6**
Click Save.
Send Accounting Records to the RADIUS Server

Accounting records in remote access VPN help the VPN administrator track the services that users access and the amount of network resources they consume. Accounting information includes when users sessions start and stop, usernames, the number of bytes that pass through the device for each session, the service used, and the duration of each session. This data can then be analyzed for network management, client billing, or auditing.

You can use accounting alone or together with authentication and authorization. When you activate AAA accounting, the network access server reports user activity to the configured accounting server. You can configure a RADIUS server as the accounting server so that all the user activity information is sent from Firepower Management Center to the RADIUS server.

Note
You can use the same RADIUS server or separate RADIUS servers for authentication, authorization, and accounting in remote access VPN AAA settings.

Before you begin
Configure a RADIUS group object with RADIUS servers to which authentication requests or accounting records will be sent. See RADIUS Server Group Options, on page 656.

Ensure that the RADIUS servers are reachable from the Firepower Threat Defense device. Configure routing on your Firepower Management Center at Devices > Device Management > Edit Device > Routing to ensure connectivity to the RADIUS server.

Procedure

Step 1 On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.
Step 2 Select a remote access policy and click Edit, or create a new remote access VPN policy.
Step 3 Select the connection profile that includes AAA settings and click Edit > AAA.
Step 4 Select a RADIUS server as the Accounting Server.
Step 5 Click Save.

Delegating Group Policy Selection to Authorization Server

The group policy applied to a user is determined when the VPN tunnel is being established. You can select a group policy for a connection profile while creating a remote access VPN policy using the wizard or update the connection policy for connection profiles later. However, you can configure the AAA (RADIUS) server to assign the group policy or it is obtained from the current connection profile. If the Firepower Threat Defense
device receives attributes from the external AAA server that conflicts with those configured on the connection profile, then attributes from the AAA server always take the precedence.

You can configure ISE or the RADIUS Server to set the Authorization Profile for a user or user-group by sending IETF RADIUS Attribute 25 and map to the corresponding group policy name. You can configure specific group policy to a user or user group to push a Downloadable ACL, set a banner, Restrict VLAN, and configure the advanced option of applying an SGT to the session. These attributes are applied to all users that are part of that group when the VPN connection is established.

For more information, see the Configure Standard Authorization Policies section of Cisco Identity Services Engine Administrator Guide and RADIUS Server Attributes for Firepower Threat Defense, on page 1124.

Override the Selection of Group Policy or Other Attributes by the Authorization Server

When a remote access VPN user connects to the VPN, the group policy and other attributes configured in the connection profile are assigned to the user. However, the remote access VPN system administrator can delegate the selection of group policy and other attributes to the authorization server by configuring ISE or the RADIUS Server to set the Authorization Profile for a user or user-group. Once users are authenticated, these specific authorization attributes are pushed to the Firepower Threat Defense device.

Before you begin

Ensure that you configure a remote access VPN policy with RADIUS as the authentication server.

Procedure

Step 1  On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.
Step 2 Select a remote access policy and click Edit.
Step 3 Select RADIUS or ISE as the authorization server if not configured already.
Step 4 Select Advanced > Group Policies and add the required group policy. For detailed information about a group policy object, see Configure Group Policy Objects, on page 645.

You can map only one group policy to a connection profile; but you can create multiple group policies in a remote access VPN policy. These group policies can be referenced in ISE or the RADIUS server and configured to override the group policy configured in the connection profile by assigning the authorization attributes in the authorization server.

Step 5 Deploy the configuration on the target Firepower Threat Defense device.
Step 6 On the authorization server, create an Authorization Profile with RADIUS attributes for IP address and downloadable ACLs.

When the group policy is configured in the authorization server selected for remote access VPN, the group policy overrides the group policy configured in the connection profile for the remote access VPN user after the user is authenticated.

Related Topics
Configure Group Policy Objects, on page 645

Deny VPN Access to a User Group

When you do not want an authenticated user or user group to be able to use VPN, you can configure a group policy to deny VPN access. You can configure a group policy in a remote access VPN policy and reference it in the ISE or RADIUS server configuration for authorization.

Before you begin
Ensure that you have configured remote access VPN using the Remote Access Policy wizard and configured authentication settings for the remote access VPN policy.

Procedure

Step 1 On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.
Step 2 Select a remote access policy and click Edit.
Step 3 Select Advanced > Group Policies.
Step 4 Select a group policy and click Edit or add a new group policy.
Step 5 Select Advanced > Session Settings and set Simultaneous Login Per User to 0 (zero). This stops the user or user group from connecting to the VPN even once.
Step 6 Click Save to save the group policy and then save the remote access VPN configuration.
Step 7 Configure ISE or the RADIUS server to set the Authorization Profile for that user/user-group to send IETF RADIUS Attribute 25 and map to the corresponding group policy name.
Step 8 Configure the ISE or RADIUS server as the authorization server in the remote access VPN policy.
Step 9 Save and deploy the remote access VPN policy.
Restrict Connection Profile Selection for a User Group

When you want to enforce a single connection profile on a user or user group, you can choose to disable the connection profile so that the group alias or URLs are not available for the users to select when they connect using the AnyConnect VPN client.

For example, if your organization wants to use specific configurations for different VPN user groups such as mobile users, corporate-issued laptop users, or personal laptop users, you can configure connection a profile specific to each of these user groups and apply the appropriate connection profile when the user connects to the VPN.

The AnyConnect client, by default, shows a list of the connection profiles (by connection profile name, alias, or alias URL) configured in Firepower Management Center and deployed on Firepower Threat Defense. If custom connection profiles are not configured, AnyConnect shows the DefaultWEBVPNGroup connection profile. Use the following procedure to enforce a single connection profile for a user group.

**Before you begin**

- On your Firepower Management Center web interface, configure remote access VPN using the remote access VPN policy wizard with Authentication Method as 'Client Certificate Only' or 'Client Certificate + AAA'. Choose the username fields from the certificate.
- Configure ISE or RADIUS server for authorization and associate the group policy with the authorization server.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Action Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>On your Firepower Management Center web interface, choose Devices &gt; VPN &gt; Remote Access.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Select a remote access policy and click Edit.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Select Access Interfaces and disable Allow users to select connection profile while logging in.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Click Advanced &gt; Certificate Maps.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Select Use the configured rules to match a certificate to a Connection Profile.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Select the Certificate Map Name or click the Add icon to add a certificate rule.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Select the Connection Profile, and click Ok.</td>
</tr>
</tbody>
</table>

With this configuration, when a user connects from the AnyConnect client, the user will have the mapped connection profile and will be authenticated to use the VPN.

**Update the AnyConnect Client Profile for Remote Access VPN Clients**

AnyConnect Client Profile is an XML file that contains an administrator-defined end user requirements and authentication policies to be deployed on a VPN client system as part of AnyConnect. It makes the preconfigured network profiles available to end users.
You can use the GUI-based AnyConnect Profile Editor, an independent configuration tool, to create an AnyConnect Client Profile. The standalone profile editor can be used to create a new or modify existing AnyConnect profile. You can download the profile editor from Cisco Software Download Center.

See the AnyConnect Profile Editor chapter in the appropriate release of the Cisco AnyConnect Secure Mobility Client Administrator Guide for details.

**Before you begin**

- Ensure that you have configured remote access VPN using the Remote Access Policy wizard and deployed the configuration on Firepower Threat Defense device. See Create a New Remote Access VPN Policy, on page 1111.
- On your Firepower Management Center web interface, go to Objects > Object Management > VPN > AnyConnect File and add the new AnyConnect client image.

**Procedure**

| Step 1 | On your Firepower Management Center web interface, choose Devices > VPN > Remote Access. |
| Step 2 | Select a remote access VPN policy and click Edit. |
| Step 3 | Select the connection profile that includes the client profile to be edited, and click Edit. |
| Step 4 | Click Edit Group Policy > AnyConnect > Profiles. |
| Step 5 | Select the client profile XML file from the list or click Add to add a new client profile. |
| Step 6 | Save the group policy, connection profile, and then the remote access VPN policy. |
| Step 7 | Deploy the changes. Changes to the client profile will be updated on the VPN clients when they connect to the remote access VPN gateway. |

**Related Topics**

**RADIUS Dynamic Authorization**

Firepower Threat Defense has the capability to use RADIUS servers for user authorization of VPN remote access and firewall cut-through-proxy sessions using dynamic access control lists (ACLs) or ACL names per user. To implement dynamic ACLs for dynamic authorization or RADIUS Change of Authorization (RADIUS CoA), you must configure the RADIUS server to support them. When the user tries to authenticate, the RADIUS server sends a downloadable ACL or ACL name to the Firepower Threat Defense. Access to a given service is either permitted or denied by the ACL. Firepower Threat Defense deletes the ACL when the authentication session expires.

- RADIUS Server Attributes for Firepower Threat Defense, on page 1124
Configuring RADIUS Dynamic Authorization

Before you begin:

- Only one interface can be configured in the security zone or interface group if it is referred in a RADIUS Server.

- A dynamic authorization enabled RADIUS server requires Firepower Threat Defense 6.3 or later for the dynamic authorization to work.

- Interface selection in RADIUS server is not supported on Firepower Threat Defense 6.2.3 or earlier versions. The interface option will be ignored during deployment.

Two-Factor Authentication

You can configure two-factor authentication for the remote access VPN. With two-factor authentication, the user must supply a username and static password, plus an additional item such as an RSA token or a passcode. Two-factor authentication differs from using a second authentication source in that two-factor is configured
Configuring RSA Two-Factor Authentication

About this task:
You can configure the RADIUS or AD server as the authentication agent in the RSA server, and use the server in Firepower Management Center as the primary authentication source in the remote access VPN.

When using this approach, the user must authenticate using a username that is configured in the RADIUS or AD server, and concatenate the password with the one-time temporary RSA token, separating the password and token with a comma: `password,token`.

In this configuration, it is typical to use a separate RADIUS server (such as one supplied in Cisco ISE) to provide authorization services. You would configure the second RADIUS server as the authorization and, optionally, accounting server.

Before you begin:
Ensure that the following configurations are complete before configuring RADIUS two-factor authentication on Firepower Threat Defense:

On the RSA Server
- Configure RADIUS or Active Directory server as an authentication agent.
- Generate and download the configuration (`sdconf.rec`) file.
- Create a token profile, assign the token to the user, and distribute the token to the user. Download and install the token on the remote access VPN client system.

For more information, see RSA SecureID Suite documentation.

On the ISE Server
- Import the configuration (`sdconf.rec`) file generated on the RSA server.
- Add the RSA server as the external identity source and specify the shared secret.

Table 84: Procedure

<table>
<thead>
<tr>
<th>Step</th>

<th>More Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Log on to your Firepower Management Center web interface.</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Create a RADIUS server group.</td>
<td>RADIUS Server Group Options, on page 656</td>
</tr>
</tbody>
</table>
The RADIUS or AD server must be the same server that is configured as the authentication agent in RSA server.

For two-factor authentication, make sure that the timeout is updated to 60 seconds or more in the AnyConnect client profile XML file as well.

**Create a RADIUS Server object within the new RADIUS server group, with RADIUS or AD server as the host and with a timeout of 60 seconds or more.**

**Create a new remote access VPN policy using the wizard or edit an existing remote access VPN policy.**

**Select RADIUS as the authentication server and then select the newly-created RADIUS server group as the authentication server.**

**Deploy the configuration changes.**

---

### Configuring Duo Two-Factor Authentication

**About this task:**

You can configure the Duo RADIUS server as the primary authentication source. This approach uses the Duo RADIUS Authentication Proxy. (You cannot use a direct connection with the Duo Cloud Service over LDAPS.)

For the detailed steps to configure Duo, see https://duo.com/docs/cisco-firepower.

You would then configure Duo to forward authentication requests directed to the proxy server to use another RADIUS server, or an AD server, as the first authentication factor, and the Duo Cloud Service as the second factor.

When using this approach, the user must authenticate using a username that is configured on both the Duo Cloud or web server, and the associated RADIUS server. The user must enter the password configured in the RADIUS server, followed by one of the following Duo codes:

- **Duo-passcode.** For example, *my-password*,123456.
- **push.** For example, *my-password,push*. Use push to tell Duo to send a push authentication to the Duo Mobile app, which the user must have already installed and registered.
- **sms.** For example, *my-password,sms*. Use sms to tell Duo to send an SMS message with a new batch of passcodes to the user’s mobile device. The user’s authentication attempt will fail when using sms. The user must then re-authenticate and enter the new passcode as the secondary factor.
- **phone.** For example, *my-password,phone*. Use phone to authenticate using phone callback.

For more information on login options with examples, see https://guide.duo.com/anyconnect.
Before you begin:

Before configuring two-factor authentication with Duo Authentication Proxy on Firepower Threat Defense, ensure that you complete the following configurations:

- Configure a working primary authentication (RADIUS or AD) for your remote access VPN users before you begin to deploy Duo.

- Install Duo proxy service on a Windows or Linux machine within your network to integrate Duo with Firepower Threat Defense remote access VPN. This Duo proxy server also acts as a RADIUS server.

Download and install the most recent Duo authentication proxy from the following location:

- Windows: https://dl.duosecurity.com/duoauthproxy-latest.exe
- Linux: https://dl.duosecurity.com/duoauthproxy-latest-src.tgz

Verify the checksum at https://duo.com/docs/checksums#duo-authentication-proxy.

- Configure Duo authentication file authproxy.cfg. Follow instructions on the https://duo.com/docs/cisco-firepower#configure-the-proxy page to configure the authentication configuration settings.

  The authproxy.cfg configuration file must contain the details for RADIUS or ISE server, Firepower Threat Defense device, Duo proxy server details, Integration Key, Secret key, and API host details.

- Ensure that you have the right API host information in the authproxy.cfg file.

- Configure other required settings such as secondary authentication factor in the newly installed Duo proxy server at Duo Security Server > Duo Admin Panel > Applications > CISCO RADIUS VPN.

Secondary Authentication

Secondary authentication or double authentication in Firepower Threat Defense adds an additional layer of security to remote access VPN connections by using two different authentication servers. With secondary authentication enabled, an AnyConnect VPN user must provide two sets of credentials to login to the VPN gateway.

Firepower Threat Defense remote access VPN supports secondary authentication in AAA Only and Client Certificate & AAA authentication methods.

**Figure 43: Remote Access VPN Secondary or Double Authentication**

VPN tunnel is established only if both primary and secondary authentications are successful

**Related Topics**

Configure Remote Access VPN Secondary Authentication, on page 1155

**Configure Remote Access VPN Secondary Authentication**

When remote access VPN authentication is configured to use both client certificate and authentication sever, VPN client authentication is done using both the client certificate validation and AAA server.

**Before you begin**

- Configure two authentication (AAA) servers—the primary and secondary authentication servers, and required identity certificates. The authentication servers can be RADIUS server, and AD or LDAP realms.
- Ensure that the AAA servers are reachable from the Firepower Threat Defense device for the remote access VPN configuration to work. Configure routing (at Devices > Device Management > Edit Device > Routing) to ensure connectivity to the AAA servers.

**Procedure**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>On your Firepower Management Center web interface, choose Devices &gt; VPN &gt; Remote Access.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Select a remote access policy and click <strong>Edit</strong>; or click <strong>Add</strong> to create a new remote access VPN policy.</td>
</tr>
<tr>
<td>Step 3</td>
<td>For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click <strong>Edit</strong>.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Click <strong>AAA &gt; Authentication Method</strong>, <strong>AAA</strong> or <strong>Client Certificate &amp; AAA</strong>.</td>
</tr>
</tbody>
</table>

- When you select the **Authentication Method** as:

  **Client Certificate & AAA** — Authentication is done using both client certificate and AAA server.
  - **AAA** — If you select the **Authentication Server** as RADIUS, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select AD and LDAP from the Authentication Server drop-down list, you must manually select the **Authorization Server** and **Accounting Server** respectively.
  - Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

- Use secondary authentication — Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to **AAA only** and **Client Certificate & AAA** authentication methods.

Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the AnyConnect login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

**Note** — By default, secondary authentication is not required.

**Authentication Server** — Secondary authentication server to provide secondary username and password for VPN users.

Select the following under **Username for secondary authentication**:

- **Prompt**: Prompts the users to enter the username and password while logging on to VPN gateway.

- **Use primary authentication username**: The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.

- **Map username from client certificate**: Prefills the secondary username from the client certificate.
  - If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: CN (Common Name) and OU.
(Organisational Unit) respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.

See **Authentication Method** descriptions for more information about primary and secondary field mapping.

- **Prefill username from certificate on user login window**: Prefills the secondary username from the client certificate when the user connects via AnyConnect VPN client.
  - **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.

- **Use secondary username for VPN session**: The secondary username is used for reporting user activity during a VPN session.

For more information, see *Configure AAA Settings for Remote Access VPN, on page 1120*.

### Single Sign-on Authentication with SAML 2.0

#### About SAML Single Sign-on Authentication

Security Assertion Markup Language (SAML) is an open standard for logging users into applications based on their sessions in another context. Organizations already know the identity of users when users are logged in to their Active Directory (AD) domain or the intranet. They use this identity information to log users into other applications, such as web-based applications by using SAML. Individual applications do not need to store credentials and users do not have to remember and manage different sets of credentials for individual applications. SAML sing sign-on (SSO) works by transferring the user’s identity from one place (the identity provider) to another (the service provider).

#### SAML Single Sign-on with Firepower Threat Defense

The Firepower Threat Defense device supports SAML 2.0 single sign-on (SSO) authentication for remote access VPN connections using the AnyConnect Secure Mobility Client. You need the following to configure SAML 2.0 SSO on Firepower Threat Defense:

- **Identity Provider (IdP)**—The Duo Access Gateway acts as the identity provider to perform user authentication and issues assertions.
- **Service Provider (SP)**—The FTD device acts as the service provider and obtains the authentication assertion from the identity provider.
- **VPN Client**—The AnyConnect Security Mobility Client performs SAML 2.0 authentication via embedded browser.
**Configuring a SAML Single Sign-on Authentication**

**Before you begin**

Ensure that you have done the following before you configure SAML single sign-on with FTD remote access VPN:

- Create an account with Duo
- Download and install the Duo Access Gateway
- Obtain the following from your SAML identity provider (Duo)
  - Identity Provider Entity ID URL
  - Sign-in URL
  - Sign-out URL
  - Identity provider certificate
- Create a SAML single sign-on server object under Object > Object Management > AAA Server > Single Sign-on Server

You can also create a single sign-on server object in the connection profile settings when you create a new remote access VPN configuration using the wizard.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose Devices &gt; VPN &gt; Remote Access.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click Add to create a new remote access VPN or edit an existing VPN configuration.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Configure the Connection Profile &gt; AAA settings and select Authentication Method &gt; SAML.</td>
</tr>
</tbody>
</table>
| Step 4 | Select the required SAML single sign-on server as the Authentication Server.  
**Note** For a new remote access VPN configuration: when you configure the Connection Profile settings, you can click + next to the Authentication Server list to create a new SAML single sign-on server object.  
For more information about creating a single sign-on server object, see Single Sign-on Server, on page 659.  
Step 5 | Configure the required settings for the remote access VPN. |
| Step 6 | Save the remote access VPN configuration and deploy it on your Firepower Threat Defense device. |

Remote Access VPN Examples

How to Limit AnyConnect Bandwidth Per User

This section provides instructions to limit the maximum bandwidth consumed by VPN users when the users connect using the Cisco AnyConnect VPN client to Firepower Threat Defense remote access VPN gateway. You can limit the maximum bandwidth by using a Quality of Service (QoS) policy in Firepower Threat Defense, to ensure that a single user or group or users do not take over the entire resource. This configuration lets you give priority to critical traffic, prevent bandwidth hogging, and manage network. If a user exceeds the maximum rate, the Firepower Threat Defense drops the excess traffic.

Create and Set up an Active Directory Realm

This section provides instructions to create a realm and specify the VPN users and user groups whose activity you want to monitor.

**Procedure**

**Step 1** On your Firepower Management Center web interface, choose System > Integration > Realms.

**Step 2** Click New realm, specify the realm details, and click OK.

**Step 3** Enter the required details on the following tabs and then click Save:

- **Directory**—You can specify more than one directory for a realm, in which case each domain controller is queried in the order listed on the realm's Directory page to match user and group credentials for user control.

  See Configure a Realm Directory, on page 2323.

- **Realm Configuration**—You can update the realm settings entered while creating the realm.

- **User Download**—You can include or exclude users and groups from being downloaded to Firepower Management Center.
Create a QoS Policy and Rule

QoS policies deployed to managed devices govern rate limiting. You can create a QoS policy by selecting a realm to limit the VPN bandwidth a user or user group can consume. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Procedure

Step 1 On your Firepower Management Center web interface, choose Devices > QoS > New Policy.
Step 2 Enter a Name and, optionally, a Description.
Step 3 Choose the Available Devices where you want to deploy the QoS policy, then click Add to Policy, or drag and drop to the Selected Devices.

Note Select the same device where you want to deploy the remote access VPN policy. You must assign devices before you deploy the policy.

Step 4 On QoS policy Rules, click Add Rule.
Step 5 Enter a Name.
Step 6 Configure rule components:
  - **Enabled**—Specify whether the rule is Enabled.
  - **Apply QoS On**—Choose the interfaces you want to rate limit, either Interfaces in Destination Interface Objects or Interfaces in Source Interface Objects. Your choice must correspond with a populated interface constraint (not any).
  - **Traffic Limit Per Interface**—Enter a Download Limit and an Upload Limit in Mbits/sec. The default value of Unlimited prevents matching traffic from being rate limited in that direction.
  - **Users**—Click the Users tab, and select the newly-created realm and users to limit the VPN traffic. Click other tabs corresponding to the conditions you want to add. You must configure a source or destination interface condition, corresponding to your choice for Apply QoS On.
  - **Comments**—Click the Comments tab, add a comment, and click OK.

Step 7 Save the rule.

In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.
Procedure

Step 1 On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.

Step 2 Create a new remote access VPN policy using the wizard. And select the newly-created realm as the Authentication Server or edit an existing remote access VPN policy and performing the following:
   a) Select the connection profile that you want to assign for your VPN users and click Edit.
   b) Select AAA > Authentication Method > AAA or Certificate & AAA.
   c) Select the required realm as the Authentication Server.
   d) Update other connection profile options, if required, and save the connection profile.

Step 3 Complete the required configurations for remote access VPN policy and click Save.

How to Use VPN Identity for User-id Based Access Control Rules

### Create and Set up an Active Directory Realm

This section provides instructions to create a realm and specify the VPN users and user groups whose activity you want to monitor.

#### Procedure

**Step 1** On your Firepower Management Center web interface, choose **System > Integration > Realms**.

**Step 2** Click **New realm**, specify the realm details, and click **OK**.

**Step 3** Enter the required details on the following tabs and then click **Save**:

- **Directory**—You can specify more than one directory for a realm, in which case each domain controller is queried in the order listed on the realm’s **Directory** page to match user and group credentials for user control.
  
  See **Configure a Realm Directory**, on page 2323.

- **Realm Configuration**—You can update the realm settings entered while creating the realm.

- **User Download**—You can include or exclude users and groups from being downloaded to Firepower Management Center.

**Step 4** Slide **State** to the right to enable a realm to be able to use it for user control. See **Manage a Realm**, on page 2326.

**Step 5** Click download to download users and user groups to Firepower Management Center. See **Download Users and Groups**, on page 2324.

**Step 6** Click **Save**.

#### Related Topics

- **Create a Realm**, on page 2314

### Create an Identity Policy and an Identity Rule

Identity policies contain identity rules to perform user authentication based on the realm and authentication method associated with the traffic. Identity rules associate sets of traffic with a realm and an authentication method: passive authentication, active authentication, or no authentication. You must fully configure the realms and authentication methods you plan to use before you can invoke them in your identity rules.

#### Procedure

**Step 1** On your Firepower Management Center web interface, choose **Policies > Access Control > Identity** and click **New Policy**.

**Step 2** Enter a **Name** and **Description**, and then click **Save**.

**Step 3** To add a rule to the policy, click **Add Rule**, and enter a **Name**.

**Step 4** Specify whether the rule is **Enabled**.

**Step 5** To add the rule to an existing category, indicate where you want to **Insert** the rule. To add a new category, click **Add Category**.
Associate an Identity Policy with an Access Control Policy

You must associate an identity policy with an access control policy that is deployed on the Firepower Threat Defense device where the remote access VPN policy will be deployed.

Procedure

Step 1 On your Firepower Management Center web interface, choose Policies > Access Control > Access Control.
Step 2 Select the required access control policy and click Edit.
Step 3 In the access control policy editor, click Advanced.
Step 4 Click Edit (✓) in the Identity Policy Settings area.
   If View (advisor) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck Inherit from base policy to enable editing.
Step 5 Choose an identity policy from the drop-down list.
   You can click edit in edit the identity policy.
Step 6 Click OK.
Step 7 Click Save to save the access control policy.

Create and Manage Identity Policies, on page 2373

Create or Update a Remote Access VPN Policy

Procedure

Step 1 On your Firepower Management Center web interface, choose Devices > VPN > Remote Access.
Step 2 Create a new remote access VPN policy using the wizard. And select the newly-created realm as the Authentication Server or edit an existing remote access VPN policy and performing the following:
   a) Select the connection profile that you want to assign for your VPN users and click Edit.
   b) Select AAA > Authentication Method > AAA or Certificate & AAA.
   c) Select the required realm as the Authentication Server.
   d) Update other connection profile options, if required, and save the connection profile.
**Step 3**  Complete the required configurations for remote access VPN policy and click **Save**.

VPN Monitoring for Firepower Threat Defense

This chapter describes Firepower Threat Defense VPN monitoring tools, parameters, and statistics information.

- VPN Summary Dashboard, on page 1165
- VPN Session and User Information, on page 1166
- VPN Health Events, on page 1167

VPN Summary Dashboard

Firepower System dashboards provide you with at-a-glance views of current system status, including data about the events collected and generated by the system. You can use the VPN dashboard to see consolidated information about VPN users, including the current status of users, device types, client applications, user geolocation information, and duration of connections.

Viewing the VPN Summary Dashboard

Remote access VPNs provide secure connections for remote users, such as mobile users or telecommuters. Monitoring these connections provides important indicators of connection and user session performance at a glance.

You must be an Admin user in a leaf domain to perform this task.

Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Step 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Choose <strong>Overview</strong> &gt; <strong>Dashboards</strong> &gt; <strong>Access Controlled User Statistics</strong> &gt; <strong>VPN.</strong></td>

</tr>
<tr>
<td>• VPN Users by Duration.</td>
<td></td>
</tr>
<tr>
<td>• VPN Users by Client Application.</td>
<td></td>
</tr>
<tr>
<td>• VPN Users by Client Country.</td>
<td></td>
</tr>
</tbody>
</table>
What to do next

The VPN dashboard is a complex, highly customizable monitoring feature that provides exhaustive data.

- For complete information on how to use dashboards in the Firepower System, see Dashboards, on page 377.
- For information on how to modify the VPN dashboard widgets, see Configuring Widget Preferences, on page 392.

VPN Session and User Information

The Firepower System generates events that communicate the details of user activity on your network, including VPN-related activity. The Firepower System monitoring capabilities enable you to determine quickly whether remote access VPN problems exist and where they exist. You can then apply this knowledge and use your network management tools to reduce or eliminate problems for your network and users. Optionally, you can logout remote access VPN users as needed.

Viewing Remote Access VPN Active Sessions

Analysis > Users > Active Sessions

Lets you view the currently logged-in VPN users at any given point in time with supporting information such as the user name, login duration, authentication type, assigned/public IP address, device details, client version, end point information, throughput, bandwidth consumed group policy, tunnel group etc. The system also provides the ability to filter current user information, log users out, and delete users from the summary list.

Note

If you have configured your VPN in a high-availability deployment, the device name displayed against active VPN sessions can be the primary or secondary device that identified the user session.

- To learn more about active sessions; see Viewing Active Session Data, on page 2880.
- To learn more about the contents of the columns in the active sessions table; see Active Sessions, Users, and User Activity Data, on page 2873.

Viewing Remote Access VPN User Activity

Analysis > Users > User Activity

Lets you view the details of user activity on your network. The system logs historical events and includes VPN-related information such as connection profile information, IP address, geolocation information, connection duration, throughput, and device information.

- To learn more about user activity; see Viewing User Activity Data, on page 2885.
- To learn more about the contents of the columns in the user activity table; see Active Sessions, Users, and User Activity Data, on page 2873.
VPN Health Events

The Health Events page allows you to view VPN health events logged by the health monitor on the Firepower Management Center. When one or more VPN tunnels between Firepower System devices are down, these events are tracked:

- Site-to-site VPN for Firepower Threat Defense
- Remote access VPN for Firepower Threat Defense

See Health Monitoring, on page 399 for more details on how you can use the health monitor to check the status of critical functionality across your Firepower System deployment.

Viewing VPN Health Events

When you access health events from the Health Events page on your Firepower Management Center, you retrieve all health events for all managed appliances. You can narrow the events by specifying the module which generated the health events you want to view.

You must be an Admin, Maintenance User, or Security Analyst to perform this task.

Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Choose System &gt; Health &gt; Events.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Select VPN Status under the Module Name column.</td>
</tr>
</tbody>
</table>

See Health Event Views, on page 430 for more details on system health events.
Viewing VPN Health Events
VPN Troubleshooting for Firepower Threat Defense

This chapter describes Firepower Threat Defense VPN troubleshooting tools and debug information.

- System Messages, on page 1169
- VPN System Logs, on page 1169
- Debug Commands, on page 1170

System Messages

The Message Center is the place to start your troubleshooting. This feature allows you to view messages that are continually generated about system activities and status. To open the Message Center, click System Status, located to the immediate right of the Deploy button in the main menu. See System Messages, on page 455 for details on using the Message Center.

VPN System Logs

You can enable system logging (syslog) for FTD devices. Logging information can help you identify and isolate network or device configuration problems. When you enable VPN logging, these syslogs are sent from FTD devices to the Firepower Management Center for analysis and archiving.

Any VPN syslogs that are displayed have a default severity level ‘ERROR’ or higher (unless changed). VPN logging is managed through FTD platform settings. You can adjust the message severity level by editing the VPN Logging Settings in the FTD platform settings policy for targeted devices (Platform Settings > Syslog > Logging Setup). See About Configuring Syslog, on page 1369 for details on enabling VPN logging, configuring syslog servers, and viewing the system logs.

Note

VPN syslogs are automatically enabled to be sent to the Firepower Management Center by default whenever a device is configured with site-to-site or remote access VPNs.
Viewing VPN System Logs

The Firepower System captures event information to help you to gather additional information about the source of your VPN problems. Any VPN syslogs that are displayed have a default severity level ‘ERROR’ or higher (unless changed). By default the rows are sorted by the Time column.

You must be an Admin user in a leaf domain to perform this task.

Before you begin

Enable VPN logging by checking the Enable Logging to FMC check box in the FTD platform settings (Devices > Platform Settings > Syslog > Logging Setup). See About Configuring Syslog, on page 1369 for details on enabling VPN logging, configuring syslog servers, and viewing the system logs.

Procedure

Step 1 Choose Devices > VPN > Troubleshooting.
Step 2 You have the following options:

• Search — To filter current message information, click Edit Search.
• View — To view VPN details associated with the selected message in the view, click View.
• View All — To view VPN details for all messages in the view, click View All.
• Delete — To delete selected messages from the database, click Delete or click Delete All to delete all the messages.

Debug Commands

This section explains how you use debug commands to help you diagnose and resolve VPN-related problems. Not all available debug commands are described in this section. Commands are included here based on their usefulness in assisting you to diagnose VPN-related problems.

Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use debug commands only to troubleshoot specific problems or during troubleshooting sessions with the Cisco Technical Assistance Center (TAC). Moreover, it is best to use debug commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased debug command processing overhead will affect system use.

You can view debug output in a CLI session only. Output is directly available when connected to the Console port, or when in the diagnostic CLI (enter system support diagnostic-cli). You can also view output from the regular Firepower Threat Defense CLI using the show console-output command.

To show debugging messages for a given feature, use the debug command. To disable the display of debug messages, use the no form of this command. Use no debug all to turn off all debugging commands.

\[ \text{debug feature [subfeature] [level]} \]
\[ \text{no debug feature [subfeature]} \]
Syntax Description

<table>
<thead>
<tr>
<th>feature</th>
<th>Specifies the feature for which you want to enable debugging. To see available features, use the debug ? command for CLI help.</th>
</tr>
</thead>
<tbody>
<tr>
<td>subfeature</td>
<td>(Optional) Depending on the feature, you can enable debug messages for one or more subfeatures. Use ? to see the available subfeatures.</td>
</tr>
<tr>
<td>level</td>
<td>(Optional) Specifies the debugging level. The level might not be available for all features. Use ? to see the available levels.</td>
</tr>
</tbody>
</table>

Command Default

The default debugging level is 1.

Example

With multiple sessions running on a remote access VPN, troubleshooting can be difficult given the size of the logs. You can use the debug webvpn condition command to set up filters to target your debug process more precisely.

d-debug webvpn condition {group name | p-ipaddress ip_address [{subnet subnet_mask | prefix length}] | reset | user name}

Where:

- group name filters on a group policy (not a tunnel group or connection profile).
- p-ipaddress ip_address [{subnet subnet_mask | prefix length}] filters on the public IP address of the client. The subnet mask (for IPv4) or prefix (for IPv6) is optional.
- reset resets all filters. You can use the no debug webvpn condition command to turn off a specific filter.
- user name filters by username.

If you configure more than one condition, the conditions are conjoined (ANDed), so that debugs are shown only if all conditions are met.

After setting up the condition filter, use the base debug webvpn command to turn on the debug. Simply setting the conditions does not enable the debug. Use the show debug and show webvpn debug-condition commands to view the current state of debugging.

The following shows an example of enabling a conditional debug on the user jdoe.

```
firepower# debug webvpn condition user jdoe
firepower# show webvpn debug-condition
INFO: Webvpn conditional debug is turned ON
INFO: User name filters:
INFO: jdoe
firepower# debug webvpn
INFO: debug webvpn enabled at level 1.
firepower# show debug
ddebug webvpn enabled at level 1
INFO: Webvpn conditional debug is turned ON
INFO: User name filters:
INFO: jdoe
```

<td>(Optional) Specifies the AAA shim debug level. Use <code>?</code> to see the available levels.</td>
</tr>
<tr>
<td>url-redirect</td>
<td>(Optional) Enables AAA url-redirect debugging.</td>
</tr>
</tbody>
</table>

#### Command Default

The default debugging level is 1.

### debug crypto

See the following commands for debugging configurations or settings associated with crypto.

**debug crypto** [ca | condition | engine | ike-common | ikev1 | ikev2 | ipsec | ss-apic]

#### Syntax Description

<table>
<thead>
<tr>
<th>crypto</th>
<th>Enables debugging for <code>crypto</code>. Use <code>?</code> to see the available subfeatures.</th>
</tr>
</thead>
</table>
**debug crypto ca**

See the following commands for debugging configurations or settings associated with crypto ca.

```
do debug crypto ca [cluster | messages | periodic-authentication | scep-proxy | transactions | trustpool] [1-255]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>crypto ca</th>
<th>Enables debugging for crypto ca. Use ? to see the available subfeatures.</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster</td>
<td>(Optional) Specifies the PKI cluster debug level. Use ? to see the available levels.</td>

<tr>
<td>periodic-authentication</td>
<td>(Optional) Specifies the PKI periodic-authentication debug level. Use ? to see the available levels.</td>
</tr>
</tbody>
</table>
**debug crypto ikev1**

See the following commands for debugging configurations or settings associated with Internet Key Exchange version 1 (IKEv1).

`debug crypto ikev1 [timers] [1-255]`

**Syntax Description**
- `ikev1` Enables debugging for `ikev1`. Use `?` to see the available subfeatures.
- `timers` (Optional) Enables debugging for IKEv1 timers.
- `1-255` (Optional) Specifies the debugging level.

**Command Default**
The default debugging level is 1.

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>

### debug ldap

See the following commands for debugging configurations or settings associated with LDAP (Lightweight Directory Access Protocol).

```
debug  ldap  [1-255]
```

#### Syntax Description

- **ldap**
  
  Enables debugging for LDAP. Use `?` to see the available subfeatures.
debug ssl

See the following commands for debugging configurations or settings associated with SSL sessions.

ddebug ssl [cipher | device] [1-255]

Syntax Description

ssl
Enables debugging for SSL. Use ? to see the available subfeatures.
cipher
(Optional) Specifies the SSL cipher debug level. Use ? to see the available levels.
device
(Optional) Specifies the SSL device debug level. Use ? to see the available levels.
1-255
(Optional) Specifies the debugging level.

Command Default

The default debugging level is 1.

Related Commands

Command | Description
---|---
show debug ldap | Shows the currently active debug settings for LDAP.
undebug ldap | Disables debugging for LDAP. This command is a synonym for no debug ldap.

debug webvpn

See the following commands for debugging configurations or settings associated with WebVPN.

ddebug webvpn [anyconnect | chunk | cifs | citrix | compression | condition | cstp-auth | customization | failover | html | javascript | kcd | listener | mus | nfs | request | response | saml | session | task | transformation | url | util | xml]

Syntax Description

webvpn
Enables debugging for WebVPN. Use ? to see the available subfeatures.
anyconnect
(Optional) Specifies the WebVPN AnyConnect debug level. Use ? to see the available levels.
chunk
(Optional) Specifies the WebVPN chunk debug level. Use ? to see the available levels.

PART XI

Firepower Threat Defense Advanced Settings

- Threat Defense Service Policies, on page 1181
- FlexConfig Policies for Firepower Threat Defense, on page 1199
- Alarms for the Cisco ISA 3000, on page 1251
You can use Firepower Threat Defense Service Policies to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple actions or rules applied to an interface or applied globally.

- About Firepower Threat Defense Service Policies, on page 1181
- Requirements and Prerequisites for Service Policies, on page 1183
- Guidelines and Limitations for Service Policies, on page 1183
- Configure Firepower Threat Defense Service Policies, on page 1184
- Examples for Service Policy Rules, on page 1192
- Monitoring Service Policies, on page 1196
- History for Firepower Threat Defense Service Policy, on page 1197

**About Firepower Threat Defense Service Policies**

You can use Firepower Threat Defense Service Policies to apply services to specific traffic classes. With service policies, you are not limited to applying the same services to all connections that enter the device or a given interface.

A traffic class is a combination of the interface and an extended access control list (ACL). The ACL “allow” rules determine which connections are part of the class. Any “denied” traffic in the ACL simply does not have the service applied to it: these connections are not actually dropped. You can use IP addresses and TCP/UCP ports to identify matching connections as precisely as you require.

There are two types of traffic class:

- **Interface-based rules**—If you specify a security zone or interface group in a service policy rule, the rule applies to the ACL “allowed” traffic that goes through any interface that is part of the interface objects.

  For a given feature, interface-based rules applied to the ingress interface always take precedence over global rules: if an ingress interface-based rule applies to a connection, any matching global rule is ignored. If no ingress interface or global rule applies, then an interface service rule on the egress interface is applied.

- **Global rules**—These rules apply to all interfaces. If an interface-based rule does not apply to a connection, the global rules are checked and applied to any connections that the ACL “allows.” If none apply, then the connections proceed without any services applied.
A given connection can match only one traffic class, either interface-based or global, for a given feature. There should be at most one rule for a given interface object/traffic flow combination.

Service policy rules are applied after access control rules. These services are configured only for connections you are allowing.

**How Service Policies Relate to FlexConfig and Other Features**

Prior to version 6.3(0), you could configure connection-related service rules using the TCP_Embryonic_Conn_Limit and TCP_Embryonic_Conn_Timeout pre-defined FlexConfig objects. You should remove those objects and redo your rules using the Firepower Threat Defense Service Policy. If you created any custom FlexConfig objects to implement any of these connection-related features (that is, set `connection` commands), you should also remove those objects and implement the features through the service policy.

Because connection-related service policy features are treated as a separate feature group from other service-rule implemented features, you should not run into problems with overlapping traffic classes. However, please be mindful when configuring the following:

- QoS Policy rules are implemented using the service policy CLI. These rules are applied before connection-based service policy rules. However, both QoS and connection settings can be applied to the same or overlapping traffic classes.

- You can use FlexConfig policies to implement customized application inspections and NetFlow. Use the `show running-config` command to examine the CLI that already configures service rules, including the `policy-map`, `class-map`, and `service-policy` commands. Netflow and application inspection are compatible with QoS and connection settings, but you need to understand the existing configuration before implementing FlexConfig. Connection settings are applied before application inspections and Netflow.

**Note**

Traffic classes that are created from the Firepower Threat Defense Service Policy are named `class_map_ACLname`, where `ACLname` is the name of the extended ACL object used in the service policy rule.

**What Are Connection Settings?**

Connection settings comprise a variety of features related to managing traffic connections, such as a TCP flow through the Firepower Threat Defense device. Some features are named components that you would configure to supply specific services.

Connection settings include the following:

- **Global timeouts for various protocols**—All global timeouts have default values, so you need to change them only if you are experiencing premature connection loss. You configure global timeouts in the Firepower Threat Defense Platform policy. Select **Devices > Platform Settings**.

- **Connection timeouts per traffic class**—You can override the global timeouts for specific types of traffic using service policies. All traffic class timeouts have default values, so you do not have to set them.

- **Connection limits and TCP Intercept**—By default, there are no limits on how many connections can go through (or to) the Firepower Threat Defense device. You can set limits on particular traffic classes.
using service policy rules to protect servers from denial of service (DoS) attacks. Particularly, you can set limits on embryonic connections (those that have not finished the TCP handshake), which protects against SYN flooding attacks. When embryonic limits are exceeded, the TCP Intercept component gets involved to proxy connections and ensure that attacks are throttled.

- **Dead Connection Detection (DCD)**—If you have persistent connections that are valid but often idle, so that they get closed because they exceed idle timeout settings, you can enable Dead Connection Detection to identify idle but valid connections and keep them alive (by resetting their idle timers). Whenever idle times are exceeded, DCD probes both sides of the connection to see if both sides agree the connection is valid. The `show service-policy` command output includes counters to show the amount of activity from DCD. You can use the `show conn detail` command to get information about the initiator and responder and how often each has sent probes.

- **TCP sequence randomization**—Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. By default, the Firepower Threat Defense device randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions. Randomization prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session. You can disable randomization per traffic class if desired.

- **TCP Normalization**—The TCP Normalizer protects against abnormal packets. You can configure how some types of packet abnormalities are handled by traffic class. You can configure TCP Normalization using the FlexConfig policy.

- **TCP State Bypass**—You can bypass TCP state checking if you use asymmetrical routing in your network.

### Requirements and Prerequisites for Service Policies

**Model Support**

FTD

**Supported Domains**

Any

**User Roles**

Admin
Access Admin
Network Admin

### Guidelines and Limitations for Service Policies

- Service policies apply to routed or switch interfaces only, in either routed or transparent mode. They do not apply to inline set or passive interfaces.

- You can have at most 25 traffic classes for a given interface or the global policy. Specifically, this means that you cannot have more than 25 service policy rules for the global policy for a given security zone or interface group. However, for interfaces, because the same interface can appear in both a security zone
and interface group, be aware that the actual limitation is based on the interfaces, and not the zone/group. Thus, you might be prevented from having 25 rules per zone/group based on the membership of your zones/groups.

- You can have at most one rule for a given interface object/traffic flow combination.

- When you make service policy changes to the configuration, all new connections use the new service policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. If you want all connections to immediately use the new policy, you need to disconnect the current connections so they can reconnect using the new policy. From an SSH or Console CLI session, enter the `clear conn` or `clear local-host` commands.

## Configure Firepower Threat Defense Service Policies

You can use Firepower Threat Defense Service Policies to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple actions or rules applied to an interface or applied globally.

### Procedure

**Step 1** Choose Policies > Access Control > Access Control, and click Edit (ขวา) for the access control policy whose Firepower Threat Defense Service Policy you want to edit.

**Step 2** Click Advanced.

**Step 3** Click Edit (ขวา) in the Threat Defense Service Policy group.

A dialog box opens that shows the existing policy. The policy consists of an ordered list of rules, separated between global rules (which apply to all interfaces) and interface-based rules. The table shows the interface object and extended access control list name (which combined defines the traffic class for the rule), and the services applied.

**Step 4** Do any of the following:

- Click Add Rule to create a new rule. See Configure a Service Policy Rule, on page 1185.

- Click Edit (ขวา) to edit an existing rule. See Configure a Service Policy Rule, on page 1185.

- Click Delete (ลบ) to delete a rule.

- Click a rule and drag it to a new location to move it. You cannot drag rules between the interface and global lists, instead you must edit the rule to change the interface/global setting. The first rule in the list that matches a connection is applied to the connection.

**Step 5** Click OK when you are finished editing the policy.

**Step 6** Click Save on Advanced window. The changes are not saved until you click save.
Configure a Service Policy Rule

Configure service policy rules to apply services to specific traffic classes.

Before you begin

Go to Objects > Object Management > Access List > Extended and create an extended access list that defines the traffic to which the rule applies. The rule is applied to any connections that match Allow rules in the extended access list. Define the ACL rules precisely, so that your service policy rule applies to only the traffic that requires the service.

If you are creating an interface-based rule, you must also have configured the interfaces on the assigned devices and added them to security zones or interface groups.

Procedure

Step 1 If you are not already in the Firepower Threat Defense Service Policy dialog box, choose Policies > Access Control > Access Control, edit the access control policy, click Advanced, then edit the Threat Defense Service Policy.

Step 2 Do any of the following:

• Click Add Rule to create a new rule.

• Click Edit (✓) to edit an existing rule.

The service policy rule wizard opens to step you through the process of configuring the rule.

Step 3 In the Interface Object step, select the option that defines the interfaces that will use the policy.

• Apply Globally—Select this option to create a global rule, which applies to all interfaces.

• Select Interface Objects—Select this option to create an interface-based rule. Then, select the security zones or interface objects that contain the desired interfaces, and click > to move them to the Next selected list. The service policy rule will be configured on each interface contained in the selected objects; it is not configured on the zone/group itself.

Click when the interface criteria is complete.

Step 4 In the Traffic Flow step, select the extended ACL object that defines the connections to which the rule applies, then click Next.

Step 5 In the Connection Setting step, configure the services to apply to this traffic class.

• Enable TCP State Bypass (TCP connections only)—Implement TCP State Bypass. Connections subject to TCP State Bypass are not inspected by any inspection engines, and they bypass all TCP state checking and TCP normalization. For detailed information, see Bypass TCP State Checks for Asynchronous Routing (TCP State Bypass), on page 1187.

Note Use TCP State Bypass for troubleshooting purposes or when asymmetric routing cannot be resolved. This feature disables multiple security features, which can cause a high number of connections if you do not implement it properly with a narrowly-defined traffic class.
- **Randomize TCP Sequence Number** (TCP connections only)—Whether to enable or disable TCP sequence number randomization. Randomization is enabled by default. For more information, see Disable TCP Sequence Randomization, on page 1191.

- **Enable Decrement TTL** (TCP connections only)—Decrement the time-to-live (TTL) on packets that match the class. If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as OSPF hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences.

  **Note** If you want the Firepower Threat Defense device to appear on traceroutes, you must configure the decrement TTL option and also set the ICMP unreachable rate limit in the platform settings policy. See Make the Firepower Threat Defense Device Appear on Traceroutes, on page 1195.

- **Connections**—Limits for the number of connections allowed for the entire class. You can configure these options:
  - **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections that are allowed, between 0 and 2000000, for the entire class. For TCP, this count applies to established connections only. The default is 0, which allows unlimited connections. Because the limit is applied to a class, one attacking host can consume all the connections and leave none for the rest of the hosts that are matched to the class. Set the per-client limit to ameliorate this problem.
  - **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections (those that have not finished the TCP handshake) allowed, between 0 and 2000000. The default is 0, which allows unlimited connections. By setting a non-zero limit, you enable TCP Intercept, which protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. Also set the per-client options to protect against SYN flooding. For more information, see Protect Servers from a SYN Flood DoS Attack (TCP Intercept), on page 1192.

- **Connections Per Client**—Limits for the number of connections allowed for a given client (source IP address). You can configure these options:
  - **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections allowed per client, between 0 and 2000000. For TCP, this includes established, half-open (embryonic), and half-closed connections. The default is 0, which allows unlimited connections. This option restricts the maximum number of simultaneous connections that are allowed for each host that is matched to the class.
  - **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections allowed per client, between 0 and 2000000. The default is 0, which allows unlimited connections. For more information, see Protect Servers from a SYN Flood DoS Attack (TCP Intercept), on page 1192.

- **Connections Timeout**—The timeout settings to apply to the traffic class. These timeouts override the global timeouts defined in the platform settings policy. You can configure the following:
  - **Embryonic** (TCP connections only)—The timeout period until a TCP embryonic (half-open) connection is closed, between 0:0:5 and 1193:00:00. The default is 0:0:30.
  - **Half Closed** (TCP connections only)—The idle timeout period until a half-closed connection is closed, between 0:0:30 and 1193:0:0. The default is 0:10:0. Half-closed connections are not affected.
by Dead Connection Detection (DCD). Also, the system does not send a reset when taking down half-closed connections.

- **Idle** (TCP, UDP, ICMP, IP connections)—The idle timeout period after which an established connection of any protocol closes, between 0:0:1 and 1193:0:0. The default is 1:0:0, unless you select the TCP State Bypass option, where the default is 0:2:0.

- **Reset Connection Upon Timeout** (TCP connections only)—Whether to send a TCP RST packet to both end systems after idle connections are removed.

- **Detect Dead Connections** (TCP connections only)—Whether to enable Dead Connection Detection (DCD). Before expiring an idle connection, the system probes the end hosts to determine if the connection is valid. If both hosts respond, the connection is preserved, otherwise the connection is freed. When operating in transparent firewall mode, you must configure static routes for the endpoints. You cannot configure DCD on connections that are also offloaded, so do not configure DCD on connections you are fast-pathing in the prefilter policy. Use the `show conn detail` command in the FTD CLI to track how many DCD probes have been sent by the initiator and responder.

Configure the following options:

- **Detection Timeout**—The time duration in hh:mm:ss format to wait after each unresponsive DCD probe before sending another probe, between 0:0:1 and 24:0:0. The default is 0:0:15.

  For systems that are operating in a cluster or high-availability configuration, we recommend that you do not set the interval to less than one minute (0:1:0). If the connection needs to be moved between systems, the changes required take longer than 30 seconds, and the connection might be deleted before the change is accomplished.

- **Detection Retries**—The number of consecutive failed retries for DCD before declaring the connection dead, from 1 to 255. The default is 5.

**Step 6**  
Click **Finish** to save your changes.

The rule is added to the bottom of the appropriate list, either Interfaces or Global. Global rules are matched in top-down order. Rules in the Interfaces list are matched in top down order for each interface object. Place rules for narrowly-defined traffic classes above broader rules, to ensure the right services get applied. You can move rules within each list by using drag and drop. You cannot move rules between lists.

---

**Bypass TCP State Checks for Asynchronous Routing (TCP State Bypass)**

If you have an asynchronous routing environment in your network, where the outbound and inbound flow for a given connection can go through two different Firepower Threat Defense devices, you need to implement TCP State Bypass on the affected traffic.

However, TCP State Bypass weakens the security of your network, so you should apply bypass on very specific, limited traffic classes.

The following topics explain the problem and solution in more detail.
The Asynchronous Routing Problem

By default, all traffic that goes through the Firepower Threat Defense device is inspected using the Adaptive Security Algorithm and is either allowed through or dropped based on the security policy. The Firepower Threat Defense device maximizes the firewall performance by checking the state of each packet (new connection or established connection) and assigning it to either the session management path (a new connection SYN packet), the fast path (an established connection), or the control plane path (advanced inspection).

TCP packets that match existing connections in the fast path can pass through the Firepower Threat Defense device without rechecking every aspect of the security policy. This feature maximizes performance. However, the method of establishing the session in the fast path using the SYN packet, and the checks that occur in the fast path (such as TCP sequence number), can stand in the way of asymmetrical routing solutions: both the outbound and inbound flow of a connection must pass through the same Firepower Threat Defense device.

For example, a new connection goes to Security Appliance 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through Security Appliance 1, then the packets match the entry in the fast path, and are passed through. But if subsequent packets go to Security Appliance 2, where there was not a SYN packet that went through the session management path, then there is no entry in the fast path for the connection, and the packets are dropped. The following figure shows an asymmetric routing example where the outbound traffic goes through a different Firepower Threat Defense device than the inbound traffic:

*Figure 44: Asymmetric Routing*

If you have asymmetric routing configured on upstream routers, and traffic alternates between two Firepower Threat Defense devices, then you can configure TCP state bypass for specific traffic. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. This feature treats TCP traffic much as it treats a UDP connection: when a non-SYN packet matching the specified networks enters the Firepower Threat Defense device, and there is not a fast path entry, then the packet goes through the session management path to establish the connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.
Guidelines and Limitations for TCP State Bypass

TCP State Bypass Unsupported Features

The following features are not supported when you use TCP state bypass:

- Application inspection—Inspection requires both inbound and outbound traffic to go through the same Firepower Threat Defense device, so inspection is not applied to TCP state bypass traffic.
- Snort inspection—Inspection requires both inbound and outbound traffic to go through the same device. However, Snort inspection is not automatically bypassed for TCP state bypass traffic. You must also configure a prefilter fastpath rule for the same traffic class for which you configure TCP state bypass.
- TCP Intercept, maximum embryonic connection limit, TCP sequence number randomization—The Firepower Threat Defense device does not keep track of the state of the connection, so these features are not applied.
- TCP normalization—The TCP normalizer is disabled.
- Stateful failover.

TCP State Bypass NAT Guidelines

Because the translation session is established separately for each Firepower Threat Defense device, be sure to configure static NAT on both devices for TCP state bypass traffic. If you use dynamic NAT, the address chosen for the session on Device 1 will differ from the address chosen for the session on Device 2.

Configure TCP State Bypass

To bypass TCP state checking in asynchronous routing environments, carefully define a traffic class that applies to the affected hosts or networks only, then enable TCP State Bypass on the traffic class using a service policy. You must also configure a corresponding prefilter fastpath policy for the same traffic to ensure the traffic also bypasses inspection.

Because bypass reduces the security of the network, limit its application as much as possible.

Procedure

**Step 1**

Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from 10.1.1.1 to 10.2.2.2, do the following:

a) Choose **Objects > Object Management**.

b) Choose **Access List > Extended** from the table of contents.

c) Click **Add Extended Access List**.

d) Enter a **Name** for the object, for example, bypass.

e) Click **Add** to add a rule.

f) Keep **Allow** for the action.

g) Enter 10.1.1.1 beneath the **Source** list and click **Add**, and 10.2.2.2 beneath the **Destination** list, and click **Add**.

h) Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, and click **Add**. Do not enter a port number, simply add TCP as the protocol, which will cover all ports.
i) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.

j) Click **Save** on the Extended Access List Object dialog box to save the ACL object.

### Step 2
Configure the TCP state bypass service policy rule.

For example, to configure TCP state bypass for this traffic class globally, do the following:

a) Choose **Policies > Access Control > Access Control**, and edit the policy assigned to the devices that require this service.

b) Click Advanced, and click **Edit** for the **Threat Defense Service Policy**.

c) Click **Add Rule**.

d) Select **Apply Globally > Next**.

e) Select the extended ACL object you created for this rule and click **Next**.

f) Select **Enable TCP State Bypass**.

g) (Optional.) Adjust the **Idle** timeout for bypassed connections. The default is 2 minutes.

h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

i) Click **OK** to save the changes to the service policy.

j) Click **Save** on **Advanced** to save the changes to the access control policy.

### Step 3
Configure a prefilter fastpath rule for the traffic class.

You cannot use the ACL object in the prefilter rule, so you need to recreate the traffic class either directly in the prefilter rule, or by first creating network objects that define the class.

The following procedure assumes that you already have a prefilter policy attached to the access control policy. If you have not created a prefilter policy yet, go to **Policies > Access Control > Prefilter** and first create the policy. You can then follow this procedure to attach it to the access control policy and create the rule.

Keeping with our example, this procedure creates a fastpath rule for TCP traffic from 10.1.1.1 to 10.2.2.2.

a) Choose **Policies > Access Control > Access Control**, and edit the policy that has the TCP bypass service policy rule.

b) Click the link for the **Prefilter Policy**, which is to the left immediately under the policy description.

c) In the Prefilter Policy dialog box, select the policy to assign to the device if the correct one is not already selected. Do not click OK yet.

Because you cannot add rules to the default prefilter policy, you must choose a custom policy.

d) In the Prefilter Policy dialog box, click the **Edit**. This action opens a new browser window where you can edit the policy.

e) Click **Add Prefilter Rule** and configure a rule with the following properties.

- **Name**—Any name that you find meaningful will do, such as TCPBypass.

- **Action**—Select **Fastpath**.

- **Interface Objects**—If you configured TCP state bypass as a global rule, leave the default, any, for both source and destination. If you created an interface-based rule, select the same interface objects you used for rule in the **Source Interface Objects** list, and keep any as the destination.

- **Networks**—Add 10.1.1.1 to the **Source Networks** list, and 10.2.2.2 to the **Destination Networks** list. You can either use network objects or manually add the addresses.

- **Ports**—Under **Selected Source Ports**, select TCP(6), **do not enter a port**, and click **Add**. This will apply the rule to all (and only) TCP traffic, regardless of TCP port number.
f) Click **Add** to add the rule to the prefilter policy.
g) Click **Save** to save your changes to the prefilter policy.

You can now close the prefilter edit window and return to the access control policy edit window.

h) In the access control policy edit window, the Prefilter Policy dialog box should still be open. Click **OK** to save your changes to the prefilter policy assignment.
i) Click **Save** on the access control policy to save the changed prefilter policy assignment, if you changed it.

You can now deploy the changes to the affected devices.

---

## Disable TCP Sequence Randomization

Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. The Firepower Threat Defense device randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session.

You can disable TCP initial sequence number randomization if necessary, for example, because data is getting scrambled. Following are some situations where you might want to disable randomization.

- If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
- If you use eBGP multi-hop through the device, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- If you use a WAAS device that requires the Firepower Threat Defense device not to randomize the sequence numbers of connections.
- If you enable hardware bypass for the ISA 3000, and TCP connections are dropped when the ISA 3000 is no longer part of the data path.

### Procedure

**Step 1**

Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from any host to 10.2.2.2, do the following:

a) Choose **Objects > Object Management**.
b) Choose **Access List > Extended** from the table of contents.
c) Click **Add Extended Access List**.
d) Enter a **Name** for the object, for example, preserve-sq-no.
e) Click **Add** to add a rule.
f) Keep **Allow** for the action.
g) Leave the **Source** list empty, enter 10.2.2.2 beneath the **Destination** list, and click **Add**.
h) Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, and click **Add**. Do not enter a port number, simply add TCP as the protocol, which will cover all ports.
i) Click Add on the Extended Access List Entry dialog box to add the rule to the ACL.

j) Click Save on the Extended Access List Object dialog box to save the ACL object.

### Step 2

Configure the service policy rule that disables TCP sequence number randomization.

For example, to disable randomization for this traffic class globally, do the following:

a) Choose Policies > Access Control > Access Control, and edit the policy assigned to the devices that require this service.

b) Click Advanced, and click the Edit (✓) for the Threat Defense Service Policy.

c) Click Add Rule.

d) Select Apply Globally > Next.

e) Select the extended ACL object you created for this rule and click Next.

f) Deselect Randomize TCP Sequence Number.

g) (Optional.) Adjust the other connection options as needed.

h) Click Finish to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

i) Click OK to save the changes to the service policy.

j) Click Save on Advanced to save the changes to the access control policy.

You can now deploy the changes to the affected devices.

---

### Examples for Service Policy Rules

The following topics provide examples of service policy rules.

#### Protect Servers from a SYN Flood DoS Attack (TCP Intercept)

A SYN-flooding denial of service (DoS) attack occurs when an attacker sends a series of SYN packets to a host. These packets usually originate from spoofed IP addresses. The constant flood of SYN packets keeps the server SYN queue full, which prevents it from servicing connection requests from legitimate users.

You can limit the number of embryonic connections to help prevent SYN flooding attacks. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination.

When the embryonic connection threshold of a connection is crossed, the Firepower Threat Defense device acts as a proxy for the server and generates a SYN-ACK response to the client SYN request using the SYN cookie method (see Wikipedia for details on SYN cookies). When the Firepower Threat Defense device receives an ACK back from the client, it can then authenticate that the client is real and allow the connection to the server. The component that performs the proxy is called TCP Intercept.

Setting connection limits can protect a server from a SYN flood attack. You can optionally enable TCP Intercept statistics and monitor the results of your policy. The following procedure explains the end-to-end process.

#### Before you begin

- Ensure that you set the embryonic connection limit lower than the TCP SYN backlog queue on the server that you want to protect. Otherwise, valid clients can no longer access the server during a SYN attack.
To determine reasonable values for embryonic limits, carefully analyze the capacity of the server, the network, and server usage.

- Depending on the number of CPU cores on your Firepower Threat Defense device model, the maximum concurrent and embryonic connections can exceed the configured numbers due to the way each core manages connections. In the worst case scenario, the device allows up to n-1 extra connections and embryonic connections, where n is the number of cores. For example, if your model has 4 cores, if you configure 6 concurrent connections and 4 embryonic connections, you could have an additional 3 of each type. To determine the number of cores for your model, enter the `show cpu core` command in the device CLI.

**Procedure**

**Step 1** Create the extended ACL that defines the traffic class, which is the list of servers you want to protect.

For example, to define a traffic class to protect the web servers with the IP addresses 10.1.1.5 and 10.1.1.6:

a) Choose **Objects > Object Management**.
b) Choose **Access List > Extended** from the table of contents.
c) Click **Add Extended Access List**.
d) Enter a **Name** for the object, for example, protected-servers.
e) Click **Add** to add a rule.
f) Keep **Allow** for the action.
g) Leave the **Source** list empty, enter 10.1.1.5 beneath the **Destination** list, and click **Add**.
h) Also enter 10.1.1.6 beneath the **Destination** list and click **Add**.
i) Click **Port**, select **HTTP** in the available ports list, and click **Add to Destination**. If your server also support HTTPS connections, also add that port.
j) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.
k) Click **Save** on the Extended Access List Object dialog box to save the ACL object.

**Step 2** Configure the service policy rule that sets embryonic connection limits.

For example, to set the total concurrent embryonic limit to 1000 connections, and the per-client limit to 50 connections, do the following:

a) Choose **Policies > Access Control > Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced**, and click **Edit (✓)** for the **Threat Defense Service Policy**.
c) Click **Add Rule**.
d) Select **Apply Globally > Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Enter 1000 for **Connections > Maximum Embryonic**.
g) Enter 50 for **Connections Per Client > Maximum Embryonic**.
h) (Optional.) Adjust the other connection options as needed.
i) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.
j) Click **OK** to save the changes to the service policy.
k) Click **Save** on **Advanced** to save the changes to the access control policy.

**Step 3** (Optional.) Configure the rates for TCP Intercept statistics.
TCP Intercept uses the following options to determine the rate for collecting statistics. All options have default values, so if these rates suit your needs, you can skip this step.

- **Rate Interval**—The size of the history monitoring window, between 1 and 1440 minutes. The default is 30 minutes. During this interval, the system samples the number of attacks 30 times.

- **Burst Rate**—The threshold for syslog message generation, between 25 and 2147483647. The default is 400 per second. When the burst rate is exceeded, the device generates syslog message 733104.

- **Average Rate**—The average rate threshold for syslog message generation, between 25 and 2147483647. The default is 200 per second. When the average rate is exceeded, the device generates syslog message 733105.

If you want to adjust these options, do the following:

a) Choose **Objects > Object Management**.

b) Choose **FlexConfig > Text Object**.

c) Click **Edit** for the threat_defense_statistics system-defined object.

d) Although you can directly change the values, the recommended approach is to open the **Override** section and click **Add** to create a device override.

e) Select the devices to which you will assign the service policy (through the access control policy assignment) and click **Add** to move them to the selected list.

f) Click **Override**.

g) The object must have 3 entries, so click **Count** as needed until you get 3.

h) Enter the values you need, in order from 1-3, as rate interval, burst rate, and average rate. Consult the object description to verify you enter the values in the right order.

i) Click **Add** in the Object Override dialog box.

j) Click **Save** in the Edit Text Object dialog box.

### Step 4 Enable TCP Intercept statistics. ###

You must configure a FlexConfig policy to enable TCP Intercept statistics.

a) Choose **Devices > FlexConfig**.

b) If you already have a policy assigned to the devices, edit it. Otherwise, create a new policy and assign it to the affected devices.

c) Select the **Threat_Detection_Configure** object in the **Available FlexConfig** list and click **>>**. The object is added to the **Selected Append FlexConfigs** list.

d) Click **Save**.

e) (Optional.) You can verify that you have the right settings by clicking **Preview Config** and selecting one of the devices.

The system generates the CLI commands that will be written to the device during the next deployment. These commands will include those needed for the service policy as well as those needed for threat detection statistics. Scroll to the bottom of the preview to see the appended CLI. The TCP Intercept statistics command should look something like the following, if you use the default values (line break added for clarity):

```
###Flex-config Appended CLI ###

threat-detection statistics tcp-intercept rate-interval 30
burst-rate 400 average-rate 200
```
Step 5 You can now deploy the changes to the affected devices.

Step 6 Monitor the TCP Intercept statistics from the device CLI using the following commands:

- `show threat-detection statistics top tcp-intercept [all | detail]`—View the top 10 protected servers under attack. The `all` keyword shows the history data of all the traced servers. The `detail` keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

  Note You can use the `shun` command to block attacking host IP addresses. To remove the block, use the `no shun` command.

- `clear threat-detection statistics tcp-intercept`—Erases TCP Intercept statistics.

Example:

```
hostname(config)# show threat-detection statistics top tcp-intercept
Top 10 protected servers under attack (sorted by average rate)
Monitoring window size: 30 mins Sampling interval: 30 secs
<Rank> <Server IP:Port> <Interface> <Ave Rate> <Cur Rate> <Total> <Source IP (Last Attack Time)>
----------------------------------------------------------------------------------
1 10.1.1.5:80 inside 1249 9503 2249245 <various> Last: 10.0.0.3 (0 secs ago)
2 10.1.1.6:80 inside 10 10 6080 10.0.0.200 (0 secs ago)
```

Make the Firepower Threat Defense Device Appear on Traceroutes

By default, the Firepower Threat Defense device does not appear on traceroutes as a hop. To make it appear, you need to decrement the time-to-live on packets that pass through the device, and increase the rate limit on ICMP unreachable messages. To accomplish this, you must configure a service policy rule and adjust the ICMP platform settings policy.

Note If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as OSPF hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences. Keep these considerations in mind when defining your traffic class.

Procedure

Step 1 Create the extended ACL that defines the traffic class for which to enable traceroute reporting.

For example, to define a traffic class for all addresses, but excluding OSPF traffic, do the following:

a) Choose `Objects` > `Object Management`.
b) Choose `Access List` > `Extended` from the table of contents.
c) Click `Add Extended Access List`.
d) Enter a `Name` for the object, for example, traceroute-enabled.
e) Click `Add` to add a rule to exclude OSPF.
f) Change the action to **Block**, click **Port**, select **OSPFIGP (89)** as the protocol beneath the **Destination Ports** list, and click **Add** to add the protocol to the selected list.

g) Click **Add** on the Extended Access List Entry dialog box to add the OSPF rule to the ACL.

h) Click **Add** to add a rule to include all other connections.

i) Keep **Allow** for the action, and leave both the Source and Destination lists empty.

j) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.

   Ensure that the OSPF deny rule is above the Allow Any rule. Drag and drop to move the rules if necessary.

k) Click **Save** on the Extended Access List Object dialog box to save the ACL object.

**Step 2**

Configure the service policy rule that decrements the time-to-live value.

For example, to decrement time-to-live globally, do the following:

a) Choose **Policies > Access Control > Access Control**, and edit the policy assigned to the devices that require this service.

b) Click **Advanced**, and click **Edit (keyboard)** for the **Threat Defense Service Policy**.

c) Click **Add Rule**.

d) Select **Apply Globally** and click **Next**.

e) Select the extended ACL object you created for this rule and click **Next**.

f) Select **Enable Decrement TTL**.

(g) (Optional.) Adjust the other connection options as needed.

h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

i) Click **OK** to save the changes to the service policy.

j) Click **Save** on **Advanced** to save the changes to the access control policy.

   You can now deploy the changes to the affected devices.

**Step 3**

Increase the rate limit on ICMP unreachable messages.

a) Choose **Devices > Platform Settings**.

b) If you already have a policy assigned to the devices, edit it. Otherwise, create a new Firepower Threat Defense platform settings policy and assign it to the affected devices.

c) Select **ICMP** from the table of contents.

(d) Increase the **Rate Limit**, for example, to 50. You can ignore the **Burst Size**, it is not used.

   You can leave the ICMP rules table empty, it is not related to this task.

c) Click **Save**.

**Step 4**

You can now deploy the changes to the affected devices.

---

**Monitoring Service Policies**

You can monitor service-policy related information using the device CLI. Following are some useful commands.

• **show conn [detail]**

   Shows connection information. Detailed information uses flags to indicate special connection characteristics. For example, the “b” flag indicates traffic subject to TCP State Bypass.
When you use the `detail` keyword, you can see information about Dead Connection Detection (DCD) probing, which shows how often the connection was probed by the initiator and responder. For example, the connection details for a DCD-enabled connection would look like the following:

TCP dmz: 10.5.4.11/5555 inside: 10.5.4.10/40299,
flags UO , idle 1s, uptime 32m10s, timeout 1m0s, bytes 11828,
cluster sent/rcvd bytes 0/0, owners (0,255)
Traffic received at interface dmz
  Locally received: 0 (0 byte/s)
Traffic received at interface inside
  Locally received: 11828 (6 byte/s)
Initiator: 10.5.4.10, Responder: 10.5.4.11
DCD probes sent: Initiator 5, Responder 5

- `show service-policy`
  Shows service policy statistics, including Dead Connection Detection (DCD) statistics.

- `show threat-detection statistics top tcp-intercept [all | detail]`
  View the top 10 protected servers under attack. The `all` keyword shows the history data of all the traced servers. The `detail` keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

History for Firepower Threat Defense Service Policy
The following topics describe how to configure and deploy FlexConfig policies.

- FlexConfig Policy Overview, on page 1199
- Requirements and Prerequisites for FlexConfig Policies, on page 1219
- Guidelines and Limitations for FlexConfig, on page 1219
- Customizing Device Configuration with FlexConfig Policies, on page 1219
- Examples for FlexConfig, on page 1233
- History for FlexConfig, on page 1247

FlexConfig Policy Overview

A FlexConfig policy is a container of an ordered list of FlexConfig objects. Each object includes a series of Apache Velocity scripting language commands, ASA software configuration commands, and variables that you define. The contents of each FlexConfig object is essentially a program that generates a sequence of ASA commands that will then be deployed to the assigned devices. This command sequence then configures the related feature on the FTD device.

FTD uses ASA configuration commands to implement some features, but not all features. There is no unique set of FTD configuration commands. Instead, the point of FlexConfig is to allow you to configure features that are not yet directly supported through Firepower Management Center policies and settings.

Caution

Cisco strongly recommends using FlexConfig policies only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not prohibited. Enabling features through FlexConfig policies may cause unintended results with other configured features.

You may contact the Cisco Technical Assistance Center for support concerning FlexConfig policies that you have configured. The Cisco Technical Assistance Center does not design or write custom configurations on any customer's behalf. Cisco expresses no guarantees for correct operation or interoperability with other Firepower System features. FlexConfig features may become deprecated at any time. For fully guaranteed feature support, you must wait for Firepower Management Center support. When in doubt, do not use FlexConfig policies.
**Recommended Usage for FlexConfig Policies**

There are two main recommended uses for FlexConfig:

- You are converting from ASA to FTD, and there are compatible features you are using (and need to continue using) that Firepower Management Center does not directly support. In this case, use the `show running-config` command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Experiment with the object’s deployment settings (once/everytime and append/prepend) to get the right setting. Verify by comparing `show running-config` output on the two devices.

- You are using FTD but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

The system includes a set of predefined FlexConfig objects that represent tested configurations. If the feature you need is not represented by these objects, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control, which the ASA implements using separate features. Because many features are not configured using CLI commands, you will not see every policy represented within the output of `show running-config`.

At all times, keep in mind that there is not a one-to-one overlap between ASA and FTD. Do not attempt to completely recreate an ASA configuration on a FTD device. You must carefully test any feature that you configure using FlexConfig.

---

**CLI Commands in FlexConfig Objects**

FTD uses ASA configuration commands to configure some features. Although not all ASA features are compatible with FTD, there are some features that can work on FTD but that you cannot configure in Firepower Management Center policies. You can use FlexConfig objects to specify the CLI required to configure these features.

If you decide to use FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig policies do not validate CLI command syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference:

The following topics explain more about configuration commands.
Determine the ASA Software Version and Current CLI Configuration

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the FTD device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from a FTD configuration. Many FTD policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and FTD configuration.

To view this information, make an SSH connection to the device's management interface and issue the following commands:

- `show version system` and look for the Cisco Adaptive Security Appliance Software Version number. (If you issue the command through the Firepower Management Center CLI tool, omit the `system` keyword.)
- `show running-config` to view the current CLI configuration.
- `show running-config all` to include all the default commands in the current CLI configuration.

You can also issue these commands from within Firepower Management Center using the following procedure.

**Procedure**

**Step 1** Choose System > Health > Monitor.

**Step 2** Click the name of the device targeted by the FlexConfig policy.

You might need to click the open/close arrow in the Count column in the Status table to see any devices.

**Step 3** Choose Advanced Troubleshooting.

**Step 4** Choose Threat Defense CLI.

**Step 5** Choose `show` as the command, and type `version` or one of the other commands as the parameter.

**Step 6** Click Execute.

For version, search the output for the Cisco Adaptive Security Appliance Software Version number.

You can select the output and press Ctrl+C, then paste it into a text file for later analysis.

**Prohibited CLI Commands**

The purpose of FlexConfig is to configure features that are available on ASA devices that you cannot configure on FTD devices using Firepower Management Center.

Thus, you are prevented from configuring ASA features that have equivalents in Firepower Management Center. The following table lists some of these prohibited command areas.

In addition, some `clear` commands are prohibited because they overlap with managed policies, and can delete part of the configuration for a managed policy.

The FlexConfig object editor prevents you from including prohibited commands in the object.

**Template Scripts**

You can use scripting language to control processing within a FlexConfig object. Scripting language instructions are a subset of commands supported in the Apache Velocity 1.3.1 template engine, a Java-based scripting language that supports looping, if/else statements, and variables.

To learn how to use the scripting language, see the *Velocity Developer Guide* at [http://velocity.apache.org/engine/devel/developer-guide.html](http://velocity.apache.org/engine/devel/developer-guide.html).

**FlexConfig Variables**

You can use variables in a FlexConfig object in cases where part of a command or processing instruction depends on runtime information rather than static information. During deployment, the variables are replaced with strings obtained from other configurations for the device based on the type of variable:
• Policy object variables are replaced with strings obtained from objects defined in Firepower Management Center.

• System variables are replaced with information obtained from the device itself or from policies configured for it.

• Processing variables are loaded with the contents of policy object or system variables as scripting commands are processed. For example, in a loop, you iteratively load one value from a policy object or system variable into a processing variable, then use the processing variable to form a command string or perform some other action. These processing variables do not show up in the Variables list within a FlexConfig object. Also, you do not add them using the Insert menu in the FlexConfig object editor.

• Secret key variables are replaced with the single string defined for the variable within the FlexConfig object.

Variables start with the $ character, except for secret keys, which start with the @ character. For example, $ifname is a policy object variable in the following command, whereas @keyname is a secret key.

interface $ifname
key @keyname

---

**Note**

The first time you insert a policy object or system variable, you must do so through the Insert menu in the FlexConfig object editor. This action adds the variable to the Variables list at the bottom of the FlexConfig object editor. But you must type in the variable string on subsequent uses, even when using system variables. If you are adding a processing variable, which does not have an object or system variable assignment, do not use the Insert menu. If you are adding a secret key, always use the Insert menu. Secret key variables do not show up in the Variables list.

Whether a variable is resolved as a single string, a list of strings, or a table of values depends on the type of policy object or system variable you assign to the variable. (Secret keys always resolve to a single string.) You must understand what will be returned in order to process the variables correctly.

The following topics explain the various types of variable and how to process them.

### How to Process Variables

At runtime, a variable can resolve to a single string, a list of strings of the same type, a list of strings of different types, or a table of named values. In addition, variables that resolve to multiple values can be of determinate or indeterminate length. You must understand what will be returned in order to process the values correctly.

Following are the main possibilities.

#### Single Value Variables

If a variable always resolves to a single string, use the variable directly without modification in the FlexConfig script.

For example, the predefined text variable tcpMssBytes always resolves to a single value (which must be numeric). The **Sysopt_basic** FlexConfig then uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, tcpMssMinimum:

```
#if($tcpMssMinimum == "true")
```
In this example, you would use the Insert menu in the FlexConfig object editor to add the first use of $tcpMssBytes, but you would type in the variable directly on the #else line.

Secret key variables are a special type of single value variable. For secret keys, you always use the Insert menu to add the variable, even for second and subsequent uses. These variables do not show up in the Variables list within the FlexConfig object. For example, if you wanted to hide the keys for EIGRP configuration, you could copy the Eigrp_Interface_Configure FlexConfig, and replace the $eigrpAuthKey and $eigrpAuthKeyId variables with secret keys, @SecretEigrpAuthKey and @SecretEigrpAuthKeyId.

authentication key eigrp $eigrpAS @SecretEigrpAuthKey key-id @SecretEigrpAuthKeyId

Note
Policy object variables for network objects also equate to a single IP address specification, either a host address, network address, or address range. However, in this case, you must know what type of address to expect, because the ASA commands require specific address types. For example, if a command requires a host address, using a network object variable that points to an object that contains a network address will result in an error during deployment.

Multiple Value Variables, All Values Are the Same Type

Several policy object and system variables resolve to multiple values of the same type. For example, an object variable that points to a network object group resolves to a list of the IP addresses within the group. Similarly, the system variable $SYS_FW_INTERFACE_NAME_LIST resolves to a list of interface names.

You can also create text objects for multiple values of the same type. For example, the predefined text object enableInspectProtocolList can contain more than one protocol name.

Multiple value variables that resolve to a list of items of the same type are frequently of indeterminate length. For example, you cannot know beforehand how many interfaces on a device are named, as users can configure or unconfigure interfaces at any time.

Thus, you would typically use a loop to process multiple value variables of the same type. For example, the predefined FlexConfig Default_Inspection_Protocol_Enable uses a #foreach loop to go through the enableInspectProtocolList object and process each value.

policy-map global_policy
class inspection_default
    #foreach ( $protocol in $enableInspectProtocolList)
        inspect $protocol
    #end

In this example, the script assigns each value in turn to the $protocol variable, which is then used in an ASA inspect command to enable the inspection engine for that protocol. In this case, you simply type in $protocol as a variable name. You do not use the Insert menu to add it, because you are not assigning an object or system value to the variable. However, you must use the Insert menu to add $enableInspectProtocolList.

The system loops through the code between #foreach and #end until there are no values remaining in $enableInspectProtocolList.
Multiple Value Variables, Values Are Different Types

You can create multiple value text objects, but have each value serve a different purpose. For example, the predefined netflow_Destination text object should have 3 values, in order, interface name, destination IP address, and UDP port number.

Objects defined in this way should have a determinate number of values. Otherwise, they would be hard to process.

Use the get method to process these objects. Type .get(n) at the end of the object name, replacing n with an index into the object. Start counting at 0, even though the text object lists its values starting at 1.

For example, the Netflow_Add_Destination object uses the following line to add the 3 values from netflow_Destination to the ASA flow-export command.

```java
flow-export destination $netflow_Destination.get(0) $netflow_Destination.get(1) $netflow_Destination.get(2)
```

In this example, you would use the Insert menu in the FlexConfig object editor to add the first use of $netflow_Destination, and then .get(0). But you would type in the variable directly for the $netflow_Destination.get(1) and $netflow_Destination.get(2) specifications.

Multiple Value Variables that Resolve to a Table of Values

Some system variables return a table of values. These variables include MAP in their name, for example, $SYS_FTD_ROUTED_INTF_MAP_LIST. The routed interface map returns data that looks like the following (line returns added for clarity):

```java
[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[], intf_subnet_mask_v4=255.255.255.0, intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=, intf_logical_name=outside},
 {intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[], intf_subnet_mask_v4=255.255.255.0, intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=, intf_logical_name=inside},
 {intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[], intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=, intf_ipv6_link_local_address=, intf_logical_name=},
 {intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[], intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=, intf_ipv6_link_local_address=, intf_logical_name=diagnostic}]
```

In the above example, information is returned for 4 interfaces. Each interface includes a table of named values. For example, intf_hardwarare_id is the name of the interface hardware name property, and returns strings such as GigabitEthernet0/0.

This type of variable is typically of indeterminate length, so you need to use looping to process the values. But you also need to add the property name to the variable name to indicate which value to retrieve.

For example, IS-IS configuration requires that you add the ASA isis command to an interface that has a logical name in interface configuration mode. However, you enter that mode using the interface’s hardware name. Thus, you need to identify which interfaces have logical names, then configure just those interfaces using their hardware names. The ISIS_Interface_Configuration predefined FlexConfig does this using an if/then
structure nested in a loop. In the following code, you can see that the #foreach scripting command loads each interface map into the $intf variable, then the #if statement keys off the intf_logical_name value in the map ($intf.intf_logical_name), and if the value is in the list defined in the isisIntfList predefined text variable, enters the interface command using the intf_hardwarare_id value ($intf.intf_hardwarare_id). You would need to edit the isisIntfList variable to add the names of the interfaces on which to configure IS-IS.

```plaintext
#foreach ($intf in $SYS_FTD_ROUTED_INTF_MAP_LIST)
#if ($isIsIntfList.contains($intf.intf_logical_name))
  interface $intf.intf_hardwarare_id
  isis
  #if ($isIsAddressFamily.contains("ipv6"))
  ipv6 router isis
  #end
#end
#end
```

**How to See What a Variable Will Return for a Device**

An easy way to evaluate what a variable will return is to create a simple FlexConfig object that does nothing more than process an annotated list of variables. Then, you can assign it to a FlexConfig policy, assign the policy to a device, save the policy, then preview the configuration for that device. The preview will show the resolved values. You can select the preview text, press Ctrl+C, then paste the output into a text file for analysis.

---

**Note**

Do not deploy this FlexConfig to the device, however, because it will not contain any valid configuration commands. You would get deployment errors. After obtaining the preview, delete the FlexConfig object from the FlexConfig policy and save the policy.

For example, you could construct the following FlexConfig object:

Following is a network object group variable for the IPv4-Private-All-RFC1918 object:

```plaintext
$IPv4_Private_addresses
```

Following is the system variable SYS_FW_MANAGEMENT_IP:

```plaintext
$SYS_FW_MANAGEMENT_IP
```

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

```plaintext
$SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST
```

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

```plaintext
$SYS_FTD_ROUTED_INTF_MAP_LIST
```

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

```plaintext
$SYS_FW_INTERFACE_NAME_LIST
```

The preview of this object might look like the following (line returns added for clarity):

```plaintext
###Flex-config Prepended CLI ###
```
### CLI generated from managed features ###

### Flex-config Appended CLI ###

Following is a network object group variable for the IPv4-Private-All-RFC1918 object:

\[[10.0.0.0, 172.16.0.0, 192.168.0.0]\]

Following is the system variable SYS_FW_MANAGEMENT_IP:

192.168.0.171

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

\[dns, ftp, h323 h225, h323 ras, rsh, rtsp, sqlnet, skinny, sunrpc, xdmcp, sip, netbios, tftp, icmp, icmp error, ip-options\]

Following is the system variable SYS_FTD_ROUTED_INIF_MAP_LIST:

\[
\begin{align*}
&\{ \text{intf\_hardware\_id=GigabitEthernet0/0, intf\_ipv6\_eui64\_addresses=[],}
\text{intf\_ipv6\_prefix\_addresses=[],}
\text{intf\_subnet\_mask\_v4=255.255.255.0,}
\text{intf\_ip\_addr\_v4=10.100.10.1,}
\text{intf\_ipv6\_link\_local\_address=,}
\text{intf\_logical\_name=outside}\}, \\
&\{ \text{intf\_hardware\_id=GigabitEthernet0/1, intf\_ipv6\_eui64\_addresses=[],}
\text{intf\_ipv6\_prefix\_addresses=[],}
\text{intf\_subnet\_mask\_v4=255.255.255.0,}
\text{intf\_ip\_addr\_v4=10.100.11.1,}
\text{intf\_ipv6\_link\_local\_address=,}
\text{intf\_logical\_name=inside}\}, \\
&\{ \text{intf\_hardware\_id=GigabitEthernet0/2, intf\_ipv6\_eui64\_addresses=[],}
\text{intf\_ipv6\_prefix\_addresses=[],}
\text{intf\_subnet\_mask\_v4=,}
\text{intf\_ip\_addr\_v4=,}
\text{intf\_ipv6\_link\_local\_address=,}
\text{intf\_logical\_name=}\}, \\
&\{ \text{intf\_hardware\_id=Management0/0, intf\_ipv6\_eui64\_addresses=[],}
\text{intf\_ipv6\_prefix\_addresses=[],}
\text{intf\_subnet\_mask\_v4=,}
\text{intf\_ip\_addr\_v4=,}
\text{intf\_ipv6\_link\_local\_address=,}
\text{intf\_logical\_name=diagnostic}\}\]
\]

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

\[outside, inside, diagnostic\]

---

### FlexConfig Policy Object Variables ###

A policy object variable is associated with a specific policy object configured in the Object Manager. When you insert a policy object variable in a FlexConfig object, you give the variable a name and select the object associated with it.

Although you can give the variable the exact same name as the associated object, the variable itself is not the same thing as the associated object. You must use the Insert > Insert Policy Object > Object Type menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the object. Simply typing in the name of the object preceded by a $ sign does not create a policy object variable.

You can create variables to point to the following types of object. Ensure that you create the right type of object for each variable. To create objects, go to the Objects > Object Management page.

- **Text Objects**—For text strings, which can include IP addresses, numbers, and other free-form text such as interface or zone names. Select FlexConfig > Text Object from the table of contents, then click Add Text Object. You can configure these objects to contain a single value or multiple values. These objects
are highly flexible and built specifically for use within FlexConfig objects. For detailed information, see Configure FlexConfig Text Objects, on page 1225.

- **Network**—For IP addresses. You can use network objects or groups. Select **Network** from the table of contents, then select **Add Network** > **Add Object** or **Add Group**. If you use a group object, the variable returns a list of each IP address specification within the group. Addresses can be host, network, or address ranges, depending on the object contents. See Network Objects, on page 564.

- **Security Zones**—For interfaces within a security zone or interface group. Select **Interface** from the table of contents, then select **Add** > **Security Zone** or **Interface Group**. A security zone variable returns a list of the interfaces within that zone or group for the device being configured. See Interface Objects: Interface Groups and Security Zones, on page 572.

- **Standard ACL Object**—For standard access control lists. A standard ACL variable returns the name of the standard ACL object. Select **Access List** > **Standard** from the table of contents, then click **Add Standard Access List Object**. See Access List, on page 634.

- **Extended ACL Object**—For extended access control lists. An extended ACL variable returns the name of the extended ACL object. Select **Access List** > **Extended** from the table of contents, then click **Add Extended Access List Object**. See Access List, on page 634.

- **Route Map**—For route map objects. A route map variable returns the name of the route map object. Select **Route Map** from the table of contents, then click **Add Route Map**. See Route Maps, on page 631.

### FlexConfig System Variables

System variables are replaced with information obtained from the device itself or from policies configured for it.

You must use the **Insert** > **Insert System Variable** > **Variable Name** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the system variable. Simply typing in the name of the system variable preceded by a $ sign does not create a system variable within the context of the FlexConfig object.

The following table explains the available system variables. Before using a variable, examine what is typically returned for the variable; see How to See What a Variable Will Return for a Device, on page 1207.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYS_FW_OS_MODE</td>
<td>The operating system mode of the device. Possible values are ROUTED or TRANSPARENT.</td>
</tr>
<tr>
<td>SYS_FW_OS_MULTIPLICITY</td>
<td>Whether the device is running in single or multiple context mode. Possible values are SINGLE, MULTI, or NOT_APPLICABLE.</td>
</tr>
<tr>
<td>SYS_FW_MANAGEMENT_IP</td>
<td>The management IP address of the device</td>
</tr>
<tr>
<td>SYS_FW_HOST_NAME</td>
<td>The device hostname</td>
</tr>
<tr>
<td>SYS_FTD_INTF_POLICY_MAP</td>
<td>A map with interface name as key and policy-map as value. This variable returns nothing if there are no interface-based service policies defined on the device.</td>
</tr>
<tr>
<td>SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST</td>
<td>The list of protocols for which inspection is enabled.</td>
</tr>
</tbody>
</table>
Predefined FlexConfig Objects

The predefined FlexConfig objects provide tested configurations for select features. Use these objects if you need to configure these features, which otherwise cannot be configured through Firepower Management Center.

The following table lists the available objects. Make note of the associated text objects. You must edit these text objects to customize the behavior of the predefined FlexConfig object. The text objects make it possible for you to customize the configuration using the IP addresses and other attributes required by your network and device.

If you need to modify a predefined FlexConfig object, copy the object, make changes to the copy, and save it with a new name. You cannot directly edit a predefined FlexConfig object.

Although you might be able to configure other ASA-based features using FlexConfig, the configuration of those features has not been tested. If an ASA feature overlaps with something that you can configure in Firepower Management Center policies, do not attempt to configure it through FlexConfig.

For example, Snort inspection includes the HTTP protocol, so do not enable ASA-style HTTP inspection. (In fact, you cannot add http to the enableInspectProtocolList object. In this case, you are prevented from misconfiguring your device.) Instead, configure the access control policy to perform application or URL filtering, as needed, to implement your HTTP inspection requirements.
<table>
<thead>
<tr>
<th>FlexConfig Object Name</th>
<th>Description</th>
<th>Associated Text Objects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default_DNS_Configure</td>
<td>Configure the Default DNS group, which defines the DNS servers that can be used when resolving fully-qualified domain names on the data interfaces. This allows you to use commands in the CLI, such as ping, using host names rather than IP addresses. Starting with version 6.3, configure DNS for the data interfaces in the Firepower Threat Defense Platform Settings policy.</td>
<td>defaultDNSNameServerList, defaultDNSParameters</td>
</tr>
<tr>
<td>Default_Inspection_Protocol_Disable</td>
<td>Disables protocols in the global_policy default policy map.</td>

### Predefined Text Objects

There are several predefined text objects. These objects are associated with variables used in the predefined FlexConfig objects. In most cases, you must edit these objects to add values if you use the associated FlexConfig object, or you will see errors during deployment. Although some of these objects contain default values, others are empty.

For information on editing text objects, see Configure FlexConfig Text Objects, on page 1225.

Guidelines and Limitations for FlexConfig

• If you make a mistake in the FlexConfig policy, the system will roll back all changes included in the deployment attempt that includes the failed FlexConfig. Because rollback due to a failed deployment includes clearing the configuration, this can be disruptive to your network. Consider timing deployments that include FlexConfig changes to non-business hours. Also, consider isolation the deployment so it includes just FlexConfig changes, and no other policy updates.

• When you use the VxLAN_Make_VNI object, you must deploy the same FlexConfig to all units in a cluster or high availability pair before you form the cluster or high availability pair. The Management Center requires the VXLAN interfaces to match on all devices before forming the cluster or high availability pair.

• If you want to configure Equal-Cost-Multi-Path (ECMP) routing using traffic zones, the zone command differs for FTD devices compared to the one used on ASA. Although you can still follow the instructions in the ASA general configuration guide, use zone name ecmp instead of the ASA version of the command. Otherwise, the operation of the traffic zone feature is identical between the ASA and FTD.

Note
The system also configures zone name passive commands to configure passive zones if you define some interfaces as passive. This is handled automatically based on your interface configuration. Do not use FlexConfig to create passive traffic zones.

Customizing Device Configuration with FlexConfig Policies

Use FlexConfig policies to customize the configuration of a FTD device.

Before using FlexConfig, try to configure all the policies and settings you need using the other features in Firepower Management Center. FlexConfig is a method of last resort to configure ASA-based features that are compatible with FTD but which are not otherwise configurable in Firepower Management Center.

Following is the end-to-end procedure for configuring and deploying a FlexConfig policy.
Procedure

Step 1
Determine the CLI command sequence that you want to configure.

If you have a functioning configuration on an ASA device, use `show running-config` to get the sequence of commands that you need. Make adjustments to items such as interface names and IP addresses as needed.

If this is for a new feature, it is best to try to implement it on an ASA device in a lab setting to verify that you have the correct command sequence.

For more information, see the following topics:

- Recommended Usage for FlexConfig Policies, on page 1200
- CLI Commands in FlexConfig Objects, on page 1200

Step 2
Select Objects > Object Management, then select FlexConfig > FlexConfig Objects from the table of contents.

Examine the predefined FlexConfig objects to determine if any will be able to generate the commands you need. Click View (ıldır) to see the object contents. If an existing object is close to what you want, start by making a copy of the object, and then edit the copy. See Predefined FlexConfig Objects, on page 1210.

Examining the objects will also give you an idea of the structure, command syntax, and expected sequencing for a FlexConfig object.

**Note** If you find any objects that you will use, either directly or as copies, examine the Variables list at the bottom of the object. Make note of the variable names, except those in all capitals that start with SYS, which are system variables. These variables are text objects that you will probably need to edit and define overrides for, especially if the default value column shows the object has no value.

Step 3
If you need to create your own FlexConfig objects, determine what variables you will need and create the associated objects.

The CLI you need to deploy might contain IP addresses, interface names, port numbers, and other parameters that you might want to adjust over time. These are best isolated into variables, which point to objects that contain the necessary values. You might also need variables for strings that are part of the configuration but which might change over time.

Also, determine if you need different values for each device to which you will assign the policy. For example, you might want to configure the feature on three devices, but you might need to specify a different interface name or IP address on a given command for each of these devices. If you need to customize the object for each device, ensure that you enable overrides when creating the object, and then define the override values per device.

See the following topics for an explanation of the various types of variables and how to configure the related objects when necessary.

- FlexConfig Variables, on page 1203
- FlexConfig Policy Object Variables, on page 1208
- FlexConfig System Variables, on page 1209
- Configure FlexConfig Text Objects, on page 1225
Step 4 If you are using the predefined FlexConfig objects, edit the text objects used as variables. See Configure FlexConfig Text Objects, on page 1225.

Step 5 (If necessary.) Configure FlexConfig Objects, on page 1221.

You need to create objects only if the predefined objects cannot do the job.

Step 6 Configure the FlexConfig Policy, on page 1227.

Step 7 Set Target Devices for a FlexConfig Policy, on page 1228.

You can also assign the policy to devices when you create the policy. The policy must have at least one assigned device before you can preview it.

Step 8 Preview the FlexConfig Policy, on page 1228.

You must save changes before you can preview the policy.

Verify that the generated commands are the ones intended, and that all variables are resolving correctly.

Step 9 Choose Deploy > Deployment in the menu bar.

Step 10 Select the devices assigned to the policy, and click Deploy.

Wait for deployment to complete.

Step 11 Verify the Deployed Configuration, on page 1229.

Step 12 (If necessary.) Remove Features Configured Using FlexConfig, on page 1231.

Unlike other types of policy, simply unassigning a FlexConfig from a device might not remove the related configuration. If you want to remove a FlexConfig-generated configuration, you follow the cited procedure.

If you are removing a Feature because it is now directly supported by the product, see also Convert from FlexConfig to Managed Feature, on page 1232.

---

**Configure FlexConfig Objects**

Use FlexConfig objects to define a configuration to be deployed to a device. Each FlexConfig policy is composed of a list of FlexConfig objects, so the objects are essentially code modules composed of Apache Velocity scripting commands, ASA software configuration commands, and variables.

There are several predefined FlexConfig objects that you can use directly, or you can make copies if you need to edit them. You can also create your own objects from scratch. A FlexConfig object’s content can range from a single simple command string to elaborate CLI command structures that use variables and scripting commands to deploy commands whose content can differ from device to device or deployment to deployment.

You can also create FlexConfig policy objects when defining FlexConfig policies.

**Before you begin**

Keep the following in mind:

- FlexConfig objects translate into commands that are then deployed to the device. These commands are already issued in global configuration mode. Therefore, do not include the `enable` and `configure terminal` commands as part of the FlexConfig object.
Configure FlexConfig Objects

• Determine what types of variables you will need, and create any policy objects that you will require. You cannot create objects for variables while editing a FlexConfig object.

• Ensure that your commands do not conflict in any way with the VPN or access control configuration on the devices.

• If there is more than one set of commands for an interface, only the last set of commands is deployed. Therefore, we recommend you not use beginning and ending commands to configure interfaces. For an example of configuring interfaces, see the ISIS_Interface_Configuration predefined FlexConfig object.

Procedure

Step 1  Choose Objects > Object Management.

Step 2  Choose FlexConfig > FlexConfig Object from the list of object types.

Step 3  Do one of the following:

• Click Add FlexConfig Object to create a new object.

• Click Edit ( ) to edit an existing object.

• Click View ( ) to see the contents of a predefined object.

• If you want to edit a predefined object, click Copy ( ) to create a new object with the same contents.

Step 4  Enter a Name and optionally, a description for the object.

Step 5  In the object body area, enter the commands and instructions to produce the required configuration.

The object content is a sequence of scripting commands and configuration commands that generate a valid ASA software command sequence. The FTD device uses ASA software commands to configure some features. For more information on scripting and configuration commands, see:

• Template Scripts, on page 1203

• CLI Commands in FlexConfig Objects, on page 1200

You can use variables to supply information that can be known only at runtime, or which can differ from device to device. You simply type in processing variables, but you must use the Insert menu to add variables that are associated with policy objects or system variables, or which are secret keys. For a complete discussion of variables, see FlexConfig Variables, on page 1203.

• To insert system variables, choose Insert > Insert System Variable > Variable Name. For a detailed explanation of these variables, see FlexConfig System Variables, on page 1209.

• To insert policy object variables, choose Insert > Insert Policy Object > Object Type, selecting the appropriate type of object. Then, give the variable a name (which can be the same name as the associated policy object), select the object to associate with the variable, and click Save. For a detailed explanation of these types, see FlexConfig Policy Object Variables, on page 1208. For more detail on the procedure, see Add a Policy Object Variable to a FlexConfig Object, on page 1224.

• To insert secret key variables, choose Insert > Secret Key and define the variable name and value. For more detail on the procedure, see Configure Secret Keys, on page 1224.
Note You must use the Insert menu to create a new policy object or system variable. However, for subsequent uses of that variable, you must type it in, $ included. This is also true for system variables: the first time you use it, add it from the Insert menu. Then, type it out for subsequent uses. If you use the Insert menu more than once for a system variable, the system variable is added to the Variables list multiple times, and the FlexConfig will not validate, meaning you cannot save your changes. For processing variables (those not associated with a policy object or system variable), simply type in the variable. If you are adding a secret key, always use the Insert menu. Secret key variables do not show up in the Variables list.

Step 6 Choose the deployment frequency and type.

- **Deployment**—Whether to deploy the commands in the object **Once** or **Everytime**. The only way to choose the right option is to test the results of deployment.

Start by selecting **Everytime**. Then, after you attach the object to a FlexConfig policy, deploy the configuration. After a successful deployment, come back to the FlexConfig policy and preview the configuration for one of the assigned devices as described in Preview the FlexConfig Policy, on page 1228. If the section labeled ###CLI generated from managed features ### contains commands that clear or negate the commands in the object, and the ###Flex-config Appended CLI ### section contains the commands to reconfigure the feature, you know that **Everytime** is the right option.

Even if you do not see negate commands, make some minor change to the device configuration, then run another deployment. If the deployment completes successfully, you can check the deployment transcript (see Verify the Deployed Configuration, on page 1229). If you see that the commands were issued again (even when they were already configured) without error, then you can keep **Everytime**.

Change to **Once** only if the system does not first negate the commands in the object before issuing them again, or if the deployment results in errors that are specific to the command. In some cases, the system does not allow you to issue a command that is already configured, but this is the exception.

Some additional tips:

- If the FlexConfig object points to system-managed objects such as network or ACL objects, choose **Everytime**. Otherwise, updates to the objects might not get deployed.

- Use **Once** if the only thing you do in the object is to clear a configuration. Then, remove the object from the FlexConfig policy after the next deployment.

- **Type**—Select one of the following:

  - **Append**—(The default.) Commands in the object are put at the end of the configurations generated from the Firepower Management Center policies. You must use Append if you use policy object variables, which point to objects generated from managed objects. If commands generated for other policies overlap with those specified in the object, you should select this option so your commands are not overwritten. This is the safest option.

  - **Prepend**—Commands in the object are put at the beginning of the configurations generated from the Firepower Management Center policies. You would typically use prepend for commands that clear or negate a configuration.

Step 7 (Optional.) Click **Validate** above the object body to check the integrity of the script.

The object is always validated when you click **Save**. You cannot save an invalid object.
Add a Policy Object Variable to a FlexConfig Object

You can insert variables into a FlexConfig policy object that are associated with other types of policy object. When the FlexConfig is deployed to a device, these variables resolve to the names or content of the associated object.

Use the following procedure for the first use of a policy object variable in a FlexConfig object. If you need to refer to the object again, type in the variable (including the $ sign). To understand how to use these variables, see How to Process Variables, on page 1204.

Procedure

Step 1  Choose Insert > Insert Policy Object > Object Type, selecting the appropriate type of object.

Step 2  Enter a name for the variable, and optionally, a description.

The name must be unique within the context of the FlexConfig object. It cannot include spaces. You are allowed to use the exact same name as the object associated with the variable.

Step 3  Select the object to associate with the variable and click Add to move it to the Selected Object list.

You can associate a variable with a single object only.

Note  For text objects, you can select any of the predefined objects as needed. However, many of these objects have no default values. You must update the objects to add the required values either directly or as overrides for the device to which you will deploy the FlexConfig object. Trying to deploy a FlexConfig without updating these objects typically results in deployment errors.

Step 4  Click Save.

The variable appears in the Variables list at the bottom of the FlexConfig object editor.

Configure Secret Keys

A secret key is any single-string variable whose content you want to mask, such as passwords. The system provides special treatment for these variables to help you prevent the dissemination of sensitive information.

Secret key variables do not show up in the Variables list in the FlexConfig object.

Use the following procedure to create, insert, and otherwise manage secret key variables in a FlexConfig object. Unlike other types of variables, you can use the Insert command every time you need to insert a given secret key variable. With respect to processing, these variables behave like single-value text object variables; see Single Value Variables, on page 1204.
Any data defined in a secret key variable is masked from users except when previewing a FlexConfig policy. In addition, if you export a FlexConfig policy, the content of any secret key variable is erased. When you import the policy, you will need to manually edit each secret key variable to enter the data.

**Procedure**

**Step 1** While editing a FlexConfig Policy Object, choose **Insert > Secret Key**.

**Step 2** In the Insert Secret Key dialog box, do any of the following:

- To create a new key, click **Add Secret Key**, then fill in the following information and click **Add**.
  - **Secret Key Name**—The name of the variable. This name appears in the FlexConfig object prefixed with @.
  - **Password, Confirm Password**—The secret string, which is masked with asterisks as you type.

- To insert a secret key variable in the FlexConfig object, select the check box for the variable.

- To edit the value of a secret key variable, click **Edit** for the variable. Make your changes and click **Add**.

- To delete a secret key variable, click **Delete** for the variable.

**Step 3** Click **Save**.

---

**Configure FlexConfig Text Objects**

Use text objects in FlexConfig objects as the target of policy object variables. You can use variables to supply information that can be known only at runtime, or which can differ from device to device. During deployment, variables that point to text objects are replaced by the content of the text object.

Text objects contain free-form strings, which can be keywords, interface names, numbers, IP addresses, and so forth. The content depends on how you will use the information within a FlexConfig script.

Before creating or editing a text object, determine exactly what content you will need. This includes how you intend to process the object, which will help you decide between creating a single string or multiple string object. Read the following topics:

- **FlexConfig Variables**, on page 1203
- **How to Process Variables**, on page 1204

**Procedure**

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose **FlexConfig > Text Object** from the list of object types.
Configure FlexConfig Text Objects

Step 3  
Do one of the following:

• Click Add Text Object to create a new object.

• Click Edit (✓) to edit an existing object. You are allowed to edit the predefined text objects, which is required if you intended to use the predefined FlexConfig objects.

Step 4  
Enter a Name and optionally, a description for the object.

Step 5  
(New objects only.) Choose a Variable Type from the drop-down list:

• Single—If the object should contain a single text string.

• Multiple—If the object should contain a list of text strings.

You cannot change the variable type after you save the object.

Step 6  
If the variable type is Multiple, use the up and down arrows to specify a Count.

Rows are added or removed from the object as you change the number.

Step 7  
Add content to the object.

You can either click in the text box next to a variable number and type in a value, or you can set up device overrides for each device that will be assigned a FlexConfig object that uses the text object. You can also do both, in which case the values configured in the base object act as default values in cases where an override does not exist for a given device.

When editing predefined objects, it is a good practice to use device overrides, so that the system defaults remain in place for other users who might need to use the object in different FlexConfig policies. The approach you take depends on the requirements of your organization.

Tip  
Some predefined objects require multiple values where each value serves a specific purpose. Read the description text carefully to determine the expected values in the object. In some cases, the instructions specify that you must use overrides instead of changing the base values. In the case of enableInspectProtocolList, you are prevented from entering protocols whose inspection is incompatible with Snort inspection.

If you decide to use device overrides, do the following.

a)  Select Allow Overrides.

b)  Expand the Overrides area (if necessary) and click Add.

If an override already exists for the device, click edit for the override to change it.

c)  On Targets in the Add Object Override dialog box, select the device for which you are defining values and click Add to move it to the Selected Devices list.

d)  Click Override, adjust the Count as needed, then click in the variable fields and type in the values for the device.

e)  Click Add.

Step 8  
Click Save.

What to do next

• If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 495.
Configure the FlexConfig Policy

A FlexConfig policy contains two ordered lists of FlexConfig objects, one prepended list and one appended list. For an explanation of prepend/append, see Configure FlexConfig Objects, on page 1221.

FlexConfig policies are shared policies that you can assign to multiple devices.

Procedure

Step 1
Choose Devices > FlexConfig.

Step 2
Do one of the following:

- Click New Policy to create a new FlexConfig Policy. You are prompted to enter a name. Optionally, select devices in the Available Devices list and click Add to Policy to assign devices. Click Save.

- Click Edit (edit mode) to edit an existing Policy. You can change the name or description by clicking them in edit mode.

- Click Copy (copy) to create a new policy with the same contents. You are prompted for a name. Device assignments are not retained for the copy.

- Click delete to remove a policy you no longer need.

Step 3
Select the FlexConfig objects required for the policy from the Available FlexConfig list and click > to add them to the policy.

Objects are automatically added to the prepended or appended list based on the deployment type specified in the FlexConfig object.

To remove a selected object, click Delete (delete) next to an object.

Step 4
For each selected object, click View (view) next to the object to identify the variables used in the object.

Except for system variables, which start with SYS, you need to ensure that the objects associated with the variables are not empty. A blank or brackets with nothing between them, [], indicate an empty object. You will need to edit these objects before deploying the policy.

Note If you use object overrides, those values will not show up in this view. Thus, an empty default value does not necessarily mean that you have not updated the object with the required values. Previewing the configuration will show whether the variables resolve correctly for a given device. See Preview the FlexConfig Policy, on page 1228.

Step 5
Click Save.

What to do next

- Set target devices for the policy; see Set Target Devices for a FlexConfig Policy, on page 1228.

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Set Target Devices for a FlexConfig Policy

When you create a FlexConfig policy, you can select the devices that use the policy. You can subsequently change device assignments for the policy as described below.

**Procedure**

**Step 1** Choose Devices > FlexConfig and edit a FlexConfig policy.

**Step 2** Click Policy Assignments.

**Step 3** On Targeted Devices, build your target list:

- Add—Choose one or more Available Devices, then click Add to Policy or drag and drop into the list of Selected Devices. You can assign the policy to devices, high availability pairs, and clustered devices.

- Delete—Click Delete (🗑️) next to a single device, or select multiple devices, right-click, then choose Delete Selection.

**Step 4** Click OK to save your selection.

**Step 5** Click Save to save the FlexConfig policy.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Preview the FlexConfig Policy

Preview a FlexConfig policy to see how the FlexConfig objects get translated into CLI commands. The preview shows the commands that will be generated for a selected device from the scripts and variables used in the FlexConfig objects. The variables are resolved based on the configuration for the device, so you get a clear idea of what will be deployed.

Use the preview to look for potential problems in the FlexConfig objects. Correct the objects until the preview shows the expected results.

You must preview the configuration separately for each device, because the variables can resolve differently based on the device configuration.
**Procedure**

**Step 1** Choose **Devices > FlexConfig** and edit a FlexConfig policy.

**Step 2** If there are any pending changes, click **Save**.

The preview shows results only for those FlexConfig objects that were in the most recently saved version of the policy. You must save the policy to see a preview of newly-added objects.

**Step 3** Click **Preview Config**.

**Step 4** Choose a device from the **Select Device** drop-down list.

The system retrieves information from the device and configured policies, and determines what CLI commands will be generated on the next deployment to the device. You can select the output and use Ctrl+C to copy it to the clipboard, where you can paste it into a text file for further analysis.

The preview includes the following sections:

- **Flex-config Prepended CLI**—These are the commands generated by FlexConfigs that are prepended to the configuration.
- **CLI generated from managed features**—These are commands generated for policies configured in Firepower Management Center. Commands are generated for new or changed policies since the last successful deployment to the device. These commands do not represent all commands needed to implement the assigned policies. No commands in this section are generated from FlexConfig objects.
- **Flex-config Appended CLI**—These are the commands generated by FlexConfigs that are appended to the configuration.

**Step 5** Click **Close** to close the preview dialog.

---

**Verify the Deployed Configuration**

After you deploy a FlexConfig policy to a device, verify that the deployment was successful and that the resulting configuration is what you expected. Also, verify that the device is performing as expected.

**Procedure**

**Step 1** To verify that deployment was successful:

a) Click **System Status** in the menu bar, which is unnamed between **Deploy** and **System**.

The icon looks like one of the following, and it might include a number if there are errors:

- **Indicates No Warnings** — Indicates no warnings or errors are present on the system.
- **Indicates One or More Warnings** — Indicates one or more warnings and no errors are present on the system.
- **Indicates One or More Errors** — Indicates one or more errors and any number of warnings are present on the system.

b) On **Deployments**, verify that the deployment was successful.
c) To see more detailed information, especially for failed deployments, click **Show History**.

d) Select the deployment job in the list of jobs in the left column.

Jobs are listed in reverse chronological order, with the most recent job at the top of the list.

e) Click download in the **Transcript** column for the device in the right column.

The deployment transcript includes commands sent to the device, and any responses returned from the device. These response can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands that you sent through FlexConfig. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

**Note** There is no distinction made in the transcript between commands sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that Firepower Management Center (FMC) sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. FTD does not use the security level for anything. Messages relevant to FlexConfig are in the CLI Apply section of the transcript.

```
========= CLI APPLY =========
FMC >> interface GigabitEthernet0/0
FMC >> nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

**Step 2** Verify that the deployed configuration includes the expected commands.

You can do this by making an SSH connection to the device's management IP address. Use the `show running-config` command to view the configuration.

Alternatively, use the CLI tool within Firepower Management Center.

a) Choose **System > Health > Monitor** and click the name of the device.

You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

b) Click **Advanced Troubleshooting**.

c) Click **Threat Defense CLI**.

d) Select `show` as the command, and type `running-config` as the parameter.

e) Click **Execute**.

The running configuration appears in the text box. You can select the configuration and press Ctrl+C, then paste it into a text file for later analysis.

**Step 3** Verify that the device is performing as expected.

Use the `show` commands related to the feature to see detailed information and statistics. For example, if you enabled additional protocol inspections, the `show service-policy` command provides this information. The exact commands to use are feature-dependent and should be mentioned in the ASA configuration guide and command reference you used to learn how to configure the feature.

If commands that show statistics indicate that numbers are not changing (for example, hit counts, connection counts, and so forth), the configuration might be valid but not meaningful. If you know that traffic is going through the device that should show up in statistics, look for what is missing in your configuration. For example, NAT or access rules might be dropping or changing traffic before a feature can act on it.
You can use the `show` commands from an SSH session or through the Firepower Management Center CLI tool.

However, if the `show` command that you need to use is not available directly within the FTD CLI, you will need make an SSH connection to the device to use the commands. From the CLI, enter the following command sequence to enter Privileged EXEC mode within the diagnostic CLI. From there, you should be able to enter these otherwise unsupported `show` commands.

```plaintext
> system support diagnostic-cli
Attaching to Diagnostic CLI ... Press 'Ctrl+a then d' to detach.
Type help or '?' for a list of available commands.
firepower> enable
Password: <press enter, do not enter a password>
firepower#
```

---

## Remove Features Configured Using FlexConfig

If you decide you need to remove a set of configuration commands you configured using FlexConfig, you might need to manually remove that configuration. Unassigning the FlexConfig policy from a device might not remove all of the configuration.

To manually remove the configuration, you create new FlexConfig objects to clear or negate the configuration commands.

### Before you begin

To determine if you need to manually remove some or all of the configuration generated by an object:

1. Examine the configuration preview, as described in Preview the FlexConfig Policy, on page 1228. If the `###CLI generated from managed features ###` section contains the clear or negate commands to remove all of the commands in the FlexConfig object, then you can simply remove the object from the FlexConfig policy, save, and redeploy.

2. Remove the object from the FlexConfig policy, save the change, then preview the configuration again. If the `###CLI generated from managed features ###` section still does not include the required clear or negate commands, you must follow this procedure to manually remove the configuration.

### Procedure

**Step 1** Choose **Objects** > **Object Management** and create the FlexConfig Objects to clear or negate the configuration commands.

If a feature has a `clear` command that can remove all configuration settings, then use that command. For example, the predefined Eigrp_Unconfigure_All object contains a single command that removes all EIGRP-related configuration commands:

```
clear configure router eigrp
```
If there is not a **clear** command for the feature, you need to use the **no** form of each command you want to remove. For example, the predefined Sysopt_basic_negate object removes the commands configured through the predefined Sysopt_basic object.

```
no sysopt traffic detailed-statistics
no sysopt connection timewait
```

You would typically configure a FlexConfig object that removes configurations as a prepended, deploy once object.

**Step 2** Choose **Devices > FlexConfig** and create a new FlexConfig policy or edit the existing policy.

If you want to preserve the FlexConfig policy that deploys the configuration commands, create a new policy specifically for negating the commands, and assign the devices to the policy. Then, add the new FlexConfig objects to the policy.

If you want to completely remove the FlexConfig configuration objects from all devices, you can simply delete those commands from the existing FlexConfig policy and replace them with the objects that negate the configuration.

**Step 3** Click **Save** to save the FlexConfig policy.

**Step 4** Click **Preview Config** and verify that the clear and negation commands are generating correctly.

**Step 5** Choose **Deploy > Deployment** in the menu bar, select the device, and click **Deploy**.

Wait for deployment to complete.

**Step 6** Verify that the commands were removed.

View the running configuration on the device to confirm that the commands are removed. For more detailed information, see **Verify the Deployed Configuration, on page 1229**.

**Step 7** While editing the FlexConfig policy, click **Policy Assignments** and remove the device. Optionally, remove the FlexConfig Objects from the policy.

Assuming that the FlexConfig policy simply removes the unwanted configuration commands, there is no need to keep the policy assigned to the device after the removal is complete.

However, if the FlexConfig policy retains options that you still want configured on the device, remove the negation objects from the policy. They are no longer needed.

---

**Convert from FlexConfig to Managed Feature**

Each software release adds managed features to the product, that is, features that you configure directly through policies that are controlled outside of FlexConfig. This can deprecate FlexConfig commands that you are currently using; your configurations are not automatically converted. After the upgrade, you cannot assign or create FlexConfig objects using the newly deprecated commands. After upgrading software, examine your FlexConfig policies and objects.

When a feature you configured using FlexConfig starts to be supported as a managed feature, you must convert from using FlexConfig to using the managed feature. In most cases, your existing FlexConfig configurations continue to work post-upgrade and you can still deploy. However, in some cases, using deprecated commands can cause deployment issues. Configuring a feature in both the GUI and FlexConfig is not supported.
Procedure

Step 1
Remove the FlexConfig, as explained in Remove Features Configured Using FlexConfig, on page 1231.

Step 2
Configure the settings in the newly supported managed feature.
The release notes have a list of new features for the release.

Examples for FlexConfig

Following are some examples of using FlexConfig.

How to Configure Precision Time Protocol (ISA 3000)

The Precision Time Protocol (PTP) is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. These device clocks are generally of varying precision and stability. The protocol is designed specifically for industrial, networked measurement and control systems, and is optimal for use in distributed systems because it requires minimal bandwidth and little processing overhead.

A PTP system is a distributed, networked system consisting of a combination of PTP and non-PTP devices. PTP devices include ordinary clocks, boundary clocks and transparent clocks. Non-PTP devices include network switches, routers and other infrastructure devices.

You can configure the FTD device to be a transparent clock. The FTD device does not synchronize its clock with the PTP clocks. The FTD device will use the PTP default profile, as defined on the PTP clocks.

When you configure the PTP devices, you define a domain number for the devices that are meant to function together. Thus, you can configure multiple PTP domains, and then configure each non-PTP device to use the PTP clocks for one specific domain.

Before you begin

Determine the domain number configured on the PTP clocks that the device should use. This example assumes the PTP domain number is 10. Also, determine the interfaces through which the system can reach the PTP clocks in the domain.

Following are guidelines for configuring PTP:

• This feature is only available on the Cisco ISA 3000 appliance.
• Cisco PTP supports multicast PTP messages only.
• PTP is available only for IPv4 networks, not for IPv6 networks.
• PTP configuration is supported on physical Ethernet data interfaces, whether stand-alone or bridge group members. It is not supported on the management interface, subinterfaces, EtherChannels, Bridge Virtual Interfaces (BVI), or any other virtual interfaces.
• PTP flows on VLAN subinterfaces are supported, assuming the appropriate PTP configuration is present on the parent interface.
• You must ensure that PTP packets are allowed to flow through the device. PTP traffic is identified by UDP destination ports 319 and 320, and destination IP address 224.0.1.129, so any access control rule that allows this traffic should work.

• In Routed firewall mode, you must enable Multicast routing for PTP multicast groups. In addition, if an interface on which you enable PTP is not in a bridge group, you must configure the interface to join the IGMP multicast group 224.0.1.129. If the physical interface is a bridge group member, you do not configure it to join the IGMP multicast group.

Procedure

Step 1

(Routed mode only.) Enable Multicast routing, and configure the IGMP group for the interfaces.

In Routed mode, you must enable Multicast routing. In addition, for stand-alone physical interfaces, that is, those that are not bridge group members, you must also configure the interface to join the 224.0.1.129 IGMP group. You cannot configure bridge group members to join an IGMP group, but PTP configuration on bridge group members will work without the IGMP join.

Perform this procedure for each device on which you will configure PTP.

Note

Write down the hardware names of each PTP-clock-facing interface on each device, for example, GigabitEthernet1/1.

a) Choose Devices > Device Management, and edit the device.
b) Click Routing.
c) Select Multicast Routing > IGMP.
d) Select the Enable Multicast Routing check box.
e) Click Join Group.
f) Click Add, and in the Add IGMP Join Group Parameters dialog box, configure the following options and click OK.
   • Interface—Select the PTP-clock-facing stand-alone interface.
   • Join Group—Click + to add a new network object. Create a Host object with the address 224.0.1.129. When configuring additional interfaces, simply select this object.

Repeat this step for each PTP-clock-facing stand-alone interface on the device.

g) Click Save on the Routing page.

Step 2

Create the FlexConfig object to enable PTP globally and on the interface.

The following procedure assumes that the PTP-clock-facing interface is the same on every device you are configuring. If you have used different interfaces on different devices, you need to create separate objects for each distinct combination. For example, if you use GigabitEthernet1/1 on devices A and B, GigabitEthernet1/2 on devices C and D, and both GigabitEthernet1/1 and 1/2 on devices E and F, you need 3 separate FlexConfig objects, and subsequently, 3 separate FlexConfig policies (explained in the next step).

a) Choose Objects > Object Management.
b) Choose FlexConfig > FlexConfig Object from the table of contents.
c) Click Add FlexConfig Object, configure the following properties, and click Save.
   • Name—The object name. For example, Enable_PTP.
• **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.

• **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features. This ensures that any other changes you make to interface configuration are configured before these commands.

• **Object body**—In the object body, type the commands needed to configure PTP globally and on each PTP-clock-facing interface. For example, the commands needed for the global configuration for PTP domain 10 and the interface configuration on GigabitEthernet1/1 are:

```
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
  ptp enable
```

The object body should look similar to the following:

```
<table>
<thead>
<tr>
<th>Insert</th>
<th>Deployment:</th>
<th>Type:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Everytime</td>
<td>Append</td>
</tr>
</tbody>
</table>

ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
  ptp enable
```

**Step 3** Create the FlexConfig policy and assign it to the devices.

If you created multiple FlexConfig objects for different combinations of PTP-clock-facing interfaces, you need to create separate FlexConfig policies for each object, and assign those policies to the correct devices based on the interfaces you need to configure. Repeat the following procedure for each group of devices.

a) Choose **Devices > FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the PTP FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

```
<table>
<thead>
<tr>
<th>#</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Enable_PTP</td>
<td></td>
</tr>
</tbody>
</table>
```

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.
The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the PTP FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the PTP commands, you should see something similar to the following:

```bash
### Flex-config Appended CLI ###
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
  ptp enable
```

**Step 4**

Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See **Verify the Deployed Configuration**, on page 1229.

**Step 5**

Verify the PTP configuration on each device.

From an SSH or Console session into each device, verify the PTP settings:

```bash
> show ptp clock
PTP CLOCK INFO
  PTP Device Type: End to End Transparent Clock
  Operation mode: One Step
  Clock Domain: 10
  Number of PTP ports: 4
> show ptp port
PTP PORT DATASET: GigabitEthernet1/1
  Port identity: Port Number: 1
  PTP version: 2
  Port state: Enabled

PTP PORT DATASET: GigabitEthernet1/2
  Port identity: Port Number: 2
  PTP version: 2
  Port state: Disabled

PTP PORT DATASET: GigabitEthernet1/3
  Port identity: Port Number: 3
  PTP version: 2
  Port state: Disabled

PTP PORT DATASET: GigabitEthernet1/4
  Port identity: Port Number: 4
  PTP version: 2
  Port state: Disabled
```
How to Configure Automatic Hardware Bypass for Power Failure (ISA 3000)

You can enable hardware bypass so that traffic continues to flow between an interface pair during a power outage. Supported interface pairs are copper interfaces GigabitEthernet 1/1 and 1/2; and GigabitEthernet 1/3 and 1/4. If you have a fiber Ethernet model, only the copper Ethernet pair (GigabitEthernet 1/1 and 1/2) supports hardware bypass.

When hardware bypass is active, traffic passes between these interface pairs at layer 1. The FTD CLI will see the interfaces as being down. No firewall functions are in place, so make sure you understand the risks of allowing traffic to pass through the device.

In CLI Console or an SSH session, use the `show hardware-bypass` command to monitor the operational status.

Before you begin

For hardware bypass to work:

- You must place the interface pairs in the same bridge group.
- You must attach the interfaces to access ports on the switch. Do not attach them to trunk ports.

We recommend that you disable TCP sequence number randomization globally using the Threat Defense Service Policy attached to the access control policy assigned to the device. By default, the ISA 3000 rewrites the initial sequence number (ISN) of TCP connections passing through it to a random number. When hardware bypass is activated, the ISA 3000 is no longer in the data path and does not translate the sequence numbers. The receiving client receives an unexpected sequence number and drops the connection, so the TCP session needs to be re-established. Even with TCP sequence number randomization disabled, some TCP connections will have to be re-established because of the link that is temporarily down during the switchover.

Procedure

Step 1

Create the FlexConfig object to enable automatic bypass.

a) Choose **Objects > Object Management**.
b) Choose **FlexConfig > FlexConfig Object** from the table of contents.
c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Enable_HW-Bypass.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to enable automatic hardware bypass. For example, the commands needed for both possible interface pairs:

```
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

The object body should look similar to the following:
Step 2 Create the FlexConfig policy and assign it to the devices.

a) Choose Devices > FlexConfig.

b) Either click New Policy, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

   When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the hardware bypass FlexConfig object in the User Defined folder in the table of contents and click > to add it to the policy.

   The object should be added to the Selected Appended FlexConfigs list.

d) Click Save.

e) If you have not yet assigned all the targeted devices to the policy, click the Policy Assignments link below Save and make the assignments now.

f) Click Preview Config, and in the Preview dialog box, select one of the assigned devices.

   The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the hardware bypass FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the hardware bypass commands, you should see something similar to the following:

   ```
   ###Flex-config Appended CLI ###
   hardware-bypass GigabitEthernet 1/1-1/2
   hardware-bypass GigabitEthernet 1/3-1/4
   ```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click Proceed to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the Deployed Configuration, on page 1229.
What to do next

If you want to manually invoke hardware bypass or manually turn it off, you need to create two FlexConfig objects:

- One that manually starts bypass, which would contain one or both of the following commands, depending on whether you want to invoke bypass for both pairs:
  
  ```
  hardware-bypass manual GigabitEthernet 1/1-1/2
  hardware-bypass manual GigabitEthernet 1/3-1/4
  ```

- One that manually turns off bypass, which would contain one or both of the following commands:

  ```
  no hardware-bypass manual GigabitEthernet 1/1-1/2
  no hardware-bypass manual GigabitEthernet 1/3-1/4
  ```

You would then need to add one or the other object to the FlexConfig policy, and deploy changes, to either turn bypass on or off. You would also need to immediately remove the object from the FlexConfig policy after deployment. If you manually invoke bypass, you would then need to repeat the process to turn it off again. Thus, using this manual method requires frequent and careful editing of the FlexConfig policy and additional deployments.

How to Configure Policy Based Routing

You can implement policy-based routing (PBR) features using FlexConfig. For example, the following graphic shows how to load balance traffic between networks based on source IP address. In this case, we will assume that the 10.1.0.0/16 network generates high priority traffic, which should go over the higher bandwidth link to ISP-A, and 10.2.0.0/16 is lower priority and should go over the slower, lower bandwidth link to ISP-B.
Before you begin

This procedure assumes that you have already configured the interfaces as follows:

- GigabitEthernet0/0.
  - Interface name: inside
  - IP address: 10.1.1.1/24
  - Note that other routers in the network use this interface as the gateway for routes for the 10.1.0.0/16 and 10.2.0.0/16 address spaces.

- GigabitEthernet0/1.
  - Interface name: outside-1
  - IP address: 192.168.6.5/24

- GigabitEthernet0/2.
  - Interface name: outside-2
  - IP address: 172.16.7.6/24
Procedure

Step 1
Create the extended ACL objects to match traffic from the 10.1.0.0/16 and 10.2.0.0/16 address spaces. You must create separate ACLs, because you will apply different actions to the traffic in the route map.

a) Choose Objects > Object Management.
b) Select Access List > Extended from the table of contents. You must configure an extended access list to specify the traffic source addresses.
c) Click the Add Extended Access List button.
d) Enter a name for the access list, such as high-priority.
e) Click the Add button, and create the rule for the high-priority address space. The key characteristics are:
   • Action—Allow.
   • Source Networks—Enter 10.1.0.0/16 in the edit box below the list and click Add. Alternatively, you can define a network object for this network address.

f) Click Add at the bottom of the dialog box. This adds the rule to the access list.

g) Click Save.
h) Repeat the process to create a second access list with the following attributes:
   • Name—low-priority.
   • Action—Allow.
   • Source Networks—Enter 10.2.0.0/16 in the edit box below the list and click Add. Alternatively, you can define a network object for this network address.

Step 2
Create the route map that defines the next hop addresses for these address spaces.

a) While still on the objects page, click Route Map in the table of contents.
b) Click the Add Route Map button.
c) Enter a name for the object, such as **load-balance**.

d) Click **Add** and create a rule for high-priority traffic with the following attributes:

- **Sequence No.**—10.
- **Redistribution**—Allow.
- **Match Clauses > IPv4 > Address**—Select the **Access List** radio button, then **Available Access Lists > Extended**, and move the high-priority ACL to the selected list.

  ![Match Clauses and Set Clauses](image)

- **Set Clauses > BGP Clauses > Others**—In **IPv4 Settings > Next Hop**, select **Specific IP**, then enter the gateway for ISP-A, **192.168.6.6** into the **Specific IP edit box**.
e) Click Add to add the rule to the route map.

f) Click Add and create a rule for low-priority traffic with the following attributes:
   - **Sequence No.**—20.
   - **Redistribution**—Allow.
   - **Match Clauses > IPv4 > Address**—Select the Access List radio button, then Available Access Lists > Extended, and move the low-priority ACL to the selected list.
   - **Set Clauses > BGP Clauses > Others**—In IPv4 Settings > Next Hop, select Specific IP, then enter the gateway for ISP-B, 172.16.7.7 into the Specific IP edit box.

g) Click Add to add the rule to the route map.

h) Click Save.

**Step 3**
Create the FlexConfig object that enables PBR on the inside interface using the route map.

a) While still on the objects page, click FlexConfig > FlexConfig Object in the table of contents.

b) Find the Policy_Based_Routing object, then click the Copy ( ).

   This is a system-defined object, but it is not usable until you edit it. It does not point to a text object that you can simply update with the name of your route map. You must always create a custom object for this system-defined object.

c) When you click the copy icon, the system opens a dialog box with the new object, with the default name Policy_Based_Routing_Copy. Make these basic changes:
   - **Name**—Enter a meaningful name. For example, if you are configuring PBR for device FTD1, perhaps PBR_FTD1.
   - **Description**—Delete the description or make it meaningful for your purposes.
   - **Deployment**—Keep Once.
   - **Type**—Keep Append.

d) The body of the object has the following lines.

```
interface GigabitEthernet0/0
    policy-route route-map $r-map-object
```

   Note that the “interface GigabitEthernet0/0” line already is set to configure the correct interface for this example. If you were to apply PBR to a different interface, you would need to correct the interface hardware name.
The $r-map-object string actually is not a real variable, and it points to nothing. You need to replace this string.

e) Delete the $r-map-object string, and leave your cursor on the “policy-route route-map” line, one space after route-map.

f) Select **Insert > Insert Policy Object > Route Map**.

g) In the Route Map Variable dialog box, configure the following:

   • **Variable Name**—Any name will do, such as **pbr-route-map**.

   • **Selected Object**—Move the load-balance route map object from the available list to the selected list.

h) Click **Save** in the Route Map Variable dialog box.

The FlexConfig object should now look like the following, where your variable is now in the variables list at the bottom of the dialog box.
Step 4  Add the FlexConfig object to the FlexConfig policy that is assigned to the device.

a) Choose Devices > FlexConfig.
b) Assuming you do not already have a FlexConfig policy assigned to this device, click New Policy, give the policy a name and select the FTD1 device to assign the policy to it, then click Save.
c) Find the object under the User Defined folder in the available objects list, then click > to add it to the selected objects list.
d) Click **Save** to save the policy.

e) Click **Preview Config**, then in the preview dialog box, select the FTD1 device.

The preview includes CLI generated from both the FlexConfig objects and the parts of the FMC-managed configuration that are implemented using configuration commands. These are separated into sections. The commands that will be configured based on what we have done in this example are the following. You can verify you are getting the expected results using this preview.

```plaintext
### Flex-config Prepended CLI ###
### CLI generated from managed features ###
configure session OBJECT
object-group service ProxySG_ExtendedACL_4294969626
  service-object ip
object-group service ProxySG_ExtendedACL_4294969648
  service-object ip
commit noconfirm revert-save
configure session FMC_SESSION_1
  access-list high-priority extended permit object-group
    ProxySG_ExtendedACL_4294969626 10.1.0.0 255.255.0.0 any
  access-list low-priority extended permit object-group
    ProxySG_ExtendedACL_4294969648 10.2.0.0 255.255.0.0 any
commit noconfirm revert-save
route-map load-balance permit 10
  match ip address high-priority
  set ip next-hop 192.168.6.6
route-map load-balance permit 20
  match ip address low-priority
  set ip next-hop 172.16.7.7

### Flex-config Appended CLI ###
interface GigabitEthernet0/0
  policy-route route-map load-balance
```
f) Click **Close** to shut the preview dialog box.

---

**What to do next**

You can now deploy the configuration to the device.

---

Alarms for the Cisco ISA 3000

You can configure the alarm system on a Cisco ISA 3000 device to alert you when undesirable conditions occur.

• About Alarms, on page 1251
• Defaults for Alarms, on page 1253
• Requirements and Prerequisites for Alarms, on page 1254
• Configure the Alarms for the ISA 3000, on page 1254
• Monitoring Alarms, on page 1262
• History for Alarms, on page 1263

About Alarms

You can configure the ISA 3000 to issue alarms for a variety of conditions. If any conditions do not match the configured settings, the system triggers an alarm, which is reported by way of LEDs, syslog messages, SNMP traps, and through external devices connected to the alarm output interface. By default, triggered alarms issue syslog messages only.

You can configure the alarm system to monitor the following:

• Power supply.
• Primary and secondary temperature sensors.
• Alarm input interfaces.

The ISA 3000 has internal sensors plus two alarm input interfaces and one alarm output interface. You can connect external sensors, such as door sensors, to the alarm inputs. You can connect external alarm devices, such as buzzers or lights, to the alarm output interface.

The alarm output interface is a relay mechanism. Depending on the alarm conditions, the relay is either energized or de-energized. When it is energized, any device connected to the interface is activated. A de-energized relay results in the inactive state of any connected devices. The relay remains in an energized state as long as alarms are triggered.

For information about connecting external sensors and the alarm relay, see Cisco ISA 3000 Industrial Security Appliance Hardware Installation Guide.
Alarm Input Interfaces

You can connect the alarm input interfaces (or contacts) to external sensors, such as one that detects if a door is open.

Each alarm input interface has a corresponding LED. These LEDs convey the alarm status of each alarm input. You can configure the trigger and severity for each alarm input. In addition to the LED, you can configure the contact to trigger the output relay (to activate an external alarm), to send syslog messages, and to send SNMP traps.

The following table explains the statuses of the LEDs in response to alarm conditions for the alarm inputs. It also explains the behavior for the output relay, syslog messages, and SNMP traps, if you enable these responses to the alarm input.

<table>
<thead>
<tr>
<th>Alarm Status</th>

<td>Solid green</td>
<td>Relay de-energized</td>
<td>Syslog generated</td>
<td>—</td>
</tr>
</tbody>
</table>

Alarm Output Interface

You can connect an external alarm, such as a buzzer or light, to the alarm output interface.

The alarm output interface functions as a relay and also has a corresponding LED, which conveys the alarm status of an external sensor connected to the input interface, and internal sensors such as the dual power supply and temperature sensors. You configure which alarms should activate the output relay, if any.

The following table explains the statuses of the LEDs and output relay in response to alarm conditions. It also explains the behavior for syslog messages, and SNMP traps, if you enable these responses to the alarm.

<table>
<thead>
<tr>

<td>Syslog generated</td>
<td>—</td>
</tr>
</tbody>
</table>
Syslog Alarms

By default, the system sends syslog messages when any alarm is triggered. You can disable syslog messaging if you do not want the messages.

For syslog alarms to work, you must also enable diagnostic logging. Choose Device > Platform Settings, add or edit an FTD platform settings policy that is assigned to the device, and configure destinations and settings on the Syslog page. For example, you can configure a syslog server, console logging, or internal buffer logging.

Without enabling a destination for diagnostic logging, the alarm system has nowhere to send syslog messages.

SNMP Alarms

You can optionally configure the alarms to send SNMP traps to your SNMP server. For SNMP trap alarms to work, you must also configure SNMP settings.

Choose Device > Platform Settings, add or edit an FTD platform settings policy that is assigned to the device, and enable SNMP and configure settings on the SNMP page.

Defaults for Alarms

The following table specifies the defaults for alarm input interfaces (contacts), redundant power supply, and temperature.

Configure the Alarms for the ISA 3000

You use FlexConfig to configure alarms for the ISA 3000. The following topics explain how to configure the different types of alarms.

Configure Alarm Input Contacts

If you connect the alarm input contacts (interfaces) to external sensors, you can configure the contacts to issue alarms based on the input from the sensor. In fact, the contacts are enabled by default to send syslog messages if the contact is closed, that is, if the electrical current stops flowing through the contact. You need to configure the contact only if the defaults do not meet your requirements.

The alarm contacts are numbered 1 and 2, so you need to understand how you have wired the physical pins to configure the correct settings. You configure the contacts separately.

Procedure

Step 1
Create the FlexConfig object to configure the alarm input contacts.

a) Choose Objects > Object Management.
b) Choose FlexConfig > FlexConfig Object from the table of contents.
c) Click Add FlexConfig Object, configure the following properties, and click Save.

  • Name—The object name. For example, Configure_Alarm_Contacts.
  • Deployment—Select Everytime. You want this configuration to be sent in every deployment to ensure it remains configured.
  • Type—Keep the default, Append. The commands are sent to the device after the commands for directly-supported features.
  • Object body—In the object body, type the commands needed to configure the alarm contacts. The following steps explain the commands.

  d) Configure a description for the alarm contact.
alarm contact \{1 | 2\} description \textit{string} \\
For example, to set the description of contact 1 to "Door Open," enter the following:

\begin{verbatim}
alarm contact 1 description Door Open
\end{verbatim}

e) Configure the severity for the alarm contact.

\begin{verbatim}
alarm contact \{1 | 2 | any\} severity \{major | minor | none\}
\end{verbatim}

Instead of configuring one contact, you can specify \textit{any} to change the severity for all contacts. The severity controls the behavior of the LED associated with the contact.

- **major** — The LED blinks red.
- **minor** — The LED is solid red. This is the default.
- **none** — The LED is off.

For example, to set the severity of contact 1 to Major, enter the following:

\begin{verbatim}
alarm contact 1 severity major
\end{verbatim}

f) Configure the trigger for the alarm contact.

\begin{verbatim}
alarm contact \{1 | 2 | any\} trigger \{open | closed\}
\end{verbatim}

Instead of configuring one contact, you can specify \textit{any} to change the trigger for all contacts. The trigger determines the electrical condition that signals an alert.

- **open** — The normal condition for the contact is closed, that is, the electrical current is running through the contact. An alert is triggered if the contact becomes open, that is, the electrical current stops flowing.

- **closed** — The normal condition for the contact is open, that is, the electrical current does not run through the contact. An alert is triggered if the contact becomes closed, that is, the electrical current starts running through the contact. This is the default.

For example, you connect a door sensor to alarm input contact 1, and its normal state has no electrical current flowing through the alarm contact (it is open). If the door is opened, the contact is closed and electrical current flows through the alarm contact. You would set the alarm trigger to closed so that the alarm goes off when the electrical current starts flowing.

\begin{verbatim}
alarm contact 1 trigger closed
\end{verbatim}

g) Configure the actions to take when the alarm contact is triggered.

\begin{verbatim}
alarm facility input-alarm \{1 | 2\} \{relay | syslog | notifies\}
\end{verbatim}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay** — Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.

- **syslog** — Send a syslog message. This option is enabled by default.

- **notifies** — Send an SNMP trap.
For example, to enable all actions for the alarm input contact 1, enter the following:

- `alarm facility input-alarm 1 relay`
- `alarm facility input-alarm 1 syslog`
- `alarm facility input-alarm 1 notifies`

h) Verify that the object body contains the commands you want.

For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

- `alarm contact 1 description Door Open`
- `alarm contact 1 severity major`
- `alarm contact 1 trigger closed`
- `alarm facility input-alarm 1 relay`
- `alarm facility input-alarm 1 syslog`
- `alarm facility input-alarm 1 notifies`

The object body should look similar to the following:

```
# Insert | # | Deployment: Everytime | Type: Append

alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

i) Click Save.

**Step 2** Create the FlexConfig policy and assign it to the devices.

a) Choose Devices > FlexConfig.

b) Either click New Policy, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the alarm contact FlexConfig object in the User Defined folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

```
# Name
1 Configure_Alarm_Contacts
```

d) Click Save.

e) If you have not yet assigned all the targeted devices to the policy, click the Policy Assignments link below Save and make the assignments now.

f) Click Preview Config, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the
Configure Power Supply Alarms

The ISA 3000 has two power supplies. By default, the system operates in single-power mode. However, you can configure the system to operate in dual mode, where the second power supply automatically provides power if the primary power supply fails. When you enable dual-mode, the power supply alarm is automatically enabled to send syslog alerts, but you can disable the alert altogether, or also enable SNMP traps or the alarm hardware relay.

The following procedure explains how to enable dual mode, and how to configure the power supply alarms.

**Procedure**

**Step 1**  
Create the FlexConfig object to configure the power supply alarm.  
a) Choose Objects > Object Management.  
b) Choose FlexConfig > FlexConfig Object from the table of contents.  
c) Click Add FlexConfig Object, configure the following properties, and click Save.  
   - **Name**—The object name. For example, Power_Supply_Alarms.  
   - **Deployment**—Select Everytime. You want this configuration to be sent in every deployment to ensure it remains configured.  
   - **Type**—Keep the default, Append. The commands are sent to the device after the commands for directly-supported features.  
   - **Object body**—In the object body, type the commands needed to configure the power supply alarms. The following steps explain the commands.  

d) Enable dual power supply mode.  

```
power-supply dual
```
For example:

```
power-supply dual
```

e) Configure the actions to take when the power supply alarm is triggered.

```
alarm facility power-supply rps {relay | syslog | notifies | disable}
```

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.
- **disable**—Disable the power supply alarm. Any other actions configured for the power supply alarm are inoperable.

For example, to enable all actions for the power supply alarm, enter the following:

```
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

f) Verify that the object body contains the commands you want.

For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

The object body should look similar to the following:

```
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

g) Click Save.

**Step 2**

Create the FlexConfig policy and assign it to the devices.

a) Choose **Devices > FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the power supply alarm FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.
The object should be added to the **Selected Appended FlexConfigs** list.

![Selected Appended FlexConfigs](image)

**d)** Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

**f)** Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the power supply alarm commands, you should see something similar to the following:

```
### Flex-config Appended CLI ###
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

**Step 3**

**Deploy your changes.**

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See **Verify the Deployed Configuration, on page 1229**.

---

**Configure Temperature Alarms**

You can configure alarms based on the temperature of the CPU card in the device.

You can set a primary and secondary temperature range. If the temperature drops below the low threshold, or exceeds the high threshold, the alarm is triggered.

The primary temperature alarm is enabled by default for all alarm actions: output relay, syslog, and SNMP. The default settings for the primary temperature range is -40°C to 92°C.

The secondary temperature alarm is disabled by default. You can set the secondary temperature within the range -35°C to 85°C.

Because the secondary temperature range is more restrictive than the primary range, if you set either the secondary low or high temperature, that setting disables the corresponding primary setting, even if you configure non-default values for the primary setting. You cannot enable two separate high and two separate low temperature alarms.

Thus, in practice, you should configure the primary only, or the secondary only, setting for high and low.
Procedure

**Step 1** Create the FlexConfig object to configure the temperature alarms.

a) Choose **Objects > Object Management**.

b) Choose **FlexConfig > FlexConfig Object** from the table of contents.

c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

   • **Name**—The object name. For example, Configure_Temperature_Alarms.

   • **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.

   • **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.

   • **Object body**—In the object body, type the commands needed to configure the temperature alarms. The following steps explain the commands.

d) Configure the acceptable temperature range.

   ```
   alarm facility temperature {primary | secondary} {low | high} temperature
   ```

   The temperature is in Celsius. The allowed range for the primary alarm is -40 to 92, which is also the default range. The allowed range for the secondary alarm is -35 to 85. The low value must be lower than the high value.

   For example, to set a more restrictive temperature range of -20 to 80, which falls within the allowed range for the secondary alarm, configure the secondary alarm as follows:

   ```
   alarm facility temperature secondary low -20
   alarm facility temperature secondary high 80
   ```

e) Configure the actions to take when the temperature alarm is triggered.

   ```
   alarm facility temperature {primary | secondary} {relay | syslog | notifies}
   ```

   You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

   • **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.

   • **syslog**—Send a syslog message.

   • **notifies**—Send an SNMP trap.

   For example, to enable all actions for the secondary temperature alarm, enter the following:

   ```
   alarm facility temperature secondary relay
   alarm facility temperature secondary syslog
   alarm facility temperature secondary notifies
   ```

f) Verify that the object body contains the commands you want.

   For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:
Configure Temperature Alarms

Step 2
Create the FlexConfig policy and assign it to the devices.

a) Choose Devices > FlexConfig.

b) Either click New Policy, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the temperature alarms FlexConfig object in the User Defined folder in the table of contents and click > to add it to the policy.

The object should be added to the Selected Appended FlexConfigs list.

d) Click Save.

e) If you have not yet assigned all the targeted devices to the policy, click the Policy Assignments link below Save and make the assignments now.

f) Click Preview Config, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the temperature alarms commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

g) Click Save.

Step 3
Deploy your changes.
Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click Proceed to continue with the deployment. After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the Deployed Configuration, on page 1229.

---

Monitoring Alarms

The following topics explain how to monitor and manage alarms.

Monitoring Alarm Status

You can use the following commands in the CLI to monitor alarms.

- **show alarm settings**
  Shows the current configuration for each possible alarm.

- **show environment alarm-contact**
  Shows information about the physical status of the input alarm contacts.

- **show facility-alarm relay**
  Shows information about the alarms that have triggered the output relay.

- **show facility-alarm status [info | major | minor]**
  Shows information on all alarms that have been triggered. You can limit the view by filtering on major or minor status. The info keyword provides the same output as using no keyword.

Monitoring Syslog Messages for Alarms

Depending on the type of alarms you configure, you might see the following syslog messages.

**Dual Power Supply Alarms**

- %FTD-1-735005: Power Supply Unit Redundancy OK
- %FTD-1-735006: Power Supply Unit Redundancy Lost

**Temperature Alarms**

In these alarms, *Celsius* is replaced by the temperature detected on the device, in Celsius.

- %FTD-6-806001: Primary alarm CPU temperature is High *Celsius*
- %FTD-6-806002: Primary alarm for CPU high temperature is cleared
- %FTD-6-806003: Primary alarm CPU temperature is Low *Celsius*
- %FTD-6-806004: Primary alarm for CPU Low temperature is cleared
Turning Off the External Alarm

If you are using an external alarm that is attached to the alarm output, and the alarm is triggered, you can turn off the external alarm from the device CLI using the `clear facility-alarm output` command. This command de-energizes the output pin and also turns off the output LED.

About System Configuration

System configuration settings apply to either a Firepower Management Center or a Classic managed device (ASA FirePOWER, NGIPSv):

• For the Firepower Management Center these configuration settings are part of a "local" system configuration. Note that system configuration on the Firepower Management Center is specific to a single system, and changes to a FMC's system configuration affect only that system.

• For a Classic managed device, you apply a configuration from the Firepower Management Center as part of a platform settings policy. You create a shared policy to configure a subset of the system configuration settings, appropriate for managed devices, that are likely to be similar across a deployment.

Navigating the Firepower Management Center System Configuration

The system configuration identifies basic settings for a Firepower Management Center.

Procedure

Step 1 Choose System > Configuration.
Step 2 Use the navigation panel to choose configurations to change; see Table 86: System Configuration Settings, on page 1269 for more information.

System Configuration Settings

Note that for managed devices, many of these configurations are handled by a platform settings policy applied from the FMC; see Platform Settings Policies, on page 1331.
## Table 86: System Configuration Settings

---

**Appliance Information**

The System > Configuration page of the web interface includes the information listed in the table below. Unless otherwise noted, all fields are read-only.

---

**Note**

See also the Help > About page, which includes similar but slightly different information.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A descriptive name you assign to the FMC appliance. Although you can use the host name as the name of the appliance, entering a different name in this field does not change the host name. This name is used in certain integrations. For example, it appears in the Devices list for integrations with SecureX and Cisco SecureX threat response.</td>
</tr>
</tbody>
</table>
### HTTPS Certificates

Secure Sockets Layer (SSL)/TLS certificates enable Firepower Management Centers to establish an encrypted channel between the system and a web browser. A default certificate is included with all Firepower devices, but it is not generated by a certificate authority (CA) trusted by any globally known CA. For this reason, consider replacing it with a custom certificate signed by a globally known or internally trusted CA.

The FMC supports 4096-bit HTTPS certificates. If the certificate used by the FMC was generated using a public server key larger than 4096 bits, you will not be able to log in to the FMC web interface. If this happens, contact Cisco TAC.

### Default HTTPS Server Certificates

If you use the default server certificate provided with an appliance, do not configure the system to require a valid HTTPS client certificate for web interface access because the default server certificate is not signed by the CA that signs your client certificate.
The lifetime of the default server certificate depends on when the certificate was generated. To view your default server certificate expiration date, choose System > Configuration > HTTPS Certificate.

Note that some Firepower software upgrades can automatically renew the certificate. For more information, see the appropriate version of the Cisco Firepower Release Notes.

On the Firepower Management Center, you can renew the default certificate on the System > Configuration > HTTPS Certificate page.

**Custom HTTPS Server Certificates**

You can use the Firepower Management Center web interface to generate a server certificate request based on your system information and the identification information you supply. You can use that request to sign a certificate if you have an internal certificate authority (CA) installed that is trusted by your browser. You can also send the resulting request to a certificate authority to request a server certificate. After you have a signed certificate from a certificate authority (CA), you can import it.

**HTTPS Server Certificate Requirements**

When you use HTTPS certificates to secure the connection between your web browser and the Firepower appliance web interface, you must use certificates that comply with the Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile (RFC 5280). When you import a server certificate to the appliance, the system rejects the certificate if it does not comply with version 3 (X.509 v3) of that standard.

Before importing an HTTPS server certificate, be certain it includes the following fields:

<table>
<thead>
<tr>
<th>Certificate Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serial number</td>
<td>A positive integer assigned to the certificate by the issuing CA. Issuer and serial number together uniquely identify the certificate. See RFC 5280, section 4.1.2.2.</td>
</tr>
<tr>
<td>Signature</td>
<td>Identifier for the algorithm used by the CA to sign the certificate. Must match the signatureAlgorithm field. See RFC 5280, section 4.1.2.3.</td>
</tr>
<tr>
<td>Issuer</td>
<td>Identifies the entity that signed and issued the certificate. See RFC 5280, section 4.1.2.4.</td>
</tr>
<tr>
<td>Validity</td>
<td>Interval during which the CA warrants that it will maintain information about the status of the certificate. See RFC 5280, section 4.1.2.5.</td>
</tr>
<tr>
<td>Subject</td>
<td>Identifies the entity associated with the public key stored in the subject public key field; must be an X.500 distinguished name (DN). See RFC 5280, section 4.1.2.6.</td>
</tr>
<tr>
<td>Certificate Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Subject Alternative Name</td>
<td>Domain names and IP addresses secured by the certificate. Subject Alternative Name is defined in section RFC 5280, section 4.2.1.6.</td>
</tr>
<tr>
<td></td>
<td>We recommend you use this field if the certificate is used for multiple domains or IP addresses.</td>
</tr>
<tr>
<td>Subject Public Key Info</td>
<td>Public key and an identifier for its algorithm. See RFC 5280, section 4.1.2.7.</td>
</tr>
<tr>
<td>Authority Key Identifier</td>
<td>Provides a means of identifying the public key corresponding to the private key used to sign a certificate. See RFC 5280, section 4.2.1.1.</td>
</tr>
<tr>
<td>Subject Key Identifier</td>
<td>Provides a means of identifying certificates that contain a particular public key. See RFC 5280, section 4.2.1.2.</td>
</tr>
<tr>
<td>Key Usage</td>
<td>Defines the purpose of the key contained in the certificates. See RFC 5280, section 4.2.1.3.</td>
</tr>
<tr>
<td>Basic Constraints</td>
<td>Identifies whether the certificate Subject is a CA, and the maximum depth of validation certification paths that include this certificate. See RFC 5280, section 4.2.1.9. This field is not strictly required for server certificates used in Firepower appliances, but we strongly recommend including this field and specifying critical CA:FALSE.</td>
</tr>
<tr>
<td>Extended Key Usage extension</td>
<td>Indicates one or more purposes for which the certified public key may be used, in addition to or in place of the basic purposes indicated in the Key Usage extension. See RFC 5280, section 4.2.1.1.2. Be certain you import certificates that can be used as server certificates.</td>
</tr>
<tr>
<td>signatureAlgorithm</td>
<td>Identifier for the algorithm the CA used to sign the certificate. Must match the Signature field. See RFC 5280, section 4.1.1.2.</td>
</tr>
<tr>
<td>signatureValue</td>
<td>Digital signature. See RFC 5280, section 4.1.1.3.</td>
</tr>
</tbody>
</table>

**HTTPS Client Certificates**

You can restrict access to the Firepower System web server using client browser certificate checking. When you enable user certificates, the web server checks that a user’s browser client has a valid user certificate selected. That user certificate must be generated by the same trusted certificate authority that is used for the server certificate. The browser cannot load the web interface under any of the following circumstances:

- The user selects a certificate in the browser that is not valid.
To verify client browser certificates, configure the system to use the online certificate status protocol (OCSP) or load one or more certificate revocation lists (CRLs). Using the OCSP, when the web server receives a connection request it communicates with the certificate authority to confirm the client certificate's validity before establishing the connection. If you configure the server to load one or more CRLs, the web server compares the client certificate against those listed in the CRLs. If a user selects a certificate that is listed in a CRL as a revoked certificate, the browser cannot load the web interface.

If you choose to verify certificates using CRLs, the system uses the same CRLs to validate both client browser certificates and audit log server certificates.

### Viewing the Current HTTPS Server Certificate

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose System &gt; Configuration.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click HTTPS Certificate.</td>
</tr>
</tbody>
</table>

### Generating an HTTPS Server Certificate Signing Request

If you install a certificate that is not signed by a globally known or internally trusted CA, the user's browser displays a security warning when they try to connect to the web interface.

A certificate signing request (CSR) is unique to the appliance or device from which you generated it. You cannot generate a CSR for multiple devices from a single appliance. Although all fields are optional, we recommend entering values for the following: CN, Organization, Organization Unit, City/Locality, State/Province, Country/Region, and Subject Alternative Name.

The key generated for the certificate request is in Base-64 encoded PEM format.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose System &gt; Configuration.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click HTTPS Certificate.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Click Generate New CSR.</td>
</tr>
</tbody>
</table>
The following figure shows an example.

**Step 4** Enter a country code in the **Country Name (two-letter code)** field.

**Step 5** Enter a state or province postal abbreviation in the **State or Province** field.

**Step 6** Enter a **Locality or City**.

**Step 7** Enter an **Organization** name.

**Step 8** Enter an **Organizational Unit (Department)** name.

**Step 9** Enter the fully qualified domain name of the server for which you want to request a certificate in the **Common Name** field.

**Note** Enter the fully qualified domain name of the server exactly as it should appear in the certificate in the **Common Name** field. If the common name and the DNS hostname do not match, you receive a warning when connecting to the appliance.

**Step 10** To request a certificate that secures multiple domain names or IP addresses, enter the following information in the **Subject Alternative Name** section:

a) **Domain Names**: Enter the fully qualified domains and subdomains (if any) secured by the Subject Alternative Name.

b) **IP Addresses**: Enter the IP addresses secured by the Subject Alternative Name.

**Step 11** Click **Generate**.

**Step 12** Open a text editor.

**Step 13** Copy the entire block of text in the certificate request, including the **BEGIN CERTIFICATE REQUEST** and **END CERTIFICATE REQUEST** lines, and paste it into a blank text file.

**Step 14** Save the file as `servername.csr`, where `servername` is the name of the server where you plan to use the certificate.

**Step 15** Click **Close**.

**What to do next**

- Submit the certificate request to the certificate authority.
When you receive the signed certificate, import it to the Firepower Management Center; see Importing HTTPS Server Certificates, on page 1276.

**Importing HTTPS Server Certificates**

If the signing authority that generated the certificate requires you to trust an intermediate CA, you must also supply a certificate chain (or certificate path).

If you require client certificates, accessing an appliance via the web interface will fail when the server certificate does not meet either of the following criteria:

- The certificate is signed by the same CA that signed the client certificate.
- The certificate is signed by a CA that has signed an intermediate certificate in the certificate chain.

---

**Caution**
The Firepower Management Center supports 4096-bit HTTPS certificates. If the certificate used by the Firepower Management Center was generated using a public server key larger than 4096 bits, you will not be able to log in to the FMC web interface. For more information about updating HTTPS Certificates to Version 6.0.0, see "Update Management Center HTTPS Certificates to Version 6.0" in Firepower System Release Notes, Version 6.0. If you generate or import an HTTPS Certificate and cannot log in to the FMC web interface, contact Support.

---

**Before you begin**

- Generate a certificate signing request; see Generating an HTTPS Server Certificate Signing Request, on page 1274.
- Upload the CSR file to the certificate authority where you want to request a certificate, or use the CSR to create a self-signed certificate.
- Confirm that the certificate meets the requirements described in HTTPS Server Certificate Requirements, on page 1272.

**Procedure**

**Step 1** Choose **System > Configuration**.

**Step 2** Click **HTTPS Certificate**.

**Step 3** Click **Import HTTPS Server Certificate**.

**Step 4** Open the server certificate in a text editor, copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Paste this text into the **Server Certificate** field.

**Step 5** Whether you must supply a **Private Key** depends on how you generated the Certificate Signing Request:

- If you generated the Certificate Signing Request using the Firepower Management Center web interface (as described in Generating an HTTPS Server Certificate Signing Request, on page 1274), the system already has the private key and you need not enter one here.
- If you generated the Certificate Signing Request using some other means, you must supply the private key here. Open the private key file and copy the entire block of text, include the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines. Paste this text into the **Private Key** field.
Step 6 Open any required intermediate certificates, copy the entire block of text for each, and paste it into the Certificate Chain field.

Step 7 Click Save.

---

Requiring Valid HTTPS Client Certificates

Use this procedure to require users connecting to the FMC web interface to supply a user certificate. The system supports validating HTTPS client certificates using either OCSP or imported CRLs in Privacy-enhanced Electronic Mail (PEM) format.

If you choose to use CRLs, to ensure that the list of revoked certificates stays current, you can create a scheduled task to update the CRLs. The system displays the most recent refresh of the CRLs.

Note To access the web interface after enabling client certificates, you must have a valid client certificate present in your browser (or a CAC inserted in your reader).

Before you begin

- Import a server certificate signed by the same certificate authority that signed the client certificate to be used for the connection; see Importing HTTPS Server Certificates, on page 1276.
- Import the server certificate chain if needed; see Importing HTTPS Server Certificates, on page 1276.

Procedure

Step 1 Choose System > Configuration.
Step 2 Click HTTPS Certificate.
Step 3 Choose Enable Client Certificates. If prompted, select the appropriate certificate from the drop-down list.
Step 4 You have three options:
  - To verify client certificates using one or more CRLs, select Enable Fetching of CRL and continue with Step 5.
  - To verify client certificates using OCSP, select Enable OCSP and skip to Step 7.
  - To accept client certificates without checking for revocation, skip to Step 8.
Step 5 Enter a valid URL to an existing CRL file and click Add CRL. Repeat to add up to 25 CRLs.
Step 6 Click Refresh CRL to load the current CRL or CRLs from the specified URL or URLs.
Note Enabling fetching of the CRL creates a scheduled task to regularly update the CRL or CRLs. Edit the task to set the frequency of the update.
Step 7 Verify that the client certificate is signed by the certificate authority loaded onto the appliance and the server certificate is signed by a certificate authority loaded in the browser certificate store. (These should be the same certificate authority.)
Saving a configuration with enabled client certificates, with no valid client certificate in your browser certificate store, disables all web server access to the appliance. Make sure that you have a valid client certificate installed before saving settings.

**Step 8**  
Click **Save**.

[Configuring Certificate Revocation List Downloads](#), on page 271

---

##Renewing the Default HTTPS Server Certificate

You can only view server certificates for the appliance you are logged in to.

**Procedure**

**Step 1**  
Choose **System** > **Configuration**.

**Step 2**  
Click **HTTPS Certificate**.

The button appears only if your system is configured to use the default HTTPS server certificate.

**Step 3**  
Click **Renew HTTPS Certificate**. (This option appears on the display below the certificate information only if your system is configured to used the default HTTPS server certificate.)

**Step 4**  
(Optional) In the **Renew HTTPS Certificate** dialog box, select **Generate New Key** to generate a new key for the certificate.

**Step 5**  
In the **Renew HTTPS Certificate** dialog box, click **Save**.

**What to do next**

You can confirm that the certificate has been renewed by checking that that certificate validity dates displayed on the **HTTPS Certificate** page have updated.

---

##External Database Access Settings

You can configure the Firepower Management Center to allow read-only access to its database by a third-party client. This allows you to query the database using SQL using any of the following:

- industry-standard reporting tools such as Actuate BIRT, JasperSoft iReport, or Crystal Reports
- any other reporting application (including a custom application) that supports JDBC SSL connections
- the Cisco-provided command-line Java application called RunQuery, which you can either run interactively or use to obtain comma-separated results for a single query

Use the Firepower Management Center's system configuration to enable database access and create an access list that allows selected hosts to query the database. Note that this access list does not also control appliance access.
You can also download a package that contains the following:
- RunQuery, the Cisco-provided database query tool
- InstallCert, a tool you can use to retrieve and accept the SSL certificate from the Firepower Management Center you want to access
- the JDBC driver you must use to connect to the database

See the *Firepower System Database Access Guide* for information on using the tools in the package you downloaded to configure database access.

## Enabling External Access to the Database

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Choose System &gt; Configuration.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click External Database Access.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Select the Allow External Database Access check box.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Enter an appropriate value in the Server Hostname field. Depending on your third-party application requirements, this value can be either the fully qualified domain name (FQDN), IPv4 address, or IPv6 address of the Firepower Management Center. <strong>Note</strong> In an FMC high availability setup, enter only the active peer details. We do not recommend entering details of the standby peer.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Next to Client JDBC Driver, click Download and follow your browser’s prompts to download the client.zip package.</td>
</tr>
<tr>
<td>Step 6</td>
<td>To add database access for one or more IP addresses, click Add Hosts. An IP Address field appears in the Access List field.</td>
</tr>
<tr>
<td>Step 7</td>
<td>In the IP Address field, enter an IP address or address range, or any.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Click Add.</td>
</tr>
<tr>
<td>Step 9</td>
<td>Click Save. <strong>Tip</strong> If you want to revert to the last saved database settings, click Refresh.</td>
</tr>
</tbody>
</table>

## Database Event Limits

To manage disk space, the FMC periodically prunes the oldest intrusion events, audit records, Security Intelligence data, and URL filtering data from the event database. For each event type, you can specify how many records the FMC retains after pruning; never rely on the event database containing more records of any type than the retention limit configured for that type. To improve performance, tailor the event limits to the
number of events you regularly work with. You can optionally choose to receive email notifications when pruning occurs. For some event types, you can disable storage.

To manually delete individual events, use the event viewer. (Note that in Versions 6.6.0+, you cannot manually delete connection or security Intelligence events in this way.) You can also manually purge the database; see Data Storage, on page 289.

**Configuring Database Event Limits**

**Before you begin**

- If you want to receive email notifications when events are pruned from the Firepower Management Center's database, you must configure an email server; see Configuring a Mail Relay Host and Notification Address, on page 1307.

**Procedure**

1. Choose **System > Configuration**.
2. Choose **Database**.
3. For each of the databases, enter the number of records you want to store.

   For information on how many records each database can maintain, see Database Event Limits, on page 1280.

4. Optionally, in the **Data Pruning Notification Address** field, enter the email address where you want to receive pruning notifications.

5. Click **Save**.

**Database Event Limits**

The following table lists the minimum and maximum number of records for each event type that you can store on a Firepower Management Center.

**Management Interfaces**

After setup, you can change the management network settings, including adding more management interfaces, hostname, search domains, DNS servers, and HTTP proxy on the FMC.

**About FMC Management Interfaces**

By default, the FMC manages all devices on a single management interface. You can also perform initial setup on the management interface and log into the FMC on this interface as an administrator. The management interface is also used to communicate with the Smart Licensing server, to download updates, and to perform other management functions.

For information about device management interfaces, see About Device Management Interfaces, on page 317.

**Management Interfaces on the FMC**

The FMC uses the eth0 interface for initial setup, HTTP access for administrators, management of devices, as well as other management functions such as licensing and updates.

You can also configure additional management interfaces on the same network, or on different networks. When the FMC manages large numbers of devices, adding more management interfaces can improve throughput and performance. You can also use these interfaces for all other management functions. You might want to use each management interface for particular functions; for example, you might want to use one interface for HTTP administrator access and another for device management.

For device management, the management interface carries two separate traffic channels: the management traffic channel carries all internal traffic (such as inter-device traffic specific to managing the device), and the event traffic channel carries all event traffic (such as web events). You can optionally configure a separate event-only interface on the FMC to handle event traffic; you can configure only one event interface. Event traffic can use a large amount of bandwidth, so separating event traffic from management traffic can improve the performance of the FMC. For example, you can assign a 10 GigabitEthernet interface to be the event interface, if available, while using 1 GigabitEthernet interfaces for management. You might want to configure an event-only interface on a completely secure, private network while using the regular management interface on a network that includes Internet access, for example. You can also use both management and event interfaces on the same network if the goal is only to take advantage of increased throughput. Managed devices will send management traffic to the FMC management interface and event traffic to the FMCs event-only interface. If the managed device cannot reach the event-only interface, then it will fall back to sending events to the management interface.
All management interfaces support HTTP administrator access as controlled by your Access List configuration (Configure an Access List, on page 1297). Conversely, you cannot restrict an interface to only HTTP access; management interfaces always support device management (management traffic, event traffic, or both).

Note

Only the eth0 interface supports DHCP IP addressing. Other management interfaces only support static IP addresses.

Management Interface Support Per FMC Model

See the hardware installation guide for your model for the management interface locations.

See the following table for supported management interfaces on each FMC model.

Network Routes on FMC Management Interfaces

Management interfaces (including event-only interfaces) support only static routes to reach remote networks. When you set up your FMC, the setup process creates a default route to the gateway IP address that you specify. You cannot delete this route; you can only modify the gateway address.

You can configure multiple management interfaces on some platforms. The default route does not include an egress interface, so the interface chosen depends on the gateway address you specify, and which interface's network the gateway belongs to. In the case of multiple interfaces on the default network, the device uses the lower-numbered interface as the egress interface.
At least one static route is recommended per management interface to access remote networks. We recommend placing each interface on a separate network to avoid potential routing problems, including routing problems from other devices to the FMC. If you do not experience problems with interfaces on the same network, then be sure to configure static routes correctly. For example, on the FMC both eth0 and eth1 are on the same network, but you want to manage a different group of devices on each interface. The default gateway is 192.168.45.1. If you want eth1 to manage devices on the remote 10.6.6.0/24 destination network, you can create a static route for 10.6.6.0/24 through eth1 with the same gateway of 192.168.45.1. Traffic to 10.6.6.0/24 will hit this route before it hits the default route, so eth1 will be used as expected.

If you want to use two FMC interfaces to manage remote devices that are on the same network, then static routing on the FMC may not scale well, because you need separate static routes per device IP address.

Another example includes separate management and event-only interfaces on both the FMC and the managed device. The event-only interfaces are on a separate network from the management interfaces. In this case, add a static route through the event-only interface for traffic destined for the remote event-only network, and vice versa.

### NAT Environments

Network address translation (NAT) is a method of transmitting and receiving network traffic through a router that involves reassigning the source or destination IP address. The most common use for NAT is to allow private networks to communicate with the internet. Static NAT performs a 1:1 translation, which does not pose a problem for FMC communication with devices, but port address translation (PAT) is more common. PAT lets you use a single public IP address and unique ports to access the public network; these ports are dynamically assigned as needed, so you cannot initiate a connection to a device behind a PAT router.

Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the FMC specifies the device IP address when you add a device, and the device specifies the FMC IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. The FMC and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

For example, you add a device to the FMC, and you do not know the device IP address (for example, the device is behind a PAT router), so you specify only the NAT ID and the registration key on the FMC; leave the IP address blank. On the device, you specify the FMC IP address, the same NAT ID, and the same registration key. The device registers to the FMC’s IP address. At this point, the FMC uses the NAT ID instead of IP address to authenticate the device.

Although the use of a NAT ID is most common for NAT environments, you might choose to use the NAT ID to simplify adding many devices to the FMC. On the FMC, specify a unique NAT ID for each device you want to add while leaving the IP address blank, and then on each device, specify both the FMC IP address and the NAT ID. Note: The NAT ID must be unique per device.

The following example shows three devices behind a PAT IP address. In this case, specify a unique NAT ID per device on both the FMC and the devices, and specify the FMC IP address on the devices.
The following example shows the FMC behind a PAT IP address. In this case, specify a unique NAT ID per device on both the FMC and the devices, and specify the device IP addresses on the FMC.

**Figure 46: NAT ID for FMC Behind PAT**

Device 1: 10.10.10.1
Register with FMC: blank

Management and Event Traffic Channel Examples

If you use a data interface for management on an FTD, you cannot use separate management and event interfaces for that device.

Note

The following example shows the Firepower Management Center and managed devices using only the default management interfaces.

Figure 47: Single Management Interface on the Firepower Management Center

The following example shows the Firepower Management Center using separate management interfaces for devices; and each managed device using 1 management interface.

Figure 48: Multiple Management Interfaces on the Firepower Management Center

The following example shows the Firepower Management Center and managed devices using a separate event interface.

Figure 49: Separate Event Interface on the Firepower Management Center and Managed Devices
The following example shows a mix of multiple management interfaces and a separate event interface on the Firepower Management Center and a mix of managed devices using a separate event interface, or using a single management interface.

Figure 50: Mixed Management and Event Interface Usage

Modify FMC Management Interfaces

Modify the management interface settings on the Firepower Management Center. You can optionally enable additional management interfaces or configure an event-only interface.

⚠️ **Caution**

Be careful when making changes to the management interface to which you are connected; if you cannot re-connect because of a configuration error, you need to access the FMC console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

📝 **Note**

If you change the FMC IP address, then see Edit the FMC IP Address or Hostname on the Device, on page 364. If you change the FMC IP address or hostname, you should also change the value at the device CLI so the configurations match. Although in most cases, the management connection will be reestablished without changing the FMC IP address or hostname on the device, in at least one case, you must perform this task for the connection to be reestablished: when you added the device to the FMC and you specified the NAT ID only. Even in other cases, we recommend keeping the FMC IP address or hostname up to date for extra network resiliency.

📝 **Note**

In a high availability configuration, when you modify the management IP address of a registered Firepower device from the device CLI or from Firepower Management Center, the secondary Firepower Management Center does not reflect the changes even after an HA synchronization. To ensure that the secondary Firepower Management Center is also updated, switch roles between the two Firepower Management Centers, making the secondary Firepower Management Center as the active unit. Modify the management IP address of the registered Firepower device on the device management page of the now active Firepower Management Center.

**Before you begin**

- For information about how device management works, see About Device Management Interfaces, on page 317.
• If you use a proxy:
  • Proxies that use NT LAN Manager (NTLM) authentication are not supported.
  • If you use or will use Smart Licensing, the proxy FQDN cannot have more than 64 characters.

Procedure

**Step 1** Choose **System > Configuration**, and then choose **Management Interfaces**.

**Step 2** In the **Interfaces** area, click **Edit** next to the interface that you want to configure.

All available interfaces are listed in this section. You cannot add more interfaces.

You can configure the following options on each management interface:

- **Enabled**—Enable the management interface. Do **not** disable the default eth0 management interface. Some processes require the eth0 interface.

- **Channels**—Configure an event-only interface; you can configure only one event interface on the FMC. To do so, uncheck the **Management Traffic** check box, and leave the **Event Traffic** check box checked. You can optionally disable **Event Traffic** for the management interface(s). In either case, the device will try to send events to the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel. You cannot disable both event and management channels on an interface.

- **Mode**—Specify a link mode. Note that any changes you make to auto-negotiation are ignored for GigabitEthernet interfaces.

- **MDI/MDIX**—Set the **Auto-MDI** setting.

- **MTU**—Set the maximum transmission unit (MTU). The default is 1500. The range within which you can set the MTU can vary depending on the model and interface type.

  Because the system automatically trims 18 bytes from the configured MTU value, any value below 1298 does not comply with the minimum IPv6 MTU setting of 1280, and any value below 594 does not comply with the minimum IPv4 MTU setting of 576. For example, the system automatically trims a configured value of 576 to 558.

- **IPv4 Configuration**—Set the IPv4 IP address. Choose:
  
  - **Static**—Manually enter the **IPv4 Management IP** address and **IPv4 Netmask**.
  
  - **DHCP**—Set the interface to use DHCP (eth0 only).

  - **Disabled**—Disable IPv4. Do **not** disable both IPv4 and IPv6.

- **IPv6 Configuration**—Set the IPv6 IP address. Choose:
  
  - **Static**—Manually enter the **IPv6 Management IP** address and **IPv6 Prefix Length**.

  - **DHCP**—Set the interface to use DHCPv6 (eth0 only).

  - **Router Assigned**—Enable stateless autoconfiguration.

  - **Disabled**—Disable IPv6. Do **not** disable both IPv4 and IPv6.
• IPv6 DAD—When you enable IPv6, enable or disable duplicate address detection (DAD). You might want to disable DAD because the use of DAD opens up the possibility of denial of service attacks. If you disable this setting, you need check manually that this interface is not using an already-assigned address.

**Step 3**  
In the **Routes** area, edit a static route by clicking **Edit (стрелка)**, or add a route by clicking **Add (плюс)**. View the route table by clicking **закладка**.

You need a static route for each additional interface to reach remote networks. For more information about when new routes are needed, see Network Routes on FMC Management Interfaces, on page 1283.

**Note**  
For the default route, you can change only the gateway IP address. The egress interface is chosen automatically by matching the specified gateway to the interface's network.

You can configure the following settings for a static route:

• **Destination**—Set the destination address of the network to which you want to create a route.

• **Netmask or Prefix Length**—Set the netmask (IPv4) or prefix length (IPv6) for the network.

• **Interface**—Set the egress management interface.

• **Gateway**—Set the gateway IP address.

**Step 4**  
In the **Shared Settings** area, set network parameters shared by all interfaces.

**Note**  
If you selected **DHCP** for the eth0 interface, you cannot manually specify some shared settings derived from the DHCP server.

You can configure the following shared settings:

• **Hostname**—Set the FMC hostname. The hostname must start and end with a letter or digit, and have only letters, digits, or a hyphen. If you change the hostname, reboot the FMC if you want the new hostname reflected in syslog messages. Syslog messages do not reflect a new hostname until after a reboot.

• **Domains**—Set the search domain(s) for the FMC, separated by commas. These domains are added to hostnames when you do not specify a fully-qualified domain name in a command, for example, `ping system`. The domains are used only on the management interface, or for commands that go through the management interface.

• **Primary DNS Server, Secondary DNS Server, Tertiary DNS Server**—Set the DNS servers to be used in order of preference.

• **Remote Management Port**—Set the remote management port for communication with managed devices. The FMC and managed devices communicate using a two-way, SSL-encrypted communication channel, which by default is on port 8305.

**Note**  
Cisco **strongly** recommends that you keep the default settings for the remote management port, but if the management port conflicts with other communications on your network, you can choose a different port. If you change the management port, you must change it for all devices in your deployment that need to communicate with each other.

**Step 5**  
In the **ICMPv6** area, configure ICMPv6 settings.
• **Allow Sending Echo Reply Packets**—Enable or disable Echo Reply packets. You might want to disable these packets to guard against potential denial of service attacks. Disabling Echo Reply packets means you cannot use IPv6 ping to the FMC management interfaces for testing purposes.

• **Allow Sending Destination Unreachable Packets**—Enable or disable Destination Unreachable packets. You might want to disable these packets to guard against potential denial of service attacks.

**Step 6**

In the **Proxy** area, configure HTTP proxy settings.

The FMC is configured to directly-connect to the internet on ports TCP/443 (HTTPS) and TCP/80 (HTTP). You can use a proxy server, to which you can authenticate via HTTP Digest.

See proxy requirements in the prerequisites to this topic.

a) Check the **Enabled** check box.

b) In the **HTTP Proxy** field, enter the IP address or fully-qualified domain name of your proxy server.

   See requirements in the prerequisites to this topic.

c) In the **Port** field, enter a port number.

d) Supply authentication credentials by choosing **Use Proxy Authentication**, and then provide a **User Name** and **Password**.

**Step 7**

Click **Save**.

**Step 8**

If you change the FMC IP address, then see If you change the FMC IP address, then see **Edit the FMC IP Address or Hostname on the Device** on page 364.

If you change the FMC IP address or hostname, you should also change the value at the device CLI so the configurations match. Although in most cases, the management connection will be reestablished without changing the FMC IP address or hostname on the device, in at least one case, you must perform this task for the connection to be reestablished: when you added the device to the FMC and you specified the NAT ID only. Even in other cases, we recommend keeping the FMC IP address or hostname up to date for extra network resiliency.

---

### Shut Down or Restart

Use the web interface to control the shut down and restart of processes on the FMC. You can:

• **Shut down**: Initiate a graceful shutdown of the appliance.

  ![Caution](image)

  **Caution**  Do **not** shut off Firepower appliances using the power button; it may cause a loss of data. Using the web interface (or CLI) prepares the system to be safely powered off and restarted without losing configuration data.

• **Reboot**: Shut down and restart gracefully.

• **Restart the console**: Restart the communications, database, and HTTP server processes. This is typically used during troubleshooting.
For virtual devices, refer to the documentation for your virtual platform. For VMware in particular, custom power options are part of VMware Tools.

**Shut Down or Restart the FMC**

**Procedure**

**Step 1** Choose System > Configuration.

**Step 2** Choose Process.

**Step 3** Do one of the following:

<table>
<thead>
<tr>
<th>Action</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shut down</td>
<td>Click <strong>Run Command</strong> next to <strong>Shutdown Management Center</strong>.</td>
</tr>
<tr>
<td>Reboot</td>
<td>Click <strong>Run Command</strong> next to <strong>Reboot Management Center</strong>. <strong>Note</strong> Rebooting logs you out, and the system runs a database check that can take up to an hour to complete.</td>
</tr>
<tr>
<td>Restart the console</td>
<td>Click <strong>Run Command</strong> next to <strong>Restart Management Center Console</strong>. <strong>Note</strong> Restarting may cause deleted hosts to reappear in the network map.</td>
</tr>
</tbody>
</table>

**Related Topics**

Snort® Restart Scenarios, on page 502

**Remote Storage Management**

On Firepower Management Centers, you can use the following for local or remote storage for backups and reports:

- Network File System (NFS)
- Server Message Block (SMB)/Common Internet File System (CIFS)
- Secure Shell (SSH)

You cannot send backups to one remote system and reports to another, but you can choose to send either to a remote system and store the other on the Firepower Management Center.

**Tip**

After configuring and selecting remote storage, you can switch back to local storage only if you have not increased the connection database limit.
Configuring Local Storage

Procedure

Step 1  Choose System > Configuration.
Step 2  Choose Remote Storage Device.
Step 3  Choose Local (No Remote Storage) from the Storage Type drop-down list.
Step 4  Click Save.

Configuring NFS for Remote Storage

Before you begin

• Ensure that your external remote storage system is functional and accessible from your FMC.

Procedure

Step 1  Choose System > Configuration.
Step 2  Click Remote Storage Device.
Step 3  Choose NFS from the Storage Type drop-down list.
Step 4  Add the connection information:
  • Enter the IPv4 address or hostname of the storage system in the Host field.
  • Enter the path to your storage area in the Directory field.
Step 5  Optionally, check the Use Advanced Options check box and enter any required command line options; see Remote Storage Management Advanced Options, on page 1294.
Step 6  Under System Usage:
  • Choose Use for Backups to store backups on the designated host.
  • Choose Use for Reports to store reports on the designated host.
  • Enter Disk Space Threshold for backup to remote storage. Default is 90%.
Step 7  To test the settings, click Test.
Step 8  Click Save.
Configuring SMB for Remote Storage

Before you begin

Ensure that your external remote storage system is functional and accessible from your FMC:

- The system recognizes top-level SMB shares, not full file paths. You must use Windows to share the exact directory you want to use.
- Make sure the Windows user you will use to access the SMB share from the FMC has ownership of and read/change access to the share location.
- To ensure security, you should install SMB 2.0 or greater.

Procedure

Step 1  Choose System > Configuration.
Step 2  Click Remote Storage Device.
Step 3  Choose SMB from the Storage Type drop-down list.
Step 4  Add the connection information:
  • Enter the IPv4 address or hostname of the storage system in the Host field.
  • Enter the share of your storage area in the Share field.
  • Optionally, enter the domain name for the remote storage system in the Domain field.
  • Enter the username for the storage system in the Username field and the password for that user in the Password field.

Step 5  Optionally, check the Use Advanced Options check box and enter any required command line options; see Remote Storage Management Advanced Options, on page 1294.
Step 6  Under System Usage:
  • Choose Use for Backups to store backups on the designated host.
  • Choose Use for Reports to store reports on the designated host.
Step 7  To test the settings, click Test.
Step 8  Click Save.

Configuring SSH for Remote Storage

Before you begin

- Ensure that your external remote storage system is functional and accessible from your Firepower Management Center.
Procedure

Step 1  Choose System > Configuration.
Step 2  Click Remote Storage Device.
Step 3  Choose SSH from the Storage Type drop-down list.
Step 4  Add the connection information:
• Enter the IP address or host name of the storage system in the Host field.
• Enter the path to your storage area in the Directory field.
• Enter the storage system’s user name in the Username field and the password for that user in the Password field. To specify a network domain as part of the connection user name, precede the user name with the domain followed by a forward slash (/).
• To use SSH keys, copy the content of the SSH Public Key field and place it in your authorized_keys file.
Step 5  Optionally, check the Use Advanced Options check box and enter any required command line options; see Remote Storage Management Advanced Options, on page 1294.
Step 6  Under System Usage:
• Choose Use for Backups to store backups on the designated host.
• Choose Use for Reports to store reports on the designated host.
Step 7  If you want to test the settings, you must click Test.
Step 8  Click Save.

Remote Storage Management Advanced Options

If you select the Network File System (NFS) protocol, Server Message Block (SMB) protocol, or SSH to use secure file transfer protocol (SFTP) to store your reports and backups, you can select the Use Advanced Options check box to use one of the mount binary options as documented in an NFS, SMB, or SSH mount man page.

If you select SMB, you can enter the security mode in the Command Line Options field using the following format:

```
sec=mode
```

where mode is the security mode you want to use for remote storage.

Table 89: SMB Security Mode Settings

<table>
<thead>
<tr>
<th>Mode</th>

</tbody>
</table>
### Change Reconciliation

To monitor the changes that users make and ensure that they follow your organization’s preferred standard, you can configure the system to send, via email, a detailed report of changes made over the past 24 hours. Whenever a user saves changes to the system configuration, a snapshot is taken of the changes. The change reconciliation report combines information from these snapshots to present a clear summary of recent system changes.

The following sample graphic displays a User section of an example change reconciliation report and lists both the previous value for each configuration and the value after changes. When users make multiple changes to the same configuration, the report lists summaries of each distinct change in chronological order, beginning with the most recent.

You can view changes made during the previous 24 hours.

### Configuring Change Reconciliation

**Before you begin**

- Configure an email server to receive emailed reports of changes made to the system over a 24 hour period; see Configuring a Mail Relay Host and Notification Address, on page 1307 for more information.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Choose System &gt; Configuration.</td>
</tr>
<tr>
<td>2</td>
<td>Click Change Reconciliation.</td>
</tr>
<tr>
<td>3</td>
<td>Check the Enable check box.</td>
</tr>
<tr>
<td>4</td>
<td>Choose the time of day you want the system to send out the change reconciliation report from the Time to Run drop-down lists.</td>
</tr>
<tr>
<td>5</td>
<td>Enter email addresses in the Email to field.</td>
</tr>
<tr>
<td>6</td>
<td>If you want to include policy changes, check the Include Policy Configuration check box.</td>
</tr>
</tbody>
</table>

**Tip** Once you have added email addresses, click Resend Last Report to send recipients another copy of the most recent change reconciliation report.
Step 7: If you want to include all changes over the past 24 hours, check the **Show Full Change History** check box.

Step 8: Click **Save**.

**Related Topics**
- Using the Audit Log to Examine Changes, on page 450

---

### Change Reconciliation Options

The **Include Policy Configuration** option controls whether the system includes records of policy changes in the change reconciliation report. This includes changes to access control, intrusion, system, health, and network discovery policies. If you do not select this option, the report will not show changes to any policies. This option is available on Firepower Management Centers only.

The **Show Full Change History** option controls whether the system includes records of all changes over the past 24 hours in the change reconciliation report. If you do not select this option, the report includes only a consolidated view of changes for each category.

**Note** The change reconciliation report does not include changes to Firepower Threat Defense interfaces and routing settings.

---

### Policy Change Comments

You can configure the Firepower System to track several policy-related changes using the comment functionality when users modify access control, intrusion, or network analysis policies.

With policy change comments enabled, administrators can quickly assess why critical policies in a deployment were modified. Optionally, you can have changes to intrusion and network analysis policies written to the audit log.

---

### Configuring Comments to Track Policy Changes

You can configure the Firepower System to prompt users for comments when they modify an access control policy, intrusion policy, or network analysis policy. You can use comments to track users’ reasons for policy changes. If you enable comments on policy changes, you can make the comment optional or mandatory. The system prompts the user for a comment when each new change to a policy is saved.

**Procedure**

#### Step 1
Choose **System > Configuration**.

The system configuration options appear in the left navigation panel.

#### Step 2
Configure the policy comment preferences for any of the following:

- Click **Access Control Preferences** for comment preferences for access control policies.
- Click **Intrusion Policy Preferences** for comment preferences for intrusion policies.
• Click **Network Analysis Policy Preferences** for comment preferences for network analysis policies.

**Step 3** You have the following choices for each policy type:

- **Disabled**—Disables change comments.
- **Optional**—Gives users the option to describe their changes in a comment.
- **Required**—Requires users to describe their changes in a comment before saving.

**Step 4** Optionally for intrusion or network analysis policy comments:

- Check **Write changes in Intrusion Policy to audit log** to write all intrusion policy changes to the audit log.
- Check **Write changes in Network Analysis Policy to audit log** to write all network analysis policy changes to the audit log.

**Step 5** Click **Save**.

---

**Access List**

You can limit access to the FMC by IP address and port. By default, the following ports are enabled for any IP address:

- 443 (HTTPS) for web interface access.
- 22 (SSH) for CLI access.

You can also add access to poll for SNMP information over port 161. Because SNMP is disabled by default, you must first enable SNMP before you can add SNMP access rules. For more information, see **Configure SNMP Polling**, on page 1309.

**Caution**

By default, access is not restricted. To operate in a more secure environment, consider adding access for specific IP addresses and then deleting the default **any** option.

---

**Configure an Access List**

This access list does not control external database access. See **Enabling External Access to the Database**, on page 1279.

**Caution**

If you delete access for the IP address that you are currently using to connect to the FMC, and there is no entry for “IP=any port=443”, you will lose access when you save.

To configure access lists for Classic devices, use device platform settings. See **Configure Access Lists for Classic Devices**, on page 1337.
Before you begin

By default, the access list includes rules for HTTPS and SSH. To add SNMP rules to the access list, you must first enable SNMP. For more information, see Configure SNMP Polling, on page 1309.

Procedure

Step 1  Choose System > Configuration.
Step 2  (Optional) Click SNMP to configure SNMP if you want to add SNMP rules to the access list. By default, SNMP is disabled; see Configure SNMP Polling, on page 1309.
Step 3  Click Access List.
Step 4  To add access for one or more IP addresses, click Add Rules.
Step 5  In the IP Address field, enter an IP address or address range, or any.
Step 6  Choose SSH, HTTPS, SNMP, or a combination of these options to specify which ports you want to enable for these IP addresses.
Step 7  Click Add.
Step 8  Click Save.

Firepower System IP Address Conventions, on page 18

Audit Logs

The Firepower Management Center records user activity in read-only audit logs. You can review audit log data in several ways:

- Use the web interface: Auditing the System, on page 445.
  
  Audit logs are presented in a standard event view where you can view, sort, and filter audit log messages based on any item in the audit view. You can easily delete and report on audit information and you can view detailed reports of the changes that users make.

- Stream audit log messages to the syslog: Stream Audit Logs to Syslog, on page 1299.

- Stream audit log messages to an HTTP server: Stream Audit Logs to an HTTP Server, on page 1300.

Streaming audit log data to an external server allows you to conserve space on the FMC. Note that sending audit information to an external URL may affect system performance.

Optionally, you can secure the channel for audit log streaming, enable TLS and mutual authentication using TLS certificates; see Audit Log Certificate, on page 1301.

Streaming to Multiple Syslog Servers

You can stream audit log data to a maximum of five syslog servers. However, if you have enabled TLS for secured audit log streaming, you can stream only to a single syslog server.

Classic devices also maintain audit logs. To stream audit logs from a Classic devices, see Stream Audit Logs from Classic Devices, on page 1337.
Stream Audit Logs to Syslog

When this feature is enabled, audit log records appear in the syslog in the following format:

```
Date Time Host [Tag] Sender: User_Name@User_IP, Subsystem, Action
```

Where the local date, time, and originating hostname precede the bracketed optional tag, and the sending device name precedes the audit log message.

For example, if you specify a tag of `FMC-AUDIT-LOG` for audit log messages from your management center, a sample audit log message from your FMC could appear as follows:

```
Mar 01 14:45:24 localhost [FMC-AUDIT-LOG] Dev-MC7000: admin@10.1.1.2, Operations > Monitoring, Page View
```

If you specify a severity and facility, these values do not appear in syslog messages; instead, they tell the system that receives the syslog messages how to categorize them.

To stream audit logs from Classic devices, use device platform settings: Stream Audit Logs from Classic Devices, on page 1337.

**Before you begin**

Make sure the FMC can communicate with the syslog server. When you save your configuration, the system uses port 7/UDP to verify that the syslog server is reachable. Then, the system uses port 514/UDP to stream audit logs. If you secure the channel (optional, see Audit Log Certificate, on page 1301), the system uses 6514/TCP.

**Procedure**

1. **Step 1** Choose System > Configuration.
2. **Step 2** Click Audit Log.
3. **Step 3** Choose Enabled from the Send Audit Log to Syslog drop-down menu.
4. **Step 4** The following fields are applicable only for audit logs sent to syslog:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The IP address or the fully qualified name of the syslog server to which you will send audit logs. You can add a maximum of five syslog hosts, separated by commas. <strong>Note</strong> You can specify multiple syslog hosts, only when TLS is disabled for the Audit Server Certificate.</td>
</tr>
<tr>
<td>Facility</td>
<td>The subsystem that creates the message. Choose a facility described in Syslog Alert Facilities, on page 2517. For example, choose AUDIT.</td>
</tr>
<tr>
<td>Severity</td>
<td>The severity of the message. Choose a severity described in Syslog Severity Levels, on page 2518.</td>
</tr>
</tbody>
</table>
Stream Audit Logs to an HTTP Server

When this feature is enabled, the appliance sends audit log records to an HTTP server in the following format:

```
Date Time Host [Tag] Sender: User_Name@User_IP, Subsystem, Action
```

Where the local date, time, and originating hostname precede the bracketed optional tag, and the sending appliance or device name precedes the audit log message.

For example, if you specify a tag of FROMMC, a sample audit log message could appear as follows:

```
Mar 01 14:45:24 localhost [FROMMC] Dev-MC7000: admin@10.1.1.2, Operations > Monitoring, Page View
```

To stream audit logs from Classic devices, use device platform settings: Stream Audit Logs from Classic Devices, on page 1337.

Before you begin

Make sure the device can communicate with the HTTP server. Optionally, secure the channel; see Audit Log Certificate, on page 1301.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose <strong>System</strong> &gt; <strong>Configuration</strong>.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click <strong>Audit Log</strong>.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Optionally, in the <strong>Tag</strong> field, enter the tag name that you want to appear with the message. For example, if you want all audit log records to be preceded with FROMMC, enter FROMMC in the field.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Choose <strong>Enabled</strong> from the <strong>Send Audit Log to HTTP Server</strong> drop-down list.</td>
</tr>
<tr>
<td>Step 5</td>
<td>In the <strong>URL to Post Audit</strong> field, designate the URL where you want to send the audit information. Enter a URL that corresponds to a Listener program that expects the HTTP POST variables as listed:</td>
</tr>
<tr>
<td></td>
<td>• subsystem</td>
</tr>
<tr>
<td></td>
<td>• actor</td>
</tr>
<tr>
<td></td>
<td>• event_type</td>
</tr>
</tbody>
</table>

Step 5 (Optional) To test whether the IP address of the syslog servers are valid, click **Test Syslog Server**. The system displays the result for each server.

Step 6 Click **Save**.
To allow encrypted posts, use an HTTPS URL. Sending audit information to an external URL may affect system performance.

Step 6  Click **Save**.

**Audit Log Certificate**

You can use Transport Layer Security (TLS) certificates to secure communications between Firepower appliances and a trusted audit log server.

**Client Certificates (Required)**

For *each appliance* (client certificates are unique), you must generate a certificate signing request (CSR), submit it to a Certificate Authority (CA) for signing, then import the signed certificate onto the appliance.

You cannot use the FMC to import audit log certificates onto its managed devices. These certificates are unique to each appliance, and you must log into *each appliance* to import them locally:

- For the FMC, use the local system configuration: **Obtain a Signed Audit Log Client Certificate for the FMC**, on page 1302 and **Import an Audit Log Client Certificate into the FMC**, on page 1303.

- For ASA FirePOWER and NGIPSv, generate a CSR with a tool like OpenSSL, then use the CLI to import the signed certificate: **configure audit_cert import**.

**Server Certificates (Optional)**

For additional security, we recommend you require mutual authentication between Firepower appliances and the audit log server. To accomplish this, load one or more certificate revocation lists (CRLs). You cannot stream audit logs to servers with revoked certificates listed in those CRLs.

Firepower supports CRLs encoded in Distinguished Encoding Rules (DER) format. Note that these are the same CRLs that the system uses to validate HTTPS client certificates for the FMC web interface.

To require valid audit log server certificates, use the FMC web interface:

- For the FMC, use the local system configuration: **Require Valid Audit Log Server Certificates**, on page 1304.

Securely Stream Audit Logs

If you stream the audit log to a trusted HTTP server or syslog server, you can use Transport Layer Security (TLS) certificates to secure the channel between the FMC and the server. You must generate a unique client certificate for each appliance you want to audit.

To securely stream audit logs to Classic devices, see Stream Audit Logs from Classic Devices, on page 1337.

Before you begin
See ramifications of requiring client and server certificates at Audit Log Certificate, on page 1301.

Procedure

Step 1 Obtain and install a signed client certificate on the FMC:
   a) Obtain a Signed Audit Log Client Certificate for the FMC, on page 1302:
      Generate a Certificate Signing Request (CSR) from the FMC based on your system information and the identification information you supply.
      Submit the CSR to a recognized, trusted certificate authority (CA) to request a signed client certificate.
      If you will require mutual authentication between the FMC and the audit log server, the client certificate must be signed by the same CA that signed the server certificate to be used for the connection.
   b) After you receive the signed certificate from the certificate authority, import it into the FMC. See Import an Audit Log Client Certificate into the FMC, on page 1303.

Step 2 Configure the communication channel with the server to use Transport Layer Security (TLS) and enable mutual authentication.
See Require Valid Audit Log Server Certificates, on page 1304.

Step 3 Configure audit log streaming if you have not yet done so.
See Stream Audit Logs to Syslog, on page 1299 or Stream Audit Logs to an HTTP Server, on page 1300.

Obtain a Signed Audit Log Client Certificate for the FMC

Important
The Audit Log Certificate page is not available on a standby Firepower Management Center in a high availability setup. You cannot perform this task from a standby Firepower Management Center.

The system generates certificate request keys in Base-64 encoded PEM format.

Before you begin
Keep the following in mind:
  • To ensure security, use a globally recognized and trusted Certificate Authority (CA) to sign your certificate.
• If you will require mutual authentication between the appliance and the audit log server, the same Certificate Authority must sign both the client certificate and the server certificate.

Procedure

Step 1  Choose System > Configuration.
Step 2  Click Audit Log Certificate.
Step 3  Click Generate New CSR.
Step 4  Enter a country code in the Country Name (two-letter code) field.
Step 5  Enter a state or province postal abbreviation in the State or Province field.
Step 6  Enter a Locality or City.
Step 7  Enter an Organization name.
Step 8  Enter an Organizational Unit (Department) name.
Step 9  Enter the fully qualified domain name of the server for which you want to request a certificate in the Common Name field.

Note  If the common name and the DNS hostname do not match, audit log streaming will fail.

Step 10  Click Generate.
Step 11  Open a new blank file with a text editor.
Step 12  Copy the entire block of text in the certificate request, including the BEGIN CERTIFICATE REQUEST and END CERTIFICATE REQUEST lines, and paste it into a blank text file.
Step 13  Save the file as clientname.csr, where clientname is the name of the appliance where you plan to use the certificate.
Step 14  Click Close.

What to do next

• Submit the certificate signing request to the certificate authority that you selected using the guidelines in the "Before You Begin" section of this procedure.

• When you receive the signed certificate, import it to the appliance; see Import an Audit Log Client Certificate into the FMC, on page 1303.

Import an Audit Log Client Certificate into the FMC

In an FMC high availability setup, you must use the active peer.

For ASA FirePOWER and NGIPSv, use the CLI to import a signed certificate: configure audit_cert import.

Before you begin

• Obtain a Signed Audit Log Client Certificate for the FMC, on page 1302.

• Make sure you are importing the signed certificate for the correct appliance. Each certificate is unique to a specific appliance or device.
If the signing authority that generated the certificate requires you to trust an intermediate CA, be prepared to provide the necessary certificate chain (or certificate path). The CA that signed the client certificate must be the same CA that signed any intermediate certificates in the certificate chain.

**Procedure**

- **Step 1**: On the FMC, choose **System > Configuration**.
- **Step 2**: Click **Audit Log Certificate**.
- **Step 3**: Click **Import Audit Client Certificate**.
- **Step 4**: Open the client certificate in a text editor, copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Paste this text into the **Client Certificate** field.
- **Step 5**: To upload a private key, open the private key file and copy the entire block of text, including the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines. Paste this text into the **Private Key** field.
- **Step 6**: Open any required intermediate certificates, copy the entire block of text for each, and paste it into the **Certificate Chain** field.
- **Step 7**: Click **Save**.

**Require Valid Audit Log Server Certificates**

The system supports validating audit log server certificates using imported CRLs in Distinguished Encoding Rules (DER) format.

**Note**

If you choose to verify certificates using CRLs, the system uses the same CRLs to validate both audit log server certificates and certificates used to secure the HTTP connection between an appliance and a web browser.

**Important**

You cannot perform this procedure on the standby Firepower Management Center in a high availability pair.

**Before you begin**

- Understand the ramifications of requiring mutual authentication and of using certificate revocation lists (CRLs) to ensure that certificates are still valid. See **Audit Log Certificate**, on page 1301.
- Obtain and import the client certificate following the steps in **Securely Stream Audit Logs**, on page 1302 and the topics referenced in that procedure.

**Procedure**

- **Step 1**: On the FMC, choose **System > Configuration**.
- **Step 2**: Click **Audit Log Certificate**.
Step 3  To use Transport Layer Security to securely stream the audit log to an external server, choose Enable TLS.

Step 4  If you want to accept server certificates without verification (not recommended):
   a) Deselect Enable Mutual Authentication.
   b) Click Save and skip the remainder of this procedure.

Step 5  To verify the certificate of the audit log server, choose Enable Mutual Authentication.

Step 6  (If you enabled mutual authentication) To automatically recognize certificates that are no longer valid:
   a) Select Enable Fetching of CRL.
      
      **Note**  Enabling fetching of the CRL creates a scheduled task to regularly update the CRL or CRLs.
   b) Enter a valid URL to an existing CRL file and click Add CRL.
      Repeat to add up to 25 CRLs.
   c) Click Refresh CRL to load the current CRL or CRLs from the specified URL or URLs.

Step 7  Verify that you have a valid server certificate generated by the same certificate authority that created the client certificate.

Step 8  Click Save.

---

**What to do next**

(Optional) Set the frequency of CRL updates. See Configuring Certificate Revocation List Downloads, on page 271.

---

**View the Audit Log Client Certificate on the FMC**

You can view the audit log client certificate only for the appliance that you are logged in to. In FMC high availability pairs, you can view the certificate only on the active peer.

To view audit log certificates on Classic devices, use `show audit_cert`.

**Procedure**

Step 1  Choose System > Configuration.

Step 2  Click Audit Log Certificate.

---

**Dashboard Settings**

Dashboards provide you with at-a-glance views of current system status through the use of widgets: small, self-contained components that provide insight into different aspects of the Firepower System. The Firepower System is delivered with several predefined dashboard widgets.

You can configure the Firepower Management Center so that Custom Analysis widgets are enabled on the dashboard.
Enabling Custom Analysis Widgets for Dashboards

Use Custom Analysis dashboard widgets to create a visual representation of events based on a flexible, user-configurable query.

**Procedure**

**Step 1** Choose System > Configuration.

**Step 2** Click Dashboard.

**Step 3** Check the **Enable Custom Analysis Widgets** check box to allow users to add Custom Analysis widgets to dashboards.

**Step 4** Click **Save**.

DNS Cache

You can configure the system to resolve IP addresses automatically on the event view pages. You can also configure basic properties for DNS caching performed by the appliance. Configuring DNS caching allows you to identify IP addresses you previously resolved without performing additional lookups. This can reduce the amount of traffic on your network and speed the display of event pages when IP address resolution is enabled.

**Configuring DNS Cache Properties**

DNS resolution caching is a system-wide setting that allows the caching of previously resolved DNS lookups.

**Procedure**

**Step 1** Choose **System** > **Configuration**.

**Step 2** Choose **DNS Cache**.

**Step 3** From the **DNS Resolution Caching** drop-down list, choose one of the following:

- **Enabled**—Enable caching.
- **Disabled**—Disable caching.

**Step 4** In the **DNS Cache Timeout (in minutes)** field, enter the number of minutes a DNS entry remains cached in memory before it is removed for inactivity.

The default setting is 300 minutes (five hours).

**Step 5** Click **Save**.
Email Notifications

Configure a mail host if you plan to:

- Email event-based reports
- Email status reports for scheduled tasks
- Email change reconciliation reports
- Email data-pruning notifications
- Use email for discovery event, impact flag, correlation event alerting, intrusion event alerting, and health event alerting

When you configure email notification, you can select an encryption method for the communication between the system and mail relay host, and can supply authentication credentials for the mail server if needed. After configuring, you can test the connection.

Configuring a Mail Relay Host and Notification Address

Procedure

**Step 1** Choose **System > Configuration**.

**Step 2** Click **Email Notification**.

**Step 3** In the **Mail Relay Host** field, enter the hostname or IP address of the mail server you want to use. The mail host you enter **must** allow access from the appliance.

**Step 4** In the **Port Number** field, enter the port number to use on the email server.

Typical ports include:

- 25, when using no encryption
- 465, when using SSLv3
- 587, when using TLS

**Step 5** Choose an **Encryption Method**:

- **TLS**—Encrypt communications using Transport Layer Security.
- **SSLv3**—Encrypt communications using Secure Socket Layers.
- **None**—Allow unencrypted communication.

**Note** Certificate validation is not required for encrypted communication between the appliance and mail server.

**Step 6** In the **From Address** field, enter the valid email address you want to use as the source email address for messages sent by the appliance.
Step 7 Optionally, to supply a user name and password when connecting to the mail server, choose Use Authentication. Enter a user name in the Username field. Enter a password in the Password field.

Step 8 To send a test email using the configured mail server, click Test Mail Server Settings. A message appears next to the button indicating the success or failure of the test.

Step 9 Click Save.

Language Selection
You can use the Language page to specify a different language for the web interface.

Set the Language for the Web Interface
The language you specify here is used for the web interface for every user. You can choose from:
- English
- Chinese (simplified)
- Chinese (traditional)
- Japanese
- Korean

Procedure

Step 1 Choose System > Configuration.
Step 2 Click Language.
Step 3 Choose the language you want to use.
Step 4 Click Save.

Login Banners
You can use the Login Banner page to specify session, login, or custom message banners for a security appliance or shared policy.

You can use ASCII characters and carriage returns to create a custom login banner. The system does not preserve tab spacing. If your login banner is too large or causes errors, Telnet or SSH sessions can fail when the system attempts to display the banner.
Customize the Login Banner

To customize login banners for Classic devices, use device platform settings. See Customize the Login Banner for Classic Devices, on page 1340.

Procedure

**Step 1** Choose System > Configuration.
**Step 2** Choose Login Banner.
**Step 3** In the Custom Login Banner field, enter the login banner text you want to use.
**Step 4** Click Save.

SNMP Polling

You can enable Simple Network Management Protocol (SNMP) polling. This feature supports use of versions 1, 2, and 3 of the SNMP protocol. This feature allows access to the standard management information base (MIB), which includes system details such as contact, administrative, location, service information, IP addressing and routing information, and transmission protocol usage statistics.

**Note**

When selecting SNMP versions for the SNMP protocol, note that SNMPv2 only supports read-only communities and SNMPv3 only supports read-only users. SNMPv3 also supports encryption with AES128.

Enabling SNMP polling does not cause the system to send SNMP traps; it only makes the information in the MIBs available for polling by your network management system.

Configure SNMP Polling

To configure SNMP polling on Classic managed devices, use the device platform settings. See Configure SNMP Polling on Classic Devices, on page 1342.

**Before you begin**

Add SNMP access for each computer you plan to use to poll the system. See Configure an Access List, on page 1297.

**Note**

The SNMP MIB contains information that could be used to attack your deployment. We recommend that you restrict your access list for SNMP access to the specific hosts that will be used to poll for the MIB. We also recommend you use SNMPv3 and use strong passwords for network management access.
## Time and Time Synchronization

Synchronizing the system time on your Firepower Management Center (FMC) and its managed devices is essential to successful operation of your Firepower System. We recommend that you specify NTP servers during FMC initial configuration, but you can use the information in this section to establish or change time synchronization settings after initial configuration is complete.

Use a Network Time Protocol (NTP) server to synchronize system time on the FMC and all devices. The FMC supports secure communications with NTP servers using MD5 or SHA-1 symmetric key authentication; for system security, we recommend using this feature.

The FMC can also be configured to connect solely with authenticated NTP servers; using this option improves security in a mixed-authentication environment, or when migrating your system to different NTP servers. It is redundant to use this setting in an environment where all reachable NTP servers are authenticated.

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Choose <strong>System &gt; Configuration</strong>.</td>
</tr>
<tr>
<td>2</td>
<td>Click <strong>SNMP</strong>.</td>
</tr>
<tr>
<td>3</td>
<td>From the <strong>SNMP Version</strong> drop-down list, choose the SNMP version you want to use:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Version 1</strong> or <strong>Version 2</strong>: Enter a read-only SNMP community name in the <strong>Community String</strong> field, then skip to the end of the procedure.</td>
</tr>
<tr>
<td></td>
<td>Note</td>
</tr>
<tr>
<td></td>
<td>• <strong>Version 3</strong>: Click <strong>Add User</strong> to display the user definition page. SNMPv3 only supports read-only users and encryption with AES128.</td>

<td>Click <strong>Add</strong>.</td>
</tr>
<tr>
<td>12</td>
<td>Click <strong>Save</strong>.</td>
</tr>
</tbody>
</table>

---

### Note

If you specified an NTP server for the FMC during initial configuration, the connection with that NTP server is not secured. You must edit the configuration for that connection to specify MD5 or SHA-1 keys.
Unintended consequences can occur when time is not synchronized between the FMC and managed devices.

To synchronize time on FMC and managed devices, see:

- **Recommended**: Synchronize Time on the FMC with an NTP Server, on page 131
  This topic provides instructions for configuring your FMC to synchronize with an NTP server or servers and includes links to instructions on configuring managed devices to synchronize with the same NTP server or servers.
- **Otherwise**: Synchronize Time Without Access to a Network NTP Server, on page 131
  This topic provides instructions for setting the time on your FMC, configuring your FMC to serve as an NTP server, and links to instructions on configuring managed devices to synchronize with the FMC NTP server.

**Synchronize Time on the FMC with an NTP Server**

Time synchronization among all of the components of your system is critically important.

The best way to ensure proper time synchronization between Firepower Management Center and all managed devices is to use an NTP server on your network.

The FMC supports NTPv4.

You must have Admin or Network Admin privileges to do this procedure.

**Before you begin**

Note the following:

- If your FMC and managed devices cannot access a network NTP server, do not use this procedure. Instead, see Synchronize Time Without Access to a Network NTP Server, on page 131.

- Do not specify an untrusted NTP server.

- If you plan to establish a secure connection with an NTP server (recommended for system security), obtain an SHA-1 or MD5 key number and value configured on that NTP server.

- Connections to NTP servers do not use configured proxy settings.

- Firepower 4100 Series devices and Firepower 9300 devices cannot use this procedure to set the system time. Instead, configure those devices to use the same NTP server(s) that you configure using this procedure. For instructions, see the documentation for your hardware model.

**Caution**

If the Firepower Management Center is rebooted and your DHCP server sets an NTP server record different than the one you specify here, the DHCP-provided NTP server will be used instead. To avoid this situation, configure your DHCP server to use the same NTP server.
**Procedure**

**Step 1** Choose **System > Configuration**.

**Step 2** Click **Time Synchronization**.

**Step 3** If **Serve Time via NTP** is **Enabled**, choose **Disabled** to disable the FMC as an NTP server.

**Step 4** For the **Set My Clock** option, choose **Via NTP**.

**Step 5** Click **Add**.

**Step 6** In the **Add NTP Server** dialog box, enter the host name or IPv4 or IPv6 address of an NTP server.

**Step 7** (Optional) To secure communication between your FMC and the NTP server:
   - Select **MD5** or **SHA-1** from the **Key Type** drop-down list.
   - Enter the corresponding MD5 or SHA-1 **Key Number** and **Key Value** from the specified NTP server.

**Step 8** Click **Add**.

**Step 9** To add more NTP servers, repeat Steps 5 through 8.

**Step 10** (Optional) To force the FMC to use only an NTP server that successfully authenticates, check the **Use the authenticated NTP server only** check box.

**Step 11** Click **Save**.

---

**What to do next**

Set managed devices to synchronize with the same NTP server or servers:

- Configure device platform settings: Configure NTP Time Synchronization for Threat Defense, on page 1386 and Synchronize Time on Classic Devices with an NTP Server, on page 1341.

  Note that even if you force the FMC to make a secure connection with an NTP server (Use the authenticated NTP server only), device connections to that server do not use authentication.

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

**Synchronize Time Without Access to a Network NTP Server**

If your devices cannot directly reach the network NTP server, or your organization does not have a network NTP server, a physical-hardware Firepower Management Center can serve as an NTP server.

---

**Important**

- Do not use this procedure unless you have no other NTP server. Instead, use the procedure in Synchronize Time on the FMC with an NTP Server, on page 1311.

- Do not use a virtual Firepower Management Center as an NTP server.

To change the time manually after configuring the Firepower Management Center as an NTP server, you must disable the NTP option, change the time manually, and then re-enable the NTP option.
Procedure

Step 1  Manually set the system time on the Firepower Management Center:
   a) Choose System > Configuration.
   b) Click Time Synchronization.
   c) If Serve Time via NTP is Enabled, choose Disabled.
   d) Click Save.
   e) For Set My Clock, choose Manually in Local Configuration.
   f) Click Save.
   g) In the navigation panel at the left side of the screen, click Time.
   h) Use the Set Time drop-down lists to set the time.
   i) If the time zone displayed is not UTC, click it and set the time zone to UTC.
   j) Click Save.
   k) Click Done.
   l) Click Apply.

Step 2  Set the Firepower Management Center to serve as an NTP server:
   a) In the navigation panel at the left side of the screen, click Time Synchronization.
   b) For Serve Time via NTP, choose Enabled.
   c) Click Save.

Step 3  Set managed devices to synchronize with the Firepower Management Center NTP server:
   a) In the Time Synchronization settings for the platform settings policy assigned to your managed devices,
      set the clock to synchronize Via NTP from Management Center.
   b) Deploy the change to managed devices.

For instructions:

- For Firepower Threat Defense devices, see Configure NTP Time Synchronization for Threat Defense, on page 1386.
- For all other devices, see Synchronize Time on Classic Devices with an NTP Server, on page 1341.

About Changing Time Synchronization Settings

- Your Firepower Management Center and its managed devices are heavily dependent on accurate time. The system clock is a system facility that maintains the time of the Firepower System. The system clock is set to Universal Coordinated Time (UTC), which is the primary time standard by which the world regulates clocks and time.

  DO NOT ATTEMPT TO CHANGE THE SYSTEM TIME. Changing the system time zone from UTC is NOT supported, and doing so will require you to reimage the device to recover from an unsupported state.

- If you configure the FMC to serve time using NTP, and then later disable it, the NTP service on managed devices still attempts to synchronize time with the FMC. You must update and redeploy any applicable platform settings policies to establish a new time source.
To change the time manually after configuring the Firepower Management Center as an NTP server, you must disable the NTP option, change the time manually, and then re-enable the NTP option.

View Current System Time, Source, and NTP Server Connection Status

Time settings are displayed on most pages in local time using the time zone you set on the Time Zone page in User Preferences (the default is America/New York), but are stored on the appliance using UTC time.

Restriction

The Time Zone function (in User Preferences) assumes that the default system clock is set to UTC time. DO NOT ATTEMPT TO CHANGE THE SYSTEM TIME. Be advised that changing the system time from UTC is NOT supported, and doing so will require you to reimage the device to recover from an unsupported state.

Procedure

Step 1 Choose System > Configuration.
Step 2 Click Time.

The current time is displayed using the time zone specified for your account in User Preferences.

If your appliance uses an NTP server: For information about the table entries, see NTP Server Status, on page 1314.

NTP Server Status

If you are synchronizing time from an NTP server, you can view connection status on the Time page (choose System > Configuration).

Table 90: NTP Status

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NTP Server</td>
<td>The IP address or name of the configured NTP server.</td>
</tr>
<tr>
<td>Status</td>
<td>The status of the NTP server time synchronization:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Being Used</strong> indicates that the appliance is synchronized with the NTP server.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Available</strong> indicates that the NTP server is available for use, but time is not yet synchronized.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Not Available</strong> indicates that the NTP server is in your configuration, but the NTP daemon is unable to use it.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Pending</strong> indicates that the NTP server is new or the NTP daemon was recently restarted. Over time, its value should change to <strong>Being Used</strong>, <strong>Available</strong>, or <strong>Not Available</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Unknown</strong> indicates that the status of the NTP server is unknown.</td>
</tr>
</tbody>
</table>
Global User Configuration Settings

Global User Configuration settings affect all users on the Firepower Management Center. Configure these settings on the User Configuration page (System > Configuration > User Configuration):

- **Password Reuse Limit**: The number of passwords in a user’s most recent history that cannot be reused. This limit applies to web interface access for all users. For the admin user, this applies to CLI access as well; the system maintains separate password lists for each form of access. Setting the limit to zero (the default) places no restrictions on password reuse. See Set Password Reuse Limit, on page 1316.

- **Track Successful Logins**: The number of days that the system tracks successful logins to the Firepower Management Center, per user, per access method (web interface or CLI). When users log in, the system displays their successful login count for the interface being used. When Track Successful Logins is set to zero (the default), the system does not track or report successful login activity. See Track Successful Logins, on page 1317.

- **Max Number of Login Failures**: The number of times in a row that users can enter incorrect web interface login credentials before the system temporarily blocks the account from access for a configurable time period. If a user continues login attempts while the temporary lockout is in force:
  - The system refuses access for that account (even with a valid password) without informing the user that a temporary lockout is in force.
  - The system continues to increment the failed login count for that account with each login attempt.
  - If the user exceeds the Maximum Number of Failed Logins configured for that account on the individual User Configuration page, the account is locked out until an admin user reactivates it.

- **Set Time in Minutes to Temporarily Lockout Users**: The duration in minutes for a temporary web interface user lockout if Max Number of Failed Logins is non-zero.
**Max Concurrent Sessions Allowed:** The number of sessions of a particular type (read-only or read/write) that can be open at the same time. The type of session is determined by the roles assigned to a user. If a user is assigned only read-only roles, that user's session is counted toward the **Read Only** session limit. If a user has any roles with write privileges, the session is counted toward the **Read/Write** session limit. For example, if a user is assigned the Admin role and the **Maximum sessions for users with Read/Write privileges/CLI users** is set to 5, the user will not be allowed to log in if there are already five other users logged in that have read/write privileges.

**Note**
Predefined user roles and custom user roles that the system considers read-only for the purposes of concurrent session limits, are labeled with (Read Only) in the role name on the System > Users > Users and the System > Users > User Roles. If a user role does not contain (Read Only) in the role name, the system considers the role to be read/write. The system automatically applies (Read Only) to roles that meet the required criteria. You cannot make a role read-only by adding that text string manually to the role name.

For each type of session, you can set a maximum limit ranging from 1 to 1024. When **Max Concurrent Sessions Allowed** is set to zero (the default), the number of concurrent sessions is unlimited.

If you change the concurrent session limit to a value more restrictive, the system will not close any currently open sessions; it will, however, prevent new sessions beyond the number specified from being opened.

### Set Password Reuse Limit

If you enable the **Password Reuse Limit**, the system keeps encrypted **password histories** for FMC users. Users cannot reuse passwords in their histories. You can specify the number of stored passwords for each user, per access method (web interface or CLI). A user's current password counts towards this number. If you lower the limit, the system deletes older passwords from the history. Increasing the limit does not restore deleted passwords.

**Procedure**

1. Choose System > Configuration.
2. Click User Configuration.
3. Set the **Password Reuse Limit** to the number of passwords you want to maintain in the history (maximum 256).
   - To disable password reuse checking, enter 0.
4. Click Save.
Track Successful Logins

Use this procedure to enable tracking successful logins for each user for a specified number of days. When this tracking is enabled, the system displays the successful login count when users log into the web interface or the CLI.

**Note**

If you lower the number of days, the system deletes records of older logins. If you then increase the limit, the system does not restore the count from those days. In that case, the reported number of successful logins may be temporarily lower than the actual number.

**Procedure**

**Step 1** Choose **System > Configuration**.

**Step 2** Click **User Configuration**.

**Step 3** Set **Track Successful Login Days** to the number of days to track successful logins (maximum 365).

To disable login tracking, enter 0.

**Step 4** Click **Save**.

Enabling Temporary Lockouts

Enable the temporary timed lockout feature by specifying the number of failed login attempts in a row that the system allows before the lockout goes into effect.

**Procedure**

**Step 1** Choose **System > Configuration**.

**Step 2** Click **User Configuration**.

**Step 3** Set the **Max Number of Login Failures** to the maximum number of consecutive failed login attempts before the user is temporarily locked out.

To disable the temporary lockout, enter zero.

**Step 4** Set the **Time in Minutes to Temporarily Lockout Users** to the number of minutes to lock out users who have triggered a temporary lockout.

When this value is zero, users do not have to wait to retry to log in, even if the **Max Number of Login Failures** is non-zero.

**Step 5** Click **Save**.
Set Maximum Number of Concurrent Sessions

You can specify the maximum number of sessions of a particular type (read-only or read/write) that can be open at the same time. The type of session is determined by the roles assigned to a user. If a user is assigned only read-only roles, that user’s session is counted toward the Read Only session limit. If a user has any roles with write privileges, the session is counted toward the Read/Write session limit.

**Procedure**

**Step 1** Choose System > Configuration.
**Step 2** Click User Configuration.
**Step 3** For each type of session (Read Only and Read/Write), set the Max Concurrent Sessions Allowed to the maximum number of sessions of that type that can be open at the same time.

To apply no limits on concurrent users by session type, enter zero.

**Note** If you change the concurrent session limit to a value more restrictive, the system will not close any currently open sessions; it will, however, prevent new sessions beyond the number specified from being opened.

**Step 4** Click Save.

Session Timeouts

Unattended login sessions may be security risks. You can configure the amount of idle time before a user’s login session times out due to inactivity.

Note that you can exempt specific web interface users from timeout, for scenarios where you plan to passively, securely monitor the system for long periods of time. Users with the Administrator role, whose complete access to menu options poses an extra risk if compromised, cannot be made exempt from session timeouts.

Configure Session Timeouts

To configure session timeouts for Classic devices, use device platform settings. See Configure Session Timeouts for Classic Devices, on page 1342.

**Procedure**

**Step 1** Choose System > Configuration.
**Step 2** Click CLI Timeout.
**Step 3** Configure session timeouts:

- Web interface (FMC only): Configure the Browser Session Timeout (Minutes). The default value is 60; the maximum value is 1440 (24 hours).

To exempt users from this session timeout, see Add an Internal User at the Web Interface.
Step 4  Click Save.

Vulnerability Mapping

The Firepower System automatically maps vulnerabilities to a host IP address for any application protocol traffic received or sent from that address, when the server has an application ID in the discovery event database and the packet header for the traffic includes a vendor and version.

For any servers which do not include vendor or version information in their packets, you can configure whether the system associates vulnerabilities with server traffic for these vendor and versionless servers.

For example, a host serves SMTP traffic that does not have a vendor or version in the header. If you enable the SMTP server on the Vulnerability Mapping page of a system configuration, then save that configuration to the Firepower Management Center managing the device that detects the traffic, all vulnerabilities associated with SMTP servers are added to the host profile for the host.

Although detectors collect server information and add it to host profiles, the application protocol detectors will not be used for vulnerability mapping, because you cannot specify a vendor or version for a custom application protocol detector and cannot select the server for vulnerability mapping.

Mapping Vulnerabilities for Servers

This procedure requires any Smart License or the Protection classic license.

Procedure

Step 1  Choose System > Configuration.
Step 2  Choose Vulnerability Mapping.
Step 3  You have the following choices:
  • To prevent vulnerabilities for a server from being mapped to hosts that receive application protocol traffic without vendor or version information, clear the check box for that server.
  • To cause vulnerabilities for a server to be mapped to hosts that receive application protocol traffic without vendor or version information, check the check box for that server.

Tip  You can check or clear all check boxes at once using the check box next to Enabled.

Step 4  Click Save.
Remote Console Access Management

You can use a Linux system console for remote access on supported systems via either the VGA port (which is the default) or the serial port on the physical appliance. Use the Console Configuration page to choose the option most suitable to the physical layout of your organization’s Firepower deployment.

On supported physical-hardware-based Firepower systems, you can use Lights-Out Management (LOM) on a Serial Over LAN (SOL) connection to remotely monitor or manage the system without logging into the management interface of the system. You can perform limited tasks, such as viewing the chassis serial number or monitoring such conditions as fan speed and temperature, using a command line interface on an out-of-band management connection. The cable connection to support LOM varies by FMC model:

- For FMC models MC1600, MC2600, and MC4600, use a connection with the CIMC port to support LOM. See the Cisco Firepower Management Center 1600, 2600, and 4600 Getting Started Guide for more information.
- For all other FMC hardware models, use a connection with the default (eth0) management port to support LOM. See the Cisco Firepower Management Center Getting Started Guide for your hardware model.

You must enable LOM for both the system and the user you want to manage the system. After you enable the system and the user, you use a third-party Intelligent Platform Management Interface (IPMI) utility to access and manage your system.

Configuring Remote Console Settings on the System

You must be an Admin user to perform this procedure.

Before you begin

- Disable Spanning Tree Protocol (STP) on any third-party switching equipment connected to the device’s management interface.
- If you plan to enable Lights-Out Management see the Getting Started Guide for your appliance for information about installing and using an Intelligent Platform Management Interface (IPMI) utility.

Procedure

Step 1 Choose System > Configuration.
Step 2 Click Console Configuration.
Step 3 Choose a remote console access option:
  - Choose VGA to use the appliance's VGA port.
  - Choose Physical Serial Port to use the appliance's serial port.
  - Choose Lights-Out Management to use an SOL connection on the FMC. (This may use the default management port or the CIMC port depending on your FMC model. See the Getting Started Guide for your model for more information.)

Step 4 To configure LOM via SOL:
• Choose the address **Configuration** for the system (DHCP or Manual).

• If you chose manual configuration, enter the necessary IPv4 settings:
  
  • Enter the **IP Address** to be used for LOM.
  
  **Note** The LOM IP address must be different from and in the same subnet as the FMC management interface IP address.

  • Enter the **Netmask** for the system.

  • Enter the **Default Gateway** for the system.

**Step 5**  
Click **Save**.

**Step 6**  
The system displays the following warning: "You will have to reboot your system for these changes to take effect." Click **OK** to reboot now or **Cancel** to reboot later.

---

**What to do next**

• If you configured serial access, be sure the rear-panel serial port is connected to a local computer, terminal server, or other device that can support remote serial access over ethernet as described in the *Getting Started Guide* for your FMC model.

---

**Lights-Out Management User Access Configuration**

You must explicitly grant Lights-Out Management permissions to users who will use the feature. LOM users also have the following restrictions:

• You must assign the Administrator role to the user.

• The username may have up to 16 alphanumeric characters. Hyphens and longer user names are not supported for LOM users.

• A user’s LOM password is the same as that user’s system password. The password must comply with the requirements described in *User Passwords*, on page 50. Cisco recommends that you use a complex, non-dictionary-based password of the maximum supported length for your appliance and change it every three months.

• Physical Firepower Management Centers can have up to 13 LOM users.

Note that if you deactivate, then reactivate, a user with LOM while a that user is logged in, or restore a user from a backup during that user’s login session, that user may need to log back into the web interface to regain access to **impitool** commands.

**Enabling Lights-Out Management User Access**

You must be an Admin user to perform this procedure.
Use this task to grant LOM access to an existing user. To grant LOM access to a new user, see Add an Internal User, on page 53.

**Procedure**

**Step 1** Choose System > Users > Users.

**Step 2** To grant LOM user access to an existing user, click Edit (✓) next to a user name in the list.

**Step 3** Under User Configuration, enable the Administrator role.

**Step 4** Check the Allow Lights-Out Management Access check box.

**Step 5** Click Save.

**Serial Over LAN Connection Configuration**

You use a third-party IPMI utility on your computer to create a Serial Over LAN connection to the appliance. If your computer uses a Linux-like or Mac environment, use IPMItool; for Windows environments, you can use IPMIutil or IPMItool, depending on your Windows version.

---

**Note** Cisco recommends using IPMItool version 1.8.12 or greater.

**Linux**

IPMItool is standard with many distributions and is ready to use.

**Mac**

You must install IPMItool on a Mac. First, confirm that your Mac has Apple's XCode Developer tools installed, making sure that the optional components for command line development are installed (UNIX Development and System Tools in newer versions, or Command Line Support in older versions). Then you can install macports and the IPMItool. Use your favorite search engine for more information or try these sites:

http://www.macports.org/
http://github.com/ipmitool/ipmitool/

**Windows**

For Windows Versions 10 and greater with Windows Subsystem for Linux (WSL) enabled, as well as some older versions of Windows Server, you can use IPMItool. Otherwise, you must compile IPMIutil on your Windows system; you can use IPMIutil itself to compile. Use your favorite search engine for more information or try this site:

http://ipmiutil.sourceforge.net/man.html#ipmiutil
Understanding IPMI Utility Commands

Commands used for IPMI utilities are composed of segments as in the following example for IPMItool on Mac:

```
    ipmitool -I lanplus -H IP_address -U user_name command
```

where:

- `ipmitool` invokes the utility.
- `-I lanplus` specifies to use an encrypted IPMI v2.0 RMCP+ LAN Interface for the session.
- `-H IP_address` indicates the IP address you have configured for Lights-Out Management on the appliance you want to access.
- `-U user_name` is the name of an authorized remote session user.
- `command` is the name of the command you want to use.

Note: Cisco recommends using IPMItool version 1.8.12 or greater.

The same command for IPMIutil on Windows looks like this:

```
    ipmiutil command -V 4 -J 3 -N IP_address -U user_name
```

This command connects you to the command line on the appliance where you can log in as if you were physically present at the appliance. You may be prompted to enter a password.

Configuring Serial Over LAN with IPMItool

You must be an Admin user with LOM access to perform this procedure.

Procedure

Using IPMItool, enter the following command, and a password if prompted:

```
    ipmitool -I lanplus -H IP_address -U user_name sol activate
```

Configuring Serial Over LAN with IPMIutil

You must be an Admin user with LOM access to perform this procedure.

Procedure

Using IPMIutil, enter the following command, and a password if prompted:
Lights-Out Management Overview

Lights-Out Management (LOM) provides the ability to perform a limited set of actions over an SOL connection on the default (eth0) management interface without the need to log into the system. You use the command to create a SOL connection followed by one of the LOM commands. After the command is completed, the connection ends.

⚠️ **Caution**

In rare cases, if your computer is on a different subnet than the system's management interface and the system is configured for DHCP, attempting to access LOM features can fail. If this occurs, you can either disable and then re-enable LOM on the system, or use a computer on the same subnet as the system to ping its management interface. You should then be able to use LOM.

⚠️ **Caution**

Cisco is aware of a vulnerability inherent in the Intelligent Platform Management Interface (IPMI) standard (CVE-2013-4786). Enabling Lights-Out Management (LOM) on an system exposes this vulnerability. To mitigate this vulnerability, deploy your systems on a secure management network accessible only to trusted users and use a complex, non-dictionary-based password of the maximum supported length for your system and change it every three months. To prevent exposure to this vulnerability, do not enable LOM.

If all attempts to access your system have failed, you can use LOM to restart your system remotely. Note that if a system is restarted while the SOL connection is active, the LOM session may disconnect or time out.

⚠️ **Caution**

Do not restart your system unless it does not respond to any other attempts to restart. Remotely restarting does not gracefully reboot the system and you may lose data.

<table>
<thead>
<tr>
<th>IPMItool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(not applicable)</td>
<td>Enables admin privileges for the IPMI session</td>

</table>

For example, to display a list of appliance information, the IPMItool command is:

```
ipmitool -I lanplus -H IP_address -U user_name sdr
```

**Note**
Cisco recommends using IPMItool version 1.8.12 or greater.

The same command with the IPMIutil utility is:

```
ipmiutil sensor -V 4 -J 3 -N IP_address -U username
```

### Configuring Lights-Out Management with IPMItool

You must be an Admin user with LOM access to perform this procedure.

**Procedure**

Enter the following command for IPMItool and a password if prompted:

```
ipmitool -I lanplus -H IP_address -U user_name command
```

### Configuring Lights-Out Management with IPMIutil

You must be an Admin user with LOM access to perform this procedure.

**Procedure**

Enter the following command for IPMIutil and a password if prompted:

```
ipmiutil -J 3 -N IP_address -U username command
```
REST API Preferences

The Firepower REST API provides a lightweight interface for third-party applications to view and manage appliance configuration using a REST client and standard HTTP methods. For more information on the Firepower REST API, see the Firepower REST API Quick Start Guide.

By default, the Firepower Management Center allows requests from applications using the REST API. You can configure the Firepower Management Center to block this access.

Enabling REST API Access

Note
In deployments using Firepower Management Center high availability, this feature is available only in the active Firepower Management Center.

Procedure

Step 1
Choose the Cog (Cog) in the upper right corner to open the system menu.

Step 2
Click REST API Preferences.

Step 3
To enable or disable REST API access to the Firepower Management Center, check or uncheck the Enable REST API check box.

Step 4
Click Save.

Step 5
Access the REST API Explorer at:
https://<management_center_IP_or_name>:<https_port>/api/api-explorer

VMware Tools and Virtual Systems

VMware Tools is a suite of performance-enhancing utilities intended for virtual machines. These utilities allow you to make full use of the convenient features of VMware products. Firepower virtual appliances running on VMware support the following plugins:

- guestInfo
- powerOps
- timeSync
- vmbackup

You can also enable VMware Tools on all supported versions of ESXi. For a list of supported versions, see the Cisco Firepower NGIPSv Quick Start Guide for VMware. For information on the full functionality of VMware Tools, see the VMware website (http://www.vmware.com/).
Enabling VMware Tools on the Firepower Management Center for VMware

Because NGIPSv does not have a web interface, you must use the CLI to enable VMware Tools on that platform; see the Cisco Firepower NGIPSv Quick Start Guide for VMware.

**Procedure**

**Step 1** Choose System > Configuration.
**Step 2** Click VMware Tools.
**Step 3** Click Enable VMware Tools.
**Step 4** Click Save.

(Optional) Opt Out of Web Analytics Tracking

By default, in order to improve Firepower products, Cisco collects non-personally-identifiable usage data, including but not limited to page interactions, browser versions, product versions, user location, and management IP addresses or hostnames of your Firepower Management Center appliances.

Data collection begins after you accept the End User License Agreement. If you do not want Cisco to continue to collect this data, you can opt out using the following procedure.

**Procedure**

**Step 1** Choose System > Configuration.
**Step 2** Click Web Analytics.
**Step 3** Make your choice and click Save.

What to do next

(Optional) Determine whether to share data via the Cisco Success Network, on page 206.
## History for System Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Version</th>
<th>Details</th>
</tr>
</thead>
</table>
| Subject Alternative Name (SAN) | 6.6     | When creating an HTTPS certificate for the FMC, you can specify SAN fields. We recommend you use SAN if the certificate secures multiple domain names or IP addresses. For more information about SAN, see RFC 5280, section 4.2.1.6. New/modified screens:  
  System > Configuration > HTTPS Certificate  
  Supported platforms: FMC |
| HTTPS Certificates            | 6.6     | The default HTTPS server certificate provided with the system now expires in 800 days. If your appliance uses a default certificate that was generated before you upgraded to Version 6.6, the certificate lifetime varies depending on the Firepower version being used when the certificate was generated. See Default HTTPS Server Certificates, on page 1271 for more information. New/modified screens: None.  
  Supported platforms: Hardware FMCs. |
| Secure NTP                    | 6.5     | The FMC supports secure communications with NTP servers using SHA1 or MD5 symmetric key authentication. New/modified screens:  
  System > Configuration > Time Synchronization  
  Supported platforms: FMC |
| Web analytics                 | 6.5     | Web analytics data collection begins after you accept the EULA. As previously, you can opt not to continue to share data. See (Optional) Opt Out of Web Analytics Tracking, on page 1327. |
| Automatic CLI access for the FMC | 6.5     | When you use SSH to log into the FMC, you automatically access the CLI. Although strongly discouraged, you can then use the CLI `expert` command to access the Linux shell.  
  **Note** This feature deprecates the Version 6.3 ability to enable and disable CLI access for the FMC. As a consequence of deprecating this option, the virtual FMC no longer displays the System > Configuration > Console Configuration page, which still appears on physical FMCs. |
<table>
<thead>
<tr>
<th>Feature</th>
<th>Version</th>
<th>Details</th>
</tr>
</thead>
</table>
| Configurable session limits for read-only and read/write access       | 6.5     | Added the **Max Concurrent Sessions Allowed** setting. This setting allows the administrator to specify the maximum number of sessions of a particular type (read-only or read/write) that can be open at the same time.  
**Note** Predefined user roles and custom user roles that the system considers read-only for the purposes of concurrent session limits, are labeled with *(Read Only)* in the role name on the **System > Users > Users** and the **System > Users > User Roles**. If a user role does not contain *(Read Only)* in the role name, the system considers the role to be read/write.  
New/modified screens:  
**System > Configuration > User Configuration**  
**System > Users > User Roles**  
Supported Platforms: FMC                                                                 |
| Ability to disable Duplicate Address Detection (DAD) on management interfaces | 6.4     | When you enable IPv6, you can disable DAD. You might want to disable DAD because the use of DAD opens up the possibility of denial of service attacks. If you disable this setting, you need check manually that this interface is not using an already-assigned address.  
New/modified screens:  
**System > Configuration > Management Interfaces > Interfaces > Edit Interface** dialog box > IPv6 DAD check box  
Supported Platforms: FMC                                                                 |
| Ability to disable ICMPv6 Echo Reply and Destination Unreachable messages on management interfaces | 6.4     | When you enable IPv6, you can now disable ICMPv6 Echo Reply and Destination Unreachable messages. You might want to disable these packets to guard against potential denial of service attacks. Disabling Echo Reply packets means you cannot use IPv6 ping to the device management interfaces for testing purposes.  
New/modified screens:  
**System > Configuration > Management Interfaces > ICMPv6**  
New/modified commands: `configure network ipv6 destination-unreachable`, `configure network ipv6 echo-reply`  
Supported Platforms: FMC (web interface only), FTD (CLI only), ASA FirePOWER module (CLI only), NGIPSv (CLI only) |
<table>
<thead>
<tr>
<th>Feature</th>
<th>Version</th>
<th>Details</th>
</tr>
</thead>
</table>
| Global User Configuration Settings               | 6.3     | Added the **Track Successful Logins** setting. The system can track the number of successful logins each FMC account has performed within a selected number of days. When this feature is enabled, on log in users see a message reporting how many times they have successfully logged in to the system in the past configured number of days. (Applies to web interface as well as shell/CLI access.)  
Added the **Password Reuse Limit** setting. The system can track the password history for each account for a configurable number of previous passwords. The system prevents all users from re-using passwords that appear in that history. (Applies to web interface as well as shell/CLI access.)  
Added the **Max Number of Login Failures** and **Set Time in Minutes to Temporarily Lockout Users** settings. These allow the administrator to limit the number of times in a row a user can enter incorrect web interface login credentials before the system temporarily blocks the account for a configurable period of time.  
New screen: **System > Configuration > User Configuration**  
Supported Platforms: FMC                                                                                                                                                                                                                                                                  |
| HTTPS Certificates                                | 6.3     | The default HTTPS server certificate provided with the system now expires in three years. If your appliance uses a default server certificate that was generated before you upgraded to Version 6.3, the server certificate will expire 20 years from when it was first generated. If you are using the default HTTPS server certificate the system now provides the ability to renew it.  
New/modified screens:  
**System > Configuration > HTTPS Certificate** page > **Renew HTTPS Certificate**.  
Supported platforms: FMC                                                                                                                                                                                                                                                                  |
| Ability to enable and disable CLI access for the FMC | 6.3     | New/Modified screens:  
New check box available to administrators in FMC web interface: **Enable CLI Access** on the **System > Configuration > Console Configuration** page.  
- Checked: Logging into the FMC using SSH accesses the CLI.  
  - Unchecked: Logging into FMC using SSH accesses the Linux shell. This is the default state for fresh Version 6.3 installations as well as upgrades to Version 6.3 from a previous release.  
Previous to Version 6.3, there was only one setting on the **Console Configuration** page, and it applied to physical devices only. So the **Console Configuration** page was not available on virtual FMCs. With the addition of this new option, the **Console Configuration** page now appears on virtual FMCs as well as physical. However, for virtual FMCs, this check box is the only thing that appears on the page.  
Supported platforms: FMC                                                                                                                                                                                                                                                                  |
Platform Settings Policies

The following topics explain platform settings policies and how to deploy them to managed devices:

- Introduction to Platform Settings, on page 1331
- Requirements and Prerequisites for Platform Settings Policies, on page 1332
- Managing Platform Settings Policies, on page 1332
- Create a Platform Settings Policy, on page 1333
- Setting Target Devices for a Platform Settings Policy, on page 1333

Introduction to Platform Settings

A platform settings policy is a shared set of features or parameters that define the aspects of a managed device that are likely to be similar to other managed devices in your deployment, such as time settings and external authentication.

A shared policy makes it possible to configure multiple managed devices at once, which provides consistency in your deployment and streamlines your management efforts. Any changes to a platform settings policy affects all the managed devices where you applied the policy. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

For example, your organization’s security policies may require that your appliances have a “No Unauthorized Use” message when a user logs in. With platform settings, you can set the login banner once in a platform settings policy.

You can also benefit from having multiple platform settings policies on a Firepower Management Center. For example, if you have different mail relay hosts that you use under different circumstances or if you want to test different access lists, you can create several platform settings policies and switch between them, rather than editing a single policy.

Related Topics

- Configure Platform Settings for Classic Devices, on page 1336

Requirements and Prerequisites for Platform Settings Policies

Model Support

Any, but you must create the correct type of policy for the target devices:

- **Firepower Settings** to create a shared policy for Classic managed devices: ASA FirePOWER, NGIPSv.
- **Threat Defense Settings** to create a shared policy for Firepower Threat Defense managed devices.

Supported Domains

Any

User Roles

Admin
Access Admin
Network Admin

Managing Platform Settings Policies

Use the Platform Settings page (**Devices > Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The Status column shows the device targets for the policy.

**Procedure**

**Step 1** Choose **Devices > Platform Settings**.

**Step 2** Manage your platform settings policies:

- **Create** — To create a new platform settings policy, click **New Policy**; see Create a Platform Settings Policy, on page 1333.

- **Copy** — To copy a platform settings policy, click **Copy**.

- **Edit** — To modify the settings in an existing platform settings policy, click **Edit**.

- **Delete** — To delete a policy that is not in use, click **Delete**, then confirm your choice.

**Caution** You should not delete a policy that is the last deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.
Create a Platform Settings Policy

Platform settings for Firepower Threat Defense devices differ from platform settings for Classic devices. When you create a new platform settings policy you must choose a type: Firepower (for Classic managed devices) or Threat Defense (for FTD devices).

Procedure

Step 1 Choose Devices > Platform Settings.
Step 2 Click New Policy.
Step 3 Choose a device type from the drop-down list:
   - Firepower Settings to create a shared policy for Classic managed devices.
   - Threat Defense Settings to create a shared policy for Firepower Threat Defense managed devices.
Step 4 Enter a Name for the new policy and optionally, a Description.
Step 5 Optionally, choose the Available Devices where you want to apply the policy and click Add to Policy (or drag and drop) to add the selected devices. You can enter a search string in the Search field to narrow the list of devices.
Step 6 Click Save.
The system creates the policy and opens it for editing.
Step 7 Configure the platform settings based on the device platform type:
   - For Firepower Settings, see Platform Settings for Classic Devices, on page 1335.
   - For Threat Defense Settings, see Platform Settings for Firepower Threat Defense, on page 1345.
Step 8 Click Save.

What to do next
Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Setting Target Devices for a Platform Settings Policy

You can add targeted devices at the same time you create a new policy, or you can change them later.

Procedure

Step 1 Choose Devices > Platform Settings.
Step 2 Click Edit (✓) next to the platform settings policy that you want to edit.

What to do next
Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Setting Target Devices for a Platform Settings Policy

Step 3  Click **Policy Assignment**.

Step 4  Do any of the following:

- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add to Policy**. You can also drag and drop.

- To remove a device assignment, click **Delete** (🗑️) next to a device, high-availability pair, or device group in the **Selected Devices** list.

Step 5  Click **OK**.

What to do next

- Deploy configuration changes; see **Deploy Configuration Changes**, on page 495.
Platform Settings for Classic Devices

The following topics explain Firepower platform settings and how to configure them on Classic devices:

- About Platform Settings for Classic Devices, on page 1335
- Requirements for Platform Settings for Classic Devices, on page 1336
- Configure Platform Settings for Classic Devices, on page 1336

About Platform Settings for Classic Devices

*Platform settings* for managed devices are policy-based so that you can apply the same configuration to multiple devices. Use a *Firepower* platform settings policy with Classic devices:

- ASA FirePOWER modules
- NGIPSv

Note that for the FMC, many of these settings are handled in the *system configuration*; see System Configuration, on page 1267.

### Table 92: Firepower Platform Settings for Classic Devices

<table>

### Requirements for Platform Settings for Classic Devices

**License Requirements**
None.

**Model Requirements**
You can apply a Firepower platform settings policy to any Classic device.

**Domain Requirements**
None.
You can apply a Firepower platform setting policy at any Domain level.

### Configure Platform Settings for Classic Devices

Platform settings for managed devices are policy-based so that you can apply the same configuration to multiple devices. Use a Firepower platform settings policy with Classic devices.

**Procedure**

#### Step 1
Choose **Devices > Platform Settings** and create or edit a Firepower policy.

See About Platform Settings for Classic Devices, on page 1335 and Create a Platform Settings Policy, on page 1333.

#### Step 2
Choose the **Available Devices** where you want to deploy the policy by clicking **Policy Assignment**.

#### Step 3
Click **Add to Policy** (or drag and drop) to add the selected devices.
Configure Access Lists for Classic Devices

By default, access to Firepower devices is not restricted. Port 22 (SSH) is open for CLI access. To operate in a more secure environment, consider adding access for specific IP addresses. You can also add access to poll for SNMP information over port 161.

Procedure

Step 1 Choose Devices > Platform Settings and create or edit a Firepower policy.
Step 2 Click Access List.
Step 3 To add access for one or more IP addresses, click Add Rules.
Step 4 In the IP Address field, enter an IP address or address range, or any.
Step 5 Choose SSH, HTTPS, SNMP, or a combination of these options to specify which ports you want to enable for these IP addresses.
Step 6 Click Add.
Step 7 Click Save.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Stream Audit Logs from Classic Devices

Firepower appliances generate records (or audit logs) of user interactions. You can stream these audit logs to a syslog or HTTP server. Note that sending audit information to an external URL may affect system performance.

Optionally, you can use Transport Layer Security (TLS) certificates to secure communications between Firepower devices and a trusted audit log server. For each device (client certificates are unique), you must generate a certificate signing request (CSR), submit it to a Certificate Authority (CA) for signing, then import the signed certificate onto the device. You cannot use the FMC to import audit log certificates onto its managed devices. These certificates are unique to each device, and you must log into each device to import them.

To ensure security, use a globally recognized and trusted CA. The same CA must sign:

- Both the client certificate and the server certificate, if you plan to require mutual authentication between the device and the audit log server.
- Any intermediate certificates in the certificate chain. If the signing CA requires you to trust an intermediate CA, you must provide the necessary certificate chain (or certificate path).
Audit logs have the following format:

```
timestamp host [tag] appliance_name: username@ip_address, subsystem, action
```

For example:

```
Mar 01 14:45:24 localhost [FIREPOWER] MyFirepowerAppliance: admin@10.1.1.2, System > Configuration, Page View
```

Note that the tag is optional and user-configurable. Syslog events also have an optional facility and severity.

**Before you begin**

Make sure your devices can communicate with the server or servers where you plan to stream audit logs. For syslog streaming, the system uses port 7/UDP to verify that the syslog server is reachable when you save the configuration. Then, the system uses port 514/UDP to stream audit logs. If you secure the channel, the system uses 6514/TCP.

**Procedure**

**Step 1**  
(Optional) Set up secure communications with the audit log server.  
For ASA FirePOWER and NGIPSv, you can generate a CSR with a tool like OpenSSL, then use the CLI to import the signed certificate: `configure audit_cert import`.  
To verify that the certificate imported correctly, use `show audit_cert`.

**Step 2**  
On the FMC, choose Devices > Platform Settings and create or edit a Firepower policy.

**Step 3**  
Click Audit Log to configure audit log streaming.

Syslog streaming:

- a) Set Send Audit Log to Syslog to Enabled.
- b) Provide Host information for the syslog server: IP address or fully qualified name.
- c) Choose a Facility (Syslog Alert Facilities, on page 2517) and Severity (Syslog Severity Levels, on page 2518).

**Attention**  
When you enable Send Audit Log to Syslog and provide Host information, syslog messages are also sent to the configured host in addition to the audit logs; see Filter Syslogs from Audit Logs, on page 1340.

HTTP streaming:

- a) Set Send Audit Log to HTTP Server to Enabled.
- b) Provide a URL to Post Audit where you want to send audit logs. HTTPS is supported.

  The URL must correspond to a Listener program that expects the following HTTP POST variables:
  `subsystem, actor, event_type, message, action_source_ip, action_destination_ip, result, time, tag (if provided)`.

**Step 4**  
(Optional) Enter a Tag in include in each message. For example, you might want to tag Firepower audit logs with FIREPOWER.

**Step 5**  
Click Save.  
If you configured syslog streaming, the system verifies that the syslog server is reachable.
What to do next

- (Optional) If you configured secure communications, we recommend you also require mutual authentication between the device and the audit log server: Require Valid Audit Log Server Certificates for Classic Devices, on page 1339.

- (Optional) If you enabled streaming the audit logs to a syslog server and want to filter the syslog messages from the audit logs: Filter Syslogs from Audit Logs, on page 1340.

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Require Valid Audit Log Server Certificates for Classic Devices

For additional security, we recommend you require mutual authentication between Firepower appliances and the audit log server. To accomplish this, load one or more certificate revocation lists (CRLs). You cannot stream audit logs to servers with revoked certificates listed in those CRLs.

Firepower supports CRLs encoded in Distinguished Encoding Rules (DER) format. Note that these are the same CRLs that the system uses to validate HTTPS client certificates for the FMC web interface.

Before you begin

Obtain and import a signed client certificate onto each device. For ASA FirePOWER and NGIPSv, you can generate a CSR with a tool like OpenSSL, then use the CLI to import the signed certificate: configure audit_cert import.

Use a globally recognized and trusted CA. The same CA must sign the client certificates you imported and the server certificate you will require with this procedure.

Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Choose Devices &gt; Platform Settings and create or edit a Firepower policy.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click Audit Log Certificate.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Select Enable TLS, then Enable Mutual Authentication.</td>
</tr>
<tr>
<td></td>
<td>We recommend you enable mutual authentication. If you do not, the device will accept server certificates without verification.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Select Enable Fetching of CRL, provide the URL to a CRL file, and click Add CRL.</td>
</tr>
<tr>
<td></td>
<td>You can add up to 25 CRLs. When you deploy, the system will schedule CRL updates. To set the update frequency, see Configuring Certificate Revocation List Downloads, on page 271.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Click Save.</td>
</tr>
</tbody>
</table>

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Filter Syslogs from Audit Logs

When you enable **Send Audit Log to Syslog** and provide **Host** information, syslog messages are also sent to the configured host in addition to the audit logs. This behavior is caused by the fact that the `/etc/syslog-ng.d/syslog-tls.conf` is created when you deploy the Firepower platform settings policy, which results in syslog messages being forwarded/sent to the configured host, instead of only sending the audit logs.

If your auditing policy does not want or require these syslog records, you can prevent those syslogs from being streamed to the configured host. To filter syslogs from audit logs, you must have access to an appliance’s **admin** user account, and you must be able to either access the appliance’s console or open a secure shell.

⚠️ **Caution**

Make sure that only authorized personnel have access to the appliance and to its **admin** account.

**Procedure**

**Step 1**

In the `/etc/syslog-ng.conf` file, comment out the `@include "/etc/syslog-ng.d/*.conf"` line.

*Example:*

```bash
#@include "/etc/syslog-ng.d/*.conf"
```

**Step 2**

Reload the syslog configuration file. Use the `syslog-ng-ctl reload` command to reload the configuration file without having to restart the application.

*Example:*

```bash
syslog-ng-ctl reload
```

Customize the Login Banner for Classic Devices

You can customize the CLI login banner for Classic devices. Note that if the banner is too large or causes errors, CLI sessions can fail when the system attempts to display the banner.

**Procedure**

**Step 1**

Choose **Devices > Platform Settings** and create or edit a Firepower policy.

**Step 2**

Choose **Login Banner**.

**Step 3**

In the **Custom Login Banner** field, enter the login banner text you want to use.

The system will not preserve tab spacing.

**Step 4**

Click **Save**.

**What to do next**

Deploy configuration changes; see **Deploy Configuration Changes, on page 495**.
Synchronize Time on Classic Devices with an NTP Server

Synchronizing the system time on your Firepower Management Center and all its managed devices is essential to successful operations. If your deployment includes FTD devices, see Configure NTP Time Synchronization for Threat Defense, on page 1386.

The device supports NTPv4.

⚠️ Caution

Unintended consequences can occur when time is not synchronized between the FMC and managed devices.

After you deploy, it may take a few minutes for managed devices to synchronize with the configured NTP servers.

**Before you begin**

Make sure the device can communicate with the NTP server or servers you plan to use. You can either:

- (Recommended.) Use the same NTP servers as the FMC: Synchronize Time on the FMC with an NTP Server, on page 1311.

  Note that even if you configure secure communications between the FMC and an NTP server (**Use the authenticated NTP server only**), device connections to that server do not use authentication.

  If you choose this option, the device gets its time directly from the configured NTP server. If the device's configured NTP servers are not reachable for any reason, it synchronizes its time with the FMC.

- If your device cannot reach an NTP server or your organization does not have one, you must use the **Via NTP from Management Center** option discussed in the following procedure.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose Devices &gt; Platform Settings and create or edit a Firepower policy.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click Time Synchronization.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Specify how time is synchronized:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Via NTP from</strong>: If your Firepower Management Center is using NTP servers on the network, select this option and enter the fully-qualified DNS name (such as ntp.example.com), or IPv4 or IPv6 address, of the same NTP servers you specified in System &gt; Configuration &gt; Time Synchronization. If the NTP servers are not reachable, the Firepower Management Center acts as an NTP server.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Via NTP from Management Center</strong>: (Default). The managed device gets time from the NTP servers you configured for the Firepower Management Center (except for authenticated NTP servers) and synchronizes time with those servers directly. However, if any of the following are true, the managed device synchronizes time from the Firepower Management Center:</td>
</tr>
<tr>
<td></td>
<td>• The Firepower Management Center’s NTP servers are not reachable by the device.</td>
</tr>
<tr>
<td></td>
<td>• The Firepower Management Center has no unauthenticated servers.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Click Save.</td>
</tr>
</tbody>
</table>
What to do next
Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Configure Session Timeouts for Classic Devices
Unattended login sessions may be security risks. You can configure the amount of idle time before a user’s login session times out due to inactivity. The maximum value is 24 hours, or 1440 minutes.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose Devices &gt; Platform Settings and create or edit a Firepower policy.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click CLI Timeout.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Enter a CLI Timeout (Minutes).</td>
</tr>
<tr>
<td>Step 4</td>
<td>Click Save.</td>
</tr>
</tbody>
</table>

What to do next
Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Configure SNMP Polling on Classic Devices
Simple Network Management Protocol (SNMP) polling allows access to the standard management information base (MIB) on Firepower devices, which includes system details such as contact, administrative, location, service information, IP addressing and routing information, and transmission protocol usage statistics. Note that enabling SNMP polling does not cause the system to send SNMP traps; it only makes the information in the MIBs available for polling by your network management system.

The system supports SNMPv1, v2, and v3. SNMPv2 only supports read-only communities and SNMPv3 only supports read-only users. SNMPv3 also supports encryption with AES128.

Before you begin
Add SNMP access for each computer you plan to use to poll the system. See Configure Access Lists for Classic Devices, on page 1337.

Note
The SNMP MIB contains information that could be used to attack your deployment. We recommend that you restrict your access list for SNMP access to the specific hosts that will be used to poll for the MIB. We also recommend you use SNMPv3 and use strong passwords for network management access.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose Devices &gt; Platform Settings and create or edit a Firepower policy.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click SNMP.</td>
</tr>
</tbody>
</table>
Step 3 From the SNMP Version drop-down list, choose the SNMP version you want to use:

- **Version 1** or **Version 2**: Enter a read-only SNMP community name in the Community String field, then skip to the end of the procedure.

  **Note** Do not include special characters (< > / % # & ?', etc.) in the SNMP community string name.

- **Version 3**: Click Add User to display the user definition page. SNMPv3 only supports read-only users and encryption with AES128.

Step 4 Enter a Username.
Step 5 Choose the protocol you want to use for authentication from the Authentication Protocol drop-down list.
Step 6 Enter the password required for authentication with the SNMP server in the Authentication Password field.
Step 7 Re-enter the authentication password in the Verify Password field.
Step 8 Choose the privacy protocol you want to use from the Privacy Protocol list, or choose None to not use a privacy protocol.
Step 9 Enter the SNMP privacy key required by the SNMP server in the Privacy Password field.
Step 10 Re-enter the privacy password in the Verify Password field.
Step 11 Click Add.
Step 12 Click Save.

**What to do next**

Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Configure SNMP Polling on Classic Devices
Platform Settings for Firepower Threat Defense

Platform settings for FTD devices configure a range of unrelated features whose values you might want to share among several devices. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

- Configure ARP Inspection, on page 1345
- Configure Banners, on page 1346
- Configure DNS, on page 1347
- Configure External Authentication for SSH, on page 1349
- Configure Fragment Handling, on page 1353
- Configure HTTP, on page 1354
- Configure ICMP Access Rules, on page 1356
- Configure SSL Settings, on page 1357
- Configure Secure Shell, on page 1361
- Configure SMTP, on page 1362
- Configure SNMP for Threat Defense, on page 1363
- About Configuring Syslog, on page 1369
- Configure Global Timeouts, on page 1384
- Configure NTP Time Synchronization for Threat Defense, on page 1386
- Configure Device Time Zone for Policy Application, on page 1387
- History for Firepower Threat Defense Platform Settings, on page 1388

Configure ARP Inspection

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.
When you enable ARP inspection, the Firepower Threat Defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

• If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.

• If there is a mismatch between the MAC address, the IP address, or the interface, then the Firepower Threat Defense device drops the packet.

• If the ARP packet does not match any entries in the static ARP table, then you can set the Firepower Threat Defense device to either forward the packet out all interfaces (flood), or to drop the packet.

*Note* The dedicated interface never floods packets even if this parameter is set to flood.

**Procedure**

**Step 1** Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2** Select ARP Inspection.

**Step 3** Add entries to the ARP inspection table.

a) Click Add to create a new entry, or click Edit if the entry already exists.

b) Select the desired options.

• **Inspect Enabled**—To perform ARP inspection on the selected interfaces and zones.

• **Flood Enabled**—Whether to flood ARP requests that do not match static ARP entries out all interfaces other than the originating interface or the dedicated management interface. This is the default behavior. If you do not elect to flood ARP requests, then only those requests that exactly match static ARP entries are allowed.

• **Security Zones**—Add the zones that contain the interfaces on which to perform the selected actions. The zones must be switched zones. For interfaces not in a zone, you can type the interface name into the field below the Selected Security Zone list and click Add. These rules will be applied to a device only if the device includes the selected interfaces or zones.

  c) Click OK.

**Step 4** Add static ARP entries according to Add a Static ARP Entry, on page 809.

**Step 5** Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**Configure Banners**

You can configure messages to show users when they connect to the device command line interface (CLI).
Procedure

Step 1  Select Devices > Platform Settings and create or edit an FTD policy.
Step 2  Select Banner.
Step 3  Configure the banner.

Following are some tips and requirements for banners.

- Only ASCII characters are allowed. You can use line returns (press Enter), but you cannot use tabs.
- You can dynamically add the hostname or domain name of the device by including the variables $(hostname) or $(domain).
- Although there is no absolute length restriction on banners, Telnet or SSH sessions will close if there is not enough system memory available to process the banner messages.
- From a security perspective, it is important that your banner discourage unauthorized access. Do not use the words "welcome" or "please," as they appear to invite intruders in. The following banner sets the correct tone for unauthorized access:

  You have logged in to a secure device.
  If you are not authorized to access this device, log out immediately or risk criminal charges.

Step 4  Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure DNS

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. There are two DNS server settings that apply to different types of traffic: data and special management traffic. Data traffic includes any services that use FQDNs for which a DNS lookup is necessary, such as Access Control Rules and Remote Access VPN. Special management traffic includes traffic originating on the Management interface such as FMC management and database updates. This procedure only applies to data DNS servers. For management DNS settings, see the CLI configure network dns servers and configure network dns searchdomains commands.

To determine the correct interface for DNS server communications, the FTD uses a routing lookup, but which routing table is used depends on the interfaces for which you enable DNS. See the interface settings below for more information.

Before you begin

- Ensure you have created a DNS server group. For instructions, see Creating DNS Server Group Objects, on page 628.
- Ensure that the FTD has appropriate static or dynamic routes to access the DNS servers.
**Procedure**

| Step 1 | Select Devices > Platform Settings and create or edit a Firepower Threat Defense policy. |
| Step 2 | Click DNS. |
| Step 3 | Check Enable DNS name resolution by device. |
| Step 4 | Choose the DNS Server Group that you have already created. |
| Step 5 | (Optional) Enter the Expiry Entry Timer and Poll Timer values in minutes. |

These options apply to FQDNs that are specified in network objects only. These do not apply to FQDNs used in other features.

- **Expiration Entry Timer** specifies the time limit to remove the IP address of a resolved FQDN from the DNS lookup table after its time-to-live (TTL) expires. Removing an entry requires the table to be recompiled, so frequent removals can increase the processing load on the device. This setting virtually extends the TTL.

- **Poll Timer** specifies the time limit after which the device queries the DNS server to resolve the FQDN that was defined in a network object. An FQDN is resolved periodically either when the poll timer has expired, or when the TTL of the resolved IP entry has expired, whichever occurs first.

| Step 6 | Enable DNS lookups on all interfaces or on specific interfaces. These choices also affect which routing tables are used. |

Note that enabling DNS lookups on an interface is not the same as specifying the source interface for lookups. The FTD always uses a route lookup to determine the source interface.

- No interfaces selected—Enables DNS lookups on all interfaces, including Management and management-only interfaces. The FTD checks the data routing table, and if no route is found, falls back to the management-only routing table.

- Specific interfaces selected but not the Enable DNS Lookup via diagnostic interface also option—Enables DNS lookups on the specified interfaces. The FTD checks the data routing table only.

- Specific interfaces selected plus the Enable DNS Lookup via diagnostic interface also option—Enables DNS lookups on the specified interfaces and the interface. The FTD checks the data routing table, and if no route is found, falls back to the management-only routing table.

- Only the Enable DNS Lookup via diagnostic interface also option—Enables DNS lookups on . The FTD checks only the management-only routing table. Be sure to configure an IP address for the Diagnostic interface on the Devices > Device Management > edit device > Interfaces page.

| Step 7 | Click Save. |

**What to do next**

To use FQDN objects for access control rules, create an FQDN network object which can then be assigned to an access control rule. For instructions see, Creating Network Objects, on page 565.
Configure External Authentication for SSH

**Note**
You must have administrator privileges to perform this task.

When you enable external authentication for management users, the FTD verifies the user credentials with an LDAP or RADIUS server as specified in an external authentication object.

**Attention**
External authentication is not supported on FTD virtual devices.

**Sharing External Authentication Objects**
External authentication objects can be used by the FMC and FTD devices. You can share the same object between the FMC and devices, or create separate objects. Note that the FTD supports defining users on the RADIUS server, while the FMC requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the FTD, but if you want to define users on the RADIUS server, you must create separate objects for the FTD and the FMC.

**Note**
The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-30 seconds for LDAP, and 1-300 seconds for RADIUS). If you set the timeout to a higher value, the FTD external authentication configuration will not work.

**Assigning External Authentication Objects to Devices**
For the FMC, enable the external authentication objects directly on **System > Users > External Authentication**; this setting only affects FMC usage, and it does not need to be enabled for managed device usage. For FTD devices, you must enable the external authentication object in the platform settings that you deploy to the devices, and you can only activate one external authentication object per policy. An LDAP object with CAC authentication enabled cannot also be used for CLI access.

**FTD Supported Fields**
Only a subset of fields in the external authentication object are used for FTD SSH access. If you fill in additional fields, they are ignored. If you also use this object for the FMC, those fields will be used. This procedure only covers the supported fields for the FTD. For other fields, see Configure External Authentication.

**Usernames**
Usernames must be Linux-valid usernames and be lower-case only, using alphanumeric characters plus period (.) or hyphen (-). Other special characters such as at sign (@) and slash (/) are not supported. You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the FMC; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the FMC.

If you previously configured the same username for an internal user using the **configure user add** command, the FTD first checks the password against the internal user, and if that fails, it checks the AAA server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal
users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

**Privilege Level**

LDAP users always have Config privileges. RADIUS users can be defined as either Config or Basic users.

**Before you begin**

- SSH access is enabled by default on the management interface. To enable SSH access on data interfaces, see Configure Secure Shell, on page 1361. SSH is not supported to the Diagnostic interface.

- Inform RADIUS users of the following behavior to set their expectations appropriately:

  - The first time an external user logs in, FTD creates the required structures but cannot simultaneously create the user session. The user simply needs to authenticate again to start the session. The user will see a message similar to the following: "New external username identified. Please log in again to start a session."

  - Similarly, if the user’s Service-Type authorization was changed since the last login, the user will need to re-authenticate. The user will see a message similar to the following: "Your authorization privilege has changed. Please log in again to start a session."

**Procedure**

**Step 1** Select **Devices > Platform Settings** and create or edit an FTD policy.

**Step 2** Click **External Authentication**.

**Step 3** Click the **Manage External Authentication Server** link.

You can also open the External Authentication screen by clicking **System > Users > External Authentication**.

**Step 4** Configure an LDAP Authentication Object.

a) Click **Add External Authentication Object**.

b) Set the **Authentication Method** to LDAP

c) Enter a **Name** and optional **Description**.

d) Choose a **Server Type** from the drop-down list.

e) For the **Primary Server**, enter a **Host Name/IP Address**.

**Note** If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

f) (Optional) Change the **Port** from the default.

g) (Optional) Enter the **Backup Server** parameters.

h) Enter **LDAP-Specific Parameters**.

  - **Base DN**—Enter the base distinguished name for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
• **(Optional) Base Filter**—For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.`

• **User Name**—Enter a distinguished name for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at your example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.

• **Password** and **Confirm Password**—Enter and confirm the password for the user.

• **(Optional) Show Advanced Options**—Configure the following advanced options.
  
  • **Encryption**—Click **None**, **TLS**, or **SSL**.
    
    **Note** If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.

  • **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking Choose File.

• **(Not Used) User Name Template**—Not used by the FTD.

• **Timeout**—Enter the number of seconds before rolling over to the backup connection between 1 and 30. The default is 30.

  **Note** The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the FTD external authentication configuration will not work.

  i) **(Optional) Set the CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **CLI Access Attribute** field.

  j) **Set the CLI Access Filter**.

  Choose one of the following methods:

  • To use the same filter you specified when configuring authentication settings, choose **Same as Base Filter**.

  • To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The names on the LDAP server must be Linux-valid usernames:

• Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)

• All lowercase
k) Click Save.

**Step 5**
For LDAP, if you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings.

a) Choose **System > Users > External Authentication**.

b) Click **Refresh** next to the LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device. The Firepower Threat Defense Platform Settings will also show that it is "Out-of-Date on x targeted devices."

c) Deploy configuration changes; see **Deploy Configuration Changes, on page 495**.

**Step 6**
Configure a RADIUS Authentication Object.

a) Define users on the RADIUS server using the Service-Type attribute.

The following are supported values for the Service-Type attribute:

- **Administrator (6)**—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- **NAS Prompt (7)** or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as `show` commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Alternatively, you can predefine users in the external authentication object (see Step 6.j, on page 1353). To use the same RADIUS server for the FTD and FMC while using the Service-Type attribute method for the FTD, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the FMC), and the other object leaves the **CLI Access Filter** empty (for use with FTDs).

b) In FMC, click **Add External Authentication Object**.

c) Set the **Authentication Method** to RADIUS.

d) Enter a **Name** and optional **Description**.

e) For the **Primary Server**, enter a **Host Name/IP Address**.

**Note** If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

f) (Optional) Change the **Port** from the default.

g) Enter a **RADIUS Secret Key**.

h) (Optional) Enter the **Backup Server** parameters.
i) Enter **RADIUS-Specific Parameters**.
   - **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection. The default is 30.
   - **Retries**—Enter the number of times the primary server connection should be tried before rolling over to the backup connection. The default is 3.

j) (Optional) Instead of using RADIUS-defined users, under **CLI Access Filter**, enter a comma-separated list of usernames in the **Administrator CLI Access User List** field. For example, enter `jchrichton, aerynsun, rygel`.

You may want to use the **CLI Access Filter** method for FTD so you can use the same external authentication object with FTD and other platform types. Note that if you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:
   - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
   - All lowercase
   - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

**Note** If you want to only define users on the RADIUS server, you must leave this section empty.

k) Click **Save**.

**Step 7** Return to **Devices > > Platform Settings > External Authentication**.

**Step 8** Click **Refresh** to view any newly-added objects.

For LDAP when you specify SSL or TLS encryption, you must upload a certificate for the connection; otherwise, the server will not be listed on this window.

**Step 9** Click **Slider enabled** next to the External Authentication object you want to use. You can only enable one object.

**Step 10** Click **Save**.

**Step 11** Deploy configuration changes; see **Deploy Configuration Changes, on page 495**.

---

**Configure Fragment Handling**

By default, the FTD device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments by setting **Chain** to 1. Fragmented packets are often used as Denial of Service (DoS) attacks.
Note

These settings establish the defaults for devices assigned this policy. You can override these settings for specific interfaces on a device by selecting **Override Default Fragment Setting** in the interface configuration. When you edit an interface, you can find the option on **Advanced > Security Configuration**. Select **Devices > Device Management**, edit a FTD device, and select **Interfaces** to edit interface properties.

**Procedure**

**Step 1** Select **Devices > Platform Settings** and create or edit an FTD policy.

**Step 2** Select **Fragment Settings**.

**Step 3** Configure the following options. Click **Reset to Defaults** if you want to use the default settings.

- **Size (Block)**—The maximum number of packet fragments from all connections collectively that can be waiting for reassembly. The default is 200 fragments.
- **Chain (Fragment)**—The maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets. Set this option to 1 to disallow fragments.
- **Timeout (Sec)**—The maximum number of seconds to wait for an entire fragmented packet to arrive. The default is 5 seconds. If all fragments are not received within this time, all fragments are discarded.

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**Configure HTTP**

If you want to allow HTTPS connections to one or more interfaces on the FTD device, configure HTTPS settings. You can use HTTPS to download packet captures for troubleshooting.

**Before you begin**

- When you manage the FTD using the Firepower Management Center, HTTPS access to the FTD is only for viewing packet capture files. The FTD does not have a web interface for configuration in this management mode.

- HTTPS local users can only be configured at the CLI using the `configure user add` command. By default, there is an `admin` user for which you configured the password during initial setup. AAA external authentication is not supported.

- The physical management interface is shared between the Diagnostic logical interface and the Management logical interface; this configuration applies only to the Diagnostic logical interface, if used, or to other data interfaces. The Management logical interface is separate from the other interfaces on the device. It is used to set up and register the device to the Firepower Management Center. It has a separate IP address and static routing.

- To use HTTPS, you do not need an access rule allowing the host IP address. You only need to configure HTTPS access according to this section.
• You can only use HTTPS to a reachable interface; if your HTTPS host is located on the outside interface, you can only initiate a management connection directly to the outside interface.

• You cannot configure both HTTPS and AnyConnect remote access SSL VPN on the same interface for the same TCP port. For example, if you configure remote access SSL VPN on the outside interface, you cannot also open the outside interface for HTTPS connections on port 443. If you must configure both features on the same interface, use different ports. For example, open HTTPS on port 4443.

• The device allows a maximum of 5 concurrent HTTPS connections.

• You need network objects that define the hosts or networks you will allow to make HTTPS connections to the device. Select Objects > Object Management to configure objects.

Note: You cannot use the system-provided any network object group. Instead, use any-ipv4 or any-ipv6.

Procedure

Step 1 Select Devices > Platform Settings and create or edit an FTD policy.
Step 2 Select HTTP.
Step 3 Enable the HTTPS server by clicking Enable HTTP server.
Step 4 (Optional) Change the HTTPS port. The default is 443.
Step 5 Identify the interfaces and IP addresses that allow HTTPS connections.

Use this table to limit which interfaces will accept HTTPS connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click Add to add a new rule, or click Edit to edit an existing rule.
b) Configure the rule properties:

• IP Address—The network object that identifies the hosts or networks you are allowing to make HTTPS connections. Choose an object from the drop-down menu, or add a new network object by clicking +.

• Security Zones—Add the zones that contain the interfaces to which you will allow HTTPS connections. For interfaces not in a zone, you can type the interface name into the field below the Selected Security Zone list and click Add. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click OK.

Step 6 Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.
Configure ICMP Access Rules

By default, you can send ICMP packets to any interface using either IPv4 or IPv6, with these exceptions:

- The Firepower Threat Defense device does not respond to ICMP echo requests directed to a broadcast address.
- The Firepower Threat Defense device only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

To protect the device from attacks, you can use ICMP rules to limit ICMP access to interfaces to particular hosts, networks, or ICMP types. ICMP rules function like access rules, where the rules are ordered, and the first rule that matches a packet defines the action.

If you configure any ICMP rule for an interface, an implicit deny ICMP rule is added to the end of the ICMP rule list, changing the default behavior. Thus, if you want to simply deny a few message types, you must include a permit any rule at the end of the ICMP rule list to allow the remaining message types.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process.

Before you begin

Ensure that the objects needed in the rules already exist. Select Objects > Object Management to configure objects. You need network objects that define the desired hosts or networks, and port objects that define the ICMP message types you want to control.

Procedure

Step 1 Select Devices > Platform Settings and create or edit an FTD policy.
Step 2 Select ICMP.
Step 3 Configure ICMP rules.
   a) Click Add to add a new rule, or click Edit to edit an existing rule.
   b) Configure the rule properties:
      • Action—Whether to permit (allow) or deny (drop) matching traffic.
      • ICMP Service—The port object that identifies the ICMP message type.
      • Network—The network object that identifies the hosts or networks whose access you are controlling.
      • Security Zones—Add the zones that contain the interfaces that you are protecting. For interfaces not in a zone, you can type the interface name into the field below the Selected Security Zone list and click Add. These rules will be applied to a device only if the device includes the selected interfaces or zones.
   c) Click OK.
Step 4 (Optional.) Set rate limits on ICMPv4 Unreachable messages.
Configure SSL Settings

**Procedure**

**Step 1** Select **Devices > Platform Settings** and create or edit a Firepower Threat Defense policy.

**Step 2** Select **SSL**.

**Step 3** Add entries to the **Add SSL Configuration** table.
   a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.
   b) Select the required security configurations from the drop-down list.
      - **Protocol Version**—Specifies the TLS protocols to be used while establishing remote access VPN sessions.
      - **Security Level**—Indicates the kind of security positioning you would like to set up for the SSL.

**Step 4** Select the **Available Algorithms** based on the protocol version that you select and click **Add** to include them for the selected protocol. For more information, see About SSL Settings, on page 1358.

   The algorithms are listed based on the protocol version that you select. Each security protocol identifies unique algorithm for setting up the security level.

**Step 5** Click **OK** to save the changes.

**What to do next**

Select **Deploy > Deployment** and click **Deploy** to deploy the policy to the assigned devices.
About SSL Settings

The Firepower Threat Defense device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. The SSL Settings window lets you configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL.

Configure the SSL Settings at the following location:

**Devices > Platform Settings > SSL**

**Fields**

**Minimum SSL Version as Server**—Specify the minimum SSL/TLS protocol version that the Firepower Threat Defense device uses when acting as a server. For example, when it functions as a Remote Access VPN Gateway.

**TLS Version**—Select one of the following TLS versions from the drop-down list:

<table>
<thead>
<tr>
<th>TLS Version</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS V1</td>
<td>Accepts SSLv2 client hellos and negotiates TLSv1 (or greater).</td>
</tr>
<tr>
<td>TLSV1.1</td>
<td>Accepts SSLv2 client hellos and negotiates TLSv1.1 (or greater).</td>
</tr>
<tr>
<td>TLSV1.2</td>
<td>Accepts SSLv2 client hellos and negotiates TLSv1.2 (or greater).</td>
</tr>
</tbody>
</table>

**DTLS Version**—Select the DTLS versions from the drop-down list, based on the selected TLS version. By default, DTLSv1 is configured on FTD device, you can choose the DTLS version as per your requirement.

**Note**

Ensure that the TLS protocol version is higher than or equal to the DTLS protocol version selected. TLS protocol versions support the following DTLS versions:

<table>
<thead>
<tr>
<th>TLS Version</th>
<th>DTLS Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS V1</td>
<td>DTLSv1</td>
</tr>
<tr>
<td>TLSV1.1</td>
<td>DTLSv1</td>
</tr>
<tr>
<td>TLSV1.2</td>
<td>DTLSv1, DTLSv1.2</td>
</tr>
</tbody>
</table>

**Diffie-Hellman Group**—Choose a group from the drop-down list. Available options are Group1 - 768-bit modulus, Group2 - 1024-bit modulus, Group5 - 1536-bit modulus, Group14 - 2048-bit modulus, 224-bit prime order, and Group24 - 2048-bit modulus, 256-bit prime order. The default is Group1.

**Elliptical Curve Diffie-Hellman Group**—Choose a group from the drop-down list. Available options are Group19 - 256-bit EC, Group20 - 384-bit EC, and Group21 - 521-bit EC. The default value is Group19.

TLSv1.2 adds support for the following ciphers:

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
• AES256-GCM-SHA384
• ECDHE-ECDSA-AES256-SHA384
• ECDHE-RSA-AES256-SHA384
• ECDHE-ECDSA-AES128-GCM-SHA256
• ECDHE-RSA-AES128-GCM-SHA256
• DHE-RSA-AES128-GCM-SHA256
• RSA-AES128-GCM-SHA256
• ECDHE-ECDSA-AES128-SHA256
• ECDHE-RSA-AES128-SHA256

---

**Note**

ECDSA and DHE ciphers are the highest priority.

The SSL configuration table can be used to specify the protocol version, security level, and Cipher algorithms that you want to support on the Firepower Threat Defense devices.

**Protocol Version**—Lists the protocol version that the Firepower Threat Defense device supports and uses for SSL connections. Available protocol versions are:

• Default
• TLSV1
• TLSV1.1
• TLSV1.2
• DTLSv1
• DTLSv1.2

**Security Level**—Lists the cipher security levels that Firepower Threat Defense device supports and uses for SSL connections.

If you have Firepower Threat Defense devices with evaluation license, the security level is Low by default. With Firepower Threat Defense smart license, the default security level is High. You can choose one of the following options to configure the required security level:

• **All** includes all ciphers, including NULL-SHA.
• **Low** includes all ciphers, except NULL-SHA.
• **Medium** includes all ciphers, except NULL-SHA, DES-CBC-SHA, RC4-SHA, and RC4-MD5 (this is the default).
• **Fips** includes all FIPS-compliant ciphers, except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA.
• **High** includes only AES-256 with SHA-2 ciphers and applies to TLS version 1.2 and the default version.
• **Custom** includes one or more ciphers that you specify in the Cipher algorithms/custom string box. This option provides you with full control of the cipher suite using OpenSSL cipher definition strings.

**Cipher Algorithms/Custom String**—Lists the cipher algorithms that Firepower Threat Defense device supports and uses for SSL connections. For more information about ciphers using OpenSSL, see [https://www.openssl.org/docs/apps/ciphers.html](https://www.openssl.org/docs/apps/ciphers.html)

The Firepower Threat Defense device specifies the order of priority for supported ciphers as:

Ciphers supported by TLSv1.2 only

<table>
<thead>
<tr>
<th>Cipher Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECDHE-ECDSA-AES256-GCM-SHA384</td>
</tr>
<tr>
<td>ECDHE-RSA-AES256-GCM-SHA384</td>
</tr>
<tr>
<td>DHE-RSA-AES256-GCM-SHA384</td>
</tr>
<tr>
<td>AES256-GCM-SHA384</td>
</tr>
<tr>
<td>ECDHE-ECDSA-AES256-SHA384</td>
</tr>
<tr>
<td>ECDHE-RSA-AES256-SHA384</td>
</tr>
<tr>
<td>DHE-RSA-AES256-SHA256</td>

</table>
Configure Secure Shell

If you enabled FMC access on a data interface, such as outside, you should enable SSH on that interface using this procedure. This section describes how to enable SSH connections to one or more data interfaces on the FTD. SSH is not supported to the Diagnostic logical interface.

**Note**
SSH is enabled by default on the Management interface; however, this screen does not affect Management SSH access.

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the Firepower Management Center. SSH for data interfaces shares the internal and external user list with SSH for the Management interface. Other settings are configured separately: for data interfaces, enable SSH and access lists using this screen; SSH traffic for data interfaces uses the regular routing configuration, and not any static routes configured at setup or at the CLI.

For the Management interface, to configure an SSH access list, see the `configure ssh-access-list` command in the Firepower Threat Defense Command Reference. To configure a static route, see the `configure network static-routes` command. By default, you configure the default route through the Management interface at initial setup.

To use SSH, you do not also need an access rule allowing the host IP address. You only need to configure SSH access according to this section.

You can only SSH to a reachable interface; if your SSH host is located on the outside interface, you can only initiate a management connection directly to the outside interface.

The device allows a maximum of 5 concurrent SSH connections.

**Note**
On all appliances, after a user makes three consecutive failed attempts to log into the CLI via SSH, the system terminates the SSH connection.

**Before you begin**

- You can configure SSH internal users at the CLI using the `configure user add` command; see Add an Internal User at the CLI, on page 131. By default, there is an admin user for which you configured the password during initial setup. You can also configure external users on LDAP or RADIUS by configuring External Authentication in platform settings. See Configure External Authentication for SSH, on page 1349.

- You need network objects that define the hosts or networks you will allow to make SSH connections to the device. Select Objects > Object Management to configure objects.

**Note**
You cannot use the system-provided any network object. Instead, use any-ipv4 or any-ipv6.
Procedure

**Step 1**  Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2**  Select Secure Shell.

**Step 3**  Identify the interfaces and IP addresses that allow SSH connections.

Use this table to limit which interfaces will accept SSH connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click Add to add a new rule, or click Edit to edit an existing rule.

b) Configure the rule properties:

   • **IP Address**—The network object that identifies the hosts or networks you are allowing to make SSH connections. Choose an object from the drop-down menu, or add a new network object by clicking +.

   • **Security Zones**—Add the zones that contain the interfaces to which you will allow SSH connections. For interfaces not in a zone, you can type the interface name into the field below the Selected Security Zone list and click Add. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click OK.

**Step 4**  Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**Configure SMTP**

You must identify an SMTP server if you configure email alerts in the Syslog settings. The source email address you configure for Syslog must be a valid account on the SMTP servers.

**Before you begin**

Ensure that the network objects that define the host address of the primary and secondary SMTP servers exist. Select Objects > Object Management to define the objects. Alternatively, you can create the objects while editing the policy.

**Procedure**

**Step 1**  Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2**  Click SMTP Server.

**Step 3**  Select the network objects that identify the Primary Server IP Address and optionally, the Secondary Server IP Address.

**Step 4**  Click Save.
You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

### Configure SNMP for Threat Defense

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

The Simple Network Management Protocol (SNMP) enables monitoring of network devices from a central location. Cisco security appliances support network monitoring using SNMP versions 1, 2c, and 3, as well as traps and SNMP read access; SNMP write access is not supported.

SNMPv3 supports read-only users and encryption with DES (deprecated), 3DES, AES256, AES192, and AES128.

---

**Note**
The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption.

---

**Note**
To create an alert to an external SNMP server, access **Policies > Action > Alerts**

---

**Procedure**

1. **Step 1**  
   Select **Devices > Platform Settings** and create or edit an FTD policy.

2. **Step 2**  
   Select **SNMP**.

3. **Step 3**  
   Enable SNMP and configure basic options.

   - **Enable SNMP Servers**—Whether to provide SNMP information to the configured SNMP hosts. You can deselect this option to disable SNMP monitoring while retaining the configuration information.
   - **Read Community String, Confirm**—Enter the password used by a SNMP management station when sending requests to the FTD device. The SNMP community string is a shared secret among the SNMP management stations and the network nodes being managed. The security device uses the password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces and special characters are not permitted.
   - **System Administrator Name**—Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
   - **Location**—Enter the location of this security device (for example, Building 42, Sector 54). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
Port—Enter the UDP port on which incoming requests will be accepted. The default is 161.

Step 4 (SNMPv3 only.) Add SNMPv3 Users, on page 1364.
Step 5 Add SNMP Hosts, on page 1366.
Step 6 Configure SNMP Traps, on page 1367.
Step 7 Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

### Add SNMPv3 Users

**Note** You create users for SNMPv3 only. These steps are not applicable for SNMPv1 or SNMPv2c.

Note that SNMPv3 only supports read-only users.

SNMP users have a specified username, an authentication password, an encryption password, and authentication and encryption algorithms to use.

**Note** When using SNMPv3 with clustering or High Availability, if you add a new cluster unit after the initial cluster formation or you replace a High Availability unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.

The authentication algorithm options are MD5 (deprecated, pre-6.5 only), SHA, and SHA256.

**Note** The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm.

The encryption algorithm options are DES (deprecated, pre-6.5 only), 3DES, AES256, AES192, and AES128.

**Note** The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption.
Procedure

Step 1  Select Devices > Platform Settings and create or edit an FTD policy.

Step 2  Click SNMP > Users.

Step 3  Click Add.

Step 4  Select the security level for the user from the Security Level drop-down list.

• **Auth**—Authentication but No Privacy, which means that messages are authenticated.

• **No Auth**—No Authentication and No Privacy, which means that no security is applied to messages.

• **Priv**—Authentication and Privacy, which means that messages are authenticated and encrypted.

Step 5  Enter the name of the SNMP user in the Username field. Usernames must be 32 characters or less.

Step 6  Select the type of password, you want to use in the Encryption Password Type drop-down list.

• **Clear text**—The FTD device will still encrypt the password when deploying to the device.

• **Encrypted**—The FTD device will directly deploy the encrypted password.

Step 7  In the Auth Algorithm Type drop-down list, select the type of authentication you want to use: SHA, SHA256.

Note  The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm.

Step 8  In the Authentication Password field, enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values.

Note  The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the Confirm field.

Step 9  In the Encryption Type drop-down list, select the type of encryption you want to use: AES128, AES192, AES256, 3DES.

Note  To use AES or 3DES encryption, you must have the appropriate license installed on the device.

Note  The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption.

Step 10  Enter the password to use for encryption in the Encryption Password field. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows (where each xx is one octal):

• AES 128 requires 16 octals

• AES 192 requires 24 octals
• AES 256 requires 32 octals
• 3DES requires 32 octals
• DES can be any size

**Note** For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the Confirm field.

**Step 11** Click OK.

**Step 12** Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Add SNMP Hosts

Use Host to add or edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the FTD device.

You can add up to 4000 hosts. However, only 128 of this number can be for traps.

**Before you begin**

Ensure that the network objects that define the SNMP management stations exist. Select Device > Object Management to configure network objects.

**Note** The supported network objects include IPv6 hosts, IPv4 hosts, IPv4 range and IPv4 subnet addresses.

**Procedure**

**Step 1** Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2** Click SNMP > Hosts.

**Step 3** Click Add.

**Step 4** In the IP Address field, either enter a valid IPv6 or IPv4 host or select the network object that defines the SNMP management station's host address.

The IP address can be an IPv6 host, IPv4 host, IPv4 range or IPv4 subnet.

**Step 5** Select the appropriate SNMP version from the SNMP version drop-down list.

(SNMPv3 only.) Select the username of the SNMP user that you configured from the User Name drop-down list.

**Note** You can associate up to 23 SNMP users per SNMP host.
Configure SNMP Traps

Use SNMP Traps to configure SNMP traps (event notifications) for the FTD device. Traps are different from browsing; they are unsolicited “comments” from the FTD device to the management station for certain events,
such as linkup, linkdown, and syslog event generated. An SNMP object ID (OID) for the device appears in
SNMP event traps sent from the device.

Some traps are not applicable to certain hardware models. These traps will be ignored if you apply the policy
to one of these models. For example, not all models have field-replaceable units, so the Field Replaceable
Unit Insert/Delete trap will not be configured on those models.

SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF
and documented in various RFCs. SNMP traps are compiled into the FTD software.

If needed, you can download RFCs, standard MIBs, and standard traps from the following location:
http://www.ietf.org/

Browse the complete list of Cisco MIBs, traps, and OIDs from the following location:
SNMP Object Navigator

In addition, download Cisco OIDs by FTP from the following location:

Procedure

Step 1  Select Devices > Platform Settings and create or edit an FTD policy.

Step 2  Click SNMP > SNMP Traps to configure SNMP traps (event notifications) for the FTD device.

Step 3  Select the appropriate Enable Traps options. You can select either or both options.

  a) Check Enable All SNMP Traps to quickly select all traps in the subsequent four sections.
  b) Check Enable All Syslog Traps to enable transmission of trap-related syslog messages.

Note  SNMP traps are of higher priority than other notification messages from the FTD as they are expected
to be near real-time. When you enable all SNMP or syslog traps, it is possible for the SNMP process
to consume excess resources in the agent and in the network, causing the system to hang. If you
notice system delays, unfinished requests, or timeouts, you can selectively enable SNMP and syslog
traps. You can also limit the rate at which syslog messages are generated by severity level or message
ID. For example, all syslog message IDs that begin with the digits 212 are associated with the SNMP
class; see Limit the Rate of Syslog Message Generation, on page 1381.

Step 4  The event-notification traps in the Standard section are enabled by default for an existing policy:

  • Authentication – Unauthorized SNMP access. This authentication failure occurs for packets with an
  incorrect community string.

  • Link Up – One of the device’s communication links has become available (it has “come up”), as indicated
  in the notification.

  • Link Down – One of the device’s communication links has failed, as indicated in the notification.

  • Cold Start – The device is reinitializing itself such that its configuration or the protocol entity
  implementation may be altered.

  • Warm Start – The device is reinitializing itself such that its configuration and the protocol entity
  implementation is unaltered.

Step 5  Select the desired event-notification traps in the Entity MIB section:
**Field Replaceable Unit Insert** – A Field Replaceable Unit (FRU) has been inserted, as indicated. (FRUs include assemblies such as power supplies, fans, processor modules, interface modules, etc.)

**Field Replaceable Unit Delete** – A Field Replaceable Unit (FRU) has been removed, as indicated in the notification

**Configuration Change** – There has been a hardware change, as indicated in the notification

**Step 6** Select the desired event-notification traps in the Resource section:

- **Connection Limit Reached** – This trap indicates that a connection attempt was rejected because the configured connections limit has been reached.

**Step 7** Select the desired event-notification traps in the Other section:

- **NAT Packet Discard** – This notification is generated when IP packets are discarded by the NAT function. Available Network Address Translation addresses or ports have fallen below configured threshold.

- **CPU Rising Threshold** – This notification is generated when rising CPU utilization exceeds a predefined threshold for a configured period of time. Check this option to enable CPU rising threshold notifications:
  - **Percentage** – The default value is 70 percent for the high threshold notification; the range is between 10 and 94 percent. The critical threshold is hardcoded at 95 percent.
  - **Period** – The default monitoring period is 1 minute; the range is between 1 and 60 minutes.

- **Memory Rising Threshold** – This notification is generated when rising memory utilization exceeds a predefined threshold, thus reducing available memory. Check this option to enable memory rising threshold notifications:
  - **Percentage** – The default value is 70 percent for the high threshold notification; the range is between 50 and 95 percent.

- **Failover** – This notification is generated when there is a change in the failover state as reported by the CISCO-UNIFIED-FIREWALL-MIB.

- **Cluster** – This notification is generated when there is a change in the cluster health as reported by the CISCO-UNIFIED-FIREWALL-MIB.

**Step 8** Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**About Configuring Syslog**

You can enable system logging (syslog) for FTD devices. Logging information can help you identify and isolate network or device configuration problems. You can also send some security events to a syslog server. The following topics explain logging and how to configure it.
About Syslog

System logging is a method of collecting messages from devices to a server running a syslog daemon. Logging to a central syslog server helps in aggregation of logs and alerts. Cisco devices can send their log messages to a UNIX-style syslog service. A syslog service accepts messages and stores them in files, or prints them according to a simple configuration file. This form of logging provides protected long-term storage for logs. Logs are useful both in routine troubleshooting and in incident handling.

Table 93: System Logs for Firepower Threat Defense

<table>
<thead>
<tr>
<th>Logs Related To</th>
<th>Details</th>
<th>Configure In</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device and system health, network configuration</td>
<td>This syslog configuration generates messages for features running on the data plane, that is, features that are defined in the CLI configuration that you can view with the <code>show running-config</code> command. This includes features such as routing, VPN, data interfaces, DHCP server, NAT, and so forth. Data plane syslog messages are numbered, and they are the same as those generated by devices running ASA software. However, Firepower Threat Defense does not necessarily generate every message type that is available for ASA Software. For information on these messages, see Cisco Firepower Threat Defense Syslog Messages at <a href="https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html">https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html</a>. This configuration is explained in the following topics.</td>
<td>Platform Settings</td>
</tr>
<tr>
<td>Security events</td>
<td>This syslog configuration generates alerts for file and malware, connection, Security Intelligence, and intrusion events. For details, see About Sending Syslog Messages for Security Events, on page 2582 and subtopics.</td>
<td>Platform Settings and the Logging in an access control policy</td>
</tr>
<tr>
<td>(All devices) Policies, rules, and events</td>
<td>This syslog configuration generates alerts for access control rules, intrusion rules, and other advanced services as described in Configurations Supporting Alert Responses, on page 2514. These messages are not numbered. For information on configuring this type of syslog, see Creating a Syslog Alert Response, on page 2516.</td>
<td>Alert Responses and the Logging in an access control policy</td>
</tr>
</tbody>
</table>

You can configure more than one syslog server, and control the messages and events sent to each server. You can also configure different destinations, such as console, email, internal buffer, and so forth.

Severity Levels

The following table lists the syslog message severity levels.

Table 94: Syslog Message Severity Levels

<table>
<thead>
<tr>
<th>Level Number</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>emergencies</td>
<td>System is unusable.</td>
</tr>
<tr>
<td>1</td>
<td>alert</td>
<td>Immediate action is needed.</td>
</tr>
<tr>
<td>Level Number</td>
<td>Severity Level</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>2</td>
<td>critical</td>
<td>Critical conditions.</td>
</tr>
<tr>
<td>3</td>
<td>error</td>
<td>Error conditions.</td>
</tr>
<tr>
<td>4</td>
<td>warning</td>
<td>Warning conditions.</td>
</tr>
<tr>
<td>5</td>
<td>notification</td>
<td>Normal but significant conditions.</td>
</tr>
<tr>
<td>6</td>
<td>informational</td>
<td>Informational messages only.</td>
</tr>
<tr>
<td>7</td>
<td>debugging</td>
<td>Debugging messages only.</td>
</tr>
</tbody>
</table>

Log at this level only temporarily, when debugging issues. This log level can potentially generate so many messages that system performance can be affected.

Firepower Threat Defense does not generate syslog messages with a severity level of zero (emergencies).

**Syslog Message Filtering**

You can filter generated syslog messages so that only certain syslog messages are sent to a particular output destination. For example, you could configure the Firepower Threat Defense device to send all syslog messages to one output destination and to send a subset of those syslog messages to a different output destination.

Specifically, you can direct syslog messages to an output destination according to the following criteria:

- Syslog message ID number
  (This does not apply to syslog messages for security events such as connection and intrusion events.)
- Syslog message severity level
- Syslog message class (equivalent to a functional area)
  (This does not apply to syslog messages for security events such as connection and intrusion events.)

You customize these criteria by creating a message list that you can specify when you set the output destination. Alternatively, you can configure the Firepower Threat Defense device to send a particular message class to each type of output destination independently of the message list.

(Message lists do not apply to syslog messages for security events such as connection and intrusion events.)

**Syslog Message Classes**

This topic does not apply to messages for security events (connection, intrusion, etc.)

You can use syslog message classes in two ways:
• Specify an output location for an entire category of syslog messages.
• Create a message list that specifies the message class.

The syslog message class provides a method of categorizing syslog messages by type, equivalent to a feature or function of the device. For example, the rip class denotes RIP routing.

All syslog messages in a particular class share the same initial three digits in their syslog message ID numbers. For example, all syslog message IDs that begin with the digits 611 are associated with the vpnc (VPN client) class. Syslog messages associated with the VPN client feature range from 611101 to 611323.

In addition, most of the ISAKMP syslog messages have a common set of prepended objects to help identify the tunnel. These objects precede the descriptive text of a syslog message when available. If the object is not known at the time that the syslog message is generated, the specific heading = value combination does not appear.

The objects are prefixed as follows:
Group = groupname, Username = user, IP = IP_address

Where the group is the tunnel-group, the username is the username from the local database or AAA server, and the IP address is the public IP address of the remote access client or Layer 2 peer.

The following table lists the message classes and the range of message IDs in each class.

### Table 95: Syslog Message Classes and Associated Message ID Numbers

### Guidelines for Logging

This section includes guidelines and limitations that you should review before configuring logging.

#### IPv6 Guidelines

- IPv6 is supported. Syslogs can be sent using TCP or UDP.
- Ensure that the interface configured for sending syslogs is enabled, IPv6 capable, and the syslog server is reachable through the designated interface.
- Secure logging over IPv6 is not supported.
**Additional Guidelines**

- The syslog server must run a server program called syslogd. Windows provides a syslog server as part of its operating system.

- To view logs generated by the Firepower Threat Defense device, you must specify a logging output destination. If you enable logging without specifying a logging output destination, the Firepower Threat Defense device generates messages but does not save them to a location from which you can view them. You must specify each different logging output destination separately.

- If you use TCP as the transport protocol, the system opens 4 connections to the syslog server to ensure that messages are not lost. If you are using the syslog server to collect messages from a very large number of devices, and the combined connection overhead is too much for the server, use UDP instead.

- It is not possible to have two different lists or classes being assigned to different syslog servers or same locations.

- You can configure up to 16 syslog servers.

- The syslog server should be reachable through the Firepower Threat Defense device. You should configure the device to deny ICMP unreachable messages on the interface through which the syslog server is reachable and to send syslogs to the same server. Make sure that you have enabled logging for all severity levels. To prevent the syslog server from crashing, suppress the generation of syslogs 313001, 313004, and 313005.

- The number of UDP connections for syslog is directly related to the number of CPUs on the hardware platform and the number of syslog servers you configure. At any point in time, there can be as many UDP syslog connections as there are CPUs times the number of configured syslog servers. For example, for each syslog server:
  - A Firepower 4110 can have up to 22 UDP syslog connections.
  - A Firepower 4120 can have up to 46 UDP syslog connections.

This is the expected behavior. Note that the global UDP connection idle timeout applies to these sessions, and the default is 2 minutes. You can adjust that setting if you want to close these session more quickly, but the timeout applies to all UDP connections, not just syslog.

- When the Firepower Threat Defense device sends syslogs via TCP, the connection takes about one minute to initiate after the syslogd service restarts.

---

**Configure Syslog Logging for FTD Devices**

**Tip**

If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See **FTD Platform Settings That Apply to Security Event Syslog Messages**, on page 1376.

To configure syslog settings, perform the following steps:

**Before you begin**

See requirements in **Guidelines for Logging**, on page 1374.
FTD Platform Settings That Apply to Security Event Syslog Messages

"Security events" include connection, Security Intelligence, intrusion, and file and malware events.

Some of the syslog settings on the Devices > Platform Settings > Threat Defense Settings > Syslog page and its tabs apply to syslog messages for security events, but most apply only to messages for events related to system health and networking.

The following settings apply to syslog messages for security events:

- **Logging Setup** tab:
  - Send syslogs in EMBLEM format

- **Syslog Settings** tab:
  - Enable Timestamp on Syslog Messages
  - Timestamp Format
  - Enable Syslog Device ID

- **Syslog Servers** tab:
  - All options on the Add Syslog Server form (and the list of configured servers).
Enable Logging and Configure Basic Settings

You must enable logging for the system to generate syslog messages for data plane events.

You can also set up archiving on flash or an FTP server as a storage location when the local buffer becomes full. You can manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

The following procedure explains some of the basic syslog settings.

**Procedure**

**Step 1** Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2** Select Syslog > Logging Setup.

**Step 3** Enable logging and configure basic logging settings.

- **Enable Logging**—Turns on data plane system logging for the Firepower Threat Defense device.
- **Enable Logging on the Failover Standby Unit**—Turns on logging for the standby for the Firepower Threat Defense device, if available.
- **Send syslogs in EMBLEM format**—Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages; EMBLEM is not compatible with TCP.

**Note**

Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in FMC, if you want to display the PRI value in the syslog messages of the managed FTD, ensure to enable the EMBLEM format. For more information on PRI, see RFC5424.

- **Send debug messages as syslogs**—Redirects all the debug trace output to the syslog. The syslog message does not appear in the console if this option is enabled. Therefore, to see debug messages, you must enable logging at the console and configure it as the destination for the debug syslog message number and logging level. The syslog message number used is 71101. Default logging level for this syslog is debug.
- **Memory Size of Internal Buffer**—Specify the size of the internal buffer to which syslog messages are saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 52428800.

**Step 4** (Optional) Enable VPN logging by checking the Enable Logging to FMC check box. Choose the syslog severity level for VPN messages from the Logging Level drop-down list.

For information on the levels, see Severity Levels, on page 1370.

**Step 5** (Optional) Configure an FTP server if you want to save log buffer contents to the server before the buffer is overwritten. Specify the FTP Server information.
Enable Logging Destinations

You must enable a logging destination to see messages at that destination. When enabling a destination, you must also specify the message filter for the destination.

Tip
If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1376.

Procedure

Step 1 Select Devices > Platform Settings and create or edit an FTD policy.

Step 2 Select Syslog > Logging Destinations.

Step 3 Click Add to enable a destination and apply a logging filter, or edit an existing destination.

Step 4 In the Logging Destinations dialog box, select a destination and configure the filter to use for a destination:

a) Choose the destination you are enabling in the Logging Destination drop-down list. You can create one filter per destination: Console, E-Mail, Internal buffer, SNMP trap, SSH Sessions, and Syslog servers.

   Note Console and SSH session logging works in the diagnostic CLI only. Enter system support diagnostic-cli.

b) In Event Class, choose the filter that will apply to all classes not listed in the table.

   You can configure these filters:
• **Filter on severity** — Select the severity level. Messages at this level or higher are sent to the destination.

• **Use Event List** — Select the event list that defines the filter. You create these lists on the Event Lists page.

• **Disable Logging** — Prevents messages from being sent to this destination.

c) If you want to create filters per event class, click **Add** to create a new filter, or edit an existing filter, and select the event class and severity level to limit messages in that class. Click **OK** to save the filter.

   For an explanation of the event classes, see **Syslog Message Classes, on page 1371**.

d) Click **OK**.

**Step 5**

Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

### Send Syslog Messages to an E-mail Address

You can set up a list of recipients for syslog messages to be sent as e-mails.

**Tip**

If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See **FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1376**.

**Before you begin**

- Configure an SMTP server on the SMTP Server platform settings page
- **Enable Logging and Configure Basic Settings, on page 1377**
- **Enable Logging Destinations**

**Procedure**

**Step 1**

Select Devices > **Platform Settings** and create or edit an FTD policy.

**Step 2**

Select **Syslog > Email Setup**.

**Step 3**

Specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages.

**Step 4**

Click **Add** to enter a new e-mail address recipient of the specified syslog messages.

**Step 5**

Choose the severity level of the syslog messages that are sent to the recipient from the drop-down list.

The syslog message severity filter used for the destination e-mail address causes messages of the specified severity level and higher to be sent. For information on the levels, see **Severity Levels, on page 1370**.

**Step 6**

Click **OK**.
Step 7  
Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

Create a Custom Event List

An event list is a custom filter you can apply to a logging destination to control which messages are sent to the destination. Normally, you filter messages for a destination based on severity only, but you can use an event list to fine-tune which messages are sent based on a combination of event class, severity, and message identifier (ID).

Creating a custom event list is a two-step process. You create a custom list in the Event Lists, and then use the event list to define the logging filter for the various types of destination, in the Logging Destinations.

Tip
If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1376.

Procedure

Step 1  
Select Devices > Platform Settings and create or edit an FTD policy.

Step 2  
Select Syslog > Events List.

Step 3  
Configure an event list.
   a) Click Add to add a new list, or edit an existing list.
   b) Enter a name for the event list in the Name field. Spaces are not allowed.
   c) To identify messages based on severity or event class, select the Severity/Event Class tab and add or edit entries.
      For information on the available classes see Syslog Message Classes, on page 1371.
      For information on the levels, see Severity Levels, on page 1370.
      Certain event classes are not applicable for the device in transparent mode. If such options are configured then they will be bypassed and not deployed.
   d) To identify messages specifically by message ID, select the Message ID and add or edit the IDs.
      You can enter a range of IDs using a hyphen, for example, 100000-200000. IDs are six digits. For information on how the initial three digits map to features, see Syslog Message Classes, on page 1371.
      For specific message numbers, see Cisco ASA Series Syslog Messages.
   e) Click OK to save the event list.

Step 4  
Click Logging Destinations and add or edit the destination that should use the filter.

Step 5  
Click Save.
You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**Limit the Rate of Syslog Message Generation**

You can limit the rate at which syslog messages are generated by severity level or message ID. You can specify individual limits for each logging level and each Syslog message ID. If the settings conflict, the Syslog message ID limits take precedence.

---

**Tip**

If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See **FTD Platform Settings That Apply to Security Event Syslog Messages**, on page 1376.

---

**Procedure**

**Step 1** Select **Devices > Platform Settings** and create or edit an FTD policy.

**Step 2** Select **Syslog > Rate Limit**.

**Step 3** To limit message generation by severity level, click **Logging Level > Add** and configure the following options:

- **Logging Level**—The severity level you are rate limiting. For information on the levels, see **Severity Levels**, on page 1370.
- **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
- **Interval**—The number of seconds before the rate limit counter resets.

**Step 4** Click **OK**.

**Step 5** To limit message generation by syslog message ID, click **Syslog Level > Add** and configure the following options:

- **Syslog ID**—The syslog message ID you are rate limiting. For specific message numbers, see **Cisco ASA Series Syslog Messages**.
- **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
- **Interval**—The number of seconds before the rate limit counter resets.

**Step 6** Click **OK**.

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**Configure Syslog Settings**

You can configure general syslog settings to set the facility code to be included in syslog messages that are sent to syslog servers, specify whether a timestamp is included in each message, specify the device ID to
include in messages, view and modify the severity levels for messages, and disable the generation of specific messages.

If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), some settings on this page do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 1376.

**Procedure**

**Step 1** Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2** Select Syslog > Syslog Settings.

**Step 3** Select a system log facility for syslog servers to use as a basis to file messages in the Facility drop-down list.

The default is LOCAL4(20), which is what most UNIX systems expect. However, because your network devices share available facilities, you might need to change this value for system logs.

Facility values are not typically relevant for security events. If you need to include Facility values in messages, see Facility in Security Event Syslog Messages, on page 2593.

**Step 4** Select the Enable timestamp on each syslog message check box to include the date and time a message was generated in the syslog message.

**Step 5** Select the Timestamp Format for the syslog message:

- The Legacy (MMM dd yyyy HH:mm:ss) format is the default format for syslog messages.
  
  When this timestamp format is selected, the messages do not indicate the time zone, which is always UTC.
  
- RFC 5424 (yyyy-MM-ddTHH:mm:ssZ) uses the ISO 8601 timestamp format as specified in the RFC 5424 syslog format.
  
  If you select the RFC 5424 format, a “Z” is appended to the end of each timestamp to indicate that the timestamp uses the UTC time zone.

**Step 6** If you want to add a device identifier to syslog messages (which is placed at the beginning of the message), check the Enable Syslog Device ID check box and then select the type of ID.

- **Interface**—To use the IP address of the selected interface, regardless of the interface through which the appliance sends the message. Select the security zone that identifies the interface. The zone must map to a single interface.

- **User Defined ID**—To use a text string (up to 16 characters) of your choice.

- **Host Name**—To use the hostname of the device.

**Step 7** Use the Syslog Message table to alter the default settings for specific syslog messages. You need to configure rules in this table only if you want to change the default settings. You can change the severity assigned to a message, or you can disable the generation of a message.

By default, Netflow is enabled and the entries are shown in the table.

a) To suppress syslog messages that are redundant because of Netflow, select Netflow Equivalent Syslogs.

This adds the messages to the table as suppressed messages.

**Note** If any of these syslog equivalents are already in the table, your existing rules are not overwritten.
b) To add a rule, click **Add**.

c) You select the message number whose configuration you want to change, from the **Syslog ID** drop down list and then select the new severity level from the **Logging Level** drop down list, or select **Suppressed** to disable the generation of the message. Typically, you would not change the severity level and disable the message, but you can make changes to both fields if desired.

d) Click **OK** to add the rule to the table.

**Step 8**

Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**What to do next**

- Deploy configuration changes; see **Deploy Configuration Changes**, on page 495.

**Related Topics**

- **FTD Platform Settings That Apply to Security Event Syslog Messages**, on page 1376

---

**Configure a Syslog Server**

To configure a syslog server to handle messages generated from your system, perform the following steps.

If you want this syslog server to receive security events such as connection and intrusion events, see also **FTD Platform Settings That Apply to Security Event Syslog Messages**, on page 1376.

**Before you begin**

- See requirements in **Guidelines for Logging**, on page 1374.

- Make sure your devices can reach your syslog collector on the network.

**Procedure**

**Step 1**

Select **Devices > Platform Settings** and create or edit an FTD policy.

**Step 2**

Select **Syslog > Syslog Server**.

**Step 3**

Check the **Allow user traffic to pass when TCP syslog server is down** check box, to allow traffic if any syslog server that is using the TCP protocol is down.

**Step 4**

Enter a size of the queue for storing syslog messages on the security appliance when syslog server is busy in the **Message queue size (messages)** field. The minimum is 1 message. The default is 512. Specify 0 to allow an unlimited number of messages to be queued (subject to available block memory).

**Step 5**

Click **Add** to add a new syslog server.

- In the **IP Address** drop-down list, select a network host object that contains the IP address of the syslog server.

- Choose the protocol (either TCP or UDP) and enter the port number for communications between the Firepower Threat Defense device and the syslog server.

  - **UDP** is faster and uses less resources on the device than **TCP**.
The default ports are 514 for UDP, 1470 for TCP. Valid non-default port values for either protocol are 1025 through 65535.

c) Check the **Log messages in Cisco EMBLEM format (UDP only)** check box to specify whether to log messages in Cisco EMBLEM format (available only if UDP is selected as the protocol).

**Note** Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in FMC, only when you enable logging in Cisco EMBLEM format, the PRI value in the syslog messages of the managed FTD is displayed. For more information on PRI, see RFC5424.

d) Check the **Enable Secure Syslog** check box to encrypt the connection between the device and server using SSL/TLS over TCP.

**Note** You must select TCP as the protocol to use this option. You must also upload the certificate required to communicate with the syslog server on the Devices > Certificates page. Finally, upload the certificate from the Firepower Threat Defense device to the syslog server to complete the secure relationship and allow it to decrypt the traffic. The Enable Secure Syslog option is not supported on the device Management interface.

e) Select **Device Management Interface** or **Security Zones or Named Interfaces** to communicate with the syslog server.

- **Device Management Interface**: Send syslogs out of the Management interface. We recommend that you use this option when configuring syslog on Snort events.

  **Note** The Device Management Interface option does not support the Enable Secure Syslog option.

- **Security Zones or Named Interfaces**: Select the interfaces from the list of Available Zones and click Add. If you type in the diagnostic interface name, you must also configure an IP address for the Diagnostic interface (edit the device settings from the Device Management page and select the Interfaces tab). For more information about the management/diagnostic interface, see Diagnostic Interface, on page 757.

f) Click OK.

**Step 6** Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

**Configure Global Timeouts**

You can set the global idle timeout durations for the connection and translation slots of various protocols. If the slot has not been used for the idle time specified, the resource is returned to the free pool.

You can also set a time out for console sessions with the device.
Procedure

**Step 1**  
Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2**  
Select Timeouts.

**Step 3**  
Configure the timeouts you want to change.

For any given setting, select **Custom** to define your own value, **Default** to return to the system default value. In most cases, the maximum timeout is 1193 hours.

You can disable some timeouts by selecting **Disable**.

- **Console Timeout**—The idle time until a connection to the console is closed, range is 0 or 5 to 1440 minutes. The default is 0, which means the session does not time out. If you change the value, existing console sessions use the old timeout value. The new value applies to new connections only.

- **Translation Slot (xlate)**—The idle time until a NAT translation slot is freed. This duration must be at least 1 minute. The default is 3 hours.

- **Connection (Conn)**—The idle time until a connection slot is freed. This duration must be at least 5 minutes. The default is 1 hour.

- **Half-Closed**—The idle time until a TCP half-closed connection closes. A connection is considered half-closed if both the FIN and FIN-ACK have been seen. If only the FIN has been seen, the regular connection timeout applies. The minimum is 30 seconds. The default is 10 minutes.

- **UDP**—The idle time until a UDP connection closes. This duration must be at least 1 minute. The default is 2 minutes.

- **ICMP**—The idle time after which general ICMP states are closed. The default (and minimum) is 2 seconds.

- **RPC/Sun RPC**—The idle time until a SunRPC slot is freed. This duration must be at least 1 minute. The default is 10 minutes.

  In a Sun RPC-based connection, when the parent connection is deleted or timed-out, a new child connection may not be considered as a part of the parent-child connection, and thereby the new connection could be evaluated as per the policy or rules set in the system. After the parent connection has timed-out the existing child connections are valid only until the timeout value set is reached.

- **H.225**—The idle time until an H.225 signaling connection closes. The default is 1 hour. To close a connection immediately after all calls are cleared, a timeout of 1 second (0:0:1) is recommended.

- **H.323**—The idle time after which H.245 (TCP) and H.323 (UDP) media connections close. The default (and minimum) is 5 minutes. Because the same connection flag is set on both H.245 and H.323 media connections, the H.245 (TCP) connection shares the idle timeout with the H.323 (RTP and RTCP) media connection.

- **SIP**—The idle time until a SIP signaling port connection closes. This duration must be at least 5 minutes. The default is 30 minutes.

- **SIP Media**—The idle time until a SIP media port connection closes. This duration must be at least 1 minute. The default is 2 minutes. The SIP media timer is used for SIP RTP/RTCP with SIP UDP media packets, instead of the UDP inactivity timeout.

- **SIP Disconnect**—The idle time after which SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message, between 0:0:1 and 0:10:0. The default is 2 minutes (0:2:0).
• **SIP Invite**—The idle time after which pinholes for PROVISIONAL responses and media xlates will be closed, between 0:1:0 and 00:30:0. The default is 3 minutes (0:3:0).

• **SIP Provisional Media**—The timeout value for SIP provisional media connections, between 1 and 30 minutes. The default is 2 minutes.

• **Floating Connection**—When multiple routes exist to a network with different metrics, the system uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To make it possible to use better routes, set the timeout to a value between 0:0:30 and 1193:0:0.

• **Xlate PAT**—The idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.

• **TCP Proxy Reassembly**—The idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).

• **ARP Timeout**—(Transparent mode only.) The number of seconds between ARP table rebuilds, from 60 to 4294967. The default is 14,400 seconds (4 hours).

### Step 4

Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure NTP Time Synchronization for Threat Defense

Use a Network Time Protocol (NTP) server to synchronize the clock settings on your devices. We recommend you configure all FTDs managed by an FMC to use the same NTP server as the FMC. The FTD gets its time directly from the configured NTP server. If the FTD's configured NTP servers are not reachable for any reason, it synchronizes its time with the FMC.

The device supports NTPv4.

---

### Note

If you are deploying FTD on the Firepower 4100/9300 chassis, you must configure NTP on the Firepower 4100/9300 chassis so that Smart Licensing will work properly and to ensure proper timestamps on device registrations. You should use the same NTP server for the Firepower 4100/9300 chassis and the Firepower Management Center.

---

### Before you begin

- If your organization has one or more NTP servers that your FTD can reach, use the same NTP server or servers for your devices that you have configured for Time Synchronization on the **System > Configuration** page on your FMC.

- If you selected **Use the authenticated NTP server only** when configuring NTP server or servers for the FMC, for your devices use only the NTP server or servers that are configured to authenticate with the
FMC. (The managed devices will use the same NTP servers as the FMC, but their NTP connections will not use authentication.)

- If your device cannot reach an NTP server or your organization does not have one, you must use the Via NTP from Defense Center option as discussed in the following procedure.

**Procedure**

**Step 1** Select Devices > Platform Settings and create or edit an FTD policy.

**Step 2** Select Time Synchronization.

**Step 3** Configure one of the following clock options:

- **Via NTP from Defense Center**—(Default). The managed device gets time from the NTP servers you configured for the Firepower Management Center (except for authenticated NTP servers) and synchronizes time with those servers directly. However, if any of the following are true, the managed device synchronizes time from the Firepower Management Center:
  - The Firepower Management Center’s NTP servers are not reachable by the device.
  - The Firepower Management Center has no unauthenticated servers.

- **Via NTP from**—If your Firepower Management Center is using NTP servers on the network, select this option and enter the fully-qualified DNS name (such as ntp.example.com), or IPv4 or IPv6 address, of the same NTP servers you specified in System > Configuration > Time Synchronization. If the NTP servers are not reachable, the Firepower Management Center acts as an NTP server.

**Step 4** Click Save.

**What to do next**

- Make sure the policy is assigned to your devices. See Setting Target Devices for a Platform Settings Policy, on page 1333.

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

- If your Firepower system includes Classic devices, set up time synchronization for those devices. See Synchronize Time on Classic Devices with an NTP Server, on page 1341.

---

**Configure Device Time Zone for Policy Application**

By default, the system uses the UTC time zone. To designate a different time zone for a device, use this procedure.

The time zone you specify will be used only for time-based policy application in policies that support this functionality.
Procedure

**Step 1** Select Devices > Platform Settings and create or edit an FTD policy.
You can also create time zone objects from the Objects > Object Management > Time Zone page.

**Step 2** Create a new time zone object by clicking +.

**Step 3** Select the time zone.

**Step 4** Click Save.

What to do next

- Make sure the policy is assigned to your devices. See Setting Target Devices for a Platform Settings Policy, on page 1333.
- Create time range objects, select applicable time ranges in access control and prefilter rules, and assign the parent policies to devices associated with the correct time zone.
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

History for Firepower Threat Defense Platform Settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Version</th>
<th>Details</th>

CHAPTER 55

Security Certifications Compliance

The following topics describe how to configure your system to comply with security certifications standards:

- Security Certifications Compliance Modes, on page 1391
- Security Certifications Compliance Characteristics, on page 1392
- Security Certifications Compliance Recommendations, on page 1393
- Enable Security Certifications Compliance, on page 1396

Security Certifications Compliance Modes

Your organization might be required to use only equipment and software complying with security standards established by the U.S. Department of Defense and global certification organizations. Firepower supports compliance with the following security certifications standards:

- Common Criteria (CC): a global standard established by the international Common Criteria Recognition Arrangement, defining properties for security products
- Unified Capabilities Approved Products List (UCAPL): a list of products meeting security requirements established by the U.S. Defense Information Systems Agency (DISA)

Note

The U.S. Government has changed the name of the Unified Capabilities Approved Products List (UCAPL) to the Department of Defense Information Network Approved Products List (DODIN APL). References to UCAPL in this documentation and the Firepower Management Center web interface can be interpreted as references to DODIN APL.

- Federal Information Processing Standards (FIPS) 140: a requirements specification for encryption modules

You can enable security certifications compliance in CC mode or UCAPL mode. Enabling security certifications compliance does not guarantee strict compliance with all requirements of the security mode selected. For more information on hardening procedures, refer to the guidelines for this product provided by the certifying entity.

Caution

After you enable this setting, you cannot disable it. If you need to take an appliance out of CC or UCAPL mode, you must reimage.
## Security Certifications Compliance Characteristics

The following table describes behavior changes when you enable CC or UCAPL mode. (Restrictions on login accounts refer to command line access, not web interface access.)

<table>
<thead>
<tr>
<th>System Change</th>
<th>Firepower Management Center</th>
<th>Classic Managed Devices</th>
<th>Firepower Threat Defense</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIPS compliance is enabled.</td>
<td>Yes</td>

<td>No</td>
</tr>
<tr>
<td>The admin user can be locked out after a maximum number of failed login attempts configurable through the web interface.</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Notes
- **UCAPL Mode** indicates whether a behavior change is enabled in UCAPL mode.
- **CC Mode** indicates whether a behavior change is enabled in CC mode.
- UCAPL mode adds additional security features to the system.
- Restrictions on login accounts refer to command line access, not web interface access.
Security Certifications Compliance Recommendations

Cisco recommends that you observe the following best practices when using a system with security certifications compliance enabled:

- To enable security certifications compliance in your deployment, enable it first on the Firepower Management Center, then enable it in the same mode on all managed devices.

⚠️ Caution: The Firepower Management Center will not receive event data from a managed device unless both are operating in the same security certifications compliance mode.

- For all users, enable password strength checking and set the minimum password length to the value required by the certifying agency.

- If you are using Firepower Management Centers in a high-availability configuration, configure them both to use the same security certifications compliance mode.

- When you configure Firepower Threat Defense on a Firepower 4100/9300 Chassis to operate in CC or UCAPL mode, you should also configure the Firepower 4100/9300 Chassis to operate in CC mode. For more information, see the *Cisco FXOS Firepower Chassis Manager Configuration Guide*.
• Do not configure the system to use any of the following features:
  • Email reports, alerts, or data pruning notifications.
  • Nmap Scan, Cisco IOS Null Route, Set Attribute Value, or ISE EPS remediations.
  • Remote storage for backups or reports.
  • Third-party client access to the system database.
  • External notifications or alerts transmitted via email (SMTP), SNMP trap, or syslog.
  • Audit log messages transmitted to an HTTP server or to a syslog server without using SSL certificates to secure the channel between the appliance and the server.

• Do not enable external authentication using LDAP or RADIUS in deployments using CC mode.
• Do not enable CACs in deployments using CC mode.
• Disable access to the Firepower Management Center and managed devices via the Firepower REST API in deployments using CC or UCAPL mode.
• Enable CACs in deployments using UCAPL mode.
• Do not configure SSO in deployments using CC mode.
• Do not configure Firepower Threat Defense devices into a high availability pair unless they are both using the same security certifications compliance mode.

Note
The Firepower System does not support CC or UCAPL mode for:
• Firepower Threat Defense devices in clusters
• Firepower Threat Defense container instances on the Firepower 4100/9300

Appliance Hardening
For information about features you can use to further harden your Firepower system, see the latest versions of the Cisco Firepower Management Center Hardening Guide and the Cisco Firepower Threat Defense Hardening Guide, as well as the following topics within this document:
• Licensing the Firepower System, on page 151
• User Accounts for FMC, on page 47
• Logging into the Firepower System, on page 23
• Audit Logs, on page 1298
• Audit Log Certificate, on page 1301
• Time and Time Synchronization, on page 1310
• Configure NTP Time Synchronization for Threat Defense, on page 1386
Protecting Your Network

See the following topics to learn about Firepower System features you can configure to protect your network:

- Access Control Policies, on page 1535
- Blocking Traffic with Security Intelligence, on page 1603
- Getting Started with Intrusion Policies, on page 1885
- Tuning Intrusion Policies Using Rules, on page 1895
- The Intrusion Rules Editor, on page 1949
- Update Intrusion Rules, on page 218
- Globally Limiting Intrusion Event Logging, on page 1943
Enable Security Certifications Compliance

This configuration applies to either a Firepower Management Center or managed device:
- For the Firepower Management Center, this configuration is part of the system configuration.
- For a managed device, you apply this configuration from the FMC as part of a platform settings policy.

In either case, the configuration does not take effect until you save your system configuration changes or deploy the shared platform settings policy.

⚠️ Caution

After you enable this setting, you cannot disable it. If you need to take the appliance out of CC or UCAPL mode, you must reimage.

Before you begin

- We recommend you register all devices that you plan to be part of your deployment to the FMC before enabling security certifications compliance on any appliances.
- Firepower Threat Defense devices cannot use an evaluation license; your Cisco Smart Software Manager account must be enabled for export-controlled features.
- Firepower Threat Defense devices must be deployed in routed mode.
- You must be an Admin user to perform this task.

Procedure

Step 1

Depending on whether you are configuring an FMC or a managed device:
• FMC: Choose System > Configuration.
• Classic device: Choose Devices > Platform Settings and create or edit a Firepower policy.
• FTD device: Choose Devices > Platform Settings and create or edit a Firepower Threat Defense policy.

Step 2 Click UCAPL/CC Compliance.

Note Appliances reboot when you enable UCAPL or CC compliance. The FMC reboots when you save the system configuration; managed devices reboot when you deploy configuration changes.

Step 3 To permanently enable security certifications compliance on the appliance, you have two choices:
• To enable security certifications compliance in Common Criteria mode, choose CC from the drop-down list.
• To enable security certifications compliance in Unified Capabilities Approved Products List mode, choose UCAPL from the drop-down list.

Step 4 Click Save.

What to do next
• If you have not already, apply Control and Protection licenses to all Classic devices in your deployment.
• Establish additional configuration changes as described in the guidelines for this product provided by the certifying entity.
• Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Enable Security Certifications Compliance
PART XIII

Network Address Translation (NAT)

• NAT Policy Management, on page 1401
• Network Address Translation (NAT) for Firepower Threat Defense, on page 1407
CHAPTER 56

NAT Policy Management

The following topics describe how to manage NAT policies for your Firepower System:

• Requirements and Prerequisites for NAT Policies, on page 1401
• Managing NAT Policies, on page 1401
• Creating NAT Policies, on page 1402
• Configuring NAT Policies, on page 1403
• Configuring NAT Policy Targets, on page 1404
• Copying NAT Policies, on page 1405

Requirements and Prerequisites for NAT Policies

Model Support
Any, but you must select the correct type of policy for the device model:

• Threat Defense NAT for FTD devices.

Supported Domains
Any

User Roles
Admin
Access Admin
Network Admin

Managing NAT Policies

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.
Administrators in ancestor domains can target NAT policies to devices in descendant domains, which descendant domains can use or replace with customized local policies. If a NAT policy targets devices in different descendant domains, administrators in the descendant domains can view information about target devices belonging to their domain only.

**Procedure**

**Step 1** Choose Devices > NAT.

**Step 2** Manage your NAT policies:

- Copy — Click Copy next to the policy you want to copy; see Copying NAT Policies, on page 1405.
- Create — Click New Policy; see Creating NAT Policies, on page 1402.
- Delete — Click Delete next to the policy you want to delete, then click OK. When prompted whether to continue, you are also informed if another user has unsaved changes in the policy.

**Caution** After you have deployed a NAT policy to a managed device, you cannot delete the policy from the device. Instead, you must deploy a NAT policy with no rules to remove the NAT rules already present on the managed device. You also cannot delete a policy that is the last deployed policy on any of its target devices, even if it is out of date. Before you can delete the policy completely, you must deploy a different policy to those targets.

- Deploy—Choose Deploy > Deployment; see Deploy Configuration Changes, on page 495.
- Edit — Click Edit; see Configuring NAT Policies, on page 1403.

**Creating NAT Policies**

When you create a new NAT policy you must, at minimum, give it a unique name. Although you are not required to identify policy targets at policy creation time, you must perform this step before you can deploy the policy. If you apply a NAT policy with no rules to a device, the system removes all NAT rules from that device.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Administrators in ancestor domains can target NAT policies to devices in descendant domains, which descendant domains can use or replace with customized local policies. If a NAT policy targets devices in different descendant domains, administrators in the descendant domains can view information about target devices belonging to their domain only.
### Procedure

**Step 1** Choose **Devices > NAT**.

**Step 2** From the **New Policy** drop-down list, choose **Threat Defense NAT**.

**Step 3** Enter a unique **Name**.

   In a multidomain deployment, policy names must be unique within the domain hierarchy. The system may identify a conflict with the name of a policy you cannot view in your current domain.

**Step 4** Optionally, enter a **Description**.

**Step 5** Choose the devices where you want to deploy the policy:

   - Choose a device in the **Available Devices** list, and click **Add to Policy**.
   - Click and drag a device from the **Available Devices** list to the **Selected Devices** list.
   - Remove a device from the **Selected Devices** list by clicking **Delete (🗑️)** next to the device.

**Step 6** Click **Save**.

---

**What to do next**

Deploy configuration changes; see **Deploy Configuration Changes, on page 495**.

---

### Configuring NAT Policies

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Administrators in ancestor domains can target NAT policies to devices in descendant domains, which descendant domains can use or replace with customized local policies. If a NAT policy targets devices in different descendant domains, administrators in the descendant domains can view information about target devices belonging to their domain only.

If you change the type of an interface to a type that is not valid for use with a NAT policy that targets a device with that interface, the policy labels the interface as deleted. Click **Save** in the NAT policy to automatically remove the interface from the policy.

**Procedure**

**Step 1** Choose **Devices > NAT**.

**Step 2** Click **Edit (✓)** next to the NAT policy you want to modify.

If **View (👀)** appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Configure your NAT policies:
• To modify the policy name or description, click the Name or Description field, delete any characters as needed, then enter the new name or description. In a multidomain deployment, policy names must be unique within the domain hierarchy. The system may identify a conflict with the name of a policy you cannot view in your current domain.
• To manage policy targets, see Configuring NAT Policy Targets, on page 1404.
• To save your policy changes, click Save.
• To add a rule to a policy, click Add Rule.
• To edit an existing rule, click Edit ( ) next to the rule.
• To delete a rule, click Delete ( ) next to the rule, then click OK.
• To enable or disable an existing rule, right-click a rule, choose State, and choose Disable or Enable.
• To view any warnings or errors in the policy, click Show Warnings, then choose a Device. Warnings and errors mark configurations that could adversely affect traffic flow or prevent the policy from deploying.
• To change the number of rules displayed on the page, use the Rows Per Page drop-down list.

What to do next
Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Configuring NAT Policy Targets

You can identify the managed devices you want to target with your policy while creating or editing a policy. You can search a list of available devices and high-availability pairs, and add them to a list of selected devices.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Administrators in ancestor domains can target NAT policies to devices in descendant domains, which descendant domains can use or replace with customized local policies. If a NAT policy targets devices in different descendant domains, administrators in the descendant domains can view information about target devices belonging to their domain only.

Procedure

**Step 1** Choose Devices > NAT.

**Step 2** Click Edit ( ) next to the NAT policy you want to modify.

If View ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Click Policy Assignments.

**Step 4** Do any of the following:

• To assign a device, high-availability pair, or device group to the policy, select it in the Available Devices list and click Add to Policy. You can also drag and drop.
To remove a device assignment, click **Delete** next to a device, high-availability pair, or device group in the **Selected Devices** list.

**Step 5**

Click **OK**.

---

**What to do next**

- Deploy configuration changes; see *Deploy Configuration Changes, on page 495*.

---

## Copying NAT Policies

You can make a copy of a NAT policy. The copy includes all policy rules and configurations.

In a multidomain deployment, you can copy policies from current and ancestor domains.

**Procedure**

**Step 1**

Choose **Devices > NAT**.

**Step 2**

Click **Copy** next to the NAT policy you want to copy.

**Step 3**

Enter a unique **Name** for the policy.

In a multidomain deployment, policy names must be unique within the domain hierarchy. The system may identify a conflict with the name of a policy you cannot view in your current domain.

**Step 4**

Click **OK**.
Copying NAT Policies
CHAPTER 57

Network Address Translation (NAT) for Firepower Threat Defense

The following topics explain Network Address Translation (NAT) and how to configure it on Firepower Threat Defense devices.

- Why Use NAT?, on page 1407
- NAT Basics, on page 1408
- Guidelines for NAT, on page 1416
- Configure NAT for Threat Defense, on page 1421
- Translating IPv6 Networks, on page 1458
- Monitoring NAT, on page 1471
- Examples for NAT, on page 1472
- History for FTD NAT, on page 1515

Why Use NAT?

Each computer and device within an IP network is assigned a unique IP address that identifies the host. Because of a shortage of public IPv4 addresses, most of these IP addresses are private, not routable anywhere outside of the private company network. RFC 1918 defines the private IP addresses you can use internally that should not be advertised:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into legal, routable addresses that can be used on the public Internet. In this way, NAT conserves public addresses because it can be configured to advertise at a minimum only one public address for the entire network to the outside world.

Other functions of NAT include:

- Security—Keeping internal IP addresses hidden discourages direct attacks.
- IP routing solutions—Overlapping IP addresses are not a problem when you use NAT.
• Flexibility—You can change internal IP addressing schemes without affecting the public addresses available externally; for example, for a server accessible to the Internet, you can maintain a fixed IP address for Internet use, but internally, you can change the server address.

• Translating between IPv4 and IPv6 (Routed mode only)—If you want to connect an IPv6 network to an IPv4 network, NAT lets you translate between the two types of addresses.

---

**Note**

NAT is not required. If you do not configure NAT for a given set of traffic, that traffic will not be translated, but will have all of the security policies applied as normal.

---

**NAT Basics**

The following topics explain some of the basics of NAT.

**NAT Terminology**

This document uses the following terminology:

• **Real address/host/network/interface**—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the “real” network. Note that you can translate any network connected to the device, not just an inside network. Therefore if you configure NAT to translate outside addresses, “real” can refer to the outside network when it accesses the inside network.

• **Mapped address/host/network/interface**—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the “mapped” network.

---

**Note**

During address translation, IP addresses configured for the device interfaces are not translated.

• **Bidirectional initiation**—Static NAT allows connections to be initiated bidirectionally, meaning both to the host and from the host.

• **Source and destination NAT**—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address.

**NAT Types**

You can implement NAT using the following methods:
• Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See Dynamic NAT, on page 1425.

• Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See Dynamic PAT, on page 1431.

• Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See Static NAT, on page 1440.

• Identity NAT—A real address is statically translated to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See Identity NAT, on page 1449.

NAT in Routed and Transparent Mode

You can configure NAT in both routed and transparent firewall mode. You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. The following sections describe typical usage for each firewall mode.

NAT in Routed Mode

The following figure shows a typical NAT example in routed mode, with a private network on the inside.

*Figure 51: NAT Example: Routed Mode*

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is translated to a mapped address, 209.165.201.10.

2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the Firepower Threat Defense device receives the packet because the Firepower Threat Defense device performs proxy ARP to claim the packet.
3. The Firepower Threat Defense device then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

**NAT in Transparent Mode or Within a Bridge Group**

Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks. It can perform a similar function within a bridge group in routed mode.

NAT in transparent mode, or in routed mode between members of the same bridge group, has the following requirements and limitations:

- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the Firepower Threat Defense device sends an ARP request to a host on the other side of the Firepower Threat Defense device, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.
- Translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

The following figure shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

*Figure 52: NAT Example: Transparent Mode*

1. When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.
2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the Firepower Threat Defense device receives the packet because the upstream router includes this mapped network in a static route directed to the Firepower Threat Defense device management IP address.

3. The Firepower Threat Defense device then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.75. Because the real address is directly-connected, the Firepower Threat Defense device sends it directly to the host.

4. For host 192.168.1.2, the same process occurs, except for returning traffic, the Firepower Threat Defense device looks up the route in its routing table and sends the packet to the downstream router at 10.1.1.3 based on the Firepower Threat Defense device static route for 192.168.1.0/24.

**Auto NAT and Manual NAT**

You can implement address translation in two ways: *auto NAT* and *manual NAT*.

We recommend using auto NAT unless you need the extra features that manual NAT provides. It is easier to configure auto NAT, and it might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, you might see a failure in the translation of indirect addresses that do not belong to either of the objects used in the rule.)

**Auto NAT**

All NAT rules that are configured as a parameter of a network object are considered to be *auto NAT* rules. This is a quick and easy way to configure NAT for a network object. You cannot create these rules for a group object, however.

Although these rules are configured as part of the object itself, you cannot see the NAT configuration in the object definition through the object manager.

When a packet enters an interface, both the source and destination IP addresses are checked against the auto NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use manual NAT for that kind of functionality, where you can identify the source and destination address in a single rule.

**Manual NAT**

Manual NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

---

**Note**

For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then you must specify the source ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.
The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

**Comparing Auto NAT and Manual NAT**

The main differences between these two NAT types are:

- **How you define the real address.**
  - Auto NAT—The NAT rule becomes a parameter for a network object. The network object IP address serves as the original (real) address.
  - Manual NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object group for the real address means that manual NAT is more scalable.

- **How source and destination NAT is implemented.**
  - Auto NAT—Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Manual NAT—A single rule translates both the source and destination. A packet matches one rule only, and further rules are not checked. Even if you do not configure the optional destination address, a matching packet still matches one manual NAT rule only. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.

- **Order of NAT Rules.**
  - Auto NAT—Automatically ordered in the NAT table.
  - Manual NAT—Manually ordered in the NAT table (before or after auto NAT rules).

**NAT Rule Order**

Auto NAT and manual NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3, until a match is found. For example, if a match is found in section 1, sections 2 and 3 are not evaluated. The following table shows the order of rules within each section.
### Table 96: NAT Rule Table

<table>
<thead>
<tr>
<th>Table Section</th>
<th>Rule Type</th>
<th>Order of Rules within the Section</th>
</tr>
</thead>
</table>
| Section 1     | Manual NAT   | Applied on a first match basis, in the order they appear in the configuration. Because the first match is applied, you must ensure that specific rules come before more general rules, or the specific rules might not be applied as desired. By default, manual NAT rules are added to section 1. By "specific rules first," we mean:  
  - Static rules should come before dynamic rules.  
  - Rules that include destination translation should come before rules with source translation only.  
  If you cannot eliminate overlapping rules, where more than one rule might apply based on the source or destination address, be especially careful to follow these recommendations. |
| Section 2     | Auto NAT     | If a match in section 1 is not found, section 2 rules are applied in the following order:  
  1. Static rules.  
  2. Dynamic rules.  
  **Within each rule type, the following ordering guidelines are used:**  
  1. Quantity of real IP addresses—from smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses.  
  2. For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0.  
  3. If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman. |
| Section 3     | Manual NAT   | If a match is still not found, section 3 rules are applied on a first match basis, in the order they appear in the configuration. This section should contain your most general rules. You must also ensure that any specific rules in this section come before general rules that would otherwise apply. |

For section 2 rules, for example, you have the following IP addresses defined within network objects:  
- 192.168.1.0/24 (static)  
- 192.168.1.0/24 (dynamic)  
- 10.1.1.0/24 (static)
- 192.168.1.1/32 (static)
- 172.16.1.0/24 (dynamic) (object def)
- 172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:
- 192.168.1.1/32 (static)
- 10.1.1.0/24 (static)
- 192.168.1.0/24 (static)
- 172.16.1.0/24 (dynamic) (object abc)
- 172.16.1.0/24 (dynamic) (object def)
- 192.168.1.0/24 (dynamic)

**NAT Interfaces**

Except for bridge group member interfaces, you can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside.

*Figure 53: Specifying Any Interface*

However, the concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. This could result in many similar rules where only one interface is different. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

---

**Note**

You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. When specifying interfaces, you do so indirectly by selecting the interface object that contains the interface.
Configuring Routing for NAT

The FTD device needs to be the destination for any packets sent to the translated (mapped) address.

When sending packets, the device uses the destination interface if you specify one, or a routing table lookup if you do not, to determine the egress interface. For identity NAT, you have the option to use a route lookup even if you specify a destination interface.

The type of routing configuration needed depends on the type of mapped address, as explained in the following topics.

Addresses on the Same Network as the Mapped Interface

If you use addresses on the same network as the destination (mapped) interface, the Firepower Threat Defense device uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the Firepower Threat Defense device does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

If you configure the mapped interface to be any interface, and you specify a mapped address on the same network as one of the mapped interfaces, then if an ARP request for that mapped address comes in on a different interface, then you need to manually configure an ARP entry for that network on the ingress interface, specifying its MAC address. Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses, so this situation would not occur. Configure the ARP table in the ingress interface's Advanced settings.

Addresses on a Unique Network

If you need more addresses than are available on the destination (mapped) interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the Firepower Threat Defense device.

Alternatively for routed mode, you can configure a static route on the Firepower Threat Defense device for the mapped addresses using any IP address on the destination network as the gateway, and then redistribute the route using your routing protocol. For example, if you use NAT for the inside network (10.1.1.0/24) and use the mapped IP address 209.165.201.5, then you can configure a static route for 209.165.201.5 255.255.255.255 (host address) to the 10.1.1.99 gateway that can be redistributed.

For transparent mode, if the real host is directly-connected, configure the static route on the upstream router to point to the Firepower Threat Defense device: specify the bridge group IP address. For remote hosts in transparent mode, in the static route on the upstream router, you can alternatively specify the downstream router IP address.

The Same Address as the Real Address (Identity NAT)

The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.
Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for “any” IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches “any” address). The Firepower Threat Defense device will then proxy ARP for the address, even though the packet is not actually destined for the Firepower Threat Defense device. (Note that this problem occurs even if you have a manual NAT rule; although the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the “source” address). If the Firepower Threat Defense device ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the Firepower Threat Defense device.

Guidelines for NAT

The following topics provide detailed guidelines for implementing NAT.

Firewall Mode Guidelines for NAT

NAT is supported in routed and transparent firewall mode.

However, configuring NAT on bridge group member interfaces (interfaces that are part of a Bridge Group Virtual Interface, or BVI) has the following restrictions:

- When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself.

- When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.

- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.

- You cannot translate between IPv4 and IPv6 networks (NAT64/46) when the source and destination interfaces are members of the same bridge group. Static NAT/PAT 44/66, dynamic NAT44/66, and dynamic PAT44 are the only allowed methods; dynamic PAT66 is not supported. However, you can do NAT64/46 between members of different bridge groups, or between a bridge group member (source) and standard routed interface (destination).

Note

You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes.

IPv6 NAT Guidelines

NAT supports IPv6 with the following guidelines and restrictions.

- For standard routed mode interfaces, you can also translate between IPv4 and IPv6.

- You cannot translate between IPv4 and IPv6 for interfaces that are members of the same bridge group. You can translate between two IPv6 or two IPv4 networks only. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
• You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

• For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.

• When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

IPv6 NAT Best Practices

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

• NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only).

• NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address. You can also optionally translate the addresses net-to-net, where the first IPv4 address maps to the first IPv6 address, the second to the second, and so on.

• NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

NAT Support for Inspected Protocols

Some application layer protocols that open secondary connections, or that embedded IP addresses in packets, are inspected to provide the following services:

• Pinhole creation—Some application protocols open secondary TCP or UDP connections either on standard or negotiated ports. Inspection opens pinholes for these secondary ports so that you do not need to create access control rules to allow them.

• NAT rewrite—Protocols such as FTP embed IP addresses and ports for the secondary connections in packet data as part of the protocol. If there is NAT translation involved for either of the endpoints, the inspection engines rewrite the packet data to reflect the NAT translation of the embedded addresses and ports. The secondary connections would not work without NAT rewrite.

• Protocol enforcement—Some inspections enforce some degree of conformance to the RFCs for the inspected protocol.
The following table lists the inspected protocols that apply NAT rewrite and their NAT limitations. Keep these limitations in mind when writing NAT rules that include these protocols. Inspected protocols not listed here do not apply NAT rewrite. These inspections include GTP, HTTP, IMAP, POP, SMTP, SSH, and SSL.

**Note**
NAT rewrite is supported on the listed ports only. For some of these protocols, you can extend inspection to other ports using Network Analysis Policies, but NAT rewrite is not extended to those ports. This includes DCERPC, DNS, FTP, and Sun RPC inspection. If you use these protocols on non-standard ports, do not use NAT on the connections.

### Additional Guidelines for NAT

- For interfaces that are members of a bridge group, you write NAT rules for the member interfaces. You cannot write NAT rules for the Bridge Virtual Interface (BVI) itself.

- You cannot write NAT rules for a Virtual Tunnel Interface (VTI), which are used in site-to-site VPN. Writing rules for the VTIs source interface will not apply NAT to the VPN tunnel. To write NAT rules that will apply to VPN traffic tunneled on a VTI, you must use "any" as the interface; you cannot explicitly specify interface names.

- (Auto NAT only.) You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address.

- If a VPN is defined on an interface, inbound ESP traffic on the interface is not subject to the NAT rules. The system allows the ESP traffic for established VPN tunnels only, dropping traffic not associated with an existing tunnel. This restriction applies to ESP and UDP ports 500 and 4500.

- If you define a site-to-site VPN on a device that is behind a device that is applying dynamic PAT, so that UDP ports 500 and 4500 are not the ones actually used, you must initiate the connection from the device that is behind the PAT device. The responder cannot initiate the security association (SA) because it does not know the correct port numbers.
If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the `clear xlate` command in the device CLI. However, clearing the translation table disconnects all current connections that use translations.

If you create a new NAT rule that should apply to an existing connection (such as a VPN tunnel), you need to use `clear conn` to end the connection. Then, the attempt to re-establish the connection should hit the NAT rule and the connection should be NAT'ed correctly.

**Note**
If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the `clear xlate` or `clear conn` commands. This safeguard ensures that the same address is not assigned to multiple hosts.

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- A network object used in NAT cannot include more than 131,838 IP addresses, either explicitly or implied in a range of addresses or a subnet. Break up the address space into smaller ranges and write separate rules for the smaller objects.
- (Manual NAT only.) When using `any` as the source address in a NAT rule, the definition of “any” traffic (IPv4 vs. IPv6) depends on the rule. Before the Firepower Threat Defense device performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the Firepower Threat Defense device can determine the value of `any` in a NAT rule. For example, if you configure a rule from “any” to an IPv6 server, and that server was mapped from an IPv4 address, then `any` means “any IPv6 traffic.” If you configure a rule from “any” to “any,” and you map the source to the interface IPv4 address, then `any` means “any IPv4 traffic” because the mapped interface address implies that the destination is also IPv4.
- You can use the same mapped object or group in multiple NAT rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify “any” interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), specify the interface name instead of the interface address.
  - The failover interface IP address.
  - (Transparent mode.) The management IP address.
  - (Dynamic NAT.) The standby interface IP address when VPN is enabled.

- Avoid using overlapping addresses in static and dynamic NAT policies. For example, with overlapping addresses, a PPTP connection can fail to get established if the secondary connection for PPTP hits the static instead of dynamic xlate.
- You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.
• If you specify a destination interface in a rule, then that interface is used as the egress interface rather than looking up the route in the routing table. However, for identity NAT, you have the option to use a route lookup instead.

• If you use PAT on Sun RPC traffic, which is used to connect to NFS servers, be aware that the NFS server might reject connections if the PAT-ed port is above 1024. The default configuration of NFS servers is to reject connections from ports higher than 1024. The error is typically "Permission Denied." Mapping ports above 1024 happens if you do not select the option to include the reserved ports (1-1023) in the port range of a PAT pool. You can avoid this problem by changing the NFS server configuration to allow all port numbers.

• NAT applies to through traffic only. Traffic generated by the system is not subject to NAT.

• Do not name a network object or group pat-pool, using any combination of upper- or lower-case letters.

• The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

• You cannot use NAT on the internal payload of Protocol Independent Multicast (PIM) registers.

Configure NAT for Threat Defense

Network address translation can be very complex. We recommend that you keep your rules as simple as possible to avoid translation problems and difficult troubleshooting situations. Careful planning before you implement NAT is critical. The following procedure provides the basic approach.

The NAT policy is a shared policy. You assign the policy to devices that should have similar NAT rules.

Whether a given rule in the policy applies to an assigned device is determined by the interface objects (security zones or interface groups) used in the rule. If the interface objects include one or more interface for the device, the rule is deployed to the device. Thus, you can configure rules that apply to subsets of devices within a single shared policy by carefully designing your interface objects. Rules that apply to “any” interface object are deployed to all devices.

You can configure multiple NAT policies if groups of your devices require significantly different rules.

Procedure

Step 1

Select Devices > NAT.

• Click New Policy > Threat Defense NAT to create a new policy. Give the policy a name, optionally assign devices to it, and click Save.

You can change device assignments later by editing the policy and clicking Policy Assignments.

• Click Edit (✓) to edit an existing Threat Defense NAT policy. Note that the page also shows Firepower NAT policies, which are not used by FTD devices.

Step 2

Decide what kinds of rules you need.

You can create dynamic NAT, dynamic PAT, static NAT, and identity NAT rules. For an overview, see NAT Types, on page 1408.
Decide which rules should be implemented as manual or auto NAT. For a comparison of these two implementation options, see Auto NAT and Manual NAT, on page 1411.

Decide which rules should be custom per device. Because you can assign a NAT policy to multiple devices, you can configure a single rule on many devices. However, you might have rules that should be interpreted differently by each device, or some rules that should apply to a subset of devices only.

Use interface objects to control on which devices a rule is configured. Then, use object overrides on network objects to customize the addresses used per device.

For detailed information, see Customizing NAT Rules for Multiple Devices, on page 1422.

Create the rules as explained in the following sections.

- Dynamic NAT, on page 1425
- Dynamic PAT, on page 1431
- Static NAT, on page 1440
- Identity NAT, on page 1449

Manage the NAT policy and rules. You can do the following to manage the policy and its rules.

- To edit the policy name or description, click in those fields, type in your changes, and click outside the fields.

- To view only those rules that apply to a specific device, click Filter by Device and select the desired device. A rule applies to a device if it uses an interface object that includes an interface on the device.

- To change the devices to which the policy is assigned, click the Policy Assignments link and modify the selected devices list as desired.

- To change whether a rule is enabled or disabled, right click the rule and select the desired option from the State command. You can temporarily disable a rule without deleting it using these controls.

- To edit a rule, click Edit (✓) for the rule.

- To delete a rule, click Delete (🗑️) for the rule.

Click Save.

You can now go to Deploy > Deployment and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customizing NAT Rules for Multiple Devices

Because the NAT policy is shared, you can assign a given policy to more than one device. However, you can configure at most one auto NAT rule for a given object. Thus, if you want to configure different translations
for an object based on the specific device doing the translation, you need to carefully configure the interface objects (security zones or interface groups) and define network object overrides for the translated address. The interface objects determine on which devices a rule gets configured. The network object overrides determine what IP addresses are used by a given device for that object.

Consider the following scenario:

- FTD-A and FTD-B have inside networks 192.168.1.0/24 attached to the interface named “inside.”
- On FTD-A, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.100.10.10 - 10.100.10.200 range when going to the “outside” interface.
- On FTD-B, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.200.10.10 - 10.200.10.200 range when going to the “outside” interface.

To accomplish the above, you would do the following. Although this example rule is for dynamic auto NAT, you can generalize the technique for any type of NAT rule.

**Procedure**

**Step 1** Create the security zones for the inside and outside interfaces.

a) Choose **Objects > Object Management**.

b) Select **Interface Objects** from the table of contents and click **Add > Security Zone**. (You can use interface groups instead of zones.)

c) Configure the inside zone properties.

   - **Name**—Enter a name, for example, **inside-zone**.
   - **Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
   - **Selected Interfaces**—Add the FTD-A/inside and FTD-B/inside interfaces to the selected list.

d) Click **Save**.

e) Click **Add > Security Zone** and define the outside zone properties.

   - **Name**—Enter a name, for example, **outside-zone**.
   - **Interface Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
   - **Selected Interfaces**—Add the FTD-A/outside and FTD-B/outside interfaces to the selected list.

f) Click **Save**.

**Step 2** Create the network object for the original inside network on the Object Management page.

a) Select **Network** from the table of contents and click **Add Network > Add Object**.

b) Configure the inside network properties.

   - **Name**—Enter a name, for example, **inside-network**.
   - **Network**—Enter the network address, for example, **192.168.1.0/24**.

c) Click **Save**.

**Step 3** Create the network object for the translated NAT pool and define overrides.
Customizing NAT Rules for Multiple Devices

Network Address Translation (NAT)

Step 4 Configure the NAT rule.

a) Select Devices > NAT and create or edit an FTD NAT policy.
b) Click Add Rule.
c) Configure the following properties:
   • NAT Rule = Auto NAT Rule.
   • Type = Dynamic.
d) On Interface Objects, configure the following:
   • Source Interface Objects = inside-zone.
   • Destination Interface Objects = outside-zone.

Note The interface objects control on which devices the rule is configured. Because in this example the zones contain interfaces for FTD-A and FTD-B only, even if the NAT policy were assigned to additional devices, the rule would be deployed to those 2 devices only.
e) On Translation, configure the following:
   • Original Source = inside-network object.
   • Translated Source > Address = NAT-pool object.
f) Click Save.

You now have a single rule that will be interpreted differently for FTD-A and FTD-B, providing unique translations for the inside networks protected by each firewall.
Searching and Filtering the NAT Rule Table

You can search and filter the NAT rule table to help you find rules that you need to modify or view. When you filter the table, only matching rules are shown. Note that although the rule numbers change to be sequentially 1, 2, and so forth, filtering does not change the actual rule number or the rule’s location in the table relative to hidden rules. Filtering simply changes what you can see to help you locate rules that interest you.

When editing the NAT policy, you can use the fields above the table to do the following types of search/filter:

- **Filter by Device**—Click **Filter by Device**, then select the devices whose rules you want to see and click **OK**. Whether a rule applies to a device is determined by the rule's interface constraints. If you specify a security zone or interface group for either the source or destination interface, the rule applies to a device if at least one interface for the device is in the zone or group. If a NAT rule applies to any source and any destination interface, then it applies to all devices.

  If you also do a text or multiple-attribute search, the results are constrained to the selected devices.

  To remove this filter, click **Filter by Device** and deselect the devices, or select **All**, and click **OK**.

- **Simple Text Search**—In the **Filter** box, type a string and press Enter. The string is compared to all values in the rules. For example, if you enter “network-object-1,” which is the name of a network object, you would get rules that use the object in source, destination, and PAT pool attributes.

  For network and port objects, the string is also compared to the contents of the objects used in the rule. For example, if a PAT pool object includes the range 10.100.10.3-10.100.10.100, searching on either 10.100.10.3 or 10.100.10.100 (or a partial 10.100.10) will include rules that use that PAT pool object. However, the match must be exact: searching on 10.100.10.5 will not match this PAT pool object, even though the IP address is within the object’s IP address range.

  To remove the filter, click the **x** on the right side of the Filter box.

- **Multiple-Attribute Search**—If a simple text search gives you too many hits, you can configure multiple values for the search. Click in the **Filter** box to open the list of attributes, then select or enter strings for the attributes you intend to search and click the **Filter** button. These attributes are the same as the ones you would configure within a NAT rule. The attributes are AND’ed, so filtered results include only those rules that match all attributes you configured.

  - For binary attributes, such as the rule state (enabled/disabled), whether a PAT pool is configured (enabled/disabled), the direction of the rule (uni/bi), or rule type (static/dynamic), simply check or uncheck the boxes as appropriate. Select both boxes if you do not care about the attribute value. If you deselect both boxes, no rules will match the filter.

  - For string attributes, type a full or partial string relevant to that attribute. These will be object names, either for security zones/interface groups, network objects, or port objects. It can also be the network or port object contents, which are matched the same way they are for simple text searches.

  To remove the filter, click the **x** on the right side of the Filter box, or click in the Filter box to open the drop-down list, and click the Clear button.

Dynamic NAT

The following topics explain dynamic NAT and how to configure it.
About Dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, NAT assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

The following figure shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

Figure 54: Dynamic NAT

The following figure shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the packet is dropped.
Dynamic NAT Disadvantages and Advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.
  
  Use PAT or a PAT fall-back method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.

- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

Configure Dynamic Auto NAT

Use dynamic auto NAT rules to translate addresses to different IP addresses that are routable on the destination network.

Before you begin

Select Objects > Object Management and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
• **Translated Source**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

**Procedure**

**Step 1** Select Devices > NAT and create or edit an FTD NAT policy.

**Step 2** Do one of the following:

- Click the Add Rule button to create a new rule.
- Click Edit (✓) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3** Configure the basic rule options:

- **NAT Rule**—Select Auto NAT Rule.
- **Type**—Select Dynamic.

**Step 4** On Interface Objects, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. Source is the object containing the real interface, the one through which the traffic enters the device. Destination is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5** On Translation, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The network object or group that contains the mapped addresses.

**Step 6** (Optional.) On Advanced, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 1501.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the IPv6 option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

**Step 7** Click Save to add the rule.

**Step 8** Click Save on the NAT page to save your changes.
**Configure Dynamic Manual NAT**

Use dynamic manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic NAT translates addresses to different IP addresses that are routable on the destination network.

**Before you begin**

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.

- **Translated Source**—This can be a network object or group, but it cannot include a subnet. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

You can also create network objects for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

**Procedure**

**Step 1**
Select **Devices > NAT** and create or edit an FTD NAT policy.

**Step 2**
Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit ( )** to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3**
Configure the basic rule options:

- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4**
On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic
exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

Step 5
(On the Translation page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6
Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The network object or group that contains the mapped addresses.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7
(Optional.) Identify the destination service ports for service translation: **Original Destination Port, Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8
(Optional.) On **Advanced**, select the desired options:

- (For source translation only.) **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes
needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 1501.

• **Fallthrough to Interface PAT (Destination Interface)** — Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the IPv6 option.

• **IPv6** — Whether to use the IPv6 address of the destination interface for interface PAT.

Step 9  Click **Save** to add the rule.

Step 10  Click **Save** on the NAT page to save your changes.

---

### Dynamic PAT

The following topics describe dynamic PAT.

#### About Dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

The following figure shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

**Figure 56: Dynamic PAT**

![Dynamic PAT Diagram]

For the duration of the translation, a remote host on the destination network can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

After the connection expires, the port translation also expires.

---

**Note**

We recommend that you use different PAT pools for each interface. If you use the same pool for multiple interfaces, especially if you use it for "any" interface, the pool can be quickly exhausted, with no ports available for new translations.
Dynamic PAT Disadvantages and Advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the Firepower Threat Defense device interface IP address as the PAT address.

You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. For more information, see NAT Support for Inspected Protocols, on page 1417.

Dynamic PAT might also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack. You can configure a PAT pool of addresses and use a round-robin assignment of PAT addresses to mitigate this situation.

PAT Pool Object Guidelines

When creating network objects for a PAT pool, follow these guidelines.

For a PAT pool

• Ports are mapped to an available port in the 1024 to 65535 range. You can optionally include the reserved ports, those below 1024, to make the entire port range available for translations.

  When operating in a cluster, blocks of 512 ports per address are allocated to the members of the cluster, and mappings are made within these port blocks. If you also enable block allocation, the ports are distributed according to the block allocation size, whose default is also 512.

  • If you enable block allocation for a PAT pool, port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host.

  • If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT, then the other rule must also specify extended PAT.

  • If a host has an existing connection, then subsequent connections from that host use the same PAT IP address. If no ports are available, this can prevent the connection. Use the round robin option to avoid this problem.

For extended PAT for a PAT pool

• Many application inspections do not support extended PAT.

• If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.

• If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.

• For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.
• You cannot use extended PAT on units in a cluster.

For round robin for a PAT pool

• If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. However, this “stickiness” does not survive a failover. If the device fails over, then subsequent connections from a host might not use the initial IP address.

• IP address “stickiness” is also impacted if you mix PAT pool/round robin rules with interface PAT rules on the same interface. For any given interface, choose either a PAT pool or interface PAT; do not create competing PAT rules.

• Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

Configure Dynamic Auto PAT

Use dynamic auto PAT rules to translate addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select Objects > Object Management and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

• Original Source—This must be a network object (not a group), and it can be a host, range, or subnet.

• Translated Source—You have the following options to specify the PAT address:
  • Destination Interface—To use the destination interface address, you do not need a network object.
  • Single PAT address—Create a network object containing a single host.
  • PAT pool—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

Procedure

Step 1  Select Devices > NAT and create or edit an FTD NAT policy.

Step 2  Do one of the following:
  • Click the Add Rule button to create a new rule.
  • Click Edit (📝) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3  Configure the basic rule options:
Configure Dynamic Auto PAT

Network Address Translation (NAT)

Step 4 On Interface Objects, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

Step 5 On Translation, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty.

Step 6 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT > Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per service, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

- **Flat Port Range, Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is not available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For FTD devices running version 6.7 or higher, the flat port range is always
configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.

- **Block Allocation** —To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

**Step 7**  
(Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)** —Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address or PAT pool.

- **IPv6** —Whether to use the IPv6 address of the destination interface for interface PAT.

**Step 8**
Click **Save** to add the rule.

**Step 9**
Click **Save** on the NAT page to save your changes.

---

**Configure Dynamic Manual PAT**

Use dynamic manual PAT rules when auto PAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic PAT translates addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

**Before you begin**
Select **Objects > Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source** —This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.

- **Translated Source** —You have the following options to specify the PAT address:
  - **Destination Interface** —To use the destination interface address, you do not need a network object.
  - **Single PAT address** —Create a network object containing a single host.
  - **PAT pool** —Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets.

You can also create network objects for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.
For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

**Procedure**

**Step 1**
Select Devices > NAT and create or edit an FTD NAT policy.

**Step 2**
Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit ( )** to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3**
Configure the basic rule options:

- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4**
On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5**
(On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify
the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select Source Interface IP to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6** Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select Destination Interface IP. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the IPv6 option on Advanced. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave Translated Source empty.

- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for Original Destination, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7** (Optional.) Identify the destination service ports for service translation: Original Destination Port, Translated Destination Port.

Dynamic NAT does not support port translation, so leave the Original Source Port and Translated Source Port fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

**Step 8** If you are using a PAT pool, select the PAT Pool page and do the following:

a) Select Enable PAT pool.

b) Select the network object group that contains the addresses for the pool in the PAT > Address field.

You can alternatively select Destination Interface IP, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per service, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027
Configure PAT with Port Block Allocation

For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). If you allocate a block of ports, subsequent connections from the host use new randomly-selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Blocks are freed when the last xlate that uses a port in the block is removed.

The main reason for allocating port blocks is reduced logging. The port block allocation is logged, connections are logged, but xlates created within the port block are not logged. On the other hand, this makes log analysis more difficult.

Port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host. You can create a separate NAT rule that does not use block allocation for applications that use low port numbers; for twice NAT, ensure the rule comes before the block allocation rule.
Before you begin

Usage notes for NAT rules:

- You can include the **Use Round Robin Allocation** option, but you cannot include the options for extending PAT uniqueness, using a flat range, including the reserved ports, or falling through to interface PAT. Other source/destination address and port information is also allowed.

- As with all NAT changes, if you replace an existing rule, you must clear xlates related to the replaced rule to have the new rule take effect. You can clear them explicitly or simply wait for them to time out. When operating in a cluster, you must clear xlates globally across the cluster.

**Note**

If you are switching between a regular PAT and block allocation PAT rule, for object NAT, you must first delete the rule, then clear xlates. You can then create the new object NAT rule. Otherwise, you will see pat-port-block-state-mismatch drops in the **show asp drop** output.

- For a given PAT pool, you must specify (or not specify) block allocation for all rules that use the pool. You cannot allocate blocks in one rule and not in another. PAT pools that overlap also cannot mix block allocation settings. You also cannot overlap static NAT with port translation rules with the pool.

Procedure

**Step 1**

(Optional.) Configure global PAT port block allocation settings.

There are a few global settings that control port block allocation. If you want to change the defaults for these options, you must configure a FlexConfig object and add it to your FlexConfig policy.

a) Select **Objects > Object Management > FlexConfig > FlexConfig Object** and create a new object.

b) Configure the block allocation size, which is the number of ports in each block.

**xlate block-allocation size** *value*

The range is 32-4096. The default is 512. Use the “no” form to return to the default.

If you do not use the default, ensure that the size you choose divides evenly into 64,512 (the number of ports in the 1024-65535 range). Otherwise, there will be ports that cannot be used. For example, if you specify 100, there will be 12 unused ports.

c) Configure the maximum blocks that can be allocated per host.

**xlate block-allocation maximum-per-host** *number*

The limit is per protocol, so a limit of 4 means at most 4 UDP blocks, 4 TCP blocks, and 4 ICMP blocks per host. The range is 1-8, the default is 4. Use the “no” form to return to the default.

d) (Optional.) Enable interim syslog generation.

**xlate block-allocation pba-interim-logging** *seconds*

By default, the system generates syslog messages during port block creation and deletion. If you enable interim logging, the system generates the following message at the interval you specify. The messages report all active port blocks allocated at that time, including the protocol (ICMP, TCP, UDP) and source
and destination interface and IP address, and the port block. You can specify an interval from 21600-604800 seconds (6 hours to 7 days).

%ASA-6-305017: Pba-interim-logging: Active protocol block of ports for translation from
real_interface:real_host_ip to mapped_interface:mapped_ip_address/start_port_num-end_port_num

**Example:**
The following example sets the block allocation size to 64, the per-host maximum to 8, and enables interim logging every 6 hours.

```
xlate block-allocation size 64
xlate block-allocation maximum-per-host 8
xlate block-allocation pba-interim-logging 21600
```

e) Select the following options in the FlexConfig object:

- **Deployment** = Everytime
- **Type** = Append

f) Click **Save** to create the FlexConfig object.
g) Select **Devices > FlexConfig**, and create or edit the FlexConfig policy that is assigned to the devices that need to have these settings adjusted.
h) Select your object in the available objects list and click > to move it to the selected objects list.
i) Click **Save**.

You can click **Preview Config**, select one of the target devices, and verify that the xlate commands appear correctly.

---

**Step 2**

Add NAT rules that use PAT pool port block allocation.

a) Select **Devices > NAT** and add or edit the Threat Defense NAT policy.
b) Add or edit a NAT rule and configure at least the following options.

- **Type** = Dynamic
  - In Translation > Original Source, select the object that defines the source address.
  - On PAT Pool, configure the following options:
    - Select **Enable PAT Pool**
      - In PAT > Address, select a network object that defines the pat pool.
    - Select the **Block Allocation** option.

c) Save your changes to the rule and to the NAT policy.

---

**Static NAT**

The following topics explain static NAT and how to implement it.
About Static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

The following figure shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

Figure 57: Static NAT

![Static NAT Diagram]

Note

You can disable bidirectionality if desired.

Static NAT with Port Translation

Static NAT with port translation lets you specify a real and mapped protocol and port.

When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

The following figure shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

Figure 58: Typical Static NAT with Port Translation Scenario

![Static NAT with Port Translation Diagram]

Static NAT-with-port-translation rules limit access to the destination IP address for the specified port only. If you try to access the destination IP address on a different port not covered by a NAT rule, then the connection is blocked. In addition, for manual NAT, traffic that does not match the source IP address of the NAT rule will be dropped if it matches the destination IP address, regardless of the destination port. Therefore, you must add additional rules for all other traffic allowed to the destination IP address. For example, you can configure a static NAT rule for the IP address, without port specification, and place it after the port translation rule.
For applications that require application inspection for secondary channels (for example, FTP and VoIP), NAT automatically translates the secondary ports.

Following are some other uses of static NAT with port translation.

**Static NAT with Identity Port Translation**

You can simplify external access to internal resources. For example, if you have three separate servers that provide services on different ports (such as FTP, HTTP, and SMTP), you can give external users a single IP address to access those services. You can then configure static NAT with identity port translation to map the single external IP address to the correct IP addresses of the real servers based on the port they are trying to access. You do not need to change the port, because the servers are using the standard ones (21, 80, and 25 respectively).

**Static NAT with Port Translation for Non-Standard Ports**

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

**Static Interface NAT with Port Translation**

You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the device's outside interface to an inside host, then you can map the inside host IP address/port 23 to the outside interface address/port 23.

**One-to-Many Static NAT**

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

The following figure shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/first mapped IP is technically the only bidirectional translation.

**Figure 59: One-to-Many Static NAT**

For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server.
NAT has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated to the real host, but all traffic from the real host uses only the first mapped address for the source.

The following figure shows a typical few-to-many static NAT scenario.
For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

**Note**

Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

The following figure shows a typical many-to-few static NAT scenario.

### Configure Static Auto NAT

Use static auto NAT rules to translate addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

**Before you begin**

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
• **Translated Source**—You have the following options to specify the translated address:

  • **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

  • **Address**—Create a network object or group containing hosts, ranges, or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

**Procedure**

**Step 1**
Select Devices > NAT and create or edit an FTD NAT policy.

**Step 2**
Do one of the following:

  • Click the Add Rule button to create a new rule.
  • Click **Edit** (✓) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3**
Configure the basic rule options:

  • **NAT Rule**—Select **Auto NAT Rule**.
  • **Type**—Select **Static**.

**Step 4**
On **Interface Objects**, configure the following options:

  • **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5**
On **Translation**, configure the following options:

  • **Original Source**—The network object that contains the addresses you are translating.
  • **Translated Source**—One of the following:

    • To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

    • (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

    • (Optional.) **Original Port, Translated Port**—If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary.
Configure Static Manual NAT

Use static manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Static NAT translates addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select Objects > Object Management and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

• **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify Any in the rule.

• **Translated Source**—You have the following options to specify the translated address:
  • **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  • **Address**—Create a network object or group containing hosts, range, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

You can also create network objects for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static
interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports.

**Procedure**

**Step 1**
Select Devices > NAT and create or edit an FTD NAT policy.

**Step 2**
Do one of the following:
- Click the Add Rule button to create a new rule.
- Click Edit ( MODIFY ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3**
Configure the basic rule options:
- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4**
On Interface Objects, configure the following options:
- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. Source is the object containing the real interface, the one through which the traffic enters the device. Destination is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5**
(On the Translation page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify
the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6** Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on Advanced. This configures static interface NAT with port translation: the source address/port is translated to the interface’s address and the same port number.

- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7** (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port, Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port, Translated Destination Port**—Defines a port translation for the destination address.

**Step 8** (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 1501. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
• **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

• **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

**Step 9**  
Click **Save** to add the rule.

**Step 10**  
Click **Save** on the NAT page to save your changes.

---

**Identity NAT**

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate an address to itself.

The following figure shows a typical identity NAT scenario.

*Figure 63: Identity NAT*

The following topics explain how to configure identity NAT.

**Configure Identity Auto NAT**

Use static identity auto NAT rules to prevent the translation of an address. That is, to translate the address to itself.

**Before you begin**

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

• **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

• **Translated Source**—A network object or group with the exact same contents as the original source object. You can use the same object.
**Procedure**

**Step 1**  
Select Devices > NAT and create or edit an FTD NAT policy.

**Step 2**  
Do one of the following:

- Click the Add Rule button to create a new rule.
- Click Edit (✓) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3**  
Configure the basic rule options:

- **NAT Rule**—Select Auto NAT Rule.
- **Type**—Select Static.

**Step 4**  
On Interface Objects, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5**  
On Translation, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Do not configure the **Original Port** and **Translated Port** options for identity NAT.

**Step 6**  
(Optional.) On Advanced, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Do not configure this option for identity NAT.
- **Net to Net Mapping**—Do not configure this option for identity NAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**—If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

**Step 7**  
Click **Save** to add the rule.

**Step 8**  
Click **Save** on the NAT page to save your changes.
Configure Identity Manual NAT

Use static identity manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Use static identity NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select Objects > Object Management and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify Any in the rule.

- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

You can also create network objects for the Original Destination and Translated Destination if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports. You can use the same object for identity NAT.

Procedure

**Step 1**

Select Devices > NAT and create or edit an FTD NAT policy.

**Step 2**

Do one of the following:

- Click the Add Rule button to create a new rule.
- Click Edit (✓) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3**

Configure the basic rule options:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4**

On Interface Objects, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic
exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Step 5**

Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.

![Original Packet vs. Translated Packet](image)

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Interface Object** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6**

Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7**

(Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port, Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port, Translated Destination Port**—Defines a port translation for the destination address.

**Step 8**

(Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
• **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

• **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

• **Perform Route Lookup for Destination Interface**—If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

• **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

**Step 9**
Click **Save** to add the rule.

**Step 10**
Click **Save** on the NAT page to save your changes.

---

**NAT Rule Properties for Firepower Threat Defense**

Use Network Address Translation (NAT) rules to translate IP addresses to other IP addresses. You would typically use NAT rules to convert private addresses to publically routable addresses. The translation can be from one address to another, or you can use Port Address Translation (PAT) to translate many addresses to one or a few addresses, using port numbers to distinguish among the source addresses.

NAT rules include the following basic properties. The properties are the same for auto NAT and manual NAT rules except where indicated.

**NAT Type**
Whether you want to configure a **Manual NAT Rule** or an **Auto NAT Rule**. Auto NAT translates the source address only, and you cannot make different translations based on the destination address. Because auto NAT is more simple to configure, use it unless you need the added features of manual NAT. For more information on the differences, see Auto NAT and Manual NAT, on page 1411.

**Type**
Whether the translation rule is **Dynamic** or **Static**. Dynamic translation automatically chooses the mapped address from a pool of addresses, or an address/port combination when implementing PAT. Use static translation if you want to precisely define the mapped address/port.

**Enable (Manual NAT only.)**
Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page. You cannot disable auto NAT rules.

**Insert (Manual NAT only.)**
Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.
Description (Optional. Manual NAT only.)
A description of the purpose of the rule.

The following topics describe the tabs for the NAT rules properties.

**Interface Objects NAT Properties**

Interface objects (security zones or interface groups) define the interfaces to which a NAT rule applies. In routed mode, you can use the default "any" for both source and destination to apply to all interfaces of all assigned devices. However, you typically want to select specific source and destination interfaces.

**Note**
The concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

If you select interface objects, a NAT rule will be configured on an assigned device only if the device has interfaces included in all selected objects. For example, if you select both source and destination security zones, both zones must contain one or more interface for a given device.

**Source Interface Objects, Destination Interface Objects**

(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (Any) except for bridge group member interfaces.

**Translation Properties for Auto NAT**

Use the options on **Translation** to define the source addresses and the mapped translated addresses. The following properties apply to auto NAT only.

**Original Source (Always required.)**
The network object that contains the addresses you are translating. This must be a network object (not a group), and it can be a host, range, or subnet.

You cannot create auto NAT rules for the system-defined any-ipv4 or any-ipv6 objects.

**Translated Source (Usually required.)**
The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6 option on Advanced**. Do not configure a PAT pool.
• To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.

• To use a PAT pool, leave Translated Source empty. Select the PAT pool object on PAT Pool.

• Static NAT—One of the following:
  • To use a set group of addresses, select Address and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

  • (Static interface NAT with port translation.) To use the address of the destination interface, select Destination Interface IP. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the IPv6 option on the Advanced tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

• Identity NAT—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Port, Translated Port (Static NAT only.)

If you need to translate a TCP or UDP port, select the protocol in Original Port, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary. Do not configure these options for identity NAT.

Translation Properties for Manual NAT

Use the options on Translation to define the source addresses and the mapped translated addresses. The following properties apply to manual NAT only. All are optional except as indicated.

Original Source (Always required.)

The network object or group that contains the addresses you are translating. This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can specify Any in the rule.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

• Dynamic NAT—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

• Dynamic PAT—One of the following:
  • (Interface PAT.) To use the address of the destination interface, select Destination Interface IP. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the IPv6 option on Advanced. Do not configure a PAT pool.

  • To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
• To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.

**Static NAT**—One of the following:

• To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

• (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

**Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

**Original Destination**

The network object that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Translated Destination**

The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Original Source Port, Translated Source Port, Original Destination Port, Translated Destination Port**

The port objects that define the source and destination services for the original and translated packets. You can translate the ports, or select the same object to make the rule sensitive to the service without translating the ports. Keep the following rules in mind when configuring services:

• (Dynamic NAT or PAT.) You cannot do translation on the **Original Source Port** and **Translated Source Port**. You can do translation on the destination port only.

• NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

**PAT Pool NAT Properties**

When you configure dynamic NAT, you can define a pool of addresses to use for Port Address Translation using the properties on the **PAT Pool** tab.

**Enable PAT Pool**

Select this option to configure a pool of addresses for PAT.
PAT

The addresses to use for the PAT pool, one of the following:

- **Address**—The object that defines the PAT pool addresses, either a network object that includes a range, or a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

- **Destination Interface IP**—Indicates that you want to use the destination interface as the PAT address. For this option, you must select a specific **Destination Interface Object**; you cannot use **Any** as the destination interface. This is another way to implement interface PAT.

**Round Robin**

To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

**Extended PAT Table**

To use extended PAT. Extended PAT uses 65535 ports per service, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

**Flat Port Range; Include Reserved Ports**

To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is not available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For FTD devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.

**Block Allocation**

To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

**Advanced NAT Properties**

When you configure NAT, you can configure properties that provide specialized services in the **Advanced** options. All of these properties are optional: configure them only if you need the service.
Translate DNS replies that match this rule

Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 1501. This option is not available if you are doing port translation in a static NAT rule.

Fallthrough to Interface PAT (Destination Interface) (Dynamic NAT only.)

Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the IPv6 option. You cannot select this option if you already configured interface PAT as the translated address. You also cannot select the option if you configure a PAT pool.

IPv6

Whether to use the IPv6 address of the destination interface for interface PAT.

Net to Net Mapping (Static NAT only.)

For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.

Do not proxy ARP on Destination Interface (Static NAT only.)

Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Perform Route Lookup for Destination Interface (Static Identity NAT only. Routed mode only.)

If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Unidirectional (Manual NAT only, static NAT only.)

Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Translating IPv6 Networks

In cases where you need to pass traffic between IPv6-only and IPv4-only networks, you need to use NAT to convert between the address types. Even with two IPv6 networks, you might want to hide internal addresses from the outside network.

You can use the following translation types with IPv6 networks:
• NAT64, NAT46—Translates IPv6 packets into IPv4 and vice versa. You need to define two policies, one for the IPv6 to IPv4 translation, and one for the IPv4 to IPv6 translation. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

**Note**

NAT46 supports static mappings only.

• NAT66—Translates IPv6 packets to a different IPv6 address. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

**Note**

NAT64 and NAT 46 are possible on standard routed interfaces only. NAT66 is possible on both routed and bridge group member interfaces.

### NAT64/46: Translating IPv6 Addresses to IPv4

When traffic goes from an IPv6 network to an IPv4-only network, you need to convert the IPv6 address to IPv4, and return traffic from IPv4 to IPv6. You need to define two address pools, an IPv4 address pool to bind IPv6 addresses in the IPv4 network, and an IPv6 address pool to bind IPv4 addresses in the IPv6 network.

• The IPv4 address pool for the NAT64 rule is normally small and typically might not have enough addresses to map one-to-one with the IPv6 client addresses. Dynamic PAT might more easily meet the possible large number of IPv6 client addresses compared to dynamic or static NAT.

• The IPv6 address pool for the NAT46 rule can be equal to or larger than the number of IPv4 addresses to be mapped. This allows each IPv4 address to be mapped to a different IPv6 address. NAT46 supports static mappings only, so you cannot use dynamic PAT.

You need to define two policies, one for the source IPv6 network, and one for the destination IPv4 network. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

### NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet

Following is a straight-forward example where you have an inside IPv6-only network, and you want to convert to IPv4 for traffic sent to the Internet. This example assumes you do not need DNS translation, so you can perform both the NAT64 and NAT46 translations in a single manual NAT rule.
In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network.

**Procedure**

**Step 1**
Create the network object that defines the inside IPv6 network.

a) Choose Objects > Object Management.

b) Select Network from the table of contents and click Add Network > Add Object.

c) Define the inside IPv6 network.

   Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

   **New Network Object**

   ![Network Object Form](image)

   d) Click Save.

**Step 2**
Create the manual NAT rule to translate the IPv6 network to IPv4 and back again.
a) Select **Devices > NAT** and create or edit an FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Manual NAT Rule.
   - **Type** = Dynamic.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.
e) On **Translation**, configure the following:
   - **Original Source** = inside_v6 network object.
   - **Translated Source** = Destination Interface IP.
   - **Original Destination** = inside_v6 network object.
   - **Translated Destination** = any-ipv4 network object.

f) Click **OK**.
With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface. Conversely, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method.

g) Click **Save** on the NAT rules page.

**NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet and DNS Translation**

Following is a typical example where you have an inside IPv6-only network, but there are some IPv4-only services on the outside Internet that internal users need.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network. You enable DNS rewrite on the NAT46 rule, so that replies from the external DNS server can be converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

Following is a typical sequence for a web request where a client at 2001:DB8::100 on the internal IPv6 network tries to open www.example.com.

1. The client’s computer sends a DNS request to the DNS server at 2001:DB8::D1A5:CA81. The NAT rules make the following translations to the source and destination in the DNS request:
   - 2001:DB8::100 to a unique port on 209.165.201.1 (The NAT64 interface PAT rule.)
   - 2001:DB8::D1A5:CA81 to 209.165.202.129 (The NAT46 rule. D1A5:CA81 is the IPv6 equivalent of 209.165.202.129.)
2. The DNS server responds with an A record indicating that www.example.com is at 209.165.200.225. The NAT46 rule, with DNS rewrite enabled, converts the A record to the IPv6-equivalent AAAA record, and translates 209.165.200.225 to 2001:db8:D1A5:C8E1 in the AAAA record. In addition, the source and destination addresses in the DNS response are untranslated:
   • 209.165.202.129 to 2001:DB8::D1A5:CA81
   • 209.165.201.1 to 2001:db8::100

3. The IPv6 client now has the IP address of the web server, and makes an HTTP request to www.example.com at 2001:db8:D1A5:C8E1. (D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225.) The source and destination of the HTTP request are translated:
   • 2001:DB8::100 to a unique port on 209.156.101.54 (The NAT64 interface PAT rule.)
   • 2001:db8:D1A5:C8E1 to 209.165.200.225 (The NAT46 rule.)

The following procedure explains how to configure this example.

**Before you begin**

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

**Procedure**

**Step 1** Create the network objects that define the inside IPv6 and outside IPv4 networks.

- a) Choose **Objects > Object Management**.
- b) Select **Network** from the table of contents and click **Add Network > Add Object**.
- c) Define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.
d) Click Save.
e) Click Add Network > Add Object and define the outside IPv4 network.
Name the network object (for example, outside_v4_any) and enter the network address 0.0.0.0/0.

New Network Object

Name
outside_v4_any

Description

Network
- Host
- Range
- Network
- FQDN

○ Network
0.0.0.0/0

□ Allow Overrides

f) Click Save.

Step 2 Configure the NAT64 dynamic PAT rule for the inside IPv6 network.

Step 3 Configure the static NAT46 rule for the outside IPv4 network.

a) Click Add Rule.
b) Configure the following properties:
   • NAT Rule = Auto NAT Rule.
   • Type = Static.

c) On Interface Objects, configure the following:
   • Source Interface Objects = outside.
   • Destination Interface Objects = inside.

d) On Translation, configure the following:
   • Original Source = outside_v4_any network object.
   • Translated Source > Address = inside_v6 network object.

e) On Advanced, select Translate DNS replies that match this rule.
f) **Click OK.**

With this rule, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method. In addition, DNS responses are converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

---

**NAT66: Translating IPv6 Addresses to Different IPv6 Addresses**

When going from an IPv6 network to another IPv6 network, you can translate the addresses to different IPv6 addresses on the outside network. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Because you are not translating between different address types, you need a single rule for NAT66 translations. You can easily model these rules using auto NAT. However, if you do not want to allow returning traffic, you can make the static NAT rule unidirectional using manual NAT only.

**NAT66 Example, Static Translation between Networks**

You can configure a static translation between IPv6 address pools using auto NAT. The following example explains how to convert inside addresses on the 2001:db8:122:2091::/96 network to outside addresses on the 2001:db8:122:2999::/96 network.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named inside and outside. To configure interface objects, select Objects > Object Management, then select Interface.

Procedure

Step 1
Create the network objects that define the inside IPv6 and outside IPv6 NAT networks.

a) Choose Objects > Object Management.
b) Select Network from the table of contents and click Add Network > Add Object.
c) Define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.
d) Click **Save**.

e) Click **Add Network > Add Object** and define the outside IPv6 NAT network.

Name the network object (for example, outside_nat_v6) and enter the network address 2001:db8:122:2999::/96.

f) Click **Save**.

**Step 2**

Configure the static NAT rule for the inside IPv6 network.

a) Select **Devices > NAT** and create or edit an FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:
   - **Original Source** = inside_v6 network object.
   - **Translated Source > Address** = outside_nat_v6 network object.

f) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a static NAT66 translation to an address on the 2001:db8:122:2999::/96 network.

---

**NAT66 Example, Simple IPv6 Interface PAT**

A simple approach for implementing NAT66 is to dynamically assign internal addresses to different ports on the outside interface IPv6 address.

When you configure an interface PAT rule for NAT66, all the global addresses that are configured on that interface are used for PAT mapping. Link-local or site-local addresses for the interface are not used for PAT.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named inside and outside. To configure interface objects, select Objects > Object Management, then select Interface.

Procedure

Step 1  Create the network object that defines the inside IPv6 network.
   a) Choose Objects > Object Management.
   b) Select Network from the table of contents and click Add Network > Add Object.
   c) Define the inside IPv6 network.

   Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.
Step 2 Configure the dynamic PAT rule for the inside IPv6 network.

a) Select Devices > NAT and create or edit an FTD NAT policy.
b) Click Add Rule.
c) Configure the following properties:
   - NAT Rule = Auto NAT Rule.
   - Type = Dynamic.
d) On Interface Objects, configure the following:
   - Source Interface Objects = inside.
   - Destination Interface Objects = outside.
e) On Translation, configure the following:
   - Original Source = inside_v6 network object.
   - Translated Source = Destination Interface IP.
f) On Advanced, select IPv6, which indicates that the IPv6 address of the destination interface should be used.
g) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a NAT66 PAT translation to one of the IPv6 global addresses configured for the outside interface.

---

**Monitoring NAT**

To monitor and troubleshoot NAT connections, log into the device CLI and use the following commands.

- **show nat** displays the NAT rules and per-rule hit counts. There are additional keywords to show other aspects of NAT.
- **show xlate** displays the actual NAT translations that are currently active.
- **clear xlate** lets you remove an active NAT translation. You might need to remove active translations if you alter NAT rules, because existing connections continue to use the old translation slot until the connection ends. Clearing a translation allows the system to build a new translation for a client on the client's next connection attempt based on your new rules.
Examples for NAT

The following topics provide examples for configuring NAT on Threat Defense devices.

Providing Access to an Inside Web Server (Static Auto NAT)

The following example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named inside and outside. To configure interface objects, select Objects > Object Management, then select Interface.

Procedure

Step 1

Create the network objects that define the server’s private and public host addresses.

a) Choose Objects > Object Management.
b) Select Network from the table of contents and click Add Network > Add Object.
c) Define the web server’s private address.

Name the network object (for example, WebServerPrivate) and enter the real host IP address, 10.1.2.27.
d) Click **Save**.
e) Click **Add Network > Add Object** and define the public address.

Name the network object (for example, WebServerPublic) and enter the host address 209.165.201.10.

New Network Object

<table>
<thead>
<tr>
<th>Name</th>
<th>WebServerPublic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>Network</td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td>209.165.201.10</td>
</tr>
<tr>
<td>Allow Overrides</td>
<td></td>
</tr>
</tbody>
</table>

f) Click **Save**.

**Step 2**  
Configure static NAT for the object.

a) Select **Devices > NAT** and create or edit an FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server

The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network.

Typically, you configure Network Address Translation (NAT) on interface objects, translation objects, and on the NAT table.

The Firepower Management Center (FMC) NAT rule section includes the following fields:

**Type** = Static.

**Source Interface Objects** = inside.

**Destination Interface Objects** = outside.

**Original Source** = WebServerPrivate network object.

**Translated Source > Address** = WebServerPublic network object.

**Step 3**

Click **Save** on the NAT rule page.
**Before you begin**

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named inside and outside. To configure interface objects, select Objects > Object Management, then select Interface.

**Procedure**

**Step 1**

Create a network object for the dynamic NAT pool to which you want to translate the inside addresses.

a) Choose Objects > Object Management.

b) Select Network from the table of contents and click Add Network > Add Object.

c) Define the dynamic NAT pool.

   Name the network object (for example, myNATpool) and enter the network range 209.165.201.20-209.165.201.30.
**Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server**

d) Click Save.

**Step 2**  
Create a network object for the inside network.

a) Click **Add Network > Add Object**.

b) Name the network object (for example, MyInsNet) and enter the network address 10.1.2.0/24.

c) Click Save.

**Step 3**  
Create a network object for the outside web server.

a) Click **Add Network > Add Object**.

b) Name the network object (for example, MyWebServer) and enter the host address 209.165.201.12.
c) Click **Save**.

**Step 4**  
Create a network object for the translated web server address.

a) Click **Add Network > Add Object**.

b) Name the network object (for example, TransWebServer) and enter the host address 10.1.2.20.

c) Click **Save**.

**Step 5**  
Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Devices > NAT** and create or edit an FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

• **NAT Rule** = Auto NAT Rule.
Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server

- **Type** = Dynamic.

**d)** On Interface Objects, configure the following:
- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

**c)** On Translation, configure the following:
- **Original Source** = myInsNet network object.
- **Translated Source > Address** = myNATpool network group.

**f)** Click **Save**.

**Step 6**
Configure static NAT for the web server.

**a)** Click **Add Rule**.

**b)** Configure the following properties:
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

**c)** On Interface Objects, configure the following:
- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.
d) On **Translation**, configure the following:

- **Original Source** = myWebServer network object.
- **Translated Source > Address** = TransWebServer network object.

![Add NAT Rule](image)

```
<table>

</tbody>
</table>
```

e) Click **Save**.

**Step 7**  
Click **Save** on the NAT rule page.

**Inside Load Balancer with Multiple Mapped Addresses (Static Auto NAT, One-to-Many)**

The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

Procedure

**Step 1** Create a network object for the addresses to which you want to map the load balancer.

- a) Choose **Objects > Object Management**.
- b) Select **Network** from the table of contents and click **Add Network > Add Object**.
- c) Define the addresses.

Name the network object (for example, myPublicIPs) and enter the network range 209.165.201.3-209.165.201.5.
d) Click **Save**.

**Step 2** Create a network object for the load balancer.

a) Click **Add Network > Add Object**.

b) Name the network object (for example, myLBHost), enter the host address 10.1.2.27.

c) Click **Save**.

**Step 3** Configure static NAT for the load balancer.

a) Select **Devices > NAT** and create or edit an FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.

d) On **Interface Objects**, configure the following:

   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:
• **Original Source** = myLBHost network object.

• **Translated Source > Address** = myPublicIPs network group.

f) Click **Save**.

**Step 4** Click **Save** on the NAT rule page.

---

**Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation)**

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

Procedure

**Step 1** Create a network object for the FTP server.

a) Choose **Objects > Object Management**.

b) Select **Network** from the table of contents and click **Add Network > Add Object**.

c) Name the network object (for example, FTPserver), and enter the real IP address for the FTP server, **10.1.2.27**.

![Network Object Configuration](image)

New Network Object

<table>
<thead>
<tr>
<th>Name</th>
<th>FTPserver</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>Network</td>
<td>Host ☑️, Range, Network, FQDN</td>
</tr>
<tr>
<td></td>
<td>10.1.2.27</td>
</tr>
<tr>
<td>Allow Overides</td>
<td>☑️</td>
</tr>
</tbody>
</table>
Step 2  Create a network object for the HTTP server.
   a) Click Add Network > Add Object.
   b) Name the network object (for example, HTTPserver), enter the host address 10.1.2.28.

   c) Click Save.

Step 3  Create a network object for the SMTP server.
   a) Click Add Network > Add Object.
   b) Name the network object (for example, SMTPserver), enter the host address 10.1.2.29.

   c) Click Save.

Step 4  Create a network object for the public IP address used for the three servers.
   a) Click Add Network > Add Object.
   b) Name the network object (for example, ServerPublicIP) and enter the host address 209.165.201.3.

   c) Click Save.

Step 5  Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.
   a) Select Devices > NAT and create or edit an FTD NAT policy.
   b) Click Add Rule.
   c) Configure the following properties:
      • NAT Rule = Auto NAT Rule.
Network Address Translation (NAT)

Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation)

- **Type** = Static.

d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:
   - **Original Source** = FTPserver network object.
   - **Translated Source > Address** = ServerPublicIP network object.
   - **Original Port > TCP** = 21.
   - **Translated Port** = 21.

f) Click **Save**.

**Step 6**
Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add Rule**.
b) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.

c) On **Interface Objects**, configure the following:
• **Source Interface Objects** = inside.
• **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:
• **Original Source** = HTTPserver network object.
• **Translated Source > Address** = ServerPublicIP network object.
• **Original Port > TCP** = 80.
• **Translated Port** = 80.

e) Click **Save**.

**Step 7** Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.
a) Click **Add Rule**.
b) Configure the following properties:
   • **NAT Rule** = Auto NAT Rule.
   • **Type** = Static.

c) On **Interface Objects**, configure the following:
   • **Source Interface Objects** = inside.
   • **Destination Interface Objects** = outside.
d) On Translation, configure the following:

- **Original Source** = SMTPserver network object.
- **Translated Source > Address** = ServerPublicIP network object.
- **Original Port > TCP** = 25.
- **Translated Port** = 25.

![NAT Rule Configuration](image)

e) Click Save.

**Step 8**: Click Save on the NAT rule page.

---

**Different Translation Depending on the Destination (Dynamic Manual PAT)**

The following figure shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:port. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:port.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named inside and dmz. To configure interface objects, select Objects > Object Management, then select Interface.

Procedure

**Step 1** Create a network object for the inside network.

a) Choose Objects > Object Management.
b) Select Network from the table of contents and click Add Network > Add Object.
c) Name the network object (for example, myInsideNetwork), and enter the real network address, 10.1.2.0/24.

d) Click Save.

**Step 2** Create a network object for the DMZ network 1.

a) Click Add Network > Add Object.
b) Name the network object (for example, DMZnetwork1) and enter the network address 209.165.201.0/27 (subnet mask of 255.255.255.224).

![New Network Object]

- Name: DMZnetwork1
- Network: 209.165.201.0/27
- Allow Overrides

- Click Save.

**Step 3**
Create a network object for the PAT address for DMZ network 1.

a) Click **Add Network > Add Object**.

b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.

![New Network Object]

- Name: PATaddress1
- Allow Overrides

- Click Save.

**Step 4**
Create a network object for the DMZ network 2.

a) Click **Add Network > Add Object**.

b) Name the network object (for example, DMZnetwork2) and enter the network address 209.165.200.224/27 (subnet mask of 255.255.255.224).

![New Network Object]

- Name: DMZnetwork2
- Network: 209.165.200.224/27
- Allow Overrides

- Click Save.

**Step 5**
Create a network object for the PAT address for DMZ network 2.
a) Click Add Network > Add Object.

b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click Save.

**Step 6** Configure dynamic manual PAT for DMZ network 1.
a) Select Devices > NAT and create or edit an FTD NAT policy.
b) Click Add Rule.
c) Configure the following properties:
   - **NAT Rule** = Manual NAT Rule.
   - **Type** = Dynamic.

d) On Interface Objects, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = dmz.

e) On Translation, configure the following:
   - **Original Source** = myInsideNetwork network object.
   - **Translated Source > Address** = PATaddress1 network object.
   - **Original Destination > Address** = DMZnetwork1 network object.
   - **Translated Destination** = DMZnetwork1 network object.

   **Note** Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.
Step 7

Configure dynamic manual PAT for DMZ network 2.

a) Click Add Rule.

b) Configure the following properties:
   
   • **NAT Rule** = Manual NAT Rule.
   
   • **Type** = Dynamic.

c) On **Interface Objects**, configure the following:
   
   • **Source Interface Objects** = inside.
   
   • **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:
   
   • **Original Source** = myInsideNetwork network object.
   
   • **Translated Source > Address** = PATaddress2 network object.
   
   • **Original Destination > Address** = DMZnetwork2 network object.
   
   • **Translated Destination** = DMZnetwork2 network object.

f) Click **Save**.
Step 8  Click **Save** on the NAT rule page.

**Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT)**

The following figure shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129:port. When the host accesses the same server for web services, the real address is translated to 209.165.202.130:port.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named `inside` and `dmz`. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

Procedure

**Step 1**  
Create a network object for the inside network.  

a) Choose **Objects > Object Management**.  

b) Select **Network** from the table of contents and click **Add Network > Add Object**.  

c) Name the network object (for example, `myInsideNetwork`) and enter the real network address, 10.1.2.0/24.

![Network Object](image)

- **Name**: `myInsideNetwork`  
- **Description**:  
- **Network**: 10.1.2.0/24

- Click **Save**.

**Step 2**  
Create a network object for the Telnet/Web server.  

a) Click **Add Network > Add Object**.
b) Name the network object (for example, TelnetWebServer) and enter the host address 209.165.201.11.
   
   Step 3  Create a network object for the PAT address when using Telnet.
   a) Click Add Network > Add Object.
   b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.
   
   c) Click Save.

Step 4  Create a network object for the PAT address when using HTTP.
   a) Click Add Network > Add Object.
   b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.
   
   c) Click Save.

Step 5  Configure dynamic manual PAT for Telnet access.
   a) Select Devices > NAT and create or edit an FTD NAT policy.
   b) Click Add Rule.
   c) Configure the following properties:
      - Type = Dynamic.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = dmz.

e) On **Translation**, configure the following:
   - **Original Source** = myInsideNetwork network object.
   - **Translated Source > Address** = PATaddress1 network object.
   - **Original Destination > Address** = TelnetWebServer network object.
   - **Translated Destination** = TelnetWebServer network object.
   - **Original Destination Port** = TELNET port object (system-defined).
   - **Translated Destination Port** = TELNET port object (system-defined).
   
   **Note** Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.

f) Click **Save**.

**Step 6** Configure dynamic manual PAT for web access.

a) Click **Add Rule**.

b) Configure the following properties:
• **NAT Rule** = Manual NAT Rule.
• **Type** = Dynamic.

c) On **Interface Objects**, configure the following:
• **Source Interface Objects** = inside.
• **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:
• **Original Source** = myInsideNetwork network object.
• **Translated Source > Address** = PATaddress2 network object.
• **Original Destination > Address** = TelnetWebServer network object.
• **Translated Destination** = TelnetWebServer network object.
• **Original Destination Port** = HTTP port object (system-defined).
• **Translated Destination Port** = HTTP port object (system-defined).

e) Click **Save**.

**Step 7** Click **Save** on the NAT rule page.
NAT and Site-to-Site VPN

The following figure shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

Figure 70: Interface PAT and Identity NAT for Site-to-Site VPN

The following example explains the configuration for Firewall1 (Boulder).

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the devices in the VPN. In this example, we will assume the interface objects are security zones named inside-boulder and outside-boulder for the Firewall1 (Boulder) interfaces. To configure interface objects, select Objects > Object Management, then select Interfaces.

Procedure

Step 1
Create the objects to define the various networks.

a) Choose Objects > Object Management.

b) Select Network from the table of contents and click Add Network > Add Object.

c) Identify the Boulder inside network.

   Name the network object (for example, boulder-network) and enter the network address, 10.1.1.0/24.
d) Click Save.
e) Click Add Network > Add Object and define the inside San Jose network.
   Name the network object (for example, sanjose-network) and enter the network address 10.2.2.0/24.

f) Click Save.

**Step 2** Configure manual identity NAT for the Boulder network when going over the VPN to San Jose on Firewall1 (Boulder).
   a) Select Devices > NAT and create or edit an FTD NAT policy.
   b) Click Add Rule.
   c) Configure the following properties:
      - **NAT Rule** = Manual NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside-boulder.
   - **Destination Interface Objects** = outside-boulder.

e) On **Translation**, configure the following:
   - **Original Source** = boulder-network object.
   - **Translated Source > Address** = boulder-network object.
   - **Original Destination > Address** = sanjose-network object.
   - **Translated Destination** = sanjose-network object.

   **Note** Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank. This rule configures identity NAT for both source and destination.

f) On **Advanced**, select **Do not proxy ARP on Destination interface**.
g) Click **Save**.

**Step 3** Configure manual dynamic interface PAT when going to the Internet for the inside Boulder network on Firewall1 (Boulder).

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.
- **Insert Rule** = any position after the first rule. Because this rule will apply to any destination address, the rule that uses sanjose-network as the destination must come before this rule, or the sanjose-network rule will never be matched. The default is to place new manual NAT rules at the end of the "NAT Rules Before Auto NAT" section.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

d) On **Translation**, configure the following:

- **Original Source** = boulder-network object.
- **Translated Source** = **Destination Interface IP**. This option configures interface PAT using the interface contained in the destination interface object.
- **Original Destination > Address** = any (leave blank).
- **Translated Destination** = any (leave blank).
e) Click **Save**.

**Step 4** If you are also managing Firewall2 (San Jose), you can configure similar rules for that device.

- The manual identity NAT rule would be for sanjose-network when the destination is boulder-network. Create new interface objects for the Firewall2 inside and outside networks.
- The manual dynamic interface PAT rule would be for sanjose-network when the destination is "any."

---

**Rewriting DNS Queries and Responses Using NAT**

You might need to configure the Firepower Threat Defense device to modify DNS replies by replacing the address in the reply with an address that matches the NAT configuration. You can configure DNS modification when you configure each translation rule. DNS modification is also known as DNS doctoring.

This feature rewrites the address in DNS queries and replies that match a NAT rule (for example, the A record for IPv4, the AAAA record for IPv6, or the PTR record for reverse DNS queries). For DNS replies traversing from a mapped interface to any other interface, the record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the record is rewritten from the real value to the mapped value. This feature works with NAT44, NAT 66, NAT46, and NAT64.
Following are the main circumstances when you would need to configure DNS rewrite on a NAT rule.

- The rule is NAT64 or NAT46, and the DNS server is on the outside network. You need DNS rewrite to convert between DNS A records (for IPv4) and AAAA records (for IPv6).
- The DNS server is on the outside, clients are on the inside, and some of the fully-qualified domain names that the clients use resolve to other inside hosts.
- The DNS server is on the inside and responds with private IP addresses, clients are on the outside, and the clients access fully-qualified domain names that point to servers that are hosted on the inside.

**DNS Rewrite Limitations**

Following are some limitations with DNS rewrite:

- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A or AAAA record, and the PAT rule to use is ambiguous.
- If you configure a manual NAT rule, you cannot configure DNS modification if you specify the destination address as well as the source address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, the can not accurately match the IP address inside the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.
- You must enable DNS application inspection with DNS NAT rewrite enabled for NAT rules to rewrite DNS queries and responses. By default, DNS inspection with DNS NAT rewrite enabled is globally applied, so you probably do not need to change the inspection configuration.
- DNS rewrite is actually done on the xlate entry, not the NAT rule. Thus, if there is no xlate for a dynamic rule, rewrite cannot be done correctly. The same problem does not occur for static NAT.
- DNS rewrite does not rewrite DNS Dynamic Update messages (opcode 5).

The following topics provide examples of DNS rewrite in NAT rules.

**DNS64 Reply Modification**

The following figure shows an FTP server and DNS server on the outside IPv4 network. The system has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1, where D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named inside and outside. To configure interface objects, select Objects > Object Management, then select Interface.

Procedure

Step 1
Create the network objects for the FTP server, DNS server, inside network, and PAT pool.

a) Choose Objects > Object Management.

b) Select Network from the table of contents and click Add Network > Add Object.

c) Define the real FTP server address.

Name the network object (for example, ftp_server) and enter the host address, 209.165.200.225.
d) Click Save.

e) Click Add Network > Add Object and define the FTP server's translated IPv6 address.

Name the network object (for example, ftp_server_v6) and enter the host address, 2001:DB8::D1A5:C8E1.

f) Click Save.

g) Click Add Network > Add Object and define the DNS server's real address.

Name the network object (for example, dns_server) and enter the host address, 209.165.201.15.
h) Click **Save**.

i) Click **Add Network > Add Object** and define the DNS server's translated IPv6 address.

Name the network object (for example, dns_server_v6) and enter the host address, 2001:DB8::D1A5:C90F (where D1A5:C90F is the IPv6 equivalent of 209.165.201.15).

```
New Network Object

Name
dns_server_v6

Description

Network
  ○ Host  ○ Range  ○ Network  ○ FQDN
  2001:DB8::D1A5:C90F

Allow Overrides
```

j) Click **Save**.

k) Click **Add Network > Add Object** and define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:DB8::/96.

```
New Network Object

Name
inside_v6

Description

Network
  ○ Host  ○ Range  ○ Network  ○ FQDN

Allow Overrides
```
l) Click **Save**.
m) Click **Add Network > Add Object** and define the IPv4 PAT pool for the inside IPv6 network. Name the network object (for example, ipv4_pool) and enter the range 209.165.200.230-209.165.200.235.

n) Click **Save**.

**Step 2**
Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices > NAT** and create or edit an FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.

d) **On Interface Objects**, configure the following:
   - **Source Interface Objects** = outside.
   - **Destination Interface Objects** = inside.
e) **On Translation**, configure the following:
   - **Original Source** = ftp_server network object.
   - **Translated Source > Address** = ftp_server_v6 network object.
f) On **Advanced**, select the following options:
   - **Translate DNS replies that match this rule.**
   - **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

   g) Click **OK**.

**Step 3**
Configure the static NAT rule for the DNS server.

a) Click **Add Rule**.

b) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.

c) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = outside.
   - **Destination Interface Objects** = inside.

d) On **Translation**, configure the following:
   - **Original Source** = dns_server network object.
   - **Translated Source > Address** = dns_server_v6 network object.

e) On **Advanced**, select **Net to Net Mapping**, because this is a one-to-one NAT46 translation.
f) Click OK.

**Step 4** Configure the dynamic NAT with a PAT pool rule for the inside IPv6 network.

a) Click **Add Rule**.

b) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Dynamic.

c) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:
   - **Original Source** = inside_v6 network object.
   - **Translated Source > Address** = leave this field empty.
e) On **PAT Pool**, configure the following:

- **Enable PAT Pool** = select this option.
- **Translated Source > Address** = ipv4_pool network object.

f) Click **OK**.

---

**DNS Reply Modification, DNS Server on Outside**

The following figure shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure NAT to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network.
In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The system refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

**Before you begin**

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named inside and outside. To configure interface objects, select Objects > Object Management, then select Interface.

**Procedure**

**Step 1**

Create the network objects for the FTP server.

a) Choose Objects > Object Management.
b) Select Network from the table of contents and click Add Network > Add Object.
c) Define the real FTP server address.
Name the network object (for example, ftp_server) and enter the host address, 10.1.3.14.

New Network Object

Name

ftp_server

Description

Network

Host  Range  Network  FQDN

10.1.3.14

Allow Overrides

d) Click Save.

e) Click Add Network > Add Object and define the FTP server's translated address. Name the network object (for example, ftp_server_outside) and enter the host address, 209.165.201.10.

New Network Object

Name

ftp_server_outside

Description

Network

Host  Range  Network  FQDN

209.165.201.10

Allow Overrides

f) Click Save.

**Step 2** Configure the static NAT rule with DNS modification for the FTP server.

a) Select Devices > NAT and create or edit an FTD NAT policy.
b) Click Add Rule.
c) Configure the following properties:
   - NAT Rule = Auto NAT Rule.
• Type = Static.

d) On Interface Objects, configure the following:
   • Source Interface Objects = inside.
   • Destination Interface Objects = outside.

e) On Translation, configure the following:
   • Original Source = ftp_server network object.
   • Translated Source > Address = ftp_server_outside network object.

f) On Advanced, select Translate DNS replies that match this rule.

g) Click OK.

DNS Reply Modification, DNS Server on Host Network

The following figure shows an FTP server and DNS server on the outside. The system has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named inside and outside. To configure interface objects, select Objects > Object Management, then select Interface.

Procedure

**Step 1**

Create the network objects for the FTP server.

a) Choose Objects > Object Management.
b) Select Network from the table of contents and click Add Network > Add Object.
c) Define the real FTP server address.

Name the network object (for example, ftp_server) and enter the host address, 209.165.201.10.
d) Click **Save**.

e) Click **Add Network > Add Object** and define the FTP server's translated address. Name the network object (for example, ftp_server_translated) and enter the host address, 10.1.2.56.

f) Click **Save**.

**Step 2** Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices > NAT** and create or edit an FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = outside.
   - **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:
   - **Original Source** = ftp_server network object.
   - **Translated Source > Address** = ftp_server_translated network object.

f) On **Advanced**, select **Translate DNS replies that match this rule**.

![Add NAT Rule](image)

- **Original Packet**
  - **Original Source**: ftp_server
  - **Original Port**: TCP
- **Translated Packet**
  - **Translated Source > Address**: ftp_server_translated

- **Translated Port**: 

  ![Translated Packet](image)

g) Click **OK**.

<td>You can now use network range objects in Firepower Threat Defense NAT rules where appropriate.</td>
</tr>
<tr>
<td>Carrier Grade NAT enhancements.</td>
<td>6.5</td>
<td>For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). New/Modified screens: We added the <strong>Block Allocation</strong> option to the NAT PAT Pool tab for Firepower Threat Defense NAT rules. Supported platforms: Firepower Threat Defense</td>
</tr>
<tr>
<td>Ability to search and filter the FTD NAT rule table.</td>
<td>6.7</td>
<td>You can now search for rules in an FTD NAT policy to help you find rules based on IP addresses, ports, object names, and so forth. Search results include partial matches. Searching on criteria filters the rule table so only matching rules are displayed. We added a search field above the rule table when you edit an FTD NAT policy.</td>
</tr>
<tr>
<td>Changes to PAT address allocation in clustering. The PAT pool <strong>Flat Port Range</strong> option is now enabled by default and it is not configurable.</td>
<td>6.7</td>
<td>The way PAT addresses are distributed to the members of a cluster is changed. Previously, addresses were distributed to the members of the cluster, so your PAT pool would need a minimum of one address per cluster member. Now, the control unit instead divides each PAT pool address into equal-sized port blocks and distributes them across cluster members. Each member has port blocks for the same PAT addresses. Thus, you can reduce the size of the PAT pool, even to as few as one IP address, depending on the amount of connections you typically need to PAT. Port blocks are allocated in 512-port blocks from the 1024-65535 range. You can optionally included the reserved ports, 1-1023, in this block allocation when you configure PAT pool rules. For example, in a 4-node cluster, each node gets 32 blocks with which it will be able to handle 16384 connections per PAT pool IP address compared to a single node handling all 65535 connections per PAT pool IP address. As part of this change, PAT pools for all systems, whether standalone or operating in a cluster, now use a flat port range of 1023 - 65535. Previously, you could optionally use a flat range by including the <strong>Flat Port Range</strong> option in a PAT pool rule. The <strong>Flat Port Range</strong> option is now ignored: the PAT pool is now always flat. You can optionally select the <strong>Include Reserved Ports</strong> option to include the 1 - 1023 port range within the PAT pool. Note that if you configure port block allocation (the <strong>Block Allocation</strong> PAT pool option), your block allocation size is used rather than the default 512-port block. In addition, you cannot configure extended PAT for a PAT pool for systems in a cluster.</td>

• Access Control Policy Inheritance, on page 1525

Introduction to Access Control

Access control is a hierarchical policy-based feature that allows you to specify, inspect, and log (non-fast-pathed) network traffic.

Each managed device can be targeted by one access control policy. The data that the policy’s target devices collect about your network traffic can be used to filter and control that traffic based on:

• simple, easily determined transport and network layer characteristics: source and destination, port, protocol, and so on
• the latest contextual information on the traffic, including characteristics such as reputation, risk, business relevance, application used, or URL visited
• realm, user, user group, or ISE attribute
• custom Security Group Tag (SGT)
• characteristics of encrypted traffic; you can also decrypt this traffic for further analysis
• whether unencrypted or decrypted traffic contains a prohibited file, detected malware, or intrusion attempt
• time and day (on supported devices)

Each type of traffic inspection and control occurs where it makes the most sense for maximum flexibility and performance. For example, reputation-based blocking uses simple source and destination data, so it can block prohibited traffic early in the process. In contrast, detecting and blocking intrusions and exploits is a last-line defense.

Access Control Policy Default Action

A newly created access control policy directs its target devices to handle all traffic using its default action.
In a simple access control policy, the default action specifies how target devices handle all traffic. In a more complex policy, the default action handles traffic that:

- is not trusted by Intelligent Application Bypass
- is not on a Security Intelligence Block list
- is not blocked by SSL inspection (encrypted traffic only)
- matches none of the rules in the policy (except Monitor rules, which match and log—but do not handle or inspect—traffic)

The access control policy default action can block or trust traffic without further inspection, or inspect traffic for intrusions and discovery data.

You cannot perform file or malware inspection on traffic handled by the default action. Logging for connections handled by the default action is initially disabled, though you can enable it.

If you are using policy inheritance, the default action for the lowest-level descendant determines final traffic handling. Although an access control policy can inherit its default action from its base policy, you cannot enforce this inheritance.

The following table describes the types of inspection you can perform on traffic handled by each default action.

### Table 98: Access Control Policy Default Actions

</table>

The following diagram illustrates the table.
The following diagrams illustrate the **Block All Traffic** and **Trust All Traffic** default actions.

The following diagrams illustrate the **Intrusion Prevention** and **Network Discovery Only** default actions.

---

**Tip**

The purpose of **Network Discovery Only** is to improve performance in a discovery-only deployment. Different configurations can disable discovery if you are only interested in intrusion detection and prevention.

- Performance Considerations for Limited Deployments, on page 510
- Logging Connections with a Policy Default Action, on page 2689

---

**Deep Inspection Using File and Intrusion Policies**

Deep inspection uses intrusion and file policies as the last line of defense before traffic is allowed to its destination.

- **Intrusion policies** govern the system’s intrusion prevention capabilities.
For complete information, see Intrusion Detection and Prevention, on page 1851.

- File policies govern the system’s file control and AMP for Networks capabilities.

For complete information, see File Policies and Malware Protection, on page 1759.

Access control occurs before deep inspection; access control rules and the access control default action determine which traffic is inspected by intrusion and file policies.

By associating an intrusion or file policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule’s conditions, you first want to inspect the traffic with an intrusion policy, a file policy, or both.

In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique pair of intrusion policy and variable set counts as one policy.

To associate intrusion and file policies with an access control rule, see:

- Access Control Rule Configuration to Perform Intrusion Prevention, on page 1890
- Configuring an Access Control Rule to Perform Malware Protection, on page 1767

Note

By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Access Control Traffic Handling with Intrusion and File Policies

The following diagram shows the flow of traffic in an inline intrusion prevention and AMP for Networks deployment, as governed by an access control policy that contains four different types of access control rules and a default action.
In the scenario above, the first three access control rules in the policy—Monitor, Trust, and Block—cannot inspect matching traffic. Monitor rules track and log but do not inspect network traffic, so the system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important exception and caveat at Access Control Rule Monitor Action, on page 1566.) Trust and Block rules handle matching traffic without further inspection of any kind, while traffic that does not match continues to the next access control rule.

The fourth and final rule in the policy, an Allow rule, invokes various other policies to inspect and handle matching traffic, in the following order:

- **Discovery: Network Discovery Policy**—First, the network discovery policy inspects traffic for discovery data. Discovery is passive analysis and does not affect the flow of traffic. Although you do not explicitly enable discovery, you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy.

- **AMP for Networks and File Control: File Policy**—After traffic is inspected by discovery, the system can inspect it for prohibited files and malware. AMP for Networks detects and optionally blocks malware in many types of files, including PDFs, Microsoft Office documents, and others. If your organization wants to block not only the transmission of malware files, but all files of a specific type (regardless of whether the files contain malware), file control allows you to monitor network traffic for transmissions of specific file types, then either block or allow the file.

- **Intrusion Prevention: Intrusion Policy**—After file inspection, the system can inspect traffic for intrusions and exploits. An intrusion policy examines decoded packets for attacks based on patterns, and can block or alter malicious traffic. Intrusion policies are paired with variable sets, which allow you to use named values to accurately reflect your network environment.

- **Destination**—Traffic that passes all the checks described above passes to its destination.

An Interactive Block rule (not shown in the diagram) has the same inspection options as an Allow rule. This is so you can inspect traffic for malicious content when a user bypasses a blocked website by clicking through a warning page.

Traffic that does not match any access control rules in the policy with an action other than Monitor is handled by the default action. In this scenario, the default action is an Intrusion Prevention action, which allows traffic to its final destination as long as it is passed by the intrusion policy you specify. In a different deployment, you might have a default action that trusts or blocks all traffic without further inspection. Note that the system can inspect traffic allowed by the default action for discovery data and intrusions, but not prohibited files or malware. You cannot associate a file policy with the access control default action.

---

**Note**

Sometimes, when a connection is analyzed by an access control policy, the system must process the first few packets in that connection, allowing them to pass, before it can decide which access control rule (if any) will handle the traffic. However, so these packets do not reach their destination uninspected, you can specify an intrusion policy (in the Advanced settings for the access control policy) to inspect these packets and generate intrusion events.

---

**File and Intrusion Inspection Order**

In your access control policy, you can associate multiple Allow and Interactive Block rules with different intrusion and file policies to match inspection profiles to various types of traffic.
Traffic allowed by an Intrusion Prevention or Network Discovery Only default action can be inspected for discovery data and intrusions, but cannot be inspected for prohibited files or malware. You cannot associate a file policy with the access control default action.

You do not have to perform both file and intrusion inspection in the same rule. For a connection matching an Allow or Interactive Block rule:

- without a file policy, traffic flow is determined by the intrusion policy
- without an intrusion policy, traffic flow is determined by the file policy
- without either, allowed traffic is inspected by network discovery only

The system does not perform any kind of inspection on trusted traffic. Although configuring an Allow rule with neither an intrusion nor file policy passes traffic like a Trust rule, Allow rules let you perform discovery on matching traffic.

The diagram below illustrates the types of inspection you can perform on traffic that meets the conditions of either an Allow or user-bypassed Interactive Block access control rule. For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with a single access control rule.

For any single connection handled by an access control rule, file inspection occurs before intrusion inspection. That is, the system does not inspect files blocked by a file policy for intrusions. Within file inspection, simple blocking by type takes precedence over malware inspection and blocking.

For example, consider a scenario where you normally want to allow certain network traffic as defined in an access control rule. However, as a precaution, you want to block the download of executable files, examine downloaded PDFs for malware and block any instances you find, and perform intrusion inspection on the traffic.

You create an access control policy with a rule that matches the characteristics of the traffic you want to provisionally allow, and associate it with both an intrusion policy and a file policy. The file policy blocks the download of all executables, and also inspects and blocks PDFs containing malware:

- First, the system blocks the download of all executables, based on simple type matching specified in the file policy. Because they are immediately blocked, these files are subject to neither malware nor intrusion inspection.
Next, the system performs malware cloud lookups for PDFs downloaded to a host on your network. Any PDFs with a malware disposition are blocked, and are not subject to intrusion inspection.

Finally, the system uses the intrusion policy associated with the access control rule to inspect any remaining traffic, including files not blocked by the file policy.

Note
Until a file is detected and blocked in a session, packets from the session may be subject to intrusion inspection.

Access Control Policy Inheritance

Especially useful in multidomain deployments, you can nest access control policies, where each policy inherits the rules and settings from an ancestor (or base) policy. You can enforce this inheritance, or allow lower-level policies to override their ancestors.

Access control uses a hierarchical policy-based implementation. Just as you create a domain hierarchy, you can create a corresponding hierarchy of access control policies. A descendant, or child, access control policy inherits rules and settings from its direct parent, or base, policy. That base policy may have its own parent policy from which it inherits rules and settings, and so on.

An access control policy’s rules are nested between its parent policy’s Mandatory and Default rule sections. This implementation enforces Mandatory rules from ancestor policies, but allows the current policy to write rules that preempt Default rules from ancestor policies.

You can lock the following settings to enforce them in all descendant policies. Descendant policies can override unlocked settings.

- Security Intelligence — connections that are allowed or blocked based on the latest reputation intelligence for IP addresses, URLs, and domain names.
- HTTP Response pages — Displaying a custom or system-provided response page when you block a user’s website request.
- Advanced settings — Specifying associated subpolicies, network analysis settings, performance settings, and other general options.

When using policy inheritance, the default action for the lowest-level descendant determines final traffic handling. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.

Policy Inheritance and Multitenancy

Access control’s hierarchical policy-based implementation complements multitenancy.

In a typical multidomain deployment, access control policy hierarchy corresponds to domain structure, and you apply the lowest-level access control policy to managed devices. This implementation allows selective access control enforcement at a higher domain level, while lower-level domain administrators can tailor deployment-specific settings. (You must use roles, not policy inheritance and enforcement alone, to restrict administrators in descendant domains.)
For example, as a Global domain administrator for your organization, you can create an access control policy at the Global level. You can then require that all your devices, which are divided into subdomain by function, use that Global-level policy as a base policy.

When subdomain administrators log into the Firepower Management Center to configure access control, they can deploy the Global-level policy as-is. Or, they can create and deploy a descendant access control policy within the boundaries of the Global-level policy.

**Note** Although the most useful implementation of access control inheritance and enforcement complements multitenancy, you can create a hierarchy of access control policies within a single domain. You can also assign and deploy access control policies at any level.

General Best Practices for Access Control

Review the following requirements and general best practices:

• Although you can configure the system without licensing your deployment, many features require that you enable the appropriate licenses before you deploy.

• For the system to affect traffic, you must deploy relevant configurations to managed devices using routed, switched, or transparent interfaces, or inline interface pairs.

Sometimes, the system prevents you from deploying inline configurations to passively deployed devices, including inline devices in tap mode.

In other cases, the policy may deploy successfully, but attempting to block or alter traffic using passively deployed devices can have unexpected results. For example, the system may report multiple beginning-of-connection events for each blocked connection, because blocked connections are not blocked in passive deployments.

• Certain features, including URL filtering, application detection, rate limiting, and Intelligent Application Bypass, must allow some packets to pass in order for the system to identify the traffic.

To prevent these packets from reaching their destination uninspected, see Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2080 and Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2080.

• You cannot perform file or malware inspection on traffic handled by the access control policy's default action.

• Some features are only available on certain device models. Warning icons and confirmation dialog boxes designate unsupported features.

• If you will use syslog or store events externally, avoid special characters in object names such as policy and rule names. Object names should not contain special characters, such as commas, that the receiving application may use as separators.

• Logging for connections handled by the default action is initially disabled, though you can enable it.
Best practices for creating, ordering, and implementing access control rules are detailed in Best Practices for Access Control Rules, on page 1528 and subtopics.

Best Practices for Access Control Rules

Properly configuring and ordering rules is essential to building an effective deployment. The following topics summarize rule performance guidelines.

Note

When you deploy configuration changes, the system evaluates all rules together and creates an expanded set of criteria that target devices use to evaluate network traffic. If these criteria exceed the resources (physical memory, processors, and so on) of a target device, you cannot deploy to that device.

- Best Practices for URL Filtering, on page 1575

Best Practices for Ordering Rules

General guidelines:

- In general, place top-priority rules that must apply to all traffic near the top of the policy.
- Specific rules should come before general rules, especially when the specific rules are exceptions to general rules. Otherwise, traffic will match the general rule first and never hit the applicable specific rule.
- Whenever possible, put specific drop rules near the top of the policy. This ensures the earliest possible decision on undesirable traffic.
- Rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number) should come as early as possible.
- URL filtering rules and application rules and others that require inspection should come after rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number), but before rules that specify file and intrusion policies.
- Put URL filtering rules above application rules, and follow application rules with micro-application rules and Common Industrial Protocol (CIP) sub-classification application filtering rules.
- Rules that specify file policies and intrusion policies should come at the bottom of the rule order. These rules require resource-intensive deep inspection, and you should eliminate as many threats as possible using less-intensive methods first, for performance reasons, in order to minimize the number of potential threats that require deep inspection.
- Always order rules to suit your organization's needs.

Exceptions and additions to the above guidelines are noted in the sections below.
Rule Preemption

Rule preemption occurs when a rule will never match traffic because a rule earlier in the evaluation order matches the traffic first. A rule's conditions govern whether it preempts other rules. In the following example, the second rule cannot block Admin traffic because the first rule allows it:

Access Control Rule 1: allow Admin users
Access Control Rule 2: block Admin users

Any type of rule condition can preempt a subsequent rule. The VLAN range in the first SSL rule includes the VLAN in the second rule, so the first rule preempts the second:

SSL Rule 1: do not decrypt VLAN 22-33
SSL Rule 2: block VLAN 27

In the following example, Rule 1 matches any VLAN because no VLANs are configured, so Rule 1 preempts Rule 2, which attempts to match VLAN 2:

Access Control Rule 1: allow Source Network 10.4.0.0/16
Access Control Rule 2: allow Source Network 10.4.0.0/16, VLAN 2

A rule also preempts an identical subsequent rule where all configured conditions are the same:

QoS Rule 1: rate limit VLAN 1 URL www.netflix.com
QoS Rule 2: rate limit VLAN 1 URL www.netflix.com

A subsequent rule would not be preempted if any condition is different:

QoS Rule 1: rate limit VLAN 1 URL www.netflix.com
QoS Rule 2: rate limit VLAN 2 URL www.netflix.com

Example: Ordering SSL Rules to Avoid Preemption

Consider a scenario where a trusted CA (Good CA) mistakenly issued a CA certificate to a malicious entity (Bad CA), but has not yet revoked that certificate. You want to use an SSL policy to block traffic encrypted with certificates issued by the untrusted CA, but otherwise allow traffic within the trusted CA's chain of trust. After you upload the CA certificates and all intermediate CA certificates, configure an SSL policy with rules in the following order:

SSL Rule 1: Block issuer CN=www.badca.com
SSL Rule 2: Do not decrypt issuer CN=www.goodca.com

If you reverse the rules, you first match all traffic trusted by Good CA, including traffic trusted by Bad CA. Because no traffic ever matches the subsequent Bad CA rule, malicious traffic may be allowed instead of blocked.

Rule Actions and Rule Order

A rule's action determines how the system handles matching traffic. Improve performance by placing rules that do not perform or ensure further traffic handling before the resource-intensive rules that do. Then, the system can divert traffic that it might otherwise have inspected.

The following examples show how you might order rules in various policies, given a set of rules where none is more critical and preemption is not an issue.

If your rules include application conditions, also see Best Practices for Configuring Application Control, on page 535.
Optimum Order: SSL Rules

Not only does decryption require resources, but so does further analysis of the decrypted traffic. Place SSL rules that decrypt traffic last.

Note

Certain managed devices support encrypting and decrypting TLS/SSL traffic in hardware, which significantly improves performance. For more information, see TLS Crypto Acceleration, on page 1666.

1. Monitor—Rules that log matching connections, but take no other action on traffic.
2. Block, Block with reset—Rules that block traffic without further inspection.
3. Do not decrypt—Rules that do not decrypt encrypted traffic, passing the encrypted session to access control rules. The payloads of these sessions are not subject to deep inspection.
4. Decrypt - Known Key—Rules that decrypt incoming traffic with a known private key.
5. Decrypt - Resign—Rules that decrypt outgoing traffic by re-signing the server certificate.

Optimum Order: Access Control Rules

Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Place access control rules that invoke deep inspection last.

1. Monitor—Rules that log matching connections, but take no other action on traffic. (However, see the important exception and caveat at Access Control Rule Monitor Action, on page 1566.)
2. Trust, Block, Block with reset—Rules that handle traffic without further inspection. Note that trusted traffic is subject to authentication requirements imposed by an identity policy, and to rate limiting.
3. Allow, Interactive Block (no deep inspection)—Rules that do not inspect traffic further, but allow discovery. Note that allowed traffic is subject to authentication requirements imposed by an identity policy, and to rate limiting.
4. Allow, Interactive Block (deep inspection)—Rules associated with file or intrusion policies that perform deep inspection for prohibited files, malware, and exploits.

Content Restriction Rule Order

To avoid rule preemption in both SSL and access control policies, position rules governing YouTube restriction above rules governing Safe Search restriction.

When you enable Safe Search for an access control rule, the system adds the search engine category to the Selected Applications and Filters list. This application category includes YouTube. As a result, YouTube traffic matches to the Safe Search rule unless YouTube EDU is enabled in a rule with a higher evaluation priority.

A similar rule preemption occurs if you position an SSL rule with the safesearch supported filter higher in the evaluation order than an SSL rule with specific YouTube application conditions.

Related Topics
   About Content Restriction, on page 1653
Application Rule Order

Rules with application conditions are more likely to match traffic if you move them to a lower order in your list of rules.

Access control rules that use specific conditions (such as networks and IP addresses) should be ordered before rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this Wikipedia article.

For more information and an example, see Best Practices for Configuring Application Control, on page 535 and Best Practices for Application Control, on page 533.

SSL Rule Order

In general, order your rules with specific conditions (such as IP addresses and networks) before rules with general conditions (such as applications).

Allow Traffic from Certificate Pinned Sites

Some applications use a technique referred to as TLS/SSL pinning or certificate pinning, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a TLS/SSL rule with a Decrypt - Resign action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

To confirm that TLS/SSL pinning is occurring, attempt to log in to a mobile application like Facebook. If a network connection error is displayed, log in using a web browser. (For example, you cannot log in to a Facebook mobile application but can log in to Facebook using Safari or Chrome.) You can use Firepower Management Center connection events as further proof of TLS/SSL pinning.

Note

TLS/SSL pinning is not limited to mobile applications.

To allow this traffic, configure an SSL rule with the Do Not Decrypt action to match the server certificate common name or distinguished name. In the SSL policy, order this rule before all Decrypt - Resign rules that also match the traffic. You can retrieve the pinned certificate from the client's browser after a successful connection to the website. You can also view the certificate from the logged connection event, regardless of whether the connection succeeded or failed.

Prioritize ClientHello Modifications

To prioritize ClientHello modifications, place rules that match on conditions that are available in the ClientHello message before rules that match on ServerHello or server Certificate conditions.

When a managed device processes an SSL handshake, it can modify the ClientHello message to increase the likelihood of decryption. For example, it may remove compression methods because the Firepower System cannot decrypt compressed sessions.

The system modifies ClientHello messages only if it can conclusively match them to an SSL rule with either a Decrypt - Resign or Decrypt - Known Key action. The first time the system detects an encrypted session to a new server, server Certificate data is not available for ClientHello processing, which can result in an undecrypted first session. For subsequent connections from the same client, the system can match the
ClientHello message conclusively to rules with server Certificate conditions and process the message to maximize decryption potential.

If you place rules that match on ServerHello or server Certificate conditions (certificate, distinguished names, certificate status, cipher suites, version) before rules that match on ClientHello conditions (zones, networks, VLAN tags, ports, users, applications, URL categories), you can preempt ClientHello modification and increase the number of undecrypted sessions.

**Situation Where SSL Policy is Bypassed**

The SSL policy is bypassed for any connections that match access control rules with actions of Trust, Block, or Block with reset if those rules:

- Use security zone, network, geolocation, and port only as the traffic matching criteria.
- Precede other rules that require inspection, such as rules that match connections based on application or URL, or allow rules that apply intrusion or file inspection.

**URL Rule Order**

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.

If you configure exceptions to a rule, put the exception above the other rule.

**Best Practices for Simplifying and Focusing Rules**

**Simplify: Do Not Overconfigure**

If one condition is enough to match the traffic you want to handle, do not use two.

Minimize individual rule criteria. Use as few individual elements in rule conditions as possible. For example, in network conditions use IP address blocks rather than individual IP addresses.

Combining elements into objects does not improve performance. For example, using a network object that contains 50 individual IP addresses gives you only an organizational—not a performance—benefit over including those IP addresses in the condition individually.

For recommendations related to application detection, see Best Practices for Configuring Application Control, on page 535.

**Focus: Narrowly Constrain Resource-Intensive Rules, Especially by Interface**

As much as possible, use rule conditions to narrowly define the traffic handled by resource-intensive rules. Focused rules are also important because rules with broad conditions can match many different types of traffic, and can preempt later, more specific rules. Examples of resource-intensive rules include:

- SSL rules that decrypt traffic—Not only the decryption, but further analysis of the decrypted traffic, requires resources. Narrow focus, and where possible, block or choose not to decrypt encrypted traffic.
Certain Firepower Management Center models perform SSL encryption and decryption in hardware, which improves performance significantly. For more information, see TLS Crypto Acceleration, on page 1666.

- Access control rules that invoke deep inspection—Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Make sure you only invoke deep inspection where required.

For maximum performance benefit, constrain rules by interface. If a rule excludes all of a device’s interfaces, that rule does not affect that device's performance.

**Maximum Number of Access Control Rules and Intrusion Policies**

The maximum number of access control rules or intrusion policies that are supported by a target device depends on many factors, including policy complexity, physical memory, and the number of processors on the device.

If you exceed the maximum supported by your device, you cannot deploy your access control policy and must reevaluate.

Guidelines for intrusion policies:

In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique pair of intrusion policy and variable set counts as one policy.

You may want to consolidate intrusion policies or variable sets so you can associate a single intrusion policy-variable set pair with multiple access control rules. On some devices you may find you can use only a single variable set for all your intrusion policies, or even a single intrusion policy-variable set pair for the whole device.
Access Control Policies

The following topics describe how to work with access control policies:

- Access Control Policy Components, on page 1536

Access Control Policy Components

Simple Access Control Policy
Inspects all traffic with a balanced intrusion policy

Name and Description

Each access control policy must have a unique name. A description is optional.

Inheritance Settings

Policy inheritance allows you to create a hierarchy of access control policies. A parent (or base) policy defines and enforces default settings for its descendants, which is especially useful in multidomain deployments.

A policy's inheritance settings allow you to select its base policy. You can also lock settings in the current policy to force any descendants to inherit them. Descendant policies can override unlocked settings.

Policy Assignment

Each access control policy identifies the devices that use it. Each device can be targeted by only one access control policy. In a multidomain deployment, you can require that all the devices in a domain use the same base policy.

Rules

Access control rules provide a granular method of handling network traffic. Rules in an access control policy are numbered, starting at 1, including rules inherited from ancestor policies. The system matches traffic to access control rules in top-down order by ascending rule number.
Usually, the system handles network traffic according to the first access control rule where all the rule’s conditions match the traffic. Conditions can be simple or complex, and their use often depends on certain licenses.

**Default Action**

The default action determines how the system handles and logs traffic that is not handled by any other access control configuration. The default action can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data.

Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.

**Security Intelligence**

Security Intelligence is a first line of defense against malicious internet content. This feature allows you to block connections based on the latest IP address, URL, and domain name reputation intelligence. To ensure continual access to vital resources, you can override Block list entries with custom Do Not Block list entries.

**HTTP Responses**

When the system blocks a user’s website request, you can either display a generic system-provided response page, or a custom page. You can also display a page that warns users, but also allows them to continue to the originally requested site.

**Logging**

Settings for access control policy logging allow you to configure default syslog destinations for the current access control policy. The settings are applicable to the access control policy and all the included SSL, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

**Advanced Access Control Options**

Advanced access control policy settings typically require little or no modification. Often, the default settings are appropriate. Advanced settings you can modify include traffic preprocessing, SSL inspection, identity, and various performance options.

Managing Access Control Policies

The Firepower System allows you to edit system-provided access control policies and create custom access control policies.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Procedure

Step 1 Choose Policies > Access Control.

Step 2 Manage access control policies:

- Copy—Click Copy.
- Create—Click New Policy; see Creating a Basic Access Control Policy, on page 1539.
- Delete—Click Delete.
- Deploy—Choose Deploy > Deployment; see Deploy Configuration Changes, on page 495.
- Edit—Click Edit; see Editing an Access Control Policy, on page 1540.
- Inheritance—Click Plus next to a policy with descendants to expand your view of the policy’s hierarchy.
- Import/Export—Click Import/Export; see Configuration Import and Export, on page 261.

Related Topics

Out-of-Date Policies, on page 510

System-Created Access Control Policies

Depending on your devices’ initial configurations, system-provided policies can include:

- Default Access Control—Blocks all traffic without further inspection.
- Default Intrusion Prevention—Allows all traffic, but also inspects with the Balanced Security and Connectivity intrusion policy and default intrusion variable set.
- Default Network Discovery—Allows all traffic while inspecting it for discovery data but not intrusions or exploits.
Creating a Basic Access Control Policy

When you create a new access control policy, you must, at minimum, choose a default action. In most cases, logging of connections handled by a default action is initially disabled. An exception occurs if you create a subpolicy in a multidomain deployment. In that case, the system enables connection logging according to the logging configuration of the inherited default action.

Before you begin
Make sure you've addressed the steps up to this point in Setting Up Basic Policies and Configurations, on page 5.

Procedure

Step 1 Choose Policies > Access Control.
Step 2 Click New Policy.
Step 3 Enter a unique Name and, optionally, a Description.
Step 4 Optionally, choose a base policy from the Select Base Policy drop-down list.
If an access control policy is enforced on your domain, this step is not optional. You must choose the enforced policy or one of its descendants as the base policy.

Step 5 Specify the initial Default Action:

- If you chose a base policy, your new policy inherits its default action. You cannot change it here.
- Block all traffic creates a policy with the Access Control: Block All Traffic default action.
- Intrusion Prevention creates a policy with the Intrusion Prevention: Balanced Security and Connectivity default action, associated with the default intrusion variable set.
- Network Discovery creates a policy with the Network Discovery Only default action.

Tip If you want to trust all traffic by default, or if you chose a base policy and do not want to inherit the default action, you can change the default action later.

Step 6 Optionally, choose the Available Devices where you want to deploy the policy, then click Add to Policy (or drag and drop) to add the selected devices. To narrow the devices that appear, type a search string in the Search field.
If you want to deploy this policy immediately, you must perform this step.

Step 7 Click Save.

What to do next

- Optionally, further configure the new policy as described in Editing an Access Control Policy, on page 1540.
• Optionally, configure TLS server identity in the access control policy’s advanced settings to enable application and URL filtering to perform as expected in TLS 1.3-enabled sessions. For more information, see Access Control Policy Advanced Settings, on page 1546

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Related Topics
Access Control Policy Default Action, on page 1519
Setting Target Devices for an Access Control Policy, on page 1544

Editing an Access Control Policy

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Note
You can only edit access control policies that were created in the current domain. Also, you cannot edit settings that are locked by an ancestor access control policy.

Procedure

Step 1
Choose Policies > Access Control.

Step 2
Click Edit (✓) next to the access control policy you want to edit.

If View (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3
Edit your access control policy.

Tip
You can edit multiple rules at one time by shift-clicking or control-clicking multiple rules, then right-clicking and choosing Edit. Bulk editing is available for enabling and disabling rules, selecting rule action, and setting most inspection and logging settings.

Settings:

• Name and Description—Click either field and enter new information.

• Default Action—Choose a value from the Default Action drop-down list.

• Default Action Variable Set—To change the variable set associated with an Intrusion Prevention default action, click Variables (abı). In the popup window that appears, select a new variable set and click OK. You can also click Edit (✓) to edit the selected variable set in a new window. For more information, see Managing Variables, on page 587.

• Default Action Logging—To configure logging for connections handled by the default action, click Logging (¶); see Logging Connections with a Policy Default Action, on page 2689.
Managing Access Control Policy Inheritance

Before you begin
Understand how inheritance works. See Access Control Policy Inheritance, on page 1525 and subtopics.
**Procedure**

**Step 1** Edit the access control policy whose inheritance settings you want to change; see Editing an Access Control Policy, on page 1540.

**Step 2** Manage policy inheritance:

- Change Base Policy — To change the base access control policy for this policy, click **Inheritance Settings** and proceed as described in Choosing a Base Access Control Policy, on page 1542.
- Lock Settings in Descendants — To enforce this policy's settings in its descendant policies, click **Inheritance Settings** and proceed as described in Locking Settings in Descendant Access Control Policies, on page 1543.
- Required in Domains — To enforce this policy in a subdomain, click **Policy Assignment** and proceed as described in Requiring an Access Control Policy in a Domain, on page 1544.
- Inherit Settings from Base Policy — To inherit settings from a base access control policy, click **Security Intelligence, HTTP Responses, or Advanced** and proceed as directed in Inheriting Access Control Policy Settings from the Base Policy, on page 1543.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

**Choosing a Base Access Control Policy**

<table>
<thead>
<tr>
<th>Smart License</th>
<th>Classic License</th>
<th>Supported Devices</th>
<th>Supported Domains</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>

<td>Any</td>
<td>Any</td>
<td>Any</td>
<td>Admin/Access Admin</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Admin/Network Admin</td>
</tr>
</tbody>
</table>

You can use one access control policy as the base (parent) for another. By default, a child policy inherits its settings from its base policy, though you can change unlocked settings.

When you change the base policy for the current access control policy, the system updates the current policy with any locked settings from the new base policy.

**Procedure**

**Step 1** In the access control policy editor, click **Inheritance Settings**.

**Step 2** Choose a policy from the **Select Base Policy** drop-down list.

In a multidomain deployment, an access control policy may be required in the current domain. You can choose only the enforced policy or one of its descendants as the base policy.

**Step 3** Click **Save**.
What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Inheriting Access Control Policy Settings from the Base Policy**

A new child policy inherits many settings from its base policy. If these settings are unlocked in the base policy, you can override them.

If you later reinherit the settings from the base policy, the system displays the base policy's settings and dims the controls. However, the system saves the overrides you made, and restores them if you disable inheritance again.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>In the access control policy editor, click Security Intelligence, HTTP Responses, or Advanced.</td>
</tr>
<tr>
<td>2</td>
<td>Check the Inherit from base policy check box for each setting you want to inherit.</td>
</tr>
<tr>
<td></td>
<td>If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.</td>
</tr>
<tr>
<td>3</td>
<td>Click Save.</td>
</tr>
</tbody>
</table>

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Locking Settings in Descendant Access Control Policies**

Lock a setting in an access control policy to enforce the setting in all descendant policies. Descendant policies can override unlocked settings.

When you lock settings, the system saves overrides already made in descendant polices so that the overrides can be restored if you unlock settings again.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>In the access control policy editor, click Inheritance Settings.</td>
</tr>
<tr>
<td>2</td>
<td>In the Child Policy Inheritance Settings area, check the settings you want to lock.</td>

<tr>
<td></td>
<td>If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.</td>
</tr>
<tr>
<td>3</td>
<td>Click OK to save the inheritance settings.</td>
</tr>
<tr>
<td>4</td>
<td>Click Save to save the access control policy.</td>
</tr>
</tbody>
</table>
What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Requiring an Access Control Policy in a Domain

You can require that every device in a domain use the same base access control policy or one of its descendant policies.

Before you begin

- Configure at least one domain other than the Global domain.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>In the access control policy editor, click <strong>Policy Assignments</strong>.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Click <strong>Required on Domains</strong>.</td>
</tr>
</tbody>
</table>
| Step 3 | Build your domain list:
  - Add — Select the domains where you want to enforce the current access control policy, then click **Add** or drag and drop into the list of selected domains.
  - Delete — Click **Delete** (🗑️) next to a leaf domain, or right-click an ancestor domain and choose **Delete Selected**.
  - Search — Type a search string in the search field. Click **Clear** (🗑️) to clear the search. |
| Step 4 | Click **OK** to save the domain enforcement settings. |
| Step 5 | Click **Save** to save the access control policy. |

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Setting Target Devices for an Access Control Policy

An access control policy specifies the devices that use it. Each device can be targeted by only one access control policy. In multidomain deployments, you can require that all the devices in a domain use the same base policy.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>In the access control policy editor, click <strong>Policy Assignments</strong>.</td>
</tr>
<tr>
<td>Step 2</td>
<td>On <strong>Targeted Devices</strong>, build your target list:</td>
</tr>
</tbody>
</table>
• Add — Select one or more Available Devices, then click Add to Policy or drag and drop into the list of Selected Devices.

• Delete — Click Delete (🗑️) next to a single device, or select multiple devices, right-click, then choose Delete Selected.

• Search — Type a search string in the search field. Click Clear (❌) to clear the search.

Under Impacted Devices, the system lists the devices whose assigned access control policies are children of the current policy. Any change to the current policy affects these devices.

Step 3 Optionally, click Required on Domains to require that all the devices in the subdomains you choose use the same base policy. See Requiring an Access Control Policy in a Domain, on page 1544.

Step 4 Click OK to save your targeted device settings.

Step 5 Click Save to save the access control policy.

What to do next

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Logging Settings for Access Control Policies

Settings for access control policy logging allow you to configure default syslog destinations and syslog alert for the current access control policy. The settings are applicable to the access control policy and all the included SSL, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

Logging for connections handled by the default action is initially disabled.

Default Syslog Settings

Send using specific syslog alert: If you select this option, the events are sent based on the selected syslog alert as configured using the instruction in Creating a Syslog Alert Response, on page 2516. You can select the syslog alert from the list or add one by specifying the name, logging host, port, facility, and severity. For more information, see Facilities and Severities for Intrusion Syslog Alerts, on page 2527. This option is applicable to all devices.

FTD 6.3 and later: Use the syslog settings configured in the FTD Platform Settings policy deployed on the device: If you select this option and select the severity, connection or intrusion events are sent with the selected severity to syslog collectors configured in Platform Settings. Using this option, you can unify the syslog configuration by configuring it in Platform Settings and reusing the settings in access control policy. Severity selected in this section is applied to all connection and intrusion events. The default severity is ALERT.

This option is applicable only to Firepower Threat Defense devices 6.3 and later.

Note Behavior of the options is altered when both the options are selected. The dynamic Summary section shows the results of your selections.
**File and Malware Settings** are effective only after you have selected an option at the top of the page for sending syslog messages generally.

## Access Control Policy Advanced Settings

Advanced access control policy settings typically require little or no modification. The default settings are appropriate for most deployments. Note that many of the advanced preprocessing and performance options in access control policies may be modified by rule updates as described in *Update Intrusion Rules*, on page 218.

If **View ( )** appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

---

**Caution**

See *Configurations that Restart the Snort Process When Deployed or Activated*, on page 505 for a list of advanced setting modifications that restart the Snort process, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See *Snort® Restart Traffic Behavior*, on page 504 for more information.

---

### General Settings

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Maximum URL characters to store in connection events | To customize the number of characters you store for each URL requested by your users, see *Limiting Logging of Long URLs*, on page 2690.  
To customize the length of time before you re-block a website after a user bypasses an initial block, see *Setting the User Bypass Timeout for a Blocked Website*, on page 1600. |
| Allow an Interactive Block to bypass blocking for (seconds) | See *Setting the User Bypass Timeout for a Blocked Website*, on page 1600.                                                             |
The first time the system encounters a URL that does not have a locally stored category and reputation, it looks up that URL in the cloud and adds the result to the local data store, for faster processing of that URL in future.

This setting determines what the system does when it needs to look up a URL's category and reputation in the cloud.

By default, this setting is enabled: The system momentarily delays the traffic while it checks the cloud for the URL's reputation and category, and uses the cloud verdict to handle the traffic.

If you disable this setting: When the system encounters a URL that is not in its local cache, the traffic is immediately passed and handled according to the rules configured for Uncategorized and reputationless traffic.

In passive deployments, the system does not retry the lookup, as it cannot hold packets.

Disable this option to stop publishing TID data to your configured devices. For more information about TID, see Threat Intelligence Director, on page 1805.

This feature is experimental for release 6.7. Therefore, it may not work as expected; do not use it in production environments.

Enable this option for improved URL filtering performance and efficacy. For details and additional instructions, see DNS Filtering: Identify URL Reputation and Category During DNS Lookup (Beta), on page 1584 and subtopics.

To inspect traffic when you deploy configuration changes unless specific configurations require restarting the Snort process, ensure that Inspect traffic during policy apply is set to its default value (enabled).

When this option is enabled, resource demands could result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Scenarios, on page 502 for more information.

Use advanced settings to associate subpolicies (SSL, identity, prefilter) with access control; see Associating Other Policies with Access Control, on page 1550.
TLS Server Identity Discovery

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate without decrypting the entire packet.

You can enable this feature, referred to as **TLS server identity discovery**, when you either:

- Associate an SSL policy with an access control policy
- Configure advanced settings for an access control policy

To enable TLS server identity discovery, click the **Advanced** tab and select the check box as the following figure shows.

![TLS Server Identity Discovery](image)

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An SSL policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

**Note**

- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.

The following figure shows an example of enabling TLS server identity discovery in an access control policy's advanced settings.
Network Analysis and Intrusion Policies

Advanced network analysis and intrusion policy settings allow you to:

• Specify the intrusion policy and associated variable set that are used to inspect packets that must pass before the system can determine exactly how to inspect that traffic.

• Change the access control policy’s default network analysis policy, which governs many preprocessing options.

• Use custom network analysis rules and network analysis policies to tailor preprocessing options to specific security zones, networks, and VLANs.

For more information, see Advanced Access Control Settings for Network Analysis and Intrusion Policies, on page 2079.

Threat Defense Service Policy

You can use the Threat Defense Service Policy to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. This policy applies to Firepower Threat Defense devices only, and will be ignored for any other device type. The service policy rules are applied after the access control rules. For more information, see Threat Defense Service Policies, on page 1181.

File and Malware Settings

File and Malware Inspection Performance and Storage Tuning, on page 1799 provides information on performance options for file control and AMP for Networks.

Intelligent Application Bypass Settings

Intelligent Application Bypass (IAB) is an expert-level configuration that specifies applications to bypass or test for bypass if traffic exceeds a combination of inspection performance and flow thresholds. For more information, see Intelligent Application Bypass, on page 1645.

Transport/Network Layer Preprocessor Settings

Advanced transport and network preprocessor settings apply globally to all networks, zones, and VLANs where you deploy your access control policy. You configure these advanced settings in an access control
policy rather than in a network analysis policy. For more information, see Advanced Transport/Network Preprocessor Settings, on page 2170.

**Detection Enhancement Settings**

Advanced detection enhancement settings allow you to configure adaptive profiles so you can:

- Use file policies and applications in access control rules.
- Use service metadata in intrusion rules.
- In passive deployments, improve reassembly of packet fragments and TCP streams based on your network’s host operating systems.

For more information, see Adaptive Profiles, on page 2221.

**Performance Settings and Latency-Based Performance Settings**

About Intrusion Prevention Performance Tuning, on page 2063 provides information on improving the performance of your system as it analyzes traffic for attempted intrusions.

For information specific to latency-based performance settings, see Packet and Intrusion Rule Latency Threshold Configuration, on page 2068.

### Associating Other Policies with Access Control

Use an access control policy's advanced settings to associate one of each of the following subpolicies with the access control policy:

- SSL policy—Monitors, decrypts, blocks, or allows application layer protocol traffic encrypted with Secure Socket Layer (SSL) or Transport Layer Security (TLS).

  **Caution**
  
  Adding or removing an SSL policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 504 for more information.

- Identity policy—Performs user authentication based on the realm and authentication method associated with the traffic.

- Prefilter policy—Performs early traffic handling using limited network (layer 4) outer-header criteria.

**Before you begin**

Before associating an SSL policy with an access control policy, review the information about TLS server identity discovery in Access Control Policy Advanced Settings, on page 1546.

**Procedure**

**Step 1**

In the access control policy editor, click Advanced Settings.
Step 2  
Click **Edit (✓)** in the appropriate Policy Settings area. 
If **View (✓)** appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3  
Choose a policy from the drop-down list. 
If you choose a user-created policy, you can click edit that appears to edit the policy.

Step 4  
Click **OK**.

Step 5  
Click **Save** to save the access control policy.

---

What to do next

- Deploy configuration changes; see *Deploy Configuration Changes, on page 495.*

**Viewing Policy Hit Counts**

Hit count indicates the number of times a policy rule has triggered for a matching connection. You can use this information to identify the efficacy of your rules. Hit count information is available only for access control and prefilter rules applied to FTD devices. For supported policies, the hit count information is displayed even for the default action which is set for the policy.

---

**Note**

- If the Firepower Threat Defense device is rebooted, all the hit count information is reset.

- You will not be able to derive the hit count information from a device when deployment or a task is in progress on the device.

---

**Procedure**

Step 1  
Navigate to the access control or prefilter policy page.

Step 2  
Click the policy for which you want to view the hit count information.

Step 3  
On the policy page, click **Analyze Hit Counts** on the top-right of the page.

Step 4  
On the Hit Count page, select the device from the **Select a device** drop-down list.

**Note**  
If it is not the first time that you are generating hit counts for this device, then notice the last fetched hit count information next to the drop-down box. Also, verify the **Last Deployed** time to confirm recent policy changes.

Step 5  
Click **Fetch Current Hit Count** to get the hit count data.
If it is not your first attempt in accessing the hit count information for the selected device, you see Refresh instead of Fetch Current Hit Count. Click Refresh to get the latest hit count information.

**Step 6**
(Optional) Customize the table and the listings within the table by using the Filter Rules/Policy box, or the Filter by and In Last drop-down boxes, along with Cog (Cog).

The Filter by drop-down box provides important filter options like Hit Rules and Never Hit Rules which help in identifying crucial rules. The In Last drop-down box provides options to filter rules based on preset time periods.

**Step 7**
(Optional) Click on a rule name to edit it, or click View (View) in the last column to view the rule details.

Clicking on the rule name highlights it in the policy page where you can edit it.

**Note** If you have accessed the Hit Count page from the Access Control Policy page, you will not be able to view or edit prefilter rules and vice-versa.

**Step 8**
(Optional) Clear the hit count information for a rule by right-clicking the rule and selecting Clear Hit Count.

For clearing hit count information of multiple rules, you can select rules by using Ctrl and selecting Clear Hit Count after right-clicking on one of the selected rules.

**Note** Clearing hit count information will irreversibly set the hit count to zero.

**Step 9**
(Optional) Generate a CSV report of the details on the page by clicking Generate CSV on the bottom-left of the page.

**Step 10**
Click Close to return to the policy page.

---

- Moving Access Control Rules to a Prefilter Policy, on page 1564
- Positioning an Access Control Rule, on page 1566
- Access Control Rule Actions, on page 1566
- Access Control Rule Comments, on page 1569
- History for Access Control Rules, on page 1570

Introduction to Access Control Rules

Within an access control policy, access control rules provide a granular method of handling network traffic across multiple managed devices.

- **Note**

  Security Intelligence filtering, SSL inspection, user identification, and some decoding and preprocessing occur before access control rules evaluate network traffic.

  The system matches traffic to access control rules in the order you specify. In most cases, the system handles network traffic according to the first access control rule where all the rule’s conditions match the traffic.

  Each rule also has an action, which determines whether you monitor, trust, block, or allow matching traffic. When you allow traffic, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

  The following scenario summarizes the ways that traffic can be evaluated by access control rules in an inline, intrusion prevention deployment.
In this scenario, traffic is evaluated as follows:

- **Rule 1: Monitor** evaluates traffic first. Monitor rules track and log network traffic. The system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important exception and caveat at Access Control Rule Monitor Action, on page 1566.)

- **Rule 2: Trust** evaluates traffic next. Matching traffic is allowed to pass to its destination without further inspection, though it is still subject to identity requirements and rate limiting. Traffic that does not match continues to the next rule.

- **Rule 3: Block** evaluates traffic third. Matching traffic is blocked without further inspection. Traffic that does not match continues to the final rule.

- **Rule 4: Allow** is the final rule. For this rule, matching traffic is allowed; however, prohibited files, malware, intrusions, and exploits within that traffic are detected and blocked. Remaining non-prohibited, non-malicious traffic is allowed to its destination, though it is still subject to identity requirements and rate limiting. You can configure Allow rules that perform only file inspection, or only intrusion inspection, or neither.

- **Default Action** handles all traffic that does not match any of the rules. In this scenario, the default action performs intrusion prevention before allowing non-malicious traffic to pass. In a different deployment, you might have a default action that trusts or blocks all traffic, without further inspection. (You cannot perform file or malware inspection on traffic handled by the default action.)

Traffic you allow, whether with an access control rule or the default action, is automatically eligible for inspection for host, application, and user data by the network discovery policy. You do not explicitly enable discovery, although you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy; additionally, application discovery is limited for encrypted sessions.

Note that access control rules handle encrypted traffic when your SSL inspection configuration allows it to pass, or if you do not configure SSL inspection. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.
Access Control Rule Management

The Rules tab of the access control policy editor allows you to add, edit, categorize, search, filter move, enable, disable, delete, and otherwise manage access control rules in the current policy. Use the search bar to filter the list of access control policy rules. To switch between the list of rules that match the filter criteria, and all rules in the current access control policy, click Toggle.

For each access control rule, the policy editor displays its name, a summary of its conditions, the rule action, and icons that communicate the rule’s inspection options or status. These icons represent:

- Time Range Option
- Intrusion policy
- File policy
- Safe search
- YouTube EDU
- Logging
- Original Client option
- Comment
- Warning
- Errors
- Important Information

Disabled rules are dimmed and marked (disabled) beneath the rule name.

To create or edit a rule, use the access control rule editor. You can:

- Configure basic properties such as the rule’s name, state, position, and action in the upper portion of the editor.
- Add conditions using the tabs on the left side of the lower portion of the editor.
- Use the tabs on the right side of the lower portion to configure inspection and logging options, and also to add comments to the rule. For your convenience, the editor lists the rule’s inspection and logging options regardless of which tab you are viewing.

---

**Note**

Properly creating and ordering access control rules is a complex task, but one that is essential to building an effective deployment. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the access control policy interface has a robust warning and error feedback system for rules.
Access Control Rule Components

In addition to its unique name, each access control rule has the following basic components:

State
By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Position
Rules in an access control policy are numbered, starting at 1. If you are using policy inheritance, rule 1 is the first rule in the outermost policy. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

Rules can also belong to a section and a category, which are organizational only and do not affect rule position. Rule position goes across sections and categories.

Section and Category
To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize access control rules, you can create custom rule categories inside the Mandatory and Default sections.

If you are using policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default sections.

Conditions
Conditions specify the specific traffic the rule handles. Conditions can be simple or complex; their use often depends on license.

Traffic must meet all of the conditions specified in all of the tabs in a rule. For example, if the Applications tab specifies HTTP but not HTTPS, the URL category and reputation conditions in the URLs tab will not apply to HTTPS traffic.

Applicable Time
You can specify days and times during which a rule is applicable.

Action
A rule’s action determines how the system handles matching traffic. You can monitor, trust, block, or allow (with or without further inspection) matching traffic. The system does not perform deep inspection on trusted, blocked, or encrypted traffic.
Inspection

Deep inspection options govern how the system inspects and blocks malicious traffic you would otherwise allow. When you allow traffic with a rule, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

Logging

A rule’s logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. In general, you can log sessions at the beginning or end of a connection, or both. You can log connections to the database, as well as to the system log (syslog) or to an SNMP trap server.

Comments

Each time you save changes to an access control rule, you can add comments.

- Access Control Rule Comments, on page 1569

Access Control Rule Order

Rules in an access control policy are numbered, starting at 1. The system matches traffic to access control rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the first access control rule where all the rule’s conditions match the traffic. Except for Monitor rules, the system does not continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule.

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize, you can create custom rule categories inside the Mandatory or Default sections. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The system assigns rule numbers across sections and categories.

If you use policy inheritance, the current policy’s rules are nested between its parent policy’s Mandatory and Default rule sections. Rule 1 is the first rule in the outermost policy, not the current policy, and the system assigns rule numbers across policies, sections, and categories.

Any predefined user role that allows you to modify access control policies also allows you to move and modify access control rules within and among rules categories. You can, however, create custom roles that restrict users from moving and modifying rules. Any user who is allowed to modify access control policies can add rules to custom categories and modify rules in them without restriction.
Proper access control rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

Adding an Access Control Rule Category

You can divide an access control policy's Mandatory and Default rule sections into custom categories. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The system assigns rule numbers across sections and categories.

Procedure

Step 1
In the access control policy editor, click Add Category.

Tip
If your policy already contains rules, you can click a blank area in the row for an existing rule to set the position of the new category before you add it. You can also right-click an existing rule and select Insert new category.

Step 2
Enter a Name.

Step 3
From the Insert drop-down list, choose where you want to add the category:
- To insert a category below all existing categories in a section, choose into Mandatory or into Default.
- To insert a category above an existing category, choose above category, then choose a category.
To insert a category above or below an access control rule, choose **above rule** or **below rule**, then enter an existing rule number.

**Step 4**
Click **OK**.

**Step 5**
Click **Save** to save the policy.

---

### What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

## Create and Edit Access Control Rules

If you edit an access control rule that is actively in use, the changes do not apply to established connections at deploy-time. The updated rule is used to match against future connections. However, if the system is actively inspecting a connection (for example, with an intrusion policy), it **will** apply changed matching or action criteria to existing connections.

For Firepower Threat Defense, you can ensure that your changes apply to all current connections by using the FTD `clear conn` CLI command to end established connections. Note that you should only do this if it is OK to end those connections, on the assumption that the sources for the connections will then attempt to reestablish the connection and thus be matched appropriately against the new rule.

### Procedure

**Step 1**
In the access control policy editor, you have the following options:

- To add a new rule, click **Add Rule**.
- To edit an existing rule, click **Edit** (✓).
- To edit multiple rules, shift-click a range of rules or control-click multiple rules to edit, then right-click and choose an option.

If **View** (▶️) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

**Step 2**
If this is a new rule, enter a **Name**.

**Step 3**
Configure the rule components, or accept the defaults.

If you are bulk-editing multiple rules, only a subset of options are available.

- **Enabled**—Specify whether the rule is **Enabled**.
- **Position**—Specify the rule position; see Access Control Rule Order, on page 1559.
- **Action**—Choose a rule **Action**; see Access Control Rule Actions, on page 1566.

**Note**
VLAN tags in access rules only apply to inline sets; they cannot be used in access rules applied to firewall interfaces.
• Time Range—(Supported on FTD devices only) Add or choose the days and times when the rule is applicable. For details, see Creating Time Range Objects, on page 574.

• Conditions—Click the corresponding condition you want to add. See Rule Condition Types, on page 517 for more information.

• Deep Inspection—For Allow and Interactive Block rules, click Intrusion policy (畿) or File policy (푀) to configure the rule’s Inspection options. If the option is dimmed, no policy of that type is selected for the rule. See Understanding Access Control, on page 1519 for more information.

• Content Restriction—Click Safe search ( gode) or YouTube EDU (도) to configure content restriction settings on Applications of the rule editor. If the option are dimmed, content restriction is disabled for the rule. See About Content Restriction, on page 1653 for more information.

• Logging—Click Logging ( jab) to specify Logging options. If the option is dimmed, connection logging is disabled for the rule. See Best Practices for Connection Logging, on page 2684 for more information.

• Comments—Click the number in the comment column to add Comments. The number indicates how many comments the rule already contains. See Access Control Rule Comments, on page 1569 for more information.

Step 4 Save the rule.
Step 5 Click Save to save the policy.

What to do next
If you will deploy time-based rules, specify the time zone of the device to which the policy is assigned. See Configure Device Time Zone for Policy Application, on page 1387.
Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Related Topics
Best Practices for Access Control Rules, on page 1528

Enabling and Disabling Access Control Rules

When you create an access control rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing the list of rules in an access control policy, disabled rules are grayed out, although you can still modify them.

Tip You can also enable or disable an access control rule using the rule editor.

Procedure

Step 1 In the access control policy editor, right-click the rule and choose a rule state.
If View (👁) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

**Step 2**
Click **Save**.

---

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Related Topics**

Access Control Rule Components, on page 1558

---

### Copying Access Control Rules from One Access Control Policy to Another

You can copy access control rules from one access control policy to another. You can copy the rules either to the **Default** section or the **Mandatory** section of the access control policy.

**Before you begin**

Note the following conditions before you proceed:

- All the settings of the copied rules, except the comments, are retained in the pasted version. However, a new comment is added in the copied rule mentioning the source access control policy.

**Procedure**

**Step 1**
In the access control policy editor, select the rules that you want to copy with a left-click on your mouse.

**Tip**
To select multiple rules, use the Ctrl (Control) key on your keyboard.

**Step 2**
Right-click the selected rules and choose **Copy to > Another policy**.

**Step 3**
Select the destination access control policy from the **Access Policy** drop-down list.

**Step 4**
From the **Place Rules** drop-down list, choose where you want to position the copied rules:

- To position as the last set of rules in the **Default** section, choose **At the bottom (within the Default section)**.
- To position as the first set of rules in the **Mandatory** section, choose **At the top (within the Mandatory section)**.

**Step 5**
Click **Copy**.

---

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Moving Access Control Rules to a Prefilter Policy

You can move access control rules from an access control policy to the associated prefilter policy.

Before you begin

Note the following conditions before you proceed:

- When moving an access control rule to a prefilter policy the layer 7 (L7) parameters in the access control rule cannot be moved. The L7 parameters are dropped during the operation.

- The comments in the access control rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source access control policy.

- You cannot move access control rules with Monitor set as the Action parameter.

- The Action parameter in the access control rule is changed to a suitable action in the prefilter rule when moved. To know what each action in the access control rule maps to, see the following table:

<table>
<thead>
<tr>
<th>Action in the access control rule</th>
<th>Action in the prefilter rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow</td>
<td>Analyze</td>
</tr>
<tr>
<td>Block</td>
<td>Block</td>
</tr>
<tr>
<td>Block with reset</td>

- The access control rules cannot be moved to the default prefilter policy since the default prefilter policy cannot have rules.
- While moving rules from the source policy, if another user modifies those rules, the FMC displays a message. You may continue with the process after refreshing the page.

**Procedure**

**Step 1** In the access control policy editor, select the rules that you want to move with a left-click on your mouse.

**Tip** To select multiple rules, use the Ctrl (Control) key on your keyboard.

**Step 2** Right-click the selected rules and choose **Move to another policy**.

**Step 3** From the **Place Rules** drop-down list, choose where you want to position the moved rules:

- To position as the last set of rules, choose **At the bottom**.
- To position as the first set of rules, choose **At the top**.

**Step 4** Click **Move**.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Positioning an Access Control Rule

You can move an existing rule within an access control policy. When you add or move a rule to a category, the system places it last in the category.

Tip
You can move multiple rules at once by selecting the rules then cutting and pasting using the right-click menu.

Before you begin

Procedure

Step 1
In the access control rule editor, you have the following options:
- If you are adding a new rule, use the Insert drop-down list.
- If you are editing an existing rule, click Move.

Step 2
Choose where you want to move or insert the rule:
- Choose into Mandatory or into Default.
- Choose a into Category, then choose the user-defined category.
- Choose above rule or below rule, then type the appropriate rule number.

Step 3
Click Save.

Step 4
Click Save to save the policy.

What to do next
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Access Control Rule Actions

Every access control rule has an action that determines how the system handles and logs matching traffic. You can monitor, trust, block, or allow (with or without further inspection).

The access control policy’s default action handles traffic that does not meet the conditions of any access control rule with an action other than Monitor.

Access Control Rule Monitor Action

The Monitor action is not designed to permit or deny traffic. Rather, its primary purpose is to force connection logging, regardless of how matching traffic is eventually handled.
If a connection matches a Monitor rule, the next non-Monitor rule that the connection matches should determine traffic handling and any further inspection. If there are no additional matching rules, the system should use the default action.

There is an exception, however. If a Monitor rule contains layer 7 conditions—such as an application condition—the system allows early packets to pass and the connection to be established (or the SSL handshake to complete). This occurs even if the connection should be blocked by a subsequent rule; this is because these early packets are not evaluated against subsequent rules. So that these packets do not reach their destination completely un inspected, you can specify an intrusion policy for this purpose in the access control policy’s Advanced settings; see Inspection of Packets That Pass Before Traffic Is Identified, on page 2080. After the system completes its layer 7 identification, it applies the appropriate action to the remaining session traffic.

Caution

As a best practice, avoid placing layer 7 conditions on broadly-defined monitor rules high in your rule priority order, to prevent inadvertently allowing traffic into your network. Also, if locally bound traffic matches a Monitor rule in a Layer 3 deployment, that traffic may bypass inspection. To ensure inspection of the traffic, enable Inspect Local Router Traffic in the advanced device settings for the managed device routing the traffic.

Related Topics
Logging for Monitored Connections, on page 2678

Access Control Rule Trust Action

The Trust action allows traffic to pass without deep inspection or network discovery. Trusted traffic is still subject to identity requirements and rate limiting.

Note

Some protocols, such as FTP and SIP, use secondary channels, which the system opens through the process of inspection. In some cases, trusted traffic can bypass all inspection, and these secondary channels cannot be opened properly. If you run into this problem, change the trust rule to Allow.

Related Topics
Logging for Trusted Connections, on page 2678

Access Control Rule Blocking Actions

The Block and Block with reset actions deny traffic without further inspection of any kind.
Block with reset rules reset the connection, with the exception of web requests met with an *HTTP response page*. This is because the response page, which you configure to appear when the system blocks web requests, cannot display if the connection is immediately reset. For more information, see *HTTP Response Pages and Interactive Blocking*, on page 1597.

Related Topics

- Logging for Blocked Connections, on page 2679
- About HTTP Response Pages, on page 1597

**Access Control Rule Interactive Blocking Actions**

For more information, see *HTTP Response Pages and Interactive Blocking*, on page 1597.

If a user bypasses the block, the rule mimics an allow rule. Therefore, you can associate interactive block rules with file and intrusion policies, and matching traffic is also eligible for network discovery.

If a user does not (or cannot) bypass the block, the rule mimics a block rule. Matching traffic is denied without further inspection.

Note that if you enable interactive blocking, you cannot reset *all* blocked connections. This is because the response page cannot display if the connection is immediately reset. Use the *Interactive Block with reset* action to (non-interactively) block-with-reset all non-web traffic, while still enabling interactive blocking for web requests.

For more information, see *HTTP Response Pages and Interactive Blocking*, on page 1597.

Related Topics

- Logging for Allowed Connections, on page 2680
- TLS/SSL Rule Blocking Actions, on page 1716
Access Control Rule Allow Action

The Allow action allows matching traffic to pass, though it is still subject to identity requirements and rate limiting.

Optionally, you can use deep inspection to further inspect and block unencrypted or decrypted traffic before it reaches its destination:

- You can use an intrusion policy to analyze network traffic according to intrusion detection and prevention configurations, and drop offending packets depending on the configuration.
- You can perform file control using a file policy. File control allows you to detect and block your users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols.
- You can perform network-based advanced malware protection (AMP), also using a file policy. AMP for Networks can inspect files for malware, and block detected malware depending on the configuration.

The following diagram illustrates the types of inspection performed on traffic that meets the conditions of an Allow rule (or a user-bypassed Interactive Block rule). Notice that file inspection occurs before intrusion inspection; blocked files are not inspected for intrusion-related exploits.

![Diagram showing traffic flow for situations where both (or neither) an intrusion and a file policy are associated with an access control rule. The diagram includes options for traffic blocked, intrusion inspection, file inspection, discovery, passed by intrusion policy, dropped by intrusion policy, and no policies.]

For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with an access control rule. You can, however, configure one without the other. Without a file policy, traffic flow is determined by the intrusion policy; without an intrusion policy, traffic flow is determined by the file policy.

Regardless of whether the traffic is inspected or dropped by an intrusion or file policy, the system can inspect it using network discovery. However, allowing traffic does not automatically guarantee discovery inspection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy; additionally, application discovery is limited for encrypted sessions.

Access Control Rule Comments

When you create or edit an access control rule, you can add a comment. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the
change. You can display a list of all comments for a rule along with the user who added each comment and
the date the comment was added.

When you save a rule, all comments made since the last save become read-only.

To search access control rule comments, use the "Search Rules" bar on the rule listing page. See Searching
for Rules, on page 546.

URL Filtering Overview

Use the URL filtering feature to control the websites that users on your network can access:

- Category and reputation-based URL filtering—With a URL Filtering license, you can control access to websites based on the URL’s general classification (category) and risk level (reputation). This is the recommended option.

- Manual URL filtering—With any license, you can manually specify individual URLs, groups of URLs, and URL lists and feeds to achieve granular, custom control over web traffic. For more information, see Manual URL Filtering, on page 1586.

See also Blocking Traffic with Security Intelligence, on page 1603, a similar but different feature for blocking malicious URLs, domains, and IP addresses.

About URL Filtering with Category and Reputation

With a URL Filtering license, you can control access to websites based on the category and reputation of requested URLs:

- Category—A general classification for the URL. For example, ebay.com belongs to the Auctions category, and monster.com belongs to the Job Search category.

A URL can belong to more than one category.
• Reputation—How likely the URL is to be used for purposes that might be against your organization’s security policy. Reputations range from Unknown risk (level 0) or Untrusted (level 1) to Trusted (level 5).

Benefits of Category and Reputation-Based URL Filtering

URL categories and reputations help you quickly configure URL filtering. For example, you can use access control to block untrusted URLs in the Hacking category. Or, you can use QoS to rate limit traffic from sites in the Streaming Video category. There are also categories for types of threats, such as a Spyware and Adware category.

Using category and reputation data simplifies policy creation and administration. It grants you assurance that the system controls web traffic as expected. Because Cisco continually updates its threat intelligence with new URLs, as well as new categories and risks for existing URLs, the system uses up-to-date information to filter requested URLs. Sites that (for example) represent security threats, or that serve undesirable content, may appear and disappear faster than you can update and deploy new policies.

Some examples of how the system can adapt include:

• If an access control rule blocks all gaming sites, as new domains get registered and classified as Games, the system can block those sites automatically. Similarly, if a QoS rule rate limits all streaming video sites, the system can automatically limit traffic to new Streaming Video sites.

• If an access control rule blocks all malware sites and a shopping page gets infected with malware, the system can recategorize the URL from Shopping to Malware Sites and block that site.

• If an access control rule blocks untrusted social networking sites and somebody posts a link on their profile page that contains links to malicious payloads, the system can change the reputation of that page from Favorable to Untrusted and block it.

URL Category and Reputation Descriptions

Category Descriptions
A description of each URL category is available from https://www.talosintelligence.com/categories. Be sure to click Threat Categories to see those categories.

Reputation Level Descriptions
Go to https://talosintelligence.com/reputation_center/support and look in the Common Questions section.

URL Filtering Data from the Cisco Cloud

URL filtering based on category and reputation requires a data set provided by the Cisco cloud.

Generally, by default, when a valid URL Filtering license is applied to an active device, the URL category and reputation data set is downloaded from the Cisco cloud to the Firepower Management Center and pushed to devices. This locally stored data set is updated periodically.

When a user on the network accesses a URL, the system looks for a match in the local (downloaded) data set. If there is no match, the system checks a cache of results that the system previously looked up in the Cisco cloud.
cloud. If there is still no match, the system looks up the URL in the Cisco cloud and adds the result to the cache.

The set of URL categories may change periodically. When you receive notification of such changes, you should review the URL rules in your policies to see if you need to make changes. For more information, see If the URL Category Set Changes, Take Action, on page 1589.

Best Practices for URL Filtering

Keep in mind the following guidelines and limitations for URL filtering:

Filter by Category and Reputation

Follow the instructions in How to Configure URL Filtering with Category and Reputation, on page 1579.

Configure Your Policy to Inspect Packets That Must Pass Before a URL Can Be Identified

The system cannot filter URLs before:

- A monitored connection is established between a client and server.
- The system identifies the DNS, HTTP or HTTPS application in the session.
- The system identifies the requested domain or URL (for encrypted sessions, from a non-encrypted domain name, the ClientHello message or the server certificate).

This identification should occur within 3 to 5 packets, or after the server certificate exchange in the TLS/SSL handshake if the traffic is encrypted.

Important! To ensure that your system examines these initial packets that would otherwise pass, see Inspection of Packets That Pass Before Traffic Is Identified, on page 2080 and subtopics.

If early traffic matches all other rule conditions but identification is incomplete, the system allows the packet to pass and the connection to be established (or the TLS/SSL handshake to complete). After the system completes its identification, the system applies the appropriate rule action to the remaining session traffic.

Block Threat Categories

Be sure that your policies specifically address Threat categories, which identify known malicious sites. Do this in addition to blocking sites with poor reputations.

For example, to protect your network from malicious sites, you must block all Threat categories in addition to blocking sites with poor or questionable reputations.

For specifics, see Threat Categories at the URL in URL Category and Reputation Descriptions, on page 1574.

URL Conditions and Rule Order

- Position URL rules after all other rules that must be hit.
- URLs can belong to more than one category. It is possible to want to allow one category of websites and block another—whether explicitly or by relying on the default action. In this case, make sure you create and order URL rules so you get the desired effect, depending on whether the allow or the block should take precedence.
For additional guidelines for rules, see the following topics: Best Practices for Access Control Rules, on page 1528 and Rule Condition Mechanics, on page 519.

Uncategorized or Reputationless URLs

When you build a URL rule, you first choose the category you want to match. If you explicitly choose Uncategorized URLs, you cannot further constrain by reputation.

Uncategorized URLs with Untrusted reputation are handled by the Malicious Sites category. If you want to block uncategorized sites with any other reputation level (such as Questionable), you must block all uncategorized sites.

After selecting a category and a reputation level, you can optionally select Apply to unknown reputation. For example, you can create a rule that applies to sites with Untrusted, Questionable, and unknown reputations.

You cannot manually assign categories and reputations to URLs, but in access control and QoS policies, you can manually block specific URLs. See Manual URL Filtering, on page 1586. See also Dispute URL Category and Reputation, on page 1588.

URL Filtering for Encrypted Web Traffic

When performing URL filtering on encrypted web traffic, the system:

- (If DNS filtering is enabled) Checks to see if the system has previously seen the originating domain or the domain is in the local reputation database, and if so, takes action based on the reputation and category of the domain. Otherwise, the system processes the traffic based on your configurations for encrypted traffic, even if Retry URL cache miss lookup is enabled in the access control policy's advanced settings.
- Disregards the encryption protocol; a rule matches both HTTPS and HTTP traffic if the rule has a URL condition but not an application condition that specifies the protocol.
- Does not use URL lists. You must use URL objects and groups instead.
- Matches HTTPS traffic based on the subject common name in the public key certificate used to encrypt the traffic, and also evaluates the reputation of any other URLs presented at any time during the transaction, including the post-decryption HTTP URL.
- Disregards subdomains within the subject common name.
- Does not display an HTTP response page for encrypted connections blocked by access control rules (or any other configuration); see Limitations to HTTP Response Pages, on page 1597.

URL Filtering and TLS Server Identity Discovery

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate without decrypting the entire packet.

Access control policy advanced settings offer an Early application detection and URL categorization option for TLS Server Identity Discovery.

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An SSL policy is not required because traffic is not decrypted in the process of extracting the server certificate.
Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.

- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.

For more information, see Access Control Policy Advanced Settings, on page 1546.

**HTTP/2**

The system can extract HTTP/2 URLs from TLS certificates, but not from a payload.

**Manual URL Filtering**

- Specify URLs using a custom Security Intelligence list or feed object. Do not use a URL object or directly enter a URL into the rule. For details, see Manual URL Filtering Options, on page 1586.

- If you manually filter specific URLs using URL objects or by entering URLs directly into the rule, carefully consider other traffic that might be affected. To determine whether network traffic matches a URL condition, the system performs a simple substring match. If the requested URL matches any part of the string, the URLs are considered to match.

- If you use manual URL filtering to create exceptions to other rules, position the specific rule with the exceptions above the general rule that would otherwise apply.

**Search Query Parameters in URLs**

The system does not use search query parameters in the URL to match URL conditions. For example, consider a scenario where you block all shopping traffic. In that case, using a web search to search for amazon.com is not blocked, but browsing to amazon.com is.

**URL Filtering in High Availability Deployments**

For guidelines for URL filtering with Firepower Management Centers in high availability, see URL Filtering and Security Intelligence, on page 297.

**Memory Limitations for Selected Device Models**

- If you are using NGIPS, see the Cisco Firepower NGIPSv Quick Start Guide for VMware for information on allocating the correct amount of memory to perform category and reputation-based URL filtering.

- Device models with less memory store less URL data locally, and the system may therefore check the cloud more frequently to determine category and reputation for sites that are not in the local database.

  Lower-memory devices include:
  - FTD 1010
  - Virtual FTD (FTDv) with 8 GB of RAM
  - ASA 5508-X and ASA 5516-X
Filtering HTTPS Traffic

To filter encrypted traffic, the system determines the requested URL based on information passed during the TLS/SSL handshake: the subject common name in the public key certificate used to encrypt the traffic.

HTTPS filtering, unlike HTTP filtering, disregards subdomains within the subject common name. Do not include subdomain information when manually filtering HTTPS URLs in access control or QoS policies. For example, use example.com rather than www.example.com.

Tip

In an SSL policy, you can handle and decrypt traffic to specific URLs by defining a distinguished name SSL rule condition. The common name attribute in a certificate’s subject distinguished name contains the site’s URL. Decrypting HTTPS traffic allows access control rules to evaluate the decrypted session, which improves URL filtering.

Controlling Traffic by Encryption Protocol

The system disregards the encryption protocol (HTTP vs HTTPS) when performing URL filtering in access control or QoS policies. This occurs for both manual and reputation-based URL conditions. In other words, URL filtering treats traffic to the following websites identically:

- http://example.com/
- https://example.com/

To configure a rule that matches only HTTP or HTTPS traffic, add an application condition to the rule. For example, you could allow HTTPS access to a site while disallowing HTTP access by constructing two access control rules, each with an application and URL condition.

The first rule allows HTTPS traffic to the website:

Action: Allow
Application: HTTPS
URL: example.com

The second rule blocks HTTP access to the same website:

Action: Block
Application: HTTP
URL: example.com

License Requirements for URL Filtering

FTD License

- Category and reputation filtering—URL Filtering
- Manual filtering—No additional license.
Classic License

- Category and reputation filtering—URL Filtering
- Manual filtering—No additional license.

</table>
Enable URL Filtering Using Category and Reputation

You must be an Admin user to perform this task.

Before you begin

Complete prerequisites described in How to Configure URL Filtering with Category and Reputation, on page 1579.

Procedure

1. Choose System > Integration.
2. Click Cloud Services.
3. Configure URL Filtering Options, on page 1581.
4. Click Save.

URL Filtering Options

The following options are on the System > Integration page:

Enable URL Filtering

Allows traffic filtering based on a website’s general classification, or category, and risk level, or reputation. Adding a URL Filtering license automatically enables Enable URL Filtering. URL filtering must be enabled before you can choose other URL filtering options.

When you enable URL filtering, depending on how long since URL filtering was last enabled, or if this is the first time you are enabling URL filtering, the Firepower Management Center downloads URL data from the Cisco cloud. This process may take some time.

Enable Automatic Updates

Options for updating URL filtering threat data:

- If you enable the Enable Automatic Updates option on the System > Integration page, the Firepower Management Center checks the cloud every 30 minutes for updates. This option is enabled by default when you add a URL filtering license.

- If you need strict control over when the system contacts external resources, disable automatic updates on this page and instead create a recurring task using the scheduler. See Automating URL Filtering Updates Using a Scheduled Task, on page 283.

Update Now

You can perform a one-time, on-demand update by clicking the Update Now button at the top of this dialog box, but you should also either enable automatic updates or create a recurring task using the scheduler. You cannot start an on-demand update if an update is already in progress.
Although daily updates tend to be small, if it has been more than five days since your last update, new URL data may take up to 20 minutes to download, depending on your bandwidth. Then, it may take up to 30 minutes to perform the update itself.

**Query Cisco Cloud for Unknown URLs**

Allows the system to submit URLs to the cloud for threat intelligence evaluation when users browse to a website whose category and reputation are not in the local dataset. Disable this option if you do not want to submit your uncategorized URLs, for example, for privacy reasons.

This option is enabled by default if at least one managed device has a valid URL Filtering license.

Connections to uncategorized URLs do **not** match rules with category or reputation-based URL conditions. You cannot assign categories or reputations to URLs manually.

If you use SSL rules to handle encrypted traffic, see also **TLS/SSL Rule Guidelines and Limitations**, on page 1699.

**Cached URLs Expire**

This setting is relevant only if **Query Cisco Cloud for Unknown URLs** is enabled.

Caching category and reputation data makes web browsing faster. By default, cached data for URLs never expires, for fastest performance.

To minimize instances of URLs matching on stale data, you can set URLs in the cache to expire. For greater accuracy and currency of threat data, choose a shorter expiration time.

A cached URL refreshes *after* the first time a user on the network accesses it after the specified time has passed. The first user does not see the refreshed result, but the next user who visits this URL does see the refreshed result.

For more information about caching of URL data, see **URL Filtering Data from the Cisco Cloud**, on page 1574.

### Configuring URL Conditions

Protect your network by controlling access to sites based on URL category and reputation.

**Procedure**

**Step 1**

In the rule editor, click the following for URL conditions:

- Access control or QoS—Click **URLs**.
- SSL—Click **Category**.

**Step 2**

Find and choose the URL categories that you want to control:

In an access control or QoS rule, click **Category**.

For effective protection from malicious sites, you must block URLs in all Threat categories in addition to blocking URLs with poor or questionable reputation. For a list of Threat categories, see **URL Category and Reputation Descriptions**, on page 1574.

Be sure to click the arrows at the bottom of the list to see all available categories.
Step 3  
(Optional) Constrain URL categories by choosing a **Reputation**.

Note that if you explicitly match **Uncategorized** URLs, you cannot further constrain by reputation. Choosing a reputation level also includes other reputations either more or less severe than the level you choose, depending on the rule action:

- Includes less severe reputations—If the rule allows or trusts web traffic. For example, if you configure an access control rule to allow Favorable (level 4), it also automatically allows Trusted (level 5) sites.

- Includes more severe reputations—If the rule rate limits, decrypts, blocks, or monitors web traffic. For example, if you configure an access control rule to block Questionable sites (level 2), it also blocks Untrusted (level 1) sites.

If you change the rule action, the system automatically changes the reputation levels in URL conditions.

Optionally, select **Apply to unknown reputation**.

Step 4  
Click **Add to Rule**, or drag and drop.

Step 5  
Save or continue editing the rule.

---

**Example: URL Condition in an Access Control Rule**

The following graphic shows the URL condition for an access control rule that blocks all malware sites, all Untrusted sites, and all social networking sites with a reputation level of Neutral or worse.

<table>
<thead>
<tr>
<th>Selected URLs (3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any (Except Uncategorized) (Reputation 1)</td>
</tr>
<tr>
<td>Malware Sites (Any reputation)</td>
</tr>
<tr>
<td>Social Networking (Reputations 1-3)</td>
</tr>
</tbody>
</table>

The following table summarizes how you build the condition.

<table>
<thead>
<tr>
<th>Blocked URL</th>
<th>Category</th>
<th>Reputation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Malware sites, regardless of reputation</td>
<td>Malware Sites</td>
<td>Any</td>
</tr>
<tr>
<td>Any untrusted URL (level 1)</td>
<td>Any</td>
<td>1 - Untrusted</td>
</tr>
<tr>
<td>Social networking sites with a reputation level of Neutral or worse (levels 1 through 3)</td>
<td>Social Network</td>
<td>3 - Neutral</td>
</tr>
</tbody>
</table>

**What to do next**

- (Optional) Supplement or Selectively Override Category and Reputation-Based URL Filtering, on page 1587

- Return to How to Configure URL Filtering with Category and Reputation, on page 1579.
• If you are done making changes, Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Rules with URL Conditions

The following table lists rules that support URL conditions, and the types of filtering that each rule type supports.

<table>
<thead>
<tr>
<th>Rule Type</th>
<th>Supports Category and Reputation Filtering?</th>
<th>Supports Manual Filtering?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access control</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>SSL</td>
<td>Yes</td>
<td>No; use distinguished name conditions instead</td>
</tr>
<tr>
<td>QoS</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

URL Rule Order

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

• They include application conditions.
• The traffic to be inspected is encrypted.

If you configure exceptions to a rule, put the exception above the other rule.

DNS Filtering: Identify URL Reputation and Category During DNS Lookup (Beta)

This feature is experimental for release 6.7. Therefore, it may not work as expected; do not use it in production environments.

This option slightly modifies URL filtering behavior and is applicable only when URL filtering is enabled and configured.

When this option is enabled:

• The system evaluates domain category and reputation early in URL transactions, when the browser looks up the domain name to get the IP address
• Category and reputation of encrypted traffic can often be determined without decryption

If DNS filtering cannot determine the URL of encrypted traffic, that traffic is processed using your configurations for encrypted traffic.

Enable DNS Filtering to Identify URLs During Domain Lookup (Beta)

Note

This feature is experimental for release 6.7. Therefore, it may not work as expected; do not use it in production environments.
Before you begin

- URL filtering using category and reputation must be licensed, enabled, and configured.

  (DNS filtering does NOT use the following settings in the URLs tab: URL groups, URL objects, URL lists and feeds, and URLs entered into the "Enter URL" text box.)

- See limitations at DNS Filtering Limitations, on page 1585.

Procedure

**Step 1**
In your access control policy's **Advanced** tab, select **Enable reputation enforcement on DNS traffic**.

**Step 2**
In the same policy, for each access control rule that has URL category and reputation blocking configured:

- In the **Applications** tab:
  
  If there is anything other than **any** under **Selected Applications and Filters**, add **DNS** to that list.

  (Other DNS-related options in the Available Applications list are not relevant for this purpose.)

- In the **Ports** tab:

  If there is anything other than **any** under **Selected Destination Ports**, add **DNS_over_TCP** and **DNS_over_UDP**.

**Step 3**
Save your changes.

What to do next

If you are done making changes: **Deploy Configuration Changes, on page 495**.

DNS Filtering Limitations

Traffic that matches rules having action **Block with reset**, **Interactive Block**, or **Interactive Block with reset** will be treated as if the rule action were **Block**.

End users trying to access a blocked URL will experience this as an unexplained inability to connect to their page; the connection will spin and then time out.

DNS Filtering and Events

Connection events generated by DNS filtering are logged using the following fields: DNS Query, URL Category, URL Reputation, and Destination Port. The DNS Query field holds the domain name; the URL field will be blank for DNS filtering matches. The Destination Port will be 53.

Also:

- When the access control rule action is **Allow** or **Trust**, two connection events will be generated for the same traffic, one for DNS filtering (with the **DNS Query** field populated) and one for URL filtering (with the **URL** field populated).

- The first time the system encounters a particular URL, you will see two events for that single session: One event showing uncategorized/reputationless for the DNS Query, and one event showing the actual
category and reputation for the URL, which were retrieved during the DNS Query and applied to the session while processing using standard URL filtering.

Manual URL Filtering

In access control and QoS rules, you can supplement or selectively override category and reputation-based URL filtering by manually filtering individual URLs, groups of URLs, or URL lists and feeds.

For example, you might use access control to block a category of websites that are not appropriate for your organization. However, if the category contains a website that is appropriate, and to which you want to provide access, you can create a manual Allow rule for that site and place it before the Block rule for the category.

You can perform this type of URL filtering without a special license.

Manual URL filtering is not supported in SSL rules; instead, use distinguished name conditions.

Caution

Depending on how you implement manual URL filtering, URL matching may not be what you intend. See Manual URL Filtering Options, on page 1586.

Related Topics

Security Intelligence Lists and Feeds, on page 590

Manual URL Filtering Options

There are several ways to specify URLs for manual URL filtering:

Figure 71: Manual URL Filtering Options in an Access Control Rule

![Image of URL filtering options in an Access Control Rule]

---

Firepower Management Center Configuration Guide, Version 6.7
### Option | Description
--- | ---
(Best practice)  
Use custom Security Intelligence URL list or feed objects.  
This is the New URL List option on the rule page in the web interface. | This is the recommended method for manual URL filtering.  
You can create a new list or feed, or choose an existing one from the URLs sub-tab of the URLs tab in an access control or QoS rule.  
For more information, see Custom Security Intelligence Lists and Feeds, on page 596 and subtopics.

Use URL objects, individually or as groups.  
(URL objects are described at URL Objects, on page 570.)  
Or  
Enter URLs directly into the access control rule. (The Enter URL option on the rule page in the web interface.) | If you do not include a path (that is, there is no / character in the URL), the match is based on the server’s hostname only. The hostname is considered a match if it comes after the :// separator, or after any dot in the hostname. For example, ign.com matches ign.com and www.ign.com, but it does not match verisign.com.  
If you include one or more / character, the entire URL string is used for a substring match, including the server name, path, and any query parameters. However, we recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites, as servers can be reorganized and pages moved to new paths. Substring matching can also lead to unexpected matches, where the string you include in the URL object also matches paths on unintended servers or strings within query parameters.  
The Enter URL option does not support wildcards.

---

### Supplement or Selectively Override Category and Reputation-Based URL Filtering

In access control or QoS rules, you can use Security Intelligence URL lists and feeds to supplement, or to specify exceptions to, your category and reputation-based URL filtering rules.  
(In SSL rules, use distinguished name conditions to serve this purpose.)

**Before you begin**

- Configure URL filtering using category and reputation. See Configuring URL Conditions, on page 1582.
- Configure one or more Security Intelligence objects (lists or feeds) containing the URLs that you want to use for manual filtering. See Custom Security Intelligence Lists and Feeds, on page 596.

**Procedure**

1. **Step 1** Navigate to the access control or QoS policy in which you will define your rule.  
2. **Step 2** Create or edit the rule in which you will add your new condition:  
   - If you are supplementing a category- or reputation-based URL filtering rule, edit the existing rule.
If you are overriding or creating exceptions to a category- or reputation-based URL filtering rule, create a new rule.

**Step 3**
If you are creating a new rule, configure the rule name, position, action, and other options at the top of the rule.

**Important!** If the list or feed you are configuring in this procedure contains exceptions to category- or reputation-based rules, put this rule above those rules in the rule order.

**Step 4**
Click **URLs**.

**Step 5**
Click **URLs** (beside the **Category** tab.)

**Step 6**
Select the list or feed you created in the prerequisite to this task.

**Step 7**
Click **Add to Rule**.

**Step 8**
Click **Add** or continue editing the rule.

---

**What to do next**
(Optional) In SSL rules, use distinguished name conditions to configure parallel behavior.

---

### Configure URL Filtering Health Monitors

The following health policies alert if the system has problems obtaining or updating URL category and reputation data.

- **URL Filtering Monitor**
- **Threat Data Updates on Device**

To ensure that these are configured the way you want them, see #unique_310 and Configuring Health Monitoring, on page 408.

---

### Dispute URL Category and Reputation

If you disagree with a category or reputation assigned by Talos, you can submit a request for re-evaluation.

**Before you begin**
You will need your Cisco account credentials.

**Procedure**

**Step 1**
In the Firepower Management Center web interface, do one of the following:
### Location of Dispute Option

<table>
<thead>
<tr>
<th>Location of Dispute Option</th>
<th>Path to Dispute Option</th>
</tr>
</thead>
</table>
| Cloud Services configuration page           | a. Navigate to the System > Integration > Cloud Services page.  
  b. Select Dispute URL categories and reputations.                                                                                                  |
  b. Look up the URL in question.  
  c. To see Dispute at the end of the table row, hover over the relevant entry in the list of results, then click dispute. |
| URL Connection Event                        | a. Navigate to any page under the Analysis > Connections menu that has a table that includes URLs.  
  b. Right-click an item in the URL Category or URL Reputation column (show hidden columns if needed) and select an option. |

The Talos web site opens in a separate browser window.

**Step 2**  
Sign in to the Talos site with your Cisco credentials.

**Step 3**  
Review the information and follow the instructions on the Talos page.

**Step 4**  
Look for information on the Talos site about how submitted disputes are handled and what response to expect, if any.

The dispute process is independent of Firepower products.

---

### If the URL Category Set Changes, Take Action

<table>
<thead>
<tr>
<th>Smart License</th>
<th>Classic License</th>
<th>Supported Devices</th>
<th>Supported Domains</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL Filtering</td>
<td>URL Filtering</td>
<td>Any</td>
<td>Any</td>
<td>Admin/Access</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Admin/Network/Network Admin</td>
</tr>
</tbody>
</table>

The set of URL Filtering categories may occasionally change, in order to accommodate new web trends and evolving usage patterns.

These changes affect both policies and events.

Shortly before URL category changes are scheduled to occur, and after they occur, you will see alerts in the list of rules in any access control, SSL, and QoS policy that is affected by the changes, and on URL or Category in rules that you edit.

You should take action when you see these alerts.
Updates to the URL category set as described in this topic are distinct from the changes that simply add new URLs to existing categories or re-classify misclassified URLs. This topic does not apply to category changes for individual URLs.

**Procedure**

**Step 1**
If you see an alert beside a rule in an access control policy, hover over the alert to see details.

**Step 2**
If the alert mentions changes to URL categories, edit the rule to see further details.

**Step 3**
Hover over the URL or Category in the rule dialog to see general information about the type of changes.

**Step 4**
If you see an alert beside a category, click the alert to view details.

**Step 5**
If you see a "More information" link in the description of a change, click it to view information about the category on the Talos web site.

Alternately, see a list and descriptions all categories at the link in URL Category and Reputation Descriptions, on page 1574.

**Step 6**
Depending on the type of change, take appropriate action:

<table>
<thead>
<tr>
<th>Type of Category Change</th>
<th>What The System Will Do</th>
<th>What You Should Do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing category will soon be deprecated</td>
<td>Nothing yet. You have a few weeks to change affected rules.</td>
<td>Remove this category from all rules that include it. If there is a similar new category, consider using that category instead.</td>
</tr>
<tr>
<td></td>
<td>If you do not take action in that time, the system eventually will not be able to redeploy the policy.</td>
<td></td>
</tr>
<tr>
<td>New category is added</td>
<td>By default, the system does not use newly added categories.</td>
<td>Consider creating new rules for the new category.</td>
</tr>
<tr>
<td>Existing category is deleted</td>
<td>The category will appear in the rule in strikethrough text (that is, with a line through the category name.)</td>
<td>You must delete the obsolete category from the rule before you can deploy the policy.</td>
</tr>
</tbody>
</table>

**Step 7**
Check your SSL rules (Category) for these changes and take action as needed.

**Step 8**
Check your QoS rules (URL) for these changes and take action as needed.

**What to do next**
Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**URL Category and Reputation Changes: Effect on Events**

- When URL categories change, events that the system processed before the category change will be associated with their original category names and will be labeled with **Legacy**. Events that the system processed after the category change will be associated with the new categories.
Older, legacy events will age out of the system over time.

- If a URL does not have a reputation at the time it was processed, the URL Reputation column in the event viewer will be empty.

## Troubleshoot URL Filtering

### Expected URL Category is Missing from the Categories List

The URL filtering feature uses a different set of categories than the Security Intelligence feature; the category that you expect to see may be a Security Intelligence category. To see those categories, look at the URLs tab on the Security Intelligence tab in an access control policy.

### Initial Packets Are Passing Uninspected

See Inspection of Packets That Pass Before Traffic Is Identified, on page 2080 and subtopics.

### Health alert: "URL Filtering registration failure"

Verify that your FMC and any proxies can connect to the Cisco cloud. You may need information about URL Filtering and URL categories in the following topics: Internet Access Requirements, on page 2904 and Communication Port Requirements, on page 2907.

### How can I find the category and reputation of a particular URL?

Do a manual lookup. See Finding URL Category and Reputation, on page 2574.

### Error when attempting a manual lookup: "Cloud Lookup Failure for <URL>"

Make sure the feature is properly enabled. See the prerequisites in Finding URL Category and Reputation, on page 2574.

### URL appears to be incorrectly handled based on its URL category and reputation

**Problem:** The system does not handle the URL correctly based on its URL category and reputation.

**Solutions:**

- Verify that the URL category and reputation associated with the URL are what you think they are. See Finding URL Category and Reputation, on page 2574.

- The following issues may be addressed by settings described in URL Filtering Options, on page 1581, accessible using Enable URL Filtering Using Category and Reputation, on page 1581.
  - The URL cache may hold stale information. See information about the Cached URLs Expire setting in URL Filtering Options, on page 1581.
  - The local data set may not be updated with current information from the cloud. See information about the Enable Automatic Updates setting in URL Filtering Options, on page 1581.
  - The system may be configured to not check the cloud for current data. See information about the Query Cisco cloud for unknown URLs setting in URL Filtering Options, on page 1581.
• Your access control policy may be configured to pass traffic to the URL without checking the cloud. See information about the Retry URL cache miss lookup setting in Access Control Policy Advanced Settings, on page 1546.

• See also Best Practices for URL Filtering, on page 1575.

• If the URL is processed using an SSL rule, see TLS/SSL Rule Guidelines and Limitations, on page 1699 and SSL Rule Order, on page 1531

• Verify that the URL is being handled using the access control rule that you think it is being handled by, and that the rule does what you think it does. Consider rule order.

• Verify that the local URL category and reputation database on the Firepower Management Center is successfully being updated from the cloud and that managed devices are successfully being updated from the Firepower Management Center.

Status of these processes are reported in the Health Monitor, in the URL Filtering Monitor module and the Threat Data Updates on Devices module. For details, see Health Monitoring, on page 399.

If you want to immediately update the local URL category and reputation database, go to System > Integration, click Cloud Services, then click Update Now. For more information, see URL Filtering Options, on page 1581.

A URL category or reputation is not correct
For access control or QoS rules: Use manual filtering, paying careful attention to rule order. See Manual URL Filtering, on page 1586 and Configuring URL Conditions, on page 1582.

For SSL rules: Manual filtering is not supported. Instead, use distinguished name conditions.

See also Dispute URL Category and Reputation, on page 1588.

Web pages are slow to load
There is a tradeoff between security and performance. Some options:

• Consider modifying the Cached URLs Expire setting. Click System > Integration, then select Cloud Services. For information, see URL Filtering Options, on page 1581.

• Consider deselecting the Retry URL cache miss lookup setting in Access Control Policy Advanced Settings, on page 1546.

Events Do Not Include URL Category and Reputation

• Make sure you have included applicable URL rules in an access control policy, the rules are active, and the policies have been deployed to the relevant devices.

• URL category and reputation do not appear in an event if the connection is processed before it matches a URL rule.

• The rule that handles the connection must be configured for URL category and reputation.

• Even if you have configured URL categories in the Categories tab in an SSL rule, you must also configure the URLs tab in a rule in your access control policy.
DNS Filtering is not working

Make sure you have completed all prerequisites and steps in Enable DNS Filtering to Identify URLs During Domain Lookup (Beta), on page 1584.

An End User Tries to Access a Blocked URL and the Page Just Spins and Times Out

When DNS Filtering is enabled and end users access a URL that is blocked, the page will spin but not load. End users are not notified that the page is blocked. This is currently a limitation when DNS filtering is enabled.

See DNS Filtering Limitations, on page 1585.

Events Include URL Category and Reputation but URL Field is Blank

If the DNS Query field is populated and the URL field is empty, this is expected when the DNS filtering feature is enabled.

See DNS Filtering and Events, on page 1585.

Multiple Events are Generated for a Single Transaction

A single web transaction sometimes generates two connection events, one for DNS filtering and one for URL filtering. This is expected when DNS filtering is enabled and:

- the access control rule action for the traffic is Allow or Trust.
- the system encounters a URL for the first time.

See DNS Filtering and Events, on page 1585.

HTTP Response Pages and Interactive Blocking

The following topics describe how to configure custom pages to display when the system blocks web requests:

- About HTTP Response Pages, on page 1597
- Requirements and Prerequisites for HTTP Response Pages, on page 1598
- Choosing HTTP Response Pages, on page 1599
- Interactive Blocking with HTTP Response Pages, on page 1599

About HTTP Response Pages

As part of access control, you can configure an HTTP response page to display when the system blocks web requests, using either access control rules or the access control policy default action.

The response page displayed depends on how you block the session:

- **Block Response Page**: Overrides the default browser or server page that explains that the connection was denied.

- **Interactive Block Response Page**: Warns users, but also allows them to click a button (or refresh the page) to load the originally requested site. Users may have to refresh after bypassing the response page to load page elements that did not load.

If you do not choose a response page, the system blocks sessions without interaction or explanation.

Limitations to HTTP Response Pages

**Response Pages are for Access Control Rules/Default Action Only**

The system displays a response page only for unencrypted or decrypted HTTP/HTTPS connections blocked (or interactively blocked) either by access control rules or by the access control policy default action. The system does not display a response page for connections blocked by any other policy or mechanism.

**Displaying the Response Page Disables Connection Reset**

The system cannot display a response page if the connection is reset (RST packet sent). If you enable response pages, the system prioritizes that configuration. Even if you choose Block with reset or Interactive Block with reset as the rule action, the system displays the response page and does not reset matching web connections. To ensure that blocked web connections reset, you must disable response pages.
Note that all non-web traffic that matches the rule is blocked with reset.

**No Response Page for Encrypted Connections (Must Decrypt)**

The system does not display a response page for encrypted connections blocked by access control rules (or any other configuration). Access control rules evaluate encrypted connections if you did not configure an SSL policy, or your SSL policy passes encrypted traffic.

For example, the system cannot decrypt HTTP/2 or SPDY sessions. If web traffic encrypted using one of these protocols reaches access control rule evaluation, the system does not display a response page if the session is blocked.

However, the system does display a response page for connections decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. In these cases, the system encrypts the response page and sends it at the end of the reencrypted SSL stream.

**No Response Page for “Promoted” Connections**

The system does not display a response page when web traffic is blocked as a result of a promoted access control rule (an early-placed blocking rule with only simple network conditions).

**No Response Page for Certain Redirected Connections**

If a URL is entered without specifying "http" or "https", and the browser initiates the connection on port 80, and the user clicks through a response page, and the connection is subsequently redirected to port 443, the user will not see a second interactive response page because the response to this URL is already cached.

**No Response Page Before URL Identification**

The system does not display a response page when web traffic is blocked before the system identifies the requested URL; see Best Practices for URL Filtering, on page 1575.

**No Response Page with URL Category for Certain Devices**

5506-X and 5508-X devices—whether managed by an FMC or using Adaptive Device Security Manager—do not display a response page if an access control rule using URL categories is matched TLS false start traffic. TLS false start traffic is defined by RFC 7918.

### Requirements and Prerequisites for HTTP Response Pages

**Model Support**

Any

**Supported Domains**

Any

**User Roles**

- Admin
- Access Admin
Choosing HTTP Response Pages

Reliable display of HTTP response pages depends on your network configuration, traffic loads, and size of the page. Smaller pages are more likely to display successfully.

Procedure

Step 1
In the access control policy editor, click HTTP Responses.
If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck Inherit from base policy to enable editing.

Step 2
Choose the Block Response Page and Interactive Block Response Page:
- System-provided—Displays a generic response. Click View (اظهار) to view the code for this page.
- Custom—Create a custom response page. A pop-up window appears, prepopulated with system-provided code that you can replace or modify by clicking Edit ((('). A counter shows how many characters you have used.
- None—Disables the response page and blocks sessions without interaction or explanation. To quickly disable interactive blocking for the whole access control policy, choose this option.

Step 3
Click Save to save the policy.

What to do next
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Interactive Blocking with HTTP Response Pages

When you configure interactive blocking, users can load an originally requested site after reading a warning. Users may have to refresh after bypassing the response page to load page elements that did not load.

Tip
To quickly disable interactive blocking for the whole access control policy, display neither the system-provided page nor a custom page. The system then blocks all connections without interaction.

If a user does not bypass an interactive block, matching traffic is denied without further inspection. If a user bypasses an interactive block, the access control rule allows the traffic, although the traffic may still be subject to deep inspection and blocking.

By default, a user bypass is in effect for 10 minutes (600 seconds) without displaying the warning page on subsequent visits. You can set the duration to as long as a year, or you can force the user to bypass the block every time. This limit applies to every Interactive Block rule in the policy. You cannot set the limit per rule.
Logging options for interactively blocked traffic are identical to those in allowed traffic, but if a user does not bypass the interactive block, the system can log only beginning-of-connection events. When the system initially warns the user, it marks any logged beginning-of-connection event with the Interactive Block or Interactive Block with reset action. If the user bypasses the block, additional connection events logged for the session have an action of Allow.

Configuring Interactive Blocking

Procedure

Step 1  As part of access control, configure an access control rule that matches web traffic; see Create and Edit Access Control Rules, on page 1561:

- Action—Set the rule action to Interactive Block or Interactive Block with reset; see Access Control Rule Interactive Blocking Actions, on page 1568.
- Conditions—Use URL conditions to specify the web traffic to interactively block; see URL Conditions (URL Filtering), on page 539.
- Logging—Assume users will bypass the block and choose logging options accordingly; see Logging for Allowed Connections, on page 2680.
- Inspection—Assume users will bypass the block and choose deep inspection options accordingly; see Understanding Access Control, on page 1519.

Step 2  (Optional) On access control policy HTTP Responses, choose a custom interactive-block HTTP response page; see Choosing HTTP Response Pages, on page 1599.

Step 3  (Optional) On access control policy Advanced, change the user bypass timeout; see Setting the User Bypass Timeout for a Blocked Website, on page 1600.

After a user bypasses a block, the system allows the user to browse to that page without warning until the timeout period elapses.

Step 4  Save the access control policy.

Step 5  Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Setting the User Bypass Timeout for a Blocked Website

Procedure

Step 1  Log in to the FMC if you haven't already done so.

Step 2  Click Policies > Access Control .

Step 3  Click Edit ( ).

Step 4  Click Edit ( ) next to General Settings.

If View ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck Inherit from base policy to enable editing.
Step 5  In the **Allow an Interactive Block to bypass blocking for (seconds)** field, type the number of seconds that must elapse before the user bypass expires. Setting this value to 0 means the interactive block response is displayed once and the user bypass never expires.

Step 6  Click **OK**.

Step 7  Click **Save** to save the policy.

---

**What to do next**

- Deploy configuration changes; see [Deploy Configuration Changes, on page 495](#).
Setting the User Bypass Timeout for a Blocked Website
Blocking Traffic with Security Intelligence

The following topics provide an overview of Security Intelligence, including use of lists for blocking and allowing traffic and basic configuration.

- About Security Intelligence, on page 1603
- Best Practices for Security Intelligence, on page 1604
- License Requirements for Security Intelligence, on page 1604
- Requirements and Prerequisites for Security Intelligence, on page 1605
- Security Intelligence Sources, on page 1605
- Configure Security Intelligence, on page 1606
- Security Intelligence Monitoring, on page 1612
- Override Security Intelligence Blocking, on page 1612
- Troubleshooting Security Intelligence, on page 1613
- History for Security Intelligence Block Listing, on page 1614

About Security Intelligence

As an early line of defense against malicious internet content, Security Intelligence uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domain names. This is called Security Intelligence block listing.

Security Intelligence is an early phase of access control, before the system performs more resource-intensive evaluation. Using a Block list improves performance by quickly excluding traffic that does not require inspection.

You cannot use a Block list to block fastpathed traffic. Prefilter evaluation occurs before Security Intelligence filtering. Fastpathed traffic bypasses all further evaluation, including Security Intelligence.

Although you can configure custom Block lists, Cisco provides access to regularly updated intelligence feeds. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations.

You can refine Security Intelligence Block listing with Do Not Block lists and monitor-only Block lists. These mechanisms exempt traffic from being blocked by a Block list, but do not automatically trust or fastpath matching traffic. Traffic added to a Do Not Block list or monitored at the Security Intelligence stage is intentionally subject to further analysis with the rest of access control.
Best Practices for Security Intelligence

• Configure your access control policies to block threats detected by Cisco-provided Security Intelligence feeds. See Configuration Example: Security Intelligence Blocking, on page 1611.

• If you want to supplement the Cisco-provided Security Intelligence feeds with custom threat data, or manually block emerging threats:
  • For IP addresses, use custom Security Intelligence lists and feeds, or Network objects or groups. To create these, see Security Intelligence Lists and Feeds, on page 590 and Network Objects, on page 564, and their subtopics. To use them for Security Intelligence, see Configure Security Intelligence, on page 1606.
  • For URLs and domains, use custom Security Intelligence lists and feeds, not objects or groups. See details at Manual URL Filtering Options, on page 1586.
  • You can also add entries to a Block list from events. See Global and Domain Security Intelligence Lists, on page 592.

• To test new feeds, or for passive deployments, set the action from block to monitor only. See Security Intelligence Monitoring, on page 1612.

• If you need to exclude specific sites or addresses from Security Intelligence blocking, see Override Security Intelligence Blocking, on page 1612.

• If your Firepower deployment is integrated with SecureX or the related tool Cisco SecureX threat response (formerly known as Cisco Threat Response or CTR), and you use custom Security Intelligence lists and feeds, be sure to update Security Services Exchange (SSE) with these lists and feeds. For details, see instructions for configuring auto-promotion of events in the SSE online help. For general information about this integration, see Integrate with Cisco SecureX, on page 2577.

• System-provided Security Intelligence categories may change over time and without notification; you should plan to check periodically for changes, and modify your policies accordingly.

• You should also configure URL filtering, a separate feature with separate licensing requirements, for further protection against malicious sites. See URL Filtering, on page 1573.

Security Intelligence Sources

- System-provided feeds
  Cisco provides access to regularly updated intelligence feeds for domains, URLs and IP addresses. For more information, see Security Intelligence Lists and Feeds, on page 590.

  If you see a feed with "TID" in the name, this feed is not used by Security Intelligence. Instead, this feed is used by the feature described in Threat Intelligence Director, on page 1805.

- Third-party feeds
  Optionally, supplement Cisco-provided feeds with third-party reputation feeds, which are dynamic lists that the Firepower Management Center downloads from the internet on a regular basis. See Custom Security Intelligence Feeds, on page 598.

- Custom Block lists or feeds (or objects or groups)
  Block specific IP addresses, URLs, or domain names using a manually-created list or feed (for IP addresses, you can also use network objects or groups.)

  For example, if you become aware of malicious sites or addresses that are not yet blocked by a feed, add these sites to a custom Security Intelligence list and add this custom list to the Block list in the Security Intelligence tab of your access control policy, as described in Custom Security Intelligence Lists, on page 599 and Configure Security Intelligence, on page 1606.

  For IP addresses, you can optionally use network objects rather than lists or feeds for this purpose; for information, see Network Objects, on page 564. (For URLs, using lists and feeds is strongly recommended over other methods.)

- Custom Do Not Block lists or feeds
Override Security Intelligence blocking for specific sites or addresses. See Override Security Intelligence Blocking, on page 1612.

- Global Block lists (one each for Network, URL and DNS)
  While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Block List so that Security Intelligence will handle future traffic from that source. See Global and Domain Security Intelligence Lists, on page 592.

- Global Do Not Block lists (one each for Network, URL and DNS)
  While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Do Not Block List if you do not want Security Intelligence to block future traffic from that source. See Global and Domain Security Intelligence Lists, on page 592.

## Configure Security Intelligence

Each access control policy has Security Intelligence options. You can add network objects, URL objects and lists, and Security Intelligence feeds and lists to a Block list or Do Not Block list, and constrain any of these by security zone. You can also associate a DNS policy with your access control policy, and add domain names to a Block or Do Not Block list.

The number of objects in the Do Not Block lists plus the number in the Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

---

### Note

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.

### Before you begin

- Tip: For guidance on minimum configuration recommendations, see also Configuration Example: Security Intelligence Blocking, on page 1611.

- To ensure that all options are available to select, add at least one managed device to your management center.

- In passive deployments, or if you want to set Security Intelligence filtering to monitor-only, enable logging; see Logging Connections with Security Intelligence, on page 2688.

- Configure a DNS policy to take Security Intelligence action for domains. For more information, see DNS Policies, on page 1615.

### Procedure

**Step 1**

In the access control policy editor, click Security Intelligence.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck Inherit from base policy to enable editing.
Step 2 You have the following options:

- Click **Networks** to add network objects (IP addresses).
- Click **URLs** to add URL objects.

Step 3 Find the **Available Objects** you want to add to the Block or Do Not Block list. You have the following options:

- Search the available objects by typing in the **Search by name or value** field. Clear the search string by clicking **Reload (_reload) or Clear (clear).**

  - If no existing list or feed meets your needs, click **Add**, select **New Network List** or **New URL List**, and proceed as described in **Creating Security Intelligence Feeds**, on page 598 or **Uploading New Security Intelligence Lists to the Firepower Management Center**, on page 600.

  - If no existing object meets your needs, click **Add**, select **New Network Object** or **New URL Object**, and proceed as described in **Creating Network Objects**, on page 565.

Security Intelligence ignores IP address blocks using a /0 netmask.

Step 4 Choose one or more **Available Objects** to add.

Step 5 (Optional) Choose an **Available Zone** to constrain the selected objects by zone.

You cannot constrain system-provided Security Intelligence lists by zone.

Step 6 Click **Add to Do Not Block list** or **Add to Block list**, or click and drag the selected objects to either list.

To remove an object from a Block or Do Not Block list, click **Delete**. To remove multiple objects, choose the objects and right-click to **Delete Selected**.

Step 7 (Optional) Set objects on the Block list to monitor-only by right-clicking the object under **Block List**, then choosing **Monitor-only (do not block)**.

You cannot set system-provided global Security Intelligence lists to monitor only.

Step 8 Choose a DNS policy from the **DNS Policy** drop-down list.

Step 9 Click **Save**.

---

**What to do next**

- Deploy configuration changes; see **Deploy Configuration Changes**, on page 495.

**Related Topics**

- **Security Intelligence Lists and Feeds**, on page 590
- **Snort® Restart Scenarios**, on page 502

---

**Security Intelligence Options**

Use the Security Intelligence tab in the access control policy editor to configure network (IP address) and URL Security Intelligence, and to associate the access control policy with a DNS policy in which you have configured Security Intelligence for domains.
**Available Objects**

Available objects include:

- Security Intelligence categories populated by the system-provided feed.
  For details, see Security Intelligence Categories, on page 1609.

- System-provided Global Block and Do Not Block lists.
  For descriptions, see Security Intelligence Sources, on page 1605.

- Security Intelligence lists and feeds that you create under Object > Object Management > Security Intelligence.
  For descriptions, see Security Intelligence Sources, on page 1605.

- Network and URL objects and groups that are configured on the respective pages under Object > Object Management. These are different from the Security Intelligence objects in the previous bullet.
  For details about network objects, see Network Objects, on page 564. (For URLs, use Security Intelligence lists or feeds rather than objects or groups.)

**Available Zones**

Except for the system-provided Global lists, you can constrain Security Intelligence filtering by zone.

For example: To improve performance, you may want to target enforcement. As a more specific example, you can block spam only for a security zone that handles email traffic.

To enforce Security Intelligence filtering for an object on multiple zones, you must add the object to the Block or Do Not Block list separately for each zone.

**DNS Policy**

In order to match DNS traffic using Security Intelligence, you must select a DNS policy for your Security Intelligence configuration.

Using Block or Do Not Block lists, or monitoring traffic based on a DNS list or feed, also requires that you:

- Configure DNS Security Intelligence lists and feeds. See Security Intelligence Lists and Feeds, on page 590.

- Create a DNS policy. See Creating Basic DNS Policies, on page 1618 for more information.

- Configure DNS rules that reference your DNS lists or feeds. See Creating and Editing DNS Rules, on page 1620 for more information.

- Because you deploy the DNS policy as part of your access control policy, you must associate both policies. See DNS Policy Deploy, on page 1626 for more information.

**Do Not Block List**

See Override Security Intelligence Blocking, on page 1612.

To select all objects in the list, right-click an object.
Block List

See Configuration Example: Security Intelligence Blocking, on page 1611 and other topics in this chapter. For explanations of the visual indicators in the Block list, see Block List Icons, on page 1610.

To select all objects in the list, right-click an object.

Logging

Security Intelligence logging, enabled by default, logs all blocked and monitored connections handled by an access control policy’s target devices. However, the system does not log Do Not Block list matches; logging of connections on the Do Not Block list depends on their eventual disposition. Logging must be enabled for connections on the Block list before you can set objects on that list to monitor-only.

To enable, disable, or view logging settings, right-click an object in the Block list.

Related Topics

Global and Domain Security Intelligence Lists, on page 592
Security Intelligence Lists and Multitenancy, on page 593

Security Intelligence Categories

Security Intelligence categories are determined by the system-provided feeds described in Security Intelligence Lists and Feeds, on page 590.

These categories are used in the following locations:

• The Networks sub-tab on the Security Intelligence tab of an access control policy
• The URLs sub-tab beside the Networks tab on the Security Intelligence tab of an access control policy
• In a DNS policy on the DNS tab in the DNS rule configuration page
• In events generated when traffic matches Block or Monitor configurations in the above locations

Note

If your organization is using Threat Intelligence Director: When viewing events, you may see categories that indicate that the action was taken by TID, such as TID URL Block.

Categories are updated by Talos from the cloud, and this list may change independently of Firepower releases.

Table 99: Cisco Talos Intelligence Group (Talos) Feed Categories

</tr>
</tbody>
</table>

### Block List Icons

The following visual indicators may appear in the Block list on the Security Intelligence tab in an access control policy:

<table>
<thead>
<tr>
<th>Icon or Visual Indicator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block (🚫)</td>
<td>The object is set to block.</td>
</tr>
</tbody>
</table>
Configuration Example: Security Intelligence Blocking

Configure your access control policy to block all threats detectable by the system's regularly updated Security Intelligence feeds.

The number of objects in the Block lists plus the number in the Do Not Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

---

**Note**
The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.

**Before you begin**

- To ensure that all options are available to select, add at least one managed device to your management center.

- Configure a DNS policy to block all Security Intelligence threat categories for domains. For more information, see DNS Policies, on page 1615.

- If you have, or will have, custom lists of entities to block, create a Security Intelligence object of each type (URLs, DNS, Networks.) See Security Intelligence Lists and Feeds, on page 590.

**Procedure**

**Step 1** Click Policies > Access Control.

**Step 2** Create a new access control policy or edit an existing policy.

**Step 3** In the access control policy editor, click Security Intelligence.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck Inherit from base policy to enable editing.

**Step 4** Click Networks to add blocking criteria for IP addresses.

a) Scroll down in the Networks list and select all of the threat categories listed below the Global lists.

b) If applicable, select the security zones for which you want to block these threats.

c) Click Add to Block List.

d) If you have created custom lists or feeds with addresses to block, add those to the Block List using the same steps as above.
Step 5
Click URLs to add blocking criteria for URLs, and repeat the steps you followed for Networks.

Step 6
Choose a DNS policy from the DNS Policy drop-down list; see DNS Policy Overview, on page 1615.

Step 7
Click Save.

What to do next

• Enable logging for these connections; see Logging Connections with Security Intelligence, on page 2688.

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

• For additional protection, configure URL filtering to block malicious URLs. See URL Filtering, on page 1573.

Security Intelligence Monitoring

Monitoring logs connection events for traffic that would have been blocked by Security Intelligence, but does not block the traffic. Monitoring is especially useful for:

• Testing feeds before you implement them.

  Consider a scenario where you want to test a third-party feed before you implement blocking using that feed. When you set the feed to monitor-only, the system allows connections that would have been blocked to be further analyzed by the system, but also logs a record of each of those connections for your evaluation.

• Passive deployments, to optimize performance.

  Managed devices that are deployed passively cannot affect traffic flow; there is no advantage to configuring the system to block traffic. Additionally, because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Note

If configured, Threat Intelligence Director may impact the action taken (Monitor or Block.) For more information, see TID-Firepower Management Center Action Prioritization, on page 1826.

To Configure Security Intelligence Monitoring:

After you configure Security Intelligence blocking following the instructions in Configuration Example: Security Intelligence Blocking, on page 1611, right-click each applicable object in the Block list and choose Monitor-only. You cannot set system-provided Security Intelligence lists to monitor only.

Override Security Intelligence Blocking

Optionally, you can use Do Not Block lists to exempt specific domains, URLs, or IP addresses from being blocked by Security Intelligence lists or feeds.

For example, you can:
• Override the occasional false-positive block in a reputable Security Intelligence feed

• Inspect specific traffic in depth instead of blocking it early based on reputation

• Exempt otherwise-restricted transactions based on zone from Security Intelligence blocking

For example, you can add an improperly classified URL to a Do Not Block list, but then restrict the Do Not Block list object using a security zone used by those in your organization who need to access those URLs. That way, only those with a business need can access the URLs on the Do Not Block list.

Entries on a Do Not Block list are not automatically trusted or fastpathed; this traffic is intentionally subject to further analysis with the rest of access control.

Procedure

Step 1  Option 1: Add an IP address, URL, or domain from an event to the Global Do Not Block List. See Global and Domain Security Intelligence Lists, on page 592.

Step 2  Option 2: Use a custom Security Intelligence list or feed.
   a) Create the custom Security Intelligence list or feed. See Custom Security Intelligence Lists, on page 599 or Creating Security Intelligence Feeds, on page 598.
   b) For IP addresses (Networks) and URLs: Edit your access control policy, click the Security Intelligence tab, then click the custom list or feed in the Networks or URLs sub-tab, then click Add to Do Not Block List.
   c) Save your changes.
   d) For domains (DNS): See the "DNS Policy" section in the Security Intelligence Options, on page 1607 topic.
   e) Deploy your changes.

Troubleshooting Security Intelligence

Security Intelligence Categories Are Missing from the Available Options List

Symptoms: On the Security Intelligence tab of the access control policy, Security Intelligence categories (such as CnC or Exploit kit) are not displayed in the Networks tab under Available Options.

Cause:

• These categories do not appear until you have added at least one managed device to your management center. You must add a device in order to pull all TALOS feeds.

• The URL filtering feature uses a different set of categories than the Security Intelligence feature; the category that you expect to see may be a URL filtering category. To see URL filtering categories, look at the URLs tab in an access control rule.
Troubleshooting Memory Use

**Symptoms:** Connections that should be blocked by a Security Intelligence Block list are instead evaluated by access control rules. The Security Intelligence health module alerts that it is out of memory.

**Cause:** Memory limitations. Cisco Intelligence Feeds are based on the latest threat intelligence from Cisco Talos Intelligence Group (Talos). These feeds tend to get larger as time passes. When a Firepower device receives a feed update, it loads as many entries as it can into the memory it has allocated for Security Intelligence. When a device cannot load all the entries, it may not block traffic as expected. Some connections that should be blocked by a Block list instead continue to be evaluated by access control rules.

**Affected platforms:** Lower-memory devices are most likely to have this issue, especially if your Block list includes a lot of Security Intelligence categories or you also filter URLs based on category and reputation. These devices include 5508-X, 5516-X NGIPSv.

**Workaround:** If you think this is happening, redeploy configurations to the affected devices. This can allocate more memory to Security Intelligence. If the issue persists, contact Cisco Technical Assistance Center (TAC), who can help you verify the issue and propose a solution appropriate to your deployment.

### History for Security Intelligence Block Listing

You should update your access control and DNS policies to address the new categories, and check periodically for future changes.

New/modified pages: Security Intelligence tab, Networks and URLs sub-tabs; DNS rules in DNS policies

Supported platforms: FMC
DNS Policies

The following topics explain DNS policies, DNS rules, and how to deploy DNS policies to managed devices.

- DNS Policy Overview, on page 1615
- DNS Policy Components, on page 1616
- License Requirements for DNS Policies, on page 1617
- Requirements and Prerequisites for DNS Policies, on page 1617
- Managing DNS Policies, on page 1617
- DNS Rules, on page 1619
- DNS Policy Deploy, on page 1626

DNS Policy Overview

DNS-based Security Intelligence allows you to block traffic based on the domain name requested by a client, using a Security Intelligence Block list. Cisco provides domain name intelligence you can use to filter your traffic; you can also configure custom lists and feeds of domain names tailored to your deployment.

Traffic on a DNS policy Block list is immediately blocked and therefore is not subject to any further inspection—not for intrusions, exploits, malware, and so on, but also not for network discovery. You can use a Security Intelligence Do Not Block list to override a Block list and force access control rule evaluation, and, recommended in passive deployments, you can use a “monitor-only” setting for Security Intelligence filtering. This allows the system to analyze connections that would have been blocked by a Block list, but also logs the match to the Block list and generates an end-of-connection Security Intelligence event.

Note

DNS-based Security Intelligence may not work as intended for a domain name unless the DNS server deletes a domain cache entry due to expiration, or a client’s DNS cache or the local DNS server’s cache is cleared or expires.

You configure DNS-based Security Intelligence using a DNS policy and associated DNS rules. To deploy it to your devices, you must associate your DNS policy with an access control policy, then deploy your configuration to managed devices.
DNS Policy Components

A DNS policy allows you to block connections based on domain name, using a Block list, or exempt such connections from this type of blocking using a Do Not Block list. The following list describes the configurations you can change after creating a DNS policy.

**Name and Description**

Each DNS policy must have a unique name. A description is optional.

In a multidomain deployment, policy names must be unique within the domain hierarchy. The system may identify a conflict with the name of a policy you cannot view in your current domain.

**Rules**

Rules provide a granular method of handling network traffic based on the domain name. Rules in a DNS policy are numbered, starting at 1. The system matches traffic to DNS rules in top-down order by ascending rule number.

When you create a DNS policy, the system populates it with a default Global Whitelist for DNS rule and a default Global Block List for DNS rule. Both rules are fixed to the first position in their respective categories. You cannot modify these rules, but you can disable them.

In a multidomain deployment, the system also adds Descendant DNS Whitelists and Descendant DNS Block Lists rules to DNS policies in ancestor domains. These rules are fixed to the second position in their respective categories.

**Note**

If multitenancy is enabled for your Firepower Management Center, the system is organized into a hierarchy of domains, including ancestor and descendant domains. These domains are distinct and separate from the domain names used in DNS management.

A descendant list contains the domains on the Block or Do Not Block lists of Firepower System subdomain users. From an ancestor domain, you cannot view the contents of descendant lists. If you do not want subdomain users to add domains to a Block or Do Not Block list:

- disable the descendant list rules, and
- enforce Security Intelligence using the access control policy inheritance settings

The system evaluates rules in the following order:

- Global Whitelist for DNS rule (if enabled)
- Descendant DNS Whitelists rule (if enabled)
- Rules with a Whitelist action
- Global Block List for DNS rule (if enabled)
- Descendant DNS Block Lists rule (if enabled)
- Rules with an action other than Whitelist
Usually, the system handles DN-based network traffic according to the first DNS rule where all the rule’s conditions match the traffic. If no DNS rules match the traffic, the system continues evaluating the traffic based on the associated access control policy's rules. DNS rule conditions can be simple or complex.

Managing DNS Policies

Use the DNS Policy page (Policies > Access Control > DNS) to manage custom DNS policies. In addition to custom policies that you create, the system provides the Default DNS Policy, which uses the default Block list and Do Not Block list. You can edit and use this system-provided custom policy. In a multidomain deployment, this default policy uses the default Global DNS Block List, Global DNS Do Not Block List, Descendant DNS Block lists, and Descendant DNS Do Not Block lists, and can only be edited in the Global domain.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.
Creating Basic DNS Policies

Procedure

Step 1  Choose Policies > Access Control > DNS.
Step 2  Manage your DNS policy:

- Compare—To compare DNS policies, click Compare Policies and proceed as described in Comparing Policies, on page 508.
- Copy—To copy a DNS policy, click Copy and proceed as described in Editing DNS Policies, on page 1618.
- Create—To create a new DNS policy, click Add DNS Policy and proceed as described in Creating Basic DNS Policies, on page 1618.
- Delete—To delete a DNS policy, click Delete, then confirm you want to delete the policy.
- Edit—To modify an existing DNS policy, click Edit and proceed as described in Editing DNS Policies, on page 1618.

What to do next

Configure the policy. See Editing DNS Policies, on page 1618.

Editing DNS Policies

Only one person should edit a DNS policy at a time, using a single browser window. If multiple users attempt to save the same policy, only the first set of saved changes are retained.

To protect the privacy of your session, after thirty minutes of inactivity on the policy editor, a warning appears. After sixty minutes, the system discards your changes.

Procedure

Step 1  Choose Policies > Access Control > DNS.
Step 2  Click Edit next to the DNS policy you want to edit.
If View (👀) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3**  
Edit your DNS policy:

- **Name and Description**—To change the name or description, click the field and type the new information.
- **Rules**—To add, categorize, enable, disable, or otherwise manage DNS rules, click **Rules** and proceed as described in Creating and Editing DNS Rules, on page 1620.

**Step 4**  
Click **Save**.

---

**What to do next**

- Optionally, further configure the new policy as described in Logging Connections with Security Intelligence, on page 2688.
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

**DNS Rules**

DNS rules handle traffic based on the domain name requested by a host. As part of Security Intelligence, this evaluation happens after any traffic decryption, and before access control evaluation.

The system matches traffic to DNS rules in the order you specify. In most cases, the system handles network traffic according to the *first* DNS rule where all the rule’s conditions match the traffic.

In addition to its unique name, each DNS rule has the following basic components:

**State**

By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

**Position**

Rules in a DNS policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

**Conditions**

Conditions specify the specific traffic the rule handles. A DNS rule must contain a DNS feed or list condition, and can also match traffic by security zone, network, or VLAN.

**Action**

A rule’s action determines how the system handles matching traffic:

- Traffic with a **Whitelist** action is allowed, subject to further access control inspection.
• Monitored traffic is subject to further evaluation by remaining rules on the DNS Block list. If the traffic does not match a DNS Block list rule, it is inspected with access control rules. The system logs a Security Intelligence event for the traffic.

• Traffic on a Block list is dropped without further inspection. You can also return a Domain Not Found response, or redirect the DNS query to a sinkhole server.

**Related Topics**

*About Security Intelligence*, on page 1603

### Creating and Editing DNS Rules

In a DNS policy, you can add up to a total of 32767 DNS lists to the Block list and Do Not Block list rules; that is, the number of lists in the DNS policy cannot exceed 32767.

**Procedure**

**Step 1**

In the DNS policy editor, you have the following options:

• To add a new rule, click **Add DNS Rule**.
• To edit an existing rule, click **Edit**.

**Step 2**

Enter a **Name**.

**Step 3**

Configure the rule components, or accept the defaults:

• **Action**—Choose a rule **Action**; see **DNS Rule Actions**, on page 1622.
• **Conditions**—Configure the rule’s conditions; see **DNS Rule Conditions**, on page 1623.
• **Enabled**—Specify whether the rule is **Enabled**.

**Step 4**

Click **Save**.

**What to do next**

• Deploy configuration changes; see **Deploy Configuration Changes**, on page 495.

### DNS Rule Management

The **Rules** tab of the DNS policy editor allows you to add, edit, move, enable, disable, delete, and otherwise manage DNS rules within your policy.

For each rule, the policy editor displays its name, a summary of its conditions, and the rule action. Other icons represent **Warning** (⚠️), **Error** (❌), and other important **Information** (ℹ️). Disabled rules are dimmed and marked *(disabled)* beneath the rule name.

### Enabling and Disabling DNS Rules

When you create a DNS rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing the list of rules
in a DNS policy, disabled rules are dimmed, although you can still modify them. Note that you can also enable or disable a DNS rule using the DNS rule editor.

**Procedure**

**Step 1**  In the DNS policy editor, right-click the rule and choose a rule state.

**Step 2**  Click **Save**.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

**DNS Rule Order Evaluation**

Rules in a DNS policy are numbered, starting at 1. The system matches traffic to DNS rules in top-down order by ascending rule number. In most cases, the system handles network traffic according to the *first* DNS rule where *all* the rule’s conditions match the traffic:

- For Monitor rules, the system logs the traffic, then continues evaluating traffic against lower-priority DNS Block list rules.

- For non-Monitor rules, the system does **not** continue to evaluate traffic against additional, lower-priority DNS rules after that traffic matches a rule.

Note the following regarding rule order:

- The Global Whitelist for DNS is always first, and takes precedence over all other rules.

- The Descendant DNS Whitelists rule only appears in multidomain deployments, in non-leaf domains. It is always second, and takes precedence over all other rules except the Global Whitelist for DNS.

- The Do-Not-Block List section precedes the Block List section; Do-Not-Block List rules always take precedence over other rules.

- The Global Block List for DNS is always first in the Block List section, and takes precedence over all other Monitor and Block list rules.

- The Descendant DNS Block Lists rule only appears in multidomain deployments, in non-leaf domains. It is always second in the Block List section, and takes precedence over all other Monitor and Block list rules except the Global Block List.

- The Block List section contains Monitor and Block list rules.

- When you first create a DNS rule, the system positions it last in the Do-Not-Block List section if you assign a **Do Not Block** action, or last in the Block List section if you assign any other action.

You can drag and drop rules to reorder them.
DNS Rule Actions

Every DNS rule has an action that determines the following for matching traffic:

- handling—foremost, the rule action governs whether the system will block, not block, or monitor traffic that matches the rule’s conditions, based on a Block or Do Not Block list

- logging—the rule action determines when and how you can log details about matching traffic

If configured, TID also impacts action prioritization. For more information, see TID-Firepower Management Center Action Prioritization, on page 1826.

Whitelist Action

The Whitelist action allows traffic to pass to the next phase of inspection, which is access control rules.

The system does not log whitelist matches. Logging of these connections depends on their eventual disposition.

Monitor Action

The Monitor action is designed to force connection logging; matching traffic is neither immediately allowed nor blocked. Rather, traffic is matched against additional rules to determine whether to permit or deny it. The first non-Monitor DNS rule matched determines whether the system blocks the traffic. If there are no additional matching rules, the traffic is subject to access control evaluation.

For connections monitored by a DNS policy, the system logs end-of-connection Security Intelligence and connection events to the Firepower Management Center database.

Block Actions

These actions block traffic without further inspection of any kind:

- The Drop action drops the traffic.

- The Domain Not Found action returns a non-existent internet domain response to the DNS query, which prevents the client from resolving the DNS request.

- The Sinkhole action returns a sinkhole object's IPv4 or IPv6 address in response to the DNS query (A and AAAA records only). The sinkhole server can log, or log and block, follow-on connections to the IP address. If you configure a Sinkhole action, you must also configure a sinkhole object.

For a connection blocked based on the Drop or Domain Not Found actions, the system logs beginning-of-connection Security Intelligence and connection events. Because blocked traffic is immediately denied without further inspection, there is no unique end of connection to log.

For a connection blocked based on the Sinkhole action, logging depends on the sinkhole object configuration. If you configure your sinkhole object to only log sinkhole connections, the system logs end-of-connection connection events for the follow-on connection. If you configure your sinkhole object to log and block sinkhole connections, the system logs beginning-of-connection connection events for the follow-on connection, then blocks that connection.
On an ASA FirePOWER device, if you configure a DNS rule with a sinkhole action, and traffic matches the rule, the ASA blocks the follow-on sinkhole connection by default. As a workaround, run the following commands from the ASA command line:

```plaintext
asa(config)# policy-map global_policy
asa(config-pmap)# class inspection_default
asa(config-pmap-c)# no inspect dns preset_dns_map
```

If the ASA continues to block the connection, contact Support.

### DNS Rule Conditions

A DNS rule’s conditions identify the type of traffic that rule handles. Conditions can be simple or complex. You must define a DNS feed or list condition within a DNS rule. You can also optionally control traffic by security zone, network, or VLAN.

When adding conditions to a DNS rule:

- If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion.
- You can configure multiple conditions per rule. Traffic must match **all** the conditions in the rule for the rule to apply to traffic. For example, a rule with a DNS feed or list condition and network condition but no VLAN tag condition evaluates traffic based on the domain name and source or destination, regardless of any VLAN tagging in the session.
- For each condition in a rule, you can add up to 50 criteria. Traffic that matches **any** of a condition’s criteria satisfies the condition. For example, you can use a single rule to block traffic based on up to 50 DNS lists and feeds.

### Controlling Traffic Based on DNS and Security Zone

Zone conditions in DNS rules allow you to control traffic by its source security zone. A **security zone** is a grouping of one or more interfaces, which may be located across multiple devices.

#### Procedure

1. **Step 1**  
   In the DNS rule editor, click **Zones**.

2. **Step 2**  
   Find and select the zones you want to add from the Available Zones. To search for zones to add, click the **Search by name** prompt above the Available Zones list, then type a zone name. The list updates as you type to display matching zones.

3. **Step 3**  
   Click to select a zone, or right-click and then select **Select All**.

4. **Step 4**  
   Click **Add to Source**, or drag and drop.

5. **Step 5**  
   Save or continue editing the rule.
Controlling Traffic Based on DNS and Network

Network conditions in DNS rules allow you to control traffic by its source IP address. You can explicitly specify the source IP addresses for the traffic you want to control.

Procedure

Step 1  In the DNS rule editor, click Networks.
Step 2  Find and select the networks you want to add from the Available Networks, as follows:
   • To add a network object on the fly, which you can then add to the condition, click Add (++) above the Available Networks list and proceed as described in Creating Network Objects, on page 565.
   • To search for network objects to add, click the Search by name or value prompt above the Available Networks list, then type an object name or the value of one of the object’s components. The list updates as you type to display matching objects.
Step 3  Click Add to Source, or drag and drop.
Step 4  Add any source IP addresses or address blocks that you want to specify manually. Click the Enter an IP address prompt below the Source Networks list; then type an IP address or address block and click Add.

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.

Step 5  Save or continue editing the rule.

What to do next

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Controlling Traffic Based on DNS and VLAN

VLAN conditions in DNS rules allow you to control VLAN-tagged traffic. The system uses the innermost VLAN tag to identify a packet by VLAN.

When you build a VLAN-based DNS rule condition, you can manually specify VLAN tags. Alternately, you can configure VLAN conditions with VLAN tag objects, which are reusable and associate a name with one or more VLAN tags.

Procedure

Step 1  In the DNS rule editor, select VLAN Tags.
Step 2  Find and select the VLANs you want to add from the Available VLAN Tags, as follows:
To add a VLAN tag object on the fly, which you can then add to the condition, click Add (++) above the Available VLAN Tags list and proceed as described in Creating VLAN Tag Objects, on page 568.

To search for VLAN tag objects and groups to add, click the Search by name or value prompt above the Available VLAN Tags list, then type either the name of the object, or the value of a VLAN tag in the object. The list updates as you type to display matching objects.

Step 3  Click Add to Rule, or drag and drop.
Step 4  Add any VLAN tags that you want to specify manually. Click the Enter a VLAN Tag prompt below the Selected VLAN Tags list; then type a VLAN tag or range and click Add. You can specify any VLAN tag from 1 to 4094; use a hyphen to specify a range of VLAN tags.

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal VLAN tags to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.

Step 5  Save or continue editing the rule.

What to do next

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Controlling Traffic Based on DNS List, Feed, or Category

DNS conditions in DNS rules allow you to control traffic if a DNS list, feed, or category contains the domain name requested by the client. You must define a DNS condition in a DNS rule.

Regardless of whether you add a global or custom Block or Do Not Block list to a DNS condition, the system applies the configured rule action to the traffic. For example, if you add the Global Do Not Block List to a rule, and configure a Drop action, the system blocks all traffic that should have been allowed to pass to the next phase of inspection.

Procedure

Step 1  In the DNS rule editor, click DNS.
Step 2  Find and select the DNS lists and feeds you want to add from the DNS Lists and Feeds, as follows:

• To add a DNS list or feed on the fly, which you can then add to the condition, click Add (++) above the DNS Lists and Feeds list and proceed as described in Creating Security Intelligence Feeds, on page 598.

• To search for DNS lists, feeds, or categories to add, click the Search by name or value prompt above the DNS Lists and Feeds list, then type an object name or the value of one of the object’s components. The list updates as you type to display matching objects.

• For descriptions of the system-provided threat categories, see Security Intelligence Categories, on page 1609.

Step 3  Click Add to Rule, or drag and drop.
Step 4  Save or continue editing the rule.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

DNS Policy Deploy

After you finish updating your DNS policy configuration, you must deploy it as part of access control configuration.

- Associate your DNS policy with an access control policy, as described in Configure Security Intelligence, on page 1606.
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Prefiltering and Prefilter Policies

- About Prefiltering, on page 1627
- Best Practices for Prefiltering, on page 1630
- Encapsulated Traffic Handling Best Practices, on page 1630
- Requirements and Prerequisites for Prefilter Policies, on page 1631

- Prefilter Policy Hit Counts, on page 1641
- Large Flow Offloads, on page 1641
- History for Prefiltering, on page 1644

About Prefiltering

Prefiltering is the first phase of access control, before the system performs more resource-intensive evaluation. Prefiltering is simple, fast, and early. Prefiltering uses limited outer-header criteria to quickly handle traffic. Compare this to subsequent evaluation, which uses inner headers and has more robust inspection capabilities.

Configure prefiltering to:

- Improve performance—The sooner you exclude traffic that does not require inspection, the better. You can fastpath or block certain types of plaintext, passthrough tunnels based on their outer encapsulation headers, without inspecting their encapsulated connections. You can also fastpath or block any other connections that benefit from early handling.

- Tailor deep inspection to encapsulated traffic—You can rezone certain types of tunnels, so that you can later handle their encapsulated connections using the same inspection criteria. Rezoning is necessary because after prefiltering, access control uses inner headers.

Prefiltering vs Access Control

Prefilter and access control policies both allow you to block and trust traffic, though the prefiltering "trust" functionality is called "fastpathing" because it skips more inspection. The following table explains this and other differences between prefiltering and access control, to help you decide whether to configure custom prefiltering.
If you do not configure custom prefiltering, you can only approximate—not replicate—prefilter functionality with early-placed Block and Trust rules in the access control policy.

<table>

</tbody>
</table>

**Passthrough Tunnels and Access Control**

Plaintext (nonencrypted) tunnels can encapsulate multiple connections, often flowing between discontinuous networks. These tunnels are especially useful for routing custom protocols over IP networks, IPv6 traffic over IPv4 networks, and so on.

An outer *encapsulation header* specifies the source and destination IP addresses of the *tunnel endpoints*—the routed interfaces of the network devices on either side of the tunnel. Inner *payload headers* specify the source and destination IP addresses of the encapsulated connections’ actual endpoints.

Often, network security devices handle plaintext tunnels as *passthrough* traffic. That is, the device is not one of the tunnel endpoints. Instead, it is deployed between the tunnel endpoints and monitors the traffic flowing between them.
Some network security devices, such as Cisco ASA firewalls running Cisco ASA Software (rather than Firepower Threat Defense), enforce security policies using outer IP headers. Even for plaintext tunnels, these devices have no control over or insight into individual encapsulated connections and their payloads.

By contrast, the Firepower System leverages access control as follows:

- Outer header evaluation—First, prefiltering uses outer headers to handle traffic. You can block or fastpath entire plaintext, passthrough tunnels at this stage.

- Inner header evaluation—Next, the rest of access control (and other features such as QoS) use the innermost detectable level of headers to ensure the most granular level of inspection and handling possible.

If a passthrough tunnel is not encrypted, the system acts on its individual encapsulated connections at this stage. You must rezone a tunnel (see Tunnel Zones and Prefiltering, on page 1636) to act on all its encapsulated connections.

Access control has no insight into encrypted passthrough tunnels. For example, access control rules see a passthrough VPN tunnel as one connection. The system handles the entire tunnel using only the information in its outer, encapsulation header.

**Best Practices for Prefiltering**

Consider the following guidelines and limitations for prefiltering:

**Management Network Traffic**

You should fastpath management traffic that traverses FTD devices. Performing deep inspection on management traffic (using access control policies) can cause issues.

**Model Requirements**

Prefiltering is supported on Firepower Threat Defense devices only. Prefilter configurations have no effect on other devices.

**Prefilter-like Capabilities on Non-FTD Devices**

For Classic devices (ASA FirePOWER, NGIPSv):

- Use early-placed Trust and Block access control rules to approximate prefilter functionality, keeping in mind the differences between the two features. See Prefiltering vs Access Control, on page 1627.

- Match entire GRE-encapsulated tunnels using access control rules, with some limitations. See Port and ICMP Code Conditions, on page 527.

- In high availability, sessions in plaintext tunnels such as GRE v0 or IP4-in-IP have state replication if they match a tunnel allow rule.

**Encapsulated Traffic Handling Best Practices**

This topic discusses guidelines for the following types of encapsulated traffic:

- Generic Routing Encapsulation (GRE)
• Point-to-Point Protocol (PPTP)
• IPinIP
• IPv6inIP
• Teredo

**GRE v1 and PPTP bypass outer flow processing**

GRE v1 (sometimes referred to as *stateful GRE*) and PPTP traffic bypass outer flow processing. Passenger flow processing is supported for GRE v0, IPinIP, IPv6inIP, and Teredo but the following limitations apply:

- Sessions are over a single tunnel that is not load-balanced
- There is no HA or clustering replication
- Primary and secondary flow relationships are not maintained
- Prefilter policy white and black lists are not supported

**GRE v0 sequence number field must be optional**

All endpoints sending traffic on the network must send GREv0 traffic with the sequence number field as optional; otherwise, the sequence number field is removed. RFC 1701 and RFC 2784 both specify the sequence field as optional.

**How tunnels work with interfaces**

Prefilter and access control policy rules are applied to all tunnel types on routed, transparent, inline-set, inline-tap, and passive interfaces.

**References**

For more information about the GRE and PPTP protocols, see the following:

- RFC 1701, RFC 2784, and RFC 2890 (GRE protocol v0)
- RFC 2637 (PPTP and GRE protocol v1)

---

**Requirements and Prerequisites for Prefilter Policies**

**Model Support**

FTD

**Supported Domains**

Any
Configure Prefiltering

To perform custom prefiltering, configure and deploy prefilter policies to managed devices, as a part of access control.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

**Step 1** Choose **Policies > Access Control > Prefilter**.

**Step 2** Click **New Policy** to create a custom prefilter policy.

A new prefilter policy has no rules and a default action of Analyze all tunnel traffic. It performs no logging or tunnel rezoning. You can also **Copy** or **Edit** an existing policy.

**Step 3** Configure the prefilter policy's default action and its logging options.

- **Default action**—Choose a default action for supported plaintext, passthrough tunnels: **Analyze all tunnel traffic** (with access control) or **Block all tunnel traffic**.

- **Default action logging**—Click **Logging** next to the default action; see **Logging Connections with a Policy Default Action**, on page 2689. You can configure default action logging for blocked tunnels only.

**Step 4** Configure tunnel and prefilter rules.

In a custom prefilter policy, you can use both kinds of rule, in any order. Create rules depending on the specific type of traffic you want to match and the actions or further analysis you want to perform; see **Tunnel vs Prefilter Rules**, on page 1634.

**Caution** Exercise caution when using tunnel rules to assign tunnel zones. Connections in rezoned tunnels may not match security zone constraints in later evaluation. For more information, see **Tunnel Zones and Prefiltering**, on page 1636.

For detailed information on configuring rule components, see **Tunnel and Prefilter Rule Components**, on page 1634 and **Rule Management: Common Characteristics**, on page 515.

**Step 5** Evaluate rule order. To move a rule, click and drag or use the right-click menu to cut and paste.

Properly creating and ordering rules is a complex task, but one that is essential to building an effective deployment. If you do not plan carefully, rules can preempt other rules or contain invalid configurations. For more information, see **Best Practices for Access Control Rules**, on page 1528.
Step 6  Save the prefilter policy.

Step 7  For configurations that support tunnel zone constraints, appropriately handle rezoned tunnels. Match connections in rezoned tunnels by using tunnel zones as source zone constraints; see Configuring Interface Conditions, on page 521.

Step 8  Associate the prefilter policy with the access control policy deployed to your managed devices. See Associating Other Policies with Access Control, on page 1550.

Step 9  Deploy configuration changes; see Deploy Configuration Changes, on page 495.

What to do next

If you will deploy time-based rules, specify the time zone of the device to which the policy is assigned. See Configure Device Time Zone for Policy Application, on page 1387.

About Prefilter Policies

Prefiltering is a policy-based feature. In the Firepower System, an access control policy is a main configuration that invokes subpolicies and other configurations, including a prefilter policy.

Policy Components: Rules and Default Action

In a prefilter policy, tunnel rules, prefilter rules, and a default action handle network traffic:

- Tunnel and prefilter rules—First, rules in a prefilter policy handle traffic in the order you specify. Tunnel rules match specific tunnels only and support rezoning. Prefilter rules have a wider range of constraints and do not support rezoning. For more information, see Tunnel vs Prefilter Rules, on page 1634.

- Default action (tunnels only)—If a tunnel does not match any rules, the default action handles it. The default action can block these tunnels, or continue access control on their individual encapsulated connections. You cannot rezone tunnels with the default action.

There is no default action for nonencapsulated traffic. If a nonencapsulated connection does not match any prefilter rules, the system continues with access control.

Connection Logging

You can log connections fastpathed and blocked by the prefilter policy; see Other Connections You Can Log, on page 2677.

Connection events contain information on whether and how logged connections—including entire tunnels—were prefiltered. You can view this information in event views (workflows), dashboards, and reports, and use it as correlation criteria. Keep in mind that because fastpathed and blocked connections are not subject to deep inspection, associated connection events contain limited information.

Default Prefilter Policy

Every access control policy has an associated prefilter policy.

The system uses a default policy if you do not configure custom prefiltering. Initially, this system-provided policy passes all traffic to the next phase of access control. You can change the policy's default action and configure its logging options, but you cannot add rules to it or delete it.
Prefilter Policy Inheritance and Multitenancy

Access control uses a hierarchical implementation that complements multitenancy. Along with other advanced settings, you can lock a prefilter policy association, enforcing that association in all descendant access control policies. For more information, see Access Control Policy Inheritance, on page 1525.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain. The default prefilter policy belongs to the Global domain.

Tunnel vs Prefilter Rules

Whether you configure a tunnel or prefilter rule depends on the specific type of traffic you want to match and the actions or further analysis you want to perform.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Tunnel Rules</th>
<th>Prefilter Rules</th>

Tunnel and Prefilter Rule Components

State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.
Position

Rules are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic, regardless of rule type (tunnel vs prefilter).

Action

A rule's action determines how the system handles and logs matching traffic:

• Fastpath—Exempts matching traffic from all further inspection and control, including access control, identity requirements, and rate limiting. Fastpathing a tunnel fastpaths all encapsulated connections.

• Block—Blocks matching traffic without further inspection of any kind. Blocking a tunnel blocks all encapsulated connections.

• Analyze—Allows traffic to continue to be analyzed by the rest of access control, using inner headers. If passed by access control and any related deep inspection, this traffic may also be rate limited. For tunnel rules, enables rezoning with the Assign Tunnel Zone option.

Direction (Tunnel Rules Only)

A tunnel rule's direction determines how the system source and destination criteria:

• Match tunnels only from source (unidirectional)—Match source-to-destination traffic only. Matching traffic must originate from one of the specified source interfaces or tunnel endpoints, and leave through one of the destination interfaces or tunnel endpoints.

• Match tunnels from source and destination (bidirectional)—Match both source-to-destination traffic and destination-to-source traffic. The effect is identical to writing two unidirectional rules, one the mirror of the other.

Prefilter rules are always unidirectional.

Assign Tunnel Zone (Tunnel Rules Only)

In a tunnel rule, assigning a tunnel zone (whether existing or created on the fly), rezones matching tunnels. Rezoning requires the Analyze action.

Rezoning a tunnel allows other configurations—such as access control rules—to recognize all the tunnel's encapsulated connections as belonging together. By using a tunnel's assigned tunnel zone as an interface constraint, you can tailor inspection to its encapsulated connections. For more information, see Tunnel Zones and Prefiltering, on page 1636.

Caution

Exercise caution when assigning tunnel zones. Connections in rezoned tunnels may not match security zone constraints in later evaluation. See Using Tunnel Zones, on page 1637 for a brief walkthrough of a tunnel zone implementation, and a discussion of the implications of rezoning without explicitly handling rezoned traffic.

Conditions

Conditions specify the specific traffic the rule handles. Traffic must match all a rule's conditions to match the rule. Each condition type has its own tab in the rule editor.
You can prefilter traffic using the following *outer-header* constraints:

- Interface—[Interface Conditions](#), on page 520
- Network—[Tunnel Endpoint Conditions](#), on page 525 or [Network Conditions](#), on page 522
- Port—[Encapsulation Conditions](#), on page 529 or [Port and ICMP Code Conditions](#), on page 527
- VLAN—[VLAN Conditions](#), on page 526

You must constrain tunnel rules by encapsulation protocol.

**Applicable Time**

You can specify days and times that a rule is applicable.

**Logging**

A rule's logging settings govern the records the system keeps of the traffic it handles.

In tunnel and prefilter rules, you can log fastpathed and blocked traffic (the Fastpath and Block actions). For traffic subject to further analysis (the Analyze action), logging in the prefilter policy is disabled, although matching connections may still be logged by other configurations. Logging is performed on inner flows, not on the encapsulating flow. For more information, see [Logging Connections with Tunnel and Prefilter Rules](#), on page 2686.

**Comments**

Each time you save changes to a rule you can add comments. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change.

You cannot edit or delete these comments after you save the rule.

- [Best Practices for Access Control Rules](#), on page 1528

---

**Tunnel Zones and Prefiltering**

Tunnel zones allow you to use prefiltering to tailor subsequent traffic handling to encapsulated connections. A special mechanism is required because usually, the system handles traffic using the innermost detectable level of headers. This ensures the most granular level of inspection possible. But it also means that if a passthrough tunnel is not encrypted, the system acts on its individual encapsulated connections; see [Passthrough Tunnels and Access Control](#), on page 1629.

Tunnel zones solve this problem. During the first phase of access control (prefiltering) you can use outer headers to identify certain types of plaintext, passthrough tunnels. Then, you can *rezone* those tunnels by assigning a custom *tunnel zone*.

Rezoning a tunnel allows other configurations—such as access control rules— to recognize all the tunnel's encapsulated connections as belonging together. By using a tunnel's assigned tunnel zone as an interface constraint, you can tailor inspection to its encapsulated connections.

Despite its name, a tunnel zone is not a security zone. A tunnel zone does not represent a set of interfaces. It is more accurate to think of a tunnel zone as a tag that, in some cases, replaces the security zone associated with an encapsulated connection.
For configurations that support tunnel zone constraints, connections in rezoned tunnels do not match security zone constraints. For example, after you rezone a tunnel, access control rules can match its encapsulated connections with their newly assigned *tunnel zone*, but not with any original *security zone*.

See Using Tunnel Zones, on page 1637 for a brief walkthrough of a tunnel zone implementation, and a discussion of the implications of rezoning without explicitly handling rezoned traffic.

**Configurations Supporting Tunnel Zone Constraints**

Only access control rules support tunnel zone constraints.

No other configurations support tunnel zone constraints. For example, you cannot use QoS to rate limit a plaintext tunnel as a whole; you can only rate limit its individual encapsulated sessions.

**Using Tunnel Zones**

This example procedure summarizes how you might rezone GRE tunnels for further analysis, using tunnel zones. You can adapt the concepts described in this example to other scenarios where you need to tailor traffic inspection to connections encapsulated in plaintext, passthrough tunnels.

Consider a Firepower System deployment where your organization's internal traffic flows through the Trusted security zone. The Trusted security zone represents a set of sensing interfaces across multiple managed devices deployed in various locations. Your organization's security policy requires that you allow internal traffic after deep inspection for exploits and malware.

Internal traffic sometimes includes plaintext, passthrough, GRE tunnels between particular endpoints. Because the traffic profile of this encapsulated traffic is different from your "normal" interoffice activity—perhaps it is known and benign—you can limit inspection of certain encapsulated connections while still complying with your security policy.

In this example, after you deploy configuration changes:

- Plaintext, passthrough, GRE-encapsulated tunnels detected in the Trusted zone have their individual encapsulated connections evaluated by one set of intrusion and file policies.
- All other traffic in the Trusted zone is evaluated with a different set of intrusion and file policies.

You accomplish this task by *rezoning* GRE tunnels. Rezoning ensures that access control associates GRE-encapsulated connections with a custom *tunnel zone*, rather than their original Trusted *security zone*. Rezoning is required due to the way the Firepower System and access control handle encapsulated traffic; see Passthrough Tunnels and Access Control, on page 1629 and Tunnel Zones and Prefiltering, on page 1636.

**Procedure**

**Step 1**

Configure custom intrusion and file policies that tailor deep inspection to encapsulated traffic, and another set of intrusion and file policies tailored to nonencapsulated traffic.

**Step 2**

Configure custom prefiltering to rezone GRE tunnels flowing through the Trusted security zone.

Create a custom prefilter policy and associate it with access control. In that custom prefilter policy, create a tunnel rule (in this example, **GRE_tunnel_rezone**) and a corresponding tunnel zone (**GRE_tunnel**). For more information, see Configure Prefiltering, on page 1632.
Step 3

Configure access control to handle connections in rezoned tunnels.

In the access control policy deployed to your managed devices, configure a rule (in this example, **GRE_inspection**) that handles the traffic you rezoned. For more information, see Create and Edit Access Control Rules, on page 1561.

**Table 101: GRE_inspection Access Control Rule**

<table>
<thead>
<tr>
<th>Rule Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security zone condition</td>
<td>Match rezoned tunnels by using the GRE_tunnel security zone as a Source Zone constraint; see Interface Conditions, on page 520.</td>
</tr>
<tr>
<td>Action</td>
<td>Allow, with deep inspection enabled. Choose the file and intrusion policies tailored to inspect encapsulated internal traffic.</td>
</tr>
</tbody>
</table>

**Caution**

If you skip this step, the rezoned connections may match any access control rule not constrained by security zone. If the rezoned connections do not match any access control rules, they are handled by the access control policy default action. Make sure this is your intent.

Step 4

Configure access control to handle non-encapsulated connections flowing through the Trusted security zone.

In the same access control policy, configure a rule (in this example, **internal_default_inspection**) that handles non-rezoned traffic in the Trusted security zone.

**Table 102: internal_default_inspection Access Control Rule**

<table>
<thead>
<tr>
<th>Rule Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security zone condition</td>
<td>Match non-rezoned internal-only traffic by using the Trusted security zone as both a Source Zone and Destination Zone constraint.</td>
</tr>
</tbody>
</table>
Step 5

Evaluate the position of the new access control rules relative to preexisting rules. Change rule order if necessary.

If you place the two new access control rules next to each other, it does not matter which you place first.
Because you rezoned GRE tunnels, the two rules cannot preempt each other.

Step 6

Save all changed configurations.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Creating Tunnel Zones

Procedure

Step 1

Choose Objects > Object Management.

Step 2

Choose Tunnel Zones from the list of object types.

Step 3

Click Add Tunnel Zone.

Step 4

Enter a Name and, optionally, a Description.

Step 5

Click Save.

What to do next

- Assign tunnel zones to plaintext, passthrough tunnels as part of custom prefiltering; see Configure Prefiltering, on page 1632.

Moving Prefilter Rules to an Access Control Policy

You can move prefilter rules from a prefilter policy to the associated access control policy.

Before you begin

Note the following conditions before you proceed:

- Only prefilter rules can be moved to an access control policy. Tunnel rules cannot be moved.
- The prefilter rules can be moved only to the associated access control policy.
• The prefilter rules with configured interface groups cannot be moved.

• The **Action** parameter in the prefilter rule is changed to a suitable action in the access control rule when moved. To know what each action in the prefilter rule maps to, see the following table:

<table>
<thead>
<tr>
<th>Action in the prefilter rule</th>
<th>Action in the access control rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Analyze</td>
<td>Allow</td>
</tr>
<tr>
<td>Block</td>
<td>Block</td>
</tr>
<tr>
<td>Fastpath</td>
<td>Trust</td>
</tr>
</tbody>
</table>

• Similarly, based on the action configured in the prefilter rule, the logging configuration is set to an appropriate setting after the rule is moved, as mentioned in the following table.

<table>
<thead>
<tr>
<th>Action in the prefilter rule</th>
<th>Enabled Logging configurations in the access control rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Analyze</td>
<td>None of the log settings are enabled.</td>
</tr>
<tr>
<td>Block</td>
<td>• Log at Beginning of Connection&lt;br&gt;• Event Viewer&lt;br&gt;• Syslog Server&lt;br&gt;• SNMP Trap</td>
</tr>
<tr>
<td>Fastpath</td>
<td>• Log at Beginning of Connection&lt;br&gt;• Log at End of Connection&lt;br&gt;• Event Viewer&lt;br&gt;• Syslog Server&lt;br&gt;• SNMP Trap</td>
</tr>
</tbody>
</table>

• The comments in the prefilter rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source prefilter policy.

• While moving rules from the source policy, if another user modifies those rules, the FMC displays a message. You may continue with the process after refreshing the page.

### Procedure

**Step 1**  
In the prefilter policy editor, select the rules that you want to move with a left-click on your mouse.  
**Tip**  
To select multiple rules, use the Ctrl (Control) key on your keyboard.

**Step 2**  
Right-click the selected rules and choose **Move to another policy**.

**Step 3**  
Select the destination access control policy from the **Access Policy** drop-down list.
Step 4  From the **Place Rules** drop-down list, choose where you want to position the moved rules:

- To position as the last set of rules in the **Default** section, choose **At the bottom (within the Default section)**.
- To position as the first set of rules in the **Mandatory** section, choose **At the top (within the Mandatory section)**.

Step 5  Click **Move**.

---

**What to do next**

- Deploy configuration changes; see **Deploy Configuration Changes, on page 495**.

---

**Prefilter Policy Hit Counts**

Hit count indicates the number of times a policy rule has triggered for a matching connection.

For complete information on viewing prefilter policy hit counts, see **Viewing Policy Hit Counts, on page 1551**.

**Large Flow Offloads**

On devices that run FXOS (such as Firepower 4100/9300 chassis), certain traffic that you configure to be fastpathed by a prefilter policy is handled by the hardware (specifically, in the NIC), not by your Firepower Threat Defense software. Offloading these connection flows results in higher throughput and lower latency, especially for data-intensive applications such as large file transfers. This feature is especially useful for data centers. This is called **static flow offload**.

In addition, by default, Firepower Threat Defense devices offload flows based on other criteria, including trust. This is called **dynamic flow offload**.

Offloaded flows continue to receive limited stateful inspection, such as basic TCP flag and option checking. The system can selectively escalate packets to the firewall system for further processing if necessary.

Examples of applications that can benefit from offloading large flows are:

- High Performance Computing (HPC) Research sites, where the Firepower Threat Defense device is deployed between storage and high compute stations. When one research site backs up using FTP file transfer or file sync over NFS, the large amount of data traffic affects all connections. Offloading FTP file transfer and file sync over NFS reduces the impact on other traffic.

- High Frequency Trading (HFT), where the Firepower Threat Defense device is deployed between workstations and the Exchange, mainly for compliance purposes. Security is usually not a concern, but latency is a major concern.

The following flows can be offloaded:

- (Static flow offload only.) Connections that are fastpathed by the prefilter policy.

- Standard or 802.1Q tagged Ethernet frames only.

- (Dynamic flow offload only):
Inspected flows that the inspection engine decides no longer need inspection. These flows include:

- Flows handled by access control rules that apply the Trust action and are based on security zone, source and destination network and port matching only.
- TLS/SSL flows that are not selected for decryption using an SSL policy.
- Flows that are trusted by the Intelligent Application Bypass (IAB) policy either explicitly or due to exceeding flow bypass thresholds.
- Flows that match file or intrusion policies that result in trusting the flow.
- Any allowed flow that no longer needs to be inspected.

The following IPS preprocessor inspected flows:

- SSH and SMTP.
- FTP preprocessor secondary connections.
- Session Initiation Protocol (SIP) preprocessor secondary connections.

Intrusion rules that use keywords (also referred to as options)

---

**Important**

For details, exceptions, and limitations to the above, see Flow Offload Limitations, on page 1643.

---

**Use Static Flow Offload**

To offload eligible traffic to hardware, create a prefilter policy rule that applies the **Fastpath** action. Use prefilter rules for TCP/UDP, and tunnel rules for GRE.

(Not recommended.) To disable static flow offload and as a by-product, dynamic flow-offload, use FlexConfig to run the **no flow-offload enable** command. After deployment, you will have to reload the device to implement the change. For information about this command, see the *Cisco ASA Series Command Reference*, available from https://www.cisco.com/c/en/us/support/security/asa-5500-series-next-generation-firewalls/products-command-reference-list.html.

**Use Dynamic Flow Offload**

Dynamic flow offload is enabled by default.

To disable dynamic offload:

> `configure flow-offload dynamic whitelist disable`

To re-enable dynamic offload:

> `configure flow-offload dynamic whitelist enable`

Note that dynamic offload occurs only if static flow offload is enabled, regardless of whether prefiltering is configured.
Flow Offload Limitations

Not all flows can be offloaded. Even after offload, a flow can be removed from being offloaded under certain conditions. Following are some of the limitations:

**Flows that cannot be offloaded**

The following types of flows cannot be offloaded.

- Any flows that do not use IPv4 addressing, such as IPv6 addressing.
- Flows for any protocol other than TCP, UDP, and GRE.
- PPTP GRE connections cannot be offloaded.
- Flows on interfaces configured in passive, inline, or inline tap mode. Routed and switched interfaces are the only types supported.
- Flows that require inspection by Snort or other inspection engines. In some cases, such as FTP, the secondary data channel can be offloaded although the control channel cannot be offloaded.
- IPsec and TLS/DTLS VPN connections that terminate on the device.
- Flows for which you configured a policy to decrement the time-to-live (TTL) value.
- Flows that require encryption or decryption. For example, connections decrypted due to an SSL policy.
- Multicast flows in routed mode. They are supported in transparent mode if there are only two member interfaces in a bridge group.
- TCP Intercept flows.
- TCP state bypass flows. You cannot configure flow offload and TCP state bypass on the same traffic.
- Flows matching a packet capture filter with the trace option.
- Flows tagged with security groups.
- Reverse flows that are forwarded from a different cluster node, in case of asymmetric flows in a cluster.
- Centralized flows in a cluster, if the flow owner is not the control unit.
- Flows that include IP options cannot be dynamically offloaded.

**Additional Limitations**

- Flow offload and Dead Connection Detection (DCD) are not compatible. Do not configure DCD on connections that can be offloaded.
- If more than one flow that matches flow offload conditions are queued to be offloaded at the same time to the same location on the hardware, only the first flow is offloaded. The other flows are processed normally. This is called a collision. Use the show flow-offload flow command in the CLI to display statistics for this situation.
• Dynamic flow offload disables all TCP normalizer checks.

**Conditions for reversing offload**

After a flow is offloaded, packets within the flow are returned to the Firepower Threat Defense device for further processing if they meet the following conditions:

• They include TCP options other than Timestamp.

• They are fragmented.

• They are subject to Equal-Cost Multi-Path (ECMP) routing, and ingress packets move from one interface to another.

### History for Prefiltering

Intelligent Application Bypass

The following topics describe how to configure access control polices to use Intelligent Application Bypass (IAB)

- Introduction to IAB, on page 1645
- IAB Options, on page 1646
- Requirements and Prerequisites for Intelligent Application Bypass, on page 1648
- Configuring Intelligent Application Bypass, on page 1648
- IAB Logging and Analysis, on page 1649

Introduction to IAB

IAB identifies applications that you trust to traverse your network without further inspection if performance and flow thresholds are exceeded. For example, if a nightly backup significantly impacts system performance, you can configure thresholds that, if exceeded, trust traffic generated by your backup application. Optionally, you can configure IAB so that, when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

The system implements IAB on traffic allowed by access control rules or the access control policy's default action, before the traffic is subject to deep inspection. A test mode allows you to determine whether thresholds are exceeded and, if so, to identify the application flows that would have been bypassed if you had actually enabled IAB (called bypass mode).

The following graphic illustrates the IAB decision-making process:
**IAB Options**

**State**

Enables or disables IAB.

**Performance Sample Interval**

Specifies the time in seconds between IAB performance sampling scans, during which the system collects system performance metrics for comparison to IAB performance thresholds. A value of 0 disables IAB.

**Bypassable Applications and Filters**

This feature provides two mutually exclusive options:
Applications/Filters
Provides an editor where you can specify bypassable applications and sets of applications (filters). See Application Conditions (Application Control), on page 529.

All applications including unidentified applications
When an inspection performance threshold is exceeded, trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

Performance and Flow Thresholds
You must configure at least one inspection performance threshold and one flow bypass threshold. When a performance threshold is exceeded, the system examines flow thresholds and, if one threshold is exceeded, trusts the specified traffic. If you enable more than one of either, only one of each must be exceeded.

Inspection performance thresholds provide intrusion inspection performance limits that, if exceeded, trigger the inspection of flow thresholds. IAB does not use inspection performance thresholds set to 0. You can configure one or more of the following inspection performance thresholds:

Drop Percentage
Average packets dropped as a percentage of total packets, when packets are dropped because of performance overloads caused by expensive intrusion rules, file policies, decompression, and so on. This does not refer to packets dropped by normal configurations such as intrusion rules. Note that specifying an integer greater than 1 activates IAB when the specified percentage of packets is dropped. When you specify 1, any percentage from 0 through 1 activates IAB. This allows a small number of packets to activate IAB.

Processor Utilization Percentage
Average percentage of processor resources used.

Package Latency
Average packet latency in microseconds.

Flow Rate
The rate at which the system processes flows, measured as the number of flows per second. Note that this option configures IAB to measure flow rate, not flow count.

Flow bypass thresholds provide flow limits that, if exceeded, trigger IAB to trust bypassable application traffic in bypass mode or allow application traffic subject to further inspection in test mode. IAB does not use flow bypass thresholds set to 0. You can configure one or more of the following flow bypass thresholds:

Bytes per Flow
The maximum number of kilobytes a flow can include.

Packets per Flow
The maximum number of packets a flow can include.

Flow Duration
The maximum number of seconds a flow can remain open.

Flow Velocity
The maximum transfer rate in kilobytes per second.
Requirements and Prerequisites for Intelligent Application Bypass

**Model Support**
Any

**Supported Domains**
Any

**User Roles**
- Admin
- Access Admin
- Network Admin

Configuring Intelligent Application Bypass

**Caution**
Not all deployments require IAB, and those that do might use it in a limited fashion. Do not enable IAB unless you have expert knowledge of your network traffic, especially application traffic, and system performance, including the causes of predictable performance issues. Before you run IAB in bypass mode, make sure that trusting the specified traffic does not expose you to risk.

**Before you begin**
For Classic devices, you must have the Control license.

**Procedure**

**Step 1**
In the access control policy editor, click Advanced, then click Edit ( ) next to Intelligent Application Bypass Settings.

If View ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck Inherit from base policy to enable editing.

**Step 2**
Configure IAB options:
- State—Turn IAB Off or On, or enable IAB in Test mode.
- Performance Sample Interval—Enter the time in seconds between IAB performance-sampling scans. If you enable IAB, even in test mode, enter a non-zero value. Entering 0 disables IAB.
- Bypassable Applications and Filters—Choose from:
• Click the number of bypassed applications and filters and specify the applications whose traffic you want to bypass; see Configuring Application Conditions and Filters, on page 530.

• Click **All applications including unidentified applications** so that, when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

• Inspection Performance Thresholds—Click **Configure** and enter at least one threshold value.
• Flow Bypass Thresholds—Click **Configure** and enter at least one threshold value.

You must specify at least one inspection performance threshold and one flow bypass threshold; both must be exceeded for IAB to trust traffic. If you enter more than one threshold of each type, only one of each type must be exceeded. For detailed information, see IAB Options, on page 1646.

Step 3 Click **OK** to save IAB settings.
Step 4 Click **Save** to save the policy.

What to do next

• Because some packets must be allowed to pass before an application can be detected, you must configure your system to examine those packets.

  See Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2080 and Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2080.

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

IAB Logging and Analysis

IAB forces an end-of-connection event that logs bypassed flows and flows that would have been bypassed, regardless of whether you have enabled connection logging. Connection events indicate flows that are bypassed in bypass mode or that would have been bypassed in test mode. Custom dashboard widgets and reports based on connection events can display long-term statistics for bypassed and would-have-bypassed flows.

IAB Connection Events

**Action**

When **Reason** includes Intelligent App Bypass:

**Allow** -

indicates that the applied IAB configuration was in test mode and traffic for the application specified by Application Protocol remains available for inspection.

**Trust** -

indicates that the applied IAB configuration was in bypass mode and traffic for the application specified by Application Protocol has been trusted to traverse the network without further inspection.

**Reason**

Intelligent App Bypass indicates that IAB triggered the event in bypass or test mode.
Application Protocol

This field displays the application protocol that triggered the event.

Example

In the following truncated graphic, some fields are omitted. The graphic shows the Action, Reason, and Application Protocol fields for two connection events resulting from different IAB settings in two separate access control policies.

For the first event, the Trust action indicates that IAB was enabled in bypass mode and Bonjour protocol traffic was trusted to pass without further inspection.

For the second event, the Allow action indicates that IAB was enabled in test mode, so Ubuntu Update Manager traffic was subject to further inspection but would have been bypassed if IAB had been in bypass mode.

IAB Custom Dashboard Widgets

You can create a Custom Analysis dashboard widget to display long-term IAB statistics based on connection events. Specify the following when creating the widget:

- **Preset**: None
- **Table**: Application Statistics
- **Field**: any
- **Aggregate**: either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections
• **Filter:** any

**Examples**

In the following Custom Analysis dashboard widget examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.

- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

**IAB Custom Reports**

You can create a custom report to display long-term IAB statistics based on connection events. Specify the following when creating the report:

- **Table:** Application Statistics

- **Preset:** None

- **Filter:** any

- **X-Axis:** any

- **Y-Axis:** either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections

**Examples**

The following graphic shows two abbreviated report examples:
• The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.

• The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

The following topics describe how to configure access control policies to use content restriction features:

- About Content Restriction, on page 1653
- Requirements and Prerequisites for Content Restriction, on page 1654
- Using Access Control Rules to Enforce Content Restriction, on page 1655
- Using a DNS Sinkhole to Enforce Content Restriction, on page 1657

About Content Restriction

Major search engines and content delivery services provide features that allow you to restrict search results and website content. For example, schools use content restriction features to comply with the Children's Internet Protection Act (CIPA).

When implemented by search engines and content delivery services, you can enforce content restriction features only for individual browsers or users. The Firepower System allows you to extend these features to your entire network.

The system allows you to enforce:

- **Safe Search**—Supported in many major search engines, this service filters out explicit and adult-oriented content that business, government, and education environments classify as objectionable. The system does not restrict a user's ability to access the home pages for supported search engines.

- **YouTube EDU**—This service filters YouTube content for an educational environment. It allows schools to set access for educational content while limiting access to noneducational content. YouTube EDU is a different feature than YouTube Restricted Mode, which enforces restrictions on YouTube searches as part of Google's Safe Search feature. YouTube Restricted Mode is a subfeature of Safe Search. With YouTube EDU, users access the YouTube EDU home page, rather than the standard YouTube home page.

You can use two methods to configure the system to enforce these features:

**Method: Access Control Rules**

Content restriction features communicate the restricted status of a search or content query via an element in the request URI, an associated cookie, or a custom HTTP header element. You can configure access control rules to modify these elements as the system processes traffic.

**Method: DNS Sinkhole**

For Google searches, you can configure the system to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes filters for Safe Search (including YouTube Restricted Mode).
The table below describes the differences between these enforcement methods.

**Table 103: Comparison of Content Restriction Methods**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Method: Access Control Rules</th>
<th>Method: DNS Sinkhole</th>
</tr>
</thead>
<tbody>
<tr>
<td>Supported devices</td>
<td>Any</td>
<td>Firepower Threat Defense only</td>
</tr>
<tr>
<td>Search engines supported</td>
<td>Any tagged safesearch supported in the Applications tab of the rule editor</td>
<td>Google only</td>
</tr>
<tr>
<td>YouTube Restricted Mode supported</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>YouTube EDU supported</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>SSL policy required</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Hosts must be using IPv4</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Connection event logging</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

When determining which method to use, consider the following limitations:

- The access control rules method requires an SSL policy, which impacts performance.
- The Google SafeSearch VIP supports IPv4 traffic only. If you configure a DNS sinkhole to manage Google searches, any hosts on the affected network must be using IPv4.

The system logs different values for the Reason field in connection events, depending on the method:

- Access Control Rules—Content Restriction
- DNS Sinkhole—DNS Block

---

**Requirements and Prerequisites for Content Restriction**

**Model Support**

Any, or as indicated in the procedure.

**Supported Domains**

Any

**User Roles**

- Admin
- Access Admin
- Network Admin
Using Access Control Rules to Enforce Content Restriction

Caution
To avoid rule preemption, position rules governing YouTube EDU above rules governing Safe Search in both SSL and access control policies; see Content Restriction Rule Order, on page 1530.

Note
When safe search or YouTube EDU is enabled in an access control rule, inline normalization is enabled automatically. For more information, see The Inline Normalization Preprocessor, on page 2174.

Before you begin
For Classic devices, you must have the Control license.

Procedure

Step 1
Create an SSL policy; see Create Basic SSL Policies, on page 1695.

Step 2
Add SSL rules for handling Safe Search and YouTube EDU traffic:

- Choose Decrypt - Resign as the Action for the rules. The system does not support any other action for content restriction handling.

- In Applications, add selections to the Selected Applications and Filters list:
  - YouTube EDU—Add the YouTube and YouTube Upload applications.
  - Safe Search—Add the Category: search engine filter.

For more information, see Application Conditions (Application Control), on page 529

Step 3
Set rule positions for the SSL rules you added. Click and drag, or use the right-click menu to cut and paste.
To avoid preemption, position the Safe Search rule after the YouTube EDU rule.

Step 4
Create or edit an access control policy, and associate the SSL policy with the access control policy.
For more information, see Associating Other Policies with Access Control, on page 1550.

Step 5
In the access control policy, add rules for handling Safe Search and YouTube EDU traffic:

- Choose Allow as the Action for the rules. The system does not allow any other action for content restriction handling.

- In Applications, click dimmed for either Safe search (🔒) or YouTube EDU (🔒), and set related options; see Safe Search Options for Access Control Rules, on page 1656 and YouTube EDU Options for Access Control Rules, on page 1656.

These options are disabled, rather than dimmed, if you choose any Action other than Allow for the rule.
You cannot enable Safe Search and YouTube EDU restrictions for the same access control rule.
• In **Applications**, refine application selections in the **Selected Applications and Filters** list.

In most cases, enabling Safe Search or YouTube EDU populates the **Selected Applications and Filters** list with the appropriate values. The system does not automatically populate the list if a Safe Search or YouTube application is already present in the list when you enable the feature. If applications do not populate as expected, manually add them as follows:

• **YouTube EDU**—Add the **YouTube** and **YouTube Upload** applications.

• **Safe Search**—Add the **Category: search engine** filter.

For more information, see Configuring Application Conditions and Filters, on page 530.

**Step 6** Set rule positions for the access control rules you added. Click and drag, or use the right-click menu to cut and paste.

To avoid preemption, position the Safe Search rule after the YouTube EDU rule.

**Step 7** Configure the HTTP response page that the system displays when it blocks restricted content; see Choosing HTTP Response Pages, on page 1599.

**Step 8** Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

### Safe Search Options for Access Control Rules

The Firepower System supports Safe Search filtering for specific search engines only. For a list of supported search engines, see applications tagged **safesearch supported** in the **Applications** tab of the access control rule editor. For a list of unsupported search engines, see applications tagged **safesearch unsupported**.

When enabling Safe Search for an access control rule, set the following parameters:

**Enable Safe Search**

Enables Safe Search filtering for traffic that matches this rule.

**Unsupported Search Traffic**

Specifies the action you want the system to take when it processes traffic from unsupported search engines. If you choose **Block** or **Block with Reset**, you must also configure the HTTP response page that the system displays when it blocks restricted content; see Choosing HTTP Response Pages, on page 1599.

### YouTube EDU Options for Access Control Rules

When enabling YouTube EDU for an access control rule, set the following parameters:

**Enable YouTube EDU**

Enables YouTube EDU filtering for traffic that matches this rule.

**Custom ID**

Specifies the value that uniquely identifies a school or district network in the YouTube EDU initiative. YouTube provides this ID when a school or district registers for a YouTube EDU account.
If you check **Enable YouTube EDU**, you must enter a **Custom ID**. This ID is defined externally by YouTube. The system does not validate what you enter against the YouTube system. If you enter an invalid ID, YouTube EDU restrictions may not perform as expected.

---

### Using a DNS Sinkhole to Enforce Content Restriction

Typically, a DNS sinkhole directs traffic away from a particular target. This procedure describes how to configure a DNS sinkhole to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes content filters on Google and YouTube search results.

Because Google SafeSearch uses a single IPv4 address for the VIP, hosts must use IPv4 addressing.

**Caution**

If your network includes proxy servers, this content restriction method is not effective unless you position your Firepower Threat Defense devices between the proxy servers and the Internet.

This procedure describes enforcing content restriction for Google searches only. To enforce content restriction for other search engines, see [Using Access Control Rules to Enforce Content Restriction, on page 1655](#).

**Before you begin**

This procedure applies to Firepower Threat Defense only, and requires the Threat license.

**Procedure**

1. **Step 1**
   
   Obtain a list of supported Google domains via the following URL: [https://www.google.com/supported_domains](https://www.google.com/supported_domains).

2. **Step 2**
   
   Create a custom DNS list on your local computer, and add the following entries:
   
   - To enforce Google SafeSearch, add an entry for each supported Google domain.
   - To enforce YouTube Restricted Mode, add a "youtube.com" entry.

   The custom DNS list must be in text file (.txt) format. Each line of the text file must specify an individual domain name, stripped of any leading periods. For example, the supported domain "google.com" must appear as "google.com".

3. **Step 3**
   
   Upload the custom DNS list to the Firepower Management Center; see [Uploading New Security Intelligence Lists to the Firepower Management Center, on page 600](#).

4. **Step 4**
   
   Determine the IPv4 address for the Google SafeSearch VIP. For example, run `nslookup` on `forcesafesearch.google.com`.

5. **Step 5**
   
   Create a sinkhole object for the SafeSearch VIP; see [Creating Sinkhole Objects, on page 602](#).

   Use the following values for this object:
   
   - IPv4 Address—Enter the SafeSearch VIP address.
   - IPv6 Address—Enter the IPv6 loopback address (::1).
• Log Connections to Sinkhole—Click Log Connections.

• Type—Choose None.

Step 6  Create a basic DNS policy; see Creating Basic DNS Policies, on page 1618.

Step 7  Add a DNS rule for the sinkhole; see Creating and Editing DNS Rules, on page 1620.

For this rule:

• Check the Enabled check box.

• Choose Sinkhole from the Action drop-down list.

• Choose the sinkhole object you created from the Sinkhole drop-down list.

• Add the custom DNS list you created to the Selected Items list on DNS.

• (Optional) Choose a network in Networks to limit content restriction to specific users. For example, if you want to limit content restriction to student users, assign students to a different subnet than faculty, and specify that subnet in this rule.

Step 8  Associate the DNS policy with an access control policy; see Associating Other Policies with Access Control, on page 1550.

Step 9  Deploy configuration changes; see Deploy Configuration Changes, on page 495.
PART XV

Encrypted Traffic Handling

- Understanding Traffic Decryption, on page 1661
- Start Creating SSL Policies, on page 1691
- Get Started with TLS/SSL Rules, on page 1699
- Decryption Tuning Using TLS/SSL Rules, on page 1723

- Troubleshoot TLS/SSL Rules, on page 1745
Understanding Traffic Decryption

The following topics provide an overview of Transport Layer Security/Secure Sockets Layer (TLS/SSL) inspection, discuss the prerequisites for TLS/SSL inspection configuration, and detail deployment scenarios.

Because TLS and SSL are often used interchangeably, we use the expression TLS/SSL to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret TLS/SSL as referring to TLS only.

The exception is SSL policies. Because the FMC configuration option is Policies > Access Control > SSL, we use the term SSL policies although these policies are used to define rules for TLS and SSL traffic.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?.

- Traffic Decryption Explained, on page 1661
- TLS/SSL Handshake Processing, on page 1663
- TLS Crypto Acceleration, on page 1666
- TLS/SSL Best Practices, on page 1669
- How to Configure TLS/SSL Policies and Rules, on page 1678
- TLS/SSL Inspection Appliance Deployment Scenarios, on page 1680
- History for TLS/SSL, on page 1688

Traffic Decryption Explained

By default, the Firepower System cannot inspect traffic encrypted with the Secure Socket Layer (SSL) protocol or its successor, the Transport Layer Security (TLS) protocol. TLS/SSL inspection enables you to either block encrypted traffic without inspecting it, or inspect encrypted or decrypted traffic with access control. As the system handles encrypted sessions, it logs details about the traffic. The combination of inspecting encrypted traffic and analyzing encrypted session data allows greater awareness and control of the encrypted applications and traffic in your network.

TLS/SSL inspection is a policy-based feature. In the Firepower System, an access control policy is a main configuration that invokes subpolicies and other configurations, including an SSL policy. If you associate an SSL policy with access control, the system uses that SSL policy to handle encrypted sessions before it evaluates them with access control rules. If you do not configure TLS/SSL inspection, or your devices do not support it, access control rules handle all encrypted traffic.
Access control rules also handle encrypted traffic when your TLS/SSL inspection configuration allows it to pass. However, some access control rule conditions require unencrypted traffic, so encrypted traffic might match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improves performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

If the system detects a TLS/SSL handshake over a TCP connection, it determines whether it can decrypt the detected traffic. If it cannot, it applies a configured action:

- Block the encrypted traffic
- Block the encrypted traffic and reset the TCP connection
- Not decrypt the encrypted traffic

If the system cannot decrypt the traffic, it blocks the traffic without further inspection, evaluates unencrypted traffic with access control; otherwise, the system decrypts it using one of the following methods:

- Decrypt with a known private key. When an external host initiates a TLS/SSL handshake with a server on your network, the system matches the exchanged server certificate with a server certificate previously uploaded to the system. It then uses the uploaded private key to decrypt the traffic.

- Decrypt by resigning the server certificate. When a host on your network initiates a TLS/SSL handshake with an external server, the system resigns the exchanged server certificate with a previously uploaded certificate authority (CA) certificate. It then uses the uploaded private key to decrypt the traffic.

---

**Note**

The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the FMC and use it for either Decrypt - Resign or Decrypt - Known Key TLS/SSL rule actions. For more information, see Decrypt and Resign (Outgoing Traffic), on page 1671. and Known Key Decryption (Incoming Traffic), on page 1671.

Decrypted traffic is subject to the same traffic handling and analysis as originally unencrypted traffic: network, reputation, and user-based access control; intrusion detection and prevention; Cisco Advanced Malware Protection (Cisco AMP); and discovery. If the system does not block the decrypted traffic post-analysis, it re-encrypts the traffic before passing it to the destination host.

---

**Note**

Set up decrypt rules *only* if your managed device handles encrypted traffic. Decryption rules require processing overhead that can impact performance.

The Firepower System does not currently support TLS version 1.3 encryption or decryption. When users visit a web site that negotiates TLS 1.3 encryption, users might see errors similar to the following in their web browser:

- **ERR_SSL_PROTOCOL_ERROR**
- **SEC_ERROR_BAD_SIGNATURE**
- **ERR_SSL_VERSION_INTERFERENCE**

For more information about how to control this behavior, contact Cisco TAC.
TLS/SSL Handshake Processing

In this documentation, the term TLS/SSL handshake represents the two-way handshake that initiates encrypted sessions in both the SSL protocol and its successor protocol, TLS.

In an inline deployment, the Firepower System processes the TLS/SSL handshake, potentially modifying the ClientHello message and acting as a TCP proxy server for the session.

After the client establishes a TCP connection with the server (after it successfully completes the TCP three-way handshake), the managed device monitors the TCP session for any attempt to initiate an encrypted session. The TLS/SSL handshake establishes an encrypted session via the exchange of specialized packets between client and server. In the SSL and TLS protocols, these specialized packets are called handshake messages. The handshake messages communicate which encryption attributes both the client and server support:

- **ClientHello**—The client specifies multiple supported values for each encryption attribute.
- **ServerHello**—The server specifies a single supported value for each encryption attribute, which determines which encryption method the system uses during the secure session.

Although the data transmitted in the session is encrypted, the handshake messages are not.

After a TLS/SSL handshake completes, the managed device caches encrypted session data, which allows session resumption without requiring the full handshake. The managed device also caches server certificate data, which allows faster handshake processing in subsequent sessions.

### ClientHello Message Handling

The client sends the ClientHello message to the server that acts as the packet destination if a secure connection can be established. The client sends the message to initiate the TLS/SSL handshake or in response to a Hello Request message from the destination server.

If you configure TLS/SSL decryption, when a managed device receives a ClientHello message, the system attempts to match the message to TLS/SSL rules that have the Decrypt - Resign or Decrypt - Known Key action. The match relies on data from the ClientHello message and from cached server certificate data. Possible data includes:

<table>
<thead>
<tr>
<th>TLS/SSL Rule Condition</th>
<th>Data Present In</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zones</td>
<td>ClientHello</td>
</tr>
<tr>
<td>Networks</td>
<td>ClientHello</td>
</tr>
<tr>
<td>VLAN Tags</td>
<td>ClientHello</td>
</tr>
<tr>
<td>Ports</td>
<td>ClientHello</td>
</tr>
<tr>
<td>Users</td>
<td>ClientHello</td>
</tr>
<tr>
<td>Applications</td>
<td>ClientHello (Server Name Indicator extension)</td>
</tr>
<tr>
<td>Categories</td>
<td>ClientHello (Server Name Indicator extension)</td>
</tr>
</tbody>
</table>
### ClientHello Message Handling

<table>
<thead>
<tr>
<th>TLS/SSL Rule Condition</th>
<th>Data Present In</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate</td>
<td>server Certificate (potentially cached)</td>
</tr>
<tr>
<td>Distinguished Names</td>
<td>server Certificate (potentially cached)</td>
</tr>
<tr>
<td>Certificate Status</td>
<td>server Certificate (potentially cached)</td>
</tr>
<tr>
<td>Cipher Suites</td>
<td>ServerHello</td>
</tr>
<tr>
<td>Versions</td>
<td>ServerHello</td>
</tr>
</tbody>
</table>

If the ClientHello message does not match a Decrypt - Resign or Decrypt - Known Key rule, the system does not modify the message. It then determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server.

If the message matches a Decrypt - Resign or Decrypt - Known Key rule, the system modifies the ClientHello message as follows:

- **Compression methods**—Strips the `compression_methods` element, which specifies the compression methods the client supports. The Firepower System cannot decrypt compressed sessions. This modification reduces the Compressed Session type of undecryptable traffic.

- **Cipher suites**—Strips cipher suites from the `cipher_suites` element if the Firepower System does not support them. If the Firepower System does not support any of the specified cipher suites, the system transmits the original, unmodified element. This modification reduces the Unknown Cipher Suite and Unsupported Cipher Suite types of undecryptable traffic.

- **Session identifiers**—Strips any value from the `Session Identifier` element and the SessionTicket extension that does not match cached session data. If a ClientHello value matches cached data, an interrupted session can resume without the client and server performing the full TLS/SSL handshake. This modification increases the chances of session resumption and reduces the Session Not Cached type of undecryptable traffic.

- **Elliptic curves**—Strips elliptic curves from the Supported Elliptic Curves extension if the Firepower System does not support them. If the Firepower System does not support any of the specified elliptic curves, the managed device removes the extension and strips any related cipher suites from the `cipher_suites` element.

- **ALPN extensions**—Strips any value from the Application-Layer Protocol Negotiation (ALPN) extension that is unsupported in the Firepower System (for example, the SPDY and HTTP/2 protocols).

- **Other Extensions**—Strips the Next Protocol Negotiation (NPN) and TLS Channel IDs extensions.

SSL rules with a Decrypt - Resign or Decrypt - Known Key action now natively support the Extended Master Secret (EMS) extension during ClientHello negotiation, enabling more secure communications. The EMS extension is defined by [RFC 7627](https://tools.ietf.org/html/rfc7627).

---

**Note**

The system performs these ClientHello modifications by default. If your SSL policy is configured correctly, this default behavior results in more frequent decryption of traffic. To tune the default behavior for your individual network, contact Cisco TAC.
After the system modifies the ClientHello message, it determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server.

Direct communication between the client and server is no longer possible during the TLS/SSL handshake, because after message modification the Message Authentication Codes (MACs) computed by the client and server no longer match. For all subsequent handshake messages (and for the encrypted session once established), the managed device acts as a man-in-the-middle (MITM). It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. As a result, each session contains different cryptographic session details.

The cipher suites that the Firepower System can decrypt are frequently updated and do not correspond directly to the cipher suites you can use in TLS/SSL rule conditions. For the current list of decryptable cipher suites, contact Cisco TAC.

**Note**

The ServerHello and Server Certificate Message Handling

The ServerHello message is the response to a ClientHello message in a successful TLS/SSL handshake. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server Certificate message immediately follows the ServerHello message.

When the managed device receives these messages, it attempts to match them with TLS/SSL rules. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

If the messages do not match any TLS/SSL rules, the managed device performs the default action for the SSL policy. For more information, see SSL Policy Default Actions, on page 1692.

If the messages match an SSL rule, the managed device continues as appropriate:

**Action: Monitor**

The TLS/SSL handshake continues to completion. The managed device tracks and logs but does not decrypt encrypted traffic.

**Action: Block or Block with Reset**

The managed device blocks the TLS/SSL session. If appropriate, it also resets the TCP connection.

**Action: Do Not Decrypt**

The TLS/SSL handshake continues to completion. The managed device does not decrypt the application data exchanged during the TLS/SSL session.
Action: Decrypt - Known Key

The managed device attempts to match the server certificate data to an Internal Certificate object previously imported into the Firepower Management Center. Because you cannot generate an Internal Certificate object, and you must possess its private key, we assume you own the server on which you're using known key decryption.

If the certificate matches a known certificate, the TLS/SSL handshake continues to completion. The managed device uses the uploaded private key to decrypt and reencrypt the application data exchanged during the TLS/SSL session.

If the server changes its certificate between the initial connection with the client and subsequent connections, you must import the new server certificate in the Firepower Management Center for future connections to be decrypted.

Action: Decrypt - Resign

The managed device processes the server certificate message and re-signs the server certificate with the previously imported or generated certificate authority (CA). The TLS/SSL handshake continues to completion. The managed device then uses the uploaded private key to decrypt and reencrypt the application data exchanged during the TLS/SSL session.

---

**Note**

The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the FMC and use it for either Decrypt - Resign or Decrypt - Known Key TLS/SSL rule actions. For more information, see Decrypt and Resign (Outgoing Traffic), on page 1671, and Known Key Decryption (Incoming Traffic), on page 1671.

---

**TLS Crypto Acceleration**

TLS crypto acceleration accelerates the following:

- TLS/SSL encryption and decryption
- VPN, including TLS/SSL and IPsec

**Supported Hardware**

The following hardware models support TLS crypto acceleration:

- Firepower 2100 with Firepower Threat Defense
- Firepower 4100/9300 with Firepower Threat Defense

For information about TLS crypto acceleration support on Firepower 4100/9300 FTD container instances, see the *FXOS Configuration Guide*.

TLS crypto acceleration is not supported on any virtual appliances or on any hardware except for the preceding.

---

**Note**

For more information about TLS crypto acceleration and the 4100/9300, see the *FXOS Configuration Guide*. 

---
Features Not Supported by TLS crypto acceleration

Features not supported by TLS crypto acceleration include the following:

- Managed devices where FTD container instance is enabled.
- If the inspection engine is configured to preserve connections and the inspection engine fails unexpectedly, TLS/SSL traffic is dropped until the engine restarts.

This behavior is controlled by the `configure snort preserve-connection {enable | disable}` command.

TLS Crypto Acceleration Guidelines and Limitations

Keep the following in mind if your managed device has TLS crypto acceleration enabled.

**HTTP-only performance**

Using TLS crypto acceleration on a managed device that is not decrypting traffic can affect performance.

**Federal Information Processing Standards (FIPS)**

If TLS crypto acceleration and Federal Information Processing Standards (FIPS) are both enabled, connections with the following options fail:

- RSA keys less than 2048 bytes in size
- Rivest cipher 4 (RC4)
- Single Data Encryption Standard (single DES)
- Merkle–Damgard 5 (MD5)
- SSL v3

FIPS is enabled when you configure the Firepower Management Center and managed devices to operate in a security certifications compliance mode. To allow connections when operating in those modes, you can configure web browsers to accept more secure options.

For more information:

- Ciphers supported by FIPS: About SSL Settings, on page 1358.
- Security Certifications Compliance Modes, on page 1391.
- Common Criteria.

**TLS heartbeat**

Some applications use the `TLS heartbeat` extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the SSL policy's **Undecryptable Actions**:
• Block
• Block with reset

For more information, see Default Handling Options for Undecryptable Traffic, on page 1693.

To determine whether applications are using TLS heartbeat, see Troubleshoot TLS Heartbeat, on page 1748.

You can configure a Max Heartbeat Length in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, see The SSL Preprocessor, on page 2153.

TLS/SSL oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for Handshake Errors in the SSL policy's Undecryptable Actions:

• Inherit default action
• Do not decrypt
• Block
• Block with reset

If the setting for Handshake Errors in the SSL policy's Undecryptable Actions is Do Not decrypt and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does not occur.

If a significant amount of oversubscription is occurring, you have the following options:

• Upgrade your managed devices to increase TLS/SSL processing capacity.
• Change your SSL policies to add Do Not Decrypt rules for traffic that is not a high priority to decrypt.

View the Status of TLS Crypto Acceleration

This topic discusses how you can determine if TLS crypto acceleration is enabled.

Perform the following task in the Firepower Management Center.

Procedure

Step 1  Log in to the Firepower Management Center.
Step 2  Click Devices > Device Management.
Step 3  Click Edit (✓) to edit a managed device.
Step 4  Click Device page. TLS crypto acceleration status is displayed in the General section.
TLS/SSL Best Practices

This section discusses information you should keep in mind when creating your decryption policies and rules.

Because TLS and SSL are often used interchangeably, we use the expression **TLS/SSL** to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret **TLS/SSL** as referring to TLS only.

The exception is SSL policies. Because the FMC configuration option is **Policies > Access Control > SSL**, we use the term **SSL policies** although these policies are used to define rules for TLS and SSL traffic.

For more information about SSL and TLS protocols, see a resource such as [SSL vs. TLS - What's the Difference?](#).

**Related Topics**
- [The Case for Decryption](#), on page 1669
- [When to Decrypt Traffic, When Not to Decrypt](#), on page 1670
- [Other TLS/SSL Rule Actions](#), on page 1672
- [TLS/SSL Rule Components](#), on page 1675
- [TLS/SSL Rule Order Evaluation](#), on page 1676

**The Case for Decryption**

Only decrypted traffic takes advantage of the Firepower System's threat defense and policy enforcement features. Traffic that is encrypted when it passes through the Firepower System can be allowed or blocked only but it cannot be subjected to deep inspection or the full range of policy enforcement (such as intrusion prevention).

All encrypted connections are:

- Sent through the TLS/SSL decryption policy to determine if they should be decrypted or blocked.
  
  You can also configure TLS/SSL decryption rules to block encrypted traffic of types you know you do not want on your network, such as traffic that uses the nonsecure SSL protocol or traffic with an expired or invalid certificate.

- Any unblocked connections, whether or not decrypted, then go through the access control policy for a final allow or block decision.

Keep in mind that decrypting and then re-encrypting traffic adds a processing load on the device, which can reduce overall system performance.

In summary:

- Encrypted traffic can be allowed or blocked by policy; encrypted traffic cannot be inspected

- Decrypted traffic is subject to threat defense and policy enforcement; decrypted traffic can be allowed or blocked by policy
When to Decrypt Traffic, When Not to Decrypt

This section provides guidelines on when you should decrypt traffic and when you should allow it to pass through the firewall encrypted.

When not to decrypt traffic

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as TLS/SSL pinning) must remain encrypted to prevent breaking the connection

If you elect to bypass decryption for certain types of traffic, no processing is done on the traffic. The encrypted traffic is first evaluated by SSL policy and then proceeds to the access control policy, where a final allow or block decision is made. Encrypted traffic can be allowed or blocked on any TLS/SSL rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- Exact URL or URL category
- Port
- User group

SSL policies provide a Do Not Decrypt action for this traffic; for more information, see TLS/SSL Rule Do Not Decrypt Action, on page 1715.

Note

The related information links at the end of this topic explain how some aspects of rule evaluation work. Conditions such as URL and application filtering have limitations with respect to encrypted traffic. Make sure you understand those limitations.

When to decrypt traffic

All encrypted traffic must be decrypted to take advantage of the Firepower System's threat protection and policy enforcement features. To the extent your managed device allows traffic to be decrypted (subject to its memory and processing power), you should decrypt traffic that is not protected by law or regulation. If you must decide what traffic to decrypt, base your decision on the risk of allowing the traffic on your network. The Firepower System provides a flexible framework for classifying traffic using rule conditions, which include URL reputation, cipher suite, protocol, and many other factors.
The Firepower System provides two methods of decryption, which are discussed in the following sections.

Decrypt and Resign (Outgoing Traffic)

The Decrypt - Resign TLS/SSL rule action enables the Firepower System to act as a man in the middle, intercepting, decrypting, and (if the traffic is allowed) inspecting, and re-encrypting it. The Decrypt - Resign rule action is used with outgoing traffic; that is, the destination server is outside your protected network.

The FTD device negotiates with the client using an internal Certificate Authority (CA) object specified in the rule and builds an SSL tunnel between the client and the FTD device. At the same time, the device connects to the destination web site and creates an SSL tunnel between the server and the FTD device.

Thus, the client sees the CA certificate configured for the SSL decryption rule instead of the certificate from the destination server. The client must trust the certificate to complete the connection. The FTD device then performs decryption/re-encryption in both directions for traffic between the client and the destination server.

Prerequisite

To use the Decrypt - Resign rule action, you must create an internal CA object using a CA file and paired private key file. You can generate a CA and private key in the Firepower System if you don’t already have them.

Note

The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the FMC and use it for either Decrypt - Resign or Decrypt - Known Key TLS/SSL rule actions. For more information, see Decrypt and Resign (Outgoing Traffic), on page 1671. and Known Key Decryption (Incoming Traffic), on page 1671.

Related Topics

- External Certificate Objects, on page 617

Known Key Decryption (Incoming Traffic)

The Decrypt - Known Key TLS/SSL rule action uses a server's private key to decrypt traffic. The Decrypt - Known Key rule action is used with incoming traffic; that is, the destination server is inside your protected network.

The main purpose of decrypting with a known key is to protect your servers from external attacks.

Prerequisite

To use the Decrypt - Known Key rule action, you must create an internal certificate object using the server’s certificate file and paired private key file.
The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the FMC and use it for either Decrypt - Resign or Decrypt - Known Key TLS/SSL rule actions. For more information, see Decrypt and Resign (Outgoing Traffic), on page 1671. and Known Key Decryption (Incoming Traffic), on page 1671.

TLS 1.3 Server Identity Discovery

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate without decrypting the entire packet.

You can enable this feature, referred to as TLS server identity discovery, when you either:

- Associate an SSL policy with an access control policy
- Configure advanced settings for an access control policy

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An SSL policy is not required because traffic is not decrypted in the process of extracting the server certificate.

Note

- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.

The following figure shows an example of enabling TLS server identity discovery in an access control policy's advanced settings.
TLS/SSL Rule Examples

The following sections provide examples of setting up recommended TLS/SSL rules.

Block Nonsecure Protocols

This example shows how to block TLS and SSL protocols on your network that are no longer considered secure, such as TLS 1.0, TLS 1.1, and SSLv3.

You should exclude nonsecure protocols from your network because they are all exploitable. In this example:

- You can block some protocols using Version page on the SSL rule.
- Because the Firepower System considers SSLv2 as undecryptable, you can block it using the Undecryptable Actions on the SSL policy.

Procedure

Step 1 Log in to the Firepower Management System if you have not already done so.
Step 2 Click Policies > Access Control > SSL.
Step 3 Add or edit an SSL policy.
Step 4 Click Add Rule.
Step 5 In the Name field, enter a name for the rule.
Step 6 From the Action list, click Block or Block with reset.
Step 7 Click Version page.
Step 8 Check the check boxes for protocols that are no longer secure, such as SSL v3.0, TLS 1.0, and TLS 1.1. Clear the check boxes for any protocols that are still considered secure.
The following figures show an example.

Step 9
Choose other rule conditions as needed.

Step 10
Save the rule.

Step 11
On the SSL policy page, click **Undecryptable Actions**.

Step 12
From the **SSLv2 Session** list, click **Block** or **Block with reset**. The following figure shows an example.

Step 13
Click **Save**.

Step 14
Because this is a specific rule, order it earlier in your policy than more general rules such as application-matching rules.

**What to do next**
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

TLS/SSL Rule Conditions, on page 1713

TLS/SSL Rule Components

Each TLS/SSL rule has the following components.

**State**
By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

**Position**
Rules in an SSL policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

**Conditions**
Conditions specify the specific traffic the rule handles. Conditions can match traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate subject or issuer, certificate status, cipher suite, or encryption protocol version. The use of conditions can depend on target device licenses.

**Action**
A rule’s action determines how the system handles matching traffic. You can monitor, allow, block, or decrypt encrypted matching traffic. Decrypted and allowed encrypted traffic is subject to further inspection. Note that the system does not perform inspection on blocked encrypted traffic.

**Logging**
A rule’s logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. You can log a connection when the system blocks an encrypted session or allows it to pass without decryption, according to the settings in an SSL policy. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. You can log connections to the Firepower Management Center database, as well as to the system log (syslog) or to an SNMP trap server.

For more information about logging, see Best Practices for Connection Logging, on page 2684.

---

**Tip**
Properly creating and ordering TLS/SSL rules is a complex task. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the SSL policy interface has a robust warning and error feedback system for rules.

Interface Conditions, on page 520
Network Conditions, on page 522
TLS/SSL Rule Order Evaluation

When you create the TLS/SSL rule in an SSL policy, you specify its position using the Insert list in the rule editor. TLS/SSL rules in an SSL policy are numbered, starting at 1. The system matches traffic to TLS/SSL rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the first TLS/SSL rule where all the rule’s conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does not continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an action, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does not further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use specific conditions (such as network and IP addresses) should be ordered before rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules. For more information about the OSI model, see this Wikipedia article.

Tip
Proper TLS/SSL rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

- Default Handling Options for Undecryptable Traffic, on page 1693
- SSL Rule Order, on page 1531

Multi-Rule Example

The following scenario summarizes the ways that SSL rules handle traffic in an inline deployment.
In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.

- **TLS/SSL Rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.

- **TLS/SSL Rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **TLS/SSL Rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.

- **TLS/SSL Rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the SSL rule continues to the next rule.

- **TLS/SSL Rule 5: Decrypt - Resign** is the final rule. If traffic matches this rule, the system re-signs the server certificate with an uploaded CA certificate, then acts as a man-in-the-middle to decrypt traffic. The decrypted traffic is then evaluated against access control rules. Access control rules treat decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the SSL rule continues to the next rule.

- **SSL Policy Default Action** handles all traffic that does not match any of the TLS/SSL rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

## How to Configure TLS/SSL Policies and Rules

This topic provides a high-level overview of tasks you must complete to configure SSL policies and TLS/SSL rules in those policies to block, monitor, or allow TLS/SSL traffic on your network.

You must be an Admin, Access Admin, or Network Admin to perform this task. You can configure SSL policies on any device type except NGIPSv.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Create an SSL policy.</td>
<td>An SSL policy is a container for one or more rules. To use an SSL policy and its rules for access control, you must later associate the SSL policy with an access control policy. For more information, see See Create Basic SSL Policies, on page 1695.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Set a default action for your SSL policy. The default action is taken when traffic matches no rules defined by the SSL policy. See SSL Policy Default Actions, on page 1692.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Specify how undecryptable traffic should be handled. Traffic can be undecryptable for a number of reasons, including unsecure protocols, uses and unknown cipher suite, or in the event of errors with the handshake or decryption. See Default Handling Options for Undecryptable Traffic, on page 1693.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>For <strong>Decrypt - Known Key</strong> (to decrypt inbound traffic to a server in your network) TLS/SSL rules, create an internal certificate object. The internal certificate object uses your server's certificate and private key. See Internal Certificate Objects, on page 618.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>For <strong>Decrypt - Resign</strong> (to decrypt outbound traffic to a server outside of your network) TLS/SSL rules, create an internal certificate authority (CA) object. The internal CA object uses a CA and private key. See Internal Certificate Authority Objects, on page 611.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Create your TLS/SSL rules: • <strong>Block, Block with reset, Interactive block</strong>: Configuring TLS/SSL Rule Actions, on page 1716. • <strong>Do Not Decrypt</strong>, see Configuring TLS/SSL Rule Actions, on page 1716. • <strong>Decrypt - Resign</strong>, see Configuring a Decrypt - Resign Action, on page 1717. • <strong>Decrypt - Known Key</strong>, see Configuring a Decrypt - Known Key Action, on page 1718. • <strong>Monitor</strong>, see Configuring TLS/SSL Rule Actions, on page 1716.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Associate the SSL policy with an access control policy. Unless you associate your SSL policy with an access control policy, it has no effect. After you do this, you can choose to allow or block traffic that matches the access control rule and take other actions. See Associating Other Policies with Access Control, on page 1550.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Configure your access control rules to allow or block decrypted traffic. See Access Control Policy Components, on page 1536.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Deploy the access control policy to managed devices. Before your policy can take effect, it must be deployed to managed devices. See Deploy Configuration Changes, on page 495.</td>
</tr>
</tbody>
</table>
TLS/SSL Inspection Appliance Deployment Scenarios

This section presents several scenarios in which the Life Insurance Example, Inc. life insurance company (LifeIns) uses SSL inspection on encrypted traffic to help audit their processes. Based on their business processes, LifeIns plans to deploy:

- one FTD device in an inline deployment for the Underwriting Department
- one Firepower Management Center to manage both devices

Customer Service Business Processes

LifeIns created a customer-facing website for their customers. LifeIns receives encrypted questions and requests regarding policies from prospective customers through their website and through e-mail. LifeIns’s Customer Service department processes them and returns the requested information within 24 hours. Customer Service wants to expand its incoming contact metrics collection. LifeIns has an established internal audit review for Customer Service.

LifeIns also receives encrypted applications online. The Customer Service department processes the applications within 24 hours before sending the case file to the Underwriting department. Customer Service filters out any obvious false applications sent through the online form, which consumes a fair portion of their time.

Underwriting Business Processes

LifeIns’s underwriters submit encrypted medical information requests online to the Medical Repository Example, LLC medical data repository (MedRepo). MedRepo reviews the requests and transmits the encrypted records to LifeIns within 72 hours. The underwriters subsequently underwrite an application and submit policy and rate decisions. Underwriting wants to expand its metrics collection.

Lately, an unknown source has been sending spoofed responses to LifeIns. Though LifeIns’s underwriters receive training on proper Internet use, LifeIns’s IT department first wants to analyze all encrypted traffic that takes the form of medical responses, then wants to block all spoof attempts.

LifeIns places junior underwriters on six-month training periods. Lately, these underwriters have been incorrectly submitting encrypted medical regulation requests to MedRepo’s customer service department. MedRepo has submitted multiple complaints to LifeIns in response. LifeIns plans on extending their new underwriter training period to also audit underwriter requests to MedRepo.

Traffic Decryption in an Inline Deployment

LifeIns’s business requirements state that Underwriting must:

- audit new and junior underwriters, verifying that their information requests to MedRepo comply with all applicable regulations
- improve its underwriting metrics collection process
- examine all requests that appear to come from MedRepo, then drop any spoofing attempts
- drop all improper regulatory requests to MedRepo’s Customer Service department from the Underwriting department
- not audit senior underwriters
Lifeln plans to deploy a device in an inline deployment for the Underwriting department.

Traffic from MedRepo’s network goes to MedRepo’s router. It routes traffic to Lifeln’s network. The managed device receives the traffic, passes allowed traffic to Lifeln’s router, and sends events to the managing Firepower Management Center. Lifeln’s router routes traffic to the destination host.

On the managing Firepower Management Center, a user in the Access Control and SSL Editor custom role configures an SSL access control rule to:

- log all encrypted traffic sent to the Underwriting department
- block all encrypted traffic incorrectly sent from Lifeln’s underwriting department to MedRepo’s customer service department
- decrypt all encrypted traffic sent from MedRepo to Lifeln’s underwriting department, and from Lifeln’s junior underwriters to MedRepo’s requests department
- not decrypt encrypted traffic sent from the senior underwriters

The user also configures access control to inspect decrypted traffic with a custom intrusion policy and:

- block decrypted traffic if it contains a spoof attempt, and log the spoof attempt
- block decrypted traffic that contains information not compliant with regulations, and log the improper information
- allow all other encrypted and decrypted traffic

The system reencrypts allowed decrypted traffic before sending it to the destination host.

You can also cause the system to decrypt and resign the traffic using a TLS/SSL control rule with the action Decrypt - Resign or Decrypt - Known Key. If traffic matches the TLS/SSL rule, after the system modifies the ClientHello message, it determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server. For more information, see ClientHello Message Handling, on page 1663

In the following scenarios, the user submits information online to a remote server. The user’s browser establishes a TCP connection with the server, then initiates an SSL handshake. The managed device receives this traffic; based on handshake and connection details, the system logs the connection and acts on the traffic. If the system
blocks the traffic, it also closes the TCP connection. Otherwise, the client and server complete the SSL handshake, establishing the encrypted session.

### Encrypted Traffic Monitoring in an Inline Deployment

For all SSL-encrypted traffic sent to and from the Underwriting department, the system logs the connection.

The following steps occur:

1. The user submits the plain text request (help). The client encrypts this (AaBb) and sends the encrypted traffic to MedRepo’s Requests department server.
2. LifeIns's router receives the encrypted traffic and routes it to the Requests department server.
3. The managed device does not decrypt the traffic.
   The access control policy continues to process the encrypted traffic and allows it, then generates a connection event after the session ends.
4. The external router receives the traffic and routes it to the Requests department server.
5. The Underwriting department server receives the encrypted information request (AaBb) and decrypts it to plain text (help).
6. The Firepower Management Center receives the connection event.

### Undecrypted Encrypted Traffic in an Inline Deployment

For all TLS/SSL-encrypted traffic originating from the senior underwriters, the managed device allows the traffic without decrypting it and logs the connection.
The following steps occur:

1. The user submits the plain text request (help). The client encrypts this (AaBb) and sends the encrypted traffic to MedRepo’s Requests department server.
2. LifeIns's router receives the encrypted traffic and routes it to the Requests department server.
3. The managed device does not decrypt this traffic.
   The access control policy continues to process the encrypted traffic and allows it, then generates a connection event after the session ends.
4. The external router receives the traffic and routes it to the Requests department server.
5. The Requests department server receives the encrypted information request (AaBb) and decrypts it to plain text (help).
6. The Firepower Management Center receives the connection event.

**Encrypted Traffic Blocking in an Inline Deployment**

For all SMTPS email traffic improperly sent from LifeIns’s underwriting department to MedRepo’s Customer Service department, the system blocks the traffic during the SSL handshake without further inspection and logs the connection.
The following steps occur:

1. Having received the request to establish a TLS/SSL handshake from a client’s browser, the Customer Service department server sends the server certificate (cert) as the next step in the TLS/SSL handshake to the LifeIns underwriter.

2. MedRepo’s router receives the certificate and routes it to the LifeIns underwriter.

3. The managed device blocks the traffic without further inspection and ends the TCP connection. It generates a connection event.

4. The internal router does not receive the blocked traffic.

5. The underwriter does not receive the blocked traffic.

6. The Firepower Management Center receives the connection event.

**Encrypted Traffic Inspection with a Private Key in an Inline Deployment**

For all TLS/SSL-encrypted traffic sent from MedRepo to LifeIns’s underwriting department, the system uses an uploaded server private key to obtain session keys, then decrypts the traffic and logs the connection. Legitimate traffic is allowed and reencrypted before being sent to the Underwriting department.
The following steps occur:

1. The user submits the plain text request (stats). The client encrypts this (AaBbC) and sends the encrypted traffic to the Underwriting department server.

2. The external router receives the traffic and routes it to the Underwriting department server.

3. The managed device uses the session key obtained with the uploaded known private key to decrypt this traffic to plain text (stats).

   The access control policy continues to process the decrypted traffic with the custom intrusion policy and does not find a spoof attempt. The device passes the encrypted traffic (AaBbC), then generates a connection event after the session ends.

4. The internal router receives the traffic and routes it to the Underwriting department server.

5. The Underwriting department server receives the encrypted information (AaBbC) and decrypts it to plain text (stats).

6. The Firepower Management Center receives the connection event with information about the encrypted and decrypted traffic.

In contrast, any decrypted traffic that is a spoof attempt is dropped. The system logs the connection and the spoof attempt.
The following steps occur:

1. The user submits the plain text request (**spoof**), altering the traffic to appear to originate from MedRepo, LLC. The client encrypts this (**FfGgH**) and sends the encrypted traffic to the Underwriting department server.

2. The managed device uses the session key obtained with the uploaded known private key to decrypt this traffic to plain text (**spoof**).

   The access control policy continues to process the decrypted traffic with the custom intrusion policy and finds a spoof attempt. The device blocks the traffic, then generates an intrusion event. It generates a connection event after the session ends.

3. The internal router does not receive the blocked traffic.

4. The Underwriting department server does not receive the blocked traffic.

5. The Firepower Management Center receives a connection event with information about the encrypted and decrypted traffic, and an intrusion event for the spoofing attempt.

**Encrypted Traffic Inspection with a Re-signed Certificate in an Inline Deployment**

For all TLS/SSL-encrypted traffic sent from the new and junior underwriters to MedRepo’s requests department, the system uses a re-signed server certificate to obtain session keys, then decrypts the traffic and logs the connection. Legitimate traffic is allowed and reencrypted before being sent to MedRepo.

---

**Note**

When decrypting traffic in an inline deployment by re-signing the server certificate, the device acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. As a result, each session contains different cryptographic session details.
The following steps occur:

1. The user submits the plain text request (help). The client encrypts this (AaBb) and sends the encrypted traffic to the Requests department server.
2. The internal router receives the traffic and routes it to the Requests department server.
3. The managed device uses the session key obtained with a re-signed server certificate and private key to decrypt this traffic to plain text (help).

   The access control policy continues to process the decrypted traffic with the custom intrusion policy and does not find an improper request. The device reencrypts the traffic (CcDd), allowing it to pass. It generates a connection event after the session ends.
4. The external router receives the traffic and routes it to the Requests department server.
5. The Requests department server receives the encrypted information (CcDd) and decrypts it to plain text (help).
6. The Firepower Management Center receives the connection event with information about the encrypted and decrypted traffic.

---

**Note**

Traffic encrypted with a re-signed server certificate causes client browsers to warn that the certificate is not trusted. To avoid this, add the CA certificate to the organization’s domain root trusted certificates store or the client trusted certificates store.

In contrast, any decrypted traffic that contains information that does not meet regulatory requirements is dropped. The system logs the connection and the non-conforming information.
The following steps occur:

1. The user submits the plain text request (regs), which does not comply with regulatory requirements. The client encrypts this (Eefr) and sends the encrypted traffic to the Requests department server.

2. The internal router receives the traffic and routes it to the Requests department server.

3. The managed device uses the session key obtained with a re-signed server certificate and private key to decrypt this traffic to plain text (regs).
   The access control policy continues to process the decrypted traffic with the custom intrusion policy and finds an improper request. The device blocks the traffic, then generates an intrusion event. It generates a connection event after the session ends.

4. The external router does not receive the blocked traffic.

5. The Requests department server does not receive the blocked traffic.

6. The Firepower Management Center receives a connection event with information about the encrypted and decrypted traffic, and an intrusion event for the improper request.

### History for TLS/SSL

<table>

- Create Basic SSL Policies, on page 1695
- Set Default Handling for Undecryptable Traffic, on page 1696
- Editing an SSL Policy, on page 1697

SSL Policies Overview

An SSL policy determines how the system handles encrypted traffic on your network. You can configure one or more SSL policies, associate an SSL policy with an access control policy, then deploy the access control policy to a managed device. When the device detects a TCP handshake, the access control policy first handles and inspects the traffic. If it subsequently identifies a TLS/SSL-encrypted session over the TCP connection, the SSL policy takes over, handling and decrypting the encrypted traffic.

Adding or removing an SSL policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 504 for more information.

The simplest SSL policy, as shown in the following diagram, directs the device where it is deployed to handle encrypted traffic with a single default action. You can set the default action to block decryptable traffic without further inspection, or to inspect undecrypted decryptable traffic with access control. The system can then either allow or block the encrypted traffic. If the device detects undecryptable traffic, it either blocks the traffic without further inspection or does not decrypt it, inspecting it with access control.
A more complex SSL policy can handle different types of undecryptable traffic with different actions, control traffic based on whether a certificate authority (CA) issued or trusts the encryption certificate, and use SSL rules to exert granular control over encrypted traffic logging and handling. These rules can be simple or complex, matching and inspecting encrypted traffic using multiple criteria.

Note
Because TLS and SSL are often used interchangeably, we use the expression TLS/SSL to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret TLS/SSL as referring to TLS only.

The exception is SSL policies. Because the FMC configuration option is Policies > Access Control > SSL, we use the term SSL policies although these policies are used to define rules for TLS and SSL traffic.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?

TLS/SSL Rule Conditions, on page 1713

SSS Policy Default Actions

The default action for an SSL policy determines how the system handles decryptable encrypted traffic that does not match any non-monitor rule in the policy. When you deploy an SSL policy that does not contain any TLS/SSL rules, the default action determines how all decryptable traffic on your network is handled. Note that the system does not perform any kind of inspection on encrypted traffic blocked by the default action.

<td>Inherit default action</td>
<td>Do not decrypt&lt;br&gt;Block&lt;br&gt;Block with reset&lt;br&gt;Inherit default action</td>
</tr>
<tr>
<td>Session not cached</td>
<td>The TLS/SSL session has session reuse enabled, the client and server reestablished the session with the session identifier, and the system did not cache that session identifier.</td>
<td>Inherit default action</td>
<td>Do not decrypt&lt;br&gt;Block&lt;br&gt;Block with reset&lt;br&gt;Inherit default action</td>
</tr>
<tr>
<td>Handshake Errors</td>
<td>An error occurred during TLS/SSL handshake negotiation.</td>
<td>Inherit default action</td>
<td>Do not decrypt&lt;br&gt;Block&lt;br&gt;Block with reset&lt;br&gt;Inherit default action</td>
</tr>
</tbody>
</table>
When you first create an SSL policy, logging connections that are handled by the default action is disabled by default. Because the logging settings for the default action also apply to undecryptable traffic handling, logging connections handled by the undecryptable traffic actions is disabled by default.

Note that if your browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. For more information, see TLS/SSL Rule Guidelines and Limitations, on page 1699.

Manage SSL Policies

In the SSL policy editor, you can:
• Configure your policy.
• Add, edit, delete, enable, disable, and organize TLS/SSL rules.
• Add trusted CA certificates.
• Determine the handling for encrypted traffic the system cannot decrypt.
• Log traffic that is handled by the default action and undecryptable traffic actions.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.
Procedure

**Step 1** Choose Policies > Access Control > SSL.

**Step 2** Manage SSL policies:
- Associate—To associate an SSL policy with an access control policy, see Associating Other Policies with Access Control, on page 1550.
- Compare—Click Compare Policies; see Comparing Policies, on page 508.
- Copy—Click Copy.
- Create—Click New Policy; see Create Basic SSL Policies, on page 1695.
- Delete—Click Delete. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Deploy—Choose Deploy > Deployment; see Deploy Configuration Changes, on page 495.
- Edit—Click Edit; see Editing an SSL Policy, on page 1697. If View appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Import/Export—See About Configuration Import/Export, on page 261.

Create Basic SSL Policies

To configure an SSL policy, you must give the policy a unique name and specify a default action.

**Procedure**

**Step 1** Choose Policies > Access Control > SSL.

**Step 2** Click New Policy.

**Step 3** Give the policy a unique Name and, optionally, a Description.

**Step 4** Specify the Default Action; see SSL Policy Default Actions, on page 1692.

**Step 5** Configure logging options for the default action as described in Logging Connections with a Policy Default Action, on page 2689.

**Step 6** Click Save.

**What To Do Next**
- Configure rules to add to your SSL policy; see Creating and Modifying TLS/SSL Rules, on page 1706.
- Set the default handling for undecryptable traffic; see Set Default Handling for Undecryptable Traffic, on page 1696.
Set Default Handling for Undecryptable Traffic

You can set undecryptable traffic actions at the SSL policy level to handle certain types of encrypted traffic the system cannot decrypt or inspect. When you deploy an SSL policy that contains no TLS/SSL rules, the undecryptable traffic actions determine how all undecryptable encrypted traffic on your network is handled.

Depending on the type of undecryptable traffic, you can choose to:

- Block the connection.
- Block the connection, then reset it. This option is preferrable for connectionless protocols like UDP, which keep trying to connect until the connection is blocked.
- Inspect the encrypted traffic with access control.
- Inherit the default action from the SSL policy.

Procedure

Step 1
In the SSL policy editor, click Undecryptable Actions.

Step 2
For each field, choose either the SSL policy's default action or another action you want to take on the type of undecryptable traffic. See Default Handling Options for Undecryptable Traffic, on page 1693 and SSL Policy Default Actions, on page 1692 for more information.

Step 3
Click Save to save the policy.

Example

For example, to block all SSLv2 traffic, set the options as follows:
Editing an SSL Policy

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

Step 1 Choose Policies > Access Control > SSL.

Step 2 Click Edit (✓) next to the SSL policy you want to configure. If View (👀) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Configure the SSL policy:

- Describe—If you want to update your SSL policy description, click the Description field and enter the new description.

- Log—If you want to log connections for undecryptable traffic handling and traffic that does not match SSL rules, see Logging Connections with a Policy Default Action, on page 2689.

- Rename—If you want to rename your SSL policy, click the Name field and enter the new name.

- Set the default action—If you want to configure how your SSL policy handles traffic that does not match SSL rules, see SSL Policy Default Actions, on page 1692.

What to do next

- Configure default logging for connections handled by the undecryptable traffic actions; see Logging Connections with a Policy Default Action, on page 2689.

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Step 4  Edit the rules in your SSL policy:

- Add—If you want to add a rule, click **Add Rule**.
- Copy—If you want to copy a rule, right-click a selected rule and choose **Copy**.
- Cut—If you want to cut a rule, right-click a selected rule and choose **Cut**.
- Delete—To delete a rule, click **Delete** next to the rule, then click **OK**.
- Disable—To disable an enabled rule, right-click a selected rule, choose **State**, then choose **Disable**.
- Display—To display the configuration page for a specific rule attribute, click the name or value in the column for the condition on the row for the rule. For example, click the name or value in the Source Networks column to display the Networks page for the selected rule. See Network Conditions, on page 522.
- Edit—To edit a rule, click **Edit** next to the rule.
- Enable—To enable a disabled rule, right-click a selected rule, choose **State**, then choose **Enable**. Disabled rules are dimmed and marked (disabled) beneath the rule name.
- Paste—To paste a cut or copied rule, right-click a selected rule and choose **Paste Above** or **Paste Below**.

Step 5  Save or discard your configuration:

- To save your changes and continue editing, click **Save**.
- To discard your changes, click **Cancel** and, if prompted, click **OK**.

What to do next

- If the SSL policy is not already associated with an access control policy, associate it as described in Associating Other Policies with Access Control, on page 1550.
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

• TLS/SSL Rules Management, on page 1718

TLS/SSL Rules Overview

TLS/SSL rules provide a granular method of handling encrypted traffic across multiple managed devices, whether blocking the traffic without further inspection, not decrypting the traffic and inspecting it with access control, or decrypting the traffic for access control analysis.

TLS/SSL Rule Guidelines and Limitations

Keep the following points in mind when setting up your TLS/SSL rules. Properly configuring TLS/SSL rules is a complex task, but one that is essential to building an effective deployment that handles encrypted traffic. Many factors influence how you configure rules, including certain application behavior that you cannot control.
In addition, rules can preempt each other, require additional licenses, or contain invalid configurations. Thoughtfully configured rules can also reduce the resources required to process network traffic. Creating overly complex rules and ordering rules the wrong way can adversely affect performance.

For detailed information, see Best Practices for Access Control Rules, on page 1528.

For guidelines related specifically to TLS crypto acceleration, see TLS Crypto Acceleration, on page 1666.

Guideline for Using TLS/SSL Decryption

Set up Decrypt - Resign or Decrypt - Known Key rules only if your managed device handles encrypted traffic. Decryption rules require processing overhead that can impact performance.

You cannot decrypt traffic on a device that has passive or inline tap mode interfaces.

TLS/SSL Rule Unsupported Features

RC4 cipher suite is unsupported
The Rivest Cipher 4 (also referred to as RC4 or ARC4) cipher suite is known to have vulnerabilities and is considered insecure. SSL policies identify the RC4 cipher suite as unsupported; you should configure the Unsupported Cipher Suite action in policy's Undecryptable Actions page to match your organization's requirements. For more information, see Default Handling Options for Undecryptable Traffic, on page 1693.

Passive and inline tap mode interfaces not supported
TLS/SSL traffic cannot be decrypted on passive or inline tap mode interfaces.

TLS 1.3 not supported
The Firepower System does not currently support TLS version 1.3 encryption or decryption. When users visit a web site that negotiates TLS 1.3 encryption, users might see errors similar to the following in their web browser:

- ERR_SSL_PROTOCOL_ERROR
- SEC_ERROR_BAD_SIGNATURE
**ERR_SSL_VERSION_INTERFERENCE**

For more information about how to control this behavior, contact Cisco TAC.

# TLS/SSL Do Not Decrypt Guidelines

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

If you elect to bypass decryption for certain types of traffic, no processing is done on the traffic. The encrypted traffic is first evaluated by SSL policy and then proceeds to the access control policy, where a final allow or block decision is made. Encrypted traffic can be allowed or blocked on any TLS/SSL rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- Exact URL or URL category
- Port
- User group

# TLS/SSL Decrypt - Resign Guidelines

You can associate one internal Certificate Authority (CA) certificate and private key with the **Decrypt - Resign** action. If traffic matches this rule, the system re-signs the server certificate with the CA certificate, then acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains different cryptographic session details, and allows the system to decrypt and reencrypt traffic.

## Best practices

We recommend the following:

- Use the **Decrypt - Resign** rule action for decrypting *outgoing* traffic, as opposed to incoming traffic for which we recommend the **Decrypt - Known Key** rule action.

  For more information about **Decrypt - Known Key**, see TLS/SSL Decrypt - Known Key Guidelines, on page 1703.

- Always check the **Replace Key Only** check box when you set up a **Decrypt - Resign** rule action.

  When a user browses to a web site that uses a *self-signed* certificate, the user sees a security warning in the web browser and is aware that they are communicating with an unsecure site.
When a user browses to a web site that uses a trusted certificate, the user does not see a security warning.

**Details**

If you configure a rule with the Decrypt - Resign action, the rule matches traffic based on the referenced internal CA certificate’s signature algorithm type, in addition to any configured rule conditions. Because you associate one CA certificate with a Decrypt - Resign action, you cannot create a TLS/SSL rule that decrypts multiple types of outgoing traffic encrypted with different signature algorithms. In addition, any external certificate objects and cipher suites you add to the rule must match the associated CA certificate encryption algorithm type.

For example, outgoing traffic encrypted with an elliptic curve (EC) algorithm matches a Decrypt - Resign rule only if the action references an EC-based CA certificate; you must add EC-based external certificates and cipher suites to the rule to create certificate and cipher suite rule conditions.

Similarly, a Decrypt - Resign rule that references an RSA-based CA certificate matches only outgoing traffic encrypted with an RSA algorithm; outgoing traffic encrypted with an EC algorithm does not match the rule, even if all other configured rule conditions match.

**Guidelines and limitations**

Also note the following:

**Anonymous cipher suite unsupported**

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the Decrypt - Resign or Decrypt - Known Key action in the rule because anonymous cipher suites are not used for authentication.

**Decrypt - Resign rule action and a Certificate Signing Request**

To use a Decrypt - Resign rule action, you should create a Certificate Signing Request (CSR) and have it signed by a trusted certificate authority. (You can use the FMC to create a CSR: Objects > Object Management > PKI > Internal CAs.)

To be used in a Decrypt - Resign rule, your certificate authority (CA) must have at least one of the following extensions:

- **CA: TRUE**
  
  For more information, see the discussion of Basic Constraints in RFC 3280, section 4.2.1.10.

- **KeyUsage=CertSign**
  
  For more information see RFC 5280, section 4.2.1.3.

To verify your CSR or CA has at least one of the preceding extensions, you can use the openssl command as discussed in a reference such as the openssl documentation.

This is necessary because for Decrypt - Resign inspection to work, the certificate that used in the TLS/SSL policy generates certificates on-the-fly and signs them so as to act as man-in-the-middle and proxy all TLS/SSL connections.
Non-matching cipher suite

The following error is displayed if you attempt to save a TLS/SSL rule with a cipher suite that does not match the certificate. To resolve the issue, see Verify TLS/SSL Cipher Suites, on page 1754.

Traffic cannot match this rule; none of your selected cipher suites contain a signature algorithm that the resigning CA's signature algorithm

Untrusted Certificate Authority

If the client does not trust the Certificate Authority (CA) used to re-sign the server certificate, it warns the user that the certificate should not be trusted. To prevent this, import the CA certificate into the client trusted CA store. Alternatively, if your organization has a private PKI, you can issue an intermediate CA certificate signed by the root CA which is automatically trusted by all clients in the organization, then upload that CA certificate to the device.

HTTP proxy limitation

The system cannot decrypt traffic if an HTTP proxy is positioned between a client and your managed device, and the client and server establish a tunneled TLS/SSL connection using the CONNECT HTTP method. The Handshake Errors undecryptable action determines how the system handles this traffic.

Upload signed CA

If you create an internal CA object and choose to generate a certificate signing request (CSR), you cannot use this CA for a Decrypt - Resign action until you upload the signed certificate to the object.

Traffic blocking with Trust rules

In some cases, access control Trust rule actions can block matching TLS/SSL traffic. The issue is limited to any ASA device capable of running ASA with FirePOWER Services, such as ASA 5555-X devices.

Use the following guidelines:

- For TLS/SSL traffic matching either Decrypt - Resign or Do Not Decrypt rule actions, make sure access control Allow rule actions are placed before Trust rule actions.

- If there is no SSL policy, there is no issue with access control Trust rule actions.

For a list of devices that can run ASA with FirePOWER Services, see the ASA and ASA FirePOWER Module Compatibility section of Cisco ASA Compatibility.

TLS/SSL Decrypt - Known Key Guidelines

When you configure the Decrypt - Known Key action, you can associate one or more server certificates and paired private keys with the action. If traffic matches the rule, and the certificate used to encrypt the traffic matches the certificate associated with the action, the system uses the appropriate private key to obtain the session encryption and decryption keys. Because you must have access to the private key, this action is best suited to decrypt traffic incoming to servers your organization controls.

Also note the following:

Anonymous cipher suite unsupported

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)
You cannot use the Decrypt - Resign or Decrypt - Known Key action in the rule because anonymous cipher suites are not used for authentication.

**Cannot match on Distinguished Name or Certificate**

You cannot match on Distinguished Name or Certificate conditions when creating a TLS/SSL rule with a Decrypt - Known Key action. The assumption is that if this rule matches traffic, the certificate, subject DN, and issuer DN already match the certificate associated with the rule.

**Mismatched signature algorithm**

If you configure a rule with the Decrypt - Resign action, and mismatch signature algorithm type for one or more external certificate objects or cipher suites, the policy editor displays an Information (ℹ️) next to the rule. If you mismatch signature algorithm type for all external certificate objects, or all cipher suites, the policy displays a warning icon Warning (⚠️) next to the rule, and you cannot deploy the access control policy associated with the SSL policy.

**Certificate pinning**

If the customer's browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. To allow this traffic, configure a TLS/SSL rule with the Do not decrypt action to match the server certificate common name or distinguished name.

---

**TLS/SSL Block Guidelines**

If decrypted traffic matches an access control rule with an action of Interactive Block or Interactive Block with reset, the system displays a customizable response page.

Provided you enabled logging in your rule, two connection events are displayed (in Analysis > Events > Connections): One event for the interactive block and another event to indicate whether or not the user chose to continue to the site or not.

**Related Topics**

About HTTP Response Pages, on page 1597

---

**TLS/SSL Certificate Pinning Guidelines**

Some applications use a technique referred to as TLS/SSL pinning or certificate pinning, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a TLS/SSL rule with a Decrypt - Resign action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

Because TLS/SSL pinning is used to avoid man-in-the-middle attacks, there is no way to prevent or work around it. You have the following options:

- Create a Do Not Decrypt for those applications rule ordered before Decrypt - Resign rules.
- Instruct users to access the applications using a web browser.

For more information about rule ordering, see SSL Rule Order, on page 1531.

To determine whether applications are using TLS/SSL pinning, see Troubleshoot TLS/SSL Pinning, on page 1750.
TLS/SSL Heartbeat Guidelines

Some applications use the TLS heartbeat extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

You can configure a Max Heartbeat Length in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, see The SSL Preprocessor, on page 2153.

For more information, see About TLS Heartbeat, on page 1748.

TLS/SSL Anonymous Cipher Suite Limitation

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the Decrypt - Resign or Decrypt - Known Key action in the rule because anonymous cipher suites are not used for authentication.

You can add an anonymous cipher suite to the Cipher Suite condition in a TLS/SSL rule, but the system automatically strips anonymous cipher suites during ClientHello processing. For the system to use the rule, you must also configure your TLS/SSL rules in an order that prevents ClientHello processing. For more information, see SSL Rule Order, on page 1531.

TLS/SSL Normalizer Guidelines

If you enable the Normalize Excess Payload option in the inline normalization preprocessor, when the preprocessor normalizes decrypted traffic, it might drop a packet and replace it with a trimmed packet. This does not end the TLS/SSL session. If the traffic is allowed, the trimmed packet is encrypted as part of the TLS/SSL session.

Other TLS/SSL Rule Guidelines

Users and groups

If you add a group or user to a rule, then change your realm settings to exclude that group or user, the rule has no effect. (The same applies to disabling the realm.) For more information about realms, see Create a Realm, on page 2314.

Categories in TLS/SSL rules

If your SSL policy has a Decrypt - Resign action but web sites are not being decrypted, check Category page on rules associated with that policy.

In some cases, a web site redirects to another site for authentication or other purposes and the redirected site might have a different URL categorization than the site you're trying to decrypt. For example, gmail.com (Web based email category) redirects to accounts.gmail.com (Internet Portals category) for authentication. Be sure to include all relevant categories in the SSL rule.
In order to fully process traffic based on URL category, you must also configure URL filtering. See the URL Filtering, on page 1573 chapter.

Query for URLs not in the local database

If you create a Decrypt - Resign rule and users browse to a website whose category and reputation are not in the local database, data might not be decrypted. Some websites are not categorized in the local database and, if not, data from those websites is not decrypted by default.

You can control this behavior with the setting System > Integration > Cloud Services, and check Query Cisco cloud for unknown URLs.

For more information about this option, see Cisco Clouds, on page 2903.

Creating and Modifying TLS/SSL Rules

Procedure

Step 1
Log in to the Firepower Management Center.

Step 2
Click Policies > Access Control > SSL.

Step 3
Click Edit ( ) next to the SSL policy.

If View ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4
You have the following choices:
- To add a new rule, click Add Rule.
• To edit an existing rule, click Edit (✓).

**Step 5**
Enter a **Name** for the rule.

**Step 6**
Specify whether the rule is **Enabled**.

**Step 7**
Specify the rule position; see **TLS/SSL Rule Order Evaluation**, on page 1676.

**Step 8**
Click a rule **Action**; see **Configuring TLS/SSL Rule Actions**, on page 1716.

**Step 9**
Configure rule conditions and options:
  a) Click **Zones** and configure rule conditions based on security zone; see **Interface Conditions**, on page 520.
  b) Click **Networks** and configure rule conditions based on network or geolocation; see **Network Conditions**, on page 522.
  c) Click **VLAN** tags and configure rule conditions based on VLANs; see **VLAN Conditions**, on page 526.
  d) Click **Users** and configure rule conditions based on users and groups; see **User, Realm, and ISE Attribute Conditions (User Control)**, on page 539.
  e) Click **Applications** and configure rule conditions based on application; see **Application Conditions (Application Control)**, on page 529.
  f) Click **Ports** and configure rule conditions based on communication port; see **Port and ICMP Code Conditions**, on page 527.
  g) Click **Category** and configure rule conditions based on URL reputation; see the chapter on **URL Filtering**, on page 1573, including **Filtering HTTPS Traffic**, on page 1578.
  h) Click **Certificate** and configure rule conditions based on TLS/SSL server certificate; see **Server Certificate-Based TLS/SSL Rule Conditions**, on page 1724.
  i) Click **DN** and configure rule conditions based on Distinguished Name; see **Certificate Distinguished Name TLS/SSL Rule Conditions**, on page 1725.
  j) Click **Cert Status** and configure rule conditions based on TLS/SSL certificate status; see **Certificate Status TLS/SSL Rule Conditions**, on page 1728.
  k) Click **Cipher Suite** and configure rule conditions based on cipher suite; see **Cipher Suite TLS/SSL Rule Conditions**, on page 1735.
  l) Click **Version** and configure rule conditions based on TLS or SSL protocol version; see **Encryption Protocol Version TLS/SSL Rule Conditions**, on page 1739.
  m) Click **Logging** and configure logging options for the rule; see **Best Practices for Connection Logging**, on page 2684.

**Step 10**
Click **Save**.

If the following error displays, see **Verify TLS/SSL Cipher Suites**, on page 1754: **Traffic cannot match this rule; none of your selected cipher suites contain a signature algorithm that the resigning CA's signature algorithm**.

---

**What to do next**

• Deploy configuration changes; see **Deploy Configuration Changes**, on page 495.
Adding a TLS/SSL Rule to a Rule Category

Procedure

Step 1  In the SSL rule editor, from the Insert drop-down list, select Into Category, then select the category you want to use.

Step 2  Click Save.

Tip  When you save the rule, it is placed last in that category.

What to do next
• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Positioning a TLS/SSL Rule by Number

Procedure

Step 1  In the SSL rule editor, from the Insert drop-down list, select above rule or below rule, then type the appropriate rule number.

Step 2  Click Save.

Tip  When you save the rule, it is placed where you specified.

What to do next
• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

TLS/SSL Rule Traffic Handling

The system matches traffic to TLS/SSL rules in the order you specify. In most cases, the system handles encrypted traffic according to the first TLS/SSL rule where all the rule’s conditions match the traffic. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an action, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does not further inspect encrypted traffic it blocks. It does inspect encrypted and unencrypted traffic with access control. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads.
The following scenario summarizes the ways that SSL rules handle traffic in an inline deployment.
In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.

- **TLS/SSL Rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.

- **TLS/SSL Rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **TLS/SSL Rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.

- **TLS/SSL Rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the SSL rule continues to the next rule.

- **TLS/SSL Rule 5: Decrypt - Resign** is the final rule. If traffic matches this rule, the system re-signs the server certificate with an uploaded CA certificate, then acts as a man-in-the-middle to decrypt traffic. The decrypted traffic is then evaluated against access control rules. Access control rules treat decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the SSL rule continues to the next rule.

- **SSL Policy Default Action** handles all traffic that does not match any of the TLS/SSL rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

**Encrypted Traffic Inspection Configuration**

You must create reusable public key infrastructure (PKI) objects to control encrypted traffic based on encrypted session characteristics and decrypt encrypted traffic. You can add this information on the fly when uploading trusted certificate authority (CA) certificates to the SSL policy and creating SSL rule conditions, creating the associated object in the process. However, configuring these objects ahead of time reduces the chance of improper object creation.

**Decrypting Encrypted Traffic with Certificates and Paired Keys**

The system can decrypt incoming encrypted traffic if you configure an internal certificate object by uploading the server certificate and private key used to encrypt the session. If you reference that object in an SSL rule with an action of **Decrypt - Known Key** and traffic matches that rule, the system uses the uploaded private key to decrypt the session.

The system can also decrypt outgoing traffic if you configure an internal CA object by uploading a CA certificate and private key. If you reference that object in a TLS/SSL rule with an action of **Decrypt - Resign** and traffic matches that rule, the system re-signs the server certificate passed to the client browser, then acts...
as a man-in-the-middle to decrypt the session. You can optionally replace the self-signed certificate key only and not the entire certificate, in which case users see a self-signed certificate key notice in the browser.

**Controlling Traffic Based on Encrypted Session Characteristics**

The system can control encrypted traffic based on the cipher suite or server certificate used to negotiate the session. You can configure one of several different reusable objects and reference the object in a TLS/SSL rule condition to match traffic. The following table describes the different types of reusable objects you can configure:

<table>
<thead>
<tr>
<th>If you configure...</th>
<th>You can control encrypted traffic based on whether...</th>
</tr>
</thead>
<tbody>
<tr>
<td>A cipher suite list containing one or more cipher suites</td>
<td>The cipher suite used to negotiate the encrypted session matches a cipher suite in the cipher suite list</td>
</tr>
<tr>
<td>A trusted CA object by uploading a CA certificate your</td>
<td>The trusted CA trusts the server certificate used to encrypt the session, whether:</td>
</tr>
<tr>
<td>organization trusts</td>
<td>• The CA issued the certificate directly</td>
</tr>
<tr>
<td></td>
<td>• The CA issued a certificate to an intermediate CA that issued the server certificate</td>
</tr>
<tr>
<td>An external certificate object by uploading a server</td>
<td>The server certificate used to encrypt the session matches the uploaded server certificate</td>
</tr>
<tr>
<td>certificate</td>
<td></td>
</tr>
<tr>
<td>A distinguished name object containing a certificate</td>
<td>The subject or issuer common name, country, organization, or organizational unit on the certificate used to encrypt the session matches the configured distinguished name</td>
</tr>
<tr>
<td>subject or issuer distinguished name</td>
<td></td>
</tr>
</tbody>
</table>

**TLS/SSL Rule Order Evaluation**

When you create the TLS/SSL rule in an SSL policy, you specify its position using the Insert list in the rule editor. TLS/SSL rules in an SSL policy are numbered, starting at 1. The system matches traffic to TLS/SSL rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the first TLS/SSL rule where all the rule’s conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does not continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an action, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does not further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.
Rules that use specific conditions (such as network and IP addresses) should be ordered before rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules. For more information about the OSI model, see this Wikipedia article.

Tip
Proper TLS/SSL rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

**TLS/SSL Rule Conditions**

An SSL rule’s conditions identify the type of encrypted traffic the rule handles. Conditions can be simple or complex, and you can specify more than one condition type per rule. Only if traffic meets all the conditions in a rule does the rule apply to the traffic.

If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a certificate condition but no version condition evaluates traffic based on the server certificate used to negotiate the session, regardless of the session SSL or TLS version.

Every TLS/SSL rule has an associated action that determines the following for matching encrypted traffic:

- **Handling:** Most importantly, the rule action governs whether the system will monitor, trust, block, or decrypt encrypted traffic that matches the rule’s conditions
- **Logging:** The rule action determines when and how you can log details about matching encrypted traffic.

Your TLS/SSL inspection configuration handles, inspects, and logs decrypted traffic:

- The SSL policy’s undecryptable actions handle traffic that the system cannot decrypt.
- The policy’s default action handles traffic that does not meet the condition of any non-Monitor TLS/SSL rule.

You can log a connection event when the system blocks or trusts an encrypted session. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. Connection logs for encrypted sessions contain details about the encryption, such as the certificate used to encrypt that session. You can log only end-of-connection events, however:

- For blocked connections (Block, Block with reset), the system immediately ends the sessions and generates an event
For trusted connections (Do not decrypt), the system generates an event when the session ends

**TLS/SSL Rule Condition Types**

When you add or edit an SSL rule, use the tabs on the left side of the lower portion of the rule editor to add and edit rule conditions.

**Table 107: TLS/SSL Rule Condition Types**

<table>
<thead>
<tr>
<th>This Condition...</th>
<th>Matches Encrypted Traffic...</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zones</td>
<td>Entering or leaving a device via an interface in a specific security zone</td>
<td>A security zone is a logical grouping of one or more interfaces according to your deployment and security policies. Interfaces in a zone may be located across multiple devices. <strong>Note</strong> You cannot decrypt traffic on an inline or tap mode interface.</td>
</tr>
<tr>
<td>Networks</td>
<td>By its source or destination IP address, country, or continent</td>
<td>You can explicitly specify IP addresses. The geolocation feature also allows you to control traffic based on its source or destination country or continent.</td>
</tr>
<tr>
<td>VLAN Tags</td>
<td>Tagged by VLAN</td>
<td>The system uses the innermost VLAN tag to identify a packet by VLAN.</td>
</tr>
<tr>
<td>Ports</td>
<td>By its source or destination port</td>
<td>You can control encrypted traffic based on the TCP port.</td>
</tr>
<tr>
<td>Users</td>
<td>By the user involved in the session</td>
<td>You can control encrypted traffic based on the LDAP user logged into a host involved in an encrypted, monitored session. You can control traffic based on individual users or groups retrieved from a Microsoft Active Directory server.</td>
</tr>
<tr>

## TLS/SSL Rule Actions

The following sections discuss the actions available with TLS/SSL rules.

### TLS/SSL Rule Monitor Action

The **Monitor** action is not designed to permit or deny traffic. Rather, its primary purpose is to force connection logging, regardless of how matching traffic is eventually handled. Traffic is then matched against additional rules, if present, to determine whether to trust, block, or decrypt it. The first non-Monitor rule matched determines traffic flow and any further inspection. If there are no additional matching rules, the system uses the default action.

Because the primary purpose of Monitor rules is to track network traffic, the system automatically logs end-of-connection events for monitored traffic to the Firepower Management Center database, regardless of the logging configuration of the rule or default action that later handles the connection.

### TLS/SSL Rule Do Not Decrypt Action

The **Do Not Decrypt** action passes encrypted traffic for evaluation by the access control policy’s rules and default action. Because some access control rule conditions require unencrypted traffic, this traffic may match fewer rules. The system cannot perform deep inspection on encrypted traffic, such as intrusion or file inspection.

Typical reasons for a **Do Not Decrypt** rule action include:

- When decrypting TLS/SSL traffic is prohibited by law.
• Sites you know you can trust.
• Sites you can disrupt by inspecting traffic (such as Windows Update).
• To view the values of TLS/SSL fields using connection events. (You do not need to decrypt traffic to view connection event fields.) For more information, see Requirements for Populating Connection Event Fields, on page 2710.

For more information, see Default Handling Options for Undecryptable Traffic, on page 1693

TLS/SSL Rule Blocking Actions

The Firepower System provides the following TLS/SSL rule actions for traffic you do not want to pass through the system:

• **Block** to terminate the connection, resulting in an error in the client browser.
  The error message does not indicate the site was blocked due to policy. Instead, errors might indicate that there are no common encryption algorithms. It is not obvious from this message that you blocked the connection on purpose.
• **Block with reset** to terminate and reset the connection, resulting in an error in the client browser.
  The error indicates the connection was reset but does not indicate why.

---

**Tip** You cannot use the **Block** or **Block with reset** action in a passive or inline (tap mode) deployment because the device does not directly inspect the traffic. If you create a rule with the **Block** or **Block with reset** action that contains passive or inline (tap mode) interfaces within a security zone condition, the policy editor displays a warning (⚠️) next to the rule.

---

TLS/SSL Rule Decrypt Actions

The **Decrypt - Known Key** and **Decrypt - Resign** actions decrypt encrypted traffic. The system inspects decrypted traffic with access control. Access control rules handle decrypted and unencrypted traffic identically — you can inspect it for discovery data as well as detect and block intrusions, prohibited files, and malware. The system reencrypts allowed traffic before passing it to its destination.

We recommend you use a certificate from a trusted Certificate Authority (CA) to decrypt traffic. This prevents **Invalid Issuer** from being displayed in the SSL Certificate Status column in connection events.

For more information about adding trusted objects, see Trusted Certificate Authority Objects, on page 615.

Configuring TLS/SSL Rule Actions

**Before you begin**

See:

• TLS/SSL Rule Blocking Actions, on page 1716
• TLS/SSL Rule Do Not Decrypt Action, on page 1715
Encrypted Traffic Handling

Configuring a Decrypt - Resign Action

Before you begin
See TLS/SSL Decrypt - Resign Guidelines, on page 1701.

Procedure

Step 1 In the SSL rule editor, select Decrypt - Resign from the Action list.

Step 2 Select an internal CA certificate object from the list.

Step 3 Check Replace Key Only. Always check the Replace Key Only check box when you set up a Decrypt - Resign rule action.

When a user browses to a web site that uses a self-signed certificate, the user sees a security warning in the web browser and is aware that they are communicating with an unsecure site.
When a user browses to a web site that uses a trusted certificate, the user does not see a security warning.

**Step 4**  
Click **Add**.

**Step 5**  
*Optional.* To use a Trusted CA certificate in your SSL policy so you can avoid **Invalid Issuer** in the SSL Certificate Status column in connection events, add the certificate to the policy:

a) In the SSL policy editor page, click **Trusted CA Certificates**.

b) Add the CA certificate corresponding to your known key to the SSL policy.

---

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

### Configuring a Decrypt - Known Key Action

**Before you begin**

See TLS/SSL Decrypt - Known Key Guidelines, on page 1703.

**Procedure**

**Step 1**  
In the SSL rule editor, select **Decrypt - Known Key** from the **Action** drop-down list.

**Step 2**  
Click the **Click to select decryption certs** field.

**Step 3**  
Select one or more internal certificate objects in the **Available Certificates** list, then click **Add to Rule**.

**Step 4**  
Click **OK**.

**Step 5**  
Click **Add**.

**Step 6**  
*Optional.* To use a Trusted CA certificate in your SSL policy so you can avoid **Invalid Issuer** in the SSL Certificate Status column in connection events, add the certificate to the policy:

a) In the SSL policy editor page, click **Trusted CA Certificates**.

b) Add the CA certificate corresponding to your known key to the SSL policy.

---

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

### TLS/SSL Rules Management

The **Rules** page of the SSL policy editor allows you to add, edit, search, move, enable, disable, delete, and otherwise manage TLS/SSL rules in your policy.
TLS/SSL Rule Search

You can search the list of TLS/SSL rules for matching values using an alphanumeric string, including spaces and printable, special characters. The search inspects the rule name and any rule condition you have added to the rule. For rule conditions, the search matches any name or value you can add for each condition type (zone, network, application, and so on). This includes individual object names or values, group object names, individual object names or values within a group, and literal values.

You can use complete or partial search strings. The column for matching values is highlighted for each matching rule. For example, if you search on all or part of the string 100Bao, at a minimum, the Applications column is highlighted for each rule where you have added the 100Bao application. If you also have a rule named 100Bao, both the Name and Applications columns are highlighted.

You can navigate to each previous or next matching rule. A status message displays the current match and the total number of matches.

Matches may occur on any page of a multi-page rule list. When the first match is not on the first page, the page where the first match occurs is displayed. Selecting the next match when you are at the last match takes you to the first match, and selecting the previous match when you are at the first match takes you to the last match.

Searching TLS/SSL Rules

Procedure

Step 1

In the SSL policy editor, click the Search Rules prompt, type a search string, then press Enter.

Tip

Columns for rules with matching values are highlighted, with differentiated highlighting for the indicated (first) match.

Step 2

Find the rules you are interested in:

- To navigate between matching rules, click Next-Match or Previous-Match.
- To refresh the page and clear the search string and any highlighting, click Clear (X).

Enabling and Disabling TLS/SSL Rules

When you create a TLS/SSL rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing the list of rules in an SSL policy, disabled rules are grayed out, although you can still modify them. Note that you can also enable or disable a TLS/SSL rule using the rule editor.

Procedure

Step 1

In the SSL policy editor, right-click a rule and choose a rule state.
Moving a TLS/SSL Rule

**Procedure**

**Step 1**  In the SSL policy editor, select the rules by clicking in a blank area for each rule.
**Step 2**  Right-click the rule and select **Cut**.
**Step 3**  Right-click a blank area for a rule next to where you want to paste the cut rules and select **Paste above** or **Paste below**.

*Tip* You cannot copy and paste TLS/SSL rules between two different SSL policies.

**Step 4**  Click **Save**.

**What to do next**
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Adding a New TLS/SSL Rule Category

You can create custom categories between the Standard Rules and Root Rules categories to further organize your rules without having to create additional policies. You can rename and delete categories that you add. You cannot move these categories, but you can move rules into, within, and out of them.

**Procedure**

**Step 1**  In the policy editor, click **Add Category**.

*Tip* If your policy already contains rules, you can click a blank area in the row for an existing rule to set the position of the new category before you add it. You can also right-click an existing rule and select **Insert new category**.

**Step 2**  Type a **Name**.

**Step 3**  You have the following choices:
- Select **above Category** from the first **Insert** drop-down list, then select the category above which you want to position the rule from the second drop-down list.
- Select **below rule** from the drop-down list, then enter an existing rule number. This option is valid only when at least one rule exists in the policy.
• Select **above rule** from the drop-down list, then, enter an existing rule number. This option is valid only when at least one rule exists in the policy.

**Step 4**  Click **OK**.

**Tip**  Rules in a category you delete are added to the category above.

**Step 5**  Click **Save**.
Adding a New TLS/SSL Rule Category
Decryption Tuning Using TLS/SSL Rules

The following topics provide an overview of how to configure TLS/SSL rule conditions:

- TLS/SSL Rule Conditions Overview, on page 1723
- Requirements and Prerequisites for Decryption Tuning, on page 1724
- Server Certificate-Based TLS/SSL Rule Conditions, on page 1724

TLS/SSL Rule Conditions Overview

A basic TLS/SSL rule applies its rule action to all encrypted traffic inspected by the device. To better control and decrypt encrypted traffic, you can configure rule conditions to handle and log specific types of traffic. Each TLS/SSL rule can contain 0, 1, or more rule conditions; a rule matches traffic only if the traffic matches every condition in that TLS/SSL rule.

Note

When traffic matches a rule, the device applies the configured rule action to the traffic. When the connection ends, the device logs the traffic if configured to do so.

Each rule condition allows you to specify one or more properties of traffic you want to match against; these properties include details of:

- The flow of traffic, including the security zone through which it travels, IP address and port, country of origin or destination, and origin or destination VLAN.
- The user associated with a detected IP address.
- The traffic payload, including the application detected in the traffic.
- The connection encryption, including the TLS/SSL protocol version and cipher suite and server certificate used to encrypt the connection.
- The category and reputation of the URL specified in the server certificate's distinguished name.

Server Certificate-Based TLS/SSL Rule Conditions

TLS/SSL rules can handle and decrypt encrypted traffic based on server certificate characteristics. You can configure TLS/SSL rules based on the following server certificate attributes:

- Distinguished name conditions allow you to handle and inspect encrypted traffic based on the CA that issued a server certificate, or the certificate holder. Based on the issuer distinguished name, you can handle traffic based on the CA that issued a site’s server certificate.

- Certificate conditions in TLS/SSL rules allow you to handle and inspect encrypted traffic based on the server certificate used to encrypt that traffic. You can configure a condition with one or more certificates; traffic matches the rule if the certificate matches any of the condition’s certificates.

- Certificate status conditions in TLS/SSL rules allow you to handle and inspect encrypted traffic based on the status of the server certificate used to encrypt the traffic, including whether a certificate is valid, revoked, expired, not yet valid, self-signed, signed by a trusted CA, whether the Certificate Revocation List (CRL) is valid; whether the Server Name Indication (SNI) in the certificate matches the server in the request.

- Cipher suite conditions in TLS/SSL rules allow you to handle and inspect encrypted traffic based on the cipher suite used to negotiate the encrypted session.
• Session conditions in TLS/SSL rules allow you to inspect encrypted traffic based on the SSL or TLS version used to encrypt the traffic.

To detect multiple cipher suites in a rule, the certificate issuer, or the certificate holder, you can create reusable cipher suite list and distinguished name objects and add them to your rule. To detect the server certificate and certain certificate statuses, you must create external certificate and external CA objects for the rule.

Certificate Distinguished Name TLS/SSL Rule Conditions

When configuring the rule condition, you can manually specify a literal value, reference a distinguished name object, or reference a distinguished name group containing multiple objects.

You cannot configure a distinguished name condition if you also choose the Decrypt - Known Key action. Because that action requires you to choose a server certificate to decrypt traffic, the certificate already matches the traffic.

You can match against multiple subject and issuer distinguished names in a single certificate status rule condition; only one common or distinguished name needs to match to match the rule.

If you add a distinguished name manually, it can contain the common name attribute (CN). If you add a common name without CN=, the system prepends CN= before saving the object.

You can also add a distinguished name with one each of the following attributes, separated by commas: C, CN, O, OU.

In a single DN condition, you can add a maximum of 50 literal values and distinguished name objects to the Subject DNs, and 50 literal values and distinguished name objects to the Issuer DNs.

The system-provided DN object group, Cisco-Undecryptable-Sites, contains websites whose traffic the system cannot decrypt. You can add this group to a DN condition to block or not decrypt traffic to or from these websites, without wasting system resources attempting to decrypt that traffic. You can modify individual entries in the group. You cannot delete the group. System updates can modify the entries on this list, but the system preserves user changes.

The first time the system detects an encrypted session to a new server, DN data is not available for ClientHello processing, which can result in an undecrypted first session. After the initial session, the managed device caches data from the server Certificate message. For subsequent connections from the same client, the system can match the ClientHello message conclusively to rules with DN conditions and process the message to maximize decryption potential.

Controlling Encrypted Traffic by Certificate Distinguished Name

Procedure

**Step 1**
In the SSL rule editor, select DN.

**Step 2**
Find the distinguished names you want to add from the Available DNs, as follows:

• To add a distinguished name object on the fly, which you can then add to the condition, click Add (†) above the Available DNs list.
To search for distinguished name objects and groups to add, click the **Search by name or value** prompt above the **Available DNs** list, then type either the name of the object, or a value in the object. The list updates as you type to display matching objects.

**Step 3**
To select an object, click it. To select all objects, right-click and then select **Select All**.

**Step 4**
Click **Add to Subject** or **Add to Issuer**.

- **Tip** You can also drag and drop selected objects.

**Step 5**
Add any literal common names or distinguished names that you want to specify manually. Click the **Enter DN or CN** prompt below the **Subject DNs** or **Issuer DNs** list; then type a common name or distinguished name and click **Add**.

**Step 6**
Add or continue editing the rule.

---

**Example**

The following figure shows a distinguished name rule condition searching for certificates issued to goodbakery.example.com or issued by goodca.example.com. Traffic encrypted with these certificates is allowed, subject to access control.

<table>
<thead>
<tr>
<th>Subject DNs (1)</th>
<th>Issuer DNs (1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>GoodBakery</td>
<td>CN=goodca.example.com</td>
</tr>
</tbody>
</table>

The following figure shows a distinguished name rule condition searching for certificates issued to badbakery.example.com and associated domains, or certificates issued by badca.example.com. Traffic encrypted with these certificates is decrypted using a re-signed certificate.
Certificate TLS/SSL Rule Conditions

When you build a certificate-based TLS/SSL rule condition, you can upload a server certificate; you save the certificate as an external certificate object, which is reusable and associates a name with a server certificate. Alternately, you can configure certificate conditions with existing external certificate objects and object groups.

You can search the Available Certificates field in the rule condition based for external certificate objects and object groups based on the following certificate distinguished name characteristics:

- Subject or issuer common name (CN)
- Subject or issuer organization (O)
- Subject or issuer organizational unit (OU)

You can choose to match against multiple certificates in a single certificate rule condition; if the certificate used to encrypt the traffic matches any of the uploaded certificates, the encrypted traffic matches the rule.

You can add a maximum of 50 external certificate objects and external certificate object groups to the Selected Certificates in a single certificate condition.

Note the following:

- You cannot configure a certificate condition if you also select the Decrypt - Known Key action. Because that action requires you to select a server certificate to decrypt traffic, the implication is that the certificate already matches the traffic.

- If you configure a certificate condition with an external certificate object, any cipher suites you add to a cipher suite condition, or internal CA objects you associate with the Decrypt - Resign action, must
match the external certificate’s signature algorithm type. For example, if your rule’s certificate condition references an EC-based server certificate, any cipher suites you add, or CA certificates you associate with the Decrypt - Resign action, must also be EC-based. If you mismatch signature algorithm types in this case, the policy editor displays a warning next to the rule.

- The first time the system detects an encrypted session to a new server, certificate data is not available for ClientHello processing, which can result in an undecrypted first session. After the initial session, the managed device caches data from the server Certificate message. For subsequent connections from the same client, the system can match the ClientHello message conclusively to rules with certificate conditions and process the message to maximize decryption potential.

Controlling Encrypted Traffic by Certificate

Procedure

**Step 1**
In the SSL rule editor, select Certificate.

**Step 2**
Find the server certificates you want to add from the Available Certificates, as follows;

- To add an external certificate object on the fly, which you can then add to the condition, click Add (+) above the Available Certificates list.
- To search for certificate objects and groups to add, click the Search by name or value prompt above the Available Certificates list, then type either the name of the object, or a value in the object. The list updates as you type to display matching objects.

**Step 3**
To select an object, click it. To select all objects, right-click and then select Select All.

**Step 4**
Click Add to Rule.

**Tip**
You can also drag and drop selected objects.

**Step 5**
Add or continue editing the rule.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Related Topics

- External Certificate Objects, on page 617

Certificate Status TLS/SSL Rule Conditions

For each certificate status TLS/SSL rule condition you configure, you can match traffic against the presence or absence of a given status. You can select several statuses in one rule condition; if the certificate matches any of the selected statuses, the rule matches the traffic.

You can choose to match against the presence or absence of multiple certificate statuses in a single certificate status rule condition; the certificate needs to match only one of the criteria to match the rule.
You should consider, when setting this parameter, whether you're configuring a decrypt rule or a block rule. Typically, you should click Yes for a block rule and No for a decrypt rule. Examples:

- If you're configuring a Decrypt - Resign rule, the default behavior is to decrypt traffic with an expired certificate. To change that behavior, click No for Expired so traffic with an expired certificate is not decrypted and resigned.

- If you're configuring a Block rule, the default behavior is to allow traffic with an expired certificate. To change that behavior click Yes for Expired so traffic with an expired certificate is blocked.

The following table describes how the system evaluates encrypted traffic based on the encrypting server certificate's status.

**Table 108: Certificate Status Rule Condition Criteria**

<table>
<thead>
<tr>
<th>Status Check</th>
<th>Status Set to Yes</th>
<th>Status Set to No</th>

### Status Check

<table>
<thead>
<tr>
<th>Status Check</th>
<th>Status Set to Yes</th>
<th>Status Set to No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invalid CRL</td>
<td>The Certificate Revocation List (CRL) digital signature is not valid. At least one of the following is true:</td>
<td>The CRL is valid. All of the following are true:</td>
</tr>
<tr>
<td></td>
<td>• The value of the CRL’s Next Update or Last Update field is invalid.</td>
<td>• Next Update and Last Update fields are valid.</td>
</tr>
<tr>
<td></td>
<td>• The CRL is not yet valid.</td>
<td>• The CRL’s date is valid.</td>
</tr>
<tr>
<td></td>
<td>• The CRL has expired.</td>
<td>• The path is valid.</td>
</tr>
<tr>
<td></td>
<td>• An error occurred when attempting to verify the CRL path. This error occurs only if extended CRL checking is enabled.</td>
<td>• The CRL was found.</td>
</tr>
<tr>
<td></td>
<td>• CRL could not be found.</td>
<td>• The CRL matches the certificate’s scope.</td>
</tr>
<tr>
<td></td>
<td>• The only CRLs that could be found did not match the scope of the certificate.</td>
<td></td>
</tr>
<tr>
<td>Server mismatch</td>
<td>The server name does not match the server’s Server Name Indication (SNI) name, which could indicate an attempt to spoof the server name.</td>
<td>The server name matches the SNI name of the server to which the client is requesting access.</td>
</tr>
</tbody>
</table>

Note that even though a certificate might match more than one status, the rule causes an action to be taken on the traffic only once.

Checking whether a CA issued or revoked a certificate requires uploading root and intermediate CA certificates and associated CRLs as objects. You then add these trusted CA objects to an SSL policy’s list of trusted CA certificates.

**Trusting External Certificate Authorities**

You can trust CAs by adding root and intermediate CA certificates to your SSL policy, then use these trusted CAs to verify server certificates used to encrypt traffic.

If a trusted CA certificate contains an uploaded certificate revocation list (CRL), you can also verify whether a trusted CA revoked the encryption certificate.

**Procedure**

1. **Step 1** In the SSL rule editor, select *Trusted CA Certificates*.
2. **Step 2** Find the trusted CAs you want to add from the *Available Trusted CAs*, as follows:
To add a trusted CA object on the fly, which you can then add to the condition, click **Add** (†) above the **Available Trusted CAs** list.

To search for trusted CA objects and groups to add, click the **Search by name or value** prompt above the **Available Trusted CAs** list, then type either the name of the object, or a value in the object. The list updates as you type to display matching objects.

**Step 3**
To select an object, click it. To select all objects, right-click and then select **Select All**.

**Step 4**
Click **Add to Rule**.

**Tip**
You can also drag and drop selected objects.

**Step 5**
Add or continue editing the rule.

---

**What to do next**
- Add a certificate status TLS/SSL rule condition to your SSL rule. See *Matching Traffic on Certificate Status*, on page 1733 for more information.
- Deploy configuration changes; see *Deploy Configuration Changes*, on page 495.

**Related Topics**
- Trusted Certificate Authority Objects, on page 615

**Trusted External Certificate Authority Configuration**

Verified server certificates include certificates signed by trusted CAs. After you add trusted CA certificates to the SSL policy, you can configure a TLS/SSL rule with certificate status conditions to match against this traffic.

**Tip**
Upload all certificates within a root CA’s chain of trust to the list of trusted CA certificates, including the root CA certificate and all intermediate CA certificates. Otherwise, it is more difficult to detect trusted certificates issued by intermediate CAs. Also, if you configure certificate status conditions to trust traffic based on the root issuer CA, all traffic within a trusted CA’s chain of trust can be allowed without decryption, rather than unnecessarily decrypting it.

When you create an SSL policy, the system populates the Trusted CA Certificates tab with a default Trusted CA object group, Cisco Trusted Authorities.

You can modify individual entries in the group, and choose whether to include this group in your SSL policy. You cannot delete the group. System updates can modify the entries on this list, but user changes are preserved.

**Matching Traffic on Certificate Status**

**Before you begin**
- Add a trusted CA object or group to your SSL policy. See *Trusting External Certificate Authorities*, on page 1732 for more information.
Procedure

**Step 1**  In the Firepower Management Center, choose **Policies > Access Control > SSL**.

**Step 2**  Add a new policy or edit an existing policy.

**Step 3**  Add a new TLS/SSL rule or edit an existing rule.

**Step 4**  In the Add Rule or Editing Rule dialog box, choose **Cert Status**.

**Step 5**  For each certificate status, you have the following options:

- Choose **Yes** to match against the presence of that certificate status.
- Choose **No** to match against the absence of that certificate status.
- Choose **Any** to skip the condition when matching the rule. In other words, choosing **Any** means the rule matches whether the certificate status is present or absent.

**Step 6**  Add or continue editing the rule.

Example

The organization trusts the Verified Authority certificate authority. The organization does not trust the Spammer Authority certificate authority. The system administrator uploads the Verified Authority certificate and an intermediate CA certificate issued by Verified Authority to the system. Because Verified Authority revoked a certificate it previously issued, the system administrator uploads the CRL that Verified Authority provided.

The following figure shows a certificate status rule condition checking for valid certificates, those issued by a Verified Authority, are not on the CRL, and still within the Valid From and Valid To date. Because of the configuration, traffic encrypted with these certificates is not decrypted and inspected with access control.

The following figure shows a certificate status rule condition checking for the absence of a status. In this case, because of the configuration, it matches against traffic encrypted with a certificate that has not expired and monitors that traffic.
The following graphic illustrates a certificate status rule condition that matches the presence or absence of several statuses. Because of the configuration, if the rule matches incoming traffic encrypted with a certificate issued by an invalid user, self-signed, invalid, or expired, it decrypts the traffic with a known key.

The following graphic illustrates a certificate status rule condition that matches if the SNI of the request matches the server name or if the CRL is not valid. Because of the configuration, if the rule matches either condition, traffic is blocked.

What to do next

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Cipher Suite TLS/SSL Rule Conditions

The system provides predefined cipher suites you can add to a cipher suite rule condition. You can also add cipher suite list objects containing multiple cipher suites.

Note

You cannot add new cipher suites. You can neither modify nor delete predefined cipher suites.
You can add a maximum of 50 cipher suites and cipher suite lists to the **Selected Cipher Suites** in a single cipher suite condition. The system supports adding the following cipher suites to a cipher suite condition:

- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_DES_CBC_SHA
- TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA256
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA256
- TLS_DHE_RSA_WITH_DES_CBC_SHA
- TLS_DH_Anon_WITH_AES_128_GCM_SHA256
- TLS_DH_Anon_WITH_AES_256_GCM_SHA384
- TLS_DH_Anon_WITH_CAMELLIA_128_CBC_SHA
- TLS_DH_anon_WITH_CAMELLIA_128_CBC_SHA256
- TLS_DH_Anon_WITH_CAMELLIA_256_CBC_SHA
- TLS_DH_anon_WITH_CAMELLIA_256_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_NULL_SHA
- TLS_ECDHE_ECDSA_WITH_RC4_128_SHA
- TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_NULL_SHA
- TLS_ECDHE_RSA_WITH_RC4_128_SHA
- TLS_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_GCM_SHA384
- TLS_RSA_WITH_CAMELLIA_128_CBC_SHA
- TLS_RSA_WITH_CAMELLIA_128_CBC_SHA256
- TLS_RSA_WITH_CAMELLIA_256_CBC_SHA
- TLS_RSA_WITH_CAMELLIA_256_CBC_SHA256
- TLS_RSA_WITH_DES_CBC_SHA
- TLS_RSA_WITH_NULL_MD5
- TLS_RSA_WITH_NULL_SHA
- TLS_RSA_WITH_RC4_128_MD5
- TLS_RSA_WITH_RC4_128_SHA

Note the following:

- If you add cipher suites not supported for your deployment, you cannot deploy your configuration. For example, passive deployments do not support decrypting traffic with any of the ephemeral Diffie-Hellman (DHE) or ephemeral elliptic curve Diffie-Hellman (ECDHE) cipher suites. Creating a rule with these cipher suites prevents you from deploying your access control policy.

- If you configure a cipher suite condition with a cipher suite, any external certificate objects you add to a certificate condition, or internal CA objects you associate with the Decrypt - Resign action, must match the cipher suite’s signature algorithm type. For example, if your rule’s cipher suite condition references an EC-based cipher suite, any server certificates you add, or CA certificates you associate with the Decrypt - Resign action, must also be EC-based. If you mismatch signature algorithm types in this case, the policy editor displays a warning icon next to the rule.
• You can add an anonymous cipher suite to the **Cipher Suite** condition in an SSL rule, but keep in mind:
  - The system automatically strips anonymous cipher suites during ClientHello processing. For the system to use the rule, you must also configure your TLS/SSL rules in an order that prevents ClientHello processing. For more information, see SSL Rule Order, on page 1531.
  - You cannot use either the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule, because the system cannot decrypt traffic encrypted with an anonymous cipher suite.

• When specifying a cipher suite as a rule condition, consider that the rule matches on the negotiated cipher suite in the ServerHello message, rather than on the full list of cipher suites specified in the ClientHello message. During ClientHello processing, the managed device strips unsupported cipher suites from the ClientHello message. However, if this results in all specified cipher suites being stripped, the system retains the original list. If the system retains unsupported cipher suites, subsequent evaluation results in an undecrypted session.

## Controlling Encrypted Traffic by Cipher Suite

**Procedure**

**Step 1**
In the SSL rule editor, select Cipher Suite.

**Step 2**
Find the cipher suites you want to add from the **Available Cipher Suites**, as follows;

  - To add a cipher suite list on the fly, which you can then add to the condition, click **Add (➕)** above the **Available Cipher Suites** list.
  - To search for cipher suites and lists to add, click the **Search by name or value** prompt above the **Available Cipher Suites** list, then type either the name of the cipher suite, or a value in the cipher suite. The list updates as you type to display matching cipher suites.

**Step 3**
To select a cipher suite, click it. To select all cipher suites, right-click and then select **Select All**.

**Step 4**
Click **Add to Rule**.

**Tip**
You can also drag and drop selected cipher suites.

**Step 5**
Add or continue editing the rule.

**What to do next**

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Related Topics**

  - Cipher Suite Lists, on page 607
Encryption Protocol Version TLS/SSL Rule Conditions

You can choose to match against traffic encrypted with SSL version 3.0, or TLS version 1.0, 1.1, or 1.2. By default, all protocol versions are selected when you create a rule; if you select multiple versions, encrypted traffic that matches any of the selected versions matches the rule. You must select at least one protocol version when saving the rule condition.

You cannot select SSL v2.0 in a version rule condition; the system does not support decrypting traffic encrypted with SSL version 2.0. You can configure an undecryptable action to allow or block this traffic without further inspection.

Controlling Traffic by Encryption Protocol Version

Procedure

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
CHAPTER 73

Monitor SSL Hardware Acceleration

Use the show counters command in the CLI to evaluate TLS crypto acceleration behavior. This command lists a variety of metrics that inform you about normal activity, alerts, and potential fatal issues.

Use the `show counters description` command to see explanations for each counter. To view only counters related to TLS crypto acceleration, use `show counters description | include TLS_TRK`.

- Informational Counters, on page 1741
- Alert Counters, on page 1742
- Error Counters, on page 1742
- Fatal Counters, on page 1743

Informational Counters

If a system under load is working well, you should see large counts for the following counters. Because there are 2 sides to the tracker process per connection, you can see these counters increase by 2 per connection. The PRIV_KEY_RECV and SECU_PARAM_RECV counters are the most important, and are highlighted. The CONTEXT_CREATED and CONTEXT_DESTROYED counters relate to the allocation of cryptographic chip memory.

```
> show counters
 Protocol   Counter                  Value   Context
    SSLENC  CONTEXT_CREATED           258225 Summary
    SSLENC  CONTEXT_DESTROYED         258225 Summary
      TLS_TRK OPEN_SERVER_SESSION      258225 Summary
      TLS_TRK OPEN_CLIENT_SESSION      258225 Summary
      TLS_TRK UPSTREAM_CLOSE           516450 Summary
      TLS_TRK DOWNSTREAM_CLOSE         516450 Summary
      TLS_TRK FREE_SESSION             516450 Summary
      TLS_TRK CACHE_FREE               516450 Summary
      TLS_TRK PRIV_KEY_RECV             258225 Summary
      TLS_TRK NO_KEY_ENABLE            258225 Summary
      TLS_TRK SECU_PARAM_RECV           516446 Summary
      TLS_TRK DECRYPTED_ALERT           258222 Summary
      TLS_TRK DECRYPTED_APPLICATION     33568976 Summary
      TLS_TRK ALERT_RX_CNT             258222 Summary
      TLS_TRK ALERT_RX_WARNING_ALERT    258222 Summary
      TLS_TRK ALERT_RX_CLOSE_NOTIFY     258222 Summary
```
Alert Counters

We implemented the following counters according to the TLS 1.2 specification. FATAL or BAD alerts could indicate issues; however, ALERT_RX_CLOSE_NOTIFY is normal.

For details, see RFC 5246 section 7.2.

```
> show counters description | include TLS_TRK
```

Error Counters

These counters indicate system errors. These counts should be low on a healthy system. The BY_PASS counters indicate packets that have been passed directly to or from the inspection engine (Snort) process (which runs in software) without decryption. The following example lists some of the bad counters.

Counters with a value of 0 are not displayed. To view a complete list of counters, use the command **show counters description | include TLS_TRK**
Fatal Counters

The fatal counters indicate serious errors. These counters should be at or near 0 on a healthy system. The following example lists the fatal counters.

> show counters
Protocol  Counter Value  Context
CRYPTO RING_FULL  1  Summary
CRYPTO ACCELERATOR_CORE_TIMEOUT  1  Summary
CRYPTO ACCELERATOR_RESET  1  Summary
CRYPTO RSA_PRIVATE_DECRYPT_FAILED  1  Summary

The RING_FULL counter is not a fatal counter, but indicates how often the system overloaded the cryptographic chip. The ACCELERATOR_RESET counter is the number of times the TLS crypto acceleration process failed unexpectedly, which also causes the failure of pending operations, which are the numbers you see in ACCELERATOR_CORE_TIMEOUT and RSA_PRIVATE_DECRYPT_FAILED.

If you have persistent problems, disable TLS crypto acceleration (or config hwCrypto disable) and work with Cisco TAC to resolve the issues.

---

Note

You can do additional troubleshooting using the show snort tls-offload and debug snort tls-offload commands. Use the clear snort tls-offload command to reset the counters displayed in the show snort tls-offload command to zero.
Troubleshoot TLS/SSL Rules

You can diagnose a variety of error conditions using connection events; for example, your managed device might be overloaded with TLS/SSL traffic, or applications might be using TLS/SSL pinning or TLS heartbeat. These conditions might require you to adjust your SSL rules or take other actions to restore normal operation in your network.

- About TLS/SSL Oversubscription, on page 1745
- About TLS Heartbeat, on page 1748
- About TLS/SSL Pinning, on page 1749
- Verify TLS/SSL Cipher Suites, on page 1754

About TLS/SSL Oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for Handshake Errors in the SSL policy's Undecryptable Actions:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for Handshake Errors in the SSL policy's Undecryptable Actions is Do Not decrypt and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does not occur.

Troubleshoot TLS/SSL Oversubscription

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are experiencing SSL oversubscription. You must add at least the SSL Flow Flags event to the table view of connection events.
Before you begin

- Configure an SSL policy with a setting for **Handshake Errors** on **Undecryptable Actions** page.
  For more information, see Set Default Handling for Undecryptable Traffic, on page 1696.
- Enable logging for your SSL rules as discussed in Logging Decryptable Connections with SSL Rules, on page 2687.

Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>If you haven’t done so already, log in to the Firepower Management Center.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click <strong>Analysis &gt; Connections &gt; Events</strong>.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Click <strong>Table View of Connection Events</strong>.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Click <strong>x</strong> on any column in the connection events table to add additional columns for at least <strong>SSL Flow Flags</strong> and <strong>SSL Flow Messages</strong>.</td>
</tr>
</tbody>
</table>

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events. (Look in the Disabled Columns section of the dialog box.)

The columns are added in the order discussed in Connection and Security Intelligence Event Fields, on page 2693.

| Step 5 | Click **Apply**. |
TLS/SSL oversubscription is indicated by the values of `ERROR_EVENT_TRIGGERED` and `OVER_SUBSCRIBED` in the SSL Flow Flags column.

The following figure shows an example.

<table>
<thead>
<tr>
<th>SSL Flow Error</th>
<th>SSL Actual Action</th>
<th>SSL Flow Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Success</td>
<td>Block With Reset</td>
<td>ERROR_EVENT_TRIGGERED, OVER_SUBSCRIBED</td>
</tr>
<tr>
<td>Success</td>
<td>Block With Reset</td>
<td>ERROR_EVENT_TRIGGERED, OVER_SUBSCRIBED</td>
</tr>
<tr>
<td>Success</td>
<td>Block With Reset</td>
<td>ERROREVENT_TRIGGERED, OVER_SUBSCRIBED</td>
</tr>
<tr>
<td>Success</td>
<td>Block With Reset</td>
<td>ERROR_EVENT_TRIGGERED, OVER_SUBSCRIBED</td>
</tr>
</tbody>
</table>

**Step 6**

If TLS/SSL oversubscription is occurring, log into the managed device and enter any of the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>show counters</td>
<td>If the value of <code>TCP_PRX BYPASS_NOT_ENOUGH_MEM</code> is large, consider upgrading your device to one with a larger capacity for SSL traffic or use Do Not Decrypt rules for lower priority encrypted traffic.</td>
</tr>
<tr>
<td>show snort tls-offload</td>
<td>If the value of <code>BYPASS_NOT_ENOUGH_MEM</code> is large, consider upgrading your device to one with a larger capacity for SSL traffic or use Do Not Decrypt rules for lower priority encrypted traffic.</td>
</tr>
</tbody>
</table>

About TLS Heartbeat

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for *Decryption Errors* in the SSL policy's *Undecryptable Actions*:

- Block
- Block with reset

**Related Topics**

Troubleshoot TLS Heartbeat, on page 1748

Troubleshoot TLS Heartbeat

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are seeing traffic with the TLS heartbeat extension. You must add at least the *SSL Flow Messages* event to the table view of connection events.

**Before you begin**

SSL heartbeat is indicated by the value of *HEARTBEAT* in the *SSL Flow Messages* column in the table view of connection events. To determine if applications in your network use SSL heartbeat, first perform the following tasks:

- Configure an SSL policy with a setting for *Decryption Errors* on *Undecryptable Actions* page.
  
  For more information, see Set Default Handling for Undecryptable Traffic, on page 1696.

- Enable logging for your SSL rules as discussed in Logging Decryptable Connections with SSL Rules, on page 2687.

**Procedure**

**Step 1** If you haven't done so already, log in to the Firepower Management Center.

**Step 2** Click **Analysis > Connection > Events**.

**Step 3** Click **Table View of Connection Events**.

**Step 4** Click x on any column in the connection events table to add additional columns for at least *SSL Flow Flags* and *SSL Flow Messages*. 
The following example shows adding the SSL Actual Action, SSL Flow Error, SSL Flow Flags, SSL Flow Messages, SSL Policy, and SSL Rule columns to the table of connection events.

The columns are added in the order discussed in Connection and Security Intelligence Event Fields, on page 2693.

**Step 5**  
Click **Apply**.  
TLS heartbeat is indicated by the value of `HEARTBEAT` in the SSL Flow Messages column.

**Step 6**  
If applications in your network use SSL heartbeat, see TLS/SSL Rule Guidelines and Limitations, on page 1699.

**Related Topics**  
- Troubleshoot TLS Heartbeat, on page 1748  
- About TLS Heartbeat, on page 1748

### About TLS/SSL Pinning

Some applications use a technique referred to as **TLS/SSL pinning or certificate pinning**, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a TLS/SSL rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

To confirm that TLS/SSL pinning is occurring, attempt to log in to a mobile application like Facebook. If a network connection error is displayed, log in using a web browser. (For example, you cannot log in to a
Facebook mobile application but can log in to Facebook using Safari or Chrome. You can use Firepower Management Center connection events as further proof of TLS/SSL pinning.

---

**Note**

TLS/SSL pinning is not limited to mobile applications.

If applications in your network use SSL pinning, see TLS/SSL Rule Guidelines and Limitations, on page 1699

**Related Topics**

Troubleshoot TLS/SSL Pinning, on page 1750

---

**Troubleshoot TLS/SSL Pinning**

You can view connection events to determine whether or not the devices are experiencing SSL pinning. You must add at least the SSL Flow Flags and SSL Flow Messages columns to the table view of connection events.

**Before you begin**

- Enable logging for your TLS/SSL rules as discussed in Logging Decryptable Connections with SSL Rules, on page 2687.
- Log in to a mobile application like Facebook; if a network connection error displays, log in to Facebook using Chrome or Safari. If you can log in using a web browser but not the native application, SSL pinning is likely occurring.

**Procedure**

**Step 1**  
If you haven't done so already, log in to the Firepower Management Center.

**Step 2**  
Click Analysis > Connections > Events.

**Step 3**  
Click Table View of Connection Events.

**Step 4**  
Click x on any column in the connection events table to add additional columns for at least SSL Flow Flags and SSL Flow Messages.

The following example shows adding the SSL Actual Action, SSL Flow Error, SSL Flow Flags, SSL Flow Messages, SSL Policy, and SSL Rule columns to the table of connection events.
Step 5 Click Apply.

Step 6 The following paragraphs discuss how you can identify SSL pinning behavior.

Step 7 If you determine that applications in your network use SSL pinning, see TLS/SSL Rule Guidelines and Limitations, on page 1699.

What to do next

You can use TLS/SSL connection events to confirm TLS/SSL pinning is occurring by looking for any of the following:

- Applications that send an SSL ALERT Message as soon as the client receives the SERVER_HELLO, SERVER_CERTIFICATE, SERVER_HELLO_DONE message from the server, followed by a TCP Reset, exhibit the following symptoms. (The alert, Unknown CA (48), can be viewed using a packet capture.)
  - The SSL Flow Flags column displays ALERT_SEEN but not APP_DATA_C2S or APP_DATA_S2C.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: CLIENT_ALERT, CLIENT_HELLO, SERVER_HELLO, SERVER_CERTIFICATE, SERVER_KEY_EXCHANGE, SERVER_HELLO_DONE.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: CLIENT_HELLO, SERVER_HELLO, SERVER_CERTIFICATE, SERVER_KEY_EXCHANGE, SERVER_HELLO_DONE.
  - Success is displayed in the SSL Flow Error column.
• Applications that send no alerts but instead send TCP Reset after the SSL handshake is finished exhibit the following symptoms:
  • The SSL Flow Flags column does not display ALERT_SEEN, APP_DATA_C2S, or APP_DATA_S2C.
  • If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: CLIENT_HELLO, SERVER_HELLO, SERVER_CERTIFICATE, SERVER_KEY_EXCHANGE, SERVER_HELLO_DONE, CLIENT_KEY_EXCHANGE, CLIENT_CHANGE_CIPHER_SPEC, CLIENT_FINISHED, SERVER_CHANGE_CIPHER_SPEC, SERVER_FINISHED.
  • If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: CLIENT_HELLO, SERVER_HELLO, SERVER_CERTIFICATE, SERVER_KEY_EXCHANGE, SERVER_HELLO_DONE, CLIENT_KEY_EXCHANGE, CLIENT_CHANGE_CIPHER_SPEC, CLIENT_FINISHED, SERVER_CHANGE_CIPHER_SPEC, SERVER_FINISHED.
  • Success is displayed in the SSL Flow Error column.

Troubleshoot Unknown or Bad Certificates or Certificate Authorities

You can view connection events to determine whether or not the devices are experiencing unknown certificate authorities, bad certificates, or unknown certificates. This procedure can also be used if a TLS/SSL certificate has been pinned. You must add at least the SSL Flow Flags and SSL Flow Messages columns to the table view of connection events.

Before you begin
  • Set up a TLS/SSL decryption rule.
  • Enable logging for your TLS/SSL rules as discussed in Logging Decryptable Connections with SSL Rules, on page 2687.

Procedure

<table>
<thead>
<tr>

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

The columns are added in the order discussed in *Connection and Security Intelligence Event Fields*, on page 2693.

**Step 5**
Click **Apply**.

**Step 6**
The following table discusses how you can determine if a certificate or certificate authority is bad or missing.

<table>
<thead>
<tr>
<th>SSL flow flag</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_ALERT_SEEN_UNKNOWN_CA</td>
<td>Indicates a valid certificate chain or partial chain was received by an SSL client application, but the certificate was not accepted because the CA certificate could not be located or could not be matched with a known, trusted CA. This message always indicates an unrecoverable error.</td>
</tr>
<tr>
<td>CLIENT_ALERT_SEEN_BAD_CERTIFICATE</td>
<td>A certificate was corrupt, contained signatures that did not verify correctly, or had other problems.</td>
</tr>
<tr>
<td>CLIENT_ALERT_SEEN_CERTIFICATE_UNKNOWN</td>
<td>Some other (unspecified) issue arose in processing the certificate, rendering it unacceptable.</td>
</tr>
</tbody>
</table>
Verify TLS/SSL Cipher Suites

Before you begin

This topic discusses actions you must take if you see the following error when saving a TLS/SSL rule that has cipher suite conditions:

Traffic cannot match this rule; none of your selected cipher suites contain a signature algorithm that the resigning CA's signature algorithm

The error indicates that one or more of the cipher suites you chose for the TLS/SSL rule condition are incompatible with the certificate used in the TLS/SSL rule. To resolve the issue, you must have access to the certificate you're using.

Note

The tasks in this topic assume knowledge of how TLS/SSL encryption works.

Procedure

Step 1

When you attempt to save an SSL rule with either Decrypt - Resign or Decrypt - Known Key with specified cipher suites, the following error is displayed:

Example:

Traffic cannot match this rule; none of your selected cipher suites contain a signature algorithm that the resigning CA's signature algorithm

Step 2

Locate the certificate you're using to decrypt traffic and, if necessary, copy the certificate to a system that can run openssl commands.

Step 3

Run the following command to display the signature algorithm used by the certificate:

```bash
openssl x509 -in CertificateName -text -noout
```

The first few lines of output are displayed similar to the following:

Certificate:

Data:

  Version: 3 (0x2)
  Serial Number: 4105 (0x1009)
  Signature Algorithm: ecdsa-with-SHA256

Step 4

The Signature algorithm tells you the following:

- The cryptographic function used (in the preceding example, ECDSA means Elliptic Curve Digital Signature Algorithm).

- The hash function used to create a digest of the encrypted message (in the preceding example, SHA256).

Step 5

Search a resource such as OpenSSL at University of Utah for cipher suites that match those values. The cipher suite must be in RFC format.

You can also search a variety of other sites, such as Server Side TLS at the Mozilla wiki or Appendix C of RFC 5246. Cipher Suites in TLS/SSL (Schannel SSP) in Microsoft documentation has a detailed explanation of cipher suites.
Step 6  If necessary, translate the OpenSSL name to an RFC name that the Firepower Management System uses. See the RFC mapping list on the https://testssl.sh site.

Step 7  The previous example, **ecdsa-with-SHA256**, can be found in the Modern Compatibility List on the Mozilla wiki.

  a) Choose only cipher suites that have **ECDSA** and **SHA-256** in the name. These cipher suites follow:

    - ECDHE-ECDSA-AES128-GCM-SHA256
    - ECDHE-ECDSA-AES128-SHA256

  b) Find the corresponding RFC cipher suite on RFC mapping list. These cipher suites follow:

    - TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
    - TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256

Step 8  Add the preceding cipher suites to your TLS/SSL rule.
Verify TLS/SSL Cipher Suites

Advanced Malware Protection (AMP) and File Control

• File Policies and Malware Protection, on page 1759
• File and Malware Inspection Performance and Storage Tuning, on page 1799
File Policies and Malware Protection

The following topics provide an overview of file control, file policies, file rules, Advanced Malware Protection (AMP), cloud connections, and dynamic analysis connections.

• About File Policies and Advanced Malware Protection, on page 1759
• Requirements and Prerequisites for File Policies, on page 1760
• License Requirements for File and Malware Policies, on page 1761
• Best Practices for File Policies and Malware Detection, on page 1761
• How to Configure Malware Protection, on page 1764
• Cloud Connections for Malware Protection, on page 1768
• File Policies and File Rules, on page 1777
• Retrospective Disposition Changes, on page 1792
• (Optional) Malware Protection with AMP for Endpoints, on page 1792
• History for File Policies and Malware Protection, on page 1797

About File Policies and Advanced Malware Protection

To detect and block malware, use file policies. You can also use file policies to detect and control traffic by file type.

Advanced Malware Protection (AMP) for Firepower can detect, capture, track, analyze, log, and optionally block the transmission of malware in network traffic. In the Firepower Management Center web interface, this feature is called AMP for Networks, formerly called AMP for Firepower. Advanced Malware Protection identifies malware using managed devices deployed inline and threat data from the Cisco cloud.

You associate file policies with access control rules that handle network traffic as part of your overall access control configuration.

When the system detects malware on your network, it generates file and malware events. To analyze file and malware event data, see File/Malware Events and Network File Trajectory, on page 2771.

File Policies

A file policy is a set of configurations that the system uses to perform malware protection and file control, as part of your overall access control configuration. This association ensures that before the system passes a file in traffic that matches an access control rule’s conditions, it first inspects the file. Consider the following diagram of a simple access control policy in an inline deployment.
The policy has two access control rules, both of which use the Allow action and are associated with file policies. The policy’s default action is also to allow traffic, but without file policy inspection. In this scenario, traffic is handled as follows:

- Traffic that matches Rule 1 is inspected by File Policy A.
- Traffic that does not match Rule 1 is evaluated against Rule 2. Traffic that matches Rule 2 is inspected by File Policy B.
- Traffic that does not match either rule is allowed; you cannot associate a file policy with the default action.

By associating different file policies with different access control rules, you have granular control over how you identify and block files transmitted on your network.

</tr>
</tbody>
</table>

For details about Malware licenses, see:

- Malware Licenses for Firepower Threat Defense Devices, on page 161
- Malware Licenses for Classic Devices, on page 195

Best Practices for File Policies and Malware Detection

In addition to the items described below, follow the steps in How to Configure Malware Protection, on page 1764 and referenced topics.

File Rule Best Practices

Note the following guidelines and limitations when configuring file rules:

- A rule configured to block files in a passive deployment does not block matching files. Because the connection continues to transmit the file, if you configure the rule to log the beginning of the connection, you may see multiple events logged for this connection.

- A policy can include multiple rules. When you create the rules, ensure that no rule is "shadowed" by a previous rule.

- The file types supported for dynamic analysis are a subset of the file types supported for other types of analysis. To view the file types supported for each type of analysis, navigate to the file rule configuration page, select the Block Malware action, and select the checkboxes of interest.
To ensure that the system examines all file types, create separate rules (within the same policy) for
dynamic analysis and for other types of analysis.

- If a file rule is configured with a Malware Cloud Lookup or Block Malware action and the Firepower
  Management Center cannot establish connectivity with the AMP cloud, the system cannot perform any
  configured rule action options until connectivity is restored.

- Cisco recommends that you enable Reset Connection for the Block Files and Block Malware actions
to prevent blocked application sessions from remaining open until the TCP connection resets. If you do
  not reset connections, the client session will remain open until the TCP connection resets itself.

- If you are monitoring high volumes of traffic, do not store all captured files, or submit all captured files
  for dynamic analysis. Doing so can negatively impact system performance.

- You cannot perform malware analysis on all file types detected by the system. After you select values
  from the Application Protocol, Direction of Transfer, and Action drop-down lists, the system constrains
  the list of file types.

### File Detection Best Practices

Consider the following notes and limitations for file detection:

- If adaptive profiling is not enabled, access control rules cannot perform file control, including AMP.

- If a file matches a rule with an application protocol condition, file event generation occurs after the
  system successfully identifies a file’s application protocol. Unidentified files do not generate file events.

- FTP transfers commands and data over different channels. In a passive or inline tap mode deployment,
  the traffic from an FTP data session and its control session may not be load-balanced to the same internal
  resource.

- If the total number of bytes for all file names for files in a POP3, POP, SMTP, or IMAP session exceeds
  1024, file events from the session may not reflect the correct file names for files that were detected after
  the file name buffer filled.

- When transmitting text-based files over SMTP, some mail clients convert newlines to the CRLF newline
  character standard. Since Mac-based hosts use the carriage return (CR) character and Unix/Linux-based
  hosts use the line feed (LF) character, newline conversion by the mail client can modify the size of the
  file. Note that some mail clients default to newline conversion when processing an unrecognizable file
  type.

- To detect ISO files, set the "Limit the number of bytes inspected when doing file type detection" option
to a value greater than 36870, as described in File and Malware Inspection Performance and Storage
  Options, on page 1799.

- .Exe files inside some .rar archives cannot be detected, including possibly rar5.

### File Blocking Best Practices

Consider the following notes and limitations for file blocking:

- If an end-of-file marker is not detected for a file, regardless of transfer protocol, the file will not be
  blocked by a Block Malware rule or the custom detection list. The system waits to block the file until
the entire file has been received, as indicated by the end-of-file marker, and blocks the file after the marker is detected.

- If the end-of-file marker for an FTP file transfer is transmitted separately from the final data segment, the marker will be blocked and the FTP client will indicate that the file transfer failed, but the file will actually completely transfer to disk.

- File rules with Block Files and Block Malware actions block automatic resumption of file download via HTTP by blocking new sessions with the same file, URL, server, and client application detected for 24 hours after the initial file transfer attempt occurs.

- In rare cases, if traffic from an HTTP upload session is out of order, the system cannot reassemble the traffic correctly and therefore will not block it or generate a file event.

- If you transfer a file over NetBIOS-ssn (such as an SMB file transfer) that is blocked with a Block Files rule, you may see a file on the destination host. However, the file is unusable because it is blocked after the download starts, resulting in an incomplete file transfer.

- If you create file rules to detect or block files transferred over NetBIOS-ssn (such as an SMB file transfer), the system does not inspect the ongoing file transfers. However, the system inspects the new files that are transferred after you deploy an access control policy invoking the file policy.

- SMB has a functionality called multi-channel which creates multiple parallel sessions with the same IP address and different ports. For a given transaction over multi-channel, the file download is multiplexed across these sessions which is not inspected by the system as a single file.

- Files transferred concurrently in a single TCP or SMB session are not inspected.

- In a cluster environment, if an existing SMB session is moved to a new device due to a cluster role change or a device failure, then the files in any ongoing file transfers may not be inspected.

- Some SMB file transfers between Microsoft Windows systems use very high TCP window size for quick file transfers. To detect or block such file transfers, it is recommended that you increase the value of Maximum Queued Bytes and Maximum Queued Segments under Network Analysis Policy > TCP Stream Configuration > Troubleshooting Options.

- If you configure Firepower Threat Defense high availability, and failover occurs while the original active device is identifying the file, the file type is not synced. Even if your file policy blocks that file type, the new active device downloads the file.

**File Policy Best Practices**

Note the following general guidelines and limitations when configuring file policies.

- You can associate a single file policy with an access control rule whose action is Allow, Interactive Block, or Interactive Block with reset.

- You **cannot** use a file policy to inspect traffic handled by the access control default action.

- For a new policy, the web interface indicates that the policy is not in use. If you are editing an in-use file policy, the web interface tells you how many access control policies use the file policy. In either case, you can click the text to jump to the Access Control Policies page.

- For file blocking to work, the NAP policy you apply to the access control policy must be operating in Protection mode, also known as Inline mode.
• Based on your configuration, you can either inspect a file the first time the system detects it, and wait for a cloud lookup result, or pass the file on this first detection without waiting for the cloud lookup result.

• By default, file inspection of encrypted payloads is disabled. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has file inspection configured.

How to Configure Malware Protection

This topic summarizes the steps you must take to set up your Firepower system to protect your network from malicious software.

Procedure

Step 1 Plan and Prepare for Malware Protection, on page 1764
Step 2 Configure File Policies, on page 1765
Step 3 Add File Policies to Your Access Control Configuration, on page 1766
Step 4 Configure network discovery policies to associate file and malware events with hosts on your network.

(Do not simply turn on network discovery; you must configure it to discover hosts on your network to build a network map of your organization.)

See Network Discovery Policies, on page 2381 and subtopics.

Step 5 Deploy policies to managed devices.

See Deploy Configuration Changes, on page 495.

Step 6 Test your system to be sure it is processing malicious files as you expect it to.

Step 7 Set Up Maintenance and Monitoring of Malware Protection, on page 1768

What to do next

• (Optional) To further enhance detection of malware in your network, deploy and integrate Cisco's AMP for Endpoints product. See (Optional) Malware Protection with AMP for Endpoints, on page 1792 and subtopics.

• Understand how to investigate file and malware events.

See File/Malware Events and Network File Trajectory, on page 2771.

Plan and Prepare for Malware Protection

This procedure is the first set of steps in the complete process for configuring your system to provide malware protection.
Procedure

Step 1  Purchase and install licenses.  
See License Requirements for File and Malware Policies, on page 1761 and Licensing the Firepower System, on page 151.

Step 2  Understand how file policies and malware protection fit into your access control plan.  
See the chapter Understanding Access Control, on page 1519.

Step 3  Understand the file analysis and malware protection tools.  
See File Rule Actions, on page 1784 and subtopics.  
Consider also Advanced and Archive File Inspection Options, on page 1778.

Step 4  Determine whether you will use public clouds or private (on-premises) clouds for malware protection (file analysis and dynamic analysis.)  
See Cloud Connections for Malware Protection, on page 1768 and subtopics.

Step 5  If you will use private (on-premises) clouds for malware protection: Purchase, deploy, and test those products.  
For information, contact your Cisco sales representative or authorized reseller.

Step 6  Configure your firewall to allow communications with your chosen clouds.  
See Security, Internet Access, and Communication Ports, on page 2903.

Step 7  Configure connections between Firepower and the malware protection clouds (public or private).  
  • For the AMP cloud, see Change AMP Options, on page 1773.
  • If you deployed an on-premises Cisco Threat Grid appliance, see Connect to an On-Premises Dynamic Analysis Appliance, on page 1775. (Access to the public Threat Grid cloud does not require configuration.)

What to do next

Continue with the next step in the malware protection workflow:
See How to Configure Malware Protection, on page 1764.

Configure File Policies

Before you begin

Complete the tasks up to this point in the malware protection workflow:
See How to Configure Malware Protection, on page 1764.
Add File Policies to Your Access Control Configuration

An access control policy can have multiple access control rules associated with file policies. You can configure file inspection for any Allow or Interactive Block access control rule, which permits you to match different file and malware inspection profiles against different types of traffic on your network before it reaches its final destination.

Before you begin

Complete the tasks up to this point in the malware protection workflow:

See How to Configure Malware Protection, on page 1764.

Procedure

Step 1
Review guidelines for file policies in access control policies. (These are different from the file rule and file policy guidelines that you looked at previously.)

Review File and Intrusion Inspection Order, on page 1523.

Step 2
Associate the file policy with an access control policy.

See Configuring an Access Control Rule to Perform Malware Protection, on page 1767

Step 3
Assign the access control policy to managed devices.

See Setting Target Devices for an Access Control Policy, on page 1544.
Configuring an Access Control Rule to Perform Malware Protection

**What to do next**

Continue with the next step in the malware protection workflow:

See [How to Configure Malware Protection](#), on page 1764.

**Caution**

Enabling or disabling *Store files* in a *Detect Files* or *Block Files* rule, or adding the first or removing the last file rule that combines the *Malware Cloud Lookup* or *Block Malware* file rule action with an analysis option (*Spero Analysis* or *MSEXE*, *Dynamic Analysis*, or *Local Malware Analysis*) or a store files option (*Malware*, *Unknown*, *Clean*, or *Custom*), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort® Restart Traffic Behavior](#), on page 504 for more information.

**Note**

Inline normalization is enabled automatically when a file policy is included in an access control rule. For more information, see *The Inline Normalization Preprocessor*, on page 2174.

**Before you begin**

- Adaptive profiling must be enabled (its default state) as described in *Configuring Adaptive Profiles*, on page 2224 for access control rules to perform file control, including AMP.
- You must be an Admin, Access Admin, or Network Admin user to perform this task.

**Procedure**

**Step 1**
In the access control rule editor (from *Policies > Access Control*), choose an *Action* of *Allow*, *Interactive Block*, or *Interactive Block with reset*.

**Step 2**
Click *Inspection*.

**Step 3**
Choose a *File Policy* to inspect traffic that matches the access control rule, or choose *None* to disable file inspection for matching traffic.

**Step 4**
(Optional) Disable logging of file or malware events for matching connections by clicking *Logging* and unchecking *Log Files*.

**Note**
Cisco recommends that you leave file and malware event logging enabled.

**Step 5**
Save the rule.

**Step 6**
Click *Save* to save the policy.

**What to do next**

- Deploy configuration changes; see [Deploy Configuration Changes](#), on page 495.
Set Up Maintenance and Monitoring of Malware Protection

Ongoing maintenance is essential for protecting your network.

Before you begin

Configure your system to protect your network from malware.

See How to Configure Malware Protection, on page 1764 and referenced procedures.

Procedure

Step 1

Ensure that your system always has the most current and effective protection.

See Maintain Your System: Update File Types Eligible for Dynamic Analysis, on page 1777.

Step 2

Configure alerts for malware-related events and health monitoring.

See Configuring AMP for Networks Alerting, on page 2520 and information in Health Monitoring, on page 399 about the following modules:

• Local Malware Analysis
• Security Intelligence
• Threat Data Updates on Devices
• Intrusion and File Event Rate
• AMP for Firepower Status
• AMP for Endpoints Status

What to do next

Review "What to do next items" in the malware protection workflow:

See How to Configure Malware Protection, on page 1764.

Cloud Connections for Malware Protection

Connections to public or private clouds are required in order to protect your network from malware.

AMP Clouds

The Advanced Malware Protection (AMP) cloud is a Cisco-hosted server that uses big data analytics and continuous analysis to provide intelligence that the system uses to detect and block malware on your network.
The AMP cloud provides dispositions for possible malware detected in network traffic by managed devices, as well as data updates for local malware analysis and file pre-classification.

If your organization has deployed AMP for Endpoints and configured Firepower to import its data, the system imports this data from the AMP cloud, including scan records, malware detections, quarantines, and indications of compromise (IOC).

Cisco offers the following options for obtaining data from the Cisco cloud about known malware threats:

- **AMP public cloud**
  Your Firepower Management Center communicates directly with the public Cisco cloud. There are three public AMP clouds, in the United States, Europe, and Asia.

- **An AMP private cloud**
  An AMP private cloud is deployed on your network and acts as a compressed, on-premises AMP cloud, as well as an anonymized proxy to connect to the public AMP cloud. For details, see Cisco AMP Private Cloud, on page 1771.
  
  If you integrate with AMP for Endpoints, the AMP private cloud has some limitations. See AMP for Endpoints and AMP Private Cloud, on page 1795.

**Dynamic Analysis Cloud**

- **Cisco Threat Grid cloud**
  Public cloud that processes eligible files that you send for dynamic analysis, and provides threat scores and dynamic analysis reports.

- **On-premises Cisco Threat Grid appliance**
  If your organization's security policy does not allow the Firepower System to send files outside of your network, you can deploy an on-premises appliance. This appliance does not contact the public Cisco Threat Grid cloud.
  
  For more information, see Dynamic Analysis On-Premises Appliance (Cisco Threat Grid), on page 1775.

**Configure Connections to AMP and Threat Grid Clouds**

- **AMP Cloud Connection Configurations**, on page 1769
- **Dynamic Analysis Connections**, on page 1774

**AMP Cloud Connection Configurations**

The following topics describe AMP cloud connection configurations for different scenarios:

- **Choose an AMP Cloud**, on page 1770
- **Connecting to an AMP Private Cloud**, on page 1771
- **Integrate Firepower and AMP for Endpoints**, on page 1795

The following topics are also relevant:

- **Cisco AMP Private Cloud**, on page 1771
Requirements and Best Practices for AMP Cloud Connections

Requirements for AMP Cloud Connections

You must be an Admin user to set up the AMP cloud.

To ensure your FMC can communicate with the AMP cloud, see the topics under Security, Internet Access, and Communication Ports, on page 2903.

To use the legacy port for AMP communications, see Communication Port Requirements, on page 2907.

AMP and High Availability

Although they share file policies and related configurations, Firepower Management Centers in a high availability pair share neither cloud connections nor captured files, file events, and malware events. To ensure continuity of operations, and to ensure that detected files’ malware dispositions are the same on both Firepower Management Centers, both Active and Standby Firepower Management Centers must have access to the cloud.

In high availability configurations, you must configure AMP cloud connections independently on the Active and Standby instances of the Firepower Management Center; these configurations are not synchronized.

These requirements apply to both public and private AMP clouds.

AMP Cloud Connections and Multitenancy

In a multidomain deployment, you configure the AMP for Networks connection at the Global level only. Each Firepower Management Center can have only one AMP for Networks connection.

Choose an AMP Cloud

By default, a connection to the United States (US) AMP public cloud is configured and enabled for your Firepower system. (This connection appears in the web interface as AMP for Networks and sometimes AMP for Firepower.) You cannot delete or disable an AMP for Networks cloud connection, but you can switch between different geographical AMP clouds, or configure an AMP private cloud connection.

Before you begin

• If you will use an AMP private cloud, see Connecting to an AMP Private Cloud, on page 1771 instead of this topic.

• Unless Firepower is integrated with AMP for Endpoints, you can configure only one AMP cloud connection. This connection is labeled AMP for Networks or AMP for Firepower.

• If you have deployed AMP for Endpoints and you want to add one or more AMP clouds to integrate that application with Firepower, see Integrate Firepower and AMP for Endpoints, on page 1795.

• See Requirements and Best Practices for AMP Cloud Connections, on page 1770.
Procedure

Step 1  Choose AMP > AMP Management.
Step 2  Click pencil to edit the existing cloud connection.
Step 3  From the **Cloud Name** drop-down list, choose the regional cloud nearest to your Firepower Management Center.

**APJC** is Asia/Pacific/Japan/China.

Step 4  Click Save.

What to do next

- If your deployment is a high-availability configuration, see **Requirements and Best Practices for AMP Cloud Connections**, on page 1770.
- (Optional) Change AMP Options, on page 1773.

**Cisco AMP Private Cloud**

The Firepower Management Center must connect to the AMP cloud for disposition queries for files detected in network traffic and receipt of retrospective malware events. This cloud can be public or private.

Your organization may have privacy or security concerns that make frequent or direct connections between your monitored network and the AMP cloud difficult or impossible. In these situations, you can set up a Cisco AMP Private Cloud, a proprietary Cisco product that acts as a compressed, on-premises version of the AMP cloud, as well as a secure mediator between your network and the AMP cloud. Connecting a Firepower Management Center to an AMP private cloud disables existing direct connections to the public AMP cloud.

All connections to the AMP cloud funnel through the AMP private cloud, which acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes disposition queries for files detected in network traffic, receiving of retrospective malware events, and so on. The AMP private cloud does not share any of your endpoint data over an external connection.

---

**Note**

The AMP private cloud does not perform dynamic analysis, nor does it support anonymized retrieval of threat intelligence for other features that rely on Cisco Collective Security Intelligence (CSI), such as URL and Security Intelligence filtering.

**Connecting to an AMP Private Cloud**

**Before you begin**

- Configure your Cisco AMP private cloud or clouds according to the directions in the documentation for that product. During configuration, note the private cloud host name. You will need this host name in order to configure the connection on the Firepower Management Center.
• Make sure the Firepower Management Center can communicate with the AMP private cloud, and confirm that the private cloud has internet access so it can communicate with the public AMP cloud. See the topics under Security, Internet Access, and Communication Ports, on page 2903.

• Unless your deployment is integrated with AMP for Endpoints, each Firepower Management Center can have only one AMP cloud connection. This connection is labeled AMP for Networks or AMP for Firepower. If you integrate with AMP for Endpoints, you can configure multiple AMP for Endpoints cloud connections.

Procedure

Step 1 Choose AMP > AMP Management.
Step 2 Click Add AMP Cloud Connection.
Step 3 From the Cloud Name drop-down list, choose Private Cloud.
Step 4 Enter a Name.
This information appears in malware events that are generated or transmitted by AMP private cloud.
Step 5 In the Host field, enter the private cloud host name that you configured when you set up the private cloud.
Step 6 Click Browse next to the Certificate Upload Path field to browse to the location of a valid TLS or SSL encryption certificate for the private cloud. For more information, see the AMP private cloud documentation.
Step 7 If you want to use this private cloud for both AMP for Networks and AMP for Endpoints, select the Use for AMP for Firepower check box.
If you configured a different private cloud to handle AMP for Networks communications, you can clear this check box; if this is your only AMP private cloud connection, you cannot.
In a multidomain deployment, this check box appears only in the Global domain. Each Firepower Management Center can have only one AMP for Networks connection.
Step 8 To communicate with the AMP private cloud using a proxy, check the Use Proxy for Connection check box.
Step 9 Click Register, confirm that you want to disable existing direct connections to the AMP cloud, and finally confirm that you want to continue to the AMP private cloud management console to complete registration.
Step 10 Log into the management console and complete the registration process. For further instructions, see the AMP private cloud documentation.

What to do next
In high availability configurations, you must configure AMP cloud connections independently on the Active and Standby instances of the Firepower Management Center; these configurations are not synchronized.

Managing Connections to the AMP Cloud (Public or Private)

Use the Firepower Management Center to manage connections to public and private AMP clouds used for AMP for Networks or AMP for Endpoints or both.

You can delete a connection to a public or private AMP cloud if you no longer want to receive malware-related information from the cloud. Note that deregistering a connection using the AMP for Endpoints or AMP private...
cloud management console does not remove the connection from the system. Deregistered connections display a failed state on the Firepower Management Center web interface.

You can also temporarily disable a connection. When you re-enable a cloud connection, the cloud resumes sending data to the system, including queued data from the disabled period.

⚠️ Caution

For disabled connections, the public or private AMP cloud can store malware events, indications of compromise, and so on until you re-enable the connection. In rare cases—for example, with a very high event rate or a long-term disabled connection—the cloud may not be able to store all information generated while the connection is disabled.

In a multidomain deployment, the system displays connections created in the current domain, which you can manage. It also displays connections created in ancestor domains, which you cannot manage. To manage connections in a lower domain, switch to that domain. Each Firepower Management Center can have only one AMP for Networks connection, which belongs to the Global domain.

Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Select AMP &gt; AMP Management.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Manage your AMP cloud connections:</td>
</tr>
<tr>
<td></td>
<td>• Delete — Click Delete (🗑️), then confirm your choice.</td>
</tr>
<tr>
<td></td>
<td>• Enable or Disable — Click the slider, then confirm your choice.</td>
</tr>
</tbody>
</table>

What to do next

In high availability configurations, you must configure AMP cloud connections independently on the Active and Standby instances of the Firepower Management Center; these configurations are not synchronized.

Change AMP Options

Procedure

<table>
<thead>
<tr>
<th>Step 1</th>

### Dynamic Analysis Connections

#### Requirements for Dynamic Analysis

You must be an Admin, Access Admin, or Network Admin user, and be in the global domain, to use dynamic analysis.

With the appropriate license, the Firepower system automatically has access to the Cisco Threat Grid public cloud.

Dynamic analysis requires that managed devices have direct or proxied access to the Cisco Threat Grid public cloud or an on-premises Cisco Threat Grid appliance on port 443.

See also Which Files Are Eligible for Dynamic Analysis?, on page 1788.

If you will connect to an on-premises Threat Grid appliance, see also the prerequisites in Connect to an On-Premises Dynamic Analysis Appliance, on page 1775.

#### Viewing the Default Dynamic Analysis Connection

By default, the Firepower Management Center can connect to the public Cisco Threat Grid cloud for file submission and report retrieval. You can neither configure nor delete this connection.

**Procedure**

1. Choose AMP > Dynamic Analysis Connections.
2. Click Edit (✓).
Dynamic Analysis On-Premises Appliance (Cisco Threat Grid)

If your organization has privacy or security concerns around submitting files to the public Cisco Threat Grid cloud, you can deploy an on-premises Cisco Threat Grid appliance. Like the public cloud, the on-premises appliance runs eligible files in a sandbox environment, and returns a threat score and dynamic analysis report to the Firepower System. However, the on-premises appliance does not communicate with the public cloud, or any other system external to your network.

Connect to an On-Premises Dynamic Analysis Appliance

If you install an on-premises Cisco Threat Grid appliance on your network, you can configure a dynamic analysis connection to submit files and retrieve reports from the appliance. When configuring the on-premises appliance dynamic analysis connection, you register the Firepower Management Center to the on-premises appliance.

Before you begin

- Set up your on-premises Cisco Threat Grid appliance; see the Cisco Threat Grid Appliance Setup and Configuration Guide.

  For version requirements, see the Cisco Firepower Compatibility Guide.

- If your Cisco Threat Grid appliance uses a self-signed public-key certificate, download the certificate from the Threat Grid appliance; see the Cisco Threat Grid Appliance Administrator's Guide for information.

  If you use a certificate signed by a Certificate Authority (CA), the certificate must meet the following requirements:

  - The server key and signed certificate must be installed on the Threat Grid appliance. Follow the upload instructions in the Threat Grid Administrator’s Guide.

  - If there is a multi-level signing chain of CAs, all required intermediate certificates and the root certificate must be contained in a single file that will be uploaded to the FMC.

  - All certificates must be PEM-encoded.

  - The file's newlines must be UNIX, not DOS.

  - If you want to connect to the on-premises appliance using a proxy, configure the proxy; see Modify FMC Management Interfaces, on page 1287.

  - Managed devices must have direct or proxied access to the Cisco Threat Grid appliance on port 443.
Procedure

Step 1  Choose AMP > Dynamic Analysis Connections.

Step 2  Click Add New Connection.

Step 3  Enter a Name.

Step 4  Enter a Host.

Step 5  Next to Certificate Upload, click Browse to upload the certificate for the on-premises appliance.

If the Threat Grid appliance will present a self-signed certificate, upload the certificate you downloaded from that appliance.

If the Threat Grid appliance will present a CA-signed certificate, upload the file containing the certificate signing chain.

Step 6  If you want to use a configured proxy to establish the connection, select Use Proxy When Available.

Step 7  Click Register.

Step 8  Click Yes to display the on-premises Cisco Threat Grid appliance login page.

Step 9  Enter your username and password to the on-premises Cisco Threat Grid appliance.

Step 10 Click Sign in.

Step 11 You have the following options:

- If you previously registered the Firepower Management Center to the on-premises appliance, click Return.
- If you did not register the Firepower Management Center, click Activate.

Enabling Access to Dynamic Analysis Results in the Public Cloud

Cisco Threat Grid offers more detailed reporting on analyzed files than is available in the Firepower Management Center. If your organization has an account in the Cisco Threat Grid public cloud, you can access the Cisco Threat Grid portal directly to view additional details about files sent for analysis from your managed devices. However, for privacy reasons, file analysis details are available only to the organization that submitted the files. Therefore, before you can view this information, you must associate your Firepower Management Center with the files submitted by its managed devices.

Before you begin

You must have an account on the Cisco Threat Grid public cloud, and have your account credentials ready.

Procedure

Step 1  Select AMP > Dynamic Analysis Connections.

Step 2  Click Associate ( ) in the table row corresponding to the Cisco Threat Grid public cloud.

A Cisco Threat Grid portal window opens.

Step 3  Sign in to the Cisco Threat Grid public cloud.

Step 4  Click Submit Query.
Note Do not change the default value in the Devices field.

If you have difficulties with this process, contact your Cisco Threat Grid representative at Cisco TAC. It may take up to 24 hours for this change to take effect.

What to do next
After the association is activated, see Viewing Dynamic Analysis Results in the Cisco Threat Grid Public Cloud, on page 2792.

Maintain Your System: Update File Types Eligible for Dynamic Analysis

The list of file types eligible for Dynamic Analysis is determined by the vulnerability database (VDB), which is updated periodically (but no more than once per day.) If you are an Admin user, you can update file types eligible for dynamic analysis.

To ensure that your system has the current list:

Procedure

Step 1 Do one of the following:

• (Recommended) See Vulnerability Database Update Automation, on page 280

• Regularly check for new VDB updates, and Manually Update the VDB, on page 214 when needed.

If you choose this option, we recommend that you schedule regular reminders to do this.

Step 2 If your file policies specify individual file types instead of the Dynamic Analysis Capable file type category, update your file policies to use the newly supported file types.

Step 3 If the list of eligible file types changes, deploy to managed devices.

File Policies and File Rules

Create or Edit a File Policy

Before you begin
If you are configuring policies for malware protection, see all required procedures in Configure File Policies, on page 1765.

Procedure

Step 1 Select Policies > Access Control > Malware & File.
Step 2 Create a new policy, or edit an existing policy.

If you are editing an existing policy: If View ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Tip To make a copy of an existing file policy, click Copy ( ), then type a unique name for the new policy in the dialog box that appears. You can then modify the copy.

Step 3 Add one or more rules to the file policy as described in Creating File Rules, on page 1791.

Step 4 Optionally, select Advanced and configure advanced options as described in Advanced and Archive File Inspection Options, on page 1778.

Step 5 Save the file policy.

What to do next

• If you are configuring policies for malware protection, see other required procedures in Configure File Policies, on page 1765.

• Otherwise:
  • Add the file policy to an access control rule as described in Add File Policies to Your Access Control Configuration, on page 1766.
  • Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Advanced and Archive File Inspection Options

The Advanced Settings in the file policy editor has the following general options:

• First Time File Analysis—Select this option to analyze first-seen files while AMP cloud disposition is pending. The file must match a rule configured to perform a malware cloud lookup and Spero, local malware, or dynamic analysis. If you deselect this option, files detected for the first time are marked with an Unknown disposition

• Enable Custom Detection List—Block files on the custom detection list.

• Enable Clean List—If enabled, this policy will allow files that are on the clean list.

• If AMP Cloud disposition is Unknown, override disposition based upon threat score—Select an option:
  • If you select Disabled, the system will not override the disposition provided by the AMP Cloud.
  • If you set a threshold threat score, files with an AMP cloud verdict of Unknown are considered malware if their Dynamic Analysis score is equal to or worse than the threshold.
  • If you select a lower threshold value, you increase the number of files treated as malware. Depending on the action selected in your file policy, this can result in an increase of blocked files.
  • For numeric threat score ranges, see Threat Scores and Dynamic Analysis Summary Reports, on page 2791.

The Advanced Settings in the file policy editor has the following archive file inspection options:
• **Inspect Archives**—Enables inspection of the contents of archive files, for archive files as large as the Maximum file size to store advanced access control setting.

• **Block Encrypted Archives**—Blocks archive files that have encrypted contents.

• **Block Uninspectable Archives**—Blocks archive files with contents that the system is unable to inspect for reasons other than encryption. This usually applies to corrupted files, or those that exceed your specified maximum archive depth.

• **Max Archive Depth**—Blocks nested archive files that exceed the specified depth. The top-level archive file is not considered in this count; depth begins at 1 with the first nested file.

**Archive Files**

Archive files are files that contain other files, such as .zip or .rar files.

If any individual file in an archive matches a file rule with a block action, the system blocks the entire archive, not just the individual file.

For details about options for archive file inspection, see Advanced and Archive File Inspection Options, on page 1778.

**Archive Files That Can Be Inspected**

- **File types**
  
  A complete list of inspectable archive file types appears in the FMC web interface on the file rule configuration page. To view that page, see Creating File Rules, on page 1791.

  Contained files that can be inspected appears in the same page.

- **File size**
  
  You can inspect archive files as large as the Maximum file size to store file policy advanced access control setting.

- **Nested archives**
  
  Archive files can contain other archive files, which can in turn contain archive files. The level at which a file is nested is its archive file depth. Note that the top-level archive file is not included in the depth count; depth begins at 1 with the first nested file.

  The system can inspect up to three levels of nested files beneath the outermost archive file (level 0). You can configure your file policy to block archive files that exceed that depth (or a lower maximum depth that you specify).

  If you choose not to block files that exceed the maximum archive file depth of 3, when archive files that contain some extractable contents and some contents nested at a depth of 3 or greater appear in monitored traffic, the system examines and reports data only for the files it was able to inspect.

  All features applicable to uncompressed files (such as dynamic analysis and file storage) are available for nested files inside archive files.

- **Encrypted files**
  
  You can configure the system to block archives whose contents are encrypted or otherwise cannot be inspected.

- **Archives that are not inspected**
If traffic that contains an archive file is on a Security Intelligence Block list or Do Not Block list, or if the top-level archive file’s SHA-256 value is on the custom detection list, the system does not inspect the contents of the archive file.

If a nested file is blocked, the entire archive is blocked; however, if a nested file is allowed, the archive is not automatically passed (depending on any other nested files and characteristics).

.Exe files inside some .rar archives cannot be detected, including possibly rar5.

Archive File Dispositions

Archive file dispositions are based on the dispositions assigned to the files inside the archive. All archives that contain identified malware files receive a disposition of Malware. Archives without identified malware files receive a disposition of Unknown if they contain any unknown files, and a disposition of Clean if they contain only clean files.

<table>
<thead>
<tr>
<th>Archive File Disposition</th>
<th>Number of Unknown Files</th>
<th>Number of Clean Files</th>
<th>Number of Malware Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unknown</td>
<td>1 or more</td>
<td>Any</td>
<td>0</td>
</tr>
<tr>
<td>Clean</td>
<td>0</td>
<td>1 or more</td>
<td>0</td>
</tr>
<tr>
<td>Malware</td>
<td>Any</td>
<td>Any</td>
<td>1 or more</td>
</tr>
</tbody>
</table>

Archive files, like other files, may have dispositions of Custom Detection or Unavailable if the conditions for those dispositions apply.

Viewing Archive Contents and Details

If your file policy is configured to inspect archive file contents, you can use the context menu in a table on pages under the Analysis > Files menu, and the network file trajectory viewer to view information about the files inside an archive when the archive file appears in a file event, malware event, or as a captured file.

All file contents of the archive are listed in table form, with a short summary of their relevant information: name, SHA-256 hash value, type, category, and archive depth. A network file trajectory icon appears by each file, which you can click to view further information about that specific file.

Override File Disposition Using Custom Lists

If a file has a disposition in the AMP cloud that you know to be incorrect, you can add the file’s SHA-256 value to a file list that overrides the disposition from the cloud:

- To treat a file as if the AMP cloud assigned a clean disposition, add the file to the clean list.
- To treat a file as if the AMP cloud assigned a malware disposition, add the file to the custom detection list.

On subsequent detection, the device either allows or blocks the file without reevaluating the file's disposition. You can use the clean list or custom detection list per file policy.
To calculate a file's SHA-256 value, you must configure a rule in the file policy to either perform a malware cloud lookup or block malware on matching files.

For complete information about using file lists in Firepower, see File Lists, on page 602.
Alternatively, if applicable, use Centralized File Lists from AMP for Endpoints, on page 1781.

Centralized File Lists from AMP for Endpoints

If your organization has deployed AMP for Endpoints, Firepower can use Block and Allow lists created in AMP for Endpoints when it queries the AMP cloud for file dispositions.

Requirements:

- Your organization must be using the AMP public cloud.
- Your organization has deployed AMP for Endpoints.
- You have registered your Firepower system to AMP for Endpoints using the procedure in Integrate Firepower and AMP for Endpoints, on page 1795.

To create and deploy these lists, see the documentation or online help for AMP for Endpoints.

Managing File Policies

The File Policies page displays a list of existing file policies along with their last-modified dates. You can use this page to manage your file policies.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

The system checks for updates to the list of file types eligible for dynamic analysis (no more than once a day). If the list of eligible file types changes, this constitutes a change in the file policy; any access control policy using the file policy is marked out-of-date if deployed to any devices. You must deploy policies before the updated file policy can take effect on the device. See Maintain Your System: Update File Types Eligible for Dynamic Analysis, on page 1777.

Procedure

Step 1
Select Policies > Access Control > Malware & File.

Step 2
Manage your file policies:
- Compare—Click Compare Policies; see Comparing Policies, on page 508.
• Create — To create a file policy, click **New File Policy** and proceed as described in Create or Edit a File Policy, on page 1777.

• Copy — To copy a file policy, click **Copy**.
  
  If **View** appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

• Delete — If you want to delete a file policy, click **Delete** ( ), then click **Yes** and **OK** as prompted.
  
  If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

• Deploy—Choose **Deploy > Deployment**; see Deploy Configuration Changes, on page 495.

• Edit — If you want to modify an existing file policy, click **Edit** ( ).

• Report—Click **Report** ( ); see Generating Current Policy Reports, on page 509.

---

### File Rules

A file policy, like its parent access control policy, contains rules that determine how the system handles files that match the conditions of each rule. You can configure separate file rules to take different actions for different file types, application protocols, or directions of transfer.

For example, when a file matches a rule, the rule can:

• allow or block files based on simple file type matching

• block files based on disposition (whether or not evaluation indicates that it is malicious)

• store files to the device (For information, see Captured Files and File Storage, on page 1789)

• submit stored (captured) files for local malware, Spero, or dynamic analysis

In addition, the file policy can:

• automatically treat a file as if it is clean or malware based on entries in the clean list or custom detection list

• treat a file as if it is malware if the file’s threat score exceeds a configurable threshold

• inspect the contents of archive files (such as .zip or .rar)

• block archive files whose contents are encrypted, nested beyond a specified maximum archive depth, or otherwise uninspectable
# File Rule Components

**Table 111: File Rule Components**

<table>
<thead>
<tr>
<th>File Rule Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>application protocol</td>
<td>The system can detect and inspect files transmitted via FTP, HTTP, SMTP, IMAP, POP3, and NetBIOS-ssn (SMB). <strong>Any</strong>, the default, detects files in HTTP, SMTP, IMAP, POP3, FTP, and NetBIOS-ssn (SMB) traffic. To improve performance, you can restrict file detection to only one of those application protocols on a per-file rule basis.</td>
</tr>
<tr>
<td>direction of transfer</td>
<td>You can inspect incoming FTP, HTTP, IMAP, POP3, and NetBIOS-ssn (SMB) traffic for downloaded files; you can inspect outgoing FTP, HTTP, SMTP, and NetBIOS-ssn (SMB) traffic for uploaded files. <strong>Tip</strong> Use <strong>Any</strong> to detect files over multiple application protocols, regardless of whether users are sending or receiving.</td>
</tr>
<tr>
<td>file categories and types</td>
<td>The system can detect various types of files. These file types are grouped into basic categories, including multimedia (swf, mp3), executables (exe, torrent), and PDFs. You can configure file rules that detect individual file types, or on entire categories of file types. For example, you could block all multimedia files, or just ShockWave Flash (swf) files. Or, you could configure the system to alert you when a user downloads a BitTorrent (torrent) file. Note that executables include file types that can run macros and scripts, since these can contain malware. For a list of file types the system can inspect, select <strong>Policies &gt; Access Control &gt; Malware &amp; File</strong>. Create a temporary new file policy, then click <strong>Add Rule</strong>. Select a file type category and the file types that the system can inspect appear in the <strong>File Types</strong> list. <strong>Note</strong> Frequently triggered file rules can affect system performance. For example, detecting multimedia files in HTTP traffic (YouTube, for example, transmits significant Flash content) could generate an overwhelming number of events.</td>
</tr>
</tbody>
</table>
**File Rule Actions**

File rules give you granular control over which file types you want to log, block, or scan for malware. Each file rule has an associated action that determines how the system handles traffic that matches the conditions of the rule. To be effective, a file policy must contain one or more rules. You can use separate rules within a file policy to take different actions for different file types, application protocols, or directions of transfer.

**File Rule Actions**

- *Detect Files* rules allow you to log the detection of specific file types to the database, while still allowing their transmission.

- *Block Files* rules allow you to block specific file types. You can configure options to reset the connection when a file transfer is blocked, and store captured files to the managed device.

- *Malware Cloud Lookup* rules allow you to obtain and log the disposition of files traversing your network, while still allowing their transmission.

- *Block Malware* rules allow you to calculate the SHA-256 hash value of specific file types, query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.

**File Rule Action Options**

Depending on the action you select, you have different options:

<table>
<thead>
<tr>
<th>File Rule Action Option</th>
<th>Block Files capable?</th>
<th>Block Malware capable?</th>
<th>Detect Files capable?</th>
<th>Malware Cloud Lookup capable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spero Analysis* for MSEXE</td>
<td>no</td>

* For complete information about these options, see Malware Protection Options (in File Rule Actions), on page 1785 and its subtopics.

**Caution**

Enabling or disabling Store files in a Detect Files or Block Files rule, or adding the first or removing the last file rule that combines the Malware Cloud Lookup or Block Malware file rule action with an analysis option (Spero Analysis or MSEXE, Dynamic Analysis, or Local Malware Analysis) or a store files option (Malware, Unknown, Clean, or Custom), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 504 for more information.

## Malware Protection Options (in File Rule Actions)

The Firepower system applies several methods of file inspection and analysis to determine whether a file contains malware.

Depending on the options you enable in a file rule, the system inspects files using the following tools, in order:

1. Spero Analysis, on page 1787 and AMP Cloud Lookup, on page 1787
2. Local Malware Analysis, on page 1787
3. Dynamic Analysis, on page 1788

For a comparison of these tools, see Comparison of Malware Protection Options, on page 1785.

(You can also, if you choose, block all files based on their file type. For more information, see Block All Files by Type, on page 1790.)

See also information about Cisco's AMP for Endpoints product at (Optional) Malware Protection with AMP for Endpoints, on page 1792 and subtopics.

### Comparison of Malware Protection Options

The following table details the benefits and drawbacks of each type of file analysis, as well as the way each malware protection method determines a file's disposition.
## Comparison of Malware Protection Options

<table>
<thead>
<tr>
<th>Analysis Type</th>
<th>Benefit</th>
<th>Limitations</th>
<th>Malware Identification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spero analysis</td>
<td>Structural analysis of executable files, submits Spero signature to the AMP Cloud for analysis</td>
<td>Less thorough than local malware analysis or dynamic analysis, only for executable files</td>
<td>Disposition changes from Unknown to Malware only on positive identification of malware.</td>
</tr>
<tr>
<td>Local malware analysis</td>
<td>Consumes fewer resources than dynamic analysis, and returns results more quickly, especially if the detected malware is common</td>
<td>Less thorough results than dynamic analysis</td>
<td>Disposition changes from Unknown to Malware only on positive identification of malware.</td>
</tr>
<tr>
<td>Dynamic analysis</td>
<td>Thorough analysis of unknown files using Cisco Threat Grid</td>
<td>Eligible files are uploaded to the public cloud or an on-premises appliance. It takes some time to complete analysis</td>
<td>Threat score determines maliciousness of a file. Disposition can be based on the threat score threshold configured in the file policy.</td>
</tr>
<tr>
<td>Spero analysis and local malware analysis</td>
<td>Consumes fewer resources than configuring local malware analysis and dynamic analysis, while still using AMP cloud resources to identify malware</td>
<td>Less thorough than dynamic analysis, Spero analysis only for executable files</td>
<td>Disposition changes from Unknown to Malware only on positive identification of malware.</td>
</tr>
<tr>
<td>Spero analysis and dynamic analysis</td>
<td>Uses full capabilities of AMP cloud in submitting files and Spero signatures</td>
<td>Results obtained less quickly than if using local malware analysis</td>
<td>Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes based on configured threat score threshold in the file policy, and from Unknown to Malware if the Spero analysis identifies malware.</td>
</tr>
<tr>
<td>Local malware analysis and dynamic analysis</td>
<td>Thorough results in using both types of file analysis</td>
<td>Consumes more resources than either alone</td>
<td>Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if local malware analysis identifies malware, or based on configured threat score threshold in the file policy.</td>
</tr>
</tbody>
</table>
### Spero Analysis

Spero analysis examines structural characteristics such as metadata and header information in executable files. After generating a Spero signature based on this information, if the file is an eligible executable file, the device submits it to the Spero heuristic engine in the AMP cloud. Based on the Spero signature, the Spero engine determines whether the file is malware. You can also configure rules to submit files for Spero analysis without also submitting them to the AMP cloud.

Note that you cannot manually submit files for Spero analysis.

### AMP Cloud Lookup

For files that are eligible for assessment using Advanced Malware Protection, the Firepower Management Center performs a malware cloud lookup, querying the AMP cloud for the file's disposition based on its SHA-256 hash value.

To improve performance, the system caches dispositions returned by the cloud and uses the cached disposition for known files rather than querying the AMP cloud. For more information about this cache, see [Cached Disposition Longevity](#) on page 1788.

### Local Malware Analysis

Local malware analysis allows a managed device to locally inspect executables, PDFs, office documents, and other types of files for the most common types of malware, using a detection rule set provided by the Cisco Talos Intelligence Group (Talos). Because local analysis does not query the AMP cloud, and does not run the file, local malware analysis saves time and system resources.

If the system identifies malware through local malware analysis, it updates the existing file disposition from Unknown to Malware. The system then generates a new malware event. If the system does not identify malware, it does not update the file disposition from Unknown to Clean. After the system runs local malware analysis, the file policy and analysis results are used to determine the file's disposition.

### Analysis Type | Benefit | Limitations | Malware Identification
---|---|---|---
Spero analysis, local malware analysis and dynamic analysis | Most thorough results | Consumes most resources in running all three types of file analysis | Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if Spero analysis or local malware analysis identifies malware, or based on configured threat score threshold in the file policy.

(Block transmission of all files of a specified file type) | Does not require a Malware license (This option is not technically a malware protection option.) | Legitimate files will also be blocked | (No analysis is performed.)

---

Note

Preclassification does not itself determine a file's disposition; it is merely one of the factors that determine whether a file is eligible for Dynamic Analysis.

---

Advanced Malware Protection (AMP) and File Control

Spero Analysis
analysis, it caches file information such as SHA-256 hash value, timestamp, and disposition, so that if detected again within a certain period of time, the system can identify malware without additional analysis. For more information about the cache, see Cached Disposition Longevity, on page 1788.

Local malware analysis does not require establishing communications with the Cisco Threat Grid cloud. However, you must configure communications with the cloud to submit files for dynamic analysis, and to download updates to the local malware analysis ruleset.

Cached Disposition Longevity

Dispositions returned from an AMP cloud query, associated threat scores, and dispositions assigned by local malware analysis, have a time-to-live (TTL) value. After a disposition has been held for the duration specified in the TTL value without update, the system purges the cached information. Dispositions and associated threat scores have the following TTL values:

- Clean — 4 hours
- Unknown — 1 hour
- Malware — 1 hour

If a query against the cache identifies a cached disposition that timed out, the system re-queries the local malware analysis database and the AMP cloud for a new disposition.

Dynamic Analysis

You can configure your file policy to automatically submit files for dynamic analysis using Cisco Threat Grid (formerly AMP Threat Grid), Cisco’s file analysis and threat intelligence platform.

Devices submit eligible files to Cisco Threat Grid (either the public cloud or to an on-premises appliance, whichever you have specified) regardless of whether the device stores the file.

Cisco Threat Grid runs the file in a sandbox environment, analyzes the file's behavior to determine whether the file is malicious, and returns a threat score that indicates the likelihood that a file contains malware. From the threat score, you can view a dynamic analysis summary report with the reasons for the assigned threat score. You can also look in Cisco Threat Grid to view detailed reports for files that your organization submitted, as well as scrubbed reports with limited data for files that your organization did not submit.

To configure your system to perform dynamic analysis, see the topics under Dynamic Analysis Connections, on page 1774.

Which Files Are Eligible for Dynamic Analysis?

A file's eligibility for dynamic analysis depends on:

- the file type
- the file size
- the file rule's action

Additionally:

- The system submits only files that match the file rules you configure.
• The file must have a malware cloud lookup disposition of Unknown or Unavailable at the time the file is sent for analysis.
• The system must preclassify the file as potential malware.

Dynamic Analysis and Capacity Handling

Capacity handling allows you to temporarily store files that are otherwise eligible for dynamic analysis if the system is temporarily unable to submit files to the cloud, either because the device cannot communicate with the cloud or because the maximum number of submissions has been reached. The system submits the stored files when the hindering condition has passed.

Some devices can store files on the device hard drive or in a malware storage pack. See also Malware Storage Pack, on page 1790.

Captured Files and File Storage

The file storage feature allows you to capture selected files detected in traffic, and automatically store a copy of the file temporarily to a device’s hard drive, or, if installed, to the malware storage pack.

After your device captures the files, you can:
• Store captured files on the device’s hard drive for later analysis.
• Download the stored file to a local computer for further manual analysis or archival purposes.
• Manually submit eligible captured files for AMP cloud lookup or dynamic analysis.

Note that once a device stores a file, it will not re-capture it if the file is detected in the future and the device still has that file stored.

When a file is detected for the first time on your network, you can generate a file event that represents the file’s detection. However, if your file rule performs a malware cloud lookup, the system requires additional time to query the AMP cloud and return a disposition. Due to this delay, the system cannot store this file until the second time it is seen on your network, and the system can immediately determine the file’s disposition.

Whether the system captures or stores a file, you can:
• Review information about the captured file from Analysis > Files > Captured Files, including whether the file was stored or submitted for dynamic analysis, file disposition, and threat score, allowing you to quickly review possible malware threats detected on your network.
• View the file’s trajectory to determine how it traversed your network and which hosts have a copy.
• Add the file to the clean list or custom detection list to always treat the file as if it had a clean or malware disposition on future detection.

You configure file rules in a file policy to capture and store files of a specific type, or with a particular file disposition, if available. After you associate the file policy with an access control policy and deploy it to your devices, matching files in traffic are captured and stored. You can also limit the minimum and maximum file sizes to store.

Stored files are not included in system backups.
You can view captured file information under Analysis > Files > Captured Files, and download a copy for offline analysis.

Malware Storage Pack

Based on your file policy configuration, your device may store a substantial amount of file data to the hard drive. You can install a malware storage pack in the device; the system stores files to the malware storage pack, allowing more room on the primary hard drive to store events and configuration files. The system periodically deletes older files. If the device's primary hard drive does not have enough available space, and does not have an installed malware storage pack, you cannot store files.

Caution

Do not attempt to install a hard drive that was not supplied by Cisco in your device. Installing an unsupported hard drive may damage the device. Malware storage pack kits are available for purchase only from Cisco. Contact Support if you require assistance with the malware storage pack. See the Firepower System Malware Storage Pack Guide for more information.

Without a malware storage pack installed, when you configure a device to store files, it allocates a set portion of the primary hard drive’s space to captured file storage. If you configure capacity handling to temporarily store files for dynamic analysis, the system uses the same hard drive allocation to store these files until it can resubmit them to the cloud.

When you install a malware storage pack in a device and configure file storage or capacity handling, the device allocates the entire malware storage pack for storing these files. The device cannot store any other information on the malware storage pack.

When the allocated space for captured file storage fills to capacity, the system deletes the oldest stored files until the allocated space reaches a system-defined threshold. Based on the number of files stored, you may see a substantial drop in disk usage after the system deletes files.

If a device has already stored files when you install a malware storage pack, the next time you restart the device, any captured files or capacity handling files stored on the primary hard drive are moved to the malware storage pack. Any future files the device stores are stored to the malware storage pack.

Block All Files by Type

If your organization wants to block not only the transmission of malware files, but all files of a specific type, regardless of whether the files contain malware, you can do so.

File control is supported for all file types where the system can detect malware, plus many additional file types. These file types are grouped into basic categories, such as multimedia (swf, mp3), executables (exe, torrent), and PDFs.

Blocking all files based on their type is not technically a malware protection feature; it does not require a Malware license and does not query the AMP cloud.

File Rule Actions: Evaluation Order

A file policy will likely contain multiple rules with different actions for different situations. If more than one rule can apply to a particular situation, the evaluation order described in this topic applies. In general, simple blocking takes precedence over malware inspection and blocking, which takes precedence over simple detection and logging.

The order of precedence of file-rule actions is:

• Block Files
• Block Malware
• Malware Cloud Lookup
• Detect Files

If configured, TID also impacts action prioritization. For more information, see TID-Firepower Management Center Action Prioritization, on page 1826.

Creating File Rules

Caution

Enabling or disabling Store files in a Detect Files or Block Files rule, or adding the first or removing the last file rule that combines the Malware Cloud Lookup or Block Malware file rule action with an analysis option (Spero Analysis or MSEXE, Dynamic Analysis, or Local Malware Analysis) or a store files option (Malware, Unknown, Clean, or Custom), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort® Restart Traffic Behavior, on page 504 for more information.

Before you begin

If you are configuring rules for malware protection, see Configure File Policies, on page 1765.

Procedure

Step 1
In the file policy editor, click Add File Rule.

Step 2
Select an Application Protocol and Direction of Transfer as described in File Rule Components, on page 1783.

Step 3
Select one or more File Types.

The file types you see depend on the selected application protocol, direction of transfer, and action.

You can filter the list of file types in the following ways:

• Select one or more File Type Categories, then click All types in selected Categories.

• Search for a file type by its name or description. For example, type Windows in the Search name and description field to display a list of Microsoft Windows-specific files.

Tip
Hover your pointer over a file type to view its description.

Step 4
Select a file rule Action as described in File Rule Actions, on page 1784, with consideration for File Rule Actions: Evaluation Order, on page 1790.

The actions available to you depend on the licenses you have installed. See License Requirements for File and Malware Policies, on page 1761.

Step 5
Depending on the action you selected, configure options:

• reset the connection after blocking the file
• store files that match the rule
• enable Spero analysis*
• enable local malware analysis*
• enable dynamic analysis* and capacity handling

* For information about these options, see File Rule Actions, on page 1784 and Malware Protection Options (in File Rule Actions), on page 1785 and its subtopics.

Step 6 Click Add.
Step 7 Click Save to save the policy.

What to do next
• If you are configuring policies for malware protection, return to Configure File Policies, on page 1765.
• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Access Control Rule Logging for Malware Protection

When the system detects a prohibited file (including malware) according to the settings in the file policy, it automatically logs an event to the Firepower Management Center database. If you do not want to log file or malware events, you can disable this logging on a per-access-control-rule basis.

The system also logs the end of the associated connection to the Firepower Management Center database, regardless of the logging configuration of the invoking access control rule.

Retrospective Disposition Changes

File dispositions can change. For example, as new information is discovered, the AMP cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse—that a malware-identified file is actually clean. When the disposition changes for a file you queried in the past week, the AMP cloud notifies the system so it can automatically take action the next time it detects that file being transmitted. A changed disposition is called a retrospective disposition.

(Optional) Malware Protection with AMP for Endpoints

Cisco's AMP for Endpoints is a separate malware-protection product that can supplement malware protection provided by the Firepower system and be integrated with your Firepower deployment.

AMP for Endpoints is Cisco's enterprise-class Advanced Malware Protection solution that runs as a lightweight connector on individual users' endpoints (computers and mobile devices) to discover, understand, and block advanced malware outbreaks, advanced persistent threats, and targeted attacks.

Benefits of AMP for Endpoints include:
• configure custom malware detection policies and profiles for your entire organization, as well as perform flash and full scans on all your users’ files

• perform malware analysis, including view heat maps, detailed file information, network file trajectory, and threat root causes

• configure multiple aspects of outbreak control, including automatic quarantines, application blocking to stop non-quarantined executables from running, and exclusion lists

• create custom protections, block execution of certain applications based on group policy, and create custom Allowed Applications lists

• use the AMP for Endpoints management console to help you mitigate the effect of malware. The management console provides a robust, flexible web interface where you control all aspects of your AMP for Endpoints deployment and manage all phases of an outbreak.

For detailed information about AMP for Endpoints, see:

• Online help in the AMP for Endpoints management console.

### Comparison of Malware Protection: Firepower vs. AMP for Endpoints

### About Integrating Firepower with AMP for Endpoints

If your organization has deployed AMP for Endpoints, you can optionally integrate that product with your Firepower deployment.

Integration with AMP for Endpoints does not require a dedicated Firepower license.

### Benefits of Integrating Firepower and AMP for Endpoints

Integrating your AMP for Endpoints deployment with your Firepower system offers the following benefits:

- Centralized Blocked Applications and Allowed Applications lists configured in AMP for Endpoints can determine verdicts for file SHA1s sent from Firepower to the AMP cloud for disposition.  
  
  See [Centralized File Lists from AMP for Endpoints](#), on page 1781.

- The system can import malware events detected by AMP for Endpoints into Firepower Management Center so you can manage these events along with malware events generated by the Firepower system. Imported data for these events includes scans, malware detections, quarantines, blocked executions, and cloud recalls, as well as indications of compromise (IOCs) that FMC displays for hosts that it monitors.

  For more information, see [Malware Event Analysis with AMP for Endpoints](#), on page 2774.

- You can view file trajectory and other details in the AMP for Endpoints console.

  For details, see [Work with Event Data in the AMP for Endpoints Console](#), on page 2804.

---

**Important**

If you use a Cisco AMP Private Cloud, see limitations at [AMP for Endpoints and AMP Private Cloud](#), on page 1795.
AMP for Endpoints and AMP Private Cloud

If you configure a Cisco AMP private cloud to collect AMP endpoint data on your network, all AMP for Endpoints connectors send data to the private cloud, which forwards that data to the Firepower Management Center. The private cloud does not share any of your endpoint data over an external connection.

If your organization has deployed an AMP private cloud, all connections to the AMP cloud funnel through the private cloud, which acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes importing AMP for Endpoints data. The private cloud does not share any of your endpoint data over an external connection.

The following integration features are not available if you use an AMP private cloud:

- Use of Blocked Applications and Allowed Applications lists configured in AMP for Endpoints. (These lists are used to block or allow files.)
- Visibility in AMP for Endpoints of malware events generated from Firepower.

You can configure multiple private clouds to support the capacity you require.

Integrate Firepower and AMP for Endpoints

If your organization has deployed Cisco's AMP for Endpoints product, you can integrate that application with Firepower to achieve the benefits described in Benefits of Integrating Firepower and AMP for Endpoints, on page 1794.

When you integrate with AMP for Endpoints, you must configure an AMP for Endpoints connection even if you already have an AMP for Networks (AMP for Firepower) connection configured. You can configure multiple AMP for Endpoints cloud connections.

Caution

In a multidomain deployment, configure AMP for Endpoints connections at the leaf level only, especially if your leaf domains have overlapping IP space. If multiple subdomains have hosts with the same IP-MAC address pair, the system could save malware events that are generated by AMP for Endpoints to the wrong leaf domain, or associate IOCs with the wrong hosts.

However, you can configure AMP for Endpoints connections at any domain level, provided you use a separate AMP for Endpoints account for each connection. For example, each client of an MSSP might have its own AMP for Endpoints deployment.

Note

An AMP for Endpoints connection that has not registered successfully does not affect AMP for Networks.

Before you begin

- You must be an Admin user to perform this task.
- If your deployment uses Cisco AMP Private Cloud, see limitations at AMP for Endpoints and AMP Private Cloud, on page 1795.
- AMP for Endpoints must be set up and working properly on your network.
- The Firepower Management Center must have direct access to the Internet.
• Make sure your FMC and AMP for Endpoints can communicate with each other. See the topics under Security, Internet Access, and Communication Ports, on page 2903.

• If you are connecting to the AMP cloud after either restoring your Firepower Management Center to factory defaults or reverting to a previous version, use the AMP for Endpoints management console to remove the previous connection.

• You will need your AMP for Endpoints credentials to log in to the AMP for Endpoints console during this procedure.

Procedure

**Step 1** Choose **AMP > AMP Management**.

**Step 2** Click **Add AMP Cloud Connection**.

**Step 3** From the **Cloud Name** drop-down list, choose the cloud you want to use:

- The AMP cloud closest to the geographical location of your Firepower Management Center.
  - APJC is Asia/Pacific/Japan/China.
- For AMP private cloud (AMPv), choose **Private Cloud** and proceed as described in Cisco AMP Private Cloud, on page 1771.

**Step 4** If you want to use this cloud for both AMP for Networks and AMP for Endpoints, select the **Use for AMP for Firepower** check box.

If you configured a different cloud to handle AMP for Networks (AMP for Firepower) communications, you can clear this check box; if this is your only AMP cloud connection, you cannot.

In a multidomain deployment, this check box appears only in the Global domain. Each Firepower Management Center can have only one AMP for Networks connection.

**Step 5** Click **Register**.

A spinning state icon indicates that a connection is pending, for example, after you configure a connection on the Firepower Management Center, but before you authorize it using the AMP for Endpoints management console. A **Denied** (⚠️) indicates that the cloud denied the connection or the connection failed for another reason.

**Step 6** Confirm that you want to continue to the AMP for Endpoints management console, then log into the management console.

**Step 7** Using the management console, authorize the AMP cloud to send AMP for Endpoints data to the Firepower Management Center.

**Step 8** If you want to restrict the data that the FMC receives, select specific groups within your organization for which you want to receive information.

By default, the AMP cloud sends data for all groups. To manage groups, choose **Management > Groups** on the AMP for Endpoints management console. For detailed information, see the management console online help.

**Step 9** Click **Allow** to enable the connection and start the transfer of data.
Clicking **Deny** returns you to the Firepower Management Center, where the connection is marked as denied. If you navigate away from the Applications page on the AMP for Endpoints management console, and neither deny nor allow the connection, the connection is marked as pending on the Firepower Management Center’s web interface. The health monitor does **not** alert you of a failed connection in either of these situations. If you want to connect to the AMP cloud later, delete the failed or pending connection, then recreate it.

Incomplete registration of an AMP for Endpoints connection does not disable the AMP for Networks connection.

### Step 10

To verify that the connection is correctly configured:

a) On the **AMP > AMP Management** page, click the Cloud Name that includes **AMP for Endpoints** in the **Cisco AMP Solution Type** column.

b) In the AMP for Endpoints console window that displays, choose **Accounts > Applications**.

c) Verify that your Firepower Management Center is on the list.

d) In the AMP for Endpoints console window, choose **Manage > Computers**.

e) Verify that your Firepower Management Center is on the list.

### What to do next

- In the AMP for Endpoints console window, configure settings as needed. For example, define group membership for your management center and assign policies. For information, see the AMP for Endpoints online help or other documentation.

- In high availability configurations, you must configure AMP cloud connections independently on the Active and Standby instances of the Firepower Management Center; these configurations are not synchronized.

- The default health policy warns you if the Firepower Management Center cannot connect to the AMP for Endpoints portal after an initial successful connection, or if the connection is deregistered using the AMP portal.

Verify that the **AMP for Endpoints Status** monitor is enabled under **System > Health > Policy**.

---

### History for File Policies and Malware Protection

</tbody>
</table>
The following topics describe how to configure file and malware inspection performance and storage:

- File and Malware Inspection Performance and Storage Options, on page 1799
- Tuning File and Malware Inspection Performance and Storage, on page 1801

### File and Malware Inspection Performance and Storage Options

Increasing the file sizes can affect the performance of the system.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Guidelines and Restrictions</th>
</tr>
</thead>
</table>
| Limit the number of bytes inspected when   | Specifies the number of bytes inspected when performing file type detection. | 0 - 4294967295 (4GB)  
0 removes the restriction.                                                                 |
| doing file type detection                  |                                                                             | The default value is the maximum segment size of a TCP packet (1460 bytes). In most cases, the system can identify common file types using the first packet.  
To detect ISO files, enter a value greater than 36870. |
| Allow file if cloud lookup for Block       | Specifies how long the system will hold the last byte of a file that matches a Block Malware rule and that does not have a cached disposition, while malware cloud lookup occurs. If the time elapses without the system obtaining a disposition, the file passes. Dispositions of Unavailable are not cached. | 0 - 30 seconds  
Do not set this option to 0 without contacting Support.  
Cisco recommends that you use the default value to avoid blocking traffic because of connection failures. |
<p>| Malware takes longer than (seconds)        |                                                                             |                                                                                             |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Guidelines and Restrictions</th>
</tr>
</thead>

| Do not calculate SHA-256 hash values for files larger than (in bytes) | Prevents the system from storing files larger than a certain size, performing a malware cloud lookup on the files, or blocking the files if added to the custom detection list.                                                                 | 0 - 4294967295 (4GB)  
0 removes the restriction.  
This value must be greater than or equal to **Maximum file size to store (bytes)** and **Maximum file size for dynamic analysis testing (bytes)**. |
| Minimum file size for advanced file inspection and storage (bytes)   | These settings specify:  
• The file size that the system can inspect using the following detectors:  
  • Spero analysis  
  • Sandboxing and preclassification  
  • Local malware analysis/ClamAV  
  • Archive inspection  
• The file size that the system can store using a file rule.                                                                 | 0 - 10485760 (10MB)  
0 disables file storage.  
Must be less than or equal to **Maximum file size to store (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**. |
| Maximum file size for advanced file inspection and storage (bytes)    |                                                                                                                                             | 0 - 10485760 (10MB)  
0 disables file storage.  
Must be greater than or equal to **Minimum file size to store (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than (in bytes)**. |
| Minimum file size for dynamic analysis testing (bytes)                | Specifies the minimum file size the system can submit to the AMP cloud for dynamic analysis.                                                                                                           | 0 - 10485760 (10MB)  
Must be less than or equal to **Maximum file size for dynamic analysis testing (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**.  
The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis.  
The system checks the AMP cloud for updates to the minimum file size you can submit (no more than once a day). If the new minimum size is larger than your current value, your current value is updated to the new minimum, and your policy is marked out-of-date. |
### Field | Description | Guidelines and Restrictions
--- | --- | ---
**Maximum file size for dynamic analysis testing (bytes)** | Specifies the maximum file size the system can submit to the AMP cloud for dynamic analysis. | 0 -10485760 (10MB)  
Must be greater than or equal to **Minimum file size for dynamic analysis testing (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than** (in bytes).  
The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis.  
The system checks the AMP cloud for updates to the maximum file size you can submit (no more than once a day). If the new maximum size is smaller than your current value, your current value is updated to the new maximum, and your policy is marked out-of-date.

---

**Tuning File and Malware Inspection Performance and Storage**

You must be an Admin, Access Admin, or Network Admin user to perform this task.

**Procedure**

1. **Step 1**  
   In the access control policy editor, click **Advanced Settings**.

2. **Step 2**  
   Click **Edit** next to **Files and Malware Settings**.  
   If **View** appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

3. **Step 3**  
   Set any of the options described in **File and Malware Inspection Performance and Storage Options**, on page 1799.

4. **Step 4**  
   Click **OK**.

5. **Step 5**  
   Click **Save** to save the policy.

**What to do next**

- Deploy configuration changes; see **Deploy Configuration Changes**, on page 495.

**Related Topics**

- **Snort® Restart Scenarios**, on page 502
PART XVII

TID Intelligence and Threat Analysis

• Threat Intelligence Director, on page 1805
CHAPTER 77

Threat Intelligence Director

The topics in this chapter describe how to configure and use TID in the Firepower System.

- Threat Intelligence Director Overview, on page 1805
- Requirements and Prerequisites for Threat Intelligence Director, on page 1808
- How To Set Up Threat Intelligence Director, on page 1810
- Analyze TID Incident and Observation Data, on page 1818
- View and Change Threat Intelligence Director Configurations, on page 1830
- Troubleshoot Threat Intelligence Director, on page 1844
- History for Threat Intelligence Director, on page 1847

Threat Intelligence Director Overview

The Threat Intelligence Director operationalizes threat intelligence data, helping you aggregate intelligence data, configure defensive actions, and analyze threats in your environment. This feature is intended to supplement other Firepower functionality, offering an additional line of defense against threats.

When configured on your hosting platform, TID ingests data from threat intelligence sources and publishes the data to all configured managed devices (elements). For more information about the hosting platforms and elements supported in this release, see Platform, Element, and License Requirements, on page 1808.

Sources contain indicators, which contain observables. An indicator conveys all of the characteristics associated with a threat, and individual observables represent individual characteristics (e.g. a SHA-256 value) associated with the threat. Simple indicators contain a single observable, and complex indicators contain two or more observables.

Observables and the AND/OR operators between them form an indicator's pattern, as illustrated in the following examples.
After the observables are published to the elements, the elements monitor traffic and report observations to the Firepower Management Center when the system identifies observables in traffic.

The Firepower Management Center collects observations from all elements, evaluates the observations against TID indicators, and generates or updates incidents associated with the observable's parent indicator(s).

An incident is fully realized when an indicator's pattern is fulfilled. An incident is partially realized if traffic matches one or more observables in the indicator but not the entire pattern. For more information, see Observation and Incident Generation, on page 1818.

The following diagram shows data flow in a sample Firepower System configuration.

When a TID incident is fully or partially realized, the system takes the configured action (monitor, block, partially block, or no action). For details, see Factors That Affect the Action Taken, on page 1826.
TID and Security Intelligence

As part of your access control policy, Security Intelligence uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domains. Security Intelligence uniquely provides access to industry-leading threat intelligence from Cisco Talos Intelligence Group (Talos). For more information on Security Intelligence, see About Security Intelligence, on page 1603.

TID enhances the system's ability to block connections based on security intelligence from third-party sources as follows:

• **TID supports additional traffic filtering criteria**—Security Intelligence allows you to filter traffic based on IP address, URL, and (if DNS policy is enabled) domain name. TID also supports filtering by these criteria and adds support for filtering on SHA-256 hash values.

• **TID supports additional intelligence ingestion methods**—With both Security Intelligence and TID, you can import threat intelligence into the system by either manually uploading flat files or configuring the system to retrieve flat files from a third-party host. TID provides increased flexibility in managing those flat files. In addition, TID can retrieve and ingest intelligence provided in Structured Threat Information eXpression (STIX™) format.

• **TID provides granular control of filtering actions**—With Security Intelligence, you can specify filtering criteria by network, URL, or DNS object. Security Intelligence objects, especially list and feeds, can contain multiple IP addresses, URLs, or DNS domain names, but you can only block or not block based on entire objects, not based on individual components of an object. With TID, you can configure filtering actions for individual criteria (that is, simple indicators or individual observables).

• **TID configuration changes do not require redeployment**—After you modify Security Intelligence settings in the access control policy, you must redeploy the changed configuration to managed devices. With TID, after initial deployment of the access control policy to the managed devices, you can configure sources, indicators, and observables without redeploying, and the system automatically publishes new TID data to the elements.

For information about what the system does when either Security Intelligence or TID could handle a particular incident, see TID-Firepower Management Center Action Prioritization, on page 1826.

Performance Impact of Threat Intelligence Director

**Firepower Management Center**

In some cases, you may notice the following:

• The system may experience minor performance issues while ingesting particularly large STIX sources, and ingestion may take longer than expected to finish.

• The system may take up to 15 minutes to publish new or modified TID data down to elements.

**Managed Device**

There is no exceptional performance impact. TID impacts performance identically to the Firepower Management Center Security Intelligence feature.
Threat Intelligence Director and High Availability Configurations

If you host TID on the active Firepower Management Center in a high availability configuration, the system does not synchronize TID configurations and TID data to the standby Firepower Management Center. We recommend performing regular backups of TID data on your active Firepower Management Center so that you can restore the data after failover.

For details, see About Backing Up and Restoring TID Data, on page 1818.

Requirements and Prerequisites for Threat Intelligence Director

Model Support
Any

Supported Domains
Any

User Roles
Admin
Threat Intelligence Director (TID) User

Additional Requirements
The following topics explain additional requirements for using Threat Intelligence Director.

Platform, Element, and License Requirements

Hosting Platforms
You can host TID on physical and virtual Firepower Management Centers:

• running Version 6.2.2 or later of the Firepower System.
• configured with a minimum of 15 GB of memory.
• configured with REST API access enabled. See Enabling REST API Access, on page 1326.

Elements
You can use any Firepower Management Center-managed device as a TID element if the device is running Version 6.2.2 or later of the Firepower System.

Licensing
If you want to configure file policies for SHA-256 observable publishing, the Firepower System requires a Malware license (Classic or Smart).
For more information, see Configure Policies to Support TID, on page 1811 and About Firepower Licenses, on page 151.

Source Requirements

Source Type Requirements:

**STIX**

Files must be STIX Version 1.0, 1.1, 1.1.1, or 1.2 and adhere to the guidelines in the STIX documentation: [http://stixproject.github.io/documentation/suggested-practices/](http://stixproject.github.io/documentation/suggested-practices/).

STIX files can include complex indicators.

The maximum size for a STIX file is 40MB when configured via URL download or file upload. If you have STIX files larger than this, we recommend using a TAXII server.

**Flat File**

Files must be ASCII text files with one observable value per line.

Flat files include only simple indicators (one observable per indicator.)

Flat files can be up to 500 MB.

TID does not support:

- Delimiter characters separating observable values (e.g. observable, is invalid).
- Enclosing characters around observable values (e.g. "observable" is invalid).

Each file should contain only one type of content:

- **SHA-256**— SHA-256 hash values.
- **Domain**—domain names as defined in RFC 1035.
- **URL**— URLs as defined in RFC 1738.
TID normalizes any URLs that contain port, protocol, or authentication information, and uses the normalized version when detecting indicators. For example, TID normalizes any of the following URLs:

- http://example.com/index.htm
- http://example.com:8080/index.htm
- example.com:8080/index.htm
- example.com/index.htm

as:

example.com/index.htm

Or, for example, TID normalizes the following URL:

- http://abc@example.com:8080/index.htm

as

abc@example.com/index.htm/

- **IPv4**— IPv4 addresses as defined in RFC 791.
  - TID does not accept CIDR blocks.
- **IPv6**— IPv6 addresses as defined in RFC 4291.
  - TID does not accept prefix lengths.

**Source Content Limitations**

The system ingests, and matches on, only the first 1000 characters of a URL observable.

**How To Set Up Threat Intelligence Director**

If you encounter an issue during TID configuration or operation, see Troubleshoot Threat Intelligence Director, on page 1844.

**Procedure**

**Step 1**

Ensure that your installation meets the requirements for running TID.

See Platform, Element, and License Requirements, on page 1808

**Step 2**

For each managed device, configure the policies required to support TID and deploy those policies to the devices.

See Configure Policies to Support TID, on page 1811.

You can configure elements before or after you ingest intelligence data sources.
Configure Policies to Support TID

You must configure access control policies to publish TID data from the Firepower Management Center to your managed devices (elements). In addition, we recommend that you configure your access control policies to maximize observation and Firepower Management Center event generation.

For each managed device that you want to support TID, perform the steps below to configure the associated access control policy.

Elements that are configured to use TID after data has been published will automatically receive all currently-published observables.

### Procedure

**Step 1** Verify that the Enable Threat Intelligence Director check box is checked in Advanced Settings of the access control policy. This option is enabled by default.

For more information, see Access Control Policy Advanced Settings, on page 1546.

**Step 2** Add rules that allow (rather than trust) connections to the access control policy if they are not already present.

TID requires that the access control policy specify at least one rule.

Because TID depends on inspection, ensure that you allow traffic, rather than trust it, because the purpose of trusting traffic is to bypass inspection. For more information, see Creating a Basic Access Control Policy, on page 1539.

**Step 3** If you choose Intrusion Prevention as the default action for the access control policy and you want to decrypt traffic for TID detection, associate an SSL policy with the access control policy; see Associating Other Policies with Access Control, on page 1550.

**Step 4** If you want SHA-256 observables to generate observations and Firepower Management Center events:
a) Create a file policy containing one or more Malware Cloud Lookup or Block Malware file rules. For more information, see Configure File Policies, on page 1765.

b) Associate this file policy with one or more rules in the access control policy.

Step 5
If you want IPv4, IPv6, URL, or Domain Name observations to generate connection and security intelligence events, enable connection and security intelligence logging in the access control policy:

a) In access control rules where you invoked a file policy, enable Log at End of Connection and File Events: Log Files, if not already enabled.

For more information, see Logging Connections with Access Control Rules, on page 2688.

b) Verify that default logging (DNS Policy, Networks, and URLs) is enabled in your Security Intelligence settings.

For more information, see Logging Connections with Security Intelligence, on page 2688.

Step 6
Deploy configuration changes; see Deploy Configuration Changes, on page 495.

What to do next
Complete remaining items in How To Set Up Threat Intelligence Director, on page 1810

Options for Ingesting Data Sources

Choose a configuration option based on the data type and delivery mechanism you want to use.

For more information about these data types, see Source Requirements, on page 1809.

Table 114: Options for Ingesting Data Sources

<table>
<thead>
<tr>
<th>Data Type</th>

</table>
Fetch TAXII Feeds to Use as Sources

If you encounter an issue during TID configuration or operation, see Troubleshoot Threat Intelligence Director, on page 1844

Procedure

Step 1 Make sure your source meets the requirements in Source Requirements, on page 1809

Step 2 Choose Intelligence > Sources.

Step 3 Click Add (+).

Step 4 Choose TAXII as the Delivery method for the source.

Step 5 Enter information.

- If the host server requires an encrypted connection, configure the SSL Settings as described in Configure TLS/SSL Settings for a TID Source, on page 1816.
- You cannot change the Action selection for TAXII sources. Block is not an Action option for TAXII sources, as STIX data can contain complex indicators, which the system cannot block. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

However, after ingestion, you can block individual observables and simple indicators obtained from the source. For more information, see Edit TID Actions at the Source, Indicator, or Observable Level, on page 1839.

- It may take some time for the list of feeds to load.
- The Update Every interval specifies the frequency that TID retrieves updates from the TAXII source. Set an update frequency that makes sense for how often the data source is updated. For example, if the source is updated 3 times per day, set your update interval to 1440/3 or 480 minutes to regularly capture the latest data.

- After the number of days you specify for TTL, TID deletes:
  - all of the source's indicators that are not included in subsequent source updates.
  - all observables not referenced by a surviving indicator.

Step 6 If you want to immediately begin publishing to elements, confirm that the Publish Slider (○) is enabled.

When this option is enabled, the system automatically publishes the initial source data and any subsequent changes.

For details, see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.

Step 7 Click Save.
What to do next

- TAXII feeds can contain a lot of data, it may take some time for the system to ingest all of the data. To view ingestion status, refresh the Sources page.
- If you see an error for this source, hover over status for details.
- If you are doing initial TID configuration, return to How To Set Up Threat Intelligence Director, on page 1810.

Fetch Sources from a URL

Configure a URL source if you want TID to fetch files from a host.

If you encounter an issue during TID configuration or operation, see Troubleshoot Threat Intelligence Director, on page 1844

Procedure

Step 1 Make sure your source meets the requirements in Source Requirements, on page 1809
Step 2 Choose Intelligence > Sources.
Step 3 Click Add (✚).
Step 4 Choose URL as the Delivery method for the source.
Step 5 Complete the form.
  - If you are ingesting a flat file, choose a Type that describes the data contained within the source.
  - If the host server requires an encrypted connection, configure the SSL Settings as described in Configure TLS/SSL Settings for a TID Source, on page 1816.
  - For Name: To simplify sorting and handling of incidents based on TID indicators, use a consistent naming scheme across sources. For example, <source>-<type>.
    Including the source name simplifies returning to the source for further information or feedback.
    Be sure to enter the name consistently. For example, for a source with IPv4 addresses, you might always use IPV4 (not IPv4 or ipv4 or IP_v4 or IP_V4 or ip-v4 or IP-v4, IP-V4, etc.)
  - If you are ingesting a STIX file, Block is not an Action option, as STIX data can contain complex indicators, which the system cannot block. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.
    However, after ingestion, you can block individual observables and simple indicators obtained from the source. For more information, see Edit TID Actions at the Source, Indicator, or Observable Level, on page 1839.
  - Set an update frequency that makes sense for how often the data source is updated. For example, if the source is updated 3 times per day, set your update interval to 1440/3 or 480 minutes to regularly capture the latest data.
  - After the number of days you specify for the TTL interval, TID deletes:
    - all of the source's indicators that are not included in subsequent source updates.
    - all observables not referenced by a surviving indicator.
Step 6  If you want to immediately begin publishing to elements, confirm that the **Publish Slider** is enabled. When this option is enabled, the system automatically publishes the initial source data and any subsequent changes.

For details, see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.

Step 7  Click **Save**.

---

**What to do next**

- To view ingestion status, refresh the Sources page. If you see an error, hover over status for details.
- If you are doing initial TID configuration, return to How To Set Up Threat Intelligence Director, on page 1810.

### Upload a Local File to Use as a Source

Use this procedure for a one-time manual upload of a local file.

When ingesting a STIX file, TID creates a simple or complex indicator from the contents of the STIX file.

When ingesting a flat file, TID creates a simple indicator for each observable value in the file.

If you encounter an issue during TID configuration or operation, see Troubleshoot Threat Intelligence Director, on page 1844

#### Procedure

**Step 1**  Make sure your file meets the requirements in Source Requirements, on page 1809

**Step 2**  Choose **Intelligence > Sources**.

**Step 3**  Click **Add (➕)**.

**Step 4**  Choose **Upload** as the **Delivery** method for the source.

**Step 5**  Complete the form.

- If you are uploading a flat file, choose a **Type** that describes the data contained within the source.

  - For Name: To simplify sorting and handling of incidents based on TID indicators, use a consistent naming scheme across sources. For example, `<source>-<type>`. Including the source name simplifies returning to the source for further information or feedback.

  - Be sure to enter the name consistently. For example, for a source with IPv4 addresses, you might always use IPV4 (not IPv4 or ipv4 or IP_V4 or IP_v4 or IP-V4 or IP-v4, IP-V4, etc.)

- If you are uploading a STIX file, **Block** is not an **Action** option, because STIX data can contain complex indicators. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

  - However, you can block a simple indicator at the indicator or observable level. For more information, see **Edit TID Actions at the Source, Indicator, or Observable Level**, on page 1839.

- After the number of days you specify for the **TTL** interval, TID deletes:
• all of the source's indicators that are not included in a subsequent upload.
• all observables not referenced by a surviving indicator.

**Step 6**
If you want to immediately begin publishing to elements, confirm that the **Publish Slider** is enabled. If you do not publish the source at ingestion, you cannot publish all source indicators at once later; instead, you must publish each observable individually. See Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.

**Step 7**
Click **Save**.

---

**What to do next**
• To view ingestion status, refresh the Sources page. If you see an error, hover over status for details.
• If you are doing initial TID configuration, return to How To Set Up Threat Intelligence Director, on page 1810.

**Handling of Duplicate Indicators**
If a single indicator is included in multiple sources:

• Indicators from flat file sources – Each instance of the indicator generates an incident, so one encounter with a particular threat may generate multiple incidents.

• Indicators from STIX sources – If indicators from different STIX sources share the same ID, only one incident will be generated for that indicator, regardless of the number of sources that include it.

To avoid future duplicate incidents, pause publishing of all but one of the duplicated indicators. See Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.

**Configure TLS/SSL Settings for a TID Source**
Configure **SSL Settings** if the host server requires an encrypted connection.

**Before you begin**
• Begin configuring a **TAXII or URL source**, as described in Fetch TAXII Feeds to Use as Sources, on page 1813 or Fetch Sources from a URL, on page 1814.

**Procedure**

**Step 1**
In the **Edit Source** dialog, expand the **SSL Settings** section.

**Step 2**
If your server certificate is self-signed:

a) Enable **Self-Signed Certificate**.

b) Choose a **SSL Hostname Verification** method.

• **Strict**—TID requires the source **URL** to match the hostname provided in the server certificate.
If the hostname includes a wildcard, TID cannot match more than one subdomain.

- **Browser Compatible**—TID requires the source URL to match the hostname provided in the server certificate.

If the hostname includes a wildcard, TID matches all subdomains.

- **Allow All**—TID does not require the source URL to match the hostname provided in the server certificate.

For example, if `subdomain1.subdomain2.cisco.com` is your source URL and `*.cisco.com` is the hostname provided in the server certificate:

- **Strict** hostname verification fails.
- **Browser Compatible** hostname verification succeeds.
- **Allow All** hostname verification ignores the hostname values completely.

c) **For Server Certificate:**

- If you have access to the PEM-encoded self-signed server certificate, open the certificate in a text editor and copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Enter this entire string into the field.

- If you do not have access to the self-signed server certificate, leave the field blank. After you save the source, TID retrieves the certificate from the server.

**Step 3** If your server requires a user certificate:

a) **Enter a User Certificate:**

Open the PEM-encoded certificate in a text editor and copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Enter this entire string into the field.

b) **Enter a User Private Key:**

Open the private key file in a text editor and copy the entire block of text, including the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines. Enter this entire string into the field.

---

**What to do next**

- Take note of the certificate's expiration date. You may want to set a calendar reminder to enter a new server certificate after the current certificate expires.

- Continue configuring the source:
  - Fetch TAXII Feeds to Use as Sources, on page 1813
  - Fetch Sources from a URL, on page 1814

**User Roles with TID Access**

You can use Firepower Management Center user accounts to access the TID menus and pages:
Accounts with the **Admin** or **Threat Intelligence Director User** user role.

Accounts with a custom user role containing the **Intelligence** permission.

In addition, you can use Firepower Management Center user accounts with the **Admin**, **Access Admin**, or **Network Admin** user role to enable or disable TID in your access control policies.

For more information about user accounts, see **User Accounts for FMC**, on page 47.

### About Backing Up and Restoring TID Data

You can use the Firepower Management Center to back up and restore all of the data needed for TID: Element data, security intelligence events, connection events, TID configurations, and TID data. For more information, see **Backup and Restore**, on page 233.

**Note**

If you host TID on the active Firepower Management Center in a high availability configuration, the system does not synchronize TID configurations and TID data to the standby Firepower Management Center. We recommend performing regular backups of TID data on your active Firepower Management Center so that you can restore the data after failover.

<table>

### Analyze TID Incident and Observation Data

To analyze incident and observation data generated by TID elements, use the Incidents table and Incident Details page.

### Observation and Incident Generation

TID generates an incident when the first observable for an indicator is seen in traffic. Simple indicators are fully realized after a single observation. Complex indicators are partially realized until one or more additional observations fulfill their pattern. Complex indicators need not necessarily be fulfilled during a single transaction; each observable can be fulfilled separately over time, by different transactions.

**Note**

When evaluating an indicator's pattern, TID ignores unsupported and invalid objects and observables on the Do Not Block list.
After an incident is fully realized, subsequent observations trigger new incidents.

**Figure 74: Example: Indicator Patterns**

If TID ingested the observables from the example above and the observables were seen in order, incident generation would proceed as follows:

1. When the system identifies Observable A in traffic, TID:
   - Generates a fully-realized incident for Indicator 1.
   - Generates partially-realized incidents for Indicator 2 and Indicator 3.

2. When the system identifies Observable B in traffic, TID:
   - Updates the incident to fully-realized for Indicator 2, since the pattern was fulfilled.
   - Updates the incident to partially-realized for Indicator 3.

3. When the system identifies Observable C in traffic, TID:
   - Updates the incident to fully-realized for Indicator 3, since the pattern was fulfilled.

4. When the system identifies Observable A for a second time, TID:
   - Generates a new fully-realized incident for Indicator 1.
   - Generates new partially-realized incidents for Indicator 2 and Indicator 3.

If a particular indicator exists in multiple sources, you may see duplicate incidents. For more information, see Troubleshoot Threat Intelligence Director, on page 1844.
Note that incidents are generated only by actual traffic. If there is an observable for URL B, and a user visits URL A which displays a link to URL B, no incident occurs unless the user clicks the URL B link.

**View and Manage Incidents**

The Incidents page displays summary information for up to 1.1 million of the most recent TID incidents; see Incident Summary Information, on page 1821.

**Before you begin**

- Configure the feature as described in How To Set Up Threat Intelligence Director, on page 1810.
- Understand observation and incident generation, as described in Observation and Incident Generation, on page 1818.

**Procedure**

**Step 1** Select **Intelligence > Incidents**.

**Step 2** View your incidents:

- Click **Filter** to add one or more filters. The default filter is 6 hours. For more information, see Filter TID Data in Table Views, on page 1837.
- To view the date and time an incident was last updated by TID, hover the cursor over the value in the **Last Updated** column.
- To view more information about the indicator associated with the incident, click the text in the **Indicator Name** column; see View and Manage Indicators, on page 1833.

**Step 3** View additional details by clicking a value in the **Incident ID** column.

For an explanation of the details you see, see Incident Details, on page 1821.

- To view indicator details, click an indicator value (for example, an IP address or SHA-256 value) under the **Indicator** heading in the lower section of the window.
- To view observation details, click the arrow to the left of an observation immediately under the **Observations** heading.
- To view this incident on the Security Intelligence Events page, click the **Events** link in the observation details section.

**Step 4** (Optional) Enter descriptive information on the incident details page:

Tip: To maximize consistency and usefulness of the options below, plan ahead and document your naming conventions, category choices, and confidence level criteria.

- Enter any value you like in the following fields: **Name**, **Description**, and **Category**.
- Click a rating level for **Confidence**.
• Indicate the status of your investigation into the incident by choosing a value from the drop-down list in the Status field.

## Incident Summary Information

The Incidents page displays summary information for all TID incidents.

### Table 116: Incident Summary Information

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last Updated</td>
<td>The number of days since either the system or a user last updated the incident. To view the date and time of the update, hover the cursor over the value in this column.</td>
</tr>
<tr>
<td>Incident ID</td>
<td>The unique identifier for the incident. This ID has the following format: &lt;type&gt;-&lt;date&gt;-&lt;number&gt;</td>
</tr>
<tr>
<td></td>
<td>• &lt;type&gt;—The type of indicator or observable involved in the incident. For simple indicators, this value indicates the observable type: IP (IPv4 or IPv6), URL (URL), DOM (domain), or SHA (SHA-256). For complex indicators, this value is COM.</td>
</tr>
<tr>
<td></td>
<td>• &lt;date&gt;—The date (yyyymmdd) on which the incident was created.</td>
</tr>
<tr>
<td></td>
<td>• &lt;number&gt;—The daily incident number, that is, a number specifying where the incident occurs in the daily sequence of incidents. Note that this sequence starts at 0. For example, DOM-20170828-10 is the 11th incident created on that day.</td>
</tr>
<tr>
<td>Next to the identifier, the system displays an icon that indicates whether the incident is Partially Realized or Fully Realized. For more information, see Observation and Incident Generation, on page 1818.</td>
<td></td>
</tr>
<tr>
<td>Indicator Name</td>
<td>The name of the indicator involved in the incident. To view additional information about the indicator, click the value in this column; see View and Manage Indicators, on page 1833.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of indicator involved in the incident.</td>
</tr>
<tr>
<td></td>
<td>• Indicators that contain a single observable display the data type (URL, SHA-256, etc.)</td>
</tr>
<tr>
<td></td>
<td>• Indicators that contain two or more observables display as Complex.</td>
</tr>
<tr>
<td>Action Taken</td>
<td>The action taken by the system in relation to the incident. For more information, see Incident Details, on page 1821.</td>
</tr>
<tr>
<td>Status</td>
<td>The status of your investigation into the incident. For more information, see Incident Details, on page 1821.</td>
</tr>
<tr>
<td>Delete (🗑️)</td>
<td>Clicking this icon permanently deletes the incident.</td>
</tr>
</tbody>
</table>

### Incident Details

The Incident Details window displays information about a single TID incident. This window is divided into two sections:
Incident Details: Basic Information

The upper section of the Incident Details window provides the information described below.

Table 117: Basic Incident Information Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Partially-Realized IncidentID or Fully-Realized IncidentID | An icon indicating the incident's status (partially-realized or fully-realized), as well as the unique identifier for the incident.  
  **Note** When determining an incident's status, TID ignores unsupported and invalid observables and observables on the Do Not Block list. |
| Opened                       | The date and time the incident was last updated.                                                                                                                                                           |
| Name                         | A custom, optional incident name that you enter manually.  
  **Tip:** If there is information from the source in the Description field (in the bottom part of the window), use information from that field to name the incident.                                      |
| Description                  | A custom, optional incident description that you enter manually.  
  **Tip:** If there is information from the source in the Description field (in the bottom part of the window), use information from that field to describe the incident.                               |
| Observations                 | The number of observations within the incident.                                                                                                                                                            |
| Confidence                   | An optional rating that you can manually select to indicate the relative importance of the incident.                                                                                                       |
| Action Taken                 | The action taken by the system: Monitored, Blocked, or Partially Blocked.  
  **Partially Blocked** indicates that the incident contained both Monitored and Blocked observations.  
  **Note** The Action Taken indicates the action taken by the system, not necessarily the action selected in TID. For more information, see TID-Firepower Management Center Action Prioritization, on page 1826. |
| Category                     | A custom, optional tag or keyword that you manually add to the incident.                                                                                                                                    |
| Status                       | A value indicating the current stage of your analysis of the incident. All incidents are New until you change the Status for the first time.  
  This field is optional. Depending on the needs of your organization, consider using the status values as follows:  
  * New—The incident requires investigation, but you have not started investigating.  
  * Open—You are currently investigating the incident.  
  * Closed—You investigated the incident and took action.  
  * Rejected—You investigated the incident and determined there was no action to take. |
Incident Details: Indicator and Observations

The lower section of the Incident Details window provides an in-depth view of the indicator and observation information. This information is organized as Indicator fields, the indicator pattern, and Observations fields.

Indicator Section

When you first view indicator details, this section displays only the indicator name.

Click the indicator name to view the indicator on the Indicators page.

Click the down arrow next to the indicator name to view more indicator details without leaving the incident.

Detail fields include:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>The indicator description provided by the source.</td>
</tr>
<tr>
<td>Source</td>
<td>The source that contained the indicator. Click this link to access full source details.</td>
</tr>
<tr>
<td>Expires</td>
<td>The date and time the incident will expire, based on the source's TTL value.</td>
</tr>
<tr>
<td>Action</td>
<td>The action associated with the indicator. For more information, see Edit TID Actions at the Source, Indicator, or Observable Level, on page 1839.</td>
</tr>
<tr>
<td>Publish</td>
<td>The publish setting for the indicator. For more information, see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.</td>
</tr>
<tr>
<td>Download STIX</td>
<td>If the source type is STIX, click this button to download the STIX file.</td>
</tr>
</tbody>
</table>

Indicator Pattern

The indicator pattern is a graphical representation of the observables and operators that comprise the indicator. Operators link the observables within the indicator. AND relationships are indicated with the AND operator. OR relationships are indicated with the OR operator or by a close grouping of several observables.

If an observable in the pattern has already been seen, the observable box is white. If an observable has not already been seen, the observable box is grey.

In the indicator pattern:

- Click the Whitelist button to add the observable to the Do Not Block list. This icon is present in both white and grey observable boxes. For more information, see About Adding TID Observables to the Do Not Block List, on page 1843.

- If you hover the cursor over a white observable box, the system highlights the related observation in the Observations section.
• If you click a white observable box, the system highlights the related observation in the **Observations** section, scrolls that observation into view (if multiple observations are present), and expands that observation's detailed display.

• If you hover the cursor over or click a grey observable box in the indicator pattern, there is no change in the **Observations** section. Because the observable is unseen, there are no observation details to display yet.

**Observations Section**

By default, the **Observations** section displays summary information, which includes:

• The type of observable that triggered the observation (for example, Domain)

• The data that comprises the observable

• Whether the observation is the first observation or a subsequent observation (for example, 1st or 3rd)

---

**Note**

If a single observable has been seen three or more times, TID displays the first and last observation details. The details for intermediary observations are not available.

• The date and time of the observation

• The action configured for the observable

If you hover the cursor over an observation in the **Observations** section, the system highlights the related observable in the indicator pattern.

If you click an observation in the **Observations** section, the system highlights the related observable(s) in the indicator pattern and scrolls the first related observable into view (if multiple observables are present). Clicking an observation also expands the details of the observation in the **Observations** section.

Observation details include the following fields:

**Table 119: Observation Detail Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOURCE</td>
<td>The source IP address and port for the traffic that triggered the observation.</td>
</tr>
<tr>
<td>DESTINATION</td>
<td>The destination IP address and port for the traffic that triggered the observation.</td>
</tr>
<tr>
<td>ADDITIONAL INFORMATION</td>
<td>DNS and authentication information related to the traffic that triggered the observation.</td>
</tr>
<tr>
<td>Events</td>
<td>This clickable link displays if the observation generated connection, security intelligence, file, or malware events. Click the link to view the events in the Firepower Management Center event table; see <strong>About Connection Events</strong>, on page 2691.</td>
</tr>
</tbody>
</table>
View Events for a TID Observation

For more information about the Firepower Management Center events that TID observations generate, see **TID Observations in Firepower Management Center Events**, on page 1825.

The system action logged for TID-related events can vary, depending on the interaction of TID and other Firepower Management Center features. For more information about action prioritization, see **TID-Firepower Management Center Action Prioritization**, on page 1826.

**Before you begin**

- Configure the feature as described in **How To Set Up Threat Intelligence Director**, on page 1810.
- Confirm that you enabled event logging required for TID in your access control policy, as described in **Configure Policies to Support TID**, on page 1811.

**Procedure**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Choose <strong>Intelligence &gt; Incidents</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click the <strong>Incident ID</strong> value for the incident.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Click the observation in the <strong>Indicator</strong> section to display the observation box.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Expand the observation box by clicking the arrow in the upper-left corner of the box.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Click the <strong>Events</strong> link in the observation information. For more information on the Security Intelligence display, see <strong>About Connection Events</strong>, on page 2691.</td>
</tr>
</tbody>
</table>

**TID Observations in Firepower Management Center Events**

If you fully configure your access control policy, TID observations generate the following Firepower Management Center events:

**Table 120: Firepower Management Center Events Generated by Observations**

<table>
<thead>
<tr>
<th>Observation Content</th>
<th>Connection Events Table</th>
<th>Security Intelligence Events Table</th>
<th>File Events Table</th>
<th>Malware Events Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHA-256</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes, if disposition is Malware or Custom Detection.</td>
</tr>
<tr>
<td>Domain Name, URL, or IPv4/IPv6</td>
<td>Yes</td>
<td>TID-related connection events are identified with a TID-related <strong>Security Intelligence Category</strong> value.</td>
<td>Yes</td>
<td>TID-related security intelligence events are identified with a TID-related <strong>Security Intelligence Category</strong> value.</td>
</tr>
</tbody>
</table>
Factors That Affect the Action Taken

Many factors determine when the system takes action and what action the system takes when it detects traffic that matches a TID observable.

- Features like Security Intelligence take action before TID does. For details, see TID-Firepower Management Center Action Prioritization, on page 1826.
- Generally, the action configured for an observable (which may differ from the action configured for its parent indicator or source) is the action that will be taken.
- Because STIX sources can contain complex indicators, the Action setting for the source can be set only to Monitor. However, individual simple indicators or observables contained in a STIX feed or file can be set to Block.
- Action settings for indicators and observables can be inherited or individually configured to override inheritance. See Inheritance in TID Configurations, on page 1838 and Edit TID Actions at the Source, Indicator, or Observable Level, on page 1839.
- Traffic that might otherwise be actionable might be on a Do Not Block list. For details, see Add TID Observables to a Do Not Block List, on page 1843.
- The configured action is taken for both partially- and fully-realized incidents.
- An incident based on a complex indicator can be partially blocked. This can occur if the indicator includes both monitored and blocked observations.
- Pausing publishing affects actions the system takes. See About Pausing Publishing, on page 1840 and Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.
- Pausing the TID feature prevents all actions. After you resume the feature, actionable data may be different from before. For details, see Pause TID and Purge TID Data from Elements, on page 1841.

TID-Firepower Management Center Action Prioritization

If TID observable actions conflict with Firepower Management Center policy actions, the system prioritizes actions as follows:

- Security Intelligence Do Not Block
- TID Block
- Security Intelligence Block
- TID Monitor
- Security Intelligence Monitor

Specifically:
## Table 121: TID URL Observable Action vs. Security Intelligence Action

• TID Block, if SHA-256 is not in a custom detection list.
  Modified file disposition is Custom.

• Custom Detection Block, if SHA-256 is in a custom detection list.

TID Block

Modified file disposition is Custom.

---

**View and Change Threat Intelligence Director Configurations**

Use the following information to review and fine-tune your configuration as needed.

**View TID Status of Elements (Managed Devices)**

All devices that are registered to the Firepower Management Center as managed devices appear automatically on the Elements page. All properly-configured elements (as specified in Configure Policies to Support TID, on page 1811) will receive all currently-published observables, including those ingested before the element was added.

**Procedure**

1. **Step 1** Choose Intelligence > Elements.
2. **Step 2** To see whether the element is connected and TID is enabled, hover over the icon beside the element name.

**Note** After deploying, it may take up to 5 minutes for information on this page to update, including the applied access control policy and whether TID is enabled.

**View and Manage Sources**

The Sources page displays summary information about all configured sources; see Source Summary Information, on page 1831.
Procedure

**Step 1** Choose **Intelligence > Sources**.

**Step 2** View your sources:

- To filter the sources displayed on the page, click **Filter**. For more information, see Filter TID Data in Table Views, on page 1837.
- To view detailed ingestion status, hover the cursor over the text in the **Status** column. For more information, see Source Status Details, on page 1832.

**Step 3** Manage your sources:

- To edit the **Action** setting, see Edit TID Actions at the Source, Indicator, or Observable Level, on page 1839. If an action is fixed, it is the only supported action for the source **Type**.
- To edit the **Publish** setting, click **Slider**. For more information, see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.
- To pause or resume TID updating the source, click **Pause Updates** or **Resume Updates**. If you pause updates, updating is paused but existing indicators and observables remain in TID.
- To delete the source, click **Delete**. Delete is greyed out if the source is still processing. Deleting a source deletes all indicators associated with that source. Associated observables may also be deleted; they are retained if they are associated with indicators remaining in the system.

**Source Summary Information**

The Sources page displays summary information for all configured sources. The table below provides brief descriptions of the fields in the summary display. For detailed information on these fields, see descriptions in the relevant configuration topic for the source: See Options for Ingesting Data Sources, on page 1812.

**Table 126: Sources Summary Information**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The source name.</td>
</tr>
<tr>
<td>Type</td>
<td>The data format of the source (STIX or Flat File).</td>
</tr>
<tr>
<td>Delivery</td>
<td>The method TID uses to retrieve the source.</td>
</tr>
<tr>
<td>Action</td>
<td>The action (Block or Monitor) that the system is configured to perform on traffic matching the data contained within this source. For more information about TID actions, including availability, inheritance, and overriding inheritance, see Factors That Affect the Action Taken, on page 1826.</td>
</tr>
</tbody>
</table>
Source Status Details

When you hover over a source's Status value in the Sources summary page, TID provides the additional details described below.

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status Message</td>
<td>Briefly describes the current status of the source.</td>
</tr>
<tr>
<td>Last Updated</td>
<td>Specifies the date and time TID last updated the source.</td>
</tr>
<tr>
<td>Next Update</td>
<td>For TAXII and URL sources, this value specifies when TID will update the source next.</td>
</tr>
</tbody>
</table>
Data | Description
--- | ---
**Indicators** | Specifies indicator counts:
- **Consumed** — The number of indicators TID processed during the most recent source update. This number represents all indicators contained in the update, regardless of whether they were ingested or discarded.
- **Discarded** — The number of malformed indicators that the system did not add to TID during the most recent update.

Note **For TAXII sources**, TID provides separate **Last Update** and **Total** indicator counts, because TAXII updates add incremental data, rather than replacing existing data. For indicators from other source types, TID provides only the **Last Update** count, because updates from those sources replace the existing data set entirely.

If all of an indicator’s observables are **Invalid**, TID discards the indicator.

**Observables** | Specifies observable counts:
--- | ---
- **Consumed** — The number of observables TID processed during the most recent source update. This number represents all observables contained in the update, regardless of whether they were ingested or discarded.
- **Unsupported** — The number of unsupported observables that the system did not add to TID during the most recent update.

For more information about supported observable types, see information about content types in **Source Requirements**, on page 1809.

- **Invalid** — The number of invalid observables that the system did not add to TID during the most recent update.

An observable is invalid if it is improperly constructed. For example, `10.10.10.10.123` is not a valid IPv4 address.

Note **For TAXII sources**, TID provides separate **Last Update** and **Total** observable counts, because TAXII updates add incremental data, rather than replacing existing data. For observables from other source types, TID provides only the **Last Update** count, because updates from those sources replace the existing data set entirely.

---

**View and Manage Indicators**

Indicators are generated automatically from ingested sources. For more information about information on this page, see **Indicator Summary Information**, on page 1834.

**Procedure**

1. **Step 1** Choose **Intelligence > Sources**.
2. **Step 2** Click **Indicators**.
3. **Step 3** View your current indicators:
Indicator Summary Information

The Indicators page displays summary information for all indicators associated with configured sources.

**Table 127: Indicators Summary Information**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Type** | - Indicators that have a single observable list the data type of that observable (URL, SHA-256, etc.)
|          | - Indicators that have two or more observables are listed as Complex. Hover over the type to see the specific observable. |
| **Name** | The indicator name. |
| **Source** | The source that contained the indicator (the parent source). |
| **Incidents** | Information about any incidents associated with the indicator:
|             | - an icon specifying whether the incident is Partially or Fully realized |
|             | - the number of incidents associated with the indicator |
The action associated with the indicator. For more information, see Edit TID Actions at the Source, Indicator, or Observable Level, on page 1839.

Indicators can inherit Action settings from a parent source, and observables can inherit Action settings from a parent indicator. For more information, see Inheritance in TID Configurations, on page 1838.

The publish setting for the indicator. For more information, see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.

Indicators can inherit Publish settings from a parent source, and observables can inherit Publish settings from a parent indicator. For more information, see Inheritance in TID Configurations, on page 1838.

The date and time TID last updated the indicator.

The current status of the indicator:

- **Pending**—TID is ingesting the indicator's observables.
- **Completed**—TID successfully ingested all of the indicator's observables.
- **Completed With Errors**—TID finished ingesting the indicator, but some observables are unsupported or invalid.

**Indicator Details**

The Indicator Details page displays indicator and observable data for an incident.

<tbody>
<tr>
<td>Indicator Pattern</td>
<td>The observables and operators that form the indicator’s pattern. Operators link the observables within the indicator. AND relationships are indicated with the <strong>AND</strong> operator. OR relationships are indicated with the <strong>OR</strong> operator or by a close grouping of several observables. Optionally, click the <strong>Whitelist</strong> button to add an observable to the Do Not Block list. For more information, see About Adding TID Observables to the Do Not Block List, on page 1843.</td>
</tr>
</tbody>
</table>

### View and Manage Observables

The Observables page displays all successfully ingested observables; see Observable Summary Information, on page 1837.

#### Before you begin

- Configure one or more sources as described in Fetch TAXII Feeds to Use as Sources, on page 1813, Fetch Sources from a URL, on page 1814, or Upload a Local File to Use as a Source, on page 1815.

#### Procedure

**Step 1** Choose **Intelligence > Sources**.

**Step 2** Click **Observables**.

**Step 3** View your current observables:

- To filter the observables displayed on the page, click **Filter** (🔍). For more information, see Filter TID Data in Table Views, on page 1837.
- If the information in the **Value** column is cut off, hover over the value.
- To view indicators that contain the observable, click the number in the **Indicators** column. The Incidents page opens with the observable value as the filter. For more information, see View and Manage Indicators, on page 1833.

**Step 4** Manage your current observables:

- To edit the **Action**, see Edit TID Actions at the Source, Indicator, or Observable Level, on page 1839.
- To edit an observable's **Publish** setting, see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.
- To change an observable’s expiration date, modify the **TTL** for the parent source. For more information, see View and Manage Sources, on page 1830.
- To add an observable to the Do Not Block list, click the **Whitelist** button. For more information, see About Adding TID Observables to the Do Not Block List, on page 1843.
Observable Summary Information

The Observables page displays summary information for all ingested observables.

Table 129: Observables Summary Information

Filter TID Data in Table Views

Procedure

Step 1 Choose one of the following TID table views:

- Intelligence > Incidents
- Intelligence > Sources
- Intelligence > Sources > Indicators
- Intelligence > Sources > Observables

Step 2 Click Filter (검색 기호) and choose a filter attribute.

Step 3 Choose or enter a value for that filter attribute.
Filters are case-sensitive.

**Step 4**  
(Optional) To filter by multiple attributes, click **Filter** and repeat Step 2 and Step 3.

**Step 5**  
To cancel the changes you have made since you last applied the filter, click **Cancel**.

**Step 6**  
Click **Apply** to refresh the table with the filter applied.

**Step 7**  
To remove a filter attribute individually, click **Remove** next to the filter attribute and click **Apply** to refresh the table.

---

### Inheritance in TID Configurations

When TID ingests intelligence data from a source, it creates indicators and observables as child objects of that source. On creation, these child objects inherit **Action** and **Publish** settings from the parent configuration.

An indicator inherits these settings from the parent source. An indicator can only have one parent source.

An observable inherits these settings from the parent indicator(s). An observable can have multiple parent indicators.

For more information, see:

- [Inheritance of TID Settings from Multiple Parents, on page 1838](#)
- [About Overriding Inherited TID Settings, on page 1839](#)

#### Inheritance of TID Settings from Multiple Parents

If an observable has multiple parent indicators, the system compares the inherited settings from all the parents and assigns the most secure option to the observable. Thus:

- **Action**: Block is more secure than Monitor
- **Publish**: On is more secure than Off

For example, SourceA might contribute IndicatorA and related ObservableA:

<table>
<thead>
<tr>
<th>Setting</th>
<th>SourceA</th>
<th>IndicatorA</th>
<th>ObservableA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Block</td>
<td>Block</td>
<td>Block</td>
</tr>
<tr>
<td>Publish</td>
<td>Off</td>
<td>Off</td>
<td>Off</td>
</tr>
</tbody>
</table>

If SourceB later contributes IndicatorB, which also includes ObservableA, the system modifies ObservableA as follows:

<table>
<thead>
<tr>
<th>Setting</th>
<th>SourceB</th>
<th>IndicatorB</th>
<th>ObservableA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Monitor</td>
<td>Monitor</td>
<td>Block (inherited from IndicatorA)</td>
</tr>
<tr>
<td>Publish</td>
<td>On</td>
<td>On</td>
<td>On (inherited from IndicatorB)</td>
</tr>
</tbody>
</table>
In this example, ObservableA has two parents: one parent for its **Action** setting and one parent for its **Publish** setting. If you manually edit the settings for the observable and then revert the settings, the system sets the **Action** setting to the IndicatorA value and the **Publish** setting to the IndicatorB value.

### About Overriding Inherited TID Settings

To override an inherited setting, change the setting at the child level; see **Edit TID Actions at the Source, Indicator, or Observable Level**, on page 1839 and **Pause or Publish TID Data at the Source, Indicator, or Observable Level**, on page 1841. After you override an inherited setting, the child object retains that setting despite changes to the parent object(s).

For example, you might start with the following original settings, with no overrides set:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Source A</th>
<th>Indicator A</th>
<th>Observable A1</th>
<th>Observable A2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Publish</td>
<td>Off</td>
<td>Off</td>
<td>Off</td>
<td>Off</td>
</tr>
</tbody>
</table>

If you override the setting for IndicatorA, the settings would be the following:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Source A</th>
<th>Indicator A</th>
<th>Observable A1</th>
<th>Observable A2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Publish</td>
<td>Off</td>
<td>On</td>
<td>On</td>
<td>On</td>
</tr>
</tbody>
</table>

In this case, any changes to the **Publish** setting for SourceA no longer cascade automatically to IndicatorA. However, inheritance from IndicatorA to ObservableA1 and ObservableA2 continues, because the observable settings are not currently set to override values.

If you later override the setting for ObservableA1:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Source A</th>
<th>Indicator A</th>
<th>Observable A1</th>
<th>Observable A2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Publish</td>
<td>Off</td>
<td>On</td>
<td>Off</td>
<td>On</td>
</tr>
</tbody>
</table>

Any changes to the **Publish** setting for IndicatorA no longer cascade automatically to ObservableA1. However, those changes continue to cascade to ObservableA2, because it is not set to an override value.

At the observable level, you can revert from an override setting to the inherited setting, and the system resumes cascading setting changes automatically from the parent indicator to that observable.

### Edit TID Actions at the Source, Indicator, or Observable Level

**Note:**

- Editing the action for a parent sets the action for all children. If you edit the action at the source level, you set the action for all its indicators. If you edit the action at the indicator level, you set the action for all of its observables.

- Editing the action for a child interrupts inheritance. If you edit the action at the indicator level, and subsequently edit it at the source level, the indicator's action is retained until you edit the action for the individual indicator. If you edit the action at the observable level, and subsequently edit it at the indicator level, the observable's action is retained until you edit the action for the individual observable. At the observable level, you can revert automatically to the parent indicator's action. For more information about inheritance, see **Inheritance in TID Configurations**, on page 1838.
You may also want to review other Factors That Affect the Action Taken, on page 1826.

Procedure

Step 1  Choose any of the following:

- **Intelligence > Sources**
  
  **Note**  TID does not support blocking TAXII sources at the source level. If the TAXII source contains a simple indicator, you can block at the indicator or observable level.

- **Intelligence > Sources > Indicators**
  
  **Note**  TID does not support blocking complex indicators. Instead, block individual observables within the complex indicator.

- **Intelligence > Sources > Observables**

Step 2  Use the Action dropdown to choose Monitor (_monitor_icon) or Block (_block_icon).

Step 3  (Observables only) If you want to resume inheriting the action setting from the parent indicator, click Revert next to the Action setting for the observable.

About Pausing Publishing

- If you pause publishing at the feature level, the system purges all TID observables stored on your elements. This means that TID cannot detect, monitor or block threats. Other security features on your system are not affected.

- If you pause publishing at the source, indicator, or observable level, the system removes the paused TID observables from your elements, preventing them from matching traffic.

- Pausing publication for a parent pauses all children. If you pause publishing at the source level, you pause publishing for all its indicators. If you pause publishing at the indicator level, you pause publishing for all of its observables.

- Pausing publication for a child interrupts inheritance. If you pause publishing at the indicator level, and subsequently publish at the source level, publishing for the indicator remains paused until you change the individual setting for the indicator. If you pause publishing at the observable level, and subsequently publish at the indicator level, publishing for the observable remains paused until you change the individual setting for the observable. At the observable level, you can revert automatically to the parent indicator's publishing status. For more information about inheritance, see Inheritance in TID Configurations, on page 1838.

- Publishing for Uploaded sources can only be paused at the indicator level.

- For a comparison of pausing publishing for an observable vs adding the observable to the Do Not Block list, see About Adding TID Observables to the Do Not Block List, on page 1843.

- If you have specified a publish/pause setting for an individual observable or indicator, source updates do not change that setting if the update contains the same observable or indicator.
• Publishing can be disabled on the object management pages. See Modify the Observable Publication Frequency, on page 1842.

• The option on the Sources page to pause updates is not related to publishing data to elements; it applies to updating sources on the Firepower Management Center from feeds.

Pause TID and Purge TID Data from Elements

Caution
This setting pauses publishing to all elements, purges all TID observables stored on your elements, and stops inspecting traffic using the TID feature.

To disable observables at a more granular level, see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.

Data on the management center (existing incidents and configured sources, indicators, and observables, and ingestion of sources) is not affected by this setting.

Procedure

Step 1 Choose Intelligence > Settings.
Step 2 Click Pause.

What to do next
When you are ready to resume synchronizing TID data on your elements and generating observations, manually Resume publishing from this page. Existing observables on the management center are published to all elements.

Pause or Publish TID Data at the Source, Indicator, or Observable Level

If publishing is enabled at the Source level, the system automatically publishes the initial source data and any subsequent changes including:

• changes from periodic source refreshes
• changes resulting from system action (for example, TTL expiration)
• any user-initiated changes (for example, a change in the Action setting for an indicator or observable)

Note
To purge all TID observables at once from your devices (elements), see Pause TID and Purge TID Data from Elements, on page 1841.
**Modify the Observable Publication Frequency**

By default, the system publishes observables to TID elements every 5 minutes. Use this procedure to set this interval to a different value.

**Before you begin**

- Enable publication of TID data at the observable level; see Pause or Publish TID Data at the Source, Indicator, or Observable Level, on page 1841.

**Procedure**

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose **Security Intelligence > Network Lists and Feeds**.

**Step 3** Click edit next to the **Cisco-TID-Feed**.

**Step 4** Choose a value from the **Update Frequency** drop-down list:

- Choose **Disable** to stop publication of observable data to elements.
- Choose any other value to set the interval for observable publication.
Step 5  
Click Save.

---

**About Adding TID Observables to the Do Not Block List**

If you want to exempt an observable in a simple indicator from the specified **Action** (let the traffic pass without monitoring or blocking), you can add the observable to a Do Not Block list.

In a complex indicator, TID ignores observables on the Do Not Block list when evaluating traffic, but other observables in that indicator are still evaluated. For example, if an indicator includes Observable 1 and Observable 2 linked by the AND operator, and you add Observable 1 to a Do Not Block list, TID generates a fully realized incident when Observable 2 is seen.

By comparison, in the same complex indicator, if you disable publishing of Observable 1 instead of adding it to the Do Not Block list, TID generates a partially-realized incident when Observable 2 is seen.

**Note**  
If you add an observable to the Do Not Block list, this always takes precedence over the **Action** setting, whether the setting in the observable is an inherited or override value.

Source updates do not affect the Do Not Block list setting for individual observables if the update contains the same observable.

**Add TID Observables to a Do Not Block List**

For detailed information about using Do Not Block lists, see About Adding TID Observables to the Do Not Block List, on page 1843.

**Tip**  
An "Add to Do Not Block List" button ( ![ ] ) can appear in several places in the web interface. You can add an observable to a Do Not Block list in any of those locations by clicking this button.

**Procedure**

- **Step 1**  
  Click **Intelligence > Sources > Observables**.

- **Step 2**  
  Navigate to the observable that you want to allow.

- **Step 3**  
  Click ![ ] (Whitelist) for that observable.

**What to do next**  
(Optional) If you need to remove an observable from the Do Not Block list, click the button again.
View a STIX Source File

Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Select Intelligence &gt; Sources &gt; Indicators.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click the indicator name.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Click Download STIX.</td>

</tbody>
</table>

Troubleshoot Threat Intelligence Director

The sections below describe possible solutions and mitigations for common TID issues.

**Fetching or uploading flat file sources generates an error**

If the system fails to fetch or upload a flat file source, check that the data in the flat file matches the Type column on the Intelligence > Sources page.

**TAXII or URL source update generates an error**

If a TAXII or URL source update generates a source status error, check that your Server Certificate is not expired. If the certificate has expired, enter a new Server Certificate or delete the existing Server Certificate so TID can retrieve a new certificate. For more information, see Configure TLS/SSL Settings for a TID Source, on page 1816.

"Block" action is not available for an indicator or source, only "Monitor"

You can change the action for individual observables in the indicator or source.

**TID table views return "No results"**

Table views include the Sources, Indicators, Observables, and Incidents pages. If you do not see data in one of the TID table views:

- Check your table filter and consider expanding the time window for the Last Updated filter attribute; see Filter TID Data in Table Views, on page 1837.
- Verify that you correctly configured your sources; see Options for Ingesting Data Sources, on page 1812.
- Verify that you configured your access control policy and related policies to support TID; see Configure Policies to Support TID, on page 1811. For example, if your SHA-256 observables are not generating observations, verify that your deployed access control policy contains one or more access control rules that invoke a Malware Cloud Lookup or Block Malware file policy.
- Verify that you deployed the TID-supporting access control policy and related policies to your elements; see Deploy Configuration Changes, on page 495.
- Verify that you did not pause TID data publication at the feature level; see Pause TID and Purge TID Data from Elements, on page 1841.
System is experiencing slowness or decreased performance
For more information about performance impact, see Performance Impact of Threat Intelligence Director, on page 1807.

Firepower Management Center table views do not show TID data
If you are publishing observables to your elements but no TID data appears in the connection, security intelligence, file, or malware events tables, check the access control and file policies deployed to your elements. For more information, see Configure Policies to Support TID, on page 1811.

One or more elements are overwhelmed by TID data
If TID data is overwhelming one or more of your devices, consider pausing TID publishing and purging the data stored on your elements. For more information, see Pause TID and Purge TID Data from Elements, on page 1841.

System is performing a Malware Cloud Lookup instead of a TID block
This is by design. For more information, see TID-Firepower Management Center Action Prioritization, on page 1826.

System is performing a Security Intelligence or DNS Policy action instead of a TID action
This is by design. For more information, see TID-Firepower Management Center Action Prioritization, on page 1826.

TID is disabled
• Add memory to your appliance. Threat Intelligence Director can only be used on appliances with at least 15GB of memory.
• Enable REST API access for the Firepower Management Center. For more information, see Enabling REST API Access, on page 1326.

The system does not generate the TID incident or take the TID action that you expected
• Verify that all of your managed devices are properly enabled and configured for TID. See View TID Status of Elements (Managed Devices), on page 1830 and Configure Policies to Support TID, on page 1811.
• It takes at least 5-10 minutes for changes to be published to elements, and significantly longer if publishing a large data feed.
• Check the action setting for the observable. See View and Manage Observables, on page 1836.
• For a list of the other factors that influence the TID action that the system takes, see Factors That Affect the Action Taken, on page 1826.
• Elements (managed devices) may not have the threat data you think they have. See About Pausing Publishing, on page 1840.

One encounter with a particular threat generates multiple incidents
This can occur if a single indicator is included in multiple sources.
For details, see Handling of Duplicate Indicators, on page 1816.

An Overview of Intrusion Detection and Prevention

The following topics provide an overview of network analysis and intrusion policies:

- Network Analysis and Intrusion Policy Basics, on page 1853
- How Policies Examine Traffic For Intrusions, on page 1854
- System-Provided and Custom Network Analysis and Intrusion Policies, on page 1859
- License Requirements for Network Analysis and Intrusion Policies, on page 1865
- Requirements and Prerequisites for Network Analysis and Intrusion Policies, on page 1865
- The Navigation Panel: Network Analysis and Intrusion Policies, on page 1865
- Conflicts and Changes: Network Analysis and Intrusion Policies, on page 1867

Network Analysis and Intrusion Policy Basics

Network analysis and intrusion policies work together as part of the Firepower System’s intrusion detection and prevention feature.

- The term **intrusion detection** generally refers to the process of passively monitoring and analyzing network traffic for potential intrusions and storing attack data for security analysis. This is sometimes referred to as "IDS."

- The term **intrusion prevention** includes the concept of intrusion detection, but adds the ability to block or alter malicious traffic as it travels across your network. This is sometimes referred to as "IPS."

In an intrusion prevention deployment, when the system examines packets:

- A **network analysis policy** governs how traffic is **decoded** and **preprocessed** so it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.

- An **intrusion policy** uses **intrusion and preprocessor rules** (sometimes referred to collectively as **intrusion rules**) to examine the decoded packets for attacks based on patterns. Intrusion policies are paired with **variable sets**, which allow you to use named values to accurately reflect your network environment.

Both network analysis and intrusion policies are invoked by a parent access control policy, but at different times. As the system analyzes traffic, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (additional preprocessing and intrusion rules) phase. Together, network analysis and intrusion policies provide broad and deep packet inspection. They can help you detect,
alert on, and protect against network traffic that could threaten the availability, integrity, and confidentiality of hosts and their data.

The Firepower System is delivered with several similarly named network analysis and intrusion policies (for example, Balanced Security and Connectivity) that complement and work with each other. By using system-provided policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for preprocessors and other advanced settings.

You can also create custom network analysis and intrusion policies. You can tune settings in custom policies to inspect traffic in the way that matters most to you so that you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

You create, edit, save, and manage network analysis and intrusion policies using similar policy editors in the web interface. When you are editing either type of policy, a navigation panel appears on the left side of the web interface; the right side displays various configuration pages.

**How Policies Examine Traffic For Intrusions**

When the system analyzes traffic as part of your access control deployment, the network analysis (decoding and pre-processing) phase occurs before and separately from the intrusion prevention (intrusion rules and advanced settings) phase.

The following diagram shows, in a simplified fashion, the order of traffic analysis in an inline, intrusion prevention and AMP for Networks deployment. It illustrates how the access control policy invokes other policies to examine traffic, and in which order those policies are invoked. The network analysis and intrusion policy selection phases are highlighted.

In an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs), the system can block traffic without further inspection at almost any step in the illustrated process. Security Intelligence, the SSL policy, network analysis policies, file policies, and intrusion policies can all either drop or modify traffic. Only the network discovery policy, which passively inspects packets, cannot affect the flow of traffic.

Similarly, at each step of the process, a packet could cause the system to generate an event. Intrusion and preprocessor events (sometimes referred to collectively as *intrusion events*) are indications that a packet or its contents may represent a security risk.
The diagram does not reflect that access control rules handle encrypted traffic when your SSL inspection configuration allows it to pass, or if you do not configure SSL inspection. By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Note that for a single connection, although the system selects a network analysis policy before an access control rule as shown in the diagram, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does not affect how you configure preprocessing in custom network analysis policies.

Decoding, Normalizing, and Preprocessing: Network Analysis Policies

Without decoding and preprocessing, the system could not appropriately evaluate traffic for intrusions because protocol differences would make pattern matching impossible. Network analysis policies govern these traffic-handling tasks:

- **after** traffic is filtered by Security Intelligence
- **after** encrypted traffic is decrypted by an optional SSL policy
- **before** traffic can be inspected by file or intrusion policies

A network analysis policy governs packet processing in phases. First the system decodes packets through the first three TCP/IP layers, then continues with normalizing, preprocessing, and detecting protocol anomalies:

- The packet decoder converts packet headers and payloads into a format that can be easily used by the preprocessors and later, intrusion rules. Each layer of the TCP/IP stack is decoded in turn, beginning with the data link layer and continuing through the network and transport layers. The packet decoder also detects various anomalous behaviors in packet headers.

- In inline deployments, the inline normalization preprocessor reformats (normalizes) traffic to minimize the chances of attackers evading detection. It prepares packets for examination by other preprocessors and intrusion rules, and helps ensure that the packets the system processes are the same as the packets received by the hosts on your network.

Note: In a passive deployment, Cisco recommends that you enable adaptive profile updates at the access control policy level, instead of inline normalization at the network analysis level.

- Various network and transport layers preprocessors detect attacks that exploit IP fragmentation, perform checksum validation, and perform TCP and UDP session preprocessing.

  Note that some advanced transport and network preprocessor settings apply globally to all traffic handled by the target devices of an access control policy. You configure these in the access control policy rather than in a network analysis policy.

- Various application-layer protocol decoders normalize specific types of packet data into formats that the intrusion rules engine can analyze. Normalizing application-layer protocol encodings allows the system to effectively apply the same content-related intrusion rules to packets whose data is represented differently, and to obtain meaningful results.
The Modbus, DNP3, CIP, and s7complus SCADA preprocessors detect traffic anomalies and provide data to intrusion rules. Supervisory Control and Data Acquisition (SCADA) protocols monitor, control, and acquire data from industrial, infrastructure, and facility processes such as manufacturing, production, water treatment, electric power distribution, airport and shipping systems, and so on.

Several preprocessors allow you to detect specific threats, such as Back Orifice, portscans, SYN floods and other rate-based attacks.

Note that you configure the sensitive data preprocessor, which detects sensitive data such as credit card numbers and Social Security numbers in ASCII text, in intrusion policies.

In a newly created access control policy, one default network analysis policy governs preprocessing for all traffic for all intrusion policies invoked by the same parent access control policy. Initially, the system uses the Balanced Security and Connectivity network analysis policy as the default, but you can change it to another system-provided or custom network analysis policy. In a more complex deployment, advanced users can tailor traffic preprocessing options to specific security zones, networks, and VLANs by assigning different custom network analysis policies to preprocess matching traffic.

### Access Control Rules: Intrusion Policy Selection

After initial preprocessing, access control rules (when present) evaluate traffic. In most cases, the first access control rule that a packet matches is the rule that handles that traffic; you can monitor, trust, block, or allow matching traffic.

When you allow traffic with an access control rule, the system can inspect the traffic for discovery data, malware, prohibited files, and intrusions, in that order. Traffic not matching any access control rule is handled by the access control policy’s default action, which can also inspect for discovery data and intrusions.

---

**Note**

All packets, regardless of which network analysis policy preprocesses them, are matched to configured access control rules—and thus are potentially subject to inspection by intrusion policies—in top-down order.

The diagram in *How Policies Examine Traffic For Intrusions*, on page 1854 shows the flow of traffic through a device in an inline, intrusion prevention and AMP for Networks deployment, as follows:

- Access Control Rule A allows matching traffic to proceed. The traffic is then inspected for discovery data by the network discovery policy, for prohibited files and malware by File Policy A, and then for intrusions by Intrusion Policy A.

- Access Control Rule B also allows matching traffic. However, in this scenario, the traffic is not inspected for intrusions (or files or malware), so there are no intrusion or file policies associated with the rule. Note that by default, traffic that you allow to proceed is inspected by the network discovery policy; you do not need to configure this.

- In this scenario, the access control policy’s default action allows matching traffic. The traffic is then inspected by the network discovery policy, and then by an intrusion policy. You can (but do not have to) use a different intrusion policy when you associate intrusion policies with access control rules or the default action.

The example in the diagram does not include any blocking or trusting rules because the system does not inspect blocked or trusted traffic.
Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets

You can use intrusion prevention as the system’s last line of defense before traffic is allowed to proceed to its destination. Intrusion policies govern how the system inspects traffic for security violations and, in inline deployments, can block or alter malicious traffic. The main function of intrusion policies is to manage which intrusion and preprocessor rules are enabled and how they are configured.

Intrusion and Preprocessor Rules

An intrusion rule is a specified set of keywords and arguments that detects attempts to exploit vulnerabilities on your network; the system uses an intrusion rule to analyze network traffic to check if it matches the criteria in the rule. The system compares packets against the conditions specified in each rule and, if the packet data matches all the conditions specified in a rule, the rule triggers.

The system includes the following types of rules created by Cisco Talos Intelligence Group (Talos):

- **shared object intrusion rules**, which are compiled and cannot be modified (except for rule header information such as source and destination ports and IP addresses)
- **standard text intrusion rules**, which can be saved and modified as new custom instances of the rule.
- **preprocessor rules**, which are rules associated with preprocessors and packet decoder detection options in the network analysis policy. You cannot copy or edit preprocessor rules. Most preprocessor rules are disabled by default; you must enable them to use preprocessors to generate events and, in an inline deployment, drop offending packets.

When the system processes packets according to an intrusion policy, first a rule optimizer classifies all activated rules in subsets based on criteria such as: transport layer, application protocol, direction to or from the protected network, and so on. Then, the intrusion rules engine selects the appropriate rule subsets to apply to each packet. Finally, a multi-rule search engine performs three different types of searches to determine if the traffic matches the rule:

- The protocol field search looks for matches in particular fields in an application protocol.
- The generic content search looks for ASCII or binary byte matches in the packet payload.
- The packet anomaly search looks for packet headers and payloads that, rather than containing specific content, violate well-established protocols.

In a custom intrusion policy, you can tune detection by enabling and disabling rules, as well as by writing and adding your own standard text rules. You can also use Firepower recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

Variable Sets

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated **variable set**. Most variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

The system provides a single default variable set, which is comprised of predefined default variables. Most system-provided shared object rules and standard text rules use these predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable $HOME_NET to specify the protected network and the variable $EXTERNAL_NET to specify the unprotected (or outside) network. In addition,
specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the $HTTP_SERVERS and $HTTP_PORTS variables.

Tip

Even if you use system-provided intrusion policies, Cisco strongly recommends that you modify key default variables in the default set. When you use variables that accurately reflect your network environment, processing is optimized and the system can monitor relevant systems for suspicious activity. Advanced users can create and use custom variable sets for pairing with one or more custom intrusion policies.

Related Topics

Predefined Default Variables, on page 577

Intrusion Event Generation

When the system identifies a possible intrusion, it generates an intrusion or preprocessor event (sometimes collectively called intrusion events). Managed devices transmit their events to the Firepower Management Center, where you can view the aggregated data and gain a greater understanding of the attacks against your network assets. In an inline deployment, managed devices can also drop or replace packets that you know to be harmful.

Each intrusion event in the database includes an event header and contains information about the event name and classification; the source and destination IP addresses; ports; the process that generated the event; and the date and time of the event, as well as contextual information about the source of the attack and its target. For packet-based events, the system also logs a copy of the decoded packet header and payload for the packet or packets that triggered the event.

The packet decoder, the preprocessors, and the intrusion rules engine can all cause the system to generate an event. For example:

- If the packet decoder (configured in the network analysis policy) receives an IP packet that is less than 20 bytes, which is the size of an IP datagram without any options or payload, the decoder interprets this as anomalous traffic. If, later, the accompanying decoder rule in the intrusion policy that examines the packet is enabled, the system generates a preprocessor event.

- If the IP defragmentation preprocessor encounters a series of overlapping IP fragments, the preprocessor interprets this as a possible attack and, when the accompanying preprocessor rule is enabled, the system generates a preprocessor event.

- Within the intrusion rules engine, most standard text rules and shared object rules are written so that they generate intrusion events when triggered by packets.

As the database accumulates intrusion events, you can begin your analysis of potential attacks. The system provides you with the tools you need to review intrusion events and evaluate whether they are important in the context of your network environment and your security policies.
System-Provided and Custom Network Analysis and Intrusion Policies

Creating a new access control policy is one of the first steps in managing traffic flow using the Firepower System. By default, a newly created access control policy invokes system-provided network analysis and intrusion policies to examine traffic.

The following diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

Note how:

- A default network analysis policy governs the preprocessing of all traffic handled by the access control policy. Initially, the system-provided *Balanced Security and Connectivity network analysis policy* is the default.

- The default action of the access control policy allows all non-malicious traffic, as determined by the system-provided *Balanced Security and Connectivity intrusion policy*. Because the default action allows traffic to pass, the discovery feature can examine it for host, application, and user data before the intrusion policy can examine and potentially block malicious traffic.

- The policy uses default Security Intelligence options (global Block and Do Not Block lists only), does not decrypt encrypted traffic with an SSL policy, and does not perform special handling and inspection of network traffic using access control rules.

A simple step you can take to tune your intrusion prevention deployment is to use a different set of system-provided network analysis and intrusion policies as your defaults. Cisco delivers several pairs of these policies with the Firepower System.

Or, you can tailor your intrusion prevention deployment by creating and using custom policies. You may find that the preprocessor options, intrusion rule, and other advanced settings configured in those policies do not address the security needs of your network. By tuning your network analysis and intrusion policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

System-Provided Network Analysis and Intrusion Policies

Cisco delivers several pairs of network analysis and intrusion policies with the Firepower System. By using system-provided network analysis and intrusion policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos provides intrusion and preprocessor rule states as well as initial configurations for preprocessors and other advanced settings.

No system-provided policy covers every network profile, traffic mix, or defensive posture. Each covers common cases and network setups that provide a starting point for a well-tuned defensive policy. Although you can use system-provided policies as-is, Cisco strongly recommends that you use them as the base for custom policies that you tune to suit your network.
Even if you use system-provided network analysis and intrusion policies, you should configure the system’s intrusion variables to accurately reflect your network environment. At a minimum, modify key default variables in the default set.

As new vulnerabilities become known, Talos releases intrusion rule updates (also known as *Snort Rule Updates*). These rule updates can modify any system-provided network analysis or intrusion policy, and can provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default policy settings. Rule updates may also delete rules from system-provided policies and provide new rule categories, as well as modify the default variable set.

If a rule update affects your deployment, the web interface marks affected intrusion and network analysis policies as out of date, as well as their parent access control policies. You must re-deploy an updated policy for its changes to take effect.

For your convenience, you can configure rule updates to automatically re-deploy affected intrusion policies, either alone or in combination with affected access control policies. This allows you to easily and automatically keep your deployment up-to-date to protect against recently discovered exploits and intrusions.

To ensure up-to-date preprocessing settings, you must re-deploy access control policies, which also deploys any associated SSL, network analysis, and file policies that are different from those currently running, and can also can update default values for advanced preprocessing and performance options.

Cisco delivers the following network analysis and intrusion policies with the Firepower System:

**Balanced Security and Connectivity network analysis and intrusion policies**

These policies are built for both speed and detection. Used together, they serve as a good starting point for most organizations and deployment types. The system uses the Balanced Security and Connectivity policies and settings as defaults in most cases.

**Connectivity Over Security network analysis and intrusion policies**

These policies are built for organizations where connectivity (being able to get to all resources) takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled.

**Security Over Connectivity network analysis and intrusion policies**

These policies are built for organizations where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic.

**Maximum Detection network analysis and intrusion policies**

These policies are built for organizations where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policies, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known in-the-wild exploits.

**No Rules Active intrusion policy**

In the No Rules Active intrusion policy, all intrusion rules, and all advanced settings except intrusion rule thresholds, are disabled. This policy provides a starting point if you want to create your own intrusion policy instead of basing it on the enabled rules in one of the other system-provided policies.
Depending on the system-provided base policy that is selected, the settings of the policy vary. To view the policy settings, click the Edit icon next to the policy and then click the Manage Base Policy link.

**Benefits of Custom Network Analysis and Intrusion Policies**

You may find that the preprocessor options, intrusion rules, and other advanced settings configured in the system-provided network analysis and intrusion policies do not fully address the security needs of your organization.

Building custom policies can improve the performance of the system in your environment and can provide a focused view of the malicious traffic and policy violations occurring on your network. By creating and tuning custom policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

All custom policies have a base policy, also called a base layer, which defines the default settings for all configurations in the policy. A layer is a building block that you can use to efficiently manage multiple network analysis or intrusion policies.

In most cases, you base custom policies on system-provided policies, but you can use another custom policy. However, all custom policies have a system-provided policy as the eventual base in a policy chain. Because rule updates can modify system-provided policies, importing a rule update may affect you even if you are using a custom policy as your base. If a rule update affects your deployment, the web interface marks affected policies as out of date.

**Benefits of Custom Network Analysis Policies**

By default, one network analysis policy preprocesses all unencrypted traffic handled by the access control policy. That means that all packets are decoded and preprocessed according to the same settings, regardless of the intrusion policy (and therefore intrusion rule set) that later examines them.

Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default. A simple way to tune preprocessing is to create and use a custom network analysis policy as the default.

Tuning options available vary by preprocessor, but some of the ways you can tune preprocessors and decoders include:

- You can disable preprocessors that do not apply to the traffic you are monitoring. For example, the HTTP Inspect preprocessor normalizes HTTP traffic. If you are confident that your network does not include any web servers using Microsoft Internet Information Services (IIS), you can disable the preprocessor option that looks for IIS-specific traffic and thereby reduce system processing overhead.

If you disable a preprocessor in a custom network analysis policy, but the system needs to use that preprocessor to later evaluate packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although the preprocessor remains disabled in the network analysis policy web interface.

- Specify ports, where appropriate, to focus the activity of certain preprocessors. For example, you can identify additional ports to monitor for DNS server responses or encrypted SSL sessions, or ports on which you decode telnet, HTTP, and RPC traffic.
For advanced users with complex deployments, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs. (Note that ASA FirePOWER modules cannot restrict preprocessing by VLAN.)

Note
Tailoring preprocessing using custom network analysis policies—especially multiple network analysis policies—is an advanced task. Because preprocessing and intrusion inspection are so closely related, you must be careful to allow the network analysis and intrusion policies examining a single packet to complement each other.

Benefits of Custom Intrusion Policies

In a newly created access control policy initially configured to perform intrusion prevention, the default action allows all traffic, but first inspects it with the system-provided Balanced Security and Connectivity intrusion policy. Unless you add access control rules or change the default action, all traffic is inspected by that intrusion policy.

To customize your intrusion prevention deployment, you can create multiple intrusion policies, each tailored to inspect traffic differently. Then, configure an access control policy with rules that specify which policy inspects which traffic. Access control rules can be simple or complex, matching and inspecting traffic using multiple criteria including security zone, network or geographical location, VLAN, port, application, requested URL, or user.

The main function of intrusion policies is to manage which intrusion and preprocessor rules are enabled and how they are configured, as follows:

• Within each intrusion policy, you should verify that all rules applicable to your environment are enabled, and improve performance by disabling rules that are not applicable to your environment. In an inline deployment, you can specify which rules should drop or modify malicious packets.

• Firepower recommendations allow you to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

• You can modify existing rules and write new standard text rules as needed to catch new exploits or to enforce your security policies.

Other customizations you might make to an intrusion policy include:

• The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text. Note that other preprocessors that detect specific threats (back orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.

• Global thresholds cause the system to generate events based on how many times traffic matching an intrusion rule originates from or is targeted to a specific address or address range within a specified time period. This helps prevent the system from being overwhelmed with a large number of events.

• Suppressing intrusion event notifications and setting thresholds for individual rules or entire intrusion policies can also prevent the system from being overwhelmed with a large number of events.

• In addition to the various views of intrusion events within the web interface, you can enable logging to syslog facilities or send event data to an SNMP trap server. Per policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external...
responses to intrusion events. Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

**Limitations of Custom Policies**

Because preprocessing and intrusion inspection are so closely related, you **must** be careful that your configuration allows the network analysis and intrusion policies processing and examining a single packet to complement each other.

By default, the system uses one network analysis policy to preprocess all traffic handled by managed devices using a single access control policy. The following diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

```
<table>
<thead>
<tr>
<th>Security Intelligence (global list only)</th>
<th>Default Network Analysis Policy: Balanced</th>
</tr>
</thead>
<tbody>
<tr>
<td>traffic not blacklisted</td>
<td>preprocessed traffic</td>
</tr>
</tbody>
</table>
```

Notice how a default network analysis policy governs the preprocessing of all traffic handled by the access control policy. Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default.

A simple way to tune preprocessing is to create and use a custom network analysis policy as the default. However, if you disable a preprocessor in a custom network analysis policy but the system needs to evaluate preprocessed packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although it remains disabled in the network analysis policy web interface.

---

**Note**

In order to get the performance benefits of disabling a preprocessor, you **must** make sure that none of your intrusion policies have enabled rules that require that preprocessor.

---

**Tip**

You configure network analysis rules as an advanced setting in an access control policy. Unlike other types of rules in the Firepower System, network analysis rules invoke—rather than being contained by—network analysis policies.

The system matches packets to any configured network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rule is preprocessed by the default network analysis policy. While this allows you a great deal of flexibility in preprocessing traffic, keep in mind that all packets, **regardless** of which network analysis policy preprocessed them, are subsequently matched to access control rules—and thus to potential inspection by intrusion policies—in their own process. In other words, preprocessing a packet...
with a particular network analysis policy does **not** guarantee that the packet will be examined with any particular intrusion policy. You **must** carefully configure your access control policy so it invokes the correct network analysis and intrusion policies to evaluate a particular packet.

The following diagram shows in focused detail how the network analysis policy (preprocessing) selection phase occurs before and separately from the intrusion prevention (rules) phase. For simplicity, the diagram eliminates the discovery and file/malware inspection phases. It also highlights the default network analysis and default-action intrusion policies.

In this scenario, an access control policy is configured with two network analysis rules and a default network analysis policy:

- Network Analysis Rule A preprocesses matching traffic with Network Analysis Policy A. Later, you want this traffic to be inspected by Intrusion Policy A.
- Network Analysis Rule B preprocesses matching traffic with Network Analysis Policy B. Later, you want this traffic to be inspected by Intrusion Policy B.
- All remaining traffic is preprocessed with the default network analysis policy. Later, you want this traffic to be inspected by the intrusion policy associated with the access control policy’s default action.

After the system preprocesses traffic, it can examine the traffic for intrusions. The diagram shows an access control policy with two access control rules and a default action:

- Access Control Rule A allows matching traffic. The traffic is then inspected by Intrusion Policy A.
- Access Control Rule B allows matching traffic. The traffic is then inspected by Intrusion Policy B.
- The access control policy’s default action allows matching traffic. The traffic is then inspected by the default action’s intrusion policy.

Each packet’s handling is governed by a network analysis policy and intrusion policy pair, but the system does **not** coordinate the pair for you. Consider a scenario where you misconfigure your access control policy so that Network Analysis Rule A and Access Control Rule A do not process the same traffic. For example, you could intend the paired policies to govern the handling of traffic on a particular security zone, but you mistakenly use different zones in the two rules’ conditions. This could cause traffic to be incorrectly preprocessed. For this reason, tailoring preprocessing using network analysis rules and custom policies is an **advanced** task.
Note that for a single connection, although the system selects a network analysis policy before an access control rule, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does not affect how you configure preprocessing in custom network analysis policies.

### The Navigation Panel: Network Analysis and Intrusion Policies

Network analysis and intrusion policies use similar web interfaces to edit and save changes to their configurations.

A navigation panel appears on the left side of the web interface when you are editing either type of policy. The following graphic shows the navigation panel for the network analysis policy (left) and the intrusion policy (right).
A dividing line separates the navigation panel into links to policy settings you can configure with (below) or without (above) direct interaction with policy layers. To navigate to any settings page, click its name in the navigation panel. Dark shading of an item in the navigation panel highlights your current settings page. For example, in the illustration above the Policy Information page would be displayed to the right of the navigation panel.

**Policy Information**

The Policy Information page provides configuration options for commonly used settings. As shown in the illustration for the network analysis policy panel above, a *Policy Change icon* appears next to *Policy Information* in the navigation panel when the policy contains unsaved changes. The icon disappears when you save your changes.

**Rules (intrusion policy only)**

The Rules page in an intrusion policy allows you to configure rule states and other settings for shared object rules, standard text rules, and preprocessor rules.

**Firepower Recommendations (intrusion policy only)**

The Firepower Recommendations page in an intrusion policy allows you to associate the operating systems, servers, and client application protocols detected on your network with intrusion rules specifically written to protect those assets. This allows you to tailor your intrusion policy to the specific needs of your monitored network.

**Settings (network analysis policy) and Advanced Settings (intrusion policy)**

The Settings page in a network analysis policy allows you to enable or disable preprocessors and access preprocessor configuration pages. Expanding the *Settings* link displays sublinks to individual configuration pages for all enabled preprocessors in the policy.

The Advanced Settings page in an intrusion policy allows you to enable or disable advanced settings and access configuration pages for those advanced settings. Expanding the *Advanced Settings* link displays sublinks to individual configuration pages for all enabled advanced settings in the policy.
Policy Layers

The Policy Layers page displays a summary of the layers that comprise your network analysis or intrusion policy. Expanding the Policy Layers link displays sublinks to summary pages for the layers in your policy. Expanding each layer sublink displays further sublinks to the configuration pages for all rules, preprocessors, or advanced settings that are enabled in the layer.

Conflicts and Changes: Network Analysis and Intrusion Policies

When you edit a network analysis or intrusion policy, a Policy Change icon appears next to Policy Information in the navigation panel to indicate that the policy contains unsaved changes. You must save (or commit) your changes before the system recognizes them.

Note

After you save, you must deploy the network analysis or intrusion policy for your changes to take effect. If you deploy a policy without saving, the system uses the most recently saved configuration.

Resolving Editing Conflicts

The Network Analysis Policy page (Policies > Access Control, then click Network Analysis Policy or Policies > Access Control > Intrusion, then click Network Analysis Policy) and Intrusion Policy page (Policies > Access Control > Intrusion) display whether each policy has unsaved changes, as well as information about who is currently editing the policy. Cisco recommends that only one person edit a policy at a time. If you are performing simultaneous editing, the consequences are as follows:

• If you are editing a network analysis or intrusion policy at the same time another user is editing the same policy, and the other user saves their changes to the policy, you are warned when you commit the policy that you will overwrite the other user’s changes.

• If you are editing the same network analysis or intrusion policy via multiple web interface instances as the same user, and you save your changes for one instance, you cannot save your changes for the other instance.

Resolving Configuration Dependencies

To perform their particular analysis, many preprocessors and intrusion rules require that traffic first be decoded or preprocessed in a certain way, or have other dependencies. When you save a network analysis or intrusion policy, the system either automatically enables required settings, or warns you that disabled settings will have no effect on traffic, as follows:

• You cannot save an intrusion policy if you added an SNMP rule alert but did not configure SNMP alerting. You must either configure SNMP alerting or disable the rule alert, then save again.

• You cannot save an intrusion policy if it includes enabled sensitive data rules but you have not enabled the sensitive data preprocessor. You must either allow the system to enable the preprocessor and save the policy, or disable the rules and save again.

• If you disable a required preprocessor in a network analysis policy, you can still save the policy. However, the system automatically uses the disabled preprocessor with its current settings, even though the preprocessor remains disabled in the web interface.
• If you disable inline mode in a network analysis policy but enable the Inline Normalization preprocessor, you can still save the policy. However, the system warns you that normalization settings will be ignored. Disabling inline mode also causes the system to ignore other settings that allow preprocessors to modify or block traffic, including checksum verification and rate-based attack prevention.

**Committing, Discarding, and Caching Policy Changes**

While editing a network analysis or intrusion policy, if you exit the policy editor without saving your changes, the system caches those changes. Your changes are cached even when you log out of the system or experience a system crash. The system cache can store unsaved changes for one network analysis and one intrusion policy per user; you must commit or discard your changes before editing another policy of the same type. The system discards the cached changes when you edit another policy without saving your changes to the first policy, or when you import an intrusion rule update.

You can commit or discard policy changes on the Policy Information page of either the network analysis or intrusion policy editor.

In the Firepower Management Center configuration, you can control:

• whether you are prompted (or required) to comment on your network analysis or intrusion policy changes when you commit them
• whether changes and comments are recorded in the audit log

**Related Topics**

- Configuring Network Analysis Policy Preferences
- Configuring Intrusion Policy Preferences

**Exiting a Network Analysis or Intrusion Policy**

**Procedure**

If you want to exit the network analysis or intrusion policy advanced editor, you have the following choices:

• **Cache** — To exit the policy and cache changes, choose any menu or other path to another page. On exiting, click **Leave page** when prompted, or click **Stay on page** to remain in the advanced editor.
• **Discard** — To discard unsaved changes, click **Discard Changes** on the Policy Information page, then click **OK**.
• **Save** — To save changes to the policy, click **Commit Changes** on the Policy Information page. If prompted, enter a comment, and then click **OK**.
Layers in Intrusion and Network Analysis Policies

The following topics explain how to use layers in intrusion and network analysis policies:

- Layer Basics, on page 1869
- License Requirements for Network Analysis and Intrusion Policy Layers, on page 1869
- Requirements and Prerequisites for Network Analysis and Intrusion Policy Layers, on page 1870
- The Layer Stack, on page 1870
- Layer Management, on page 1874

Layer Basics

Larger organizations with many managed devices may have many intrusion policies and network analysis policies to support the unique needs of different departments, business units or, in some instances, different companies. Configurations in both policy types are contained in building blocks called layers, which you can use to efficiently manage multiple policies.

Layers in intrusion and network analysis policies work in essentially the same way. You can create and edit either policy type without consciously using layers. You can modify your policy configurations and, if you have not added user layers to your policy, the system automatically includes your changes in a single configurable layer that is initially named My Changes. You can also add up to 200 layers where you can configure any combination of settings. You can copy, merge, move, and delete user layers and, most important, share individual user layers with other policies of the same type.

The Layer Stack

Layer stacks are composed of the following:

User Layers
User-configurable layers. You can copy, merge, move, or delete any user-configurable layer and set any user-configurable layer to be shared by other policies of the same type. This layer includes the automatically-generated layer initially named My Changes.

Built-in Layers
The read-only base policy layer. The policy in this layer can be either a system-provided policy or a custom policy you created.

By default, a network analysis or intrusion policy includes a base policy layer and a My Changes layer. You can add user layers as necessary.

Each policy layer contains complete configurations for either all preprocessors in a network analysis policy or all intrusion rules and advanced settings in an intrusion policy. The lowest, base policy layer includes all the settings from the base policy you selected when you created the policy. A setting in a higher layer takes precedence over the same setting in a lower layer. Features not explicitly set in a layer inherit their settings from the next highest layer where they are explicitly set. The system flattens the layers, that is, it applies only the cumulative effect of all settings, when it handles network traffic.

Tip
You can create an intrusion or network analysis policy based solely on the default settings in the base policy. In the case of an intrusion policy, you can also use Firepower rule state recommendations if you want to tailor your intrusion policy to the specific needs of your monitored network.

The following figure shows an example layer stack that, in addition to the base policy layer and the initial My Changes layer, also includes two additional user-configurable layers, User Layer 1 and User Layer 2. Note
in the figure that each user-configurable layer that you add is initially positioned as the highest layer in the stack; thus, User Layer 2 in the figure was added last and is highest in the stack.

| User Layer 2 | User Layer 1 | User Layer (My Changes) | Base Policy Layer |

Regardless of whether you allow rule updates to modify your policy, changes in a rule update never override changes you make in a layer. This is because changes in a rule update are made in the base policy, which determines the default settings in your base policy layer; your changes are always made in a higher layer, so they override any changes that a rule update makes to your base policy.

**The Base Layer**

The base layer, also referred to as the base policy, of an intrusion or network analysis policy defines the default settings for all configurations in the policy, and is the lowest layer in the policy. When you create a new policy and change a setting without adding new layers, the change is stored in the My Changes layer, and overrides—but does not change—the setting in the base policy.

**System-Provided Base Policies**

The Firepower System provides several pairs of network analysis and intrusion policies. By using system-provided network analysis and intrusion policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for preprocessors and other advanced settings. You can use these system-provided policies as-is, or you can use them as the base for custom policies.

If you use a system-provided policy as your base, importing rule updates may modify settings in your base policy. However, you can configure a custom policy so that the system does not automatically make these changes to its system-provided base policy. This allows you to update system-provided base policies manually, on a schedule independent of rule updates. In either case, changes that a rule update makes to your base policy do not change or override settings in your My Changes or any other layer.

System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates.

**Custom Base Policies**

You can use a custom policy as your base. You can tune settings in custom policies to inspect traffic in ways that matter most to you so you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

If you change the custom policy that you use as the base for another policy, those changes are automatically used as the default settings of the policy that uses the base.

In addition, a rule update may affect your policy even if you use a custom base policy, because all policies have a system-provided policy as the eventual base in a policy chain. If the first custom policy in a chain (the one that uses the system-provided policy as its base) allows rule updates to modify its base policy, your policy may be affected.
Regardless of how changes are made to your base policy—whether by a rule update or when you modify a custom policy that you use as a base policy—they do not change or override settings in your My Changes or any other layer.

The Effect of Rule Updates on Base Policies

When you import rule updates, the system modifies system-provided intrusion, access control, and network analysis policies. Rule updates can include:

- modified network analysis preprocessor settings
- modified advanced settings in intrusion and access control policies
- new and updated intrusion rules
- modified states for existing rules
- new rule categories and default variables

Rule updates can also delete existing rules from system-provided policies.

Changes to default variables and rule categories are handled at the system level.

When you use a system-provided policy as your intrusion or network analysis base policy, you can allow rule updates to modify your base policy which, in this case, is a copy of the system-provided policy. If you allow rule updates to update your base policy, a new rule update makes the same changes in your base policy that it makes to the system-provided policy that you use as your base policy. If you have not modified the corresponding setting, a setting in your base policy determines the setting in your policy. However, rule updates do not override changes you make in your policy.

If you do not allow rule updates to modify your base policy, you can manually update your base policy after importing one or more rule updates.

Rule updates always delete intrusion rules that Talos deletes, regardless of the rule state in your intrusion policy or whether you allow rule updates to modify your base intrusion policy.

Until you re-deploy your changes to network traffic, rules in your currently deployed intrusion policies behave as follows:

- Disabled intrusion rules remain disabled.
- Rules set to Generate Events continue to generate events when triggered.
- Rules set to Drop and Generate Events continue to generate events and drop offending packets when triggered.

Rule updates do not modify a custom base policy unless both of the following conditions are met:

- You allow rule updates to modify the system-provided base policy of the parent policy, that is, the policy that originated the custom base policy.
- You have not made changes in the parent policy that override the corresponding settings in the parent’s base policy.

When both conditions are met, changes in the rule update are passed to the child policy, that is, the policy using the custom base policy, when you save the parent policy.
For example, if a rule update enables a previously disabled intrusion rule, and you have not modified the rule’s state in the parent intrusion policy, the modified rule state is passed to the base policy when you save the parent policy.

Likewise, if a rule update modifies a default preprocessor setting and you have not modified the setting in the parent network analysis policy, the modified setting is passed to the base policy when you save the parent policy.

**Changing the Base Policy**

You can choose a different system-provided or custom policy as your base policy. You can chain up to five custom policies, with four of the five using one of the other four previously created policies as its base policy; the fifth must use a system-provided policy as its base.

**Procedure**

**Step 1**
While editing your policy, click **Policy Information** in the navigation panel.

**Step 2**
You can configure the following choices:

- Choose a base policy — Choose from the **Base Policy** drop-down list.
- Allow rule updates to modify the base policy — Click **Manage Base Policy**, then check the **Update when a new Rule Update is installed** check box.

  **Tip**
  When you save your policy with the check box cleared and then import a rule update, an **Update Now** appears on the Base Policy summary page and the status message on the page updates to inform you that the policy is out of date. If you want to update your base policy with the changes in the most recently imported rule update, click **Update Now**.

**Step 3**
To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Related Topics**

- Conflicts and Changes: Network Analysis and Intrusion Policies, on page 1867

**The Firepower Recommendations Layer**

When you generate rule state recommendations in an intrusion policy, you can choose whether to automatically modify rule states based on the recommendations.

As seen in the following figure, using recommended rule states inserts a read-only, built-in Firepower Recommendations layer immediately above the base layer.
Layer Management

The Policy Layers page provides a single-page summary of the complete layer stack for your network analysis or intrusion policy. On this page you can add shared and unshared layers, copy, merge, move, and delete layers, access the summary page for each layer, and access configuration pages for enabled, disabled, and overridden configurations within each layer.

For each layer, you can view the following information:

- whether the layer is a built-in, shared user, or unshared user layer
- which layers contain the highest, that is the effective, preprocessor or advanced setting configurations, by feature name
- in an intrusion policy, the number of intrusion rules whose states are set in the layer, and the number of rules set to each rule state.

The Policy Layers page also provides a summary of the net effect of all enabled preprocessors (network analysis) or advanced settings (intrusion) and, for intrusion policies, intrusion rules.

The feature name in the summary for each layer indicates which configurations are enabled, disabled, overridden, or inherited in the layer, as follows:

<table>
<thead>
<tr>
<th>When the feature is...</th>
<th>The feature name is...</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled in the layer</td>
<td>written in plain text</td>
</tr>
<tr>
<td>disabled in the layer</td>
<td>struck out</td>
</tr>
</tbody>
</table>
When the feature is... | The feature name is...
---|---
overridden by the configuration in a higher layer | written in italic text
inherited from a lower layer | not present

You can add up to 200 layers to a network analysis or intrusion policy. When you add a layer, it appears as the highest layer in your policy. The initial state is Inherit for all features and, in an intrusion policy, no event filtering, dynamic state, or alerting rule actions are set.

You give a user-configurable layer a unique name when you add the layer to your policy. Later, you can change the name and, optionally, add or modify a description that is visible when you edit the layer.

You can copy a layer, move a layer up or down within the User Layers page area, or delete a user layer, including the initial My Changes layer. Note the following considerations:

- When you copy a layer, the copy appears as the highest layer.
- Copying a shared layer creates a layer that is initially unshared and which you can then share if you choose.
- You cannot delete a shared layer; a layer with sharing enabled that you have not shared with another policy is not a shared layer.

You can merge a user-configurable layer with another user-configurable layer immediately beneath it. A merged layer retains all settings that were unique to either layer, and accepts the settings from the higher layer if both layers included settings for the same preprocessor, intrusion rule, or advanced setting. The merged layer retains the name of the lower layer. In the policy where you create a sharable layer that you can add to other policies, you can merge an unshared layer immediately above the sharable layer with the sharable layer, but you cannot merge the sharable layer with an unshared layer beneath it. In a policy where you add a shared layer that you created in another policy, you can merge the shared layer into an unshared layer immediately beneath it and the resulting layer is no longer shared; you cannot merge an unshared layer into a shared layer beneath it.

### Shared Layers

A *shared layer* is a layer you add to your policy after creating the layer in another policy where you allow it to be shared. A *sharable layer* is a layer you allow to be shared.

The following figure shows an example master policy where you create the company-wide layer and site-specific layers for sites A and B, and allow these to be shared. You then add these as shared layers to the policies for sites A and B.

![Diagram of shared layers]

The company-wide layer in the master policy includes settings applicable to sites A and B. The site-specific layers include settings specific to each site. For example, in the case of a network analysis policy Site A might not have web servers on the monitored network and would not require the protection or processing overhead of the HTTP Inspect preprocessor, but both sites would likely require TCP stream preprocessing. You could...
enable TCP stream processing in the company-wide layer that you share with both sites, disable the HTTP
Inspect preprocessor in the site-specific layer that you share with Site A, and enable the HTTP Inspect
preprocessor in the site-specific layer that you share with Site B. By editing configurations in a higher layer
in the site-specific policies, you could also further tune the policy for each site if necessary with any
configuration adjustments.

It is unlikely that the flattened net settings in the example master policy would be useful for monitoring traffic,
but the time saved in configuring and updating the site-specific policies makes this a useful application of
policy layers.

Many other layer configurations are possible. For example, you could define policy layers by company, by
department, by network, or even by user. In the case of an intrusion policy, you could also include advanced
settings in one layer and rule settings in another.

You can allow a user-configurable layer to be shared with other policies of the same type (intrusion or network
analysis). When you modify a configuration within a sharable layer and then commit your changes, the system
updates all policies that share the layer and provides you with a list of all affected policies. You can only
change feature configurations in the policy where you created the layer.

You cannot disable sharing for a layer that you have added to another policy; you must first delete the layer
from the other policy or delete the other policy.

You cannot add a shared layer to a policy when your base policy is a custom policy where the layer you want
to share was created. To do so would give the policy a circular dependency.

In a multidomain deployment, you can add shared layers from ancestor policies to policies in descendant
domains.

Managing Layers

Procedure

Step 1 While editing your policy, click **Policy Layers** in the navigation panel.

Step 2 You can take any of the following management actions on the Policy Layers page:

- Add a shared layer from another policy — Click add shared layer Add (➕) next to User Layers, choose
the layer from the **Add Shared Layer** drop-down list, then click OK.

- Add an unshared layer — Click add layer Add (➕) next to User Layers, enter a Name, and click OK.

- Add or change the layer description — Click Edit (✍️) next to the layer, then add or change the
Description.

- Allow a layer to be shared with another policy — Click Edit (✍️) next to the layer, then clear the Sharing
check box.

- Change the layer name — Click Edit (✍️) next to the layer, then change the Name.

- Copy a layer — Click Copy (複製) for the layer.

- Delete a layer — Click Delete (🗑️) for the layer, then click OK.

- Merge two layers — Click Merge (🗑️) for the upper of the two layers, then click OK.

- Move a layer — Click any open area in the layer summary and drag until the Position Arrow points to
a line above or below a layer where you want to move the layer.
Step 3  
To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.
If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next
  • Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Conflicts and Changes: Network Analysis and Intrusion Policies, on page 1867

Navigating Layers

Procedure

Step 1  
While editing your policy, click Policy Layers in the navigation panel.

Step 2  
You can take any of the following actions to navigate through your layers:
  • Access a preprocessor or advanced settings page — If you want to access a layer-level preprocessor or advanced setting configuration page, click the feature name in the row for the layer. Configuration pages are read-only in the base policy and in shared layers.
  • Access a rule page — If you want to access a layer-level rule configuration page filtered by rule state type, click Drop and Generate Events, Generate Events, or Disabled in the summary for the layer. No rules are displayed if the layer contains no rules set to the selected rule state.
  • Display the Policy Information page — If you want to display the Policy Information page, click Policy Summary in the navigation panel.
  • Display a layer summary page — If you want to display the summary page for a layer, click the layer name in the row for the layer or, alternately, click Edit (↵) next to a user layer. You can also click View (👁) to access the read-only summary page for a shared layer.

Step 3  
To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.
If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next
  • Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Intrusion Rules in Layers

You can view individual layer settings on the Rules page for the layer, or view the net effect of all settings on the policy view of the Rules page. When you modify rule settings on the policy view of the Rules page, you are modifying the highest user-configurable layer in the policy. You can switch to another layer using the layer drop-down list on any Rules page.

The following table describes the effects of configuring the same type of setting in multiple layers.

<table>
<thead>
<tr>
<th>You can set...</th>
<th>Of this setting type...</th>
<th>To...</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>rule state</td>
<td>override a rule state set for the rule in a lower layer, and ignore all thresholds, suppressions, rate-based rule states, and alerts for that rule configured in lower layers. If you want a rule to inherit its state from the base policy or a lower layer, set the rule state to Inherit. Note that when you are working on the intrusion policy Rules page, you cannot set a rule state to Inherit because the intrusion policy Rules page is a composite view of the net effect of all rule settings.</td>
</tr>
<tr>
<td>one</td>
<td>threshold SNMP alert</td>
<td>override a setting of the same type for the rule in a lower layer. Note that setting a threshold overwrites any existing threshold for the rule in the layer.</td>
</tr>
<tr>
<td>one or more</td>
<td>suppression rate-based rule state</td>
<td>cumulatively combine settings of the same type for each selected rule down to the first layer where a rule state is set for the rule. Settings below the layer where a rule state is set are ignored.</td>
</tr>
<tr>
<td>one or more</td>
<td>comment</td>
<td>add a comment to a rule. Comments are rule-specific, not policy- or layer-specific. You can add one or more comments to a rule in any layer.</td>
</tr>
</tbody>
</table>

For example, if you set a rule state to Drop and Generate Events in one layer and to Disabled in a higher layer, the intrusion policy Rules page shows that the rule is disabled.

In another example, if you set a source-based suppression for a rule to 192.168.1.1 in one layer, and you also set a destination-based suppression for the rule to 192.168.1.2 in another layer, the Rules page shows that the cumulative effect is to suppress events for the source address 192.168.1.1 and the destination address 192.168.1.2. Note that suppression and rate-based rule state settings cumulatively combine settings of the same type for each selected rule down to the first layer where a rule state is set for the rule. Settings below the layer where a rule state is set are ignored.
Color-coding on each Rules page for a specific layer indicates whether the effective state is in a higher, lower, or the current layer, as follows:

- red—the effective state is in a higher layer
- yellow—the effective state is in a lower layer
- unshaded—the effective state is in the current layer

Because the intrusion policy Rules page is a composite view of the net effect of all rule settings, rule states are not color-coded on this page.

**Configuring Intrusion Rules in Layers**

In an intrusion policy, you can set the rule state, event filtering, dynamic state, alerting, and rule comments for a rule in any user-configurable layer. After accessing the layer where you want to make your changes, you add settings on the Rules page for the layer the same as you would on the intrusion policy Rules page.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>While editing your intrusion policy, expand <strong>Policy Layers</strong> in the navigation panel.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Expand the policy layer you want to modify.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Click <strong>Rules</strong> immediately beneath the policy layer you want to modify.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Modify any of the settings described in Tuning Intrusion Policies Using Rules, on page 1895. <strong>Tip</strong> To delete an individual setting from an editable layer, double-click the rule message on the Rules page for the layer to display rule details. Click <strong>Delete</strong> next to the setting you want to delete, then click <strong>OK</strong> twice.</td>
</tr>
<tr>
<td>Step 5</td>
<td>To save changes you made in this policy since the last policy commit, click <strong>Policy Information</strong>, then click <strong>Commit Changes</strong>. If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.</td>
</tr>
</tbody>
</table>

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Related Topics**

Conflicts and Changes: Network Analysis and Intrusion Policies, on page 1867

**Removing Rule Settings from Multiple Layers**

You can simultaneously remove a specific type of event filter, dynamic state, or alerting from multiple layers in your intrusion policy. The system removes the selected setting and copies the remaining settings for the rule to the highest editable layer in the policy.
The system removes the setting type downward through each layer where it is set until it removes all the settings or encounters a layer where a rule state is set for the rule. In the latter case, it removes the setting from that layer and stops removing the setting type.

When the system encounters the setting type in a shared layer or in the base policy, and if the highest layer in the policy is editable, the system copies the remaining settings and rule state for the rule to that editable layer. Otherwise, if the highest layer in the policy is a shared layer, the system creates a new editable layer above the shared layer and copies the remaining settings and rule state for the rule to that editable layer.

Note: Removing rule settings derived from a shared layer or the base policy causes any changes to this rule from lower layers or the base policy to be ignored. To stop ignoring changes from lower layers or the base policy, set the rule state to Inherit on the summary page for the topmost layer.

Procedure

Step 1 While editing your intrusion policy, click Rules immediately beneath Policy Information in the navigation panel.

Tip You can also choose Policy from the layer drop-down list on the Rules page for any layer, or click Manage Rules on the Policy Information page.

Step 2 Choose the rule or rules from which you want to remove multiple settings:

• Choose specific — If you want to choose specific rules, check the check box next to each rule.
• Choose all — If you want to choose all the rules in the current list, check the check box at the top of the column.

Step 3 Choose one of the following options:

• Event Filtering > Remove Thresholds
• Event Filtering > Remove Suppressions
• Dynamic State > Remove Rate-Based Rule States
• Alerting > Remove SNMP Alerts

Note: Removing rule settings derived from a shared layer or the base policy causes any changes to this rule from lower layers or the base policy to be ignored. To stop ignoring changes from lower layers or the base policy, set the rule state to Inherit on the summary page for the topmost layer.

Step 4 Click OK.

Step 5 To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
Accepting Rule Changes from a Custom Base Policy

When a custom network analysis or intrusion policy where you have not added layers uses another custom policy as its base policy, you must set a rule to inherit its rule state if:

- you delete an event filter, dynamic state, or SNMP alert that is set for the rule in the base policy, and
- you want the rule to accept subsequent changes that you make to it in the other custom policy that you use as your base policy

Procedure

Step 1 While editing your intrusion policy, expand Policy Layers in the navigation panel.

Step 2 Expand My Changes.

Step 3 Click the Rules link immediately beneath My Changes.

Step 4 Choose the rule or rules whose settings you want to accept. You have the following choices:

- Choose specific rules — If you want to choose specific rules, check the check box next to each rule.
- Choose all rules — If you want to choose all the rules in the current list, check the check box at the top of the column.

Step 5 Choose Inherit from the Rule State drop-down list.

Step 6 To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Related Topics

Conflicts and Changes: Network Analysis and Intrusion Policies, on page 1867

Preprocessors and Advanced Settings in Layers

You use similar mechanisms to configure preprocessors in a network analysis policy and advanced settings in an intrusion policy. You can enable and disable preprocessors on the network analysis Settings page and intrusion policy advanced settings on the intrusion policy Advanced Settings page. These pages also provide summaries of the effective states for all relevant features. For example, if the network analysis SSL preprocessor
is disabled in one layer and enabled in a higher layer, the Settings page shows it as enabled. Changes made on these pages appear in the top layer of the policy. Note that the Back Orifice preprocessor has no user-configurable options.

You can also enable or disable preprocessors or advanced settings and access their configuration pages on the summary page for a user-configurable layer. On this page you can modify the layer name and description and configure whether to share the layer with other policies of the same type. You can switch to the summary page for another layer by selecting the layer name beneath Policy Layers in the navigation panel.

When you enable a preprocessor or advanced setting, a sublink to the configuration page for that feature appears beneath the layer name in the navigation panel, and an Edit (✓) appears next to the feature on the summary page for the layer; these disappear when you disable the feature in the layer or set it to Inherit.

Setting the state (enabled or disabled) for a preprocessor or advanced setting overrides the state and configuration settings for that feature in lower layers. If you want a preprocessor or advanced setting to inherit its state and configuration from the base policy or a lower layer, set it to Inherit. Note that the Inherit selection is not available when you are working in the Settings or Advanced Settings page. Note also that if you inherit a feature that is currently enabled, the feature sublink in the navigation panel and the edit icon on the configuration page no longer appear.

The system uses the configuration in the highest layer where the feature is enabled. Unless you explicitly modify the configuration, the system uses the default configuration. For example, if you enable and modify the network analysis DCE/RPC preprocessor in one layer, and you also enable but do not modify it in a higher layer, the system uses the default configuration in the higher layer.

Color-coding on each layer summary page indicates whether the effective configuration is in a higher, lower, or the current layer, as follows:

- red—the effective configuration is in a higher layer
- yellow—the effective configuration is in a lower layer
- unshaded—the effective configuration is in the current layer

Because the Settings and Advanced Settings pages are composite views of all relevant settings, these page do not use color coding to indicate the positions of effective configurations.

### Configuring Preprocessors and Advanced Settings in Layers

#### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>While editing your policy, expand <strong>Policy Layers</strong> in the navigation panel, then click the name of the layer you want to modify.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>You have the following choices:</td>
</tr>
<tr>
<td></td>
<td>• Change the layer <strong>Name</strong>.</td>
</tr>
<tr>
<td></td>
<td>• Add or change the <strong>Description</strong>.</td>
</tr>
<tr>
<td></td>
<td>• Check or clear the <strong>Sharing</strong> check box to specify whether a layer can be shared with another policy.</td>
</tr>
<tr>
<td></td>
<td>• To access the configuration page for an enabled preprocessor/advanced setting, click <strong>Edit (✓)</strong> or the feature sublink.</td>
</tr>
<tr>
<td></td>
<td>• To disable a preprocessor/advanced setting in the current layer, click <strong>Disabled</strong> next to the feature.</td>
</tr>
<tr>
<td></td>
<td>• To enable a preprocessor/advanced setting in the current layer, click <strong>Enabled</strong> next to the feature.</td>
</tr>
</tbody>
</table>
• To inherit the preprocessor/advanced setting state and configuration from the settings in the highest layer below the current layer, click **Inherit**.

**Step 3**

To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

• Deploy configuration changes; see **Deploy Configuration Changes**, on page 495.

CHAPTER 80

Getting Started with Intrusion Policies

The following topics explain how to get started with intrusion policies:

- Intrusion Policy Basics, on page 1885
- License Requirements for Intrusion Policies, on page 1886
- Requirements and Prerequisites for Intrusion Policies, on page 1887
- Managing Intrusion Policies, on page 1887
- Custom Intrusion Policy Creation, on page 1888
- Editing Snort 2 Intrusion Policies, on page 1889
- Access Control Rule Configuration to Perform Intrusion Prevention, on page 1890
- Drop Behavior in an Inline Deployment, on page 1891
- Drop Behavior in a Dual System Deployment, on page 1892
- Intrusion Policy Advanced Settings, on page 1893
- Optimizing Performance for Intrusion Detection and Prevention, on page 1894

Intrusion Policy Basics

Intrusion policies are defined sets of intrusion detection and prevention configurations that inspect traffic for security violations and, in inline deployments, can block or alter malicious traffic. Intrusion policies are invoked by your access control policy and are the system’s last line of defense before traffic is allowed to its destination.

At the heart of each intrusion policy are the intrusion rules. An enabled rule causes the system to generate intrusion events for (and optionally block) traffic matching the rule. Disabling a rule stops processing of the rule.

The Firepower System delivers several base intrusion policies, which enable you to take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and preprocessor rule states (enabled or disabled), as well as provides the initial configurations for other advanced settings.

Tip

System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules.
If you create a custom intrusion policy, you can:

- Tune detection by enabling and disabling rules, as well as by writing and adding your own rules.
- Use Firepower recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.
- Configure various advanced settings such as external alerting, sensitive data preprocessing, and global rule thresholding.
- Use layers as building blocks to efficiently manage multiple intrusion policies.

In an inline deployment, an intrusion policy can block and modify traffic:

- **Drop rules** can drop matching packets and generate intrusion events. To configure an intrusion or preprocessor drop rule, set its state to Drop and Generate Events.
- Intrusion rules can use the `replace` keyword to replace malicious content.

For intrusion rules to affect traffic, you must correctly configure drop rules and rules that replace content, as well as correctly deploy managed devices inline, that is, with inline interface sets. Finally, you must enable the intrusion policy’s *drop behavior*, or *Drop when Inline* setting.

When tailoring your intrusion policy, especially when enabling and adding rules, keep in mind that some intrusion rules require that traffic first be decoded or preprocessed in a certain way. Before an intrusion policy examines a packet, the packet is preprocessed according to configurations in a network analysis policy. If you disable a required preprocessor, the system automatically uses it with its current settings, although the preprocessor remains disabled in the network analysis policy web interface.

---

**Caution**

Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet must complement each other. Tailoring preprocessing, especially using multiple custom network analysis policies, is an advanced task.

After you configure a custom intrusion policy, you can use it as part of your access control configuration by associating the intrusion policy with one or more access control rules or an access control policy’s default action. This forces the system to use the intrusion policy to examine certain allowed traffic before the traffic passes to its final destination. A variable set that you pair with the intrusion policy allows you to accurately reflect your home and external networks and, as appropriate, the servers on your network.

Note that by default, the system disables intrusion inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion inspection configured.

Managing Intrusion Policies

On the Intrusion Policy page (Policies > Access Control > Intrusion) you can view your current custom intrusion policies, along with the following information:

• the time and date the policy was last modified (in local time) and the user who modified it
• whether the Drop when Inline setting is enabled, which allows you to drop and modify traffic in an inline deployment
• which access control policies and devices are using the intrusion policy to inspect traffic
• whether a policy has unsaved changes, as well as information about who (if anyone) is currently editing the policy
• in a multidomain deployment, the domain where the policy was created

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Procedure

Step 1
Choose Policies > Access Control > Intrusion.

Step 2
Manage your intrusion policy:

• Compare—Click Compare Policies; see Comparing Policies, on page 508.

• Create — Click Create Policy; see Creating a Custom Intrusion Policy, on page 1888.

• Delete — Click Delete ( ) next to the policy you want to delete. The system prompts you to confirm and informs you if another user has unsaved changes in the policy. Click OK to confirm.
If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- **Edit** — Click **Edit ()** next to the policy you want to edit; see Editing Snort 2 Intrusion Policies, on page 1889.

  If **View ()** appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- **Export** — If you want to export an intrusion policy to import on another Firepower Management Center, click **YouTube EDU ()**; see Exporting Configurations, on page 263.

- **Deploy**—Choose **Deploy > Deployment**; see Deploy Configuration Changes, on page 495.

---

### Custom Intrusion Policy Creation

When you create a new intrusion policy you must give it a unique name, specify a base policy, and specify drop behavior.

The base policy defines the intrusion policy’s default settings. Modifying a setting in the new policy overrides—but does not change—the settings in the base policy. You can use either a system-provided or custom policy as your base policy.

The intrusion policy’s drop behavior, or **Drop when Inline** setting, determines how the system handles drop rules (intrusion or preprocessor rules whose rule state is set to Drop and Generate Events) and other intrusion policy configurations that affect traffic. You should enable drop behavior in inline deployments when you want to drop or replace malicious packets. Note that in passive deployments, the system cannot affect traffic flow regardless of the drop behavior.

### Creating a Custom Intrusion Policy

**Procedure**

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Create Policy**. If you have unsaved changes in another policy, click **Cancel** when prompted to return to the Intrusion Policy page.

**Step 3** Enter a unique **Name** and, optionally, a **Description**.

**Step 4** Choose the initial **Base Policy**.

You can use either a system-provided or another custom policy as your base policy.

**Step 5** Set the system’s drop behavior in an inline deployment as described in Setting Drop Behavior in an Inline Deployment, on page 1892.

**Step 6** Create the policy:
• Click **Create Policy** to create the new policy and return to the Intrusion Policy page. The new policy has the same settings as its base policy.

• Click **Create and Edit Policy** to create the policy and open it for editing in the advanced intrusion policy editor; see Intrusion Policy Changes, on page 1890.

---

**Related Topics**

- Intrusion Rules in Layers, on page 1878
- Conflicts and Changes: Network Analysis and Intrusion Policies, on page 1867

---

**Editing Snort 2 Intrusion Policies**

**Procedure**

**Step 1** Choose **Policies > Access Control > Intrusion.**

**Step 2** Click **Edit** next to the intrusion policy you want to configure.

If **View** appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Edit your policy:

- Change the base policy—Choose a base policy from the **Base Policy** drop-down list; see Changing the Base Policy, on page 1873.
- Configure advanced settings—Click **Advanced Settings** in the navigation panel; see Intrusion Policy Advanced Settings, on page 1893.
- Configure Firepower recommended intrusion rules—Click **Firepower Recommendations** in the navigation panel; see Generating and Applying Firepower Recommendations, on page 1926.
- Drop behavior in an inline deployment—Check or clear **Drop when Inline**; see Setting Drop Behavior in an Inline Deployment, on page 1892.
- Filter rules by recommended rule state—After you generate recommendations, click **View** next to each recommendation type. Click **View Recommended Changes** to view all recommendations.
- Filter rules by current rule state—Click **View** next to each rule state type (generate events, drop and generate events); see Intrusion Rule Filters in an Intrusion Policy, on page 1902.
- Manage policy layers—Click **Policy Layers** in the navigation panel; see Layer Management, on page 1874.
- Manage intrusion rules—Click **Manage Rules**; see Viewing Intrusion Rules in an Intrusion Policy, on page 1897.
- View settings in base policy—Click **Manage Base Policy**; see The Base Layer, on page 1871.

**Step 4** To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
Intrusion Policy Changes

When you create a new intrusion policy, it has the same intrusion rule and advanced settings as its base policy. The system caches one intrusion policy per user. While editing an intrusion policy, if you choose any menu or other path to another page, your changes stay in the system cache even if you leave the page.

Access Control Rule Configuration to Perform Intrusion Prevention

An access control policy can have multiple access control rules associated with intrusion policies. You can configure intrusion inspection for any Allow or Interactive Block access control rule, which permits you to match different intrusion inspection profiles against different types of traffic on your network before it reaches its final destination.

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated variable set. Variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

Even if you use system-provided intrusion policies, Cisco strongly recommends you configure the system’s intrusion variables to accurately reflect your network environment. At a minimum, modify default variables in the default set.

Understanding System-Provided and Custom Intrusion Policies

Cisco delivers several intrusion policies with the Firepower System. By using system-provided intrusion policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for advanced settings. You can use system-provided policies as-is, or you can use them as the base for custom policies. Building custom policies can improve the performance of the system in your environment and provide a focused view of the malicious traffic and policy violations occurring on your network.

Connection and Intrusion Event Logging

When an intrusion policy invoked by an access control rule detects an intrusion and generates an intrusion event, it saves that event to the Firepower Management Center. The system also automatically logs the end of the connection where the intrusion occurred to the Firepower Management Center database, regardless of the logging configuration of the access control rule.
Access Control Rule Configuration and Intrusion Policies

The number of unique intrusion policies you can use in a single access control policy depends on the model of the target devices; more powerful devices can handle more. Every unique pair of intrusion policy and variable set counts as one policy. Although you can associate a different intrusion policy-variable set pair with each Allow and Interactive Block rule (as well as with the default action), you cannot deploy an access control policy if the target devices have insufficient resources to perform inspection as configured.

Configuring an Access Control Rule to Perform Intrusion Prevention

You must be an Admin, Access Admin, or Network Admin to perform this task.

Procedure

Step 1 In the access control policy editor, create a new rule or edit an existing rule; see Access Control Rule Components, on page 1558.
Step 2 Ensure the rule action is set to Allow, Interactive Block, or Interactive Block with reset.
Step 3 Click .
Step 4 Choose a system-provided or custom Intrusion Policy, or choose None to disable intrusion inspection for traffic that matches the access control rule.
Step 5 If you want to change the variable set associated with the intrusion policy, choose a value from the Variable Set drop-down list.
Step 6 Click Save to save the rule.
Step 7 Click Save to save the policy.

What to do next

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Related Topics

Variable Sets, on page 575
Snort® Restart Scenarios, on page 502

Drop Behavior in an Inline Deployment

If you want to assess how your configuration would function in an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs) without actually affecting traffic, you can disable drop behavior. In this case, the system generates intrusion events but does not drop packets that trigger drop rules. When you are satisfied with the results, you can enable drop behavior.
Notethatinpassivedeploymentsorinlinedeploymentsintapmode,thesystemcannotaffecttrafficregardlessofthedropbehavior.Inotherwords,inapassivedeployment,rulessettoDropandGeneratEventsbetheidenticallytorulessettoGenerateEvents—the systemgeneratesintrusioneventsbutcannotdroppackets.

To block the transfer of malware over FTP, you must not only correctly configure AMP for Networks, but also enable **Drop when Inline** in your access control policy’s default intrusion policy.

When you view intrusion events, workflows can include the **inline result**, which indicates whether traffic was actually dropped, or whether it only would have dropped.

### Setting Drop Behavior in an Inline Deployment

#### Procedure

**Step 1** Choose Policies > Access Control > Intrusion.

**Step 2** Click Snort 2 Version next to the policy you want to edit.

If View ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Set the policy’s drop behavior:

- Check the **Drop when Inline** check box to allow intrusion rules to affect traffic and generate events.
- Clear the **Drop when Inline** check box to prevent intrusion rules from affecting traffic while still generating events.

**Step 4** Click Commit Changes to save changes you made in this policy since the last policy commit.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

### Drop Behavior in a Dual System Deployment

When there are two systems connected back to back in a network, it is normal to see the first system drop events and still record a drop or "would have dropped" event on the second system. The first system decides to drop the packets by the time it scans the last packet of the file, while the second system also investigates and identifies the traffic as "to be dropped".

For example, a 5 packet HTTP GET request whose first packet triggers a rule is blocked by the first system and only the last packet is dropped. The second system receives only 4 packets and the connection gets dropped,
but when the second system finally flushes the partial GET request while it is pruning the session, it triggers the same rule with "would have dropped" as the inline result.

**Intrusion Policy Advanced Settings**

An intrusion policy’s advanced settings require specific expertise to configure. The base policy for your intrusion policy determines which advanced settings are enabled by default and the default configuration for each.

When you choose Advanced Settings in the navigation panel of an intrusion policy, the policy lists its advanced settings by type. On the Advanced Settings page, you can enable or disable advanced settings in your intrusion policy, as well as access advanced setting configuration pages. An advanced setting must be enabled for you to configure it.

When you disable an advanced setting, the sublink and Edit link no longer appear, but your configurations are retained. Note that some intrusion policy configurations (sensitive data rules, SNMP alerts for intrusion rules) require enabled and correctly configured advanced settings.

Modifying the configuration of an advanced setting requires an understanding of the configuration you are modifying and its potential impact on your network.

**Specific Threat Detection**

The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text.

Note that other preprocessors that detect specific threats (back orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.

**Intrusion Rule Thresholds**

Global rule thresholding can prevent your system from being overwhelmed with a large number of events by allowing you to use thresholds to limit the number of times the system logs and displays intrusion events.

**External Responses**

In addition to the various views of intrusion events in the web interface, you can enable logging to system log (syslog) facilities or send event data to an SNMP trap server. Per policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external responses to intrusion events.

Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

Optimizing Performance for Intrusion Detection and Prevention

If you want the Firepower System to perform intrusion detection and prevention but do not need to take advantage of discovery data, you can optimize performance by disabling new discovery as described below.

**Before you begin**

To perform this task, you must have one of the following user roles:

- Admin, Access Admin, or Network Admin for access control.
- Admin or Discovery Admin for network discovery.

**Procedure**

**Step 1** Modify or delete rules associated with the access control policy deployed at the target device. None of the access control rules associated with that device can have user, application, or URL conditions; see Create and Edit Access Control Rules, on page 1561.

**Step 2** Delete all rules from the network discovery policy for the target device; see Configuring Network Discovery Rules, on page 2384.

**Step 3** Deploy the changed configuration to the target device; see Deploy Configuration Changes, on page 495.
CHAPTER 81

Tuning Intrusion Policies Using Rules

The following topics explain how to use rules to tune intrusion policies:

• Intrusion Rule Tuning Basics, on page 1895
• Intrusion Rule Types, on page 1895
• License Requirements for Intrusion Rules, on page 1896
• Requirements and Prerequisites for Intrusion Rules, on page 1897
• Viewing Intrusion Rules in an Intrusion Policy, on page 1897
• Intrusion Rule Filters in an Intrusion Policy, on page 1902
• Intrusion Rule States, on page 1910
• Intrusion Event Notification Filters in an Intrusion Policy, on page 1912
• Dynamic Intrusion Rule States, on page 1918
• Adding Intrusion Rule Comments, on page 1921

Intrusion Rule Tuning Basics

You can use the Rules page in an intrusion policy to configure rule states and other settings for shared object rules, standard text rules, and preprocessors rules.

You enable a rule by setting its rule state to Generate Events or to Drop and Generate Events. Enabling a rule causes the system to generate events on traffic matching the rule. Disabling a rule stops processing of the rule.

You can also set your intrusion policy so that a rule set to Drop and Generate Events in an inline deployment generates events on, and drops, matching traffic. In a passive deployment, a rule set to Drop and Generate Events just generates events on matching traffic.

You can filter rules to display a subset of rules, enabling you to select the exact set of rules where you want to change rule states or rule settings.

When an intrusion rule or rule argument requires a disabled preprocessor, the system automatically uses it with its current configuration even though it remains disabled in the network analysis policy’s web interface.

Intrusion Rule Types

An intrusion rule is a specified set of keywords and arguments that the system uses to detect attempts to exploit vulnerabilities in your network. As the system analyzes network traffic, it compares packets against the conditions specified in each rule, and triggers the rule if the data packet meets all the conditions specified in the rule.
An intrusion policy contains:

- *intrusion rules*, which are subdivided into *shared object rules* and *standard text rules*

- *preprocessor rules*, which are associated with a detection option of the packet decoder or with one of the preprocessors included with the Firepower System

The following table summarizes attributes of these rule types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Generator ID (GID)</th>
<th>Snort ID (SID)</th>
<th>Source</th>
<th>Can Copy?</th>
<th>Can Edit?</th>
</tr>
</thead>
<tbody>
<tr>
<td>shared object rule</td>
<td>3</td>
<td>lower than 1000000</td>
<td>Cisco Talos Intelligence Group (Talos)</td>
<td>yes</td>
<td>limited</td>
</tr>
<tr>
<td>standard text rule</td>
<td>1 (Global domain or legacy GID)</td>
<td>lower than 1000000</td>
<td>Talos</td>
<td>yes</td>
<td>limited</td>
</tr>
<tr>
<td></td>
<td>1000 - 2000 (descendant domain)</td>
<td>1000000 or higher</td>
<td>Created or imported by user</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>preprocessor rule</td>
<td>decoder- or preprocessor-specific</td>
<td>lower than 1000000</td>
<td>Talos</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td></td>
<td>1000000 or higher</td>
<td>Generated by the system during option configuration</td>
<td>no</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You cannot save changes to any rule created by Talos, but you can save a copy of a modified rule as a custom rule. You can modify either variables used in the rule or rule header information (such as source and destination ports and IP addresses). In a multidomain deployment, rules created by Talos belong to the Global domain. Administrators in descendant domains can save local copies of the rules, which they can then edit.

For the rules it creates, Talos assigns default rule states in each default intrusion policy. Most preprocessor rules are disabled by default and must be enabled if you want the system to generate events for preprocessor rules and, in an inline deployment, drop offending packets.

### License Requirements for Intrusion Rules

Viewing Intrusion Rules in an Intrusion Policy

You can adjust how rules are displayed in the intrusion policy, and can sort rules by several criteria. You can also display the details for a specific rule to see rule settings, rule documentation, and other rule specifics.

Procedure

Step 1  Choose Policies > Access Control > Intrusion.
Step 2  Click Edit (✓) next to the policy you want to edit.
If View (○) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
Step 3  Click Rules under Policy Information in the navigation panel.
Step 4  While viewing the rules, you can:
• Filter the rules as described in Setting a Rule Filter in an Intrusion Policy, on page 1909.
• Sort the rules by clicking the title in the top of the column you want to sort by.
• View an intrusion rule’s details as described in Viewing Intrusion Rule Details, on page 1899.
• View rules in different policy layers by choosing a layer from the Policy drop-down list.

Intrusion Rules Page Columns

The Intrusion Rules page uses the same icons in its menu bar and column headers. For example, the Rule State menu uses the same Generate Events as the Rule State column in the rule listing.
### Intrusion Rule Details

You can view rule documentation, Firepower recommendations, and rule overhead from the Rule Detail view. You can also view and add rule-specific features.

#### Table 132: Rules Page Columns

<table>
<thead>
<tr>
<th>Heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GID</td>
<td>Integer that indicates the Generator ID (GID) for the rule.</td>
</tr>
<tr>
<td>SID</td>
<td>Integer that indicates the Snort ID (SID), which acts as a unique identifier for the rule. For custom rules, the SID is 1000000 or higher.</td>
</tr>
<tr>
<td>Message</td>
<td>Message included in events generated by this rule, which also acts as the name of the rule.</td>
</tr>
<tr>
<td>Generate Events</td>
<td>The rule state for the rule:</td>
</tr>
<tr>
<td></td>
<td>• Drop and Generate Events</td>
</tr>
<tr>
<td></td>
<td>• Generate Events</td>
</tr>
<tr>
<td></td>
<td>• Disabled</td>
</tr>
<tr>
<td></td>
<td>Note the icon for a disabled rule is a dimmed version of the icon for a rule that is set to generate events without dropping traffic. Also, clicking the rule state icon for a rule allows you to change the rule state.</td>
</tr>
<tr>
<td>Firepower Recommended rule state</td>
<td>Firepower recommended rule state for the rule.</td>
</tr>
<tr>
<td>Event Filter</td>
<td>Event filter, including event thresholds and event suppression, applied to the rule.</td>
</tr>
<tr>
<td>Dynamic state</td>
<td>Dynamic rule state for the rule, which goes into effect if specified rate anomalies occur.</td>
</tr>
<tr>
<td>Errors (🚫)</td>
<td>Alerts configured for the rule (currently SNMP alerts only).</td>
</tr>
<tr>
<td>Comment (💬)</td>
<td>Comments added to the rule.</td>
</tr>
</tbody>
</table>

You can also use the layer drop-down list to switch to the Rules page for other layers in your policy. Note that, unless you add layers to your policy, the only editable views listed in the drop-down list are the policy Rules page and the Rules page for a policy layer that is originally named My Changes; note also that making changes in one of these views is the same as making the changes in the other. The drop-down list also lists the Rules page for the read-only base policy.

#### Table 133: Rule Details

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Summary</td>
<td>The rule summary. For rule-based events, this row appears when the rule documentation contains summary information.</td>
</tr>
<tr>
<td>Rule State</td>
<td>The current rule state for the rule. Also indicates the layer where the rule state is set.</td>
</tr>
</tbody>
</table>
If Firepower recommendations have been generated, an icon that represents the recommended rule state; see Intrusion Rules Page Columns, on page 1897. If the recommendation is to enable the rule, the system also indicates the network assets or configurations that triggered the recommendation.

The rule’s potential impact on system performance and the likelihood that the rule might generate false positives. Local rules do not have an assigned overhead, unless they are mapped to a vulnerability.

Thresholds currently set for this rule, as well as the facility to add a threshold for the rule.

Suppression settings currently set for this rule, as well as the facility to add suppressions for the rule.

Rate-based rule states currently set for this rule, as well as the facility to add dynamic rule states for the rule.

SNMP alerts set for this rule, as well as the facility to add an alert for the rule.

Comments added to this rule, as well as the facility to add comments for the rule.

The rule documentation for the current rule, supplied by the Cisco Talos Intelligence Group (Talos). Optionally, click Rule Documentation to view more-specific rule details.

### Viewing Intrusion Rule Details

**Procedure**

**Step 1** Choose Policies > Access Control > Intrusion.

**Step 2** Click Edit (✓) next to the policy you want to edit.

If View (🔍) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** On the navigation pane, click Rules.

**Step 4** Click the rule whose rule details you want to view, then click Show details at the bottom of the page. Rule details appear, as described in Intrusion Rule Details, on page 1898.

**Step 5** From the rule details, you can configure:

- Alerts—See Setting an SNMP Alert for an Intrusion Rule, on page 1902.
- Comments—See Adding a Comment to an Intrusion Rule, on page 1902.
- Dynamic rule states—See Setting a Dynamic Rule State from the Rule Details Page, on page 1901.
- Thresholds—See Setting a Threshold for an Intrusion Rule, on page 1900.
- Suppressions—See Setting Suppression for an Intrusion Rule, on page 1900.
Setting a Threshold for an Intrusion Rule

You can set a single threshold for a rule from the Rule Detail page. Adding a threshold overwrites any existing threshold for the rule.

Note that a **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

**Procedure**

**Step 1** From an intrusion rule’s details, click **Add** next to **Thresholds**.

**Step 2** From the **Type** drop-down list, choose the type of threshold you want to set:

- Choose **Limit** to limit notification to the specified number of event instances per time period.
- Choose **Threshold** to provide notification for each specified number of event instances per time period.
- Choose **Both** to provide notification once per time period after a specified number of event instances.

**Step 3** From the **Track By** drop-down list, choose **Source** or **Destination** to indicate whether you want the event instances tracked by source or destination IP address.

**Step 4** In the **Count** field, enter the number of event instances you want to use as your threshold.

**Step 5** In the **Seconds** field, enter a number that specifies the time period, in seconds, for which event instances are tracked.

**Step 6** Click **OK**.

**Tip** The system displays an **Event Filter** next to the rule in the Event Filtering column. If you add multiple event filters to a rule, the system includes an indication of the number of event filters.

Setting Suppression for an Intrusion Rule

You can set one or more suppressions for a rule in your intrusion policy.

Note that a **Revert** appears in a field when you type an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

**Procedure**

**Step 1** From an intrusion rule’s details, click **Add** next to **Suppressions**.

**Step 2** From the **Suppression Type** drop-down list, choose one of the following options:

- Choose **Rule** to completely suppress events for a selected rule.
- Choose **Source** to suppress events generated by packets originating from a specified source IP address.
- Choose **Destination** to suppress events generated by packets going to a specified destination IP address.

**Step 3** If you chose **Source** or **Destination** for the suppression type, in the **Network** field enter the IP address, an address block, or a comma-separated list comprised of any combination of these.

If the intrusion policy is associated with the default action of an access control policy, you can also specify or list a network variable in the default action variable set.
The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

Step 4 Click OK.

Tip The system displays an Event Filter next to the rule in the Event Filtering column next the suppressed rule. If you add multiple event filters to a rule, a number over the filter indicates the number of filters.

### Setting a Dynamic Rule State from the Rule Details Page

You can set one or more dynamic rule states for a rule. The first dynamic rule state listed has the highest priority. When two dynamic rule states conflict, the action of the first is carried out.

Dynamic rule states are policy-specific.

Note that a Revert appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

**Procedure**

**Step 1** From an intrusion rule’s details, click Add next to Dynamic State.

**Step 2** From the Track By drop-down list, choose an option to indicate how you want the rule matches tracked:

- Choose Source to track the number of hits for that rule from a specific source or set of sources.
- Choose Destination to track the number of hits for that rule to a specific destination or set of destinations.
- Choose Rule to track all matches for that rule.

**Step 3** If you set Track By to Source or Destination, enter the IP address of each host you want to track in the Network field.

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

**Step 4** Next to Rate, specify the number of rule matches per time period to set the attack rate:

- In the Count field, specify the number of rule matches you want to use as your threshold.
- In the Seconds field, specify the number of seconds that make up the time period for which attacks are tracked.

**Step 5** From the New State drop-down list, choose the new action to be taken when the conditions are met.

**Step 6** Enter a value in the Timeout field.

After the timeout occurs, the rule reverts to its original state. Enter 0 to prevent the new action from timing out.

**Step 7** Click OK.
Tip
The system displays a dynamic state ( ) next to the rule in the Dynamic State column. If you add multiple dynamic rule state filters to a rule, a number over the filters indicates the number of filters.

Setting an SNMP Alert for an Intrusion Rule

You can set an SNMP alert for a rule from the Rule Detail page.

Procedure

From an intrusion rule’s details, click Add SNMP Alert next to Alerts.

Tip
The system displays an alert Errors ( ) next to the rule in the Alerting column. If you add multiple alerts to a rule, the system includes an indication of the number of alerts.

Adding a Comment to an Intrusion Rule

Procedure

Step 1
From an intrusion rule’s details, click Add next to Comments.

Step 2
In the Comment field, enter the rule comment.

Step 3
Click OK.

Tip
The system displays a Comment ( ) next to the rule in the Comments column. If you add multiple comments to a rule, a number over the comment indicates the number of comments.

Step 4
To delete a rule comment, click Delete in the rule comments section. You can only delete a comment if the comment is cached with uncommitted intrusion policy changes.

What to do next

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Intrusion Rule Filters in an Intrusion Policy

You can filter the rules you display on the Rules page by a single criteria, or a combination of one or more criteria.

Rule filter keywords help you find the rules for which you want to apply rule settings, such as rule states or event filters. You can filter by a keyword and simultaneously select the argument for the keyword by selecting the argument you want from the Rules page filter panel.
Intrusion Rule Filters Notes

The filter you construct is shown in the Filter text box. You can click keywords and keyword arguments in the filter panel to construct a filter. When you choose multiple keywords, the system combines them using AND logic to create a compound search filter. For example, if you choose preprocessor under Category and then choose Rule Content > GID and enter 116, you get a filter of Category: “preprocessor” GID:”116”, which retrieves all rules that are preprocessor rules and have a GID of 116.

The Category, Microsoft Vulnerabilities, Microsoft Worms, Platform Specific, Preprocessor, and Priority filter groups allow you to submit more than one argument for a keyword, separated by commas. For example, you can choose os-linux and os-windows from Category to produce the filter Category:”os-windows,os-linux”, which retrieves any rules in the os-linux category or in the os-windows category.

To show the filter panel, click the Show icon.

To hide the filter panel, click the Hide icon.

Intrusion Policy Rule Filters Construction Guidelines

In most cases, when you are building a filter, you can use the filter panel to the left of the Rules page in the intrusion policy to choose the keywords/arguments you want to use.

Rule filters are grouped into rule filter groups in the filter panel. Many rule filter groups contain sub-criteria so that you can more easily find the specific rules you are looking for. Some rule filters have multiple levels that you can expand to drill down to individual rules.

Items in the filter panel sometimes represent filter type groups, sometimes represent keywords, and sometimes represent the argument to a keyword. Note the following:

• When you choose a filter type group heading that is not a keyword (Rule Configuration, Rule Content, Platform Specific, and Priority), it expands to list the available keywords.

  When you choose a keyword by clicking on a node in the criteria list, a pop-up window appears, where you supply the argument you want to filter by.

  If that keyword is already used in the filter, the argument you supply replaces the existing argument for that keyword.

  For example, if you click Drop and Generate Events under Rule Configuration > Recommendation in the filter panel, Recommendation:”Drop and Generate Events” is added to the filter text box. If you then click Generate Events under Rule Configuration > Recommendation, the filter changes to Recommendation:”Generate Events”.

• When you choose a filter type group heading that is a keyword (Category, Classifications, Microsoft Vulnerabilities, Microsoft Worms, Priority, and Rule Update), it lists the available arguments.

  When you choose an item from this type of group, the argument and the keyword it applies to are immediately added to the filter. If the keyword is already in the filter, it replaces the existing argument for the keyword that corresponds to that group.

  For example, if you click os-linux under Category in the filter panel, Category:”os-linux” is added to the filter text box. If you then click os-windows under Category, the filter changes to Category:”os-windows”.

• Reference under Rule Content is a keyword, and so are the specific reference ID types listed below it. When you choose any of the reference keywords, a pop-up window appears, where you supply an
argument and the keyword is added to the existing filter. If the keyword is already in use in the filter, the new argument you supply replaces the existing argument.

For example, if you click **Rule Content > Reference > CVE ID** in the filter panel, a pop-up window prompts you to supply the CVE ID. If you enter 2007, then CVE:“2007” is added to the filter text box. In another example, if you click **Rule Content > Reference** in the filter panel, a pop-up window prompts you to supply the reference. If you enter 2007, then Reference:“2007” is added to the filter text box.

- When you choose rule filter keywords from different groups, each filter keyword is added to the filter and any existing keywords are maintained (unless overridden by a new value for the same keyword).

  For example, if you click **os-linux** under **Category** in the filter panel, Category:“os-linux” is added to the filter text box. If you then click **MS00-006** under **Microsoft Vulnerabilities**, the filter changes to Category:“os-linux” MicrosoftVulnerabilities:“MS00-006”.

- When you choose multiple keywords, the system combines them using AND logic to create a compound search filter. For example, if you choose **preprocessor** under **Category** and then choose **Rule Content > GID** and enter 116, you get a filter of Category: “preprocessor” GID:“116”, which retrieves all rules that are preprocessor rules and have a GID of 116.

- The **Category**, **Microsoft Vulnerabilities**, **Microsoft Worms**, **Platform Specific**, and **Priority** filter groups allow you to submit more than one argument for a keyword, separated by commas. For example, you can choose **os-linux** and **os-windows** from **Category** to produce the filter Category:“os-windows,app-detect”, which retrieves any rules in the **os-linux** category or in the **os-windows** category.

The same rule may be retrieved by more than one filter keyword/argument pair. For example, the **DOS Cisco attempt** rule (SID 1545) appears if rules are filtered by the **dos** category, and also if you filter by the **High** priority.

---

**Note**

The **Cisco Talos Intelligence Group** (Talos) may use the rule update mechanism to add and remove rule filters.

Note that the rules on the Rules page may be either shared object rules (generator ID 3) or standard text rules (generator ID 1, Global domain or legacy GID: 1000 - 2000, descendant domains). The following table describes the different rule filters.

<table>
<thead>
<tr>
<th>Filter Group</th>
<th>Description</th>
<th>Multiple Argument Support?</th>
<th>Heading is...</th>
<th>Items in List are...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Configuration</td>
<td>Finds rules according to the configuration of the rule.</td>
<td>No</td>
<td>A grouping</td>
<td>keywords</td>
</tr>
<tr>
<td>Rule Content</td>
<td>Finds rules according to the content of the rule.</td>
<td>No</td>
<td>A grouping</td>
<td>keywords</td>
</tr>
<tr>
<td>Filter Group</td>
<td>Description</td>
<td>Multiple Argument Support?</td>
<td>Heading is...</td>
<td>Items in List are...</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------</td>
<td>---------------</td>
<td>---------------------</td>

<tr>
<td>Category</td>
<td>Finds rules according to the rule categories used by the rule editor. Note that local rules appear in the local sub-group.</td>
<td>Yes</td>
<td>A keyword</td>
<td>arguments</td>
</tr>
<tr>
<td>Classifications</td>
<td>Finds rules according to the attack classification that appears in the packet display of an event generated by the rule.</td>
<td>No</td>
<td>A keyword</td>
<td>arguments</td>
</tr>
<tr>
<td>Microsoft Vulnerabilities</td>
<td>Finds rules according to Microsoft bulletin number.</td>
<td>Yes</td>
<td>A keyword</td>
<td>arguments</td>
</tr>
<tr>
<td>Microsoft Worms</td>
<td>Finds rules based on specific worms that affect Microsoft Windows hosts.</td>
<td>Yes</td>
<td>A keyword</td>
<td>arguments</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Finds rules according to their relevance to specific versions of operating systems. Note that a rule may affect more than one operating system or more than one version of an operating system. For example, enabling SID 2260 affects multiple versions of Mac OS X, IBM AIX, and other operating systems.</td>
<td>Yes</td>
<td>A keyword</td>
<td>arguments</td>
</tr>
<tr>
<td>Preprocessors</td>
<td>Finds rules for individual preprocessors. Note that you must enable preprocessor rules associated with a preprocessor option to generate events and, in an inline deployment, drop offending packets for the option when the preprocessor is enabled.</td>
<td>Yes</td>
<td>A grouping</td>
<td>sub-groupings</td>
</tr>
</tbody>
</table>
### Intrusion Rule Configuration Filters

You can filter the rules listed in the Rules page by several rule configuration settings. For example, if you want to view the set of rules whose rule state does not match the recommended rule state, you can filter on rule state by selecting **Does not match recommendation**.

When you choose a keyword by clicking on a node in the criteria list, you can supply the argument you want to filter by. If that keyword is already used in the filter, the argument you supply replaces the existing argument for that keyword.

For example, if you click **Drop and Generate Events** under **Rule Configuration > Recommendation** in the filter panel, Recommendation: "Drop and Generate Events" is added to the filter text box. If you then click **Generate Events** under **Rule Configuration > Recommendation**, the filter changes to Recommendation: "Generate Events".

### Intrusion Rule Content Filters

You can filter the rules listed in the Rules page by several rule content items. For example, you can quickly retrieve a rule by searching for the rule's SID. You can also find all rules that inspect traffic going to a specific destination port.

When you select a keyword by clicking on a node in the criteria list, you can supply the argument you want to filter by. If that keyword is already used in the filter, the argument you supply replaces the existing argument for that keyword.

---

<table>
<thead>
<tr>
<th>Filter Group</th>
<th>Description</th>
<th>Multiple Argument Support?</th>
<th>Heading is...</th>
<th>Items in List are...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority</td>
<td>Finds rules according to high, medium, and low priorities. The classification assigned to a rule determines its priority. These groups are further grouped into rule categories. Note that local rules (that is, rules that you import or create) do not appear in the priority groups.</td>
<td>Yes</td>
<td>A keyword</td>
<td>arguments</td>
</tr>
<tr>
<td>Rule Update</td>
<td>Finds rules added or modified through a specific rule update. For each rule update, view all rules in the update, only new rules imported in the update, or only existing rules changed by the update.</td>
<td>No</td>
<td>A keyword</td>
<td>arguments</td>
</tr>
</tbody>
</table>
For example, if you click **SID** under **Rule Content** in the filter panel, a pop-up window appears, prompting you to supply a SID. If you type 1045, then **SID:**“1045” is added to the filter text box. If you then click **SID** again and change the SID filter to 1044, the filter changes to **SID:**“1044”.

### Table 135: Rule Content Filters

<tr>
<td>Reference</td>
<td>contain the supplied string in the reference field. You can also filter by a specific type of reference and supplied string.</td>
</tr>
<tr>
<td>Action</td>
<td>start with alert or pass.</td>
</tr>
<tr>
<td>Protocol</td>
<td>include the selected protocol.</td>
</tr>
<tr>
<td>Direction</td>
<td>are based on whether the rule includes the indicated directional setting.</td>
</tr>
<tr>
<td>Source IP</td>
<td>use the specified addresses or variables for the source IP address designation in the rule. You can filter by a valid IP address, a CIDR block/prefix length, or using variables such as $HOME_NET or $EXTERNAL_NET.</td>
</tr>
<tr>
<td>Destination IP</td>
<td>use the specified addresses or variables for the source IP address designation in the rule. You can filter by a valid IP address, a CIDR block/prefix length, or using variables such as $HOME_NET or $EXTERNAL_NET.</td>
</tr>
<tr>
<td>Source port</td>
<td>include the specified source port. The port value must be an integer between 1 and 65535 or a port variable.</td>
</tr>
<tr>
<td>Destination port</td>
<td>include the specified destination port. The port value must be an integer between 1 and 65535 or a port variable.</td>
</tr>
<tr>
<td>Rule Overhead</td>
<td>have the selected rule overhead.</td>
</tr>
<tr>
<td>Metadata</td>
<td>have metadata containing the matching key value pair. For example, type metadata:“service http” to locate rules with metadata relating to the HTTP application protocol.</td>
</tr>
</tbody>
</table>

### Intrusion Rule Categories

The Firepower System places rules in categories based on the type of traffic the rule detects. On the Rules page, you can filter by rule category, so you can set a rule attribute for all rules in a category. For example, if you do not have Linux hosts on your network, you could filter by the **os-linux** category, then disable all the rules showing to disable the entire **os-linux** category.

You can hover your pointer over a category name to display the number of rules in that category.
The Cisco Talos Intelligence Group (Talos) may use the rule update mechanism to add and remove rule categories.

**Intrusion Rule Filter Components**

You can edit your filter to modify the special keywords and their arguments that are supplied when you click on a filter in the filter panel. Custom filters on the Rules page function like those used in the rule editor, but you can also use any of the keywords supplied in the Rules page filter, using the syntax displayed when you select the filter through the filter panel. To determine a keyword for future use, click on the appropriate argument in the filter panel on the right. The filter keyword and argument syntax appear in the filter text box.

Remember that comma-separated multiple arguments for a keyword are only supported for the Category and Priority filter types.

You can use keywords and arguments, character strings, and literal character strings in quotes, with spaces separating multiple filter conditions. A filter cannot include regular expressions, wild card characters, or any special operator such as a negation character (!), a greater than symbol (>), less than symbol (<), and so on.

When you type in search terms without a keyword, without initial capitalization of the keyword, or without quotes around the argument, the search is treated as a string search and the category, message, and SID fields are searched for the specified terms.

Except for the *gid* and *sid* keywords, all arguments and strings are treated as partial strings. Arguments for *gid* and *sid* return only exact matches.

Each rule filter can include one or more keywords in the format:

```
keyword:“argument”
```

where keyword is one of the keywords in the intrusion rule filter groups and argument is enclosed in double quotes and is a single, case-insensitive, alphanumeric string to search for in the specific field or fields relevant to the keyword. Note that keywords should be typed with initial capitalization.

Arguments for all keywords except *gid* and *sid* are treated as partial strings. For example, the argument 123 returns "12345", "41235", "45123", and so on. The arguments for *gid* and *sid* return only exact matches; for example, *sid*:3080 returns only SID 3080.

Each rule filter can also include one or more alphanumeric character strings. Character strings search the rule Message field, Snort ID (SID), and Generator ID (GID). For example, the string 123 returns the strings "Lotus123", "123manis", and so on in the rule message, and also returns SID 6123, SID 12375, and so on. You can search for a partial SID by filtering with one or more character strings.

All character strings are case-insensitive and are treated as partial strings. For example, any of the strings ADMIN, admin, or Admin return "admin", "CPADMIN", "Administrator" and so on.

You can enclose character strings in quotes to return exact matches. For example, the literal string "overflow attempt" in quotes returns only that exact string, whereas a filter comprised of the two strings *overflow* and *attempt* without quotes returns "overflow attempt", "overflow multipacket attempt", "overflow with evasion attempt", and so on.

You can narrow filter results by entering any combination of keywords, character strings, or both, separated by spaces. The result includes any rule that matches all the filter conditions.

You can enter multiple filter conditions in any order. For example, each of the following filters returns the same rules:
Intrusion Rule Filter Usage

You can select predefined filter keywords from the filter panel on the left side of the Rules page in the intrusion policy. When you select a filter, the page displays all matching rules, or indicates when no rules match.

You can add keywords to a filter to further constrain it. Any filter you enter searches the entire rules database and returns all matching rules. When you enter a filter while the page still displays the result of a previous filter, the page clears and returns the result of the new filter instead.

You can also type a filter using the same keyword and argument syntax supplied when you select a filter, or modify argument values in a filter after you select it. When you type in search terms without a keyword, without initial capitalization of the keyword, or without quotes around the argument, the search is treated as a string search and the category, message, and SID fields are searched for the specified terms.

Setting a Rule Filter in an Intrusion Policy

You can filter the rules on the Rules page to display a subset of rules. You can then use any of the page features, including choosing any of the features available in the context menu. This can be useful, for example, when you want to set a threshold for all the rules in a specific category. You can use the same features with rules in a filtered or unfiltered list. For example, you can apply new rule states to rules in a filtered or unfiltered list.

All filter keywords, keyword arguments, and character strings are case-insensitive. If you click an argument for a keyword already in the filter, it replaces the existing argument.

Procedure

Step 1
Choose Policies > Access Control > Intrusion.

Step 2
Click Edit (✓) next to the policy you want to edit.

If View (劈) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3
Click Rules.

Step 4
Construct a filter using any of the following methods, separately or in combination:

- Enter a value in the Filter text box, and press Enter.
- Expand any of the predefined keywords. For example, click Rule Configuration.
- Click a keyword, and specify an argument value if prompted. For example:
  - Under Rule Configuration, you could click Rule State, choose Generate Events from the drop-down-list, and click OK.
  - Under Rule Configuration, you could click Comment, enter the string of comment text to filter by, and click OK.
Under **Category**, you could click **app-detect**, which the system uses as the argument value.

• Expand a keyword, and click an argument value. For example, expand **Rule State** and click **Generate Events**.

---

**Intrusion Rule States**

Intrusion rule states allow you to enable or disable the rule within an individual intrusion policy, as well as specify which action the system takes if monitored conditions trigger the rule.

The Cisco Talos Intelligence Group (Talos) sets the default state of each intrusion and preprocessor rule in each default policy. For example, a rule may be enabled in the Security over Connectivity default policy and disabled in the Connectivity over Security default policy. Talos sometimes uses a rule update to change the default state of one or more rules in a default policy. If you allow rule updates to update your base policy, you also allow the rule update to change the default state of a rule in your policy when the default state changes in the default policy you used to create your policy (or in the default policy it is based on). Note, however, that if you have changed the rule state, the rule update does not override your change.

When you create an intrusion rule, it inherits the default states of the rules in the default policy you use to create your policy.

**Intrusion Rule State Options**

In an intrusion policy, you can set a rule’s state to the following values:

**Generate Events**

You want the system to detect a specific intrusion attempt and generate an intrusion event when it finds matching traffic. When a malicious packet crosses your network and triggers the rule, the packet is sent to its destination and the system generates an intrusion event. The malicious packet reaches its target, but you are notified via the event logging.

**Drop and Generate Events**

You want the system to detect a specific intrusion attempt, drop the packet containing the attack, and generate an intrusion event when it finds matching traffic. The malicious packet never reaches its target, and you are notified via the event logging.

Note that rules set to this rule state generate events but do not drop packets in a passive deployment. For the system to drop packets, **Drop when Inline** must also be enabled (the default setting) in your intrusion policy and you must deploy your device inline.

**Disable**

You do not want the system to evaluate matching traffic.
Choosing either the **Generate Events** or **Drop and Generate Events** options enables the rule. Choosing **Disable** disables the rule.

Cisco **strongly** recommends that you **do not** enable all the intrusion rules in an intrusion policy. The performance of your managed device is likely to degrade if all rules are enabled. Instead, tune your rule set to match your network environment as closely as possible.

---

### Setting Intrusion Rule States

Intrusion rule states are policy-specific.

**Procedure**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Choose <strong>Policies &gt; Access Control &gt; Intrusion</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Click <strong>Edit (✓)</strong> next to the policy you want to edit.</td>
</tr>
<tr>
<td></td>
<td>If <strong>View (☐)</strong> appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip</strong> This page indicates the total number of enabled rules, the total number of enabled rules set to Generate Events, and the total number set to Drop and Generate Events. Note also that in a passive deployment, rules set to Drop and Generate Events only generate events.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Click <strong>Rules</strong> immediately under <strong>Policy Information</strong> in the navigation panel.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Choose the rule or rules where you want to set the rule state.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Choose one of the following:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Rule State &gt; Generate Events</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Rule State &gt; Drop and Generate Events</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Rule State &gt; Disable</strong></td>
</tr>
<tr>
<td>Step 6</td>
<td>To save changes you made in this policy since the last policy commit, click <strong>Policy Information</strong> in the navigation panel, then click <strong>Commit Changes</strong>.</td>
</tr>
<tr>
<td></td>
<td>If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.</td>
</tr>
</tbody>
</table>

**What to do next**

• Deploy configuration changes; see *Deploy Configuration Changes, on page 495*. 
Intrusion Event Notification Filters in an Intrusion Policy

The importance of an intrusion event can be based on frequency of occurrence, or on source or destination IP address. In some cases you may not care about an event until it has occurred a certain number of times. For example, you may not be concerned if someone attempts to log into a server until they fail a certain number of times. In other cases, you may only need to see a few occurrences to know there is a widespread problem. For example, if a DoS attack is launched against your web server, you may only need to see a few occurrences of an intrusion event to know that you need to address the situation. Seeing hundreds of the same event only overloads your system.

Intrusion Event Thresholds

You can set thresholds for individual rules, per intrusion policy, to limit the number of times the system logs and displays an intrusion event based on how many times the event is generated within a specified time period. This can prevent you from being overwhelmed with a large number of identical events. You can set thresholds per shared object rule, standard text rule, or preprocessor rule.

Intrusion Event Thresholds Configuration

To set a threshold, first specify the thresholding type.

Table 136: Thresholding Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit</td>
<td>Logs and displays events for the specified number of packets (specified by the Count argument) that trigger the rule during the specified time period. For example, if you set the type to Limit, the Count to 10, and the Seconds to 60, and 14 packets trigger the rule, the system stops logging events for the rule after displaying the first 10 that occur within the same minute.</td>
</tr>
<tr>
<td>Threshold</td>
<td>Logs and displays a single event when the specified number of packets (specified by the Count argument) trigger the rule during the specified time period. Note that the counter for the time restarts after you hit the threshold count of events and the system logs that event. For example, you set the type to Threshold, Count to 10, and Seconds to 60, and the rule triggers 10 times by second 33. The system generates one event, then resets the Seconds and Count counters to 0. The rule then triggers another 10 times in the next 25 seconds. Because the counters reset to 0 at second 33, the system logs another event.</td>
</tr>
</tbody>
</table>
Logs and displays an event once per specified time period, after the specified number (count) of packets trigger the rule. For example, if you set the type to Both, Count to two, and Seconds to 10, the following event counts result:

- If the rule is triggered once in 10 seconds, the system does not generate any events (the threshold is not met)
- If the rule is triggered twice in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time)
- If the rule is triggered four times in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time, and following events are ignored)

Next, specify tracking, which determines whether the event threshold is calculated per source or destination IP address.

**Table 137: Thresholding IP Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Calculates event instance count per source IP address.</td>
</tr>
<tr>
<td>Destination</td>
<td>Calculates event instance count per destination IP address.</td>
</tr>
</tbody>
</table>

Finally, specify the number of instances and time period that define the threshold.

**Table 138: Thresholding Instance/Time Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Count</td>
<td>The number of event instances per specified time period per tracking IP address required to meet the threshold.</td>
</tr>
<tr>
<td>Seconds</td>
<td>The number of seconds that elapse before the count resets. If you set the threshold type to limit, the tracking to Source IP, the count to 10, and the seconds to 10, the system logs and displays the first 10 events that occur in 10 seconds from a given source port. If only 7 events occur in the first 10 seconds, the system logs and displays those; if 40 events occur in the first 10 seconds, the system logs and displays 10, then begins counting again when the 10-second time period elapses.</td>
</tr>
</tbody>
</table>

Note that you can use intrusion event thresholding alone or in any combination with rate-based attack prevention, the detection_filter keyword, and intrusion event suppression.
You can also add thresholds from within the packet view of an intrusion event.

**Related Topics**
- The detection_filter Keyword, on page 2047
- Setting Threshold Options within the Packet View, on page 2752

## Adding and Modifying Intrusion Event Thresholds

You can set a threshold for one or more specific rules in an intrusion policy. You can also separately or simultaneously modify existing threshold settings. You can set a single threshold for each. Adding a threshold overwrites any existing threshold for the rule.

You can also modify the global threshold that applies by default to all rules and preprocessor-generated events associated with the intrusion policy.

A **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

A global or individual threshold on a managed device with multiple CPUs may result in a higher number of events than expected.

### Procedure

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Edit** (📝) next to the policy you want to edit.

If **View** (👀) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Click **Rules** immediately under **Policy Information** in the navigation pane.

**Step 4** Choose the rule or rules where you want to set a threshold.

**Step 5** Choose **Event Filtering > Threshold**.

**Step 6** Choose a threshold type from the **Type** drop-down list.

**Step 7** From the **Track By** drop-down list, choose whether you want the event instances tracked by **Source** or **Destination** IP address.

**Step 8** Enter a value in the **Count** field.

**Step 9** Enter a value in the **Seconds** field.

**Step 10** Click **OK**.

**Tip** The system displays an **Event Filter** next to the rule in the Event Filtering column. If you add multiple event filters to a rule, a number over the filter indicates the number of event filters.

**Step 11** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Related Topics**

- Global Rule Thresholding Basics, on page 1943

---

**Viewing and Deleting Intrusion Event Thresholds**

You may want to view or delete an existing threshold setting for a rule. You can use the Rules Details view to display the configured settings for a threshold to see if they are appropriate for your system. If they are not, you can add a new threshold to overwrite the existing values.

Note that you can also modify the global threshold that applies by default to all rules and preprocessor-generated events logged by the intrusion policy.

**Procedure**

2. Click Edit next to the policy you want to edit.
   
   If View appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
3. Click Rules immediately under Policy Information in the navigation pane.
4. Choose the rule or rules with a configured threshold you want to view or delete.
5. To remove the threshold for each selected rule, choose Event Filtering > Remove Thresholds.
6. Click OK.
7. To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.
   
   If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Related Topics**

- Global Rule Thresholding Basics, on page 1943
Intrusion Policy Suppression Configuration

You can suppress intrusion event notification when a specific IP address or range of IP addresses triggers a specific rule or preprocessor. This is useful for eliminating false positives. For example, if you have a mail server that transmits packets that look like a specific exploit, you might suppress event notification for that event when it is triggered by your mail server. The rule triggers for all packets, but you only see events for legitimate attacks.

Intrusion Policy Suppression Types

Note that you can use intrusion event suppression alone or in any combination with rate-based attack prevention, the detection_filter keyword, and intrusion event thresholding.

Tip
You can add suppressions from within the packet view of an intrusion event. You can also access suppression settings by using the right-click context menu on the intrusion rules editor page (Objects > Intrusion Rules) and on any intrusion event page (if the event was triggered by an intrusion rule).

Related Topics
- The detection_filter Keyword, on page 2047
- Setting Threshold Options within the Packet View, on page 2752

Suppressing Intrusion Events for a Specific Rule

You can suppress intrusion event notification for a rule or rules in your intrusion policy. When notification is suppressed for a rule, the rule triggers but events are not generated. You can set one or more suppressions for a rule. The first suppression listed has the highest priority. When two suppressions conflict, the action of the first is carried out.

Note that a Revert appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

Procedure

Step 1 Choose Policies > Access Control > Intrusion.
Step 2 Click Edit ( MODIFY ) next to the policy you want to edit.
   If View ( VIEW ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
Step 3 Click Rules immediately under Policy Information in the navigation panel.
Step 4 Choose the rule or rules for which you want to configure suppression conditions.
Step 5 Choose Event Filtering > Suppression.
Step 6 Choose a Suppression Type.
Step 7 If you chose Source or Destination for the suppression type, in the Network field enter the IP address, address block, or variable you want to specify as the source or destination IP address, or a comma-separated list comprised of any combination of these.
The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

**Step 8**  
Click OK.

**Tip**  
The system displays an Event Filter next to the rule in the Event Filtering column next the suppressed rule. If you add multiple event filters to a rule, a number over the filter indicates the number of event filters.

**Step 9**  
To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

---

**Viewing and Deleting Suppression Conditions**

You may want to view or delete an existing suppression condition. For example, you can suppress event notification for packets originating from a mail server IP address because the mail server normally transmits packets that look like exploits. If you then decommission that mail server and reassign the IP address to another host, you should delete the suppression conditions for that source IP address.

**Procedure**

**Step 1**  
Choose Policies > Access Control > Intrusion.

**Step 2**  
Click Edit (✓) next to the policy you want to edit.

If View (☐) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3**  
Click Rules immediately under Policy Information in the navigation panel.

**Step 4**  
Choose the rule or rules for which you want to view or delete suppressions.

**Step 5**  
You have the following choices:

- To remove all suppression for a rule, choose Event Filtering > Remove Suppressions.
- To remove a specific suppression setting, click the rule, then click Show details. Expand the suppression settings and click Delete next to the suppression settings you want to remove.

**Step 6**  
Click OK.

**Step 7**  
To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.
If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes; see [Deploy Configuration Changes, on page 495](#).

---

**Dynamic Intrusion Rule States**

Rate-based attacks attempt to overwhelm a network or host by sending excessive traffic toward the network or host, causing it to slow down or deny legitimate requests. You can use rate-based prevention to change the action of a rule in response to excessive rule matches for specific rules.

You can configure your intrusion policies to include a rate-based filter that detects when too many matches for a rule occur in a given time period. You can use this feature on managed devices deployed inline to block rate-based attacks for a specified time, then revert to a rule state where rule matches only generate events and do not drop traffic.

Rate-based attack prevention identifies abnormal traffic patterns and attempts to minimize the impact of that traffic on legitimate requests. You can identify excessive rule matches in traffic going to a particular destination IP address or addresses or coming from a particular source IP address or addresses. You can also respond to excessive matches for a particular rule across all detected traffic.

In some cases, you may not want to set a rule to the Drop and Generate Events state because you do not want to drop every packet that matches the rule, but you do want to drop packets matching the rule if a particular rate of matches occurs in a specified time. Dynamic rule states let you configure the rate that should trigger a change in the action for a rule, what the action should change to when the rate is met, and how long the new action should persist.

The following diagram shows an example where an attacker is attempting to access a host. Repeated attempts to find a password trigger a rule which has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events after rule matches occur five times in a 10-second span. The new rule attribute times out after 15 seconds.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold in the current or previous sampling period, the new action continues. The new action reverts to Generate Events only after a sampling period completes where the sampled rate was below the threshold rate.
Dynamic Intrusion Rule State Configuration

In the intrusion policy, you can configure a rate-based filter for any intrusion or preprocessor rule. The rate-based filter contains three components:

- the rule matching rate, which you configure as a count of rule matches within a specific number of seconds
- a new action to be taken when the rate is exceeded, with three available actions: Generate Events, Drop and Generate Events, and Disable
- the duration of the action, which you configure as a timeout value

Note that when started, the new action occurs until the timeout is reached, even if the rate falls below the configured rate during that time period. When the timeout is reached, if the rate has fallen below the threshold, the action for the rule reverts to the action initially configured for the rule.

You can configure rate-based attack prevention in an inline deployment to block attacks, either temporarily or permanently. Without rate-based configuration, rules set to Generate Events do generate events, but the system does not drop packets for those rules. However, if the attack traffic matches rules that have rate-based criteria configured, the rate action may cause packet dropping to occur for the period of time that the rate action is active, even if those rules are not initially set to Drop and Generate Events.

Rate-based actions cannot enable disabled rules or drop traffic that matches disabled rules.

You can define multiple rate-based filters on the same rule. The first filter listed in the intrusion policy has the highest priority. Note that when two rate-based filter actions conflict, the action of the first rate-based filter is carried out.

Setting a Dynamic Rule State from the Rules Page

You can set one or more dynamic rule states for a rule. The first dynamic rule state listed has the highest priority. When two dynamic rule states conflict, the action of the first is carried out.
Dynamic rule states are policy-specific.

A **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic rule states cannot enable disabled rules or drop traffic that matches disabled rules.</td>
</tr>
</tbody>
</table>

### Procedure

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Edit (✓)** next to the policy you want to edit.

If **View (☐)** appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Click **Rules** immediately under **Policy Information** in the navigation pane.

**Step 4** Choose the rule or rules where you want to add a dynamic rule state.

**Step 5** Choose **Dynamic State > Add Rate-Based Rule State**.

**Step 6** Choose a value from the **Track By** drop-down list.

**Step 7** If you set **Track By** to **Source** or **Destination**, enter the address of each host you want to track in the **Network** field. You can specify a single IP address, address block, variable, or a comma-separated list comprised of any combination of these.

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results.

**Step 8** Next to **Rate**, specify the number of rule matches per time period to set the attack rate:

- Enter a value in the **Count** field.
- Enter a value in the **Seconds** field.

**Step 9** From the **New State** drop-down list, specify the new action to be taken when the conditions are met.

**Step 10** Enter a value in the **Timeout** field.

After the timeout occurs, the rule reverts to its original state. Specify 0 or leave the **Timeout** field blank to prevent the new action from timing out.

**Step 11** Click **OK**.

**Tip** The system displays a **Dynamic State** next to the rule in the Dynamic State column. If you add multiple dynamic rule state filters to a rule, a number over the filter indicates the number of filters.

**Tip** To delete all dynamic rule settings for a set of rules, choose the rules on the Rules page, then choose **Dynamic State > Remove Rate-Based States**. You can also delete individual rate-based rule state filters from the rule details for the rule by choosing the rule, clicking **Show details**, then clicking **Delete** by the rate-based filter you want to remove.
Step 12  
To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

- Deploy configuration changes; see [Deploy Configuration Changes, on page 495](#).

---

**Adding Intrusion Rule Comments**

You can add comments to rules in your intrusion policy. Comments added this way are policy-specific; that is, comments you add to a rule in one intrusion policy are not visible in other intrusion policies. Any comments you add can be seen in the Rule Details view on the Rules page for the intrusion policy.

After you commit the intrusion policy changes containing the comment, you can also view the comment by clicking **Rule Comment** on the rule Edit page.

**Procedure**

**Step 1**  
Choose **Policies > Access Control > Intrusion**.

**Step 2**  
Click **Edit (✓)** next to the policy you want to edit.

If **View (👀)** appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3**  
Click **Rules** immediately under **Policy Information** in the navigation panel.

**Step 4**  
Choose the rule or rules where you want to add a comment.

**Step 5**  
Choose **Comments > Add Rule Comment**.

**Step 6**  
In the **Comment** field, enter the rule comment.

**Step 7**  
Click **OK**.

**Tip**  
The system displays a **Comment (💬)** next to the rule in the Comments column. If you add multiple comments to a rule, a number over the comment indicates the number of comments.

**Step 8**  
Optionally, delete a rule comment by clicking **Delete** next to the comment.

You can only delete a comment if the comment is cached with uncommitted intrusion policy changes. After intrusion policy changes are committed, the rule comment is permanent.

**Step 9**  
To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes; see *Deploy Configuration Changes, on page 495.*
Tailoring Intrusion Protection to Your Network Assets

The following topics describe how to use Firepower recommended rules:

- About Firepower Recommended Rules, on page 1923
- Default Settings for Firepower Recommendations, on page 1924
- Advanced Settings for Firepower Recommendations, on page 1925
- Generating and Applying Firepower Recommendations, on page 1926

About Firepower Recommended Rules

You can use Firepower intrusion rule recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets. This allows you to tailor your intrusion policy to the specific needs of your monitored network.

The system makes an individual set of recommendations for each intrusion policy. It typically recommends rule state changes for standard text rules and shared object rules. However, it can also recommend changes for preprocessor and decoder rules.

When you generate rule state recommendations, you can use the default settings or configure advanced settings. Advanced settings allow you to:

- Redefine which hosts on your network the system monitors for vulnerabilities
- Influence which rules the system recommends based on rule overhead
- Specify whether to generate recommendations to disable rules

You can also choose either to use the recommendations immediately or to review the recommendations (and affected rules) before accepting them.

Choosing to use recommended rule states adds a read-only Firepower Recommendations layer to your intrusion policy, and subsequently choosing not to use recommended rule states removes the layer.

You can schedule a task to generate recommendations automatically based on the most recently saved configuration settings in your intrusion policy.

The system does not change rule states that you set manually:
• Manually setting the states of specified rules *before* you generate recommendations prevents the system from modifying the states of those rules in the future.

• Manually setting the states of specified rules *after* you generate recommendations overrides the recommended states of those rules.

Tip The intrusion policy report can include a list of rules with rule states that differ from the recommended state.

While displaying the recommendation-filtered Rules page, or after accessing the Rules page directly from the navigation panel or the Policy Information page, you can manually set rule states, sort rules, and take any of the other actions available on the Rules page, such as suppressing rules, setting rule thresholds, and so on.

Note The Cisco Talos Intelligence Group (Talos) determines the appropriate state of each rule in the system-provided policies. If you use a system-provided policy as your base policy, and you allow the system to set your rules to the Firepower recommended rule state, the rules in your intrusion policy match the settings recommended by Cisco for your network assets.

**Recommended Rules and Multitenancy**

The system builds a separate network map for each leaf domain. In a multidomain deployment, if you enable this feature in an intrusion policy in an ancestor domain, the system generates recommendations using data from all descendant leaf domains. This can enable intrusion rules tailored to assets that may not exist in all leaf domains, which can affect performance.

### Default Settings for Firepower Recommendations

When you generate Firepower recommendations, the system searches your base policy for rules that protect against vulnerabilities associated with your network assets, and identifies the current state of rules in your base policy. The system then recommends rule states and, if you choose to, sets the rules to the recommended states.

The system performs the following basic analysis to generate recommendations:

**Table 139: Rule State Recommendations Based on Vulnerabilities**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>Disabled</td>
<td>Generate Events</td>
</tr>
<tr>
<td></td>
<td>Generate Events</td>
<td>Generate Events</td>
</tr>
<tr>
<td></td>
<td>Drop and Generate Events</td>
<td>Drop and Generate Events</td>
</tr>
<tr>
<td>No</td>
<td>Any</td>
<td>Disabled</td>
</tr>
</tbody>
</table>
Note the following in the table:

- If a rule is disabled in the base policy, or set to Generate Events, the recommended state is always Generate Events.

  For example, if the base policy is No Rules Active, in which all rules are disabled, there will be no recommendations to Drop and Generate Events.

- Recommendations to Drop and Generate Events are made only for rules already set to Drop and Generate Events in the base policy.

  If you want a rule to be set to Drop and Generate events and the rule was disabled or set to Generate Events in the base policy, you must manually reset the rule state.

When you generate recommendations without changing the advanced settings for Firepower recommended rules, the system recommends rule state changes for all hosts in your entire discovered network.

By default, the system generates recommendations only for rules with low or medium overhead, and generates recommendations to disable rules.

The system does not recommend a rule state for an intrusion rule that is based on a vulnerability that you disable using the Impact Qualification feature.

The system always recommends that you enable a local rule associated with a third-party vulnerability mapped to a host.

The system does not make state recommendations for unmapped local rules.

Related Topics

- Third-Party Product Mappings, on page 2262

## Advanced Settings for Firepower Recommendations

### Include all differences between recommendations and rule states in policy reports

By default, an intrusion policy report lists the policy's enabled rules, that is, rules set to either Generate Events or Drop and Generate Events. Enabling the **Include all differences** option also lists the rules whose recommended states differ from their saved states. For information on policy reports, see [Policy Reports](#), on page 509.

### Networks to Examine

 Specifies the monitored networks or individual hosts to examine for recommendations. You can specify a single IP address or address block, or a comma-separated list comprised of either or both.

Lists of addresses within the hosts that you specify are linked with an OR operation except for negations, which are linked with an AND operation after all OR operations are calculated.

If you want to dynamically adapt active rule processing for specific packets based on host information, you can also enable adaptive profile updates.

### Recommendation Threshold (By Rule Overhead)

Prevents the system from recommending or automatically enabling intrusion rules with a higher overhead than the threshold you choose.
Overhead is based on the rule’s potential impact on system performance and the likelihood that the rule may generate false positives. Permitting rules with higher overhead usually results in more recommendations, but can affect system performance. You can view the overhead rating for a rule in the rule detail view on the intrusion Rules page.

Note that the system does not factor rule overhead into recommendations to disable rules. Also, local rules are considered to have no overhead, unless they are mapped to a third-party vulnerability.

Generating recommendations for rules with the overhead rating at a particular setting does not preclude you from generating recommendations with different overhead, then generating recommendations again for the original overhead setting. You get the same rule state recommendations for each overhead setting each time you generate recommendations for the same rule set, regardless of the number of times you generate recommendations or how many different overhead settings you generate with. For example, you can generate recommendations with overhead set to medium, then to high, then finally to medium again; if the hosts and applications on your network have not changed, both sets of recommendations with overhead set to medium are then the same for that rule set.

Accept Recommendations to Disable Rules

Specifies whether the system disables intrusion rules based on Firepower recommendations.

Accepting recommendations to disable rules restricts your rule coverage. Omitting recommendations to disable rules augments your rule coverage.

Related Topics

Adaptive Profile Updates and Firepower Recommended Rules, on page 2223

Generating and Applying Firepower Recommendations

Starting or stopping use of Firepower recommendations may take several minutes, depending on the size of your network and intrusion rule set.

The system builds a separate network map for each leaf domain. In a multidomain deployment, if you enable this feature in an intrusion policy in an ancestor domain, the system generates recommendations using data from all descendant leaf domains. This can enable intrusion rules tailored to assets that may not exist in all leaf domains, which can affect performance.

Before you begin

• Firepower recommendations have the following requirements:
  • FTD License—Threat
  • Classic License—Protection
  • User Roles—Admin or Intrusion Admin

• Configure a network discovery policy before you begin with the steps. Configure the network discovery policy to define internal hosts so that the Firepower recommendations are suitable. See, Network Discovery Customization, on page 2382.
Procedure

Step 1  In the intrusion policy editor's navigation pane, click **Firepower Recommendations**.

Step 2  (Optional) Configure advanced settings; see Advanced Settings for Firepower Recommendations, on page 1925.

Step 3  Generate and apply recommendations.

- **Generate and Use Recommendations**—Generates recommendations and changes rule states to match. Only available if you have never generated recommendations.
- **Generate Recommendations**—Regardless of whether you are using recommendations, generates new recommendations but does not change rule states to match.
- **Update Recommendations**—If you are using recommendations, generates recommendations and changes rule states to match. Otherwise, generates new recommendations without changing rule states.
- **Use Recommendations**—Changes rule states to match any unimplemented recommendations.
- **Do Not Use Recommendations**—Stops use of recommendations. If you manually changed a rule's state before you applied recommendations, the rule state returns to the value you gave it. Otherwise, the rule state returns to its default value.

When you generate recommendations, the system displays a summary of the recommended changes. To view a list of rules where the system recommends a state change, click View next to the newly proposed rule state.

Step 4  Evaluate and adjust the recommendations you implemented.

Even if you accept most Firepower recommendations, you can override individual recommendations by setting rule states manually; see Setting Intrusion Rule States, on page 1911.

Step 5  To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Sensitive Data Detection

The following topics explain sensitive data detection and how to configure it:

- Sensitive Data Detection Basics, on page 1929
- Global Sensitive Data Detection Options, on page 1930
- Individual Sensitive Data Type Options, on page 1931
- System-Provided Sensitive Data Types, on page 1932
- License Requirements for Sensitive Data Detection, on page 1933
- Requirements and Prerequisites for Sensitive Data Detection, on page 1933
- Configuring Sensitive Data Detection, on page 1934
- Monitored Application Protocols and Sensitive Data, on page 1935
- Selecting Application Protocols to Monitor, on page 1936
- Special Case: Sensitive Data Detection in FTP Traffic, on page 1937
- Custom Sensitive Data Types, on page 1937

Sensitive Data Detection Basics

Sensitive data such as Social Security numbers, credit card numbers, driver’s license numbers, and so on may be leaked onto the Internet, intentionally or accidentally. The system provides a sensitive data preprocessor that can detect and generate events on sensitive data in ASCII text, which can be particularly useful in detecting accidental data leaks.

Global sensitive data preprocessor options control how the preprocessor functions. You can modify global options that specify the following:

- whether the preprocessor replaces all but the last four credit card or Social Security numbers in triggering packets
- which destination hosts on your network to monitor for sensitive data
- how many total occurrences of all data types in a single session result in an event

Individual data types identify the sensitive data you can detect and generate events on in your specified destination network traffic. You can modify default settings for data type options that specify the following:

- a threshold that must be met for a detected data type to generate a single per-session event
- the destination ports to monitor for each data type
• the application protocols to monitor for each data type

You can create and modify custom data types to detect data patterns that you specify. For example, a hospital might create a data type to protect patient numbers, or a university might create a data type to detect student numbers that have a unique numbering pattern.

The system detects sensitive data per TCP session by matching individual data types against traffic. You can modify the default settings for each data type and for global options that apply to all data types in your intrusion policy. The Firepower System provides predefined, commonly used data types. You can also create custom data types.

A sensitive data preprocessor rule is associated with each data type. You enable sensitive data detection and event generation for each data type by enabling the corresponding preprocessor rule for the data type. A link on the configuration page takes you to a filtered view of sensitive data rules on the Rules page, where you can enable and disable rules and configure other rule attributes.

When you save changes to your intrusion policy, you are given the option to automatically enable the sensitive data preprocessor if the rule associated with a data type is enabled and sensitive data detection is disabled.

Tip

The system does not detect encrypted or obfuscated sensitive data, or sensitive data in a compressed or encoded format such as a Base64-encoded email attachment. For example, the system would detect the phone number (555)123-4567, but not an obfuscated version where each number is separated by spaces, as in (5 5 5) 1 2 3 - 4 5 6 7, or by intervening HTML code, such as &lt;b&gt;(555)&lt;/b&gt;&lt;i&gt;123-4567&lt;/i&gt;. However, the system would detect, for example, the HTML coded number &lt;b&gt;(555)-123-4567&lt;/b&gt; where no intervening codes interrupt the numbering pattern.

Global Sensitive Data Detection Options

Global sensitive data options are policy-specific and apply to all data types.

Mask

Replaces with Xs all but the last four digits of credit card numbers and Social Security numbers in the triggering packet. The masked numbers appear in the intrusion event packet view in the web interface and in downloaded packets.

Networks

Specifies the destination host or hosts to monitor for sensitive data. You can specify a single IP address, address block, or a comma-separated list of either or both. The system interprets a blank field as any, meaning any destination IP address.

The system builds a separate network map for each leaf domain. In a multidomain deployment, using literal IP addresses to constrain this configuration can have unexpected results. Using override-enabled objects allows descendant domain administrators to tailor Global configurations to their local environments.
Global Threshold

Specifies the total number of all occurrences of all data types during a single session that the preprocessor must detect in any combination before generating a global threshold event. You can specify 1 through 65535. Cisco recommends that you set the value for this option higher than the highest threshold value for any individual data type that you enable in your policy.

Note the following points regarding global thresholds:

- You must enable preprocessor rule 139:1 to detect and generate events and, in an inline deployment, drop offending packets on combined data type occurrences.
- The preprocessor generates up to one global threshold event per session.
- Global threshold events are independent of individual data type events; that is, the preprocessor generates an event when the global threshold is reached, regardless of whether the event threshold for any individual data type has been reached, and vice versa.

Related Topics

Firepower System IP Address Conventions, on page 18

Individual Sensitive Data Type Options

At a minimum, each custom data type must specify an event threshold and at least one port or application protocol to monitor.

Each system-provided data type uses an otherwise inaccessible sd_pattern keyword to define a built-in data pattern to detect in traffic. You can also create custom data types for which you use simple regular expressions to specify your own data patterns.

Sensitive data types display in all intrusion policies where Sensitive Data Detection is enabled. System-provided data types display as read-only. For custom data types, the name and pattern fields display as read-only, but you can set the other options to policy-specific values.

In a multidomain deployment, the system displays sensitive data types created in the current domain, which you can edit. It also displays data types created in ancestor domains, which you can edit in a limited way. For ancestor data types, the name and pattern fields display as read-only, but you can set the other options to policy-specific values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Type</td>
<td>Specifies the unique name for the data type.</td>
</tr>
<tr>
<td>Threshold</td>
<td>Specifies the number of occurrences of the data type when the system generates an event. You can specify 1 through 255. Note that the preprocessor generates one event for a detected data type per session. Note also that global threshold events are independent of individual data type events; that is, the preprocessor generates an event when the data type event threshold is reached, regardless of whether the global event threshold has been reached, and vice versa.</td>
</tr>
</tbody>
</table>
## System-Provided Sensitive Data Types

Each intrusion policy includes system-provided data types for detecting commonly used data patterns such as credit card numbers, email addresses, U.S. phone numbers, and U.S. Social Security numbers with and without dashes.

Each system-provided data type is associated with a single sensitive data preprocessor rule that has a generator ID (GID) of 138. You must enable the associated sensitive data rule in the intrusion policy to generate events and, in an inline deployment, drop offending packets for each data type that you want to use in your policy.

The following table describes each data type and lists the corresponding preprocessor rule.

### Table 141: System-Provided Sensitive Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
<th>Preprocessor Rule GID:SID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credit Card Numbers</td>
<td>Matches Visa®, MasterCard®, Discover® and American Express® fifteen- and sixteen-digit credit card numbers, with or without their normal separating dashes or spaces; also uses the Luhn algorithm to verify credit card check digits.</td>
<td>138:2</td>
</tr>
<tr>
<td>Email Addresses</td>
<td>Matches email addresses.</td>
<td>138:5</td>
</tr>
<tr>
<td>U.S. Phone Numbers</td>
<td>Matches U.S. phone numbers adhering to the pattern \d(3)\d{3} ?\d{3}-\d{4}.</td>
<td>138:6</td>
</tr>
</tbody>
</table>
To reduce false positives from 9-digit numbers other than Social Security numbers, the preprocessor uses an algorithm to validate the 3-digit area number and 2-digit group number that precede the 4-digit serial number in each Social Security number. The preprocessor validates Social Security group numbers through November 2009.

Configuring Sensitive Data Detection

Because sensitive data detection can have a high impact on the performance of your Firepower System, Cisco recommends that you adhere to the following guidelines:

- Choose the No Rules Active default policy as your base intrusion policy.
- Ensure that the following settings are enabled in the corresponding network analysis policy:
  - FTP and Telnet Configuration under Application Layer Preprocessors
  - IP Defragmentation and TCP Stream Configuration under Transport/Network Layer Preprocessors.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Before you begin

For classic devices, this procedure requires the Protection or Control license.

Procedure

**Step 1**  Choose Policies > Access Control > Intrusion

**Step 2**  Click Edit (✓) next to the policy you want to edit.

If View (:none) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3**  Click Advanced Settings in the navigation panel.

**Step 4**  If Sensitive Data Detection under Specific Threat Detection is disabled, click Enabled.

**Step 5**  Click Edit (✓) next to Sensitive Data Detection.

**Step 6**  You have the following choices:

- Modify the global settings as described in Global Sensitive Data Detection Options, on page 1930.
- Choose a data type in the Targets section, and modify the data type configuration as described in Individual Sensitive Data Type Options, on page 1931.
- If you want to inspect custom sensitive data, create a custom data type; see Custom Sensitive Data Types, on page 1937.

**Step 7**  Add or remove application protocols to monitor for a data type; see Monitored Application Protocols and Sensitive Data, on page 1935.

Note  To detect sensitive data in FTP traffic, you must add the Ftp data application protocol.

**Step 8**  Optionally, to display sensitive data preprocessor rules, click Configure Rules for Sensitive Data Detection.
You can enable or disable any of the listed rules. You can also configure sensitive data rules for any of the other actions available on the Rules page, such as rule suppression, rate-based attack prevention, and so on; see Intrusion Rule Types, on page 1895 for more information.

**Step 9**

To save changes you made in this policy since the last policy commit, click **Policy Information** in the navigation panel, then click **Commit Changes**.

If you enable sensitive data preprocessor rules in your policy without enabling sensitive data detection, you are prompted to enable sensitive data detection when you save changes to your policy.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

- If you want to generate intrusion events, enable Sensitive Data Detection rules 138:2, 138:3, 138:4, 138:5, 138:6, 138:999999, or 139:1. For more information, see Intrusion Rule States, on page 1910, Global Sensitive Data Detection Options, on page 1930, System-Provided Sensitive Data Types, on page 1932, and Custom Sensitive Data Types, on page 1937.
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

**Related Topics**

  - Special Case: Sensitive Data Detection in FTP Traffic, on page 1937

---

**Monitored Application Protocols and Sensitive Data**

You can specify up to eight application protocols to monitor for each data type. At least one detector must be enabled for each application protocol you select. By default, all system-provided detectors are activated. If no detector is enabled for an application protocol, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application.

You must specify at least one application protocol or port to monitor for each data type. However, except in the case where you want to detect sensitive data in FTP traffic, Cisco recommends for the most complete coverage that you specify corresponding ports when you specify application protocols. For example, if you specify HTTP, you might also configure the well-known HTTP port 80. If a new host on your network implements HTTP, the system monitors port 80 during the interval when it is discovering the new HTTP application protocol.

In the case where you want to detect sensitive data in FTP traffic, you must specify the **FTP data** application protocol; there is no advantage in specifying a port number.

**Related Topics**

  - Activating and Deactivating Detectors, on page 2307
  - Special Case: Sensitive Data Detection in FTP Traffic, on page 1937
Selecting Application Protocols to Monitor

You can specify application protocols to monitor in both system-provided and custom sensitive data types. The application protocols you select are policy-specific.

Before you begin

For classic devices, this procedure requires the Control license.

Procedure

Step 1
Choose Policies > Access Control > Intrusion.

Step 2
Click Edit (✓) next to the policy you want to edit.

If View (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3
Click Advanced Settings in the navigation panel.

Step 4
If Sensitive Data Detection under Specific Threat Detection is disabled, click Enabled.

Step 5
Click Edit (✓) next to Sensitive Data Detection.

Step 6
Click the name of a data type under Data Types.

Step 7
Click Edit (✓) next to the Application Protocols field.

Step 8
You have the following choices:

- To add application protocols for monitoring, choose one or more application protocols from the Available list, then click right arrow (▶). You can add up to eight application protocols for monitoring.
- To remove an application protocol from monitoring, choose it from the Enabled list, then click left arrow (◀).

Step 9
Click OK.

Step 10
To save changes you made in this policy since the last policy commit, click Policy Information in the navigation pane, then click Commit Changes.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 495.

Special Case: Sensitive Data Detection in FTP Traffic, on page 1937
Special Case: Sensitive Data Detection in FTP Traffic

You usually determine which traffic to monitor for sensitive data by specifying the ports to monitor or specifying application protocols in deployments.

However, specifying ports or application protocols is not sufficient for detecting sensitive data in FTP traffic. Sensitive data in FTP traffic is found in traffic for the FTP application protocol, which occurs intermittently and uses a transient port number, making it difficult to detect. To detect sensitive data in FTP traffic, you must include the following in your configuration:

- Specify the FTP data application protocol to enable detection of sensitive data in FTP traffic.
  
  In the special case of detecting sensitive data in FTP traffic, specifying the FTP data application protocol does not invoke detection; instead, it invokes the rapid processing of the FTP/Telnet processor to detect sensitive data in FTP traffic.

- Ensure that the FTP Data detector, which is enabled by default, is enabled.

- Ensure that your configuration includes at least one port to monitor for sensitive data.

- Ensure that the file policy is enabled for the Access Control Policy.

Note that it is not necessary to specify an FTP port except in the unlikely case where you only want to detect sensitive data in FTP traffic. Most sensitive data configurations will include other ports such as HTTP or email ports. In the case where you do want to specify only one FTP port and no other ports to monitor, Cisco recommends that you specify the FTP command port 23.

Custom Sensitive Data Types

Each custom data type you create also creates a single sensitive data preprocessor rule that has a Generator ID (GID) of 138 and a Snort ID (SID) of 1000000 or greater, that is, a SID for a local rule.

You must enable the associated sensitive data rule to enable detection, generate events and, in an inline deployment, drop offending packets for each custom data type that you want to use in your policy.

To help you enable sensitive data rules, a link on the configuration page takes you to a filtered view of the intrusion policy Rules page that displays all system-provided and custom sensitive data rules. You can also display custom sensitive data rules along with any custom local rules by choosing the local filtering category on the intrusion policy Rules page. Note that custom sensitive data rules are not listed on the intrusion rules editor page (Objects > Intrusion Rules).

Once you create a custom data type, you can enable it in any intrusion policy in the system or, for multidomain deployments, in the current domain. To enable a custom data type, you must enable the associated sensitive data rule in any policy that you want to use to detect that custom data type.
Data Patterns in Custom Sensitive Data Types

You define the data pattern for a custom data type using a simple set of regular expressions comprised of the following:

- three metacharacters
- escaped characters that allow you to use the metacharacters as literal characters
- six character classes

Metacharacters are literal characters that have special meaning within regular expressions.

<table>
<thead>
<tr>
<th>Metacharacter</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Matches zero or one occurrence of the preceding character or escape sequence; that is, the preceding character or escape sequence is optional.</td>
<td>colour?r matches color or colour</td>
</tr>
<tr>
<td>{n}</td>
<td>Matches the preceding character or escape sequence n times.</td>
<td>For example, \d{2} matches 55, 12, and so on; \l{3} matches AbC, www, and so on; \w{3} matches a1B, 25C, and so on; x{5} matches xxxxx</td>
</tr>
<tr>
<td>\</td>
<td>Allows you to use metacharacters as actual characters and is also used to specify a predefined character class.</td>
<td>? matches a question mark, \ \ matches a backslash, \d matches numeric characters, and so on</td>
</tr>
</tbody>
</table>

You must use a backslash to escape certain characters for the sensitive data preprocessor to interpret them correctly as literal characters.

<table>
<thead>
<tr>
<th>Use this escaped character...</th>
<th>To represent this literal character...</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>?</td>
</tr>
<tr>
<td>{</td>
<td>{</td>
</tr>
<tr>
<td>}</td>
<td>}</td>
</tr>
<tr>
<td>\</td>
<td>\</td>
</tr>
</tbody>
</table>

When defining a custom sensitive data pattern, you can use character classes.

<table>
<thead>
<tr>
<th>Character Class</th>
<th>Description</th>
<th>Character Class Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>\d</td>
<td>Matches any numeric ASCII character 0-9</td>
<td>0-9</td>
</tr>
<tr>
<td>Character Class</td>
<td>Description</td>
<td>Character Class Definition</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>\D</td>
<td>Matches any byte that is not a numeric ASCII character</td>
<td>not 0-9</td>
</tr>
<tr>
<td>\l (lowercase “ell”)</td>
<td>Matches any ASCII letter</td>
<td>a-zA-Z</td>
</tr>
<tr>
<td>\L</td>
<td>Matches any byte that is not an ASCII letter</td>
<td>not a-zA-Z</td>
</tr>
<tr>
<td>\w</td>
<td>Matches any ASCII alphanumeric character</td>
<td>a-zA-Z0-9</td>
</tr>
<tr>
<td>\W</td>
<td>Matches any byte that is not an ASCII alphanumeric character</td>
<td>not a-zA-Z0-9</td>
</tr>
</tbody>
</table>

The preprocessor treats characters entered directly, instead of as part of a regular expression, as literal characters. For example, the data pattern 1234 matches 1234.

The following data pattern example, which is used in system-provided sensitive data rule 138:4, uses the escaped digits character class, the multiplier and option-specifier metacharacters, and the literal dash (-) and left and right parentheses () characters to detect U.S. phone numbers:

```
(\d{3}) ?\d{3}-\d{4}
```

Exercise caution when creating custom data patterns. Consider the following alternative data pattern for detecting phone numbers which, although using valid syntax, could cause many false positives:

```
(?\d{3}) ?\d{3}-?\d{4}
```

Because the second example combines optional parentheses, optional spaces, and optional dashes, it would detect, among others, phone numbers in the following desirable patterns:

- (555)123-4567
- 555123-4567
- 5551234567

However, the second example pattern would also detect, among others, the following potentially invalid patterns, resulting in false positives:

- (555 1234567
- 555) 123-4567
- 555) 123-4567

Consider finally, for illustration purposes only, an extreme example in which you create a data pattern that detects the lowercase letter a using a low event threshold in all destination traffic on a small company network. Such a data pattern could overwhelm your system with literally millions of events in only a few minutes.
Configuring Custom Sensitive Data Types

In a multidomain deployment, the system displays sensitive data types created in the current domain, which you can edit. It also displays data types created in ancestor domains, which you can edit in a limited way. For ancestor data types, the name and pattern fields display as read-only, but you can set the other options to policy-specific values.

You cannot delete a data type if the sensitive data rule for that data type is enabled in any intrusion policy.

Procedure

1. Choose Policies > Access Control > Intrusion
2. Click Edit (✓) next to the policy you want to edit.
   If View (👁️) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
3. Click Advanced Settings in the navigation panel.
4. If Sensitive Data Detection under Specific Threat Detection is disabled, click Enabled.
5. Click Edit (✓) next to Sensitive Data Detection.
6. Click Add (➕) next to Data Types.
7. Enter a name for the data type.
8. Enter the pattern you want to detect with this data type; see Data Patterns in Custom Sensitive Data Types, on page 1938.
9. Click OK.
10. Optionally, click the data type name, and modify the options described in Individual Sensitive Data Type Options, on page 1931.
11. Optionally, delete a custom data type by clicking Delete (🗑️), then OK to confirm.
   **Note** If the sensitive data rule for that data type is enabled in any intrusion policy, the system warns that you cannot delete the data type. You must disable the sensitive data rule in affected policies before attempting the deletion again; see Setting Intrusion Rule States, on page 1911.
12. To save changes you made in this policy since the last policy commit, click Policy Information in the navigation panel, then click Commit Changes.
   If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Enable the associated custom sensitive data preprocessing rule in each policy where you want to use that data type; see Setting Intrusion Rule States, on page 1911.
- Deploy configuration changes; see Deploy Configuration Changes, on page 495.
Editing Custom Sensitive Data Types

You can edit all fields in custom sensitive data types. Note, however, that when you modify the name or pattern field, these settings change in all intrusion policies on the system. You can set the other options to policy-specific values.

In a multidomain deployment, the system displays sensitive data types created in the current domain, which you can edit. It also displays data types created in ancestor domains, which you can edit in a limited way. For ancestor data types, the name and pattern fields display as read-only, but you can set the other options to policy-specific values.

Procedure

Step 1
Choose Policies > Access Control > Intrusion

Step 2
Click Edit (✓) next to the policy you want to edit.

If View (☐) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3
Click Advanced Settings in the navigation panel.

Step 4
If Sensitive Data Detection under Specific Threat Detection is disabled, click Enabled.

Step 5
Click Edit next to Sensitive Data Detection.

Step 6
In the Targets section, click the name of the custom data type.

Step 7
Click Edit Data Type Name and Pattern.

Step 8
Modify the data type name and pattern; see Data Patterns in Custom Sensitive Data Types, on page 1938.

Step 9
Click OK.

Step 10
Set the remaining options to policy-specific values; see Individual Sensitive Data Type Options, on page 1931.

Step 11
To save changes you made in this policy since the last policy commit, click Policy Information in the navigation panel, then click Commit Changes.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

• Deploy configuration changes; see Deploy Configuration Changes, on page 495.
The following topics describe how to globally limit intrusion event logging:

- Global Rule Thresholding Basics, on page 1943
- Global Rule Thresholding Options, on page 1944
- License Requirements for Global Thresholds, on page 1946
- Requirements and Prerequisites for Global Thresholds, on page 1946
- Configuring Global Thresholds, on page 1947
- Disabling the Global Threshold, on page 1947

**Global Rule Thresholding Basics**

The global rule threshold sets limits for event logging by an intrusion policy. You can set a global rule threshold across all traffic to limit how often the policy logs events from a specific source or destination and displays those events per specified time period. You can also set thresholds per shared object rule, standard text rule, or preprocessor rule in the policy. When you set a global threshold, that threshold applies for each rule in the policy that does not have an overriding specific threshold. Thresholds can prevent you from being overwhelmed with a large number of events.

Every intrusion policy contains a default global rule threshold that applies by default to all intrusion rules and preprocessor rules. This default threshold limits the number of events on traffic going to a destination to one event per 60 seconds.

You can:

- Change the global threshold.
- Disable the global threshold.
- Override the global threshold by setting individual thresholds for specific rules.

For example, you might set a global limit threshold of five events every 60 seconds, but then set a specific threshold of ten events for every 60 seconds for SID 1315. All other rules generate no more than five events in each 60-second period, but the system generates up to ten events for each 60-second period for SID 1315.
