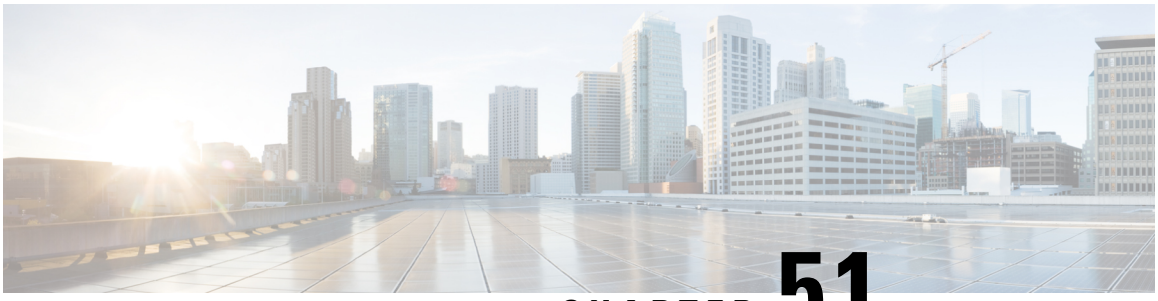
Improved portscan detection.	7.2	7.2 running Snort 3	With an improved portscan detector, you can easily configure the system to detect or prevent portscans. You can refine the networks you want to protect, set the sensitivity, and so on. For devices running Snort 2 and for devices running Version 7.1 and earlier, continue to use the network analysis policy for portscan detection. New/modified screens: We added **Threat Detection** to the access control policy's Advanced tab. New/Modified commands: **clear threat-detection portscan**, **show threat-detection portscan**.



CHAPTER 51

Intelligent Application Bypass

The following topics describe how to configure access control polices to use Intelligent Application Bypass (IAB)

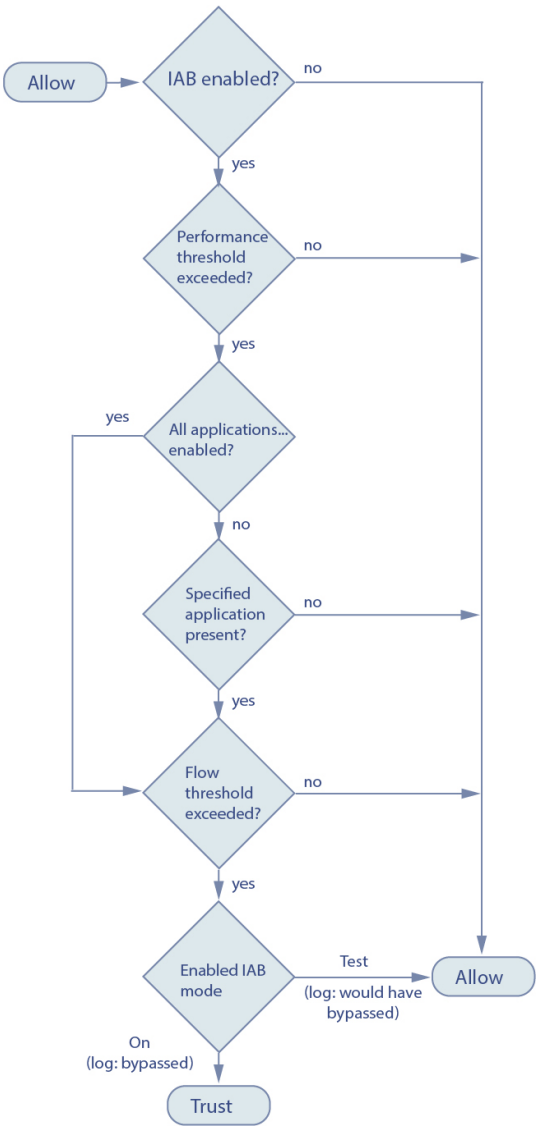
- Introduction to IAB, on page 1965
- IAB Options, on page 1966
- Requirements and Prerequisites for Intelligent Application Bypass, on page 1968
- Configuring Intelligent Application Bypass, on page 1968
- IAB Logging and Analysis, on page 1969

Introduction to IAB

IAB identifies applications that you trust to traverse your network without further inspection if performance and flow thresholds are exceeded. For example, if a nightly backup significantly impacts system performance, you can configure thresholds that, if exceeded, trust traffic generated by your backup application. Optionally, you can configure IAB so that, when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

The system implements IAB on traffic allowed by access control rules or the access control policy's default action, before the traffic is subject to deep inspection. A test mode allows you to determine whether thresholds are exceeded and, if so, to identify the application flows that would have been bypassed if you had actually enabled IAB (called *bypass mode*).

The following graphic illustrates the IAB decision-making process:



IAB Options

State

Enables or disables IAB.

Performance Sample Interval

Specifies the time in seconds between IAB performance sampling scans, during which the system collects system performance metrics for comparison to IAB performance thresholds. A value of `0` disables IAB.

Bypassable Applications and Filters

This feature provides two mutually exclusive options:

Applications/Filters
Provides an editor where you can specify bypassable applications and sets of applications (filters). See Application Rule Conditions, on page 939.

All applications including unidentified applications
When an inspection performance threshold is exceeded, trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

Performance and Flow Thresholds

You must configure at least one inspection performance threshold and one flow bypass threshold. When a performance threshold is exceeded, the system examines flow thresholds and, if one threshold is exceeded, trusts the specified traffic. If you enable more than one of either, only one of each must be exceeded.

Inspection performance thresholds provide intrusion inspection performance limits that, if exceeded, trigger the inspection of flow thresholds. IAB does not use inspection performance thresholds set to `0`. You can configure one or more of the following inspection performance thresholds:

Drop Percentage

Average packets dropped as a percentage of total packets, when packets are dropped because of performance overloads caused by expensive intrusion rules, file policies, decompression, and so on. This does not refer to packets dropped by normal configurations such as intrusion rules. Note that specifying an integer greater than 1 activates IAB when the specified percentage of packets is dropped. When you specify `1`, any percentage from 0 through 1 activates IAB. This allows a small number of packets to activate IAB.

Processor Utilization Percentage

Average percentage of processor resources used.

Packet Latency

Average packet latency in microseconds.

Flow Rate

The rate at which the system processes flows, measured as the number of flows per second. Note that this option configures IAB to measure flow *rate*, not flow *count*.

Flow bypass thresholds provide flow limits that, if exceeded, trigger IAB to trust bypassable application traffic in bypass mode or allow application traffic subject to further inspection in test mode. IAB does not use flow bypass thresholds set to `0`. You can configure one or more of the following flow bypass thresholds:

Bytes per Flow

The maximum number of kilobytes a flow can include.

Packets per Flow

The maximum number of packets a flow can include.

Flow Duration

The maximum number of seconds a flow can remain open.

Flow Velocity

The maximum transfer rate in kilobytes per second.

Requirements and Prerequisites for Intelligent Application Bypass

Model Support

Any

Supported Domains

Any

User Roles

- Admin
- Access Admin
- Network Admin

Configuring Intelligent Application Bypass

Caution Not all deployments require IAB, and those that do might use it in a limited fashion. Do not enable IAB unless you have expert knowledge of your network traffic, especially application traffic, and system performance, including the causes of predictable performance issues. Before you run IAB in bypass mode, make sure that trusting the specified traffic does not expose you to risk.

Before you begin

For Classic devices, you must have the Control license.

Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** ( ) next to **Intelligent Application Bypass Settings**.

Step 2 Configure IAB options:

- **State**—Turn IAB **Off** or **On**, or enable IAB in **Test** mode.
- **Performance Sample Interval**—Enter the time in seconds between IAB performance-sampling scans. If you enable IAB, even in test mode, enter a non-zero value. Entering `0` disables IAB.
- **Bypassable Applications and Filters**—Choose from:
  - Click the number of bypassed applications and filters and specify the applications whose traffic you want to bypass; see Configuring Application Conditions and Filters, on page 1789.

- Click **All applications including unidentified applications** so that, when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

- **Inspection Performance Thresholds**—Click **Configure** and enter at least one threshold value.
- **Flow Bypass Thresholds**—Click **Configure** and enter at least one threshold value.

You must specify at least one inspection performance threshold and one flow bypass threshold; both must be exceeded for IAB to trust traffic. If you enter more than one threshold of each type, only one of each type must be exceeded. For detailed information, see IAB Options, on page 1966.

Step 3 Click **OK** to save IAB settings.

Step 4 Click **Save** to save the policy.

What to do next

- Because some packets must be allowed to pass before an application can be detected, you must configure your system to examine those packets.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

IAB Logging and Analysis

IAB forces an end-of-connection event that logs bypassed flows and flows that would have been bypassed, regardless of whether you have enabled connection logging. Connection events indicate flows that are bypassed in bypass mode or that would have been bypassed in test mode. Custom dashboard widgets and reports based on connection events can display long-term statistics for bypassed and would-have-bypassed flows.

IAB Connection Events

Action

When **Reason** includes `Intelligent App Bypass`:

`Allow` -

indicates that the applied IAB configuration was in test mode and traffic for the application specified by **Application Protocol** remains available for inspection.

`Trust` -

indicates that the applied IAB configuration was in bypass mode and traffic for the application specified by **Application Protocol** has been trusted to traverse the network without further inspection.

Reason

`Intelligent App Bypass` indicates that IAB triggered the event in bypass or test mode.

Application Protocol

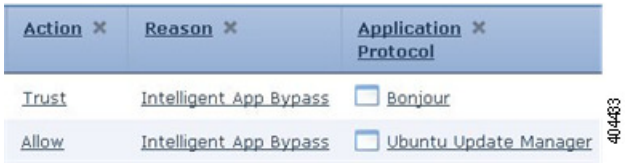
This field displays the application protocol that triggered the event.

Example

In the following truncated graphic, some fields are omitted. The graphic shows the **Action**, **Reason**, and **Application Protocol** fields for two connection events resulting from different IAB settings in two separate access control policies.

For the first event, the `Trust` action indicates that IAB was enabled in bypass mode and Bonjour protocol traffic was trusted to pass without further inspection.

For the second event, the `Allow` action indicates that IAB was enabled in test mode, so Ubuntu Update Manager traffic was subject to further inspection but would have been bypassed if IAB had been in bypass mode.



Example

In the following truncated graphic, some fields are omitted. The flow in the second event was both bypassed (**Action**: `Trust`; **Reason**: `Intelligent App Bypass`) and inspected by an intrusion rule (**Reason**: `Intrusion Monitor`). The `Intrusion Monitor` reason indicates that an intrusion rule set to **Generate Events** detected but did not block an exploit during the connection. In the example, this happened before the application was detected. After the application was detected, IAB recognized the application as bypassable and trusted the flow.

IAB Custom Dashboard Widgets

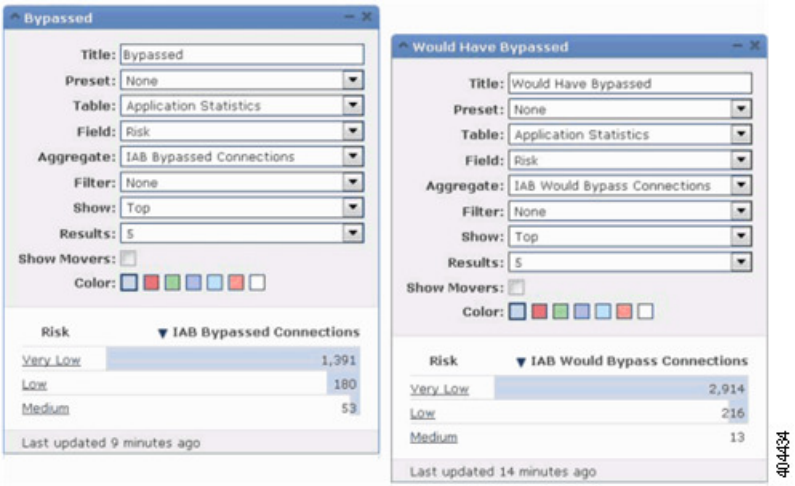
You can create a Custom Analysis dashboard widget to display long-term IAB statistics based on connection events. Specify the following when creating the widget:

- **Preset**: `None`
- **Table**: `Application Statistics`
- **Field**: any
- **Aggregate**: either of:
  - `IAB Bypassed Connections`
  - `IAB Would Bypass Connections`
- **Filter**: any

Examples

In the following Custom Analysis dashboard widget examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy. .



IAB Custom Reports

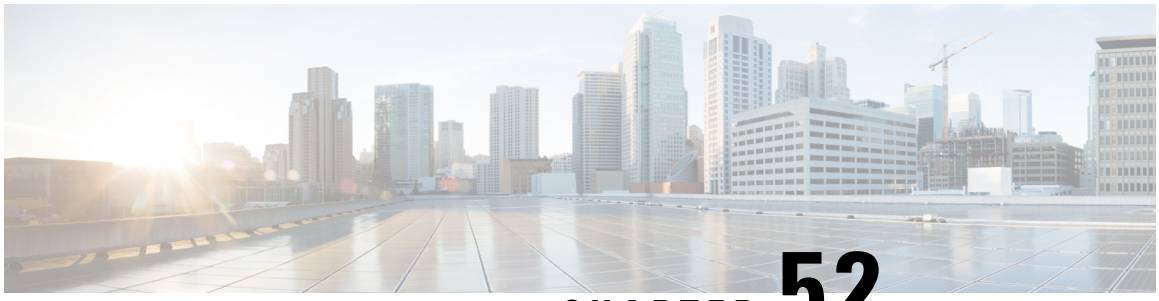
You can create a custom report to display long-term IAB statistics based on connection events. Specify the following when creating the report:

- **Table**: `Application Statistics`
- **Preset**: `None`
- **Filter**: any
- **X-Axis**: any
- **Y-Axis**: either of:
  - `IAB Bypassed Connections`
  - `IAB Would Bypass Connections`

Examples

The following graphic shows two abbreviated report examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.



CHAPTER 52

Content Restriction

The following topics describe how to configure access control policies to use content restriction features:

- About Content Restriction, on page 1973
- Requirements and Prerequisites for Content Restriction, on page 1974
- Guidelines and Limitations for Content Restriction, on page 1975
- Using Access Control Rules to Enforce Content Restriction, on page 1975
- Using a DNS Sinkhole to Enforce Content Restriction, on page 1976

About Content Restriction

Major search engines and content delivery services provide features that allow you to restrict search results and website content. For example, schools use content restriction features to comply with the Children's Internet Protection Act (CIPA).

When implemented by search engines and content delivery services, you can enforce content restriction features only for individual browsers or users. The system allows you to extend these features to your entire network.

The system allows you to enforce:

- *Safe Search*—Supported in many major search engines, this service filters out explicit and adult-oriented content that business, government, and education environments classify as objectionable. The system does not restrict a user's ability to access the home pages for supported search engines.

You can use two methods to configure the system to enforce these features:

Method: Access Control Rules
: Content restriction features communicate the restricted status of a search or content query via an element in the request URI, an associated cookie, or a custom HTTP header element. You can configure access control rules to modify these elements as the system processes traffic.

Method: DNS Sinkhole
: For Google searches, you can configure the system to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes filters for Safe Search.

The table below describes the differences between these enforcement methods.

Table 107: Comparison of Content Restriction Methods

Attribute	Method: Access Control Rules	Method: DNS Sinkhole
Supported devices	Any	Secure Firewall Threat Defense only
Search engines supported	Any tagged `safesearch supported` in the **Applications** tab of the rule editor	Google only
YouTube Restricted Mode supported	Yes	Yes
SSL policy required	Yes	No
Hosts must be using IPv4	No	Yes
Connection event logging	Yes	Yes

When determining which method to use, consider the following limitations:

- The access control rules method requires an SSL policy, which impacts performance.
- The Google SafeSearch VIP supports IPv4 traffic only. If you configure a DNS sinkhole to manage Google searches, any hosts on the affected network must be using IPv4.

The system logs different values for the **Reason** field in connection events, depending on the method:

- Access Control Rules—`Content Restriction`
- DNS Sinkhole—`DNS Block`

Requirements and Prerequisites for Content Restriction

Model Support

Any, or as indicated in the procedure.

Supported Domains

Any

User Roles

- Admin
- Access Admin
- Network Admin

Guidelines and Limitations for Content Restriction

- Safe search is supported by Snort 2 only.
- YouTube and Google do not support the YouTubeEDU feature that was implemented in access control rules. Please remove any access control rules that configure YouTubeEDU as they are not truly functional. You can also remove associated decryption rules.

Using Access Control Rules to Enforce Content Restriction

The following procedure explains how to configure access control rules to restrict content."

Note When safe search is enabled in an access control rule, inline normalization is enabled automatically.

Procedure

Step 1 Create a decryption policy.

Step 2 Add rules for handling Safe Search traffic:

- Choose **Decrypt - Resign** as the **Action** for the rules.
- In **Applications**, add selections to the **Selected Applications and Filters** list:
  - Safe Search—Add the `Category: search engine` filter.

Step 3 Set rule positions for the rules you added. Click and drag, or use the right-click menu to cut and paste.

Step 4 Create or edit an access control policy, and associate the decryption policy with the access control policy.

For more information, see Associating Other Policies with Access Control, on page 1762.

Step 5 In the access control policy, add rules for handling Safe Search traffic:

- Choose **Allow** as the **Action** for the rules.
- In **Applications**, click the icon for **Safe search** ( ) and set related options.
  - Safe Search Options for Access Control Rules, on page 1976
- In **Applications**, refine application selections in the **Selected Applications and Filters** list.

  In most cases, enabling Safe Search populates the **Selected Applications and Filters** list with the appropriate values. The system does not automatically populate the list if a Safe Search application is already present in the list when you enable the feature. If applications do not populate as expected, manually add them as follows:
  - Safe Search—Add the `Category: search engine` filter.

For more information, see Configuring Application Conditions and Filters, on page 1789.

Step 6 Set rule positions for the access control rules you added. Click and drag, or use the right-click menu to cut and paste.

Step 7 Configure the HTTP response page that the system displays when it blocks restricted content; see Choosing HTTP Response Pages, on page 1875.

Step 8 Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Safe Search Options for Access Control Rules

The system supports Safe Search filtering for specific search engines only. For a list of supported search engines, see applications tagged `safesearch supported` in the **Applications** tab of the access control rule editor. For a list of unsupported search engines, see applications tagged `safesearch unsupported`.

When enabling Safe Search for an access control rule, set the following parameters:

Enable Safe Search
Enables Safe Search filtering for traffic that matches this rule.

Unsupported Search Traffic
Specifies the action you want the system to take when it processes traffic from unsupported search engines. If you choose **Block** or **Block with Reset**, you must also configure the HTTP response page that the system displays when it blocks restricted content; see Choosing HTTP Response Pages, on page 1875.

Using a DNS Sinkhole to Enforce Content Restriction

Typically, a DNS sinkhole directs traffic away from a particular target. This procedure describes how to configure a DNS sinkhole to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes content filters on Google and YouTube search results.

Because Google SafeSearch uses a single IPv4 address for the VIP, hosts must use IPv4 addressing.

Caution If your network includes proxy servers, this content restriction method is not effective unless you position your Firewall Threat Defense devices between the proxy servers and the Internet.

This procedure enforces content restriction for Google searches only. It does not apply to any other search engine.

Before you begin

This procedure applies to Firewall Threat Defense only, and requires the IPS license.

Procedure

Step 1 Obtain a list of supported Google domains via the following URL: https://www.google.com/supported_domains.

Step 2 Create a custom DNS list on your local computer, and add the following entries:

- To enforce Google SafeSearch, add an entry for each supported Google domain.
- To enforce YouTube Restricted Mode, add a "youtube.com" entry.

The custom DNS list must be in text file (.txt) format. Each line of the text file must specify an individual domain name, stripped of any leading periods. For example, the supported domain ".google.com" must appear as "google.com".

Step 3 Upload the custom DNS list to the Firewall Management Center; see Uploading New Security Intelligence Lists to the Secure Firewall Management Center, on page 1439.

Step 4 Determine the IPv4 address for the Google SafeSearch VIP. For example, run `nslookup` on forcesafesearch.google.com.

Step 5 Create a sinkhole object for the SafeSearch VIP; see Creating Sinkhole Objects, on page 1440.

Use the following values for this object:

- IPv4 Address—Enter the SafeSearch VIP address.
- IPv6 Address—Enter the IPv6 loopback address (`::1`).
- Log Connections to Sinkhole—Click Log Connections.
- Type—Choose **None**.

Step 6 Create a basic DNS policy; see Creating Basic DNS Policies, on page 1900.

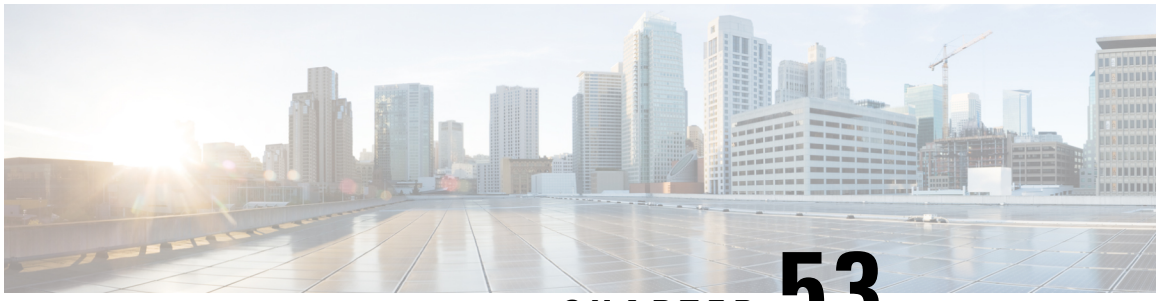
Step 7 Add a DNS rule for the sinkhole; see Creating and Editing DNS Rules, on page 1902.

For this rule:

- Check the **Enabled** check box.
- Choose `Sinkhole` from the **Action** drop-down list.
- Choose the sinkhole object you created from the **Sinkhole** drop-down list.
- Add the custom DNS list you created to the **Selected Items** list on **DNS**.
- (Optional) Choose a network in **Networks** to limit content restriction to specific users. For example, if you want to limit content restriction to student users, assign students to a different subnet than faculty, and specify that subnet in this rule.

Step 8 Associate the DNS policy with an access control policy; see Associating Other Policies with Access Control, on page 1762.

Step 9 Deploy configuration changes; see Deploy Configuration Changes, on page 259.



CHAPTER 53

Zero Trust Access

The following topics provide more information about Clientless Zero Trust Access, Universal Zero Trust Network Access; and how to configure and deploy them.

- About Clientless and Universal Zero Trust Network Access, on page 1979
- Clientless Zero Trust Access, on page 1979
- Overview of Universal Zero Trust Network Access, on page 1994
- History for Zero Trust Access, on page 2007

About Clientless and Universal Zero Trust Network Access

Zero Trust Access (ZTNA) is a general name for process that protect internal resources with identity-based access (including user trust and posture), and can provide intrusion protection, file, and malware protection.

Zero Trust Access is further divided into the following:

- *Clientless* ZTNA enables you to authenticate and authorize access to protected web based resources and applications from inside (on-premises) or outside (remote) the network using an external Security Assertion Markup Language (SAML) identity provider (IdP) policy. Use clientless ZTNA for remote users.
- *Universal* ZTNA provides identity-based network protection and can be used with both remote and on-premises users. On-premises users access a trusted network using a Secure Firewall Threat Defense while remote users install an application like Cisco Secure Client.

Clientless Zero Trust Access

Clientless Zero Trust AccessZero Trust Access is based on Zero Trust Network Access (ZTNA) principles. ZTNA is a zero trust security model that eliminates implicit trust. The model grants the least privilege access after verifying the user, the context of the request, and after analyzing the risk if access is granted.

Clientless Zero Trust AccessZero Trust Access enables you to authenticate and authorize access to protected web based resources and applications from inside (on-premises) or outside (remote) the network using an external Security Assertion Markup Language (SAML) identity provider (IdP) policy.

The features are:

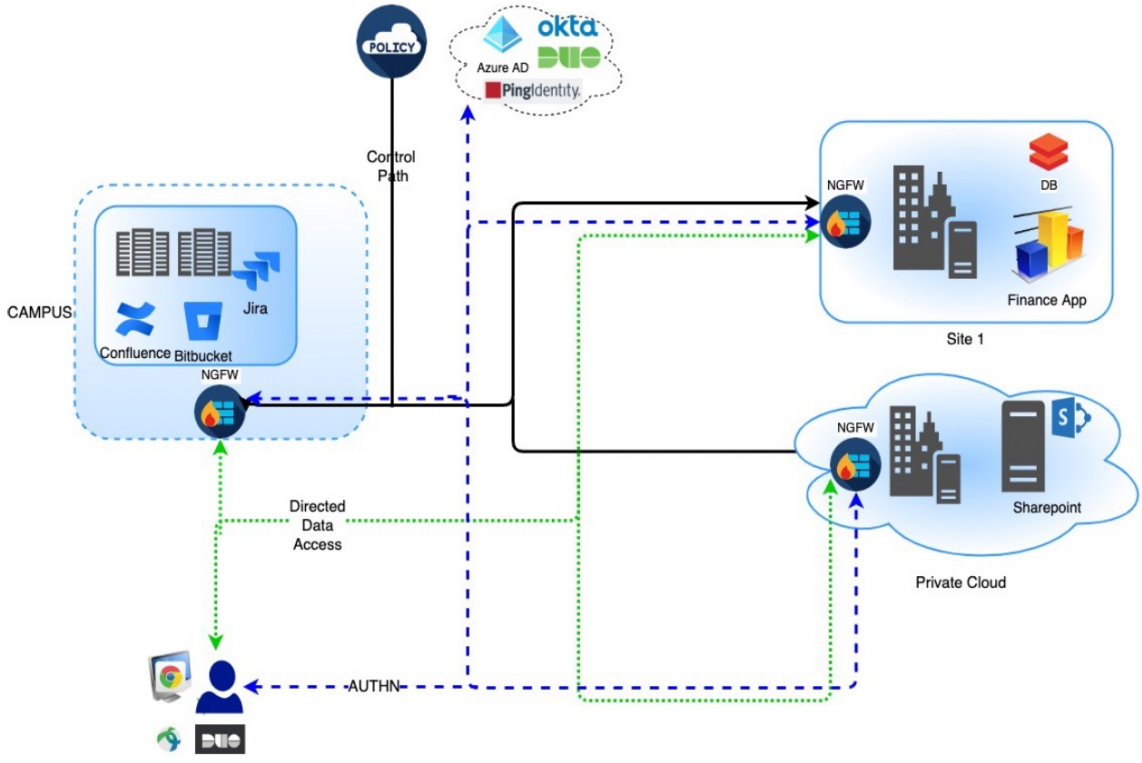
- Supports multiple SAML-based identity providers such as Duo, Azure Active Directory (Azure AD), Okta, and other identity providers.

- Client applications such as Cisco Secure Client are not required on the endpoint (client devices) for secure access.
- Access and authentication is through the browser.
- Supports only TLS web applications.
- Client device posture is supported through agents such as Duo Health, using which the posture of the device can be evaluated against a policy in Duo, and access can be provided based on the same. The same functionality can be performed in conjunction with third-party identity providers that support posture evaluation with their agents such as Okta or PingID.
- Supports HTTP-Redirect SAML binding.
- Supports application groups that make it easier to enable zero trust accessclientless zero trust access protection on a set of applications.
- Leverages threat defense intrusion and malware protection on zero trust application traffic.

You can use the Secure Firewall Management Center web interface to create a Zero Trust Application Policy that allows you to define private applications and assign threat policies to them. The policy is application specific where the administrator decides the inspection levels based on the threat perception for that application.

How Threat Defense Works with Zero Trust Access

Figure 441: Threat Defense Deployment



1. Using a browser, a remote or on-prem user sends a HTTPS request to connect to an application from an endpoint.
2. The HTTPS request is intercepted by the firewall that protects the application.
3. The firewall redirects the user to application's configured IdP for authentication.

Note In the figure, each firewall protects a set of web applications. The user can directly access the applications behind the firewall after authentication and authorization.

4. After the authentication and authorization process is complete, the firewall allows the user to access the application.

Why Use Zero Trust Access?

Zero Trust Access leverages the existing deployment of threat defense as an enforcement point to application access. It allows for segmented access to a private application with per application authorization and per application tunnel for remote and on-premises users.

The feature hides the network from users and allows users to only access applications they are authorized for. Authorization for one application in the network does not give an implicit authorization for other applications on the network, thereby reducing the attack surface significantly. In other words, every access to an application must be explicitly authorized.

Adding the zero trust access functionality to threat defense enables migration to a more secure access model without having to install or manage yet another device in the network.

The feature is easy to manage as it does not require a client and is per application access.

Components of a Zero Trust Access Configuration

A new configuration consists of a Zero Trust Application Policy, Application Group, and Applications.

- **Zero Trust Application Policy**— Consists of application groups, and grouped or ungrouped applications. Security Zones and Security Controls settings are associated at a global level for all the ungrouped applications and group of applications.

  A global port pool is assigned to the policy, by default. A unique port is automatically assigned from this pool to each private application that is configured.

  Zero Trust Application policy consists of application groups, and grouped or ungrouped applications.

- **Application Groups**—Consists of a logical group of applications that share SAML authentication settings and can optionally share Security Zones and Security Controls settings.

  Application Groups inherit the Security Zones and Security Controls settings from the global policy and can override the values.

  When an Application Group is created, the same SAML IdP configuration can be used for authenticating multiple applications. Applications that are part of an Application Group inherit the Application Group's SAML configuration. This eliminates the need to configure the SAML settings for each application. After the Application Group is created, new applications can be added to it without configuring the IdP for it.

When an end user tries to access an Application that is part of group, the user is authenticated to the Application Group for the first time. When the user tries to access other applications that are part of the same Application Group, the user is provided access without being redirected again to the IdP for authentication. This prevents overloading the IdP with requests for application access and optimizes the usage of the IdP if a limit is enabled.

- **Applications**—There are two types:
  - **Ungrouped Applications**— Are standalone applications. SAML settings must be configured for every application. The applications inherit the Security Zones and Security Controls settings from the global policy and can be overridden by the application.
  - **Grouped Applications**— Are multiple applications that are grouped under an Application Group. The SAML settings are inherited from the Application Group and cannot be overridden. However, the Security Zones and Security Controls settings can be overridden for each application.

The following certificates are required for the configuration:

- **Identity Certificate**—This certificate is used by Firewall Threat Defense to masquerade as the applications.Firewall Threat Defense behaves as a SAML Service Provider (SP). This certificate must be a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of the private applications. It is a common certificate for all applications protected by Firewall Threat Defense.
- **IdP Certificate**—The IdP provides a certificate for each defined Application or Application Group. This certificate must be configured so that Firewall Threat Defense can verify the IDP's signature on incoming SAML assertions.

Note IdP certificates are commonly included within the metadata file; otherwise, users are required to have the IdP certificate readily available during the configuration of applications.

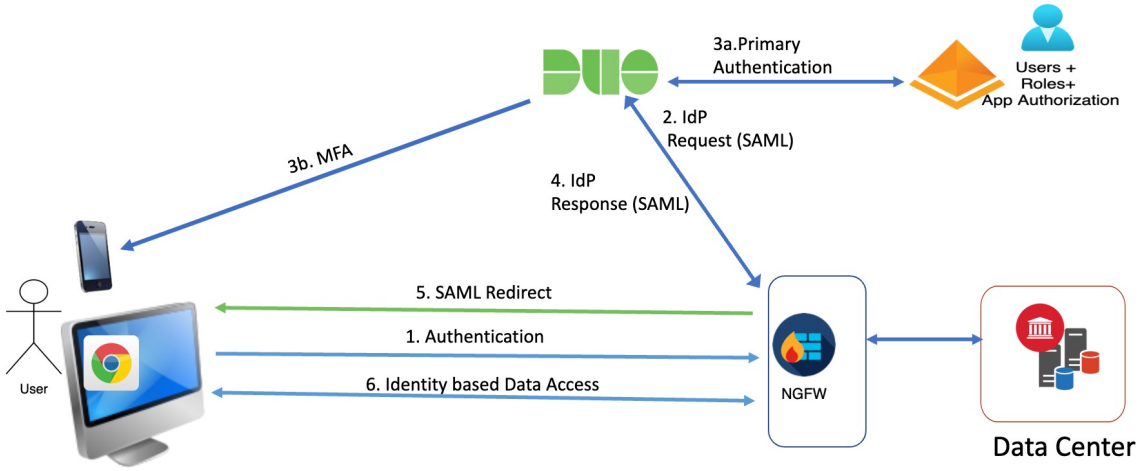
- **Application Certificate**—The encrypted traffic from user to the application is decrypted by Firewall Threat Defense using this certificate for the purpose of inspection.

Note This certificate is required to verify the cookies in the header to authorize connections, even if we are not conducting an IPS/Malware inspection.

Zero Trust Access Workflow

This figure depicts the Zero Trust Access workflow.

Figure 442: Zero Trust Access Workflow



The workflow is as follows:

1. User types the application URL in the browser.
   - If the HTTPS request is valid, the user is redirected to the mapped port (Step 6).
   - If the HTTPS request is invalid, the user is sent for authentication per application (Step 2).
2. The user is redirected to the configured identity provider (IdP).
3. **a.** The user is redirected to the configured primary authentication source.
   b. The user is challenged with the configured secondary multi-factor authentication, if any.
4. The IdP sends a SAML response to threat defense. The user ID and other necessary parameters are retrieved from the SAML response through the browser.
5. The user is redirected to the application.
6. The user is allowed access to the application after validation is successful.

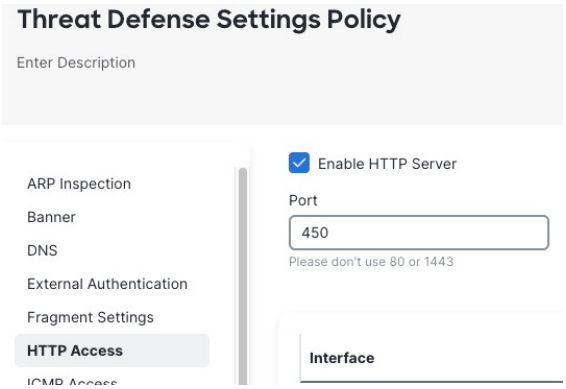
Limitations for Zero Trust Network Access

- Supports only TLS-enabled web applications. All traffic must be decrypted.
- Supports only SAML identity providers.
- Supports IPv6; however, you can use only homogeneous network address translations (NAT) scenarios such as NAT66 and NAT44.

  NAT64, and NAT46 scenarios are not supported.
- Zero trust network access is available on Firewall Threat Defense only if Snort 3 is enabled.
- By default, the Firewall Threat Defense device uses port 443 for secure communications. Because this is the same port used by TLS-enabled applications likely to be configured for zero trust network access, you must change the device's HTTP server port.

Go to **Devices** > **Platform Settings**, then edit the Threat Defense Settings policy for the device, click **HTTP Access**, select the **Enable HTTP Server** check box, and enter a port other than 443 in the field. When you're finished, click **Save** in the upper right corner of the page.

The following figure shows an example.



- All hyperlinks in protected web applications must have a relative path and are not supported on individual mode clusters.
- Protected web applications running on a virtual host or behind internal load balancers must use the same external and internal URL.
- Not supported on applications with strict HTTP Host Header validation enabled.
- If the application server hosts multiple applications and serves content based on the Server Name Indication (SNI) header in the TLS Client Hello, the external URL of the zero trust application configuration must match the SNI of that specific application.

Prerequisites for Zero Trust Application Policy

Prerequisite Type	Description
Licensing	• Smart license account with export-controlled features • (Optional) IPS and Threat licenses—It is required if security controls are used.
Configurations	Create a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of private applications. For more information, see Adding Certificate Enrollment Objects, on page 1414.
	Create a security zone through which access to private applications are regulated. For more information, see Create Security Zone and Interface Group Objects, on page 777.

Manage Zero Trust Application Policies

You can create, edit, and delete zero trust application policies.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Manage the zero trust access policies:

- Create—Click **New Policy**. See Create a Zero Trust Application Policy, on page 1985
- Edit—Click **Edit** (). See Edit a Zero Trust Application Policy, on page 1990
- Report—Click **Report** ().
- Delete—Click **Delete** ().

Step 3 Click **Save**.

What to do next

Ensure that there are no warnings before you deploy the configuration to threat defense. To deploy configuration changes, see Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create a Zero Trust Application Policy

This tasks configures a Zero Trust Application Policy.

Before you begin

Ensure that you complete all the prerequisites listed in Prerequisites for Zero Trust Application Policy, on page 1984.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**.

Step 2 Click **Add Policy**.

Step 3 In the **General** section, enter the policy name in the **Name** field. The description field is optional.

Step 4 Enter a domain name in the **Domain Name** field.

Ensure that the domain name is added to the DNS. The domain name resolves to the Firewall Threat Defense gateway interface from where the application is accessed. The domain name is used to generate the ACS URL for all private applications in an Application Group.

Step 5 Choose an existing certificate from the **Identity Certificate** drop-down list.

Click the **Add** (+) icon to configure a certificate enrollment object. For more information, see Adding Certificate Enrollment Objects, on page 1414.

Step 6 Choose a security zone from the **Security Zones** drop-down list.

Click the **Add** (+) icon to add a new security zone.

To add security zones, see Create Security Zone and Interface Group Objects, on page 777.

Step 7 In the **Global Port Pool** section, a default port range is displayed. Modify, if required. Port values range from 1024 to 65535. A unique port from this pool is assigned to each private application.

Note
This port range should avoid any conflicts with the existing NAT range.

Step 8 (Optional) In the **Security Controls** section, you can add an Intrusion or Malware and File policy:

- **Intrusion Policy**—Choose a default policy from the drop-down list or click the **Add** (+) icon to create a new custom intrusion policy. For more information, see Creating a Custom Snort 3 Intrusion Policy topic in the latest version of the Cisco Secure Firewall Management Center Snort 3 Configuration Guide.
- **Variable Set**—Choose a default variable set from the drop-down list or click the **Add** (+) icon to create a new variable set. For more information, see Creating Variable Sets, on page 1457.

  Note
  To use variable sets, you must have the Secure Firewall Threat Defense IPS license for your managed devices.

- **Malware and File Policy**—Choose an existing policy from the drop-down list. Click the **Add** (+) icon to create a new malware and file policy. For more information, see Managing File Policies, on page 2232.

Step 9 Click **Save** to save the policy.

What to do next

1. Create an Application Group. See Create an Application Group, on page 1986.
2. Create an Application. See Create an Application, on page 1988.
3. Associate a Zero Trust Application Policy with a device. See Set Targeted Devices for Zero Trust Access Policy, on page 1989
4. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an Application Group

Before you begin

Create a Zero Trust Application Policy, on page 1985

Procedure

Step 1 Click **Add Application Group**.

Step 2 In the **Application Group** section, type the name in the **Name** field and click **Next**.

Step 3 In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the values of the **Entity ID** and **Assertion Consumer Service (ACS) URL** fields or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

Step 4 In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

- **XML File Upload**—Choose a file or drag and drop the XML file.

  The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

- **Manual Configuration**—Perform these steps:
  - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
  - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
  - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

    Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add Certificate Enrollment, on page 1416.

- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

Step 5 In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**.

The re-authentication interval allows you to provide a value that determines when a user must authenticate again.

Step 6 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy. You can override these settings. Click **Next**.

Step 7 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 8 Click **Save**.

The Application Group is created and is displayed on the Zero Trust Application page.

What to do next

1. Create an Application, on page 1988.
2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an Application

Use this task to create a Grouped or Ungrouped Application.

Before you begin

1. Create a Zero Trust Application Policy, on page 1985.
2. Create an Application Group, on page 1986 (required only for Grouped Applications).

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Add Application**.

Step 4 In the **Application Settings** section, complete the following fields.

- **Application Name**—Enter the application name.
- **External URL**—Enter the URL that is used by the user to access the application.
- **Application URL**—By default, the external URL is used as the Application URL. Uncheck the **Use External URL as Application URL** check box to specify a different URL.

  If Threat Defense uses an internal DNS, the Application URL must match an entry within that DNS to ensure it resolves to the application.
- **Application Certificate**—Choose the certificate for the private application. Click the **Add** (+) icon to configure an internal certificate object. For more information, see Adding Internal Certificate Objects, on page 1412.
- **IPv4 Source Translation**—Choose the source network for NAT from the list. Click **Add** (+) to create a network object. For more information, see Network, on page 1401.

  This Network Object or Object Group is used to translate a public network source IPv4 address of an incoming request to a routable IPv4 address inside the corporate network.

  Note
  Only object or object groups of type Host or Range are supported.
- **Application Group**—Choose the Application Group from the drop-down list. See Create an Application Group, on page 1986.

  Note
  This field is not applicable for an ungrouped application.

Step 5 Click **Next**.

Step 6 Depending on the type of application:

- For a Grouped Application, the **SAML Service Provider (SP) Metadata**, **SAML Identity Provider (IdP) Metadata** , and **Re-authentication Interval** are inherited from the Application Group and do not need to be configured by the user.

- For an Ungrouped Application, perform these steps:

  a. In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the **Entity ID**, **Assertion Consumer Service (ACS) URL** of the IdP, or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

  b. In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

  - **XML File Upload**—Choose a file or drag and drop the XML file.

    The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

  - **Manual Configuration**—Perform these steps:

    - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
    - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
    - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

      Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add Certificate Enrollment, on page 1416.

  - **Configure Later**—If you do not have the IdP metadata, you can configure it later.

  Click **Next**.

  c. In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**. The reauthentication interval allows you to provide a value that determines when a user must authenticate again.

Step 7 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy or application group. You can override these settings. Click **Next**.

Step 8 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 9 Click **Save**.

The application is listed on the Zero Trust Application page and enabled by default.

What to do next

1. Set Targeted Devices for Zero Trust Access Policy, on page 1989.
2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Set Targeted Devices for Zero Trust Access Policy

Each Zero Trust Application policy can target multiple devices; each device can have one deployed policy at a time.

Before you begin

1. Create a Zero Trust Application Policy, on page 1985.
2. Create an Application Group, on page 1986.
3. Create an Application, on page 1988.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Targeted Devices**.

Step 4 Choose the devices where you want to deploy the policy using any one of the methods:

- Choose a device in the **Available Devices** list and click >> or the **Add** ( ) icon.
- To remove a device from the **Selected Devices** list, choose a device and click << or the **Delete** ( ) icon.

Step 5 Click **Apply** to save policy assignments.

Step 6 Click **Save** to save the policy.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Edit a Zero Trust Application Policy

You can edit the settings of a Zero Trust Application Policy, Application Group, or Application.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Click **Edit** (✎) next to the Zero Trust Application Policy you want to edit.

Step 3 Edit your Zero Trust Application Policy.

You can change the following settings or perform these actions:

- Name and Description—Click **Edit** (✎) next to the policy name, make your changes, and click **Apply**.
- To modify the policy settings:
  - Click **Settings**

- Modify the settings as required.

  Important
  Editing the domain name for the SAML ACS URL interrupts application access.

- Click **Save**.

- To modify the Application Group settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application Group you want to edit.
  - In each section, click **Edit** to modify the settings, as required

    Important
    Editing the Application Group name interrupts application access.

  - Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.

- To modify the Application settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application you want to edit.
  - In each section, click **Edit** to modify the settings, as required.

    Important
    Editing the Application name interrupts application access.

  - Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.

- To enable, disable, or delete multiple Applications, choose the Applications, click the required bulk action, and click **Save**.

  Note
  These actions are also available in the right-click menu.

  - To enable all Applications, click **Bulk Actions** > **Enable**.
  - To disable all Applications, click **Bulk Actions** > **Disable**.
  - To delete all Applications, click **Bulk Actions** > **Delete**.

- Click **Return to Zero Trust Application** to return to the policy page.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Monitor Zero Trust Sessions

Connection Events

After a Zero Trust Application Policy is deployed, new fields are available. To add the fields to the table view:

1. Choose **Analysis** > **Connections**.
2. Click the **Table View of Connection Events** tab.
3. In the table view of events, multiple fields are hidden by default. To change the fields that are displayed, click the **x** icon in any column name to display a field selector.
4. Select the following fields:
   - **Authentication Source**
   - **Zero Trust Application**
   - **Zero Trust Application Group**
   - **Zero Trust Application Host**
   - **Zero Trust Application Policy**
   - **Zero Trust Origin User**
   - **Zero Trust Proxy**
   - **Zero Trust Rule**
   - **Zero Trust Status**
   - **Zero Trust Tunnel ID**
5. Click **Apply**.

See Connection and Security-Related Connection Events in the Secure Firewall Management Center Administration Guide for more information on the connection events.

Zero Trust Dashboard

The Zero Trust dashboard allows you to monitor real-time data from active zero trust sessions on the devices.

The Zero Trust dashboard provides a summary of the top zero trust applications and zero trust users that are managed by the management center. Choose **Overview** > **Dashboards** > **Zero Trust** to access the dashboard.

The dashboard has the following widgets:

- Top Zero Trust Applications
- Top Zero Trust Users

CLI Commands

Log in to the device CLI and use the following commands:

CLI Command	Description
show running-config zero-trust	To view the running configuration for a zero trust configuration.
show running-config zero-trust-hybrid	To view the running configuration for a universal zero trust configuration.
show zero-trust	To display the run-time zero trust statistics and session information.
show cluster zero-trust	To display the summary of zero trust statistics across nodes in a cluster.
clear zero-trust	To clear zero trust sessions and statistics.
show counters protocol zero_trust	To view the counters that are hit for zero trust flow.

Diagnostics Tool

The diagnostics tool facilitates the troubleshooting process by detecting possible issues with zero trust configurations. The diagnostics can be classified into two types:

- **Application-specific diagnostics** are used to detect issues such as:
  - DNS-related issues
  - Misconfigurations such as socket not open, and issues with classification and NAT rules.
  - Issues with deployment of zero trust policy or SSL rules
  - Issues with source NAT issues and exhaustion of PAT pool
- **General diagnostics** are used to detect issues such as:
  - Strong cipher license not enabled
  - Invalid application certificate
  - SAML-related issues
  - Home agent and cluster bulk sync issues

To run the diagnostic tool:

1. Click Diagnostics ( ) next to the zero trust application that you want to troubleshoot. The **Diagnostics** dialog box appears.
2. Choose the device from the **Select Device** drop-down list and click **Run**. A report is generated in the **Reports** tab after the diagnostic process is complete.
3. To view, copy, or download the logs, click the **Logs** tab.

Overview of Universal Zero Trust Network Access

Universal Zero Trust Network Access (universal ZTNA) enables administrators to specifically allow access to internal network resources according to user identity including user trust and posture, without granting access to the entire network as with Remote Access VPN. Universal ZTNA is a client-based ZTNA solution that enables users to securely access internal resources and applications regardless of their location, whether remote or on-premises.

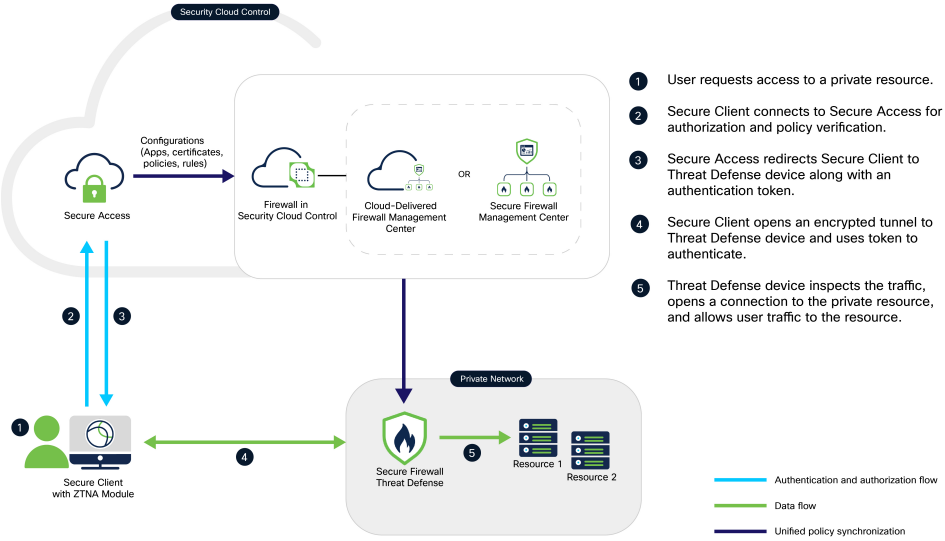
Because universal ZTNA does not assume that access granted to one application implicitly authorizes access to other applications, the network attack surface is reduced.

Universal ZTNA ensures least-privileged, per-application, per-user access with strong authentication, posture validation, and comprehensive traffic inspection. It secures applications effectively across hybrid environments.

Components of Universal ZTNA

A new configuration of universal ZTNA consists of Security Cloud Control Firewall Management (formerly called Cisco Defense Orchestrator), and Secure Access, both provisioned on the Security Cloud Control platform. Security Cloud Control Firewall Management manages the Firewall Threat Defense devices through the Secure Firewall Management Center.

Figure 443: Components of Universal ZTNA



- **Security Cloud Control Firewall Management**: Manages the configuration and deployment of universal ZTNA policies to the Firewall Threat Defense devices. The Threat Defense devices protect on-premises resources by enforcing universal ZTNA policies. Threat Defense inspects traffic and enforces intrusion prevention system (IPS), file, and malware policies on the traffic.
- **Secure Access**: Secure Access defines the access policies, posture, and security profiles for the user. It enforces the policies for user traffic through the cloud.
- **Security Cloud Control platform**: Security Cloud Control provides a unified secure management plane for both Secure Access and Firewall, simplifying the administration of universal ZTNA policies across them.

- **Secure Client**: The Secure Client is installed on the end user's device. It acts as the enforcement point that intercepts connection requests to protected internal resources, enabling secure, identity-based access.

The following sections describe how to enable universal ZTNA on a Threat Defense device. For the complete configuration of universal ZTNA, refer to the *Universal Zero Trust Network Access Configuration Guide*.

How Threat Defense Works with Universal ZTNA

A universal ZTNA-enabled Firewall Threat Defense device is a critical enforcement point that protects private resources by integrating zero trust principles with firewall capabilities. Here's how it operates to secure private resources:

- **Enforces access and Validates Policy**: A Threat Defense device intercepts all access requests to private resources. It enforces granular, context-aware access policies that verify user identity, device posture, and contextual factors before granting access. Only requests that meet the least-privilege criteria are allowed, blocking the unauthorized attempts to access resources.
- **Establishes a Secure Tunnel to the Resource**: After validating the access policy, the Threat Defense device establishes a secure, encrypted tunnel between the user's device and the private resource. This tunnel ensures that private resources are isolated from direct network exposure.
- **Inspects Traffic**: Threat Defense device continuously inspects the traffic and blocks threats before they reach the resources. The device applies the intrusion prevention system, file, and malware detection capabilities to detect and block the threats.
- **Microsegments and Prevents Lateral Movement**: The device enforces microsegmentation by restricting traffic flows to only the authorized resources. This containment prevents lateral movement within the network, limiting the impact of any potential breach.

Prerequisites for Universal Zero Trust Network Access

This topic discusses requirements and guidelines for Universal Zero Trust Network Access (universal ZTNA).

Licensing Requirements

- Secure Firewall Management Center requires a smart license account with export-controlled features. It does not function in evaluation mode for universal ZTNA.

  Secure Firewall Threat Defense devices require an IPS license if Intrusion policy is configured. If Malware policies are configured, the devices require IPS and Malware Defense licenses. For more information, refer to the "Licenses" section in the *Cisco Secure Firewall Management Center Administration Guide*.

- Secure Access requires a subscription of Cisco Secure Private Access Essentials or Advantage.

Device Requirements

- All Secure Firewall Management Center and Secure Firewall Threat Defense devices must be running Version 7.7.10 or later.
- All Secure Firewall Threat Defense devices must be configured for routed mode; transparent mode is not supported.

- In Security Cloud Control, when you are configuring universal zero trust access for a device, ensure that the Enrollment Type for the device identity certificate is an object that is created using the PKCS12 file format. No other certificate type is supported. If necessary, you can also create a new certificate object from Security Cloud Control, which supports the PKCS12 format. See Configure Security Devices.
- Configure the Domain Name System (DNS) to resolve Fully Qualified Domain Name (FQDN) of private resources. Use the Platform Settings menu on the Secure Firewall to configure the DNS. See Interface and Device Settings.
- High Availability (HA) devices *are* supported; they are displayed as one entity.
- Secure Client (with ZTNA module enabled) Version 5.1.10 and later is supported.

  The client must be running in a platform that supports Trusted Platform Module (TPM), such as Windows 11.

Guidelines on Certificate Types

- **User Device Identity Certificate**: Secure Client, which is zero trust access enabled, presents the user identity certificate during the Mutual Transport Layer Security (mTLS) session with Secure Access and Firewall Threat Defense to request access to private resources.
- **Firewall Threat Defense Device Certificate**: Threat Defense devices that are universal ZTNA-enabled use device certificates to establish secure mTLS connections with the Secure Client and Secure Access. Ensure that the device identity certificate is of type PKCS12.

  If you have already enrolled a manual certificate for the device, first export it to the PKCS12 format using the **Devices** > **Certificates** > **Export Certificate** menu on Firewall Management Center. Use the exported PKCS12 file to create a new PKCS12 certificate enrollment object.
- **Decryption Certificate**: (Optional) To decrypt the traffic that is sent to private resources, enable **Decryption** for the resources in Secure Access and provide the server certificate and key. We recommend that you use a certificate that is signed by a publicly recognized certificate authority (CA).

Supported Devices

Both on-premises Firewall Management Center and cloud-delivered Firewall Management Center can be configured to manage the devices.

Only devices that have 16 cores or more are supported. Such models of Secure Firewall Threat Defense are:

- 1150
- 3105, 3110, 3120, 3130, 3140
- 4115, 4125, 4145, 4112
- 4215, 4225, 4245
- FTDv

Limitations of Universal Zero Trust Network Access

- Universal ZTNA does not support IPv6.

- Universal ZTNA-enabled devices do not enforce policies for traffic over a site-to-site tunnel.
- Universal ZTNA does not support clustered devices.
- Universal ZTNA sessions do not support jumbo frames.
- Currently, universal ZTNA supports only the United States and Europe regions.
- Universal ZTNA supports only global VRF.
- Universal ZTNA does not support protocols such as FTP or TFP, where the data or secondary connection originates from a server.

  For example, an active FTP connection uses a persistent control connection for commands and creates temporary data connections for file transfers. Universal ZTNA does not support such data connections that originate from the server.

Integrate Firewall Management Center with Security Cloud Control

Note This task is applicable only to on-premises Firewall Management Center.

Integrating the on-premises Secure Firewall Management Center with Cisco Security Cloud Control enables you to configure your Secure Firewall Management Center and its associated Secure Firewall Threat Defense devices. These devices can then use the networks, private resources, and policies necessary to configure and manage universal ZTNA.

Note Universal ZTNA uses *only* the access policies that are defined by Secure Access. Any other access control policies and rules deployed to the Threat Defense devices from the Secure Firewall Management Center are ignored for universal ZTNA.

Before you begin

Your Cisco contact must onboard your Cisco Security Cloud Control and Secure Access systems, and create users and tenants.

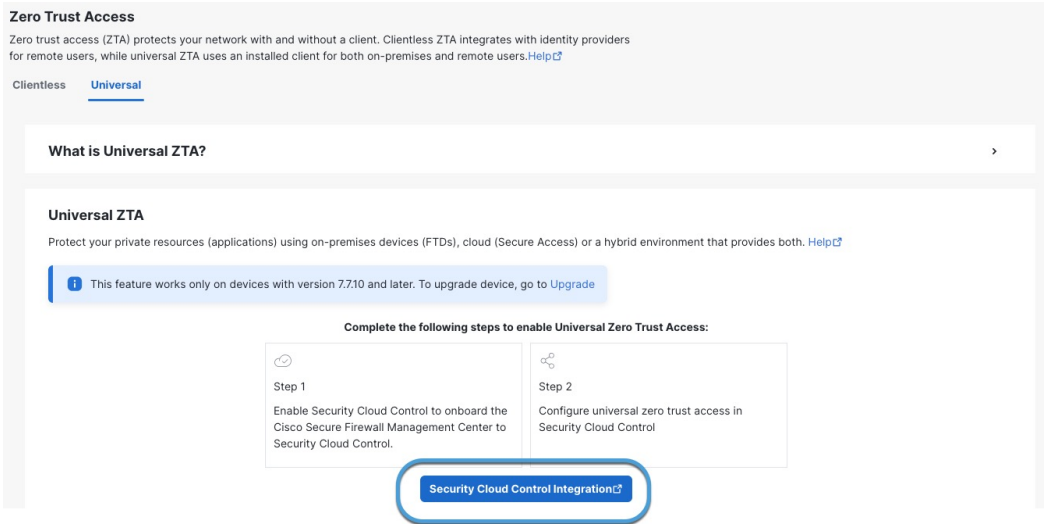
Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Policies** > **Zero Trust Application**.

Step 3 Click the **Universal** tab.

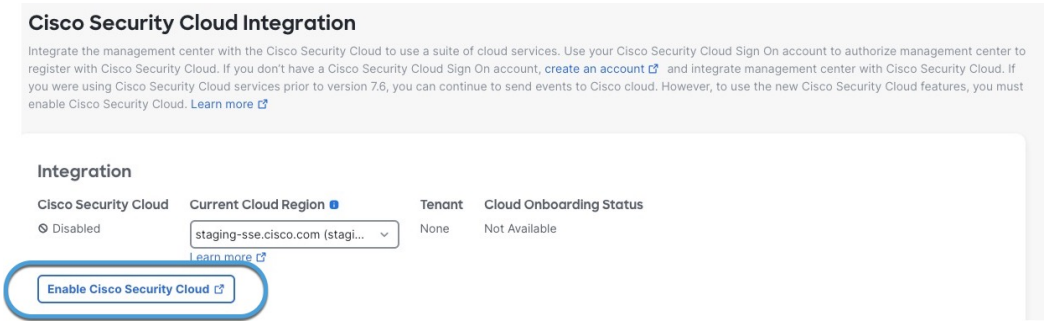
The Zero Trust Access page appears.



Step 4 Click **Security Cloud Control Integration**.

Step 5 From the **Current Cloud Region** list, click the name of your Cisco Security Cloud Control region.

Step 6 Click **Enable Cisco Security Cloud**.

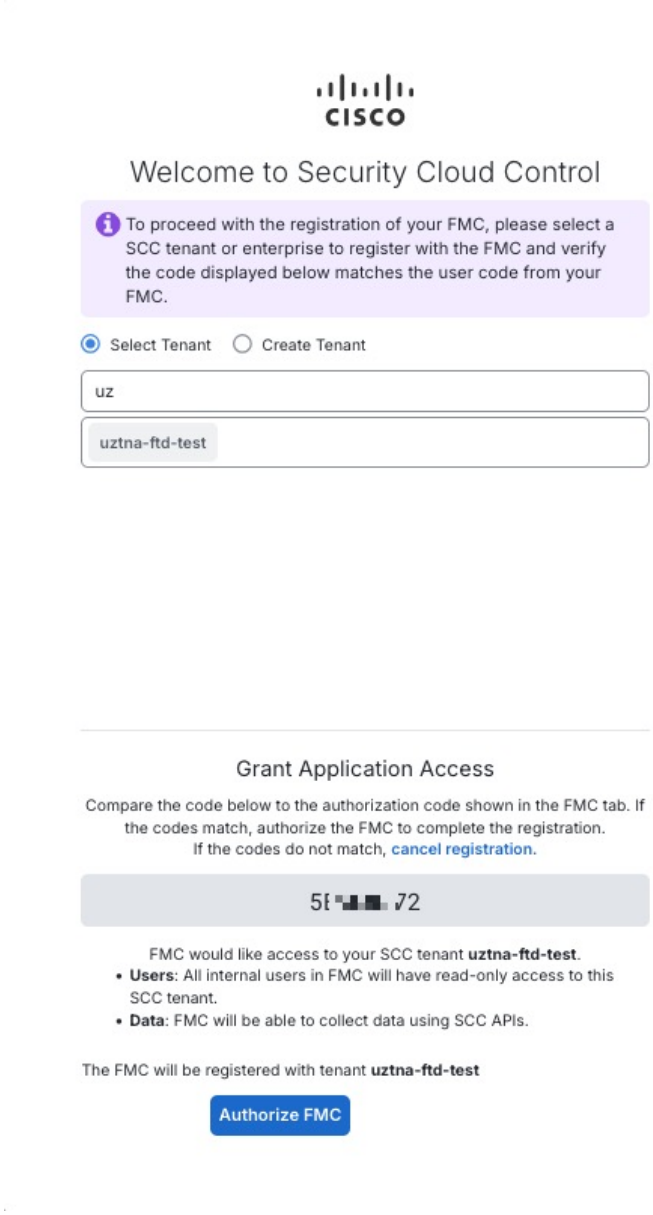


Step 7 When prompted, click **Continue to Cisco SSO**.

Step 8 Log in to Cisco Security Cloud Control.

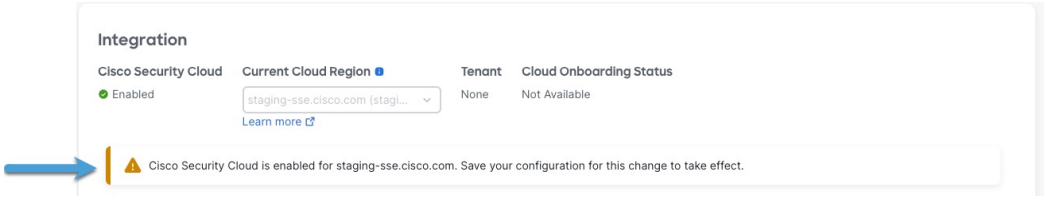
Step 9 From the **Select Tenant** list, click the name of your tenant.

Step 10 At the following page, click **Authorize FMC**.



Step 11 When prompted, close the tab page.

Step 12 A confirmation message appears to indicate that the onboarding was successful.



Step 13 Click **Save** at the bottom of the page.

It can take several minutes to save the configuration. After the configuration is saved, the page displays the onboarding status and the tenant name.

Step 14 For more information about other options on this page, see Security Cloud Control Settings, on page 2000.

Security Cloud Control Settings

The following topics discuss settings on the Cisco Security Cloud Integration page, which can be reached by choosing **Integration** > **Cisco Security Cloud** on Secure Firewall Management Center.

Event Configuration

Monitor the selected events in Cisco Security Cloud Control:

- **Send events to the cloud**: Select this check box to monitor events in Cisco Security Cloud Control; clear the check box to not monitor any events.

  You can view events in Cisco Security Cloud Control at **Firewall** > **Events & Logs**.

- **Intrusion events**: If you are using IPS policies, select this check box to monitor those policies.
- **File and malware events**: If you are using file or malware policies, select this check box to monitor those policies.
- **Connection events**: Select the check box next to the events to monitor, either **Security** (for file and IPS events) or **All**.

For more information about events, see Event Types in Security Cloud Control.

Cisco Security Cloud Support (Optional)

Optionally, select the check box to enable the following:

- **Enable Cisco Success Network**: Select the check box to enable collection of statistics discussed in *Cisco Success Network Telemetry Data Collected from Cisco Secure Firewall Management Center, Version 7.7*.
- **Enable Cisco Support Diagnostics**: Select the check box to enable collection of statistics discussed in the Cisco Secure Firewall Management Center Administration Guide.

Cisco AI Assistant for Security

Select the check box to enable the AI assistant as discussed in Use Cisco AI Assistant for Security to Manage Your Threat Defense Devices Effectively.

Cisco XDR Automation

Select the check box to enable XDR workflow automation as discussed in the Cisco XDR Help Center.

Policy Analyzer and Optimizer

Select the check box to enable the policy analyzer; click **Learn more** for details.

Zero-Touch Provisioning (ZTP)

Select the check box to enable zero-touch provisioning as discussed in the Cisco Secure Firewall Management Center Administration Guide.

Configure Security Devices

All Firewall Threat Defense devices associated with the Secure Firewall Management Center that you onboarded to Cisco Security Cloud Control are *security devices* to which you can:

- Associate private resources, which are internal applications you want to protect with identity-based access control, IPS, malware, and other protections.
- Deploy Secure Access access rules. Security devices are responsible for enforcing access rules for on-premises users, remote users, or both.

Perform these steps to enable **universal zero trust network access settings** on the Threat Defense devices. These steps include configuring the device FQDN, inside interface, outside interface, and PKCS12 certificate to enable universal ZTNA on the devices.

Before you begin

Complete all tasks discussed in Integrate Firewall Management Center with Security Cloud Control, on page 1997.

You must know the name of each device's internal and external network interfaces:

- The internal interface (also referred to as the *DMZ* interface) is used to apply access rules to on-premises users.
- The external interface is used to apply access rules to remote users.

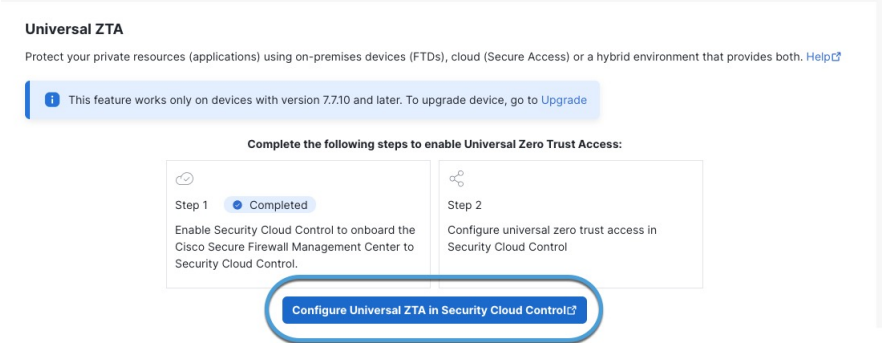
You can choose internal, external, or both types of interfaces for each security device.

Procedure

Step 1 In the Secure Firewall Management Center, click **Policies** > **Zero Trust Application**.

Step 2 Click **Configure Universal ZTA in Security Cloud Control**.

This figure shows an example.

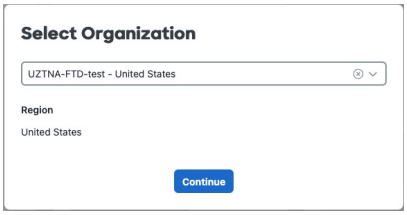


Step 3 When prompted, log in to Cisco Security Cloud Control.

Step 4 When prompted, select your organization from the drop-down list and click **Continue**.

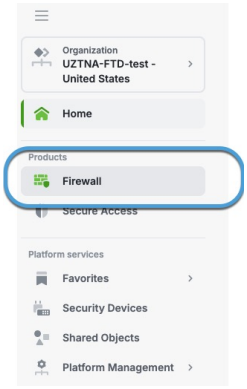
Select an organization that has both Secure Access and Secure Firewall micro applications configured.

This figure shows an example.



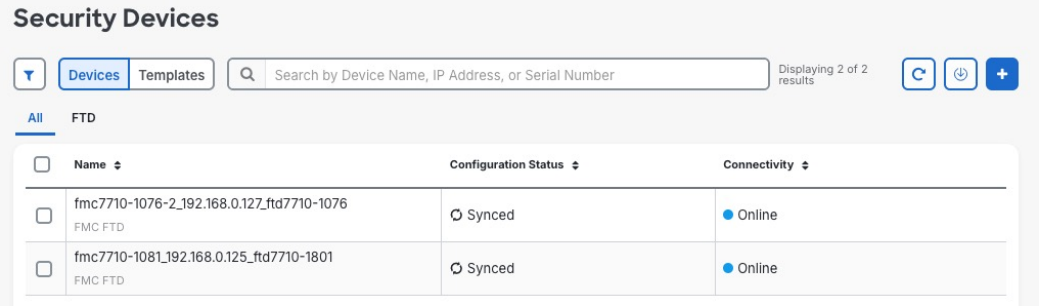
Step 5 In Cisco Security Cloud Control, in the Products section, click **Firewall**.

This figure shows an example.



Step 6 In the Manage section, click **Security Devices**.

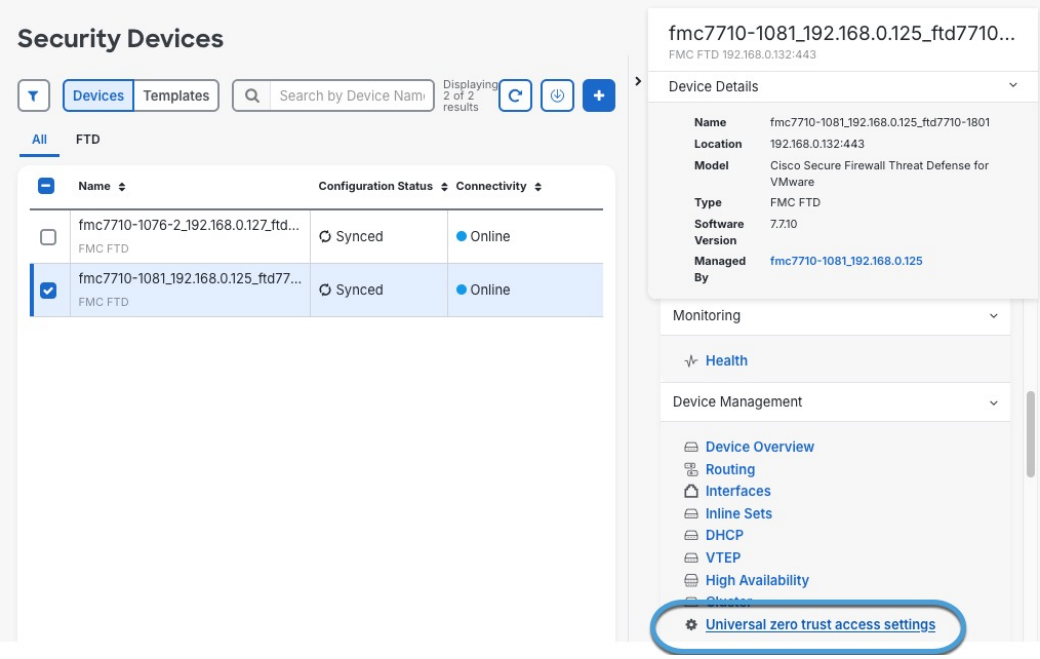
The **Security Devices** page displays the available security devices.



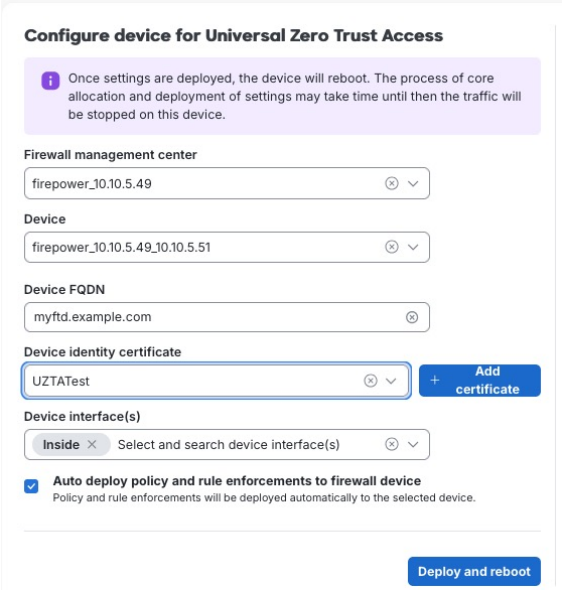
Step 7 Select the check box next to a device to add to the universal zero trust network access configuration.

Step 8 In the right pane, click **Device Management** > **Universal zero trust access settings**.

This figure shows an example.



Step 9 Enter or edit the following information on the **Configure device for Universal Zero Trust Access** page.



This table describes the configurations to enable universal ZTNA on the device.

Item	Description
Firewall management center	From the drop-down list, click the name of a Secure Firewall Management Center to use for policy deployment, monitoring, and other tasks.
Device	From the drop-down list, click the name of a device to use for rule deployment and enforcement.
Device FQDN	Enter the security device's fully qualified domain name (FQDN). The FQDN is also referred to as the TLS/SSL certificate's Common Name. The **Device identity certificate** must have a Common Name that either: • *Exactly matches* the value you enter in this field. • Matches a Subject Alternative Name (SAN) in the certificate. For more information, consult a resource such as What is the Common Name? on ssl.com.

Item	Description
Device identity certificate	From the drop-down list, click the name of an existing identity certificate from the list. Click **Add certificate** and add an identity certificate in **.p12** format (also referred to as PKCS#12; see this article on ssl.com). **Note** Universal ZTNA supports only the PKCS#12 format of certificate enrollment. In the provided fields, enter a **Name** to identify the certificate. Then copy/paste, drag/drop, or upload the certificate and private key. If the certificate is encrypted, enter its password in the provided field. You can optionally use a wildcard certificate as discussed in What is a Wildcard Certificate? on ssl.com.
Device Interface(s)	From the drop-down list, select the check box next to any of the following types of interfaces. • Internal network interface (or DMZ): deploys access rules for on-premises users only. • External network interface: deploys access rules for remote users only. • Both types of interfaces: deploys access rules for either on-premises or remote users.
Auto deploy policy and rule enforcements to firewall device	Select the check box to automatically deploy access rules to the device after they are updated on Secure Access. On the device, the Auto deploy feature selectively deploys only the Universal ZTNA access policy. It does not impact other changes or configurations on the Firewall Management Center. **Note** If there are other interdependent policies on the device (which are interlinked with the Universal ZTNA access policy), the Firewall configuration status displays an error message. The deployment then stops. In such cases, you should manually deploy the Universal ZTNA access policy from the Firewall Management Center.

Step 10 Click **Deploy and Reboot**.

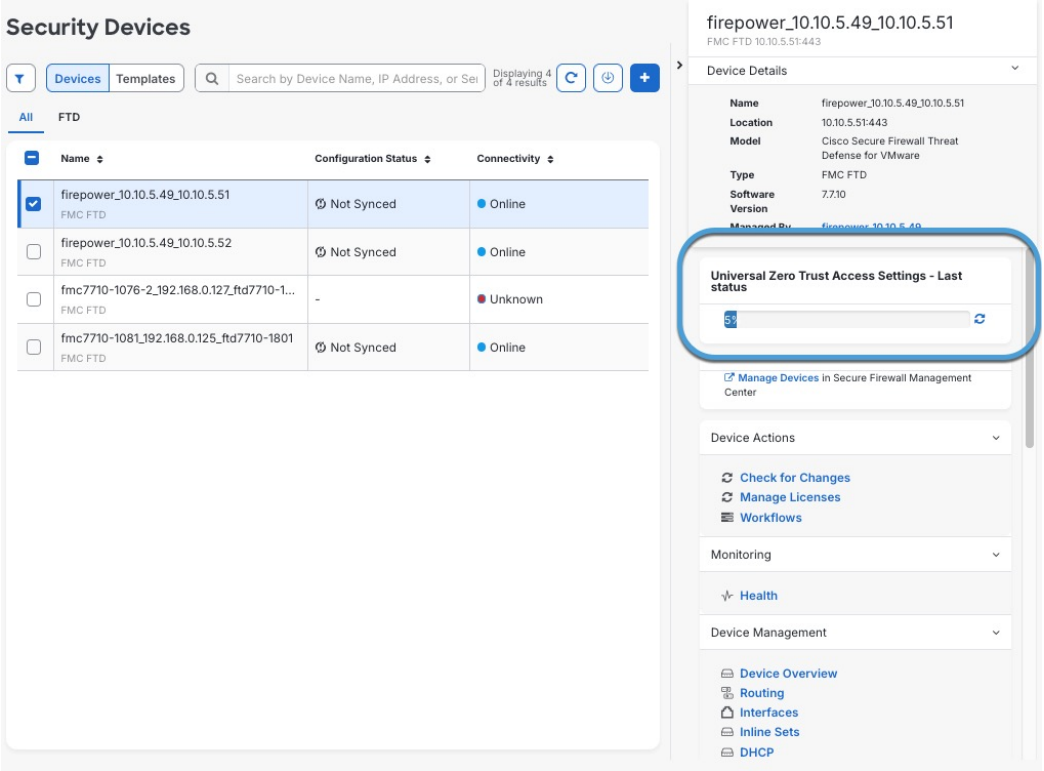
The device reboots to reallocate the system resources for universal ZTNA components.

Note
The device takes several minutes to reboot, during which time all traffic handled by the device is disrupted.

If you deploy a High Availability (HA) pair of devices, both devices reboot simultaneously.

Step 11 On the **Security Devices** page, select the check box next to the device to which you just deployed the Universal ZTNA configuration.

The right pane displays the deployment status, as shown in the figure.



For additional information, click **Device Actions** > **Workflows** in the right pane.

After the deployment completes, you can view the completion status in the **Universal Zero trust Access Settings - Last status** tab for the device.

Universal ZTNA-enabled Firewall Threat Defense device is connected to Secure Access.

What to do next

Check the availability of the Threat Defense device under Secure Access by clicking **Security Cloud Control** > **Secure Access** > **Connect** > **Network Connections** > **FTD**.

History for Zero Trust Access

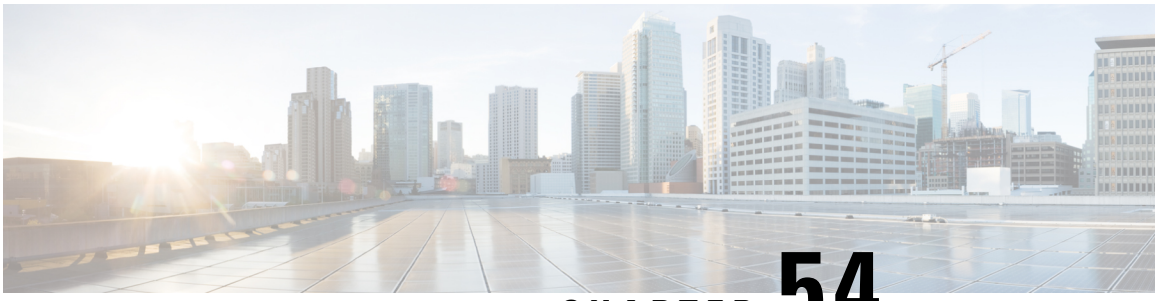
Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Universal Zero Trust Network Access (universal ZTNA).	7.7.10	7.7.10	Universal Zero Trust Network Access (universal ZTNA) is a comprehensive solution that provides secure access to internal network resources based on user identity, trust, and posture. It ensures that access to one application does not implicitly grant access to the entire network, as with remote access VPN. New/modified screens: **Policies** > **Zero Trust Application** Requires Cisco Secure Access and Security Cloud Control. Deployment restrictions: Not supported with clustered devices, container instances, or transparent mode. Supported platforms: Secure Firewall 1150, 3100, 4100, 4200, and Firewall Threat Defense Virtual.
Zero trust access enhancements.	7.4.1	7.4.1 with Snort 3	Management center now includes the following zero trust access enhancements: • You can configure source NAT for an application. The configured network object or object group translates the incoming request's public network source IP address to a routable IP address inside the application network. • You can troubleshoot the zero trust configuration issues using the diagnostics tool. New/modified screens: **Policies** > **Access Control** > **Zero Trust Application** New/modified CLI commands: **show running-config zero-trust**, **show zero-trust statistics**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Clientless zero-trust access.	7.4.0	7.4.0 with Snort 3	Zero Trust Access allows you to authenticate and authorize access to protected web based resources, applications, or data from inside (on-premises) or outside (remote) the network using an external SAML Identity Provider (IdP) policy. The configuration consists of a Zero Trust Application Policy (ZTAP), Application Group, and Applications. New/modified screens: • **Policies** > **Zero Trust Application** • **Analysis** > **Connections** > **Events** • **Overview** > **Dashboard** > **Zero Trust** New/modified CLI commands: • **show running-config zero-trust application** • **show running-config zero-trust application-group** • **show zero-trust sessions** • **show zero-trust statistics** • **show cluster zero-trust statistics** • **clear zero-trust sessions application** • **clear zero-trust sessions user** • **clear zero-trust statistics**

PART VIII

SD-WAN

- SD-WAN Capabilities, on page 2011



CHAPTER 54

SD-WAN Capabilities

This chapter describes the SD-WAN capabilities supported in the management center.

- Overview of SD-WAN Capabilities, on page 2011
- Features, on page 2012
- Using SD-WAN Wizard for Secure Branch Network Deployment, on page 2013
- Use Cases for SD-WAN Capabilities, on page 2028

Overview of SD-WAN Capabilities

Software-Defined WAN (SD-WAN) solutions replace traditional WAN routers and are agnostic to WAN transport technologies. SD-WAN provides dynamic, policy-based, application path selection across multiple WAN connections and supports service chaining for additional services such as WAN optimization and firewalls.

As organizations expand their operations across multiple branch locations, ensuring secure and streamlined connectivity becomes paramount. Deploying a secure branch network infrastructure involves complex configurations, which can be time-consuming and prone to configuration errors if not handled properly. However, organizations can overcome these challenges by leveraging the Cisco Secure Firewall Management Center (management center) and the Cisco Secure Firewall Threat Defense (threat defense) devices for a simplified and secure branch deployment.

In this guide, we explore the concept of simplifying secure branch deployment using a robust firewall solution. By integrating a secure firewall as a foundational component of the branch network architecture, organizations can establish a strong security baseline while simplifying the deployment process. This approach enables organizations to enforce unified security policies, optimize traffic routing, and ensure resilient connectivity.

Some of the SD-WAN capabilities supported on the Cisco Secure Firewall are:

- **Simplified management:**
  - SD-WAN Wizard
  - SASE: Umbrella auto tunnel deployment
  - Dynamic VTI (DVTI) hub spoke topology simplification
- **Application awareness:**
  - Direct Internet Access (DIA) for public cloud and guest user

- Policy based routing (PBR) using applications as a match criteria
- Local tunnel ID support for Umbrella

- **Increased usable bandwidth:**
  - ECMP support for load balancing across multiple ISPs and VTIs
  - Application-based load balancing using PBR

- **High availability with near zero network downtime:**
  - Dual ISP configuration
  - Optimal path selection based on application-based interface monitoring.

- **Secure Elastic Connectivity:**
  - Route-based (VTI) VPN tunnels between headquarters (hub) and branches (spokes)
  - IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP over VTI
  - DVTI hubs that support spokes with static or dynamic IP

Features

The following table lists some commonly used SD-WAN features:

Feature	Introduced in	More Information
SD-WAN Wizard	Release 7.6	Using SD-WAN Wizard for Secure Branch Network Deployment, on page 2013
Application monitoring using SD-WAN Summary dashboard	Release 7.4.1	SD-WAN Summary Dashboard, on page 1705
SD-WAN Summary Dashboard	Release 7.4	SD-WAN Summary Dashboard, on page 1705
Policy-based routing with user identity and SGTs	Release 7.4	Policy Based Routing, on page 1323
Policy-based routing using HTTP path monitoring	Release 7.4	Policy Based Routing, on page 1323
Loopback interface support for VTIs	Release 7.3	About Loopback Interfaces, on page 829
Support for dynamic VTI (DVTI) with site-to-site VPN	Release 7.3	Dynamic VTI, on page 1531
Umbrella auto tunnel	Release 7.3	Deploy a SASE Tunnel on Umbrella, on page 1555

Feature	Introduced in	More Information
Support for IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP for VTIs	Release 7.3	BGP, on page 1277 OSPF, on page 1239 EIGRP, on page 1267
Route-based site-to-site VPN with hub and spoke topology	Release 7.2	Create a Route-based Site-to-Site VPN, on page 1538

Site to Site VPN Monitoring Dashboard	Release 7.1	Monitoring the Site-to-Site VPNs, on page 1562
Direct Internet Access/Policy Based Routing	Release 7.1	Policy Based Routing, on page 1323
Equal-Cost-Multi-Path (ECMP) zone with WAN interfaces	Release 7.1	ECMP, on page 1223
ECMP zone with VTI interfaces	Release 7.1	ECMP, on page 1223
Backup VTI for route-based site-to-site VPN	Release 7.0	Route Traffic Through a Backup VTI Tunnel, on page 1549
Support for static VTI (SVTI) with site-to-site VPN	Release 6.7	Static VTI, on page 1530

Using SD-WAN Wizard for Secure Branch Network Deployment

Management Center allows you to easily configure VPN tunnels and routing configuration between your centralized headquarters (hubs) and remote branch sites (spokes) using the new SD-WAN wizard.

What are Hubs and Spokes?

Hubs: Devices that enable secure VPN connectivity to and from one or more remote branch devices or spokes. Hubs also act as a gateway for spokes to communicate with each other.

Spokes: Devices in remote branches that connect over VPN to a hub to securely access the corporate resources behind the hub. Spokes communicate with each other through the hub.

Benefits of Using SD-WAN Wizard

- Simplifies and automates the VPN and routing configuration of your SD-WAN network.
- Creates route-based VPN tunnels and simplifies the configuration process by automating tasks such as:
  - Generating tunnel interfaces of the branches.
  - Assigning IP addresses to the tunnel interfaces.

    - Configuring BGP for the SD-WAN overlay network. These configurations ensure seamless connection between hubs and spokes, and spoke to spoke through the hub.

- Provides seamless routing because hubs act as route reflectors and enable the following:
    - Provide connectivity between the spokes.
    - Determine the best routing path based on the spokes' active and backup tunnels.
- Requires minimal user input.
- Easily add multiple branches at a time.
- Provides easy dual ISP configurations.
- Enables network scaling.

Guidelines and Limitations for Using SD-WAN Wizard

Guidelines

- When you configure the DVTIs of two hubs, ensure that they have the same IPsec tunnel mode (IPv4 or IPv6).
- In a dual-hub SD-WAN topology, the hubs can be in different geographic locations and have different protected networks behind them. To ensure direct communication between these networks, ensure that you configure the following:
    - A point-to-point route-based VPN topology between the two hubs (**Devices** > **VPN** > **Site to Site**, and click **Add** > **Route-Based VPN**).
    - A dynamic routing protocol between the hubs (**Devices** > **Device Management**, click the device name and click **Routing**).
- When you configure IP address pools for spokes, ensure the following:
    - The **Allow Overrides** check box must be unchecked.
    - If you are using multiple pools, the IP addresses of the pools must not overlap.
    - IP addresses must not overlap with any of the interfaces on the spoke.
- When you create security zones or interface groups, choose **Routed** as the **Interface Type**.
- Use the spoke security zone to configure an access control policy that allows tunnel traffic to and from the spokes.
- Configure the spokes' static VTIs in an ECMP zone to load balance the application traffic. If you do not configure the ECMP zone, the remaining paths act as backup paths when the primary path goes down. Note that you must configure the spokes' static VTIs and not the physical interfaces in the ECMP zone. This configuration is not part of the SD-WAN wizard.
- In SD-WAN topologies with dual ISPs on spokes, the tunnel identity and the tunnel source of the spokes must be unique.

- If a spoke is part of multiple SD-WAN topologies, ensure that you use the same local community tag and learned route community tag in each SD-WAN topology. Note that the local community tags and learned route community tags must be different from each other.
- If a device has only IPv6 address configurations, you must configure the BGP router ID with a loopback or physical interface that has an IPv4 address (**Devices** > **Device Management**, and click **Routing** > **General Settings** > **BGP**).
- Configure unique local IKE identity for all tunnels across all your SD-WAN VPN topologies.
- Ensure that the spokes in an SD-WAN topology do not have the same protected network.
- Use distinct DVTIs for SD-WAN and route-based VPNs to avoid IPsec profile conflicts and errors.

Limitations

- You can configure a maximum of two hubs in an SD-WAN topology using the SD-WAN wizard.
- For each spoke, you can use only one WAN interface per topology. However, for dual-ISP setups, you can configure a second SD-WAN topology with the second WAN interface. For more information, see Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard, on page 2020.
- SD-WAN wizard does not support the following:
  - IKEv1
  - Cluster devices are not supported on the hub and spoke because VTI is not supported on cluster devices.
  - Extranet hubs and spokes such as ASA, Cisco IOS, Cisco Viptela, Umbrella, Meraki, or vendor devices.

Prerequisites for Using the SD-WAN Wizard

- Firewall Management Center Essentials (formerly Base) license must allow export-controlled functionality.

  Choose **System > Licenses > Smart Licenses** to verify this functionality in the Firewall Management Center.
- You must be an Admin user.
- Hub devices must be Version 7.6.0 and later.
- Spoke devices must be Version 7.3.0 and later.
- The Firewall Threat Defense devices must have an internet-routable public IP address. The IP address can be static or dynamic.
- Assign appropriate logical names and IP addresses to the interfaces of the Firewall Threat Defense devices. For example, use *inside* for the interface connected to the LAN, and *outside* for the interface connected to the internet or WAN.
- If you are using certificate-based authentication, you must enroll the certificates in the hub and spokes.
- Configure routing, NAT, and AC policies to ensure underlay connectivity between the devices.

Configure an SD-WAN Topology Using the SD-WAN Wizard

The SD-WAN wizard allows you to easily configure VPN tunnels between your centralized headquarters and remote branch sites.

Before you begin

Ensure that you review Prerequisites for Using the SD-WAN Wizard, on page 2015 and Guidelines and Limitations for Using SD-WAN Wizard, on page 2014.

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site**, and click **Add**.

Step 2 Enter a name for the SD-WAN VPN topology in the **Topology Name** field.

Step 3 Click the **SD-WAN Topology** radio button and click **Create**.

Step 4 Configure a hub:

a) Click **Add Hub**.

b) From the **Device** drop-down list, choose a hub.

c) Click **+** next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a dynamic VTI for the hub.

The **Add Virtual Tunnel Interface** dialog box is prepopulated with default configurations. However, you must configure the **Tunnel Source**, and the **Borrow IP Address**. For more information, see Add a Dynamic Virtual Tunnel Interface for a Hub, on page 2019.

d) Click **OK**.

e) In the **Hub Gateway IP Address** field, enter the public IP address of the hub's VPN interface or the tunnel source of the dynamic VTI to which the spokes connect.

This IP address is auto populated if the interface has a static IP address. If hub is behind a NAT device, you must manually configure the post-NAT IP address.

f) From the **Spoke Tunnel IP Address Pool** drop-down list, choose an IP address pool or click **+** to create an address pool.

When you add spokes, the wizard auto generates spoke tunnel interfaces, and assigns IP addresses to these spoke interfaces from this IP address pool.

g) Click **Add** to save the hub configuration.

h) (Optional) To add a secondary hub, repeat Step 4a to Step 4f.

i) Click **Next**.

Step 5 Configure spokes:

Click **Add Spoke** to add a single spoke device, or click **Add Spokes (Bulk Addition)** to add multiple spokes to your topology.

- Click **Add Spoke**. In the **Add Spoke** dialog box, configure the following parameters:

  a. From the **Device** drop-down list, choose a spoke.

  b. From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.

c. Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from this device to the remote peer. By default, this option is enabled.

d. Choose one of the following options from the **Identity Type** drop-down list:

- **Key ID**—(Default value) This value is auto populated as <*sd-wan topologyname*>_<*device_IP_address*>, for example, sdwantopo1_192.168.0.200. You can also specify a key ID of your choice.
- **Email ID**—Specify an email ID up to 127 characters.
- **IP Address**—IP address of the spoke's VPN interface.
- **Auto**—IP address of the spoke's VPN interface for pre-shared key authentication or the certificate Distinguished Name (DN) for certificate-based authentication.
- **Hostname**—Fully qualified hostname of the spoke.

e. Click **Save** to save the spoke configuration.

- Click **Add Spokes (Bulk Addition)**. In the **Add Bulk Spokes** dialog box, configure the following parameters:

a. Choose one or more devices from the **Available Devices** list and click **Add** to move the devices to **Selected Devices**.

b. Use one of the following methods to select the VPN interfaces of the spokes:

- Click the **Interface Name Pattern** radio button and specify a string to match the logical name of the internet or WAN interface of the spokes, for example, outside*, wan*.

  If the spoke has multiple interfaces with the same pattern, the first interface that matches the pattern is selected for the topology.

- Click the **Security Zone** radio button and choose a security zone with the VPN interfaces of the spokes from the drop-down list, or click + to create a security zone.

c. Click **Next**.

The wizard validates if the spokes have interfaces with the specified pattern. Only the validated devices are added to the topology.

d. Click **Add**.

e. Click **Next**.

For each spoke, the wizard automatically selects the hub's DVTI as the tunnel source IP address.

Note
If the hub’s tunnel source IP address is an IPv6 address, the wizard automatically selects the first IPv6 address of the spokes' selected interface. To edit the IPv6 address of a spoke's tunnel source, click the edit icon next to a spoke, choose an IPv6 address from the **IP Address** drop-down list, and click **Save**.

Step 6 Configure authentication settings for the devices in the SD-WAN topology:

a) **Authentication Type**—For device authentication, you can use a manual pre-shared key, an auto-generated pre-shared key, or a certificate.

- **Pre-shared Manual Key**—Specify the pre-shared key for the VPN connection.
- **Pre-shared Automatic Key**—(Default value) The wizard automatically defines the pre-shared key for the VPN connection. Specify the key length in the **Pre-shared Key Length** field. The range is 1 to 127.
- **Certificate**—When you use certificates as the authentication method, the peers obtain digital certificates from a CA server in your PKI infrastructure, and use them to authenticate each other.

b) Choose one or more algorithms from the **Transform Sets** drop-down list.
c) Choose one or more algorithms from the **IKEv2 Policies** drop-down list.
d) Click **Next**.

Step 7 Configure the SD-WAN settings:

This step involves the auto generation of spoke tunnel interfaces, and BGP configuration of the overlay network.

a) From the **Spoke Tunnel Interface Security Zone** drop-down list, choose a security zone or click **+** to create a security zone to which the wizard automatically adds the spokes' auto-generated Static Virtual Tunnel Interfaces (SVTIs).
b) Check the **Enable BGP on the VPN Overlay Topology** check box to automate BGP configurations such as neighbor configurations between the overlay tunnel interfaces and basic route redistribution from the directly connected LAN interfaces of the hubs and spokes.
c) In the **Autonomous System Number** field, enter an Autonomous System (AS) number.

AS number is a unique number for a network with a single routing policy. BGP uses AS numbers to identify networks. The spoke's BGP neighbor configuration is generated based on the corresponding hub's AS number. Range is from 0 to 65536.

- If all the hubs and spokes are in the same region, by default, **64512** is the AS number.
- If the primary and secondary hubs are in different regions, the primary hub and the spokes are configured with **64512** as the AS number, and the secondary hub is configured with a different AS number.

d) In the **Community Tag for Local Routes** field, enter the BGP community attribute to tag connected and redistributed local routes. This attribute enables easy route filtering.
e) Check the **Redistribute Connected Interfaces** check box and choose an interface group from the drop-down list or click **+** to create an interface group with connected inside or LAN interfaces for BGP route redistribution in the overlay topology.
f) Check the **Enable Multiple Paths for BGP** check box to allow multiple BGP routes to be used at the same time to reach the same destination. This option enables BGP to load-balance traffic across multiple links.

Note that when you enable this option, BGP multipath is enabled only for spokes.

g) (Optional) Check the **Secondary Hub is in Different Autonomous System** check box. This check box appears only if you have a secondary hub in this topology.
h) In the **Autonomous System Number** field, enter the AS number for the secondary hub.
i) In the **Community Tag for Learned Routes** field, enter the BGP community attribute to tag routes learned from other SD-WAN peers over the VPN tunnel. This attribute is required only for eBGP configuration when the secondary hub has a different AS number. This field appears only if you have configured two hubs in the SD-WAN topology.

j) Click **Next**.

Step 8 Click **Finish** to save and validate the SD-WAN topology.

You can view the topology in the **Site-to-Site VPN Summary** page (**Devices** > **VPN** > **Site to Site**). After you deploy the configurations to all the devices, you can see the status of all the tunnels in this page.

What to do next

- View the auto-generated spoke SVTIs and their IP addresses—Click the edit icon next to the spoke configuration and click **View Generated Tunnel Interfaces**.
- We recommend that you enable ECMP on the spoke SVTIs. Choose **Devices** > **Device Management**, and click **Routing** > **ECMP**.
- Deploy the configurations on the hub and spokes. Choose **Deploy**. Select devices and click **Deploy**.
- Verify the SD-WAN topology tunnel statuses. For more information, see Verify Tunnel Statuses of an SD-WAN Topology, on page 2025.
- Configure ACLs for the spokes' tunnel interface security zones. Choose **Policies > Access Control**.
- We recommend that you enable BGP multipath on hubs. To enable BGP multipath on hubs:
  1. Choose ECMP**Devices** > **Device Management**, and click **Routing**.
  2. Under **General Settings**, click **BGP**.
  3. Check the **Enable BGP** check box to enable BGP.
  4. In the **AS Number** field, enter the AS number that you configured in the SD-WAN topology.
  5. Click **Save**.
  6. In the left pane, choose **BGP > IPv4 or IPv6**, and click the **General** tab.
  7. In the **Forward Packets over Multiple Paths** section, click the edit icon.
  8. Configure values for **Number of Paths** and **IBGP number of paths**. We recommend that you configure these values as 8.
- For more information about configuration examples using SD-WAN wizard, see Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard, on page 2020
- Configure a PBR policy on each spoke for application-aware routing based on the application performance metrics of the WAN interfaces. For more information, see Route Application Traffic from the Branch to the Internet Using Direct Internet Access (DIA).

Add a Dynamic Virtual Tunnel Interface for a Hub

In the SD-WAN wizard, you must configure a DVTI for each hub. DVTI uses a virtual template to dynamically generate a unique virtual access interface for each VPN session.

Before you begin

In the SD-WAN wizard, click **Add Hub**, and choose a hub from the **Device** drop-down list.

Procedure

Step 1 Click + next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a DVTI for the hub.

The **Add Virtual Tunnel Interface** dialog box appears with the following prepopulated default configurations.

a. **Tunnel Type**: Dynamic.

b. **Name**: <*tunnel_source_interface_logical name*>_dynamic_vti_<*tunnel_ID*>. For example, outside_dynamic_vti_1.

c. **Enabled** check box: Checked by default.

d. **Template ID**: Unique ID for the DVTI.

e. **Tunnel Source**: Physical interface that is the source of the DVTI and is auto populated by default.

f. **IPsec Tunnel Mode**: IPv4, by default.

Step 2 Choose a security zone for the dynamic VTI from the **Security Zone** drop-down list.

Step 3 Choose a physical or loopback interface from the **Borrow IP** drop-down list, the dynamic VTI interface inherits this IP address.

Ensure that you use an IP address different from the tunnel source IP address. We recommend that you use a loopback IP address.

Step 4 Click **OK** to save the dynamic VTI.

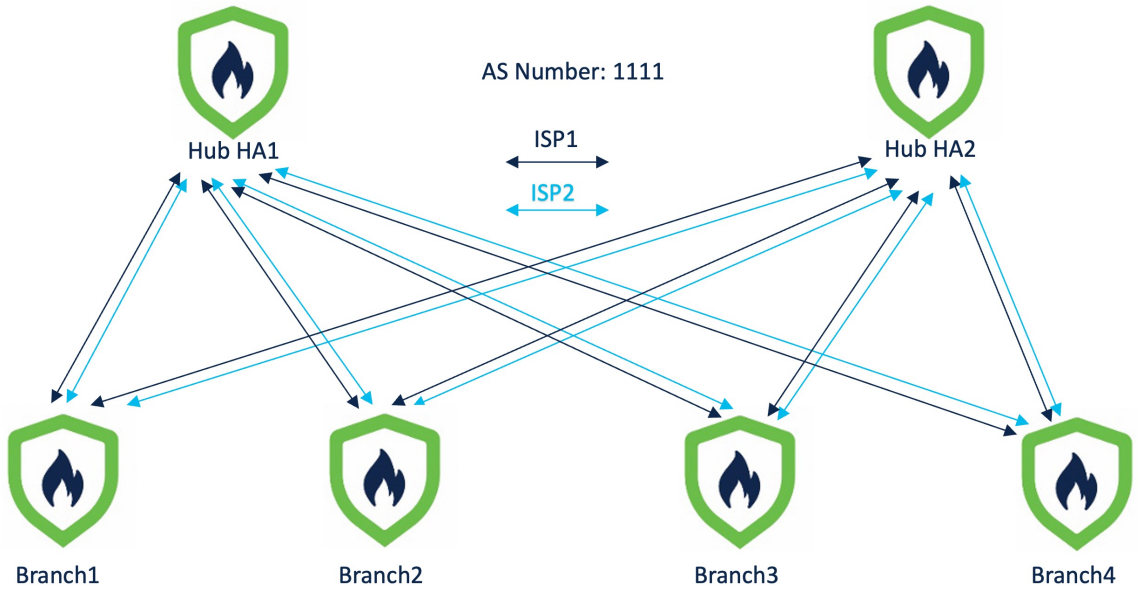
Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard

Dual ISP Deployment: Two Hubs and Four Spokes in the Same Region

In the following dual ISP topology, the hubs and the spokes are in a single region, with AS number as 1111. The hubs and spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol to exchange routing information.

- Hub HA1 and Hub HA2 are hub threat defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke threat defense devices at the branches.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 444: Dual ISP Topology with Two Hubs and Four Spokes in the Same Region



To configure this topology, you must create the following two SD-WAN topologies using the SD-WAN wizard:

SD-WAN Topology 1

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2, Branch3, Branch4
AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP1
Number of Tunnels	8

The total number of tunnels in SD-WAN Topology 1 is 8.

SD-WAN Topology 2

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2, Branch3, Branch4
AS Number	1111

Parameter	Value
VPN Interface (Spoke Tunnel Source)	ISP2
Number of Tunnels	8

The total number of tunnels in SD-WAN Topology 2 is 8.

The total number of VPN tunnels for this dual ISP deployment is 16.

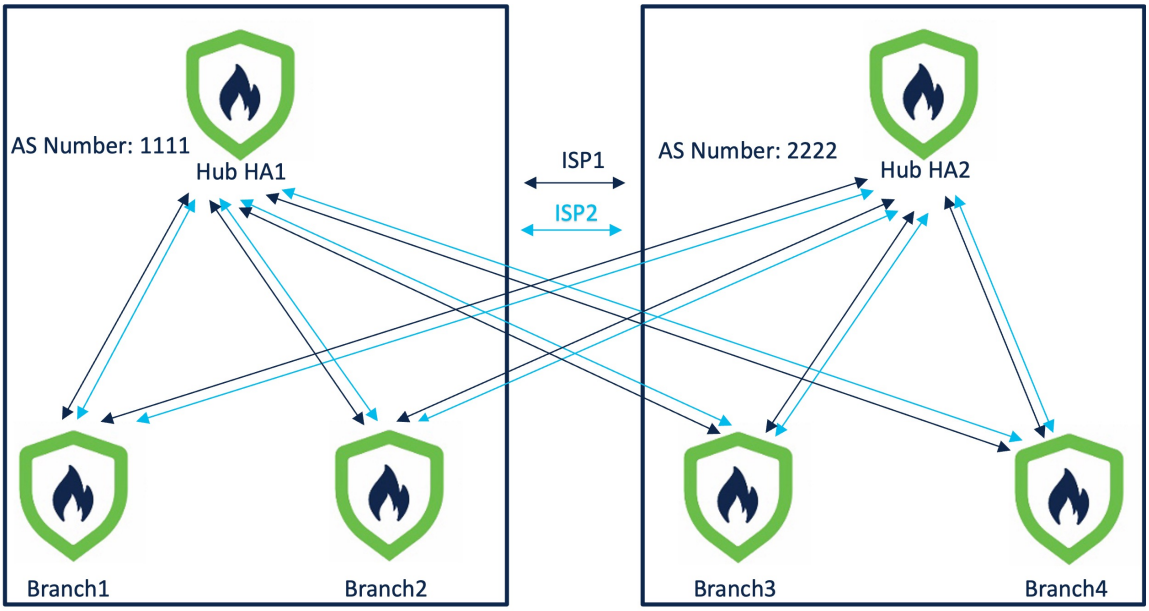
Note If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.

Dual ISP Deployment: Two Hubs and Four Spokes in Different Regions

In the following dual ISP topology, the hubs are in different regions, and have two directly connected spokes each. The hubs and their directly connected spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol, and the hubs use External Border Gateway Protocol (eBGP) to exchange routing information.

- Hub HA1 and Hub HA2 are hub threat defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke threat defense devices at the branches.
- HQ1, Branch1, and Branch2 are in a single region with AS number as 1111.
- HQ2, Branch3, and Branch4 are in a single region with AS number as 2222.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 445: Dual ISP Topology with Two Hubs and Four Spokes in Different Regions



To configure this topology, you must create the following four SD-WAN topologies using the SD-WAN wizard:

SD-WAN Topology 1

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2
AS Number	1111
Secondary AS Number	2222
VPN Interface (Spoke Tunnel Source)	ISP1

The number of tunnels in SD-WAN Topology 1 is 4.

SD-WAN Topology 2

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2
AS Number	1111

Parameter	Value
Secondary AS Number	2222
VPN Interface (Spoke Tunnel Source)	ISP2

The number of tunnels in SD-WAN Topology 2 is 4.

SD-WAN Topology 3

Parameter	Value
Primary Hub	Hub HA2
Secondary Hub	Hub HA1
Spokes	Branch3, Branch4
AS Number	2222
Secondary AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP1

The number of tunnels in SD-WAN Topology 3 is 4.

SD-WAN Topology 4

Parameter	Value
Primary Hub	Hub HA2
Secondary Hub	Hub HA1
Spokes	Branch3, Branch4
AS Number	2222
Secondary AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP2

The number of tunnels in SD-WAN Topology 4 is 4.

The total number of VPN tunnels for this dual ISP deployment is 16.

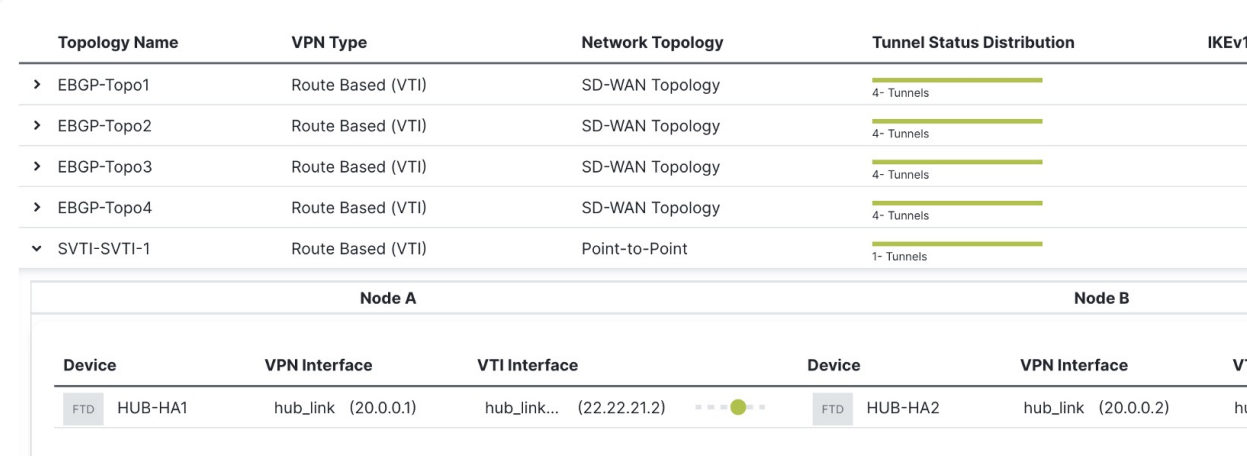
Note If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.

Verify Tunnel Statuses of an SD-WAN Topology

Verify Tunnel Statuses on the Site-to-Site VPN Summary Page

To verify if the VPN tunnels of the SD-WAN topologies are up, choose **Devices** > **VPN** > **Site to Site**.

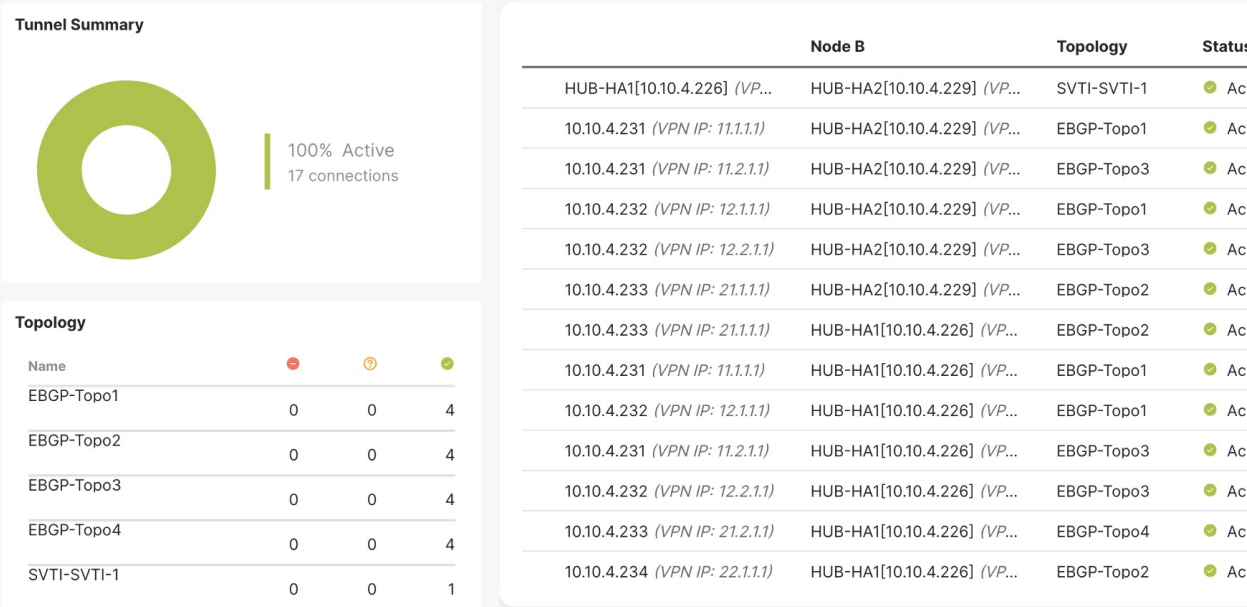
Following are the five SD-WAN topologies with two hubs and four spokes in different regions that are connected to dual ISPs:



Verify Tunnel Statuses on the Site-to-Site VPN Dashboard

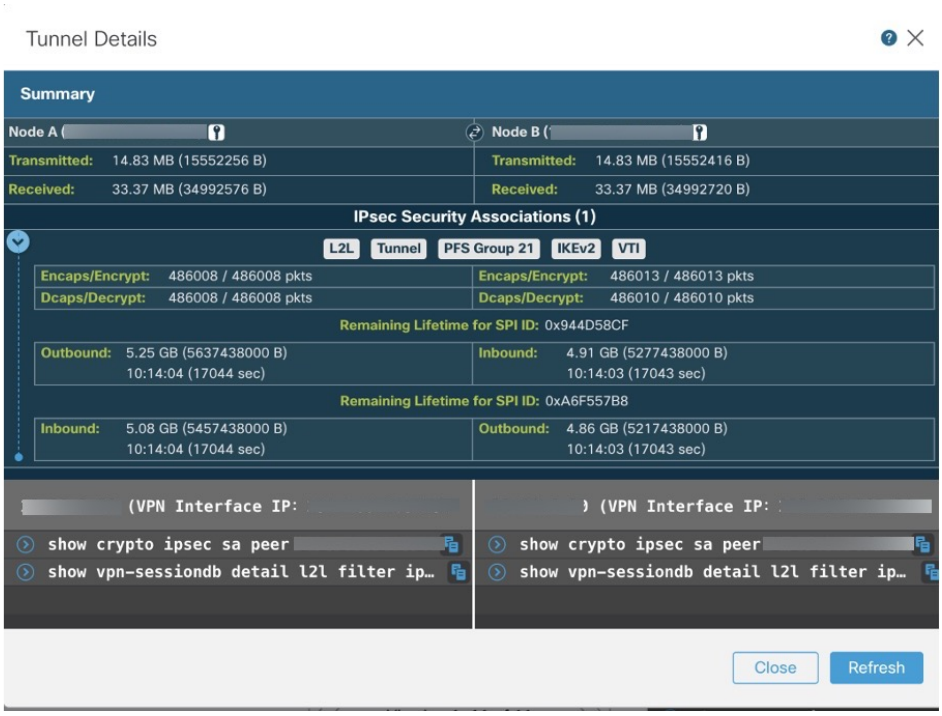
To view details of the SD-WAN VPN tunnels, choose **Overview** > **Dashboards** > **Site to Site VPN**.

Following are the VPN tunnels for an SD-WAN topology with two hubs and four spokes in different regions that are connected to dual ISPs:



To view more details of each VPN tunnel:

1. Hover over a tunnel.
2. Click the **View Full Information** ( ) icon. A pane with tunnel details and more actions appears.
3. Click the **CLI Details** tab in the side pane to view the show commands and details of the IPsec security associations.



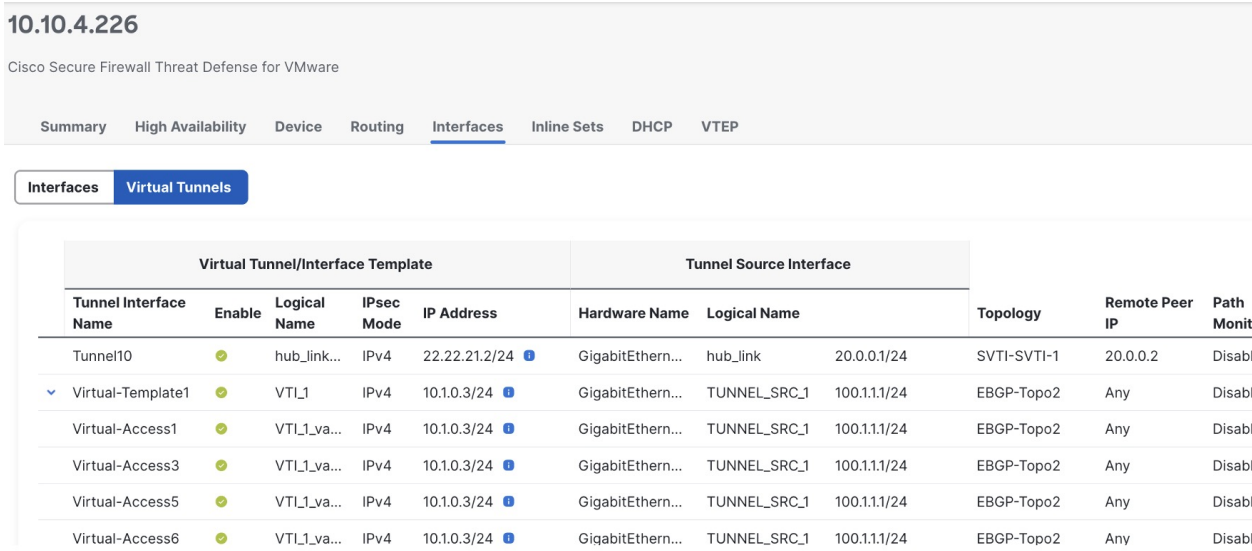
View Virtual Tunnel Interfaces of the Devices

To view the dynamic VTIs of hubs and static VTIs of spokes:

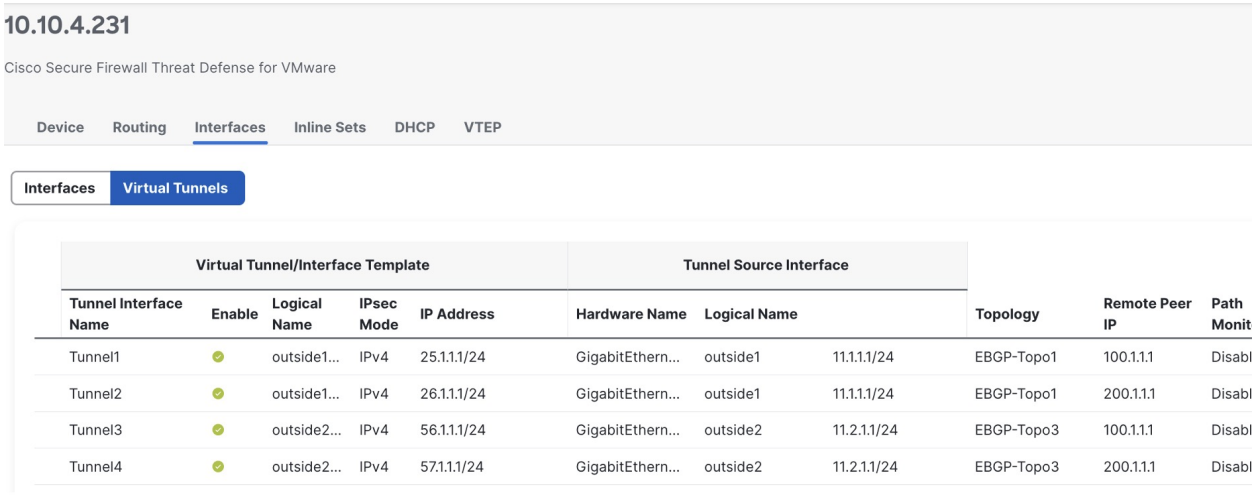
1. Choose **Devices** > **Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Interface** tab.
4. Click the **Virtual Tunnels** tab.

   For each VTI, you can view details such as name, IP address, IPsec mode, tunnel source interface details, topology, and remote peer IP.

Following image shows an example of the virtual access interfaces created dynamically by a hub's DVTI:



Following image shows an example of the static tunnel virtual interfaces (SVTIs) created on a spoke by the SD-WAN wizard:



The SD-WAN wizard assigns IP addresses to these tunnel interfaces from the IP address pool of the hub.

Verify Routing on the Hub and Branches

To verify the BGP configuration of the hubs and spokes of the SD-WAN topologies:

1. Choose **Devices** > **Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Device** tab.
4. Click **CLI** in the **General** card. The **CLI Troubleshoot** window appears.
5. Enter the following commands in the **Command** field and click **Execute**:
   - **show route**

- **show bgp summary**

Use Cases for SD-WAN Capabilities

- Simplify Branch to Hub Communication using Dynamic Virtual Tunnel Interface (DVTI)
- Route Application Traffic from the Branch to the Internet Using Direct Internet Access (DIA)
- Secure Internet Traffic Using Umbrella Auto Tunnel

CHAPTER 55

An Overview of Network Analysis and Intrusion Policies

The Snort inspection engine is an integral part of the Secure Firewall Threat Defense (formerly Firepower Threat Defense) device. This chapter provides an overview of Snort 3 and the network analysis and intrusion policies. It also provides an insight into system-provided and custom network analysis and intrusion policies.

- About Network Analysis and Intrusion Policies, on page 2031
- Snort Inspection Engine, on page 2032
- Snort 3, on page 2033
- Guidelines and Limitations for Network Analysis and Intrusion Policies, on page 2035
- How Policies Examine Traffic For Intrusions, on page 2036
- System-Provided and Custom Network Analysis and Intrusion Policies, on page 2042
- Prerequisites for Network Analysis and Intrusion Policies, on page 2048

About Network Analysis and Intrusion Policies

Network analysis and intrusion policies work together as part of the intrusion detection and prevention feature.

- The term *intrusion detection* generally refers to the process of passively monitoring and analyzing network traffic for potential intrusions and storing attack data for security analysis. This is sometimes referred to as "IDS."
- The term *intrusion prevention* includes the concept of intrusion detection, but adds the ability to block or alter malicious traffic as it travels across your network. This is sometimes referred to as "IPS."

In an intrusion prevention deployment, when the system examines packets:

- A **network analysis policy** governs how traffic is *decoded* and *preprocessed* so it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.
- An **intrusion policy** uses *intrusion and preprocessor rules* (sometimes referred to collectively as *intrusion rules*) to examine the decoded packets for attacks based on patterns. Intrusion policies are paired with *variable sets*, which allow you to use named values to accurately reflect your network environment.

Both network analysis and intrusion policies are invoked by a parent access control policy, but at different times. As the system analyzes traffic, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (additional preprocessing and intrusion rules) phase. Together,

network analysis and intrusion policies provide broad and deep packet inspection. They can help you detect, alert on, and protect against network traffic that could threaten the availability, integrity, and confidentiality of hosts and their data.

The system is delivered with several similarly named network analysis and intrusion policies (for example, Balanced Security and Connectivity) that complement and work with each other. By using system-provided policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and inspector rule states, as well as provides the initial configurations for inspectors and other advanced settings.

You can also create custom network analysis and intrusion policies. You can tune settings in custom policies to inspect traffic in the way that matters most to you so that you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

You create, edit, save, and manage network analysis and intrusion policies using similar policy editors in the web interface. When you are editing either type of policy, a navigation panel appears on the left side of the web interface; the right side displays various configuration pages.

Refer to the videos for additional support and information:

- Snort 3 Condensed Overview
- Snort 3 Extended Overview

Attention **Detection mode deprecation:** From management center Version 7.4.0, for a network analysis policy (NAP), the **Detection** inspection mode is deprecated and will be removed in an upcoming release.

The **Detection** mode was intended to be used as a test mode so that you can enable inspections and see how they behave in your network before setting it to drop traffic, that is, to show traffic that would be dropped.

This behavior is improved where all inspector drops are controlled by the rule state, and you can set each one to generate events. This is done to test them before configuring the rule state to drop traffic. As we now have granular control over traffic drops in Snort 3, the **Detection** mode only adds more complexity to the product and is not needed, so the detection mode is deprecated.

If you change a NAP in **Detection** mode to **Prevention**, the NAP that processes the traffic of intrusion events and have the result "will be dropped" will now be "dropped" and the corresponding traffic will drop the traffic from these events. This is applicable for rules whose GIDs are not 1 or 3. GIDs 1 and 3 are text/compiled rules (typically provided by Talos or from your custom/imported rules) and all other GIDs are inspections for anomalies. These are more uncommon rules to trigger in a network. Changing to **Prevention** mode is unlikely to have any impact on the traffic. You need to just disable the intrusion rule that is applicable for the dropped traffic and set it to just generate or disable.

We recommend you choose **Prevention** as the inspection mode, but if you choose **Prevention**, you cannot revert to **Detection** mode.

Snort Inspection Engine

The Snort inspection engine is an integral part of the Secure Firewall Threat Defense (formerly Firepower Threat Defense) device. The inspection engine analyzes traffic in real time to provide deep packet inspection. Network analysis and intrusion policies together utilize the Snort inspection engine's capabilities to detect and protect against intrusions.

Snort 3

Snort 3 is the latest version of the Snort inspection engine, which has vast improvements compared to the earlier version of Snort. The older version of Snort is Snort 2. Snort 3 is more efficient, and it provides better performance and scalability.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Snort 3 is architecturally redesigned to inspect more traffic with equivalent resources when compared to Snort 2. Snort 3 provides simplified and flexible insertion of traffic parsers. Snort 3 also provides new rule syntax that makes rule writing easier and shared object rule equivalents visible.

The other significant changes with Snort 3 are:

- Unlike Snort 2, which uses multiple Snort instances, Snort 3 associates multiple threads with a single Snort instance. This uses less memory, improves Snort reload times, and supports more intrusion rules and a larger network map. The number of Snort threads varies by platform and is the same as the number of Snort 2 instances for each platform. Usage is virtually transparent.
- Snort version per Firewall Threat Defense—The Snort inspection engine is Firewall Threat Defense specific and not Secure Firewall Management Center (formerly Firepower Management Center) specific. Firewall Management Center can manage several Firewall Threat Defenses, each with either versions of Snort (Snort 2 and Snort 3). Although the Firewall Management Center's intrusion policies are unique, the system applies Snort 2 or Snort 3 version of an intrusion policy for intrusion protection depending on the device's selected inspection engine.
- Decoder rules—Packet decoder rules fire only in the default intrusion policy. The system ignores decoder rules that you enable in other policies.
- Shared object rules—Snort 3 supports some but not all shared object (SO) intrusion rules (rules with a generator ID (GID) of 3). Enabled shared object rules that are not supported do not trigger.
- Multi-layer inspection for Security Intelligence—Snort 3 detects the innermost IP address regardless of the layer.
- Platform support—Snort 3 requires Firewall Threat Defense 7.0 or later. It is not supported with ASA FirePOWER or NGIPSv.
- Managed Devices—An Firewall Management Center with version 7.0 can simultaneously support version 6.4, 6.5, 6.6, 6.7, and 7.0 Snort 2 Firewall Threat Defenses, and version 7.0 Snort 3 Firewall Threat Defenses.
- Traffic interruption when switching Snort versions—Switching Snort versions interrupts traffic inspection and a few packets might drop during deployment.
- Unified policies—Irrespective of the underlying Snort engine version that is enabled in the managed Firewall Threat Defenses, the access control policies, intrusion policies, and network analysis policies configured in the Firewall Management Center work seamlessly in applying the policies. All intrusion policies in Firewall Management Center version 7.0 and above have two versions available, Snort 2 version and Snort 3 version. The intrusion policy is unified, which means that it has a common name,

base policy, and inspection mode, although there are two versions of the policy (Snort 2 version and Snort 3 version). The Snort 2 and the Snort 3 versions of the intrusion policy can be different in terms of the rule settings. However, when the intrusion policy is applied on a device, the system automatically identifies the Snort version enabled on the device and applies the rule settings configured for that version.

- Lightweight Security Package (LSP)—Replaces the Snort Rule Updates (SRU) for Snort 3 next-generation intrusion rule and configuration updates. Downloading updates downloads both the Snort 3 LSP and the Snort 2 SRU.

  LSP updates provide new and updated intrusion rules and inspector rules, modified states for existing rules, and modified default intrusion policy settings for Firewall Management Center and Firewall Threat Defense versions 7.0 or above. When you upgrade an Firewall Management Center from version 6.7 or lower to 7.0, it supports both LSPs and SRUs. LSP updates may also delete system-provided rules, provide new rule categories and default variables, and modify default variable values. For more information on LSP updates, see the *Update Intrusion Rules* topic in the latest version of the *Firepower Management Center Configuration Guide*.

- Mapping of Snort 2 and Snort 3 rules and presets—Snort 2 and Snort 3 rules are mapped and the mapping is system-provided. However, it is not a one-to-one mapping. The system-provided intrusion base policies are pre-configured for both Snort 2 and Snort 3, and they provide the same intrusion prevention although with different rule sets. The system-provided base policies for Snort 2 and Snort 3 are mapped with each other for the same intrusion prevention settings. For more information, see View Snort 2 and Snort 3 Base Policy Mapping, on page 2054.

- Synchronizing Snort 2 and Snort 3 rule override—When a Firewall Threat Defense is upgraded to 7.0, you can upgrade the inspection engine of the Firewall Threat Defense to the Snort 3 version. Firewall Management Center maps all the overrides in the existing rules of the Snort 2 version of the intrusion policies to the corresponding Snort 3 rules using the mapping provided by Talos. However, if there are additional overrides performed after the upgrade or if you have installed a new Firewall Threat Defense of version 7.0, they have to be manually synchronized. For more information, see Synchronize Snort 2 Rules with Snort 3 , on page 2054.

- Custom intrusion rules—You can create custom intrusion rules in Snort 3. You can also import the custom intrusion rules that exist for Snort 2 to Snort 3. For more information, see Custom Rules in Snort 3, on page 2075.

- Rule groups—The Firewall Management Center groups all Snort 3 rules into rule groups. Rule groups are logical groups of rules which provide an easy management interface to enhance rule accessibility, rule navigation, and a better control over the rule group security level.

  From Firewall Management Center 7.3.0, rule navigation for several levels of rule groups is supported that provides more flexibility and logical grouping of rules. The MITRE framework is added that enables you to navigate through rules using the MITRE framework. MITRE is just another category of rule groups and are a part of Talos rule groups.

Note See https://attack.mitre.org for information about MITRE.

A rule can be part of multiple rule groups, such as multiple MITRE ATT&CK rule groups, a rule category rule group, multiple "asset type" rule groups, a malware campaign, and others. The available rule groups are listed in the intrusion policy editor and can be selected to enhance policies.

With this multi-level hierarchical structure, you can traverse down to the last element, which is the “leaf rule group.” These rule groups contain sets of rules that are related to each other, such as a specific type

of vulnerability, a similar target system, or a similar threat category. Rule groups have four security levels associated with them. You can change the security level, add or remove rule groups, and you can change the rule action for rules that match traffic seen on the network. This is done to bring a satisfactory balance between security, performance, and false positive resistance.

To edit a Snort 3 intrusion policy, see Edit Snort 3 Intrusion Policies, on page 2061.

For rule group reporting in intrusion events, see Rule Group Reporting, on page 2065.

- Switching between Snort 2 and Snort 3 engines—Firewall Threat Defenses (version 7.6 and earlier) that support Snort 3 can also support Snort 2. Switching from Snort 3 to Snort 2 is not recommended from the efficacy perspective.

Important Although you can switch Snort versions freely, intrusion rule changes in one version of Snort will not be updated in the other version automatically. If you change the rule action for a rule in one version of Snort, ensure you replicate the change in the other version before switching the Snort version. System provided synchronization option only synchronizes the changes in the Snort 2 version of the intrusion policy to the Snort 3 version, and not the other way around.

Guidelines and Limitations for Network Analysis and Intrusion Policies

- A high percentage of traffic with small packets causes Snort performance to decrease. This behaviour is observed even when all the preprocessors are disabled.
- When you attempt to deploy a configuration change on a threat defense device with low memory, snort deployment is also triggered. This results in high consumption of RSS memory. Snort memory usage is also impacted if you deploy large configurations on the device, such as multiple IPS policies containing a large number of snort IPS rules, network objects, and access-control lists. You can mitigate such memory issues by optimizing the configuration. For best practices on how to configure access control rules to optimize the configuration, see Best Practices for Access Control Rules.
- If you increase the memory of a Threat Defense Virtual instance, you must redeploy the configuration for Snort 3 to utilize the additional memory.

Note The Snort 3 memory allocation is not automatically adjusted when you increase the memory of the Threat Defense Virtual instance. You must redeploy the configuration to regenerate relevant configuration files, such as `memory_allocation.lua`, which apply the updated resource limits to Snort 3.

- If an SIP stream is followed by RTP streams from the same connection, Snort inspects the initial SIP communication that is sent for connection establishment and allows SIP traffic. The RTP streams that follow the SIP communication are also trusted by default and bypass the configured rules. To prevent such scenarios, trusting the parent SIP connection or adding the parent SIP connection to a prefilter rule

ensures that only the SIP stream bypasses Snort inspection and allows the subsequent RTP streams to be evaluated separately against the corresponding rules.

- When intrusion packet events are forwarded via syslog or the eStreamer fully-qualified event feed, the packet data field may be truncated due to limitations in the buffer size available for syslog generation and the eStreamer. In such scenarios, the packet length will not match the actual packet data that is sent.
- You cannot make policy changes, switch snort versions, and deploy both these changes at the same time. You must make the required policy changes and deploy, or switch the snort versions and deploy.

Feature Limitations of Snort 3 for Firewall Management Center-Managed Firewall Threat Defense

The following table lists the features that are supported on Snort 2 but not supported on Snort 3 for Firewall Management Center-managed Firewall Threat Defense devices.

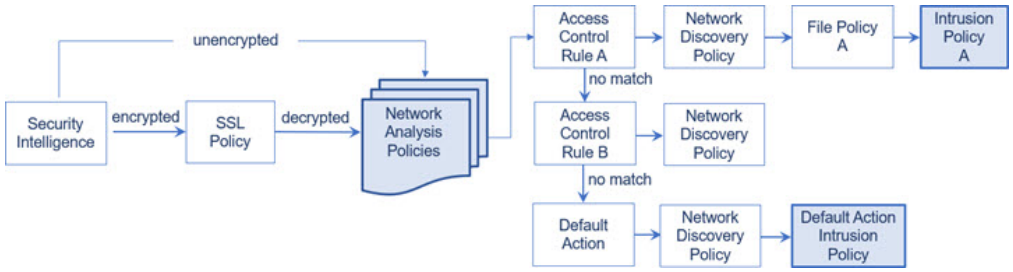
Table 108: Feature Limitations of Snort 3

Policy/Area	Features not supported
Access Control Policy	The following application settings: • Safe Search • YouTube EDU
Intrusion Policy	• Global rule thresholding • Logging configuration: • SNMP • SRU rule updates as Snort 3 supports only LSP rule updates
Other features	Event logging with FQDN names

How Policies Examine Traffic For Intrusions

When the system analyzes traffic as part of your access control deployment, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (intrusion rules and advanced settings) phase.

The following diagram shows, in a simplified fashion, the order of traffic analysis in an inline, intrusion prevention and AMP for Networks deployment. It illustrates how the access control policy invokes other policies to examine traffic, and in which order those policies are invoked. The network analysis and intrusion policy selection phases are highlighted.



In an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs), the system can block traffic without further inspection at almost any step in the illustrated process. Security Intelligence, the SSL policy, network analysis policies, file policies, and intrusion policies can all either drop or modify traffic. Only the network discovery policy, which passively inspects packets, cannot affect the flow of traffic.

Similarly, at each step of the process, a packet could cause the system to generate an event. Intrusion and preprocessor events (sometimes referred to collectively as *intrusion events*) are indications that a packet or its contents may represent a security risk.

Tip The diagram does not reflect that access control rules handle encrypted traffic when your SSL inspection configuration allows it to pass, or if you do not configure SSL inspection. By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Note that for a single connection, although the system selects a network analysis policy before an access control rule as shown in the diagram, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

Decoding, Normalizing, and Preprocessing: Network Analysis Policies

Without decoding and preprocessing, the system could not appropriately evaluate traffic for intrusions because protocol differences would make pattern matching impossible. Network analysis policies govern these traffic-handling tasks:

- **after** traffic is filtered by Security Intelligence
- **after** encrypted traffic is decrypted by an optional SSL policy
- **before** traffic can be inspected by file or intrusion policies

A network analysis policy governs packet processing in phases. First the system decodes packets through the first three TCP/IP layers, then continues with normalizing, preprocessing, and detecting protocol anomalies:

- The packet decoder converts packet headers and payloads into a format that can be easily used by the inspectors and later, intrusion rules. Each layer of the TCP/IP stack is decoded in turn, beginning with the data link layer and continuing through the network and transport layers. The packet decoder also detects various anomalous behaviors in packet headers.
- In inline deployments, the inline normalization preprocessor reformats (normalizes) traffic to minimize the chances of attackers evading detection. It prepares packets for examination by other inspectors and

intrusion rules, and helps ensure that the packets the system processes are the same as the packets received by the hosts on your network.

- Various network and transport layers inspectors detect attacks that exploit IP fragmentation, perform checksum validation, and perform TCP and UDP session preprocessing.

  Note that some advanced transport and network inspector settings apply globally to all traffic handled by the target devices of an access control policy. You configure these in the access control policy rather than in a network analysis policy.

- Various application-layer protocol decoders normalize specific types of packet data into formats that the intrusion rules engine can analyze. Normalizing application-layer protocol encodings allows the system to effectively apply the same content-related intrusion rules to packets whose data is represented differently, and to obtain meaningful results.

- The Modbus, DNP3, CIP, and s7commplus SCADA inspectors detect traffic anomalies and provide data to intrusion rules. Supervisory Control and Data Acquisition (SCADA) protocols monitor, control, and acquire data from industrial, infrastructure, and facility processes such as manufacturing, production, water treatment, electric power distribution, airport and shipping systems, and so on.

- Several inspectors allow you to detect specific threats, such as Back Orifice, portscans, SYN floods and other rate-based attacks.

  Note that you configure the sensitive data inspector, which detects sensitive data such as credit card numbers and Social Security numbers in ASCII text, in intrusion policies.

Note When TLS Server Identity is disabled, Snort 3 does not perform SNI mismatch detection. It only evaluates the SNI in the Client Hello packet and bypasses the validation of the certificate's Common Name (CN) in the Server Hello packet.

In a newly created access control policy, one default network analysis policy governs preprocessing for *all* traffic for *all* intrusion policies invoked by the same parent access control policy. Initially, the system uses the Balanced Security and Connectivity network analysis policy as the default, but you can change it to another system-provided or custom network analysis policy. In a more complex deployment, advanced users can tailor traffic preprocessing options to specific security zones, networks, and VLANs by assigning different custom network analysis policies to preprocess matching traffic.

Note For an access control policy with rule action as **Trust** and a prefilter rule with action as **Fastpath** with logging options disabled, you will observe that the end-of-flow events are still generated in the system. The events are not visible on the management center event pages.

Access Control Rules: Intrusion Policy Selection

After initial preprocessing, access control rules (when present) evaluate traffic. In most cases, the first access control rule that a packet matches is the rule that handles that traffic; you can monitor, trust, block, or allow matching traffic.

When you allow traffic with an access control rule, the system can inspect the traffic for discovery data, malware, prohibited files, and intrusions, in that order. Traffic not matching any access control rule is handled by the access control policy's default action, which can also inspect for discovery data and intrusions.

Note All packets, **regardless** of which network analysis policy preprocesses them, are matched to configured access control rules—and thus are potentially subject to inspection by intrusion policies—in top-down order.

The diagram in How Policies Examine Traffic For Intrusions, on page 2036 shows the flow of traffic through a device in an inline, intrusion prevention and AMP for Networks deployment, as follows:

- Access Control Rule A allows matching traffic to proceed. The traffic is then inspected for discovery data by the network discovery policy, for prohibited files and malware by File Policy A, and then for intrusions by Intrusion Policy A.
- Access Control Rule B also allows matching traffic. However, in this scenario, the traffic is not inspected for intrusions (or files or malware), so there are no intrusion or file policies associated with the rule. Note that by default, traffic that you allow to proceed is inspected by the network discovery policy; you do not need to configure this.
- In this scenario, the access control policy's default action allows matching traffic. The traffic is then inspected by the network discovery policy, and then by an intrusion policy. You can (but do not have to) use a different intrusion policy when you associate intrusion policies with access control rules or the default action.

The example in the diagram does not include any blocking or trusting rules because the system does not inspect blocked or trusted traffic.

Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets

You can use intrusion prevention as the system's last line of defense before traffic is allowed to proceed to its destination. Intrusion policies govern how the system inspects traffic for security violations and, in inline deployments, can block or alter malicious traffic. The main function of intrusion policies is to manage which intrusion and preprocessor rules are enabled and how they are configured.

Intrusion and Inspector Rules

An intrusion rule is a specified set of keywords and arguments that detects attempts to exploit vulnerabilities on your network; the system uses an intrusion rule to analyze network traffic to check if it matches the criteria in the rule. The system compares packets against the conditions specified in each rule and, if the packet data matches all the conditions specified in a rule, the rule triggers.

The system includes the following types of rules created by Cisco Talos Intelligence Group (Talos):

- *shared object intrusion rules*, which are compiled and cannot be modified (except for rule header information such as source and destination ports and IP addresses)
- *standard text intrusion rules*, which can be saved and modified as new custom instances of the rule.
- *preprocessor rules*, which are rules associated with inspectors and packet decoder detection options in the network analysis policy. You cannot copy or edit inspector rules. Most inspector rules are disabled by default; you must enable them to use inspectors to generate events and, in an inline deployment, drop offending packets.

When the system processes packets according to an intrusion policy, first a rule optimizer classifies all activated rules in subsets based on criteria such as: transport layer, application protocol, direction to or from the protected network, and so on. Then, the intrusion rules engine selects the appropriate rule subsets to apply to each packet. Finally, a multi-rule search engine performs three different types of searches to determine if the traffic matches the rule:

- The protocol field search looks for matches in particular fields in an application protocol.
- The generic content search looks for ASCII or binary byte matches in the packet payload.
- The packet anomaly search looks for packet headers and payloads that, rather than containing specific content, violate well-established protocols.

In a custom intrusion policy, you can tune detection by enabling and disabling rules, as well as by writing and adding your own standard text rules. You can also use Cisco recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

Note When there are insufficient packets to process specific traffic against a block rule, the system continues to evaluate the remaining traffic against other rules. If any of the remaining traffic matches a rule which is set to block, then the session is blocked. However, if the system analyses the remaining traffic to be passed, then the traffic status shows pending on the rule which is stuck for want of complete packets.

Variable Sets

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Most variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

The system provides a single default variable set, which is comprised of predefined default variables. Most system-provided shared object rules and standard text rules use these predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Tip Even if you use system-provided intrusion policies, Cisco **strongly** recommends that you modify key default variables in the default set. When you use variables that accurately reflect your network environment, processing is optimized and the system can monitor relevant systems for suspicious activity. Advanced users can create and use custom variable sets for pairing with one or more custom intrusion policies.

Important If you are creating a custom variable set, do not use a number as the first character in a custom variable set name (for example, 3Snort). This will cause Snort 3 validation to fail when you deploy a configuration to Firewall Threat Defense firewall on the Firewall Management Center.

Intrusion Event Generation

When the system identifies a possible intrusion, it generates an *intrusion or preprocessor event* (sometimes collectively called *intrusion events*). Managed devices transmit their events to the Firewall Management Center, where you can view the aggregated data and gain a greater understanding of the attacks against your network assets. In an inline deployment, managed devices can also drop or replace packets that you know to be harmful.

Each intrusion event in the database includes an event header and contains information about the event name and classification; the source and destination IP addresses; ports; the process that generated the event; and the date and time of the event, as well as contextual information about the source of the attack and its target. For packet-based events, the system also logs a copy of the decoded packet header and payload for the packet or packets that triggered the event.

The packet decoder, the preprocessors, and the intrusion rules engine can all cause the system to generate an event. For example:

- If the packet decoder (configured in the network analysis policy) receives an IP packet that is less than 20 bytes, which is the size of an IP datagram without any options or payload, the decoder interprets this as anomalous traffic. If, later, the accompanying decoder rule in the intrusion policy that examines the packet is enabled, the system generates a inspector event.
- If the IP defragmentation preprocessor encounters a series of overlapping IP fragments, the inspector interprets this as a possible attack and, when the accompanying inspector rule is enabled, the system generates a inspector event.
- Within the intrusion rules engine, most standard text rules and shared object rules are written so that they generate intrusion events when triggered by packets.

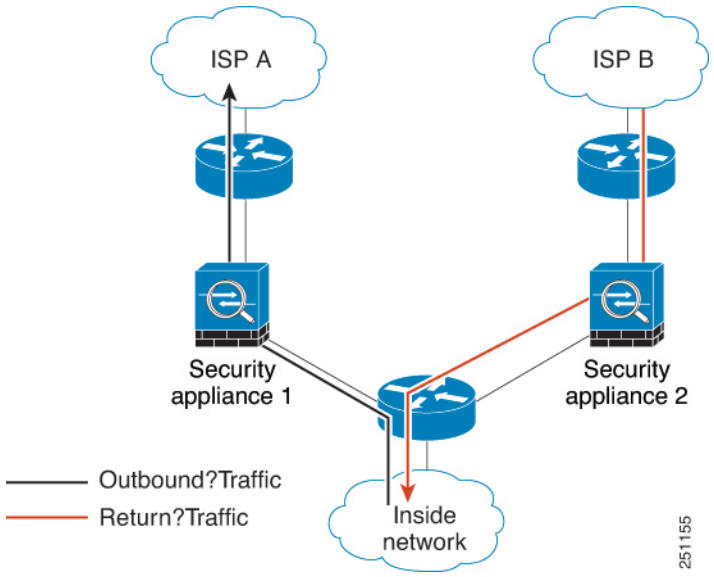
As the database accumulates intrusion events, you can begin your analysis of potential attacks. The system provides you with the tools you need to review intrusion events and evaluate whether they are important in the context of your network environment and your security policies.

Asymmetrical Flow Inspection in Snort

In an inline deployment with asymmetrical routing, packet normalization is compromised due to Snort's limited visibility of unidirectional traffic. Snort cannot account for TCP handshake parameters such as window scaling or maximum segment size (MSS) from the unseen flow direction, potentially leading to the host receiving a high volume of packets.

In the following illustration, both devices are running Snort engines. However, neither engine observes the complete traffic flow. The TCP three-way handshake of the flow is not fully captured, which limits the types of normalizations that can be applied. However, other effective normalizations are carried out on the side of the flow that is visible to the Snort engine.

Figure 446: Asymmetric Routing



In environments with asymmetric routing, Snort seamlessly adapts to the dynamics without the need for additional configuration. It dynamically adjusts its operations based on flow patterns. Note that asymmetric traffic can potentially impact firewall effectiveness and may not be the optimal choice. However, Snort is designed to provide support for such deployments when necessary.

System-Provided and Custom Network Analysis and Intrusion Policies

Creating a new access control policy is one of the first steps in managing traffic flow using the system. By default, a newly created access control policy invokes system-provided network analysis and intrusion policies to examine traffic.

The following diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

Note how:

- A default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided *Balanced Security and Connectivity network analysis policy* is the default.
- The default action of the access control policy allows all non-malicious traffic, as determined by the system-provided *Balanced Security and Connectivity intrusion policy*. Because the default action allows traffic to pass, the discovery feature can examine it for host, application, and user data before the intrusion policy can examine and potentially block malicious traffic.

- The policy uses default Security Intelligence options (global Block and Do Not Block lists only), does not decrypt encrypted traffic with an SSL policy, and does not perform special handling and inspection of network traffic using access control rules.

A simple step you can take to tune your intrusion prevention deployment is to use a different set of system-provided network analysis and intrusion policies as your defaults. Cisco delivers several pairs of these policies with the system.

Or, you can tailor your intrusion prevention deployment by creating and using custom policies. You may find that the inspector options, intrusion rule, and other advanced settings configured in those policies do not address the security needs of your network. By tuning your network analysis and intrusion policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

System-Provided Network Analysis and Intrusion Policies

Cisco delivers several pairs of network analysis and intrusion policies with the system. By using system-provided network analysis and intrusion policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos provides intrusion and inspector rule states as well as initial configurations for inspectors and other advanced settings.

No system-provided policy covers every network profile, traffic mix, or defensive posture. Each covers common cases and network setups that provide a starting point for a well-tuned defensive policy. Although you can use system-provided policies as-is, Cisco strongly recommends that you use them as the base for custom policies that you tune to suit your network.

Tip Even if you use system-provided network analysis and intrusion policies, you should configure the system's intrusion variables to accurately reflect your network environment. At a minimum, modify key default variables in the default set.

As new vulnerabilities become known, Talos releases intrusion rule updates also known as *Lightweight Security Package* (LSP). These rule updates can modify any system-provided network analysis or intrusion policy, and can provide new and updated intrusion rules and inspector rules, modified states for existing rules, and modified default policy settings. Rule updates may also delete rules from system-provided policies and provide new rule categories, as well as modify the default variable set.

If a rule update affects your deployment, the web interface marks affected intrusion and network analysis policies as out of date, as well as their parent access control policies. You must re-deploy an updated policy for its changes to take effect.

For your convenience, you can configure rule updates to automatically re-deploy affected intrusion policies, either alone or in combination with affected access control policies. This allows you to easily and automatically keep your deployment up-to-date to protect against recently discovered exploits and intrusions.

To ensure up-to-date preprocessing settings, you **must** re-deploy access control policies, which also deploys any associated SSL, network analysis, and file policies that are different from those currently running, and can also can update default values for advanced preprocessing and performance options.

Cisco delivers the following network analysis and intrusion policies with the system:

Balanced Security and Connectivity network analysis and intrusion policies

These policies are built for both speed and detection. Used together, they serve as a good starting point for most organizations and deployment types. The system uses the Balanced Security and Connectivity policies and settings as defaults in most cases.

Connectivity Over Security network analysis and intrusion policies

These policies are built for organizations where connectivity (being able to get to all resources) takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled.

Security Over Connectivity network analysis and intrusion policies

These policies are built for organizations where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic.

Maximum Detection network analysis and intrusion policies

These policies are built for organizations where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policies, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known in-the-wild exploits.

No Rules Active intrusion policy

In the No Rules Active intrusion policy, all intrusion rules, and all advanced settings except intrusion rule thresholds, are disabled. This policy provides a starting point if you want to create your own intrusion policy instead of basing it on the enabled rules in one of the other system-provided policies.

Note Depending on the system-provided base policy that is selected, the settings of the policy vary. To view the policy settings, click the **Edit** icon next to the policy and then click the **Base Policy** drop-down box.

Benefits of Custom Network Analysis and Intrusion Policies

You may find that the inspector options, intrusion rules, and other advanced settings configured in the system-provided network analysis and intrusion policies do not fully address the security needs of your organization.

Building custom policies can improve the performance of the system in your environment and can provide a focused view of the malicious traffic and policy violations occurring on your network. By creating and tuning custom policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

All custom policies have a base policy, also called a base layer, which defines the default settings for all configurations in the policy. A layer is a building block that you can use to efficiently manage multiple network analysis or intrusion policies.

In most cases, you base custom policies on system-provided policies, but you can use another custom policy. However, all custom policies have a system-provided policy as the eventual base in a policy chain. Because rule updates can modify system-provided policies, importing a rule update may affect you even if you are using a custom policy as your base. If a rule update affects your deployment, the web interface marks affected policies as out of date.

Benefits of Custom Network Analysis Policies

By default, one network analysis policy preprocesses all unencrypted traffic handled by the access control policy. That means that all packets are decoded and preprocessed according to the same settings, regardless of the intrusion policy (and therefore intrusion rule set) that later examines them.

Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default. A simple way to tune preprocessing is to create and use a custom network analysis policy as the default.

Tuning options available vary by inspector, but some of the ways you can tune inspectors and decoders include:

- You can disable inspectors that do not apply to the traffic you are monitoring. For example, the HTTP Inspect inspector normalizes HTTP traffic. If you are confident that your network does not include any web servers using Microsoft Internet Information Services (IIS), you can disable the inspector option that looks for IIS-specific traffic and thereby reduce system processing overhead.

Note If you disable a inspector in a custom network analysis policy, but the system needs to use that inspector to later evaluate packets against an enabled intrusion or inspector rule, the system automatically enables and uses the inspector although the inspector remains disabled in the network analysis policy web interface.

- Specify ports, where appropriate, to focus the activity of certain inspectors. For example, you can identify additional ports to monitor for DNS server responses or encrypted SSL sessions, or ports on which you decode telnet, HTTP, and RPC traffic.

For advanced users with complex deployments, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs. (Note that ASA FirePOWER modules cannot restrict preprocessing by VLAN.)

Note Tailoring preprocessing using custom network analysis policies—especially multiple network analysis policies—is an advanced task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful to allow the network analysis and intrusion policies examining a single packet to complement each other.

Benefits of Custom Intrusion Policies

In a newly created access control policy initially configured to perform intrusion prevention, the default action allows all traffic, but first inspects it with the system-provided Balanced Security and Connectivity intrusion policy. Unless you add access control rules or change the default action, all traffic is inspected by that intrusion policy.

To customize your intrusion prevention deployment, you can create multiple intrusion policies, each tailored to inspect traffic differently. Then, configure an access control policy with rules that specify which policy inspects which traffic. Access control rules can be simple or complex, matching and inspecting traffic using multiple criteria including security zone, network or geographical location, VLAN, port, application, requested URL, or user.

The main function of intrusion policies is to manage which intrusion and inspector rules are enabled and how they are configured, as follows:

- Within each intrusion policy, you should verify that all rules applicable to your environment are enabled, and improve performance by disabling rules that are not applicable to your environment. You can specify which rules should drop or modify malicious packets.
- Cisco recommendations allow you to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.
- You can modify existing rules and write new standard text rules as needed to catch new exploits or to enforce your security policies.

Other customizations you might make to an intrusion policy include:

- The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text. Note that other inspectors that detect specific threats (back orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.
- Global thresholds cause the system to generate events based on how many times traffic matching an intrusion rule originates from or is targeted to a specific address or address range within a specified time period. This helps prevent the system from being overwhelmed with a large number of events.
- Suppressing intrusion event notifications and setting thresholds for individual rules or entire intrusion policies can also can prevent the system from being overwhelmed with a large number of events.
- In addition to the various views of intrusion events within the web interface, you can enable logging to syslog facilities or send event data to an SNMP trap server. Per policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external responses to intrusion events. Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

Limitations of Custom Policies

Because preprocessing and intrusion inspection are so closely related, you **must** be careful that your configuration allows the network analysis and intrusion policies processing and examining a single packet to complement each other.

By default, the system uses one network analysis policy to preprocess all traffic handled by managed devices using a single access control policy. The following diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

Notice how a default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default.

A simple way to tune preprocessing is to create and use a custom network analysis policy as the default. However, if you disable a inspector in a custom network analysis policy but the system needs to evaluate preprocessed packets against an enabled intrusion or inspector rule, the system automatically enables and uses the inspector although it remains disabled in the network analysis policy web interface.

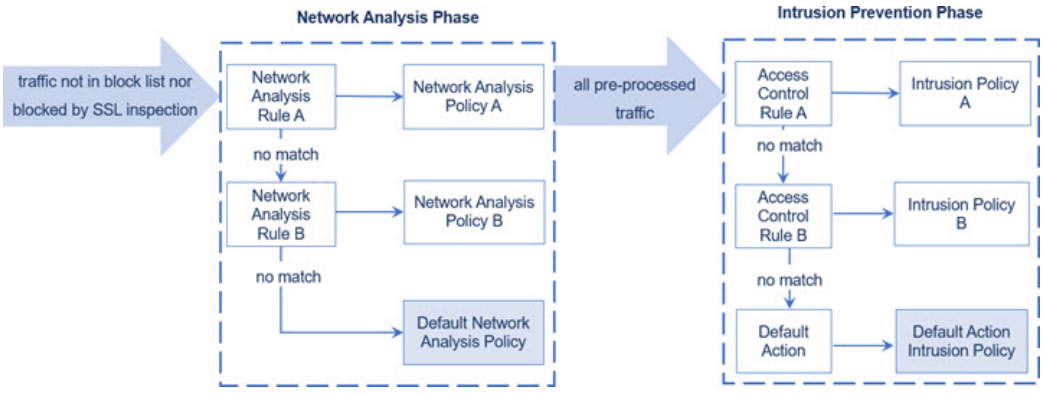
Note In order to get the performance benefits of disabling an inspector, you **must** make sure that none of your intrusion policies have enabled rules that require that inspector.

An additional challenge arises if you use multiple custom network analysis policies. For advanced users with complex deployments, you can tailor preprocessing to specific security zones, networks, and VLANs by assigning custom network analysis policies to preprocess matching traffic. (Note that ASA FirePOWER cannot restrict preprocessing by VLAN.) To accomplish this, you add custom *network analysis rules* to your access control policy. Each rule has an associated network analysis policy that governs the preprocessing of traffic that matches the rule.

Tip You configure network analysis rules as an advanced setting in an access control policy. Unlike other types of rules, network analysis rules invoke—rather than being contained by—network analysis policies.

The system matches packets to any configured network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rule is preprocessed by the default network analysis policy. While this allows you a great deal of flexibility in preprocessing traffic, keep in mind that all packets, **regardless** of which network analysis policy preprocessed them, are subsequently matched to access control rules—and thus to potential inspection by intrusion policies—in their own process. In other words, preprocessing a packet with a particular network analysis policy does **not** guarantee that the packet will be examined with any particular intrusion policy. You **must** carefully configure your access control policy so it invokes the correct network analysis and intrusion policies to evaluate a particular packet.

The following diagram shows in focused detail how the network analysis policy (preprocessing) selection phase occurs before and separately from the intrusion prevention (rules) phase. For simplicity, the diagram eliminates the discovery and file/malware inspection phases. It also highlights the default network analysis and default-action intrusion policies.



In this scenario, an access control policy is configured with two network analysis rules and a default network analysis policy:

- Network Analysis Rule A preprocesses matching traffic with Network Analysis Policy A. Later, you want this traffic to be inspected by Intrusion Policy A.
- Network Analysis Rule B preprocesses matching traffic with Network Analysis Policy B. Later, you want this traffic to be inspected by Intrusion Policy B.

- All remaining traffic is preprocessed with the default network analysis policy. Later, you want this traffic to be inspected by the intrusion policy associated with the access control policy's default action.

After the system preprocesses traffic, it can examine the traffic for intrusions. The diagram shows an access control policy with two access control rules and a default action:

- Access Control Rule A allows matching traffic. The traffic is then inspected by Intrusion Policy A.
- Access Control Rule B allows matching traffic. The traffic is then inspected by Intrusion Policy B.
- The access control policy's default action allows matching traffic. The traffic is then inspected by the default action's intrusion policy.

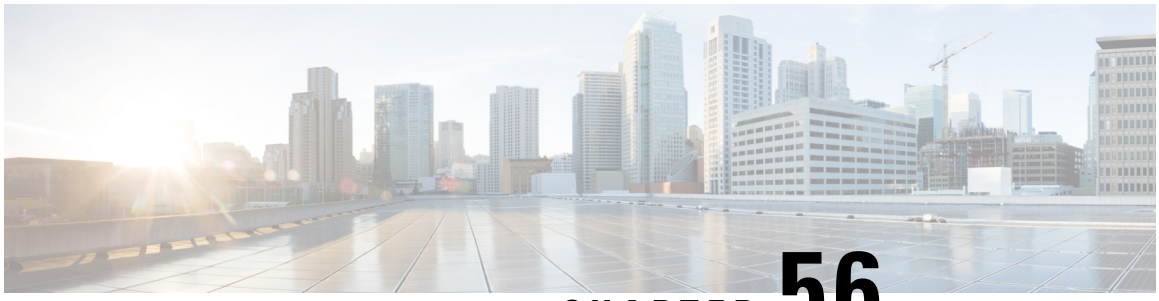
Each packet's handling is governed by a network analysis policy and intrusion policy pair, but the system does **not** coordinate the pair for you. Consider a scenario where you misconfigure your access control policy so that Network Analysis Rule A and Access Control Rule A do not process the same traffic. For example, you could intend the paired policies to govern the handling of traffic on a particular security zone, but you mistakenly use different zones in the two rules' conditions. This could cause traffic to be incorrectly preprocessed. For this reason, tailoring preprocessing using network analysis rules and custom policies is an **advanced** task.

Note that for a single connection, although the system selects a network analysis policy before an access control rule, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

Prerequisites for Network Analysis and Intrusion Policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the IPS license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.



CHAPTER 56

Migrate from Snort 2 to Snort 3

Starting with Version 7.0, Snort 3 is the default inspection engine for new Firewall Threat Defense deployments with Firewall Management Center. Snort 3 is required in Version 7.7+. If you are still using the Snort 2 inspection engine, switch to Snort 3 now for improved detection and performance.

Upgrading Firewall Threat Defense to Version 7.2 through 7.6 also upgrades eligible Snort 2 devices to Snort 3. For devices that are ineligible because they use custom intrusion or network analysis policies, manually upgrade to Snort 3 as described here.

Although you can switch individual devices back, you should not. Upgrading Firewall Threat Defense to Version 7.7+ is blocked for Snort 2 devices.

- Snort 3 Inspection Engine, on page 2049
- Prerequisites for Network Analysis and Intrusion Policies, on page 2050
- How to Migrate from Snort 2 to Snort 3, on page 2050
- View Snort 2 and Snort 3 Base Policy Mapping, on page 2054
- Synchronize Snort 2 Rules with Snort 3 , on page 2054
- Deploy Configuration Changes, on page 2055

Snort 3 Inspection Engine

Snort 3 is the default inspection engine for newly registered Firewall Threat Defense devices of version 7.0 and later. However, for Firewall Threat Defense devices of lower versions, Snort 2 is the default inspection engine. When you upgrade a managed Firewall Threat Defense device to version 7.0 or later, the inspection engine remains on Snort 2. To use Snort 3 in upgraded Firewall Threat Defenses of version 7.0 and later, you must explicitly enable it. When Snort 3 is enabled as the inspection engine of the device, the Snort 3 version of the intrusion policy that is applied on the device (through the access control policies) is activated and applied to all the traffic passing through the device.

You can switch Snort versions when required. Snort 2 and Snort 3 intrusion rules are mapped and the mapping is system-provided. However, you may not find a one-to-one mapping of all the intrusion rules in Snort 2 and Snort 3. If you change the rule action for one rule in Snort 2, that change is not retained if you switch to Snort 3 without synchronizing Snort 2 with Snort 3. For more information on synchronization, see Synchronize Snort 2 Rules with Snort 3 , on page 2054.

Prerequisites for Network Analysis and Intrusion Policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the IPS license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

How to Migrate from Snort 2 to Snort 3

Migrating from Snort 2 to Snort 3 requires you to switch the inspection engine of the Firewall Threat Defense device from Snort 2 to Snort 3.

Depending on your requirements, the tasks to complete the migration of your device from Snort 2 to Snort 3 is listed in the following table:

Step	Task	Links to Procedures
1	Enable Snort 3	• Enable Snort 3 on an Individual Device, on page 2051 • Enable Snort 3 on Multiple Devices, on page 2051
2	Convert Snort 2 custom rules to Snort 3	• Convert all Snort 2 Custom Rules across all Intrusion Policies to Snort 3, on page 2052 • Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3, on page 2053
3	Synchronize Snort 2 rules with Snort 3	Synchronize Snort 2 Rules with Snort 3 , on page 2054

Prerequisites for Migrating from Snort 2 to Snort 3

The following are the recommended prerequisites that you must consider before migrating your device from Snort 2 to Snort 3.

- Have a working knowledge of Snort. To learn about the Snort 3 architecture, see Snort 3 Adoption.
- Back up your management center. See Backup the Management Center.
- Back up your intrusion policy. See Exporting Configurations.
- Clone your intrusion policy. To do this, you can use an existing policy as the base policy to create a copy of your intrusion policy. In the **Intrusion Policies** page, click **Create Policy** and choose an existing intrusion policy from the **Base Policy** dropdown list.

Enable Snort 3 on an Individual Device

Important During the deployment process, there could be a momentary traffic loss because the current inspection engine needs to be shut down.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the device to go to the device home page.

Note
The device is marked as Snort 2 or Snort 3, showing the current version on the device.

Step 3 Click the **Device** tab.

Step 4 In the Inspection Engine section, click **Upgrade**.

Note
In case you want to disable Snort 3, click **Revert to Snort 2** in the Inspection Engine section.

Step 5 Click **Yes**.

What to do next

Deploy the changes on the device. See, Deploy Configuration Changes, on page 2055.

The system converts your policy configurations during the deployment process to make them compatible with the selected Snort version.

Enable Snort 3 on Multiple Devices

To enable Snort 3 on multiple devices, ensure all the required Firewall Threat Defense devices are on version 7.0 or later.

Important During the deployment process, there could be a momentary traffic loss because the current inspection engine needs to be shut down.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Select all the devices on which you want to enable or disable Snort 3.

Note

The devices are marked as Snort 2 or Snort 3, showing the current version on the device.

Step 3 Click **Select Bulk Action** drop-down list and choose **Upgrade to Snort 3**.

Step 4 Click **Yes**.

What to do next

Deploy the changes on the device. See, Deploy Configuration Changes, on page 2055.

The system converts your policy configurations during the deployment process to make them compatible with the selected Snort version.

Convert Snort 2 Custom IPS Rules to Snort 3

If you are using a rule set from a third-party vendor, contact that vendor to confirm that their rules successfully convert to Snort 3 or to obtain a replacement rule set written natively for Snort 3. If you have custom rules that you have written yourself, familiarize with writing Snort 3 rules prior to conversion, so you can update your rules to optimize Snort 3 detection after conversion. See the links below to learn more about writing rules in Snort 3.

- https://blog.snort.org/2020/08/how-rules-are-improving-in-snort-3.html
- https://blog.snort.org/2020/10/talos-transition-to-snort-3.html

You can refer to other blogs at https://blog.snort.org/ to learn more about Snort 3 rules.

See the following procedures to convert Snort 2 rules to Snort 3 rules using the system-provided tool.

- Convert all Snort 2 Custom Rules across all Intrusion Policies to Snort 3, on page 2052
- Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3, on page 2053

Important Snort 2 network analysis policy (NAP) settings *cannot* be copied to Snort 3 automatically. NAP settings have to be manually replicated in Snort 3.

Convert all Snort 2 Custom Rules across all Intrusion Policies to Snort 3

Procedure

Step 1 Choose **Objects** > **Intrusion Rules** .

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Ensure **All Rules** is selected in the left pane.

Step 4 Click the **Tasks** drop-down list and choose:

- **Convert Snort 2 rules and import**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.

- **Convert Snort 2 rules and download**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and download them into your local system.

Step 5 Click **OK**.

Note

- If you selected **Convert and import** in the previous step, then all the converted rules are saved under a newly created rule group **All Snort 2 Converted Global** under **Local Rules**.
- If you selected **Convert and download** in the previous step, then save the rules file locally. You can review the converted rules in the downloaded file and later upload them by following the steps in Add Custom Rules to Rule Groups, on page 2087.

Refer to the video Converting Snort 2 Rules to Snort 3 for additional support and information.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 In the **Intrusion Policies** tab, click **Show Snort 3 Sync status**.

Step 3 Click the **Sync** icon **Snort out-of-Sync** () of the intrusion policy.

Note
If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in blue**Snort in-Sync** (). It indicates that there are no custom rules to be converted.

Step 4 Read through the summary and click the **Custom Rules** tab.

Step 5 Choose:

- **Import converted rules to this policy**—To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.
- **Download converted rules**—To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and download them into your local system. You can review the converted rules in the downloaded file and later upload the file by clicking the upload icon.

Step 6 Click **Re-Sync**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

View Snort 2 and Snort 3 Base Policy Mapping

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **IPS Mapping**.

Step 4 In the **IPS Policy Mapping** dialog box, click **View Mappings** to view the Snort 3 to Snort 2 intrusion policy mapping.

Step 5 Click **OK**.

Synchronize Snort 2 Rules with Snort 3

To ensure that the Snort 2 version settings and custom rules are retained and carried over to Snort 3, the Firewall Management Center provides the synchronization functionality. Synchronization helps Snort 2 rule override settings and custom rules, which you may have altered and added over the last few months or years, to be replicated on the Snort 3 version. This utility helps to synchronize Snort 2 version policy configuration with Snort 3 version to start with similar coverage.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

If the Firewall Management Center is upgraded from 6.7 or earlier to 7.0 or later version, the system synchronizes the configuration. If the Firewall Management Center is a fresh 7.0 or later version, you can upgrade to a higher version, and the system will not synchronize any content during upgrade.

Before upgrading a device to Snort 3, if changes are made in Snort 2 version, you can use this utility to have the latest synchronization from Snort 2 version to Snort 3 version so that you start with a similar coverage.

Note On moving to Snort 3, it is recommended that you manage the Snort 3 version of the policy independently and do not use this utility as a regular operation.

Important

- Only the Snort 2 rule overrides and custom rules are copied to Snort 3 and not the other way around. You may not find a one-to-one mapping of all the intrusion rules in Snort 2 and Snort 3. Your changes to rule actions for rules that exist in both versions are synchronized when you perform the following procedure.
- Synchronization *does not* migrate the threshold and suppression settings of any custom or system-provided rules from Snort 2 to Snort 3.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **Show Snort 3 Sync status**.

Step 4 Identify the intrusion policy that is out-of-sync.

Step 5 Click the **Sync** icon **Snort out-of-Sync** ( ).

Note
If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in blue**Snort in-Sync** ( ).

Step 6 Read through the summary and download a copy of the summary if required.

Step 7 Click **Re-Sync**.

Note
- The synchronized settings will be applicable on the Snort 3 intrusion engine only if it is applied on a device, and after a successful deployment.
- Snort 2 custom rules can be converted to Snort 3 using the system-provided tool. If you have any Snort 2 custom rules click the Custom Rules tab and follow the on-screen instructions to convert the rules. For more information, see Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3, on page 2053.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Deploy Configuration Changes

After you change configurations, deploy them to the affected devices.

Note This topic covers the basic steps involved in deploying configuration changes. We *strongly* recommend that you refer the *Deploy Configuration Changes* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide* to understand the prerequisites and implications of deploying the changes before proceeding with the steps.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic.

Procedure

Step 1 On the Secure Firewall Management Center menu bar, click **Deploy** and choose **Deployment**.

The GUI page lists the devices with out-of-date configurations having **Pending**status.

- The **Modified By** column lists the users who have modified the policies or objects. Expand the device listing to view the users who have modified the policies for each policy listing.

  Note
  Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption might occur in the device during deployment.

  If this column is blank for a device, it indicates that there will be no traffic inspection interruptions on that device during deployment.

- The **Last Modified Time** column specifies the last time you made configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment.

Step 2 Identify and choose the devices on which you want to deploy configuration changes.

- Search—Search for the device name, type, domain, group, or status in the search box.
- Expand—Click **Expand Arrow** (>) to view device-specific configuration changes to be deployed.

  When you check a check box adjacent to a device, all the changes made to the device and listed under the device, are pushed for deployment. However, you can use **Policy selection** ( ) to select individual policies or specific configurations to deploy while withholding the remaining changes without deploying them.

  Note
  - When the status in the **Inspect Interruption** column indicates (**Yes**) that deploying will interrupt inspection, and perhaps traffic, on a Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).

- When there are changes to interface groups, security zones, or objects, the impacted devices are shown as out-of-date on the Firewall Management Center. To ensure that these changes take effect, the policies with these interface groups, security zones, or objects, also need to be deployed along with these changes. The impacted policies are shown as out-of-date on the **Preview**page on the Firewall Management Center.

Step 3 Click **Deploy**.

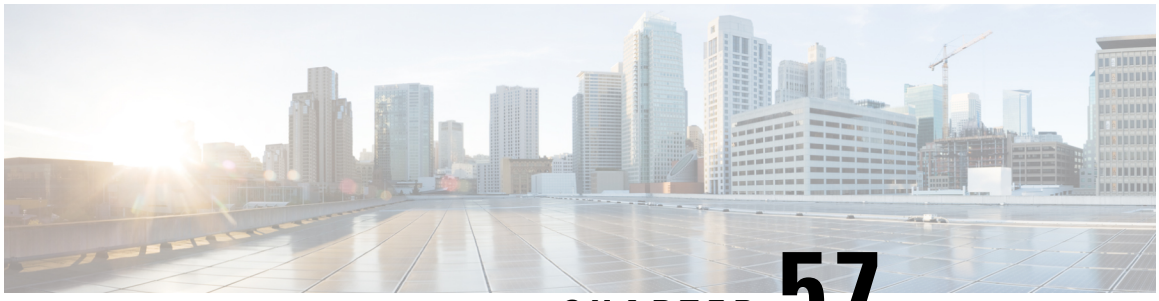
Step 4 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. You cannot proceed if the system identifies errors.
- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

What to do next

During deployment, if there is a deployment failure, there is a possibility that the failure may impact traffic. However, it depends on certain conditions. If there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For details, see the Deploy Configuration Changes topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.



CHAPTER 57

Get Started with Snort 3 Intrusion Policies

This chapter provides information on managing Snort 3 intrusion policies and access control rule configurations for intrusion detection and prevention.

- Overview of Intrusion Policies, on page 2059
- Prerequisites for Network Analysis and Intrusion Policies, on page 2060
- Create a Custom Snort 3 Intrusion Policy , on page 2060
- Edit Snort 3 Intrusion Policies, on page 2061
- Change the Base Policy of an Intrusion Policy, on page 2066
- View Snort 2 and Snort 3 Base Policy Mapping, on page 2066
- Synchronize Snort 2 Rules with Snort 3 , on page 2067
- Manage Intrusion Policies, on page 2068
- Access Control Rule Configuration to Perform Intrusion Prevention, on page 2069
- Deploy Configuration Changes, on page 2071

Overview of Intrusion Policies

Intrusion policies are defined sets of intrusion detection and prevention configurations that inspect traffic for security violations and, in inline deployments, can block or alter malicious traffic. Intrusion policies are invoked by your access control policy and are the system's last line of defense before traffic is allowed to its destination.

At the heart of each intrusion policy are the intrusion rules. An enabled rule causes the system to generate intrusion events for (and optionally block) traffic matching the rule. Disabling a rule stops processing of the rule.

The system delivers several base intrusion policies, which enable you to take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and inspector rule states (enabled or disabled), as well as provides the initial configurations for other advanced settings.

Tip System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules.

If you create a custom intrusion policy, you can:

- Tune detection by enabling and disabling rules, as well as by writing and adding your own rules.
- Use Secure Firewall recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

An intrusion policy can drop matching packets and generate intrusion events. To configure an intrusion or preprocessor drop rule, set its state to Block.

When tailoring your intrusion policy, especially when enabling and adding rules, keep in mind that some intrusion rules require that traffic first be decoded or preprocessed in a certain way. Before an intrusion policy examines a packet, the packet is preprocessed according to configurations in a network analysis policy. If you disable a required inspector, the system automatically uses it with its current settings, although the inspector remains disabled in the network analysis policy web interface.

Caution Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet **must** complement each other. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task.

After you configure a custom intrusion policy, you can use it as part of your access control configuration by associating the intrusion policy with one or more access control rules or an access control policy's default action. This forces the system to use the intrusion policy to examine certain allowed traffic before the traffic passes to its final destination. A variable set that you pair with the intrusion policy allows you to accurately reflect your home and external networks and, as appropriate, the servers on your network.

Note that by default, the system disables intrusion inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion inspection configured.

Refer to the video for additional support and information - Snort 3 Intrusion Policy Overview.

Prerequisites for Network Analysis and Intrusion Policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the IPS license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

Create a Custom Snort 3 Intrusion Policy

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Click **Create Policy**.

Step 3 Enter a unique **Name** and, optionally, a **Description**.

Step 4 Choose the **Inspection Mode**.

The selected action determines whether intrusion rules block and alert (**Prevention** mode) or only alert (**Detection** mode).

Note
Before selecting the prevention mode, you might want block rules to alert only so you can identify rules that cause a lot of false positives.

Step 5 Choose the **Base Policy**.

You can use either a system-provided policy or an existing policy as your base policy.

Step 6 Click **Save**.

The new policy has the same settings as its base policy.

What to do next

To customize the policy, see Edit Snort 3 Intrusion Policies, on page 2061.

Edit Snort 3 Intrusion Policies

While editing a Snort 3 policy, all the changes are saved instantaneously. No additional action is required to save the changes.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **Snort 3 Version** next to the intrusion policy you want to configure.

Step 4 Edit your policy:

- Change the mode—Click the **Mode** drop-down to change the inspection mode.

Caution
The inspection mode is changed only for the Snort 3 version of the policy. The existing inspection mode is retained in the Snort 2 version as is, which means that your Snort 2 and Snort 3 versions of the policy will have different inspection modes. We recommend you to use this option with caution.

- **Prevention**—Triggered Block rules create an event (alert) and drop the connection.
- **Detection**—Triggered Block rules create an alert.

  You can choose the detection mode before going for prevention. For example, before choosing the prevention mode, you might want block rules to alert only, so that you can identify rules that cause a lot of false positives.

Step 5 Click the **Base Policy** layer that defines the intrusion policy's default settings.

- Search rules—Use the search field to filter the display. You can enter the GID, SID, rule message, or reference info. For example, GID:1; SID:9621—to display only rule 1:962, SID:9621,9622,9623—to display multiple rules with different SIDs. You can also click inside the Search text box to choose any of the following options:
  - apply the filters **Action = Alert**, or **Action: Block**
  - apply the **Disabled Rules** filter
  - show **Custom/User Defined Rules**
  - filter by GID, SID, or GID:SID
  - filter by CVE
  - filter by comment
- View filtered rules—Click any of the **Presets** to view rules that are set to alert, block, disabled, and so on.

  Overridden rules indicate the rules where the rule action has been changed from the default action to a different action. Note that, once changed, the rule action status is Overridden even if you change it back to its original default action. However, if you select **Revert to default** from the **Rule Action** drop-down list, the Overridden status is removed.

  Advanced Filters provides filter options based on the Lightweight Security Package (LSP) releases, Classifications of intrusions, and Microsoft Vulnerabilities.
- View rule documentation—Click the rule ID or the **Rule Documentation** icon to display Talos documentation for the rule.
- View a rule details—Click the **Expand Arrow** (›) icon in a rule row to view the rule details.
- Add rule comments—Click **Comment** (💬) under the Comments column to add comments for a rule.

Step 6 **Group Overrides**—Click the **Group Overrides** layer that lists all the categories of rule groups. The top level parent rule groups with Description, Overrides and Enabled Groups, and so on is displayed. Parent rule groups cannot be updated and are read-only. Only the leaf rule groups can be updated. In each rule group, you can traverse up to the last leaf group. Across each group, you can override, include, and exclude rule groups. In the leaf rule groups, you can:

- Search rule groups—Use the search field to enter keywords and search for rule groups.
- In the left panel, you can choose any of the preset filter options to search for rule groups:
  - All—For displaying all rule groups.
  - Excluded—For excluded groups.
  - Included—For included groups.
  - Overridden—For rule group configuration that is overridden.
- Set the security level for a rule group—Navigate to the required rule group on the left pane and click it. Click **Edit** next to the **Security Level** of the rule group to increase or decrease the security level based on system-defined rule settings.

  In the **Edit Security Level** dialog box, you have the option to click **Revert to Default**, which reverts the changes you made.

The Firewall Management Center automatically changes the action for the rules of the rule group for the configured security level. In the **Rule Overrides** layer, notice the count of Block Rules and Disabled Rules in the **Presets** every time you change the security level.

- You can make bulk changes to the security level to change the security level of all rule groups within a particular rule category. Bulk security level applies to rule groups that have more than one rule group. After a bulk update of rule groups, you can still update the security level of any of the associated rule groups within it.

  There can be **mixed** security levels within rule groups; **mixed** indicates that the child groups contain a mix of security levels within the parent rule group.

- Include or exclude rule groups—The rule groups displayed are the default rule groups associated with the system-provided base intrusion policy. You can include and exclude rule groups from the intrusion policy. An excluded rule group is removed from the intrusion policy and its rules are not applied on the traffic. For information on uploading custom rules in Firewall Management Center, see Add Custom Rules to Rule Groups, on page 2087.

  To exclude a rule group:

  a. Navigate the Rule Groups pane and choose the rule group that you want to exclude.

  b. Click the **Exclude** hyperlink on the right-pane.

  c. Click **Exclude**.

  To include a new rule group or multiple rule groups with the uploaded custom rules or a previously excluded rule group:

  a. Click **Add** (+) next to the rule group filter dropdown list.

  b. Choose all the rule groups you want to add by checking the check box next to it.

  c. Click **Save**.

- For a leaf rule group, click the icon under the **Override** column header to see the rule action trail, which describes the sequence of overridden rule actions that can be assigned due to the base policy and group overrides for an intrusion rule. Rule actions can be obtained from either the base policy configurations or the user group override. The user group override takes the priority between the two; priority refers to the final overridden action that is assigned to the rule group.

- Click the rule count (number) under the **Rule Count** column header to see a summary of rules that are part of the rule group.

Step 7 **Recommendations**—Click the **Recommendations** layer if you want to generate and apply Cisco recommended rules. Recommendations use the host database to enable or disable rules, based on known vulnerabilities.

Step 8 **Rule Overrides**—Click the **Rule Overrides** layer to choose any of the presets to view rules, which are set to alert, block, disabled, overridden, rewrite, pass, drop, or reject.

- The **Set By** column shows the default set by state (Base Policy) or modified rule state by Group Overrides, Rule Overrides, or Recommendations. The **Set By** column in **All Rules** (in the left pane) shows the trail of rule action override actions based on priority order. The priority order of rule actions is Rule Override > Recommendations > Group Override > Base Policy.

- Modify **Rule Action**—To modify rule actions, choose either of the following:

- Bulk edit—Choose one or more rules, then choose the required action from the **Rule Action** drop-down list; and click **Save**.

  Note
  Bulk rule action changes are supported only for the first 500 rules.

- Single rule edit—Choose the action for the rule from the drop-down list in the **Rule Action** column.

Rule actions are:

- **Block**— Generates event, blocks current matching packet and all the subsequent packets in this connection.
- **Alert**— Generates only events for matching packet and does not drop packet or connection.
- **Disable**—Does not match traffic against this rule. No events are generated.
- **Revert to default**—Reverts to the system default action.
- **Pass**— No events are generated, allows packet to pass without further evaluation by any subsequent Snort rules.

  Note
  The Pass action is available only for custom rules and not for system-provided rules.

- **Drop**— Generates event, drops matching packet and does not block further traffic in this connection.
- **Reject**— Generates event, drops matching packet, blocks further traffic in this connection and sends TCP reset if it is a TCP protocol to source and destination hosts.

  Behavior of reject in different firewall modes and IP address or source or destination in relation to Client or Server: Snort sends RST packets to both client and server in cases of routed, inline, and bridged interfaces. Snort sends two RST packets. RST packet in clients directions will have source set to server's IP and destination set to client's IP. RST packet in servers direction will have source set to client's IP and destination set to server's IP.

- **Rewrite**— Generates event and overwrites packet contents based on the replace option in the rule.

For IPS rule action logging, see Rule Action Logging, on page 2065.

If there is a **React** rule, it is converted to an alert action.

Step 9 Click the **Summary** layer for a holistic view of the current changes to the policy. The policy summary page contains the following information:

- Rule distribution of the policy, that is, active rules, disabled rules, and so on.
- Option to export policy and generate report of the intrusion policy.
- Base policy details.
- Option to generate recommendations.
- Group overrides that shows the list of groups that you have overridden.
- Rule overrides that shows the list of rules that you have overridden.

- In the **Summary** layer, click the ? icon to open a popup window of the Snort helper guide that explains the Snort layering concepts.

To change the base policy, see Change the Base Policy of an Intrusion Policy, on page 2066.

Note
You can navigate to **Objects** > **Intrusion Rules** and click the **Snort 3 All Rules** tab and traverse through all the intrusion rule groups. The parent rule group lists the associated child groups and rule count.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Rule Group Reporting

The rule groups are reflected in the intrusion events generated and MITRE tactics and techniques are also called out. There are columns for MITRE tactics and techniques and for non-MITRE rule groups for intrusion events. To access the intrusion events, in Firewall Management Center, go to **Analysis** > **Intrusions** > **Events**, and click the **Table View of Events** tab. You can also view the intrusion event fields in the **Unified Events** viewer. In the **Analysis** tab, click **Unified Events**.

In the **Intrusion Events** page, the following fields are added for rule group reporting. Note that you must explicitly enable the mentioned columns.

- MITRE ATT&CK
- Rule Group

For information about these fields, see the section *Intrusion Event Fields* in the *Cisco Secure Firewall Management Center Administration Guide, 7.3*.

Rule Action Logging

From Firewall Management Center 7.2.0 onwards, in the **Intrusion Events** page, the event in the **Inline Result** column displays the same name as the IPS action applied to the rule, so that you can see the action that was applied on the traffic matching the rule.

For the IPS actions, the following table shows the events that are displayed in the **Inline Result** column of the **Intrusion Events** page and **Action** column for **Intrusion Event Type** in the **Unified Events** page.

IPS Action for Snort 3	Inline Result - Firewall Management Center 7.1.0 and earlier	Inline Result -Firewall Management Center 7.2.0 onwards
Alert	Pass	Alert
Block	Dropped/Would Have Dropped/Partially Dropped	Block/Would Block/Partial Block
Drop	Dropped/Would have dropped	Drop/Would drop
Reject	Dropped/Would have dropped	Reject/Would reject

IPS Action for Snort 3	Inline Result - Firewall Management Center 7.1.0 and earlier	Inline Result -Firewall Management Center 7.2.0 onwards
Rewrite	Allow	Rewrite

Important

- In case of a rule without the “Replace” option, the **Rewrite** action is displayed as **Would Rewrite**.
- The **Rewrite** action would also be displayed as **Would Rewrite** if the "Replace" option is specified, but the IPS policy is in Detection mode or the device is in Inline-TAP/Passive mode.

Note In case of backward compatibility (Firewall Management Center 7.2.0 managing a Firewall Threat Defense 7.1.0 device), the events mentioned are applicable only to the Alert IPS action where **Pass** is displayed as **Alert** for events. For all the other actions, the events for Firewall Management Center 7.1.0 are applicable.

Change the Base Policy of an Intrusion Policy

You can choose a different system-provided or custom policy as your base policy.

You can chain up to five custom policies, with four of the five using one of the other four previously created policies as its base policy; the fifth must use a system-provided policy as its base.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Click **Edit** (✎) next to the intrusion policy you want to configure.

Step 3 Choose a policy from the **Base Policy** drop-down list.

Step 4 Click **Save**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

View Snort 2 and Snort 3 Base Policy Mapping

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **IPS Mapping**.

Step 4 In the **IPS Policy Mapping** dialog box, click **View Mappings** to view the Snort 3 to Snort 2 intrusion policy mapping.

Step 5 Click **OK**.

Synchronize Snort 2 Rules with Snort 3

To ensure that the Snort 2 version settings and custom rules are retained and carried over to Snort 3, the Firewall Management Center provides the synchronization functionality. Synchronization helps Snort 2 rule override settings and custom rules, which you may have altered and added over the last few months or years, to be replicated on the Snort 3 version. This utility helps to synchronize Snort 2 version policy configuration with Snort 3 version to start with similar coverage.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

If the Firewall Management Center is upgraded from 6.7 or earlier to 7.0 or later version, the system synchronizes the configuration. If the Firewall Management Center is a fresh 7.0 or later version, you can upgrade to a higher version, and the system will not synchronize any content during upgrade.

Before upgrading a device to Snort 3, if changes are made in Snort 2 version, you can use this utility to have the latest synchronization from Snort 2 version to Snort 3 version so that you start with a similar coverage.

Note On moving to Snort 3, it is recommended that you manage the Snort 3 version of the policy independently and do not use this utility as a regular operation.

Important

- Only the Snort 2 rule overrides and custom rules are copied to Snort 3 and not the other way around. You may not find a one-to-one mapping of all the intrusion rules in Snort 2 and Snort 3. Your changes to rule actions for rules that exist in both versions are synchronized when you perform the following procedure.
- Synchronization *does not* migrate the threshold and suppression settings of any custom or system-provided rules from Snort 2 to Snort 3.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **Show Snort 3 Sync status**.

Step 4 Identify the intrusion policy that is out-of-sync.

Step 5 Click the **Sync** icon **Snort out-of-Sync** ( ).

Note
If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in blue**Snort in-Sync** ( ).

Step 6 Read through the summary and download a copy of the summary if required.

Step 7 Click **Re-Sync**.

Note

- The synchronized settings will be applicable on the Snort 3 intrusion engine only if it is applied on a device, and after a successful deployment.
- Snort 2 custom rules can be converted to Snort 3 using the system-provided tool. If you have any Snort 2 custom rules click the Custom Rules tab and follow the on-screen instructions to convert the rules. For more information, see Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3, on page 2053.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Manage Intrusion Policies

On the Intrusion Policy page (**Policies** > **Intrusion**) you can view your current custom intrusion policies, along with the following information:

- Number of access control policies and devices are using the intrusion policy to inspect traffic
- In a multidomain deployment, the domain where the policy was created

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Manage your intrusion policy:

- Create — Click **Create Policy**; see Create a Custom Snort 3 Intrusion Policy , on page 2060.
- Delete — Click **Delete** ( ) next to the policy you want to delete. The system prompts you to confirm and informs you if another user has unsaved changes in the policy. Click **OK** to confirm.

  If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Edit intrusion policy details — Click **Edit** ( ) next to the policy you want to edit. You can edit the **Name**, **Inspection Mode**, and the **Base Policy** of the intrusion policy.
- Edit intrusion policy settings — Click **Snort 3 Version**; see Edit Snort 3 Intrusion Policies, on page 2061.
- Export — If you want to export an intrusion policy to import on another Firewall Management Center, click Export; see the *Exporting Configurations* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.
- Deploy — Choose **Deploy** > **Deployment**; see Deploy Configuration Changes, on page 2055.
- Report — Click **Report**; see the *Generating Current Policy Reports* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*. Generates wo reports, one for each policy version.

Access Control Rule Configuration to Perform Intrusion Prevention

An access control policy can have multiple access control rules associated with intrusion policies. You can configure intrusion inspection for any Allow or Interactive Block access control rule, which permits you to match different intrusion inspection profiles against different types of traffic on your network before it reaches its final destination.

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

Tip Even if you use system-provided intrusion policies, Cisco **strongly** recommends you configure the system's intrusion variables to accurately reflect your network environment. At a minimum, modify default variables in the default set.

Understanding System-Provided and Custom Intrusion Policies

Cisco delivers several intrusion policies with the system. By using system-provided intrusion policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for advanced settings. You can use system-provided policies as-is, or you can use them as the base for custom policies. Building custom policies can improve the performance of the system in your environment and provide a focused view of the malicious traffic and policy violations occurring on your network.

Connection and Intrusion Event Logging

When an intrusion policy invoked by an access control rule detects an intrusion and generates an intrusion event, it saves that event to the Management Center. The system also automatically logs the end of the connection where the intrusion occurred to the Management Center database, regardless of the logging configuration of the access control rule.

Access Control Rule Configuration and Intrusion Policies

The number of unique intrusion policies you can use in a single access control policy depends on the model of the target devices; more powerful devices can handle more. Every unique **pair** of intrusion policy and variable set counts as one policy. Although you can associate a different intrusion policy-variable set pair with each Allow and Interactive Block rule (as well as with the default action), you cannot deploy an access control policy if the target devices have insufficient resources to perform inspection as configured.

Configure an Access Control Rule to Perform Intrusion Prevention

You must be an Admin, Access Admin, or Network Admin to perform this task.

Procedure

Step 1 In the access control policy editor, create a new rule or edit an existing rule; see the *Access Control Rule Components* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.

Step 2 Ensure the rule action is set to **Allow**, **Interactive Block**, or **Interactive Block with reset**.

Step 3 Click **Inspection**.

Step 4 Choose a system-provided or a custom intrusion policy, or choose **None** to disable intrusion inspection for traffic that matches the access control rule.

Step 5 If you want to change the variable set associated with the intrusion policy, choose a value from the **Variable Set** drop-down list.

Step 6 Click **Save** to save the rule.

Step 7 Click **Save** to save the policy.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Deploy Configuration Changes

After you change configurations, deploy them to the affected devices.

Note This topic covers the basic steps involved in deploying configuration changes. We *strongly* recommend that you refer the *Deploy Configuration Changes* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide* to understand the prerequisites and implications of deploying the changes before proceeding with the steps.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic.

Procedure

Step 1 On the Secure Firewall Management Center menu bar, click **Deploy** and choose **Deployment**.

The GUI page lists the devices with out-of-date configurations having **Pending**status.

- The **Modified By** column lists the users who have modified the policies or objects. Expand the device listing to view the users who have modified the policies for each policy listing.

  Note
  Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption might occur in the device during deployment.

  If this column is blank for a device, it indicates that there will be no traffic inspection interruptions on that device during deployment.

- The **Last Modified Time** column specifies the last time you made configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment.

Step 2 Identify and choose the devices on which you want to deploy configuration changes.

- Search—Search for the device name, type, domain, group, or status in the search box.
- Expand—Click **Expand Arrow** (>) to view device-specific configuration changes to be deployed.

  When you check a check box adjacent to a device, all the changes made to the device and listed under the device, are pushed for deployment. However, you can use **Policy selection** ( ) to select individual policies or specific configurations to deploy while withholding the remaining changes without deploying them.

  Note
  - When the status in the **Inspect Interruption** column indicates (**Yes**) that deploying will interrupt inspection, and perhaps traffic, on a Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).
  - When there are changes to interface groups, security zones, or objects, the impacted devices are shown as out-of-date on the Firewall Management Center. To ensure that these changes take effect, the policies with these interface groups, security zones, or objects, also need to be deployed along with these changes. The impacted policies are shown as out-of-date on the **Preview**page on the Firewall Management Center.

Step 3 Click **Deploy**.

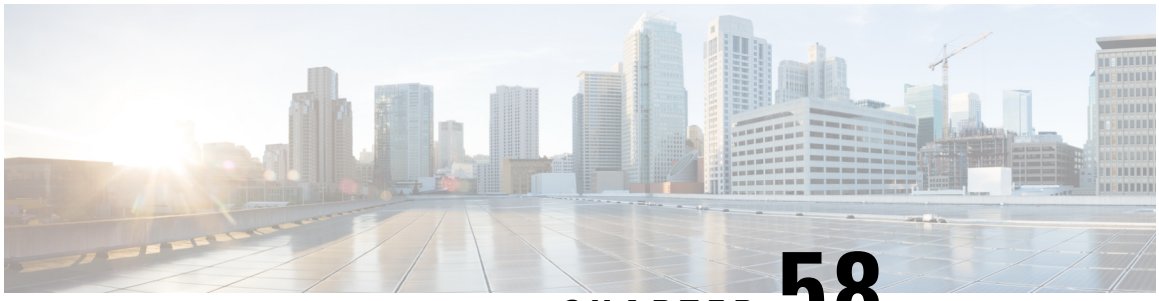
Step 4 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. You cannot proceed if the system identifies errors.
- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

What to do next

During deployment, if there is a deployment failure, there is a possibility that the failure may impact traffic. However, it depends on certain conditions. If there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For details, see the Deploy Configuration Changes topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.



CHAPTER 58

Tune Intrusion Policies Using Rules

This chapter provides information on custom rules in Snort 3, intrusion rule action, intrusion event notification filters in an intrusion policy, converting Snort 2 custom rules to Snort 3, and adding rule groups with custom rules to an intrusion policy.

- Overview of Tuning Intrusion Rules, on page 2073
- Intrusion Rule Types, on page 2074
- Prerequisites for Network Analysis and Intrusion Policies, on page 2075
- Custom Rules in Snort 3, on page 2075
- View Snort 3 Intrusion Rules in an Intrusion Policy, on page 2078
- Intrusion Rule Action, on page 2079
- Intrusion Event Notification Filters in an Intrusion Policy, on page 2080
- Add Intrusion Rule Comments, on page 2085
- Snort 2 Custom Rules Conversion to Snort 3, on page 2085
- Add Custom Rules to Rule Groups, on page 2087
- Add Rule Groups with Custom Rules to an Intrusion Policy, on page 2088
- Manage Custom Rules in Snort 3, on page 2089
- Delete Custom Rules, on page 2090
- Delete Rule Groups, on page 2090

Overview of Tuning Intrusion Rules

You can configure rule states and other settings for shared object rules, standard text rules, and inspector rules.

You enable a rule by setting its rule state to Alert or to Block. Enabling a rule causes the system to generate events on traffic matching the rule. Disabling a rule stops processing of the rule. You can also set your intrusion policy so that a rule set to Block generates events on, and drops, matching traffic.

You can filter rules to display a subset of rules, enabling you to select the exact set of rules where you want to change rule states or rule settings.

When an intrusion rule or rule argument requires a disabled inspector, the system automatically uses it with its current configuration even though it remains disabled in the network analysis policy's web interface.

Note We recommend that you do not modify shared object rules and you only enable or disable these rules for your threat defense device. To create custom Snort rules, contact Cisco support.

Intrusion Rule Types

An intrusion rule is a specified set of keywords and arguments that the system uses to detect attempts to exploit vulnerabilities in your network. As the system analyzes network traffic, it compares packets against the conditions specified in each rule, and triggers the rule if the data packet meets all the conditions specified in the rule.

An intrusion policy contains:

- *intrusion rules*, which are subdivided into *shared object rules* and *standard text rules*
- *inspector rules*, which are associated with a detection option of the packet decoder or with one of the inspectors included with the system

The following table summarizes attributes of these rule types:

Table 109: Intrusion Rule Types

Type	Generator ID (GID)	Snort ID (SID)	Source	Can Copy?	Can Edit?
shared object rule	3	lower than 1000000	Cisco Talos Intelligence Group (Talos)	yes	limited
standard text rule	1 (Global domain or legacy GID)	lower than 1000000	Talos	yes	limited
	1000 - 2000 (descendant domain)	1000000 or higher	Created or imported by user	yes	yes
preprocessor rule	decoder- or preprocessor-specific	lower than 1000000	Talos	no	no
		1000000 or higher	Generated by the system during option configuration	no	no

You cannot save changes to any rule created by Talos, but you can save a copy of a modified rule as a custom rule. You can modify either variables used in the rule or rule header information (such as source and destination ports and IP addresses). In a multidomain deployment, rules created by Talos belong to the Global domain. Administrators in descendant domains can save local copies of the rules, which they can then edit.

For the rules it creates, Talos assigns default rule states in each default intrusion policy. Most preprocessor rules are disabled by default and must be enabled if you want the system to generate events for preprocessor rules and, in an inline deployment, drop offending packets.

Prerequisites for Network Analysis and Intrusion Policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the IPS license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

Custom Rules in Snort 3

You can create a custom intrusion rule by importing a local rule file. The rule file can either have a `.txt` or `.rules` extension. The system saves the custom rule in the local rule category, regardless of the method you used to create it. A custom rule must belong to a rule group. However, a custom rule can be a part of two or more groups as well.

When you create a custom intrusion rule, the system assigns it a unique rule number, which has the format `GID:SID:Rev`. The elements of this number are:

- **GID**—Generator ID. For custom rules, it is not necessary to specify the GID. The system automatically generates the GID based on whether you are in the Global domain or a sub-domain while uploading the rules. For all standard text rules, this value is 2000 for a Global domain.
- **SID**—Snort ID. Indicates whether the rule is a local rule of a system rule. When you create a new rule, assign a unique SID to the rule.

  SID numbers for local rules start at 1000000, and the SID for each new local rule is incremented by one.
- **Rev**—The revision number. For a new rule, the revision number is one. Each time you modify a custom rule the revision number should be incremented by one.

In a custom standard text rule, you set the rule header settings and the rule keywords and arguments. You can use the rule header settings to focus the rule to only match traffic using a specific protocol and traveling to or from specific IP addresses or ports.

To check whether a SID is enabled or disabled, verify the entries in the snort.lua file located in the `./file-contents/ngfw/var/sf/detection_engines/<id>/ips/<id>` directory.

- If the SID is disabled by default, no entry will be present in the file.
- If the SID is manually enabled, you will see an entry with **enable:yes**.
- If the SID is disabled after being manually enabled, the entry remains in the file and will display **enable:no**.

Note

- Snort 3 custom rules cannot be edited. Ensure that custom rules have a valid classification message for `classtype` within the rule text. If you import a rule without a classification or wrong classification, then delete and recreate the rule.
- You can create custom intrusion rules using Snort 3. However, support for tuning and troubleshooting these rules is not available currently.
- The *classtype* in a Snort rule assigns a classification to the rule indicating the type of attack that is associated with an event. A priority level of 1-4 is also associated with each *classtype*. However, the priority level for certain *classtypes* on the Threat Defense device do not match the open-source Snort *classtype* priority levels that are mentioned in the Snort documentation. For example, *tcp-connection* has a priority of 4 in open-source Snort while a priority of 3 is assigned to it on the Threat Defense device.

Sensitive Data Detection in Snort 3

Sensitive data such as social security numbers, credit card numbers, emails, and so on may be leaked onto the internet, intentionally or accidentally. Sensitive data detection is used to detect and generate events on possible sensitive data leakage. Events are generated only if there is a transfer of significant amount of Personally Identifiable Information (PII) data. Sensitive data detection can mask PII in the output of events.

sd_pattern Option

Use the `sd_pattern` IPS option to detect and filter PII. This information includes credit card numbers, U.S. Social Security numbers, phone numbers, and email addresses. A regular expression (regex) syntax is available for defining your own PII.

The sd_pattern option has the following settings:

- Pattern—An implicit, required setting that specifies the regular expression to look for in the PDU. The regex must be written in PCRE syntax.
- Threshold—An explicit, optional setting that specifies the number of matches in the PDU required to generate an event.

  The `sd_pattern` as IPS rule option is available in Snort with no requirements for additional inspectors. The rule option's syntax is:

  ```
  sd_pattern: "<pattern>"[, threshold <count>];
  ```

  For example:

  ```
  sd_pattern:"credit_card", threshold 2;
  ```

Built-in Patterns

There are five built-in patterns for sensitive data. To use the built-in patterns in the "pattern" setting, you must specify the name of the PII type that needs to be matched and the necessary regex is substituted for it. The PII name and regex mappings or patterns are described as follows:

- credit_card—

  ```
  \d{4}\D?\d{4}\D?\d{2}\D?\d{2}\D?\d{3,4}
  ```

- us_social—

```
[0-8]\d{2}-\d{2}-\d{4}
```

- us_social_nodashes—

```
[0-8]\d{8}
```

- Email—

```
[a-zA-Z0-9!#$%&'*+\/=?^_`{|}~-]+(?:\.[a-zA-Z0-9!#$%&'*+\/=?^_`{|}~-]+)*@(?:[a-zA-Z0-9]
(?:[a-zA-Z0-9-]*[a-zA-Z0-9])?\.)+[a-zA-Z0-9](?:[a-zA-Z0-9-]*[a-zA-Z0-9])?
```

- us_phone—

```
(?:\+?1[-\.\s]?)?\(?([2-9][0-8]\d)\)?[-\.\s]([2-9]\d{2})[-\.\s](\d{4})
```

PII Name	Pattern
credit_card	`\d{4}\D?\d{4}\D?\d{2}\D?\d{2}\D?\d{3,4}`
us_social	`[0-8]\d{2}-\d{2}-\d{4}`
us_social_nodashes	`[0-8]\d{8}`
Email	`[a-zA-Z0-9!#$%&'*+\/=?^_`{\|}~-]+(?:\.[a-zA-Z0-9!#$%&'*+\/=?^_`{|}~-]+)*@(?:[a-zA-Z0-9](?:[a-zA-Z0-9-]*[a-zA-Z0-9])?\.)+[a-zA-Z0-9](?:[a-zA-Z0-9-]*[a-zA-Z0-9])?`
us_phone	`(?:\+?1[-\.\s]?)?\(?([2-9][0-8]\d)\)?[-\.\s]([2-9]\d{2})[-\.\s](\d{4})`

Masking for data matching these patterns only work with system-provided rules or built-in patterns for Credit Cards, U.S. Social Security numbers, emails, and U.S. phone numbers. Masking does not work for custom rules or user-defined PII patterns. Rules are available in the Lightweight Security Package (LSP) for sensitive data, gid:13. By default, they are not enabled in any system-provided policy.

The sensitive data rules in LSP cover all built-in patterns and have the following threshold values:

- credit_card: 2
- us_social: 2
- us_social_nodashes: 20
- email: 20
- us_phone: 20

You can use the sd_pattern option to create custom rules and modify existing rules. To do this, use the Snort 3 intrusion policy interface.

An example of a rule with sd_pattern with a custom pattern and threshold:

alert tcp (sid: 1000000001; sd_pattern:"[\w-\.]+@([\w-]+\.)+[\w-]{2,4}",threshold 4; msg: "email, threshold 4")

Examples

An example of custom rules using sensitive data detection:

Rule with built-in pattern:

```
alert tcp (
        msg:"SENSITIVE-DATA Email";
```

```
        flow:only_stream;
        pkt_data;
        sd_pattern:"email", threshold 5;
        service:http, smtp, ftp-data, imap, pop3;
        gid:2000;
        sid:1000001;
)
```

Rule with custom pattern

```
alert tcp (
        msg:"SENSITIVE-DATA US phone numbers";
        flow:only_stream;
        file_data;
        sd_pattern:"+?3?8?(0[\s\.-]\d{2}[\s\.-]\d{3}[\s\.-]\d{2}[\s\.-]\d{2})", threshold
2;
        service:http, smtp, ftp-data, imap, pop3;
        gid:2000;
        sid:1000002;
)
```

Here are some more examples of complete Snort IPS rules with built-in sensitive data patterns:

- alert tcp (sid:1; msg:"Credit Card"; sd_pattern:"credit_card", threshold 2;)
- alert tcp (sid:2; msg:"US Social Number"; sd_pattern:"us_social", threshold 2;)
- alert tcp (sid:3; msg:"US Social Number No Dashes"; sd_pattern:"us_social_nodashes", threshold 2;)
- alert tcp (sid:4; msg:"US Phone Number"; sd_pattern:"us_phone", threshold 2;)
- alert tcp (sid:5; msg:"Email"; sd_pattern:"email", threshold 2;)

Disabling data masking is not supported in the Secure Firewall Management Center and Secure Firewall Device Manager.

For information how to add custom rules to rule groups, see Add Custom Rules to Rule Groups, on page 2087.

View Snort 3 Intrusion Rules in an Intrusion Policy

You can adjust how rules are displayed in the intrusion policy. You can also display the details for a specific rule to see rule settings, rule documentation, and other rule specifics.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Click **Snort 3 Version** next to the policy.

Step 3 While viewing the rules, you can:

- Filter the rules.
- Choose a rule group to see rules related to that group.
- View an intrusion rule's details.
- View rule comments.
- View rule documentation.

See Edit Snort 3 Intrusion Policies, on page 2061 for details on performing these tasks.

Intrusion Rule Action

Intrusion rule action allows you to enable or disable the rule within an individual intrusion policy, as well as specify which action the system takes if monitored conditions trigger the rule.

The Cisco Talos Intelligence Group (Talos) sets the default action of each intrusion and inspector rule in each default policy. For example, a rule may be enabled in the Security over Connectivity default policy and disabled in the Connectivity over Security default policy. Talos sometimes uses a rule update to change the default action of one or more rules in a default policy. If you allow rule updates to update your base policy, you also allow the rule update to change the default action of a rule in your policy when the default action changes in the default policy you used to create your policy (or in the default policy it is based on). Note, however, that if you have changed the rule action, the rule update does not override your change.

When you create an intrusion rule, it inherits the default actions of the rules in the default policy you use to create your policy.

Intrusion Rule Action Options

In an intrusion policy, you can set a rule's action to the following values:

Alert

You want the system to detect a specific intrusion attempt and generate an intrusion event when it finds matching traffic. When a malicious packet crosses your network and triggers the rule, the packet is sent to its destination and the system generates an intrusion event. The malicious packet reaches its target, but you are notified through the event logging.

Block

You want the system to detect a specific intrusion attempt, drop the packet containing the attack, and generate an intrusion event when it finds matching traffic. The malicious packet never reaches its target, and you are notified through the event logging.

Disable

You do not want the system to evaluate matching traffic.

Note Choosing either the **Alert** or **Block** options enables the rule. Choosing **Disable** disables the rule.

We **strongly** recommend that you **do not** enable all the intrusion rules in an intrusion policy. The performance of your managed device is likely to degrade if all rules are enabled. Instead, tune your rule set to match your network environment as closely as possible.

Set Intrusion Rule Action

Intrusion rule actions are policy-specific.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Click **Snort 3 Version** next to the policy you want to edit.

Tip
This page shows the total number of:

- disabled rules
- enabled rules set to Alert
- enabled rules set to Block
- overridden rules

Step 3 Choose the rule or rules where you want to set the rule action.

Step 4 Choose one of the rule actions from the **Rule Action** drop-down list. See Edit Snort 3 Intrusion Policies, on page 2061 for more information about the different rule actions.

Step 5 Click **Save**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Intrusion Event Notification Filters in an Intrusion Policy

The importance of an intrusion event can be based on frequency of occurrence, or on source or destination IP address. In some cases you may not care about an event until it has occurred a certain number of times. For example, you may not be concerned if someone attempts to log into a server until they fail a certain number of times. In other cases, you may only need to see a few occurrences to know there is a widespread problem. For example, if a DoS attack is launched against your web server, you may only need to see a few occurrences of an intrusion event to know that you need to address the situation. Seeing hundreds of the same event only overwhelms your system.

Intrusion Event Thresholds

You can set thresholds for individual rules to limit the number of times the system logs and displays an intrusion event based on how many times the event is generated within a specified time period. This can prevent you from being overwhelmed with a large number of identical events. You can set thresholds per shared object rule, standard text rule, or inspector rule.

Set Intrusion Event Thresholds

To set a threshold, first specify the thresholding type.

Table 110: Thresholding Options

Option	Description
Limit	Logs and displays events for the specified number of packets (specified by the Count argument) that trigger the rule during the specified time period. For example, if you set the type to **Limit**, the **Count** to `10`, and the **Seconds** to `60`, and 14 packets trigger the rule, the system stops logging events for the rule after displaying the first 10 that occur within the same minute.
Threshold	Logs and displays a single event when the specified number of packets (specified by the Count argument) trigger the rule during the specified time period. Note that the counter for the time restarts after you hit the threshold count of events and the system logs that event. For example, you set the type to **Threshold**, **Count** to `10`, and **Seconds** to `60`, and the rule triggers 10 times by second 33. The system generates one event, then resets the Seconds and Count counters to 0. The rule then triggers another 10 times in the next 25 seconds. Because the counters reset to 0 at second 33, the system logs another event.
Both	Logs and displays an event once per specified time period, after the specified number (count) of packets trigger the rule. For example, if you set the type to **Both**, **Count** to two, and **Seconds** to `10`, the following event counts result: • If the rule is triggered once in 10 seconds, the system does not generate any events (the threshold is not met) • If the rule is triggered twice in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time) • If the rule is triggered four times in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time, and following events are ignored)

Secondly, specify tracking, which determines whether the event threshold is calculated per source or destination IP address.

Table 111: Thresholding IP Options

Option	Description
Source	Calculates event instance count per source IP address.
Destination	Calculates event instance count per destination IP address.

Finally, specify the number of instances and time period that define the threshold.

Table 112: Thresholding Instance/Time Options

Option	Description
Count	The number of event instances per specified time period per tracking IP address required to meet the threshold.

Option	Description
Seconds	The number of seconds that elapse before the count resets. If you set the threshold type to **limit**, the tracking to **Source IP**, the **count** to `10`, and the **seconds** to `10`, the system logs and displays the first 10 events that occur in 10 seconds from a given source port. If only 7 events occur in the first 10 seconds, the system logs and displays those; if 40 events occur in the first 10 seconds, the system logs and displays 10, then begins counting again when the 10-second time period elapses.

Note that you can use intrusion event thresholding alone or in any combination with rate-based attack prevention, the `detection_filter` keyword, and intrusion event suppression.

Tip You can also add thresholds from within the packet view of an intrusion event.

Set Threshold for an Intrusion Rule in Snort 3

You can set a single threshold for a rule from the Rule Detail page. Adding a threshold overwrites any existing threshold for the rule. The threshold you set for an intrusion rule is applied to each packet thread. However, the configuration is fully applied only within the context of a unique flow. There may be more alerts on different network flows, but there will not be fewer alerts than the configured number.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules** .

Step 2 Click **Snort 3 All Rules** tab.

Step 3 From an intrusion rule's Alert Configuration column, click the **None** link.

Step 4 Click **Edit** ( ).

Step 5 In the Alert Configuration window, click the **Threshold** tab.

Step 6 From the **Type** drop-down list, choose the type of threshold you want to set:

- Choose **Limit** to limit notification to the specified number of event instances per time period.
- Choose **Threshold** to provide notification for each specified number of event instances per time period.
- Choose **Both** to provide notification once per time period after a specified number of event instances.

Step 7 Choose **Source** or **Destination** in the **Track By** field to indicate whether you want the event instances tracked by source or destination IP address.

Step 8 Enter the number of event instances you want to use as your threshold in the **Count** field.

Step 9 Enter a number that specifies the time period, in seconds, for which event instances are tracked in the **Seconds** field.

Step 10 Click **Save**.

Refer to the video Snort 3 Suppression and Threshold for additional support and information.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 259.

View and Delete Intrusion Event Thresholds

To view or delete an existing threshold setting for a rule, use the Rules Details view to display the configured settings for a threshold and see if they are appropriate for your system. If they are not, you can add a new threshold to overwrite the existing values.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Choose the rule with a configured threshold as shown in the **Alert Configuration** column (the **Alert Configuration** column displays **Threshold** as a link for the rule).

Step 4 To remove the threshold for the rule, click **Threshold** link in the **Alert Configuration** column.

Step 5 Click **Edit** ( ).

Step 6 Click **Threshold** tab.

Step 7 Click **Reset**.

Step 8 Click **Save**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Intrusion Policy Suppression Configuration

You can suppress intrusion event notification when a specific IP address or range of IP addresses triggers a specific rule or inspector. This is useful for eliminating false positives. For example, if you have a mail server that transmits packets that look like a specific exploit, you might suppress event notification for that event when it is triggered by your mail server. The rule triggers for all packets, but you only see events for legitimate attacks.

Intrusion Policy Suppression Types

Note that you can use intrusion event suppression alone or in any combination with rate-based attack prevention, the `detection_filter` keyword, and intrusion event thresholding.

Tip You can add suppressions from within the packet view of an intrusion event. You can also access suppression settings by using the **Alert Configuration** column on the intrusion rules editor page (**Objects** > **Intrusion Rules** > **Snort 3 All Rules**).

Set Suppression for an Intrusion Rule in Snort 3

You can set one or more suppressions for a rule in your intrusion policy.

Before you begin

Ensure you create the required network objects to be added for source or destination suppression.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Click the **None** link in the intrusion rule's Alert Configuration column,.

Step 4 Click **Edit** ( ).

Step 5 From the **Suppressions** tab, click the add icon **Add** ( ) next to any of the following options:

- Choose **Source Networks** to suppress events generated by packets originating from a specified source IP address.
- Choose **Destination Networks** to suppress events generated by packets going to a specified destination IP address.

Step 6 Select any of the preset networks in the **Network** drop-down list.

Step 7 Click **Save**.

Step 8 (Optional) Repeat the last three steps if required.

Step 9 Click **Save** in the Alert Configuration window.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

View and Delete Suppression Conditions

You may want to view or delete an existing suppression condition. For example, you can suppress event notification for packets originating from a mail server IP address because the mail server normally transmits packets that look like exploits. If you then decommission that mail server and reassign the IP address to another host, you should delete the suppression conditions for that source IP address.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Choose the rule for which you want to view or delete suppressions.

Step 4 Click **Suppression** in the **Alert Configuration** column.

Step 5 Click **Edit** ( ).

Step 6 Click **Suppressions** tab.

Step 7 Remove the suppression by clicking **Clear** ( ) next to the suppression.

Step 8 Click **Save**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Add Intrusion Rule Comments

You can add comments to rules in your intrusion policy. Comments added this way are policy-specific; that is, comments you add to a rule in one intrusion policy are not visible in other intrusion policies.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Click **Snort 3 Version** next to the policy you want to edit.

Step 3 In the right side of the page where all the rules are listed, choose the rule where you want to add a comment.

Step 4 Click **Comment** ( ) under the **Comments** column.

Step 5 In the **Comments** field, enter the rule comment.

Step 6 Click **Add Comment**.

Step 7 Click **Save**.

Tip
The system displays a **Comment** ( ) next to the rule in the Comments column.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Snort 2 Custom Rules Conversion to Snort 3

If you are using custom rules, make sure you are prepared to manage that rule set for Snort 3 prior to conversion from Snort 2 to Snort 3. If you are using a rule set from a third-party vendor, contact that vendor to confirm that their rules will successfully convert to Snort 3 or to obtain a replacement rule set written natively for Snort 3. If you have custom rules that you have written yourself, familiarize with writing Snort 3 rules prior to conversion, so you can update your rules to optimize Snort 3 detection after conversion. See the links below to learn more about writing rules in Snort 3.

- https://blog.snort.org/2020/08/how-rules-are-improving-in-snort-3.html

- https://blog.snort.org/2020/10/talos-transition-to-snort-3.html

You can refer to other blogs at https://blog.snort.org/ to learn more about Snort 3 rules.

Important Snort 2 network analysis policy (NAP) settings *cannot* be copied to Snort 3 automatically. NAP settings have to be manually replicated in Snort 3.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Convert all Snort 2 Custom Rules across all Intrusion Policies to Snort 3

Procedure

Step 1 Choose **Objects** > **Intrusion Rules** .

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Ensure **All Rules** is selected in the left pane.

Step 4 Click the **Tasks** drop-down list and choose:

- **Convert Snort 2 rules and import**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.
- **Convert Snort 2 rules and download**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and download them into your local system.

Step 5 Click **OK**.

Note

- If you selected **Convert and import** in the previous step, then all the converted rules are saved under a newly created rule group **All Snort 2 Converted Global** under **Local Rules**.
- If you selected **Convert and download** in the previous step, then save the rules file locally. You can review the converted rules in the downloaded file and later upload them by following the steps in Add Custom Rules to Rule Groups, on page 2087.

Refer to the video Converting Snort 2 Rules to Snort 3 for additional support and information.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 In the **Intrusion Policies** tab, click **Show Snort 3 Sync status**.

Step 3 Click the **Sync** icon **Snort out-of-Sync** (🔶) of the intrusion policy.

Note
If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in blue**Snort in-Sync** (🔷). It indicates that there are no custom rules to be converted.

Step 4 Read through the summary and click the **Custom Rules** tab.

Step 5 Choose:

- **Import converted rules to this policy**—To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.
- **Download converted rules**—To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and download them into your local system. You can review the converted rules in the downloaded file and later upload the file by clicking the upload icon.

Step 6 Click **Re-Sync**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Add Custom Rules to Rule Groups

Uploading custom rules in the Firewall Management Center adds the custom rules that you have created locally to the list of all the Snort 3 rules.

Procedure

Step 1 Choose .

Policies > Intrusion No conref was created

Objects > **Intrusion Rules**

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Click the **Tasks** drop-down list.

Step 4 Click **Upload Snort 3 Rules**.

Step 5 Drag and drop the `.txt` or `.rules` file that contains the Snort 3 custom rules that you have created.

Step 6 Click **OK**.

Note
If there are any errors in the selected file, then you cannot proceed further. You can download the error file and **Replace File** link to upload version 2 of the file, after fixing the errors.

Step 7 Associate rules to a rule group to add the new rules to that group.

You can also create a new custom rule group (by clicking the **Create New Custom Rule Group** link) and then add the rules to the new group.

Note
If there are no existing local rule groups, then proceed by clicking **Create New Custom Rule Group to proceed**. Enter a **Name** for the new rule group and click **Save**.

Step 8 Choose either of the following:

- **Merge Rules** to merge the new rules that you are adding with the existing rules in the rule group.
- **Replace all rules in the group with file contents** to replace all the exiting rules with the new rules that you are adding.

Note
If you chose more than one rule group in the previous step, then only the **Merge Rules** option is available.

Step 9 Click **Next**.

Review the summary to know the new rule IDs that are being added and optionally download it.

Step 10 Click **Finish**.

Important The rule action of all the uploaded rules is in the disabled state. You have to change them to the required state to ensure the rules are active.

What to do next

- Uploading custom rules in the Firewall Management Center adds the custom rules that you have created to the list of all the Snort 3 rules. To enforce these custom rules on the traffic, add and enable these rules in the required intrusion policies. For information on adding rule groups with custom rules to an intrusion policy, see Add Rule Groups with Custom Rules to an Intrusion Policy, on page 2088. For information on enabling custom rules, see Manage Custom Rules in Snort 3, on page 2089.
- Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Add Rule Groups with Custom Rules to an Intrusion Policy

Custom rules that are uploaded in the system have to be enabled in an intrusion policy to enforce those rules on the traffic. After uploading custom rules on Firewall Management Center, add the rule group with the new custom rules in the intrusion policy.

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 In the **Intrusion Policies** tab, click the **Snort 3 Version** of the intrusion policy.

Step 3 Click **Add** (+) next to the Rule Groups search bar.

Step 4 In the **Add Rule Groups** window, click the **Expand Arrow** (>) icon next to a rule group to expand the local rule group.

Step 5 Check the check box next to the uploaded custom rules group.

Step 6 Click **Save**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Manage Custom Rules in Snort 3

Custom rules that are uploaded in the system have to be added to an intrusion policy and enabled to enforce those rules on the traffic. You can enable the uploaded custom rules across all policies or selectively on individual policies.

Follow the steps to enable custom rules in one or many intrusion policies:

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Expand **Local Rules**.

Step 4 Select the required rule group.

Step 5 Select the rules by checking the check boxes next to them.

Step 6 Select **Per Intrusion Policy** from the **Rule Actions** drop-down list.

Step 7 Choose:

- **All Policies**—to have the same rule actions for all the rules to be added.
- **Per Intrusion Policy**—to have different rule actions for each intrusion policy.

Step 8 Set the rule actions:

- If you selected All Policies in the previous step, then select the required rule action from the **Select Override state** drop-down list.
- If you selected Per Intrusion Policy in the previous step, then select the **Rule Action** against the policy name. To add more policies, click **Add Another**.

Step 9 Optionally, add a comment in the **Comments** text box.

Step 10 Click **Save**.

What to do next

Deploy the changes on the device. See, Deploy Configuration Changes, on page 2055.

Delete Custom Rules

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Expand **Local Rules** in the left pane.

Step 4 Check the check boxes of the rules you want to delete.

Step 5 Ensure that the rule action for all the rules that you select is **Disable**.

If required, follow the steps below to disable the rule action for multiple selected rules:

a) From the **Rule Actions** drop-down box, select **Per Intrusion Policy**.
b) Select **All Policies** radio button.
c) Select **Disable** from the **Select Override state** drop-down list.
d) Click **Save**.
e) Check the check boxes of the rules you want to delete.

Step 6 From the **Rule Actions** drop-down list, select **Delete**.

Step 7 Click **Delete** in the Delete Rules pop-up window.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.

Delete Rule Groups

Before you begin

Exclude the rule group you want to delete from all intrusion policies where you have included it. For steps on excluding a rule group from an intrusion policy, see Edit Snort 3 Intrusion Policies, on page 2061.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Expand **Local Rules** in the left pane.

Step 4 Select the rule group to be deleted.

Step 5 Ensure the rule action for all the rules in the group is set to **Disable** before proceeding.

If the rule action for any of the rules is anything other than **Disable**, then you cannot delete the rule group. If required, follow the steps below to disable the rule action for all the rules:

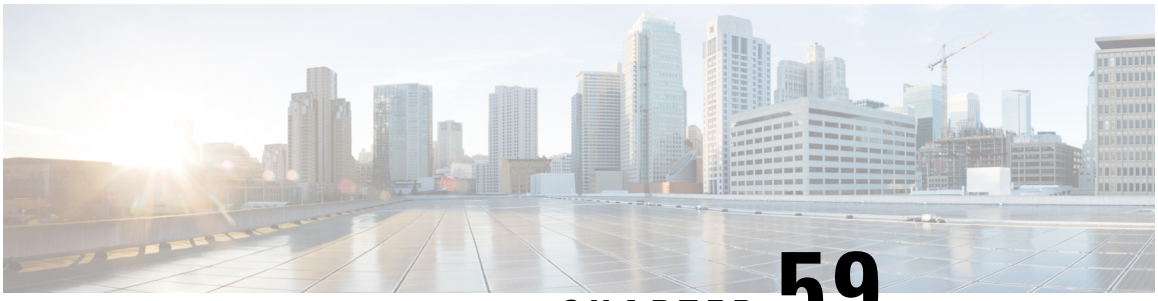
a) Check the check box below the **Rule Actions** drop-down list to select all the rules in the group.
b) From the **Rule Actions** drop-down box, select **Per Intrusion Policy**.
c) Select **All Policies** radio button.
d) Select **Disable** from the **Select Override state** drop-down list.
e) Click **Save**.

Step 6 Click the **Delete** ( ) next to the rule group.

Step 7 Click **OK** in the Delete Rule Group pop-up window.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.



CHAPTER 59

Tailor Intrusion Protection for Your Network Assets

This chapter provides an insight into Secure Firewall recommended rules and generating and applying Secure Firewall recommended rules.

- Snort 3 Rule Changes in LSP Updates , on page 2093
- Overview of Secure Firewall Recommended Rules, on page 2093
- Prerequisites for Network Analysis and Intrusion Policies, on page 2094
- Generate New Secure Firewall Recommendations in Snort 3, on page 2095

Snort 3 Rule Changes in LSP Updates

During regular Snort 3 Lightweight Security Package (LSP) updates, an existing system-defined intrusion rule may be replaced with a new intrusion rule. There could be possibilities of a single rule being replaced with multiple rules, or multiple rules being replaced with a single rule. This occurs when better detection is possible for which rules are combined or expanded. For better management, some existing system-defined rules may also be removed as a part of the LSP update.

To get notifications for changes to any *overridden* system-defined rules during LSP updates, ensure that the **Retain user overrides for deleted Snort 3 rules** check box is checked.

To navigate to the **Retain user overrides for deleted Snort 3 rules** check box, click **System** (⚙), and then choose **Configuration** > **Intrusion Policy Preferences**.

By default this check box is checked. When this check box is checked, the system retains the rule overrides in the new replacement rules that are added as a part of the LSP update. The notifications are shown in the **Tasks** tab under the Notifications icon that is located next to **System** (⚙).

Overview of Secure Firewall Recommended Rules

You can use intrusion rule recommendations to target vulnerabilities associated with host assets detected in the network. For example, operating systems, servers, and client application protocols. This allows you to tailor your intrusion policy to the specific needs of your monitored network.

The system makes an individual set of recommendations for each intrusion policy. It typically recommends rule state changes for standard text rules and shared object rules. However, it can also recommend changes for inspector and decoder rules.

When you generate rule state recommendations, you can use the default settings or configure advanced settings. Advanced settings allow you to:

- Redefine which hosts on your network the system monitors for vulnerabilities
- Influence which rules the system recommends based on rule overhead
- Specify whether to generate recommendations to disable rules

You can also choose to use the recommendations immediately or review the recommendations (and affected rules) before accepting them.

Choosing to use recommended rule states adds a read-only Secure Firewall Recommendations layer to your intrusion policy, and subsequently choosing not to use recommended rule states removes the layer.

You can schedule a task to generate recommendations automatically based on the most recently saved configuration settings in your intrusion policy.

The system does not change rule states that you set manually such as:

- Manually setting the states of specified rules *before* you generate recommendations prevents the system from modifying the states of those rules in the future.
- Manually setting the states of specified rules *after* you generate recommendations overrides the recommended states of those rules.

Tip The intrusion policy report can include a list of rules with rule states that differ from the recommended state.

While displaying the recommendation-filtered Rules page, or after accessing the Rules page directly from the navigation panel or the Policy Information page, you can manually set rule states, sort rules, and take any of the other actions available on the Rules page, such as suppressing rules, setting rule thresholds, and so on.

Note The Cisco Talos Intelligence Group (Talos) determines the appropriate state of each rule in the system-provided policies. If you use a system-provided policy as your base policy, and you allow the system to set your rules to the Secure Firewall recommended rule state, the rules in your intrusion policy match the settings recommended for your network assets.

Prerequisites for Network Analysis and Intrusion Policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the IPS license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

Generate New Secure Firewall Recommendations in Snort 3

Generate the Secure Firewall recommendations for the intrusion policy and then follow the steps that are listed here to create new recommended rule settings in Snort 3. Rule overheads are interpreted as **security levels** based on the threshold policies selected by you in Snort 3. Recommended action is based on the selected security level and if it is higher than the base policy, then the recommendation is not just limited to generating the events.

Prior to setting the Secure Firewall recommendations you should ask which of the three points listed below closely matches the goal:

- Increased Protection —Enable additional rules based on vulnerabilities found in the host database and do not automatically disable any rules. This will likely result in a larger rule set.
- Focused Protection—Enable additional rules and disable existing rules based on vulnerabilities found in the host database. This can increase or decrease the number of rules depending on vulnerabilities discovered.
- Higher Efficiency—Use the currently enabled rule set and disable any rules for vulnerabilities not found in the host database. This will likely result in a smaller enabled rule set.

Based on the response, the recommendation actions are as follows:

- Set recommendations to the next highest security level, and uncheck the disable rules.
- Set recommendations to the next highest security level, and check the disable rules.
- Set recommendations to the current security level, and check the disable rules.

Before you begin

Secure Firewall recommendations have the following requirements:

- Ensure that hosts are present in the system to generate recommendations.
- Protected networks configured for recommendations should map to the hosts present in the system

Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 Click the **Snort 3 Version** button of the intrusion policy.

Step 3 Click the **Recommendations (Not in Use)** layer to configure the rule recommendations. Click **Start**.

In the Secure Firewall Rule Recommendations window you can set the following:

- **Security Level**: Click to select the security level. Optionally, you can check the **Accept Recommendation to Disable Rules** checkbox to disable rules that are not enabled at the input security level and in protected networks. Only enable this option if you need to trim your rule set due to a high number of alerts or to improve inspection performance. The security levels are:
  - Security level 1: Connectivity Over Security

No Impact—No new rules are enabled and no existing rules are disabled. To increase the protection, select a higher security level.

Lower Security (checkbox is checked)—All rules are disabled except for the rules in the Connectivity Over Security ruleset that match potential vulnerabilities on discovered hosts. It is recommended instead to adjust the Base Policy.

- Security level 2: Balanced Security Over Connectivity

  No Impact—No new rules are enabled and no existing rules are disabled. To increase the protection, select a higher security level.

  Higher Efficiency(checkbox is checked)—Keeps existing rules that match potential vulnerabilities on discovered hosts and disables rules for vulnerabilities not found on the network.

- Security level 3: Security Over Connectivity

  Increased Security—Enables additional rules that match potential vulnerabilities on discovered hosts based on the Maximum Detection ruleset.

  Focused Security(checkbox is checked)—Enables additional rules that match vulnerabilities on discovered hosts based on the Security Over Connectivity ruleset, while disabling existing rules that do not match potential vulnerabilities on discovered hosts.

- Security level 4 : Maximum Detection

  Increased Security—Enables additional rules that match potential vulnerabilities on discovered hosts based on the Security Over Connectivity ruleset.

  Focused Security (checkbox is checked)—Enables additional rules that match vulnerabilities on discovered hosts based on the Maximum Detection ruleset, while disabling existing rules that do not match potential vulnerabilities on discovered hosts.

  Note
  Maximum Detection enables a very high number of rules and may impact performance. We recommend you to review and test this setting before deploying into a production environment.

- **Protected Networks**: Specifies the monitored networks or individual hosts to examine for recommendations. You can select one or more system or custom defined network objects from the drop-down list. By default, any IPv4 or IPv6 networks are selected, if no selection is done.

  Important
  The Secure Firewall Rule Recommendations depend on network discovery. Protected Networks apply to any hosts discovered within the ranges configured in your Network Discovery policy. For more information, see the chapter Network Discovery Policies in the *Cisco Secure Firewall Management Center Device Configuration guide*.

  Click the **Add +** button to create a new network object of type Host or Network and click **Save**.

Step 4 Generate and apply recommendations:

- **Generate**: Generates the recommendations for an intrusion policy. This action lists the rules under Recommended Rules (Not in use).
- **Generate and Apply**: Generates and applies the recommendations for an intrusion policy. This action lists the rules under Recommended Rules (In use).

Recommendations are generated successfully. A new recommendation tab appears with all the recommended rules with their corresponding recommended actions. Rule action preset filters are also available for this tab, in addition with new recommendations.

Step 5 You can verify the recommendations and then choose to apply them accordingly:

- **Accept**—Applies the previously generated recommendations for an Intrusion policy.
- **Refresh**—Regenerates and updates the rule recommendations for an Intrusion policy.
- **Edit**—It opens the Recommendations dialog box, you can provide the recommendation input values and then generate the recommendations.
- **Remove All**—Revert or remove the applied recommended rules from the policy and also removes the recommendation tab.

Under **All Rules**, there is a Recommended Rules section which displays the recommended rules.

Note
Final action for an Intrusion rule is applied based on the rule action priority order and following is the rule action priority order:

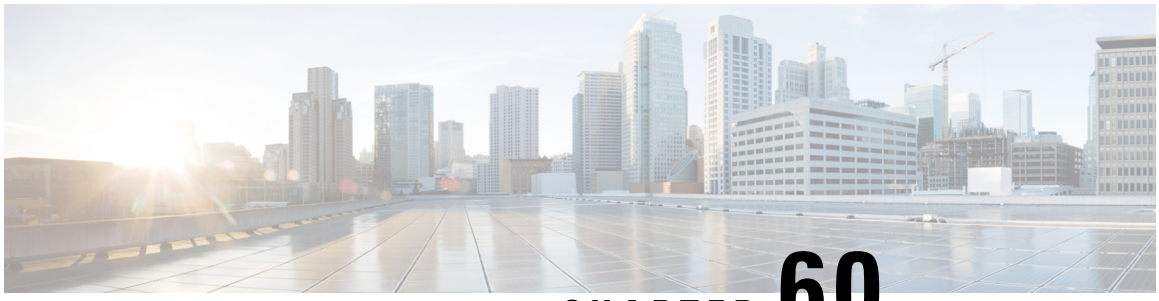
Rule Override > Generated Recommendations > Group Override > Base Policy Default Action

For enabled recommendations, Firewall Management Center considers the current state: group overrides, base policy, and recommendation configurations and priority order of actions is:

pass > block > reject > drop > rewrite > alert

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 2055.



CHAPTER 60

Intrusion Prevention Performance Tuning

The following topics describe how to refine intrusion prevention performance:

- About Intrusion Prevention Performance Tuning, on page 2099
- License Requirements for Intrusion Prevention Performance Tuning, on page 2100
- Requirements and Prerequisites for Intrusion Prevention Performance Tuning, on page 2100
- Limiting Pattern Matching for Intrusions, on page 2100
- Regular Expression Limits Overrides for Intrusion Rules, on page 2101
- Overriding Regular Expression Limits for Intrusion Rules, on page 2102
- Per Packet Intrusion Event Generation Limits, on page 2103
- Limiting Intrusion Events Generated Per Packet, on page 2103
- Packet and Intrusion Rule Latency Threshold Configuration, on page 2104
- Intrusion Performance Statistic Logging Configuration, on page 2110
- Configuring Intrusion Performance Statistic Logging, on page 2110

About Intrusion Prevention Performance Tuning

Cisco provides several features for improving the performance of your system as it analyzes traffic for attempted intrusions. You can:

- specify the number of packets to allow in the event queue. You can also, before and after stream reassembly, enable or disable inspection of packets that will be rebuilt into larger streams.
- override default match and recursion limits on PCRE that are used in intrusion rules to examine packet payload content.
- elect to have the rules engine log more than one event per packet or packet stream when multiple events are generated, allowing you to collect information beyond the reported event.
- balance security with the need to maintain device latency at an acceptable level with packet and rule latency thresholding.
- configure the basic parameters of how devices monitor and report their own performance. This allows you to specify the intervals at which the system updates performance statistics on your devices.

You configure these performance settings on a per-access-control-policy basis, and they apply to all intrusion policies invoked by that parent access control policy.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Limiting Pattern Matching for Intrusions

Procedure

Step 1 In the access control policy editor, click **Advanced** (**Policies** > **Access Control heading** > **Access Control**, click **Edit** and then click **Advanced Settings**).

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** (✎) next to **Performance Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Pattern Matching Limits** in the **Performance Settings** pop-up window.

Step 4 Enter a value for the maximum number of events to queue in the **Maximum Pattern States to Analyze Per Packet** field.

Step 5 To disable the inspection of packets that will be rebuilt into larger streams of data before and after stream reassembly in Snort 2, check the **Disable Content Checks on Traffic Subject to Future Reassembly** check box. Inspection before and after reassembly requires more processing overhead and may decrease performance.

Important
In Snort 3, the **Disable Content Checks on Traffic Subject to Future Reassembly** check box settings are:

- Checked—Indicates detecting TCP payload before reassembly. It includes inspection of packets before and after stream reassembly. This process requires more processing overhead and may decrease performance.
- Unchecked—Indicates detecting TCP payload after reassembly.

Step 6 Click **OK**.

Step 7 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Regular Expression Limits Overrides for Intrusion Rules

The default regular expression limits ensure a minimum level of performance. Overriding these limits could increase security, but could also significantly impact performance by permitting packet evaluation against inefficient regular expressions.

Caution Do not override default PCRE limits unless you are an experienced intrusion rule writer with knowledge of the impact of degenerative patterns.

Table 113: Regular Expression Constraint Options

Option	Description
Match Limit State	Specifies whether to override **Match Limit**. You have the following options: • select **Default** to use the value configured for **Match Limit** • select **Unlimited** to permit an unlimited number of attempts • select **Custom** to specify either a limit of 1 or greater for **Match Limit**, or to specify 0 to completely disable PCRE match evaluations

Option	Description
Match Limit	Specifies the number of times to attempt to match a pattern defined in a PCRE regular expression.
Match Recursion Limit State	Specifies whether to override **Match Recursion Limit**. You have the following options: • select **Default** to use the value configured for **Match Recursion Limit** • select **Unlimited** to permit an unlimited number of recursions • select **Custom** to specify either a limit of 1 or greater for **Match Recursion Limit**, or to specify 0 to completely disable PCRE recursions Note that for **Match Recursion Limit** to be meaningful, it must be smaller than **Match Limit**.
Match Recursion Limit	Specifies the number of recursions when evaluating a PCRE regular expression against the packet payload.

Overriding Regular Expression Limits for Intrusion Rules

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** (✎) next to **Performance Settings**.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Regular Expression Limits** in the **Performance Settings** pop-up window.

Step 4 You can modify any of the options as described in Regular Expression Limits Overrides for Intrusion Rules, on page 2101.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Per Packet Intrusion Event Generation Limits

When the intrusion rules engine evaluates traffic against rules, it places the events generated for a given packet or packet stream in an event queue, then reports the top events in the queue to the user interface. When configuring the intrusion event logging limits, you can specify how many events can be placed in the queue and how many are logged, and select the criteria for determining event order within the queue.

Table 114: Intrusion Event Logging Limits Options

Option	Description
Maximum Events Stored Per Packet	The maximum number of events that can be stored for a given packet or packet stream.
Maximum Events Logged Per Packet	The number of events logged for a given packet or packet stream. This cannot exceed the **Maximum Events Stored Per Packet** value.
Prioritize Event Logging By	The value used to determine event ordering within the event queue. The highest ordered event is reported through the user interface. You can select from: • `priority`, which orders events in the queue by the event priority. • `content_length`, which orders events by the longest identified content match. When events are ordered by content length, rule events always take precedence over decoder and preprocessor events.

Limiting Intrusion Events Generated Per Packet

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** (✎) next to **Performance Settings**.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Intrusion Event Logging Limits** in the **Performance Settings** pop-up window.

Step 4 You can modify any of the options in Per Packet Intrusion Event Generation Limits, on page 2103.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Packet and Intrusion Rule Latency Threshold Configuration

Each access control policy has latency-based settings that use thresholding to manage packet and rule processing performance.

Packet latency thresholding measures the total elapsed time taken to process a packet by applicable decoders, preprocessors, and rules, and ceases inspection of the packet if the processing time exceeds a configurable threshold.

Rule latency thresholding measures the elapsed time each rule takes to process an individual packet, suspends the violating rule along with a group of related rules for a specified time if the processing time exceeds the rule latency threshold a configurable consecutive number of times, and restores the rules when the suspension expires.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Latency-Based Performance Settings

By default, the system takes latency-based performance settings from the latest intrusion rule update deployed on your system.

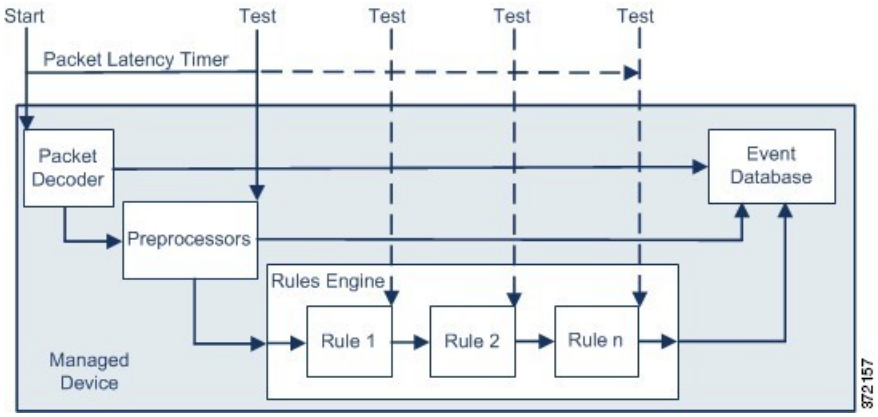
The latency settings that are actually applied depend on the security level of the network analysis policy (NAP) associated with the access control policy. Generally, this is the default NAP policy. However, if custom network analysis rules are configured, and if any of these specify a NAP policy that is more secure than the default NAP policy, then latency settings are based on the most secure NAP policy among the custom rules. If the default NAP policy or any custom rules invoke a custom NAP policy, then the security level used in the evaluation is the system-provided base policy on which each custom NAP policy is based.

The above is true regardless of whether the effective threshold and/or network analysis configurations are inherited or configured directly in the policy.

Packet Latency Thresholding

Packet latency thresholding measures elapsed time, not just processing time, in order to more accurately reflect the actual time required for the rule to process a packet. However, latency thresholding is a software-based latency implementation that does not enforce strict timing.

The trade-off for the performance and latency benefits derived from latency thresholding is that uninspected packets could contain attacks. A timer starts for each packet when decoder processing begins. Timing continues either until all processing ends for the packet or until the processing time exceeds the threshold at a timing test point.



As illustrated in the above figure, packet latency timing is tested at the following test points:

- after the completion of all decoder and preprocessor processing and before rule processing begins
- after processing by each rule

If the processing time exceeds the threshold at any test point, packet inspection ceases.

Tip Total packet processing time does not include routine TCP stream or IP fragment reassembly times.

Packet latency thresholding has no effect on events triggered by a decoder, preprocessor, or rule processing the packet. Any applicable decoder, preprocessor, or rule triggers normally until a packet is fully processed, or until packet processing ends because the latency threshold is exceeded, whichever comes first. If a drop rule detects an intrusion in an inline deployment, the drop rule triggers an event and the packet is dropped.

Note No packets are evaluated against rules after processing for that packet ceases because of a packet latency threshold violation. A rule that would have triggered an event cannot trigger that event, and for drop rules, cannot drop the packet.

Packet latency thresholding can improve system performance in both passive and inline deployments, and can reduce latency in inline deployments, by stopping inspection of packets that require excessive processing time. These performance benefits might occur when, for example:

- for both passive and inline deployments, sequential inspection of a packet by multiple rules requires an excessive amount of time
- for inline deployments, a period of poor network performance, such as when someone downloads an extremely large file, slows packet processing

In a passive deployment, stopping the processing of packets might not contribute to restoring network performance because processing simply moves to the next packet.

Packet Latency Thresholding Notes

By default, the latency-based performance settings for packet handling is disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting.

The information in this below applies only if you choose to specify custom values.

Table 115: Packet Latency Thresholding Option

Option	Description
Threshold (microseconds)	Specifies the time, in microseconds, when inspection of a packet ceases.

Enabling Packet Latency Thresholding

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** () next to **Latency-Based Performance Settings**.

If **View** () appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.

Step 3 Click **Packet Handling** in the **Latency-Based Performance Settings** pop-up window.

Step 4 Check the **Enabled** check box.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Configuring Packet Latency Thresholding

By default, the latency-based performance settings for packet handling is disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting.

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** () next to **Latency-Based Performance Settings**.

System () > **Monitoring** > **Statistics**

Step 3 If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Click **Packet Handling** in the **Latency-Based Performance Settings** pop-up window.

By default, **Installed Rule Update** is selected. We recommend using this default.

The values displayed do not reflect the automated settings.

Step 5 If you choose to specify custom values:

- Check the **Enabled** check box, and see Packet Latency Thresholding Notes, on page 2105 for recommended minimum **Threshold** settings.
- You must specify custom values in both the packet handling tab and the rule handling tab.

Step 6 Click **OK**.

Step 7 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Rule Latency Thresholding

Rule latency thresholding measures elapsed time, not just processing time, in order to more accurately reflect the actual time required for the rule to process a packet. However, latency thresholding is a software-based latency implementation that does not enforce strict timing.

The trade-off for the performance and latency benefits derived from latency thresholding is that uninspected packets could contain attacks. A timer measures the processing time each time a packet is processed against a group of rules. Any time the rule processing time exceeds a specified rule latency threshold, the system increments a counter. If the number of consecutive threshold violations reaches a specified number, the system takes the following actions:

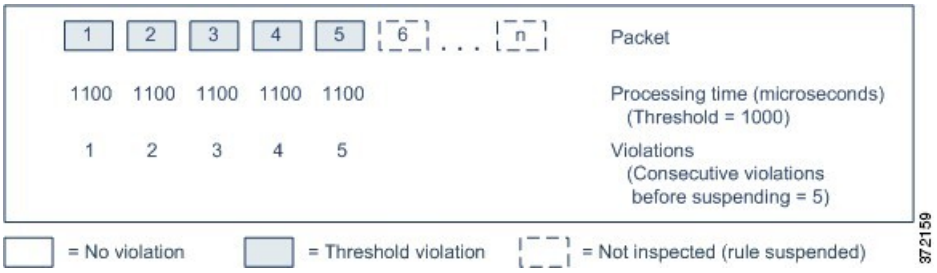
- suspends the rules for the specified period
- triggers an event indicating the rules have been suspended
- re-enables the rules when the suspension expires
- triggers an event indicating the rules have been re-enabled

The system zeroes the counter when the group of rules has been suspended, or when rule violations are not consecutive. Permitting some consecutive violations before suspending rules lets you ignore occasional rule violations that might have negligible impact on performance and focus instead on the more significant impact of rules that repeatedly exceed the rule latency threshold.

The following example shows five consecutive rule processing times that do not result in rule suspension.

In the above example, the time required to process each of the first three packets violates the rule latency threshold of 1000 microseconds, and the violations counter increments with each violation. Processing of the fourth packet does not violate the threshold, and the violations counter resets to zero. The fifth packet violates the threshold and the violations counter restarts at one.

The following example shows five consecutive rule processing times that do result in rule suspension.



In the second example, the time required to process each of the five packets violates the rule latency threshold of 1000 microseconds. The group of rules is suspended because the rule processing time of 1100 microseconds for each packet violates the threshold of 1000 microseconds for the specified five consecutive violations. Any subsequent packets, represented in the figure as packets 6 through n, are not examined against suspended rules until the suspension expires. If more packets occur after the rules are re-enabled, the violations counter begins again at zero.

Rule latency thresholding has no effect on intrusion events triggered by the rules processing the packet. A rule triggers an event for any intrusion detected in the packet, regardless of whether the rule processing time exceeds the threshold. If the rule detecting the intrusion is a drop rule in an inline deployment, the packet is dropped. When a drop rule detects an intrusion in a packet that results in the rule being suspended, the drop rule triggers an intrusion event, the packet is dropped, and that rule and all related rules are suspended.

Note Packets are not evaluated against suspended rules. A suspended rule that would have triggered an event cannot trigger that event and, for drop rules, cannot drop the packet.

Rule latency thresholding can improve system performance in both passive and inline deployments, and can reduce latency in inline deployments, by suspending rules that take the most time to process packets. Packets are not evaluated again against suspended rules until a configurable time expires, giving the overloaded device time to recover. These performance benefits might occur when, for example:

- hastily written, largely untested rules require an excessive amount of processing time
- a period of poor network performance, such as when someone downloads an extremely large file, causes slow packet inspection

Rule Latency Thresholding Notes

By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default.

The information in this topic applies only if you choose to specify custom values.

Rule latency thresholding suspends rules for the time specified by **Suspension Time** when the time rules take to process a packet exceeds **Threshold** for the consecutive number of times specified by **Consecutive Threshold Violations Before Suspending Rule**.

You can enable rule 134:1 to generate an event when rules are suspended, and rule 134:2 to generate an event when suspended rules are enabled.

Table 116: Rule Latency Thresholding Options

Option	Description
Threshold	Specifies the time in microseconds that rules should not exceed when examining a packet.
Consecutive Threshold Violations Before Suspending Rule	Specifies the consecutive number of times rules can take longer than the time set for **Threshold** to inspect packets before rules are suspended.
Suspension Time	Specifies the number of seconds to suspend a group of rules.

Configuring Rule Latency Thresholding

By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default.

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** (✎) next to **Latency-Based Performance Settings**.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Rule Handling** in the **Latency-Based Performance Settings** pop-up window.

By default, **Installed Rule Update** is selected. We recommend using this default.

The values displayed do not reflect the automated settings.

Step 4 If you choose to specify custom values:

- You can configure any of the options in Rule Latency Thresholding Notes, on page 2108.
- You must specify custom values in both the packet handling tab and the rule handling tab.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- If you want to generate events, enable latency rules 134:1 and 134:2.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Intrusion Performance Statistic Logging Configuration

Sample time (seconds) and Minimum number of packets

When the number of seconds specified elapses between performance statistics updates, the system verifies it has analyzed the specified number of packets. If it has, the system updates performance statistics. Otherwise, the system waits until it analyzes the specified number of packets.

Caution Configuring a very low value (for example 1 second) for the sample time can cause a huge impact on the device; the performance statistics logged on the device can cause disk space issues and affect the operation of the device. Hence we recommend you do not configure a very low value.

Troubleshooting Options: Log Session/Protocol Distribution

Support might ask you during a troubleshooting call to log protocol distribution, packet length, and port statistics.

Caution Do not enable **Log Session/Protocol Distribution** unless instructed to by Support.

Troubleshooting Options: Summary

Support might ask you during a troubleshooting call to configure the system to calculate the performance statistics only when the Snort process is shut down or restarted. To enable this option, you must also enable the **Log Session/Protocol Distribution** troubleshooting option.

Caution Do not enable **Summary** unless instructed to do so by Support.

Configuring Intrusion Performance Statistic Logging

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to **Performance Settings**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Click **Performance Statistics** in the pop-up window that appears.

Step 3 Modify the **Sample time** or **Minimum number of packets** as described in Intrusion Performance Statistic Logging Configuration, on page 2110.

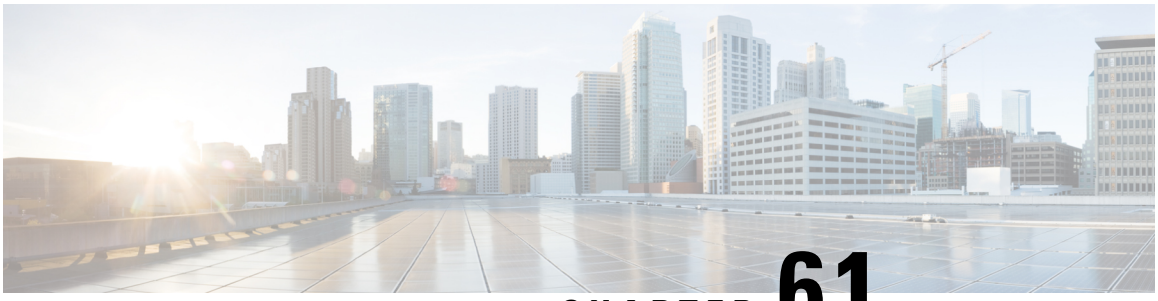
Caution
Configuring a very low value (for example 1 second) for the **Sample time** can cause a huge impact on the device; the performance statistics logged on the device can cause disk space issues and affect the operation of the device. Hence we recommend you do not configure a very low value.

Step 4 Optionally, expand the **Troubleshoot Options** section and modify those options only if asked to do so by Support.

Step 5 Click **OK**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.



CHAPTER 61

Get Started with Snort 3 Network Analysis Policies

This chapter provides an insight into network analysis policy basics, prerequisites, and how to manage network analysis policies. It also provides information on custom network analysis policy creation and network analysis policy settings.

- Overview of Network Analysis Policies, on page 2113
- Manage Network Analysis Policies, on page 2114
- Snort 3 Definitions and Terminologies for Network Analysis Policy, on page 2115
- Prerequisites for Network Analysis and Intrusion Policies, on page 2117
- Custom Network Analysis Policy Creation for Snort 3, on page 2117
- Network Analysis Policy Settings and Cached Changes, on page 2145

Overview of Network Analysis Policies

Network analysis policies govern many traffic preprocessing options, and are invoked by advanced settings in your access control policy. Network analysis-related preprocessing occurs after Security Intelligence matching and SSL decryption, but before intrusion or file inspection begins.

By default, the system uses the *Balanced Security and Connectivity* network analysis policy to preprocess all traffic handled by an access control policy. However, you can choose a different default network analysis policy to perform this preprocessing. For your convenience, the system provides a choice of several non-modifiable network analysis policies, which are tuned for a specific balance of security and connectivity by the Cisco Talos Intelligence Group (Talos). You can also create a custom network analysis policy with custom preprocessing settings.

Tip System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules. Network analysis and intrusion policies work together to examine your traffic.

You can also tailor traffic preprocessing options to specific security zones, networks, and VLANs by creating multiple custom network analysis policies, then assigning them to preprocess different traffic. (Note that ASA FirePOWER cannot restrict preprocessing by VLAN.)

Manage Network Analysis Policies

Under your user name in the toolbar, the system displays a tree of available domains. To switch domains, choose the domain you want to access.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the management center guide that matches your threat defense version.

Procedure

Step 1 Choose one of the following paths to access the network analysis policy.

- **Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy**
- **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**

Note
If your custom user role limits access to the first path listed here, use the second path to access the policy.

Step 2 Manage your network analysis policy:

- Create—If you want to create a new network analysis policy, click **Create Policy**.

  Two versions of the network analysis policy are created, a **Snort 2 Version** and a **Snort 3 Version**.

  - For the Snort 2 version, see *Custom Network Analysis Policy Creation for Snort 2* in the *Cisco Secure Firewall Management Center Configuration Guide*.
  - For the Snort 3 version, see Custom Network Analysis Policy Creation for Snort 3, on page 2117.

- Delete—If you want to delete a network analysis policy, click the **Delete** icon, then confirm that you want to delete the policy. You cannot delete a network analysis policy if an access control policy references it.

  If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Edit—If you want to edit an existing network analysis policy, click the **Edit** icon.

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Report—Click the **Report** icon; see *Generating Current Policy Reports* in the *Cisco Secure Firewall Management Center Configuration Guide*.

Snort 3 Definitions and Terminologies for Network Analysis Policy

The following table lists the Snort 3 concepts and terms used in the Network Analysis Policy.

Table 117: Snort 3 Definitions and Terminologies for Network Analysis Policy

Term	Description
Inspectors	Inspectors are plugins that process packets (similar to the Snort 2 preprocessor).
Binder inspector	Binder inspector defines the flow when a particular inspector has to be accessed and taken into consideration. When the traffic matches the conditions defined in the binder inspector, only then do the values/configurations for that inspector come into effect. For more information, see *Binder Inspector* in Custom Network Analysis Policy Creation for Snort 3, on page 2117.
Singleton inspectors	Singleton inspectors contain one instance. These inspectors do not support adding more instances like multiton inspectors. Settings of singleton inspector are applied to the entire traffic matching that inspector and not to a specific traffic segment. For more information, see *Singleton Inspectors* in Custom Network Analysis Policy Creation for Snort 3, on page 2117.
Multiton inspectors	Multiton inspectors contain multiple instances which you can configure as needed. These inspectors support configuring settings based on specific conditions, such as network, port, and VLAN. One set of supported settings is called an instance. For more information, see *Multiton Inspectors* in Custom Network Analysis Policy Creation for Snort 3, on page 2117.

Term	Description
Schema	The schema file is based on the OpenAPI JSON specification, and it validates the content that you upload or download. You can download the schema file and open it using any third-party JSON editor, such as Swagger editor. The schema file helps you to identify what parameters can be configured for inspectors with their corresponding allowed values, range, and accepted patterns to be used. For more information, see Customize the Network Analysis Policy, on page 2125.
Sample file	It is a pre-existing template that contains example configurations to help you with configuring the inspectors. You can refer to the example configurations included in the sample file and make any changes that you may require. For more information, see Customize the Network Analysis Policy, on page 2125.
Full configuration	You can download the entire inspector configurations in a single file. All information regarding the inspector configuration is available in this file. The full configuration is a merged configuration of the default configuration (rolled out as a part of the LSP updates by Cisco Talos) and the custom NAP inspector configurations. For more information, see Customize the Network Analysis Policy, on page 2125.

Term	Description
Overridden configuration	In the **Snort 3 Version** of the network analysis policy page: • Under **Actions** > **Upload**, you can click **Overridden Configuration** to upload the JSON file that contains the overridden configuration. • Under **Actions** > **Download**, you can click **Overridden Configuration** to download the inspector configuration that has been overridden. If you have not overridden any inspector configuration, then this option is disabled. When you override the inspector configuration, then this option is enabled automatically to allow you to download. For more information, see Customize the Network Analysis Policy, on page 2125.

Related Topics

Custom Network Analysis Policy Creation for Snort 3, on page 2117
Customize the Network Analysis Policy, on page 2125
Network Analysis Policy Mapping, on page 2122

Prerequisites for Network Analysis and Intrusion Policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the IPS license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

Custom Network Analysis Policy Creation for Snort 3

The default network analysis policy is tuned for typical network requirements and optimal performance. Usually, the default network analysis policy suffices most network requirements and you might not need to customize the policy. However, when you have a specific network requirement or when you are facing performance issues, the default network analysis policy can be customized. Note that customizing the network analysis policy is an advanced configuration that should be done only by advanced users or Cisco support.

Network analysis policy configuration for Snort 3 is a data-driven model, which is based on JSON and JSON Schema. Schema is based on the OpenAPI specification, and it helps you get a view of the supported inspectors, settings, settings type, and valid values. The Snort 3 inspectors are plugins that process packets (similar to the Snort 2 preprocessor). Network analysis policy configuration is available to download in the JSON format.

In Snort 3, the list of inspectors and settings are not in a one-to-one mapping with the Snort 2 list of preprocessors and settings. Also, the number of inspectors and settings available in Firewall Management Center is a subset of the inspectors and settings that Snort 3 supports. See https://snort.org/snort3 for more

information on Snort 3. See https://www.cisco.com/go/snort3-inspectors for more information on the inspectors available in Firewall Management Center.

Note

- While upgrading the Firewall Management Center to the 7.0 release, the changes that were done in the Snort 2 version of the network analysis policy are not migrated to Snort 3 after the upgrade.
- Unlike the intrusion policy, there is no option to synchronize Snort 2 network analysis policy settings to Snort 3.

Default Inspector Updates

Lightweight Security Package (LSP) updates may contain new inspectors or modifications to integer ranges for existing inspector configurations. Following the installation of an LSP, new inspectors and/or updated ranges will be available under **Inspectors** in the **Snort 3 Version** of your network analysis policy.

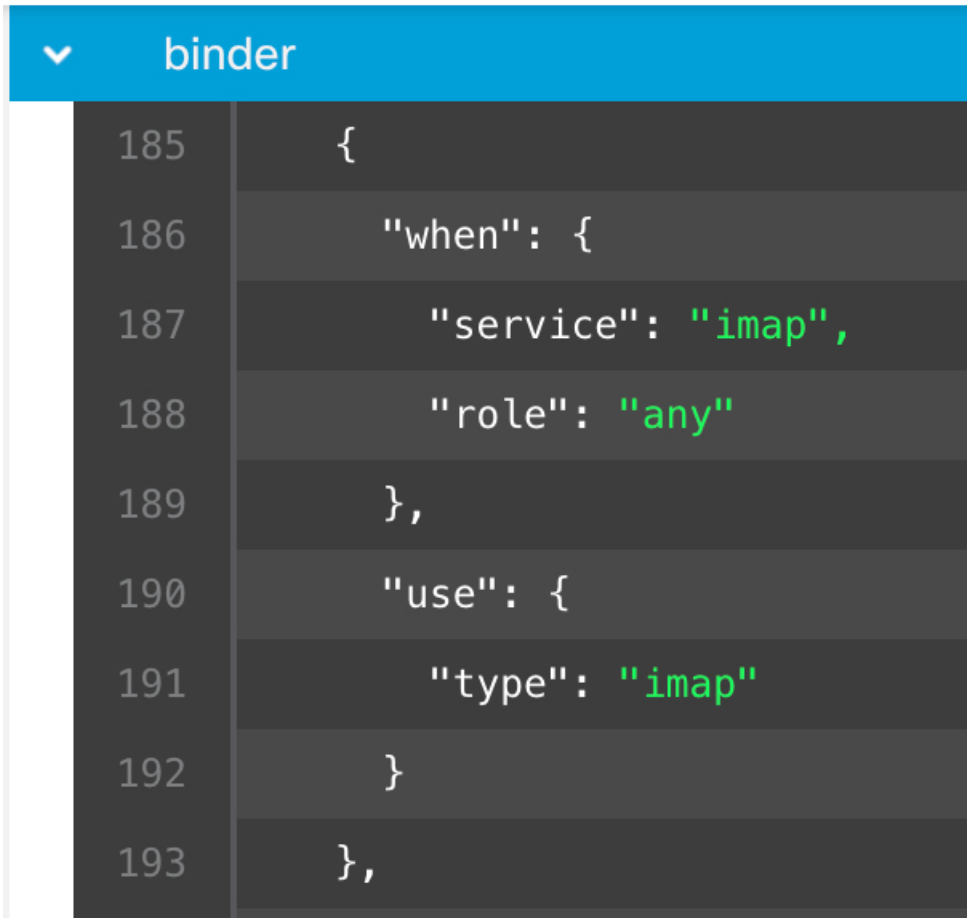
Binder Inspector

Binder inspector defines the flow when a particular inspector has to be accessed and taken into consideration. When the traffic matches the conditions defined in the binder inspector, only then the values/configurations for that inspector come into effect. For example:

For the *imap* inspector, the binder defines the following condition when it has to be accessed. That is when:

- Service is equal to imap.
- Role is equal to any.

If these conditions are met, then use the type imap.



Singleton Inspectors

Singleton inspectors contain a single instance. These inspectors do not support adding more instances like multiton inspectors. Settings of singleton inspector are applied to the entire traffic and not to a specific traffic segment.

For example:

```
{
   "normalizer":{
      "enabled":true,
      "type":"singleton",
      "data":{
         "ip4":{
            "df":true
         }
      }
   }
}
```

Multiton Inspectors

Multiton inspectors contain multiple instances which you can configure as needed. These inspectors support configuring settings based on specific conditions, such as network, port, and VLAN. One set of supported

settings is called an instance. There is a default instance, and you can also add additional instances based on specific conditions. If the traffic matches that condition, the settings from that instance are applied. Otherwise, the settings from the default instance are applied. Also, the name of the default instance is the same as the inspector's name.

For a multiton inspector, when you upload the overridden inspector configuration, you also need to include/define a matching binder condition (conditions under when the inspector has to be accessed or used) for each instance in the JSON file, otherwise, the upload will result in an error. You can also create new instances, but make sure that you include a binder condition for every new instance that you create to avoid errors.

For example:

- Multiton inspector where the default instance is modified.

```
{
   "http_inspect":{
      "enabled":true,
      "type":"multiton",
      "instances":[
         {
            "name":"http_inspect",
            "data":{
               "response_depth":5000
            }
         }
      ]
   }
}
```

- Multiton inspector where the default instance and default binder is modified.

```
{
   "http_inspect":{
      "enabled":true,
      "type":"multiton",
      "instances":[
         {
            "name":"http_inspect",
            "data":{
               "response_depth":5000
            }
         }
      ]
   },
   "binder":{
      "type":"binder",
      "enabled":true,
      "rules":[
         {
            "use":{
               "type":"http_inspect"
            },
            "when":{
               "role":"any",
               "ports":"8080",
               "proto":"tcp",
               "service":"http"
            }
         }
      ]
   }
}
```

- Multiton inspector where a custom instance and a custom binder is added.

```
{
   "http_inspect":{
      "enabled":true,
      "type":"multiton",
      "instances":[
         {
            "name":"http_inspect1",
            "data":{
               "response_depth":5000
            }
         }
      ]
   },
   "binder":{
      "type":"binder",
      "enabled":true,
      "rules":[
         {
            "use":{
               "type":"http_inspect",
               "name":"http_inspect1"
            },
            "when":{
               "role":"any",
               "ports":"8080",
               "proto":"tcp",
               "service":"http"
            }
         }
      ]
   }
}
```

Common Industrial Protocol Safety

Common Industrial Protocol (CIP) Safety is a set of extensions to the CIP that enables the safe operation of devices. It also provides fail-safe communication between different nodes on a CIP network.

The CIP Safety protocol comprises two main components:

- CIP Safety segments—Used in Forward Open messages to exchange safety parameters for the subsequent safety session.
- CIP Safety messages—Used to exchange actual safety information.

The CIP inspector detects and identifies:

- CIP as a service and client
- Payloads, such as CIP Read, CIP Admin, CIP Infrastructure, and CIP Write

  The CIP inspector can parse the CIP segments and detect the CIP Safety segments in the Forward Open requests.

To test the CIP Safety feature, you must enable the CIP inspector. See Detect and Block Safety Segments in CIP Packets, on page 2122.

Detect and Block Safety Segments in CIP Packets

Use case: To detect and block CIP safety segments while allowing other CIP packets:

- Create a custom network analysis policy called **cip_safety**.
- Create access control rules in your access control policy to block CIP Safety and to allow all other packets.

To test the CIP Safety feature, enable the CIP inspector in the management center and assign it to an access control policy.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click the **Snort 3 Version** of the network analysis policy **cip_safety** that you created.

Step 3 Under **Inspectors**, click **cip** to expand it.

The default configuration appears in the left column and the overridden configuration appears in the right column under the inspector.

Step 4 Under **Overridden Configuration** on the right column, click the **Edit Inspector** icon and change the "enabled" field in **cip** from false (default) to true.

Step 5 Click **OK**.

Step 6 Click **Save**.

Step 7 To assign the **cip** inspector to the access control policy, choose **Policies** > **Access Control** > **Edit** and choose the **Advanced Settings** option from the **More** drop-down arrow at the end of the packet flow line.

Step 8 Click **Edit** (✎) next to **Network Analysis and Intrusion Policies**.

Step 9 In the **Network Analysis and Intrusion Policies** window, choose the access control policy **cip_safety** that you created from the **Default Network Analysis Policy** drop-down list.

The CIP inspector is now enabled in the management center and you can create the custom access control rules to block CIP Safety and to allow all other CIP packets.

Step 10 After you send live traffic containing CIP Safety packet flows, go to **Connection Events** to verify that the payload is the expected payload that contains CIP Safety packet logs for the detection and block use case as mentioned in this procedure. **CIP** is detected as an application protocol and client (see the **Application Protocol** and **Client** fields), and **CIP Safety** is shown under the **Web Application** field.

Network Analysis Policy Mapping

For network analysis policies, Cisco Talos provides mapping information, which is used to find the corresponding Snort 2 version of the policies for the Snort 3 version.

This mapping ensures that the Snort 3 version of policies has its equivalent Snort 2 version.

View Network Analysis Policy Mapping

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click **NAP Mapping**.

Step 3 Expand the arrow for **View Mappings**.

The Snort 3 network analysis policies that are automatically mapped to a Snort 2 equivalent policy are displayed.

Step 4 Click **OK**.

Create a Network Analysis Policy

All the existing network analysis policies are available in Firewall Management Center with their corresponding Snort 2 and Snort 3 versions. When you create a new network analysis policy, it is created with both the Snort 2 version and the Snort 3 version.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click **Create Policy**.

Step 3 Enter the **Name** and **Description**.

Step 4 Select a **Base Policy** and click **Save**.

The new network analysis policy is created with its corresponding **Snort 2 Version** and **Snort 3 Version**.

Modify the Network Analysis Policy

You can modify the network analysis policy to change its name, description, or the base policy.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click **Edit** to change the name, description, inspection mode, or the base policy.

Attention
Detection mode deprecation: From management center 7.4.0 onwards, for a network analysis policy (NAP), the **Detection** inspection mode is deprecated and will be removed in an upcoming release.

The **Detection** mode was intended to be used as a test mode so that you can enable inspections and see how they behave in your network before setting it to drop traffic, that is, to show traffic that would be dropped.

This behavior is improved where all inspector drops are controlled by the rule state, and you can set each one to generate events. This is done to test them before configuring the rule state to drop traffic. As we now have granular control over traffic drops in Snort 3, the **Detection** mode only adds more complexity to the product and is not needed, so the detection mode is deprecated.

If you change a NAP in **Detection** mode to **Prevention**, the NAP that processes the traffic of intrusion events and have the result "will be dropped" will now be "dropped" and the corresponding traffic will drop the traffic from these events. This is applicable for rules whose GIDs are not 1 or 3. GIDs 1 and 3 are text/compiled rules (typically provided by Talos or from your custom/imported rules) and all other GIDs are inspections for anomalies. These are more uncommon rules to trigger in a network. Changing to **Prevention** mode is unlikely to have any impact on the traffic. You need to just disable the intrusion rule that is applicable for the dropped traffic and set it to just generate or disable.

We recommend you choose **Prevention** as the inspection mode, but if you choose **Prevention**, you cannot revert to **Detection** mode.

Note
If you edit the network analysis policy name, description, base policy, and inspection mode, the edits are applied to both the Snort 2 and Snort 3 versions. If you want to change the inspection mode for a specific version, then you can do that from within the network analysis policy page for that respective version.

Step 3 Click **Save**.

Search for an Inspector on the Network Analysis Policy Page

On the Snort 3 version of the network analysis policy page, you may need to search for an inspector by entering any relevant text in the search bar.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Enter an inspector's name or any relevant text to search for in the **Search** bar.

All the inspectors matching the text you search for are displayed.

For example, if you enter `pop`, then the pop inspector and the binder inspector are shown as matching results on the screen.

Customize the Network Analysis Policy, on page 2125
Make Inline Edit for an Inspector to Override Configuration, on page 2129

Copy the Inspector Configuration

You can copy the inspector configuration for the Snort 3 version of the network analysis policy according to your requirements.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to copy the configuration.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

Step 4 Click the **Copy to clipboard** icon to copy the inspector configuration to the clipboard for one or both of the following.

- **Default Configuration** in the left column
- **Overridden Configuration** in the right column

Step 5 Paste the copied inspector configuration to a JSON editor to make any edits you may require.

Related Topics

Customize the Network Analysis Policy, on page 2125

Customize the Network Analysis Policy

You can customize the Snort 3 version of the network analysis policy according to your requirements.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

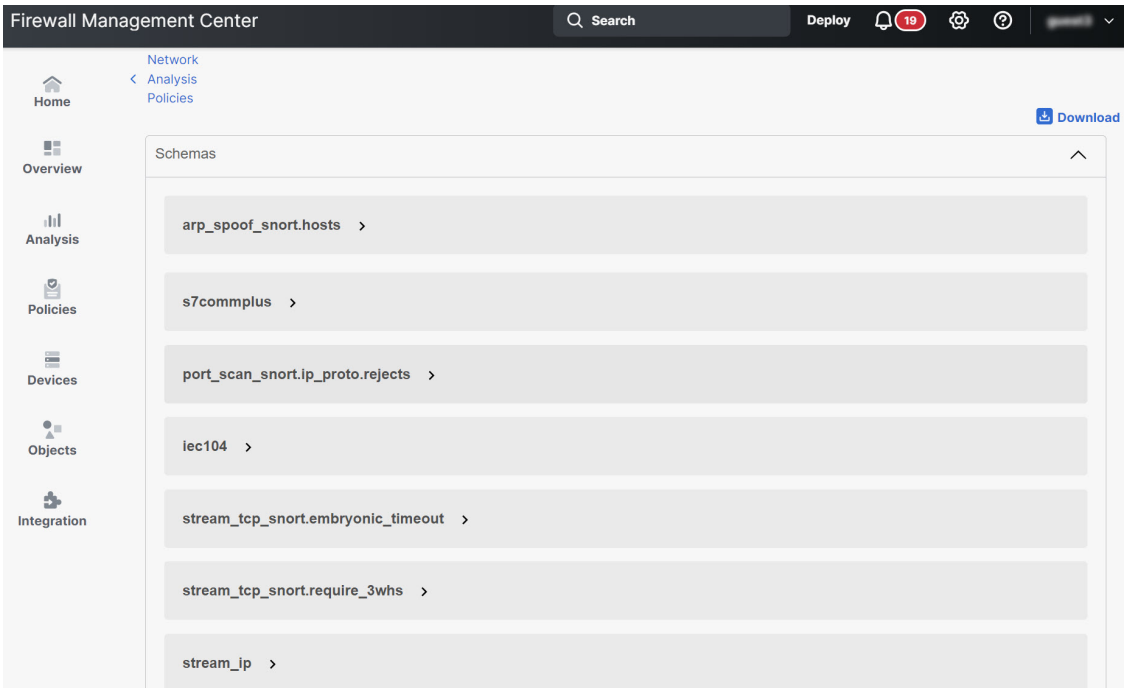
Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Click the **Actions** drop-down menu.

The following options are displayed:

- View Schema
- Download Schema / Download Sample File / Template
- Download Full Configuration
- Download Overridden Configuration
- Upload Overridden Configuration

Step 4 Click **View Schema** to open the schema file directly in a browser.



Step 5 You can download the schema file, sample file / template, full configuration, or overridden configuration as needed.

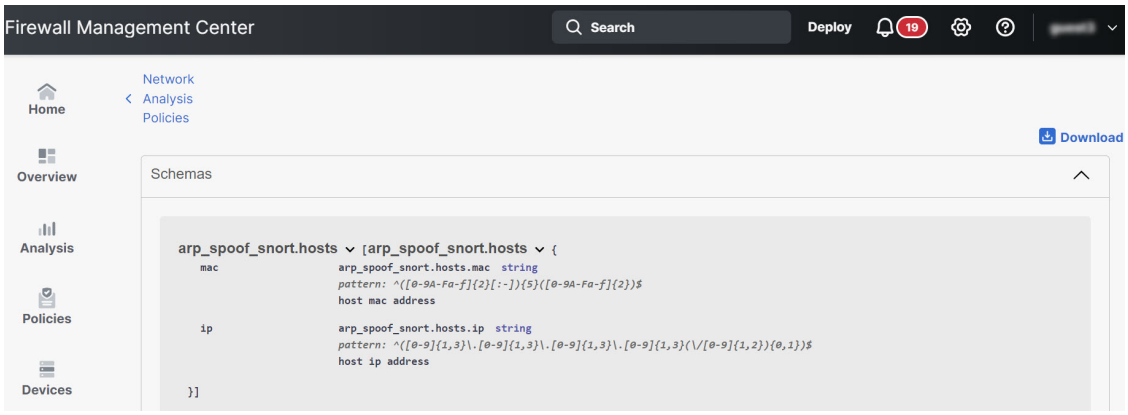
These options provide you an insight about the allowed values, range, and patterns, existing and default inspector configurations, and overridden inspector configurations.

a) Click **Download Schema** to download the schema file.

The schema file validates the content that you upload or download. You can download the schema file and open it using any third-party JSON editor. The schema file helps you to identify what parameters can be configured for inspectors with their corresponding allowed values, range, and accepted patterns to be used.

For example, for the *arp_spoof_snort* inspector, you can configure the hosts. The hosts include the *mac* and *ip* address values. The schema file shows the following accepted pattern for these values.

- **mac** – `pattern: ^([0-9A-Fa-f]{2}[:-]){5}([0-9A-Fa-f]{2})$`
- **ip** – `pattern: ^([0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}(/[0-9]{1,2}){0,1})$`



You must provide the values, range, patterns according to the accepted ones in the schema file to be able to successfully override the inspector configuration, otherwise, you get an error message.

b) Click **Download Sample File / Template** to use a pre-existing template that contains example configurations to help you with configuring the inspectors.

You can refer to the example configurations included in the sample file and make any changes that you may require.

c) Click **Download Full Configuration** to download the entire inspector configurations in a single JSON file.

Instead of expanding the inspectors separately, you can download the full configuration to look out for the information you need. All information regarding the inspector configuration is available in this file.

d) Click **Download Overridden Configuration** to download the inspector configuration that has been overridden.

Step 6 To override the existing configuration, follow the steps.

You can choose to override an inspector configuration using the following ways.

- Make inline edits for an inspector directly on the Firewall Management Center. See the topic **Make Inline Edit for an Inspector to Override Configuration** in the **Getting Started with Network Analysis Policies** chapter of the *Cisco Secure Firewall Management Center Snort 3 Configuration Guide*.
- Continue to follow the current procedure of using the **Actions** drop-down menu to upload the overridden configuration file.

If you chose to make inline edits directly in the Firewall Management Center, then you don't need to follow the current procedure further. Otherwise, you must follow this procedure completely.

a) Under **Inspectors**, expand the required inspector for which you want to override the default configuration.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

You may need to search for an inspector by entering any relevant text in in the search bar.

b) Click the **Copy to clipboard** icon to copy the default inspector configuration to the clipboard.
c) Create a JSON file and paste the default configuration in it.
d) Keep the inspector configuration that you want to override, and remove all the other configuration and instances from the JSON file.

You can also use the **Sample File / Template** to understand how to override the default configuration. This is a sample file that includes JSON snippets explaining how you can customize the network analysis policy for Snort 3.

e) Make changes to the inspector configuration as needed.

Validate the changes and make sure they conform to the schema file. For multiton inspectors, make sure that the binder conditions for all instances are included in the JSON file. See *Multiton Inspectors* in the topic **Custom Network Analysis Policy Creation for Snort 3** in the *Cisco Secure Firewall Management Center Snort 3 Configuration Guide* for more information.

f) If you are copying any further default inspector configurations, append that inspector configuration to the existing file that contains the overridden configuration.

Note
The copied inspector configuration must comply with the JSON standards.

g) Save the overridden configuration file to your system.

Step 7 From the **Actions** drop-down menu, choose Upload Overridden Configuration to upload the JSON file that contains the overridden configuration.

Caution
Upload only the changes that you require. You should not upload the entire configuration as it makes the overrides sticky in nature and therefore, any subsequent changes to the default configuration as part of the LSP updates would not be applied.

You can drag and drop a file or click to browse to the JSON file saved in your system that contains the overridden inspector configuration.

- **Merge inspector overrides** – Content in the uploaded file is merged with the existing configuration if there is no common inspector. If there are common inspectors, then the content in the uploaded file (for common inspectors) takes precedence over the previous content, and it replaces the previous configuration for those inspectors.
- **Replace inspector overrides** – Removes all previous overrides and replaces them with the new content in the uploaded file.

Attention
Choosing this option deletes all the previous overrides. Make an informed decision before you override the configuration using this option.

If any error occurs while uploading the overridden inspectors, you see the error in the **Upload Overridden Configuration File** pop-up window. You can also download the file with the error, fix the error, and reupload the file.

Step 8 In the **Upload Overridden Configuration File** pop-up window, click **Import** to upload the overridden inspector configuration.

After you upload the overridden inspector configuration, you will see an orange icon next to the inspector that signifies that it is an overridden inspector.

Also, the **Overridden Configuration** column under the inspector shows the overridden value.

You can also view all the overridden inspectors using the **Show Overrides Only** checkbox adjacent to the Search bar.

Note

Make sure that you always download the overridden configuration, open the JSON file, and append any new changes/overrides to the inspector configurations to this file. This action is needed so that you do not lose the old overridden configurations.

Step 9 (Optional) Take a backup of the overridden configuration file on your system before making any new inspector configuration changes.

Tip
We recommend that you take the backup from time to time as you override the inspector configuration.

Search for an Inspector on the Network Analysis Policy Page, on page 2124
Copy the Inspector Configuration , on page 2125

Make Inline Edit for an Inspector to Override Configuration

For the Snort 3 version of the network analysis policy, you can make an inline edit for the inspector configuration to override the configuration according to your requirements.

Alternatively, you can also use the **Actions** drop-down menu to upload the overridden configuration file. See Customize the Network Analysis Policy, on page 2125 for more information.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to override the default setting.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

Step 4 Under the **Overridden Configuration** in the right column, click **Edit Inspector** (Pencil) icon to make changes to the inspector configuration.

The Override Configuration pop-up appears where you can make the required edits.

Note
- Make sure that you keep only those settings that you want to override. If you leave a setting with the same value, that field becomes sticky. This means if that setting is changed in the future by Talos, the current value will be retained.
- If you are adding or deleting any custom instance, make sure that you add or delete a binder rule for that instance in the binder inspector as well.

Step 5 Click **OK**.

If there are any errors according to the JSON standards, it shows you an error message.

Step 6 Click **Save** to save the changes.

If the changes conform to the OpenAPI schema specification, the Firewall Management Center allows you to save the configuration, otherwise, the **Error saving overridden configuration** pop-up appears that shows the errors. You can also download the file with the errors.

Revert Unsaved Changes during Inline Edits

While making inline edits to override the configuration for an inspector , you can revert any unsaved changes. Note that this action reverts all unsaved changes to the most recently saved value, but does not revert the configuration to the default configuration for an inspector.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to revert the unsaved changes.

The default configuration is displayed in the left column and the overridden configuration is displayed in the right column under the inspector.

Step 4 Under the **Overridden Configuration** on the right column, click the **Cross** ✕ icon to revert any unsaved changes for the inspector.

Alternatively, you can click **Cancel** to cancel the changes.

If you do not have any unsaved changes to the inspector configuration, then this option is not visible.

Revert Overridden Configuration to Default Configuration

You can revert any changes that you made to override the default configuration for an inspector. This action reverts the overridden configuration to the default configuration for an inspector.

Procedure

Step 1 Go to **Policies** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to revert the overridden configuration.

The overridden inspectors are shown with the orange icon next to their name.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector. Under the **Overridden Configuration** on the right column, click **Revert to default configuration** (back arrow) icon to revert the overridden configuration for the inspector to the default configuration.

If you did not make any changes to the default configuration for the inspector, then this option is disabled.

Step 4 Click **Revert** to confirm the decision.

Step 5 Click **Save** to save the changes.

If you do not want to save the changes, you can click **Cancel** or the **Cross** ✕ icon.

Validate Snort 3 Policies

To validate the Snort 3 policies, here is a list of basic information that user can make note of:

- Current version of the Firewall Management Center can manage multiple Firewall Threat Defense versions.

- Current version of Firewall Management Center supports NAP configurations which are not applicable to previous version of Firewall Threat Defense devices.
- Current NAP Policy and validations will work based on the current version support.
- Changes may include content which is not valid for previous versions of Firewall Threat Defenses.
- Policy configuration changes are accepted if they are valid configuration for the current version and which is performed using current Snort 3 binary and NAP schema.
- For previous version Firewall Threat Defenses, validation is performed during deployment using NAP schema and Snort 3 binary for that specific version. If there is any configuration which is not applicable for the given version, user is provided information or warning that we will not deploy the configuration which is not supported on the given version and remaining configuration will get deployed.

In this procedure, when we associate the NAP policy to an Access Control Policy and deploy it on a device, for example any inspector like rate filter configuration is applied to validate the Snort 3 policies.

Procedure

Step 1 **Steps to Override NAP Policy Configuration:** Under **Inspectors** in the **Snort 3 Version** of the network analysis policy, expand the required inspector for which you want to override the default setting.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

Step 2 Under the **Overridden Configuration** on the right column, click **Edit Inspector** (Pencil) icon to make changes to any inspector like rate_filter.

The Override Configuration pop-up appears where you can make the required edits to the rate_filter inspector.

Step 3 Click **OK**.

Step 4 Click **Save** to save the changes.

Alternatively, you can also use the **Actions** drop-down menu to upload the overridden configuration file.

Step 5 Click the **Actions** drop-down menu in the **Snort 3 Version** of the network analysis policy.

Step 6 Under **Upload** you can click **Overridden Configuration** to upload the JSON file that contains the overridden configuration.

Caution
Upload only the changes that you require. You should not upload the entire configuration as it makes the overrides sticky in nature and therefore, any subsequent changes to the default configuration as part of the LSP updates will not be applied.

You can drag and drop a file or click to browse to the JSON file saved in your system that contains the overridden inspector configuration.

- **Merge inspector overrides** – Content in the uploaded file is merged with the existing configuration if there is no common inspector. If there are common inspectors, then the content in the uploaded file (for common inspectors) takes precedence over the previous content, and it replaces the previous configuration for those inspectors.
- **Replace inspector overrides** – Removes all previous overrides and replaces them with the new content in the uploaded file.

Attention
As choosing this option deletes all the previous overrides, make an informed decision before you override the configuration using this option.

If any error occurs while uploading the overridden inspectors, you see the error on the **Upload Overridden Configuration File** pop-up window. You can also download the file with the error, then fix the error and reupload the file.

Step 7 **Steps to Associate NAP Policy to Access Control Policy:** In the access control policy editor, click **Advanced**, then click **Edit** next to the Network Analysis and Intrusion Policies section.

Step 8 From the **Default Network Analysis Policy** drop-down list, select a default network analysis policy.

If you choose a user-created policy, you can click **Edit** to edit the policy in a new window. You cannot edit system-provided policies.

Step 9 Click **OK**.

Step 10 Click **Save** to save the policy.

Step 11 Alternatively, in the access control policy editor, click **Advanced**, then click **Edit** next to the Network Analysis and Intrusion Policies section.

Step 12 Click **Add Rule**.

Step 13 Configure the rule's conditions by clicking the conditions you want to add.

Step 14 Click **Network Analysis** and choose the **Network Analysis Policy** you want to use to preprocess the traffic matching this rule.

Step 15 Click **Add**.

Step 16 **Deployment:** On the Firewall Management Center menu bar, click **Deploy** and then select **Deployment**.

Step 17 Identify and choose the devices on which you want to deploy configuration changes.

- Search—Search for the device name, type, domain, group, or status in the search box.
- Expand—Click **Expand Arrow** to view device-specific configuration changes to be deployed.

  By selecting the device check box, all the changes for the device, which are listed under the device, are pushed for deployment. However, you can use the **Policy Selection** to select individual policies or configurations to deploy while withholding the remaining changes without deploying them.

  Optionally, use **Show or Hide Policy** to selectively view or hide the associated unmodified policies.

Step 18 Click **Deploy**.

Step 19 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

Note
It shows a warning that Snort 3 Network analysis policy contains inspectors or attributes that are not valid for this Firewall Threat Defense version, following the invalid settings will be skipped in deployment: Invalid inspectors are : [“rate_filter”] only for devices lower than 7.1 version.

Examples of Custom Network Analysis Policy Configuration

This is a sample file that includes JSON snippets explaining how you can customize the network analysis policy for Snort 3. You can choose to override an inspector configuration using the following ways:

- Make inline edits for an inspector directly on the Firewall Management Center. See Make Inline Edit for an Inspector to Override Configuration, on page 2129.
- Use the **Actions** drop-down menu to upload the overridden configuration file. See Customize the Network Analysis Policy, on page 2125.

Before you choose any of these options, review all the following details and examples that will help you in defining the network analysis policy overrides successfully. You must read and understand the examples for various scenarios explained here to avoid any risks and errors.

If you choose to override an inspector configuration from the **Actions** drop-down menu, you need to construct a JSON file for the network analysis policy overrides and upload the file.

For overriding an inspector configuration in the network analysis policy, you must upload only the changes that you require. You should not upload the entire configuration because it makes the overrides sticky in nature and therefore, any subsequent changes to the default values or configuration as part of the LSP updates would not be applied.

Here are the examples for various scenarios:

Enabling a Singleton Inspector when the Default State in the Base Policy is Disabled

```
{
  "rate_filter": {
    "enabled": true,
    "type": "singleton",
    "data": []
  }
}
```

Disabling a Singleton Inspector when the Default State in the Base Policy is Enabled

```
{
  "rate_filter": {
    "enabled": false,
    "type": "singleton",
    "data": []
  }
}
```

Enabling a Multiton Inspector when the Default State in the Base Policy is Disabled

```
{
  "ssh": {
    "enabled": true,
    "type": "multiton",
    "instances": []
  }
}
```

Disabling a Multiton Inspector when the Default State in the Base Policy is Enabled

```
{
  "ssh": {
```

```
    "enabled": false,
    "type": "multiton",
    "instances": []
  },
  "iec104": {
    "type": "multiton",
    "enabled": false,
    "instances": []
  }
}
```

Overriding the Default Value of Specific Setting(s) for Singleton Inspector

```
{
  "normalizer": {
    "enabled": true,
    "type": "singleton",
    "data": {
      "tcp": {
        "block": true
      },
      "ip6": true
    }
  }
}
```

Overriding Specific Setting(s) of a Default Instance (where Instance Name Matches with Inspector Type) in Multiton Inspector

```
{
  "http_inspect": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "data": {
          "unzip": false
        },
        "name": "http_inspect"
      }
    ]
  }
}
```

Adding Binder Rule for a Default Instance with Required Changes

Note Default binder rules can't be edited, they are always appended at the end.

```
{
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "use": {
          "type": "http_inspect"
        },
        "when": {
          "role": "server",
```

```
          "service": "http",
          "dst_nets": "10.1.1.0/24"
        }
      }
    ]
  }
}
```

Adding a New Custom Instance

Note Corresponding binder rule entry must be defined in the binder inspector.

```
{
  "telnet": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "name": "telnet_my_instance",
        "data": {
          "encrypted_traffic": true
        }
      }
    ]
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_my_instance"
        }
      }
    ]
  }
}
```

Overriding a Singleton Instance, Multiton Default Instance, and Creating a New Multiton Instance in a Single JSON Override

Example to show the following in a single JSON override:

- Overriding a Singleton instance (**`normalizer`** inspector)
- Overriding a Multiton default instance (**`http_inspect`** inspector)
- Creating a new Multiton instance (**`telnet`** inspector)

```
{
  "normalizer": {
    "enabled": true,
    "type": "singleton",
    "data": {
```

```
      "tcp": {
        "block": true
      },
      "ip6": true
    }
  },
  "http_inspect": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "data": {
          "unzip": false,
          "xff_headers": "x-forwarded-for true-client-ip x-another-forwarding-header"
        },
        "name": "http_inspect"
      }
    ]
  },
  "telnet": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "name": "telnet_my_instance",
        "data": {
          "encrypted_traffic": true
        }
      }
    ]
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_my_instance"
        }
      },
      {
        "use": {
          "type": "http_inspect"
        },
        "when": {
          "role": "server",
          "service": "http",
          "dst_nets": "10.1.1.0/24"
        }
      }
    ]
  }
}
```

Note You don't need to give the **name** attribute for the default instance in binder rules.

Configuring arp_spoof

Example for configuring **arp_spoof**:

Ther **arp_spoof** inspector does not have any default configurations for any attributes. This demonstrates the case where you can provide the overrides.

```
{
  "arp_spoof": {
    "type": "singleton",
    "data": {
      "hosts": [
        {
          "ip": "1.1.1.1",
          "mac": "ff:0f:f1:0f:0f:ff"
        },
        {
          "ip": "2.2.2.2",
          "mac": "ff:0f:f2:0f:0f:ff"
        }
      ]
    },
    "enabled": true
  }
}
```

Configuring rate_filter

```
{
  "rate_filter": {
    "data": [
      {
        "apply_to": "[10.1.2.100, 10.1.2.101]",
        "count": 5,
        "gid": 135,
        "new_action": "alert",
        "seconds": 1,
        "sid": 1,
        "timeout": 5,
        "track": "by_src"
      }
    ],
    "enabled": true,
    "type": "singleton"
  }
}
```

Configuring Binder Rules when Multi-Hierarchy Network Analysis Policy is Used

This example illustrates adding a new custom instance in child policy and the way binder rules should be written. Binder rules are defined as a list and therefore, it is important to pick up the rules defined in the parent policy and build the new rules on top of it as rules will not be merged automatically. The binder rules available in child policy are a source of truth in totality.

On the Firewall Threat Defense, the default Cisco Talos policy rules are appended on these user-defined overrides.

Parent Policy:

We have defined a custom instance by the name **telnet_parent_instance** and the corresponding binder rule.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": true
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

Child Policy:

This network analysis policy has the aforementioned policy as its base policy. We have defined a custom instance by the name **`telnet_child_instance`** and have also defined the binder rules for this instance. The binder rules from parent policy need to be copied here, and then child policy binder rules can be prepended or appended on top of it based on the nature of the rule.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": false
        },
        "name": "telnet_child_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet",
          "nets": "10.2.2.0/24"
        },
        "use": {
```

```
          "type": "telnet",
          "name": "telnet_child_instance"
        }
      },
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

Configuring List Inspector Attribute in General

While changing overrides for any attribute of type list, it is important to pass the full contents rather than partial override. This means if a base policy attributes are defined as:

```
{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1"
      }
    },
    {
      "entry2": {
        "key2": "value2"
      }
    }
  ]
}
```

If you want to modify **`value1`** to **`value1-new`**, the override payload must look like the following:

Correct Way:

```
{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1-new"
      }
    },
    {
      "entry2": {
        "key2": "value2"
      }
    }
  ]
}
```

Incorrect Way:

```
{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1-new"
      }
```

```
    }
  ]
}
```

You can understand this configuration by taking the trimmed values of the **alt_max_command_line_len** attribute in the **smtp** inspector. Suppose the default (base) policy configuration for **smtp** inspector is as follows:

```
{
  "smtp": {
    "type": "multiton",
    "instances": [
      {
        "name": "smtp",
        "data": {
          "decompress_zip": false,
          "normalize_cmds": "ATRN AUTH BDAT CHUNKING DATA DEBUG EHLO
           EMAL ESAM ESND ESOM ETRN EVFY EXPN HELO HELP IDENT MAIL
           NOOP ONEX QUEU QUIT RCPT RSET SAML SEND SOML STARTTLS TICK
           TIME TURN TURNME VERB VRFY X-ADAT XADR XAUTH XCIR X-DRCP X-
           ERCP XEXCH50 X-EXCH50 X-EXPS XGEN XLICENSE X-LINK2STATE XQUE
           XSTA XTRN XUSR",
          "ignore_data": false,
          "max_command_line_len": 512,
          "max_header_line_len": 1000,
          "log_rcptto": false,
          "decompress_swf": false,
          "max_response_line_len": 512,
          "b64_decode_depth": -1,
          "max_auth_command_line_len": 1000,
          "log_email_hdrs": false,
          "xlink2state": "alert",
          "binary_data_cmds": "BDAT XEXCH50",
          "auth_cmds": "AUTH XAUTH X-EXPS",
          "log_filename": false,
          "uu_decode_depth": -1,
          "ignore_tls_data": false,
          "data_cmds": "DATA",
          "bitenc_decode_depth": -1,
          "alt_max_command_line_len": [
            {
              "length": 255,
              "command": "ATRN"
            },
            {
              "command": "AUTH",
              "length": 246
            },
            {
              "length": 255,
              "command": "BDAT"
            },
            {
              "length": 246,
              "command": "DATA"
            }
          ],
          "log_mailfrom": false,
          "decompress_pdf": false,
          "normalize": "none",
          "email_hdrs_log_depth": 1464,
          "valid_cmds": "ATRN AUTH BDAT CHUNKING DATA DEBUG EHLO
           EMAL ESAM ESND ESOM ETRN EVFY EXPN HELO HELP IDENT MAIL
           NOOP ONEX QUEU QUIT RCPT RSET SAML SEND SOML STARTTLS TICK
```

```
            TIME TURN TURNME VERB VRFY X-ADAT XADR XAUTH XCIR X-DRCP X-
            ERCP XEXCH50 X-EXCH50 X-EXPS XGEN XLICENSE X-LINK2STATE XQUE
            XSTA XTRN XUSR",
          "qp_decode_depth": -1
        }
      }
    ],
    "enabled": true
  }
}
```

Now, if you want to add two more objects to the **alt_max_command_line_len** list:

```
{
    "length": 246,
    "command": "XEXCH50"
},
{
    "length": 246,
    "command": "X-EXPS"
}
```

Then the custom network analysis policy override JSON would look like the following:

```
{
  "smtp": {
    "type": "multiton",
    "instances": [
      {
        "name": "smtp",
        "data": {
          "alt_max_command_line_len": [
            {
              "length": 255,
              "command": "ATRN"
            },
            {
              "command": "AUTH",
              "length": 246
            },
            {
              "length": 255,
              "command": "BDAT"
            },
            {
              "length": 246,
              "command": "DATA"
            },
            {
              "length": 246,
              "command": "XEXCH50"
            },
            {
              "length": 246,
              "command": "X-EXPS"
            }
          ]
        }
      }
    ],
    "enabled": true
  }
}
```

Configuring Overrides when Multi-Hierarchy Network Analysis Policy is used in Multiton Inspector

This example illustrates overriding attributes in child policy and how the merged configuration will be used in the child policy for any instance. Any overrides defined in the child policy will be merged with the parent policy. Thus, if attribute1 and attribute2 are overridden in parent policy and attribute2 and attribute3 are overridden in the child policy, the merged configurations are for child policy. This means that attribute1 (defined in parent policy), attribute2 (defined in child policy), and attribute3 (defined in child policy) will be configured on the device.

Parent Policy:

Here we have defined a custom instance by the name **`telnet_parent_instance`** and overridden 2 attributes namely, **`normalize`** and **`encrypted_traffic`** in the custom instance.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": false
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

Child Policy:

This network analysis policy has the aforementioned policy as its base policy. We have overridden attribute **`encrypted_traffic`** from parent policy and also overridden new attribute **`ayt_attack_thresh`**.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "encrypted_traffic": true,
          "ayt_attack_thresh": 1
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
```

```
  }
}
```

With the above policy JSON, when you deploy the network analysis policy the following merged JSON will be configured on the device.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": true,
          "ayt_attack_thresh": 1
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

This example illustrates details for the custom network analysis policy. The same behavior is also exhibited in the default instance. Also, a similar merging would be done for Singleton inspectors.

Removing all the Inspector Overrides for the Network Analysis Policy:

Whenever you want to remove all the overrides for a specific network analysis policy, you can upload an empty JSON. While uploading the overrides, choose the option **Replace inspector overrides**.

```
{
}
```

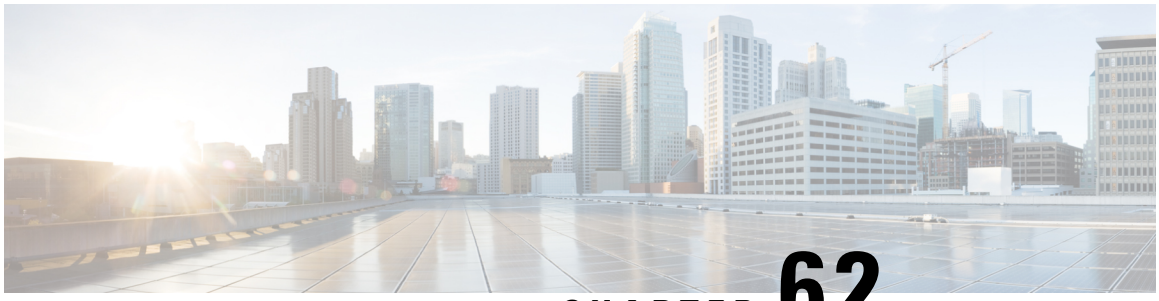
Network Analysis Policy Settings and Cached Changes

When you create a new network analysis policy, it has the same settings as its base policy.

When tailoring a network analysis policy, especially when disabling inspectors, keep in mind that some inspectors and intrusion rules require that traffic first be decoded or preprocessed in a certain way. If you disable a required inspector, the system automatically uses it with its current settings, although the inspector remains disabled in the network analysis policy web interface.

Note Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet **must** complement each other. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task.

The system caches one network analysis policy per user. While editing a network analysis policy, if you select any menu or other path to another page, your changes stay in the system cache even if you leave the page.



CHAPTER 62

Encrypted Visibility Engine

Encrypted Visibility Engine (EVE) is used to identify client applications and processes utilizing TLS encryption. It enables visibility and allows administrators to take actions and enforce policy within their environments. The EVE technology can also be used to identify and stop malware.

- Overview of Encrypted Visibility Engine, on page 2147
- How EVE Works, on page 2148
- Indications of Compromise Events, on page 2149
- QUIC Fingerprinting in EVE, on page 2149
- Configure EVE, on page 2149
- Configure EVE Exception Rules, on page 2152
- Event Enrichment, on page 2154

Overview of Encrypted Visibility Engine

The encrypted visibility engine (EVE) is used to provide more visibility into the encrypted sessions without the need to decrypt them. These insights into encrypted sessions are obtained by Cisco's open-source library that is packaged in Cisco's vulnerability database (VDB). The library fingerprints and analyzes incoming encrypted sessions and matches it against a set of known fingerprints. This database of known fingerprints is also available in the Cisco VDB.

Note The encrypted visibility engine feature is supported only on Firewall Management Center-managed devices running Snort 3. This feature is not supported on Snort 2 devices and Firewall Device Manager-managed devices.

Some of the important features of EVE are the following:

- You can take access control policy actions on the traffic using information derived from EVE.
- The VDB included in Cisco Secure Firewall has the ability to assign applications to some processes detected by EVE with a high confidence value. Alternatively, you can create custom application detectors to:
  - Map EVE-detected processes to new user-defined applications.
  - Override the built-in value of process confidence that is used to assign applications to EVE-detected processes.

See the **Configuring Custom Application Detectors** and **Specifying EVE Process Assignments** sections in the **Application Detection** chapter of the Cisco Secure Firewall Management Center Device Configuration Guide.

- EVE can detect the operating system type and version of the client that created a Client Hello packet in the encrypted traffic.
- EVE supports fingerprinting and analysis of Quick UDP Internet Connections (QUIC) traffic too. The server name from the Client Hello packet is displayed in the URL field of the **Connection Events** page.

Attention To use EVE on Firewall Management Center, you must have a valid IPS license on your device. In the absence of a IPS license, the policy displays a warning and deployment is not allowed.

Note

- EVE can detect the operating system type and version of SSL sessions. Normal usage of the operating system, such as running applications and package management software, can trigger OS detection. To view client OS detection, in addition to enabling the EVE toggle button, you must enable **Hosts** under **Policies** > **Network Discovery**. To view a list of possible operating systems on the host IP address, click **Analysis** > **Hosts** > **Network Map**, and then choose the required host.
- After enabling EVE for your access control policy, ensure that you have turned on logging for the access control rules within that policy to display the expected results on the EVE dashboard whenever any specific rule conditions are met. For more information on how to turn on logging, see Create and Edit Access Control Rules.
- EVE will not provide visibility or insights for encapsulated traffic.

How EVE Works

The Encrypted Visibility Engine (EVE) inspects the Client Hello portion of the TLS handshake to identify client processes. The Client Hello is the initial data packet that is sent to the server. This gives a good indication of the client process on the host. This fingerprint, combined with other data such as destination IP address, provides the basis for EVE's application identification. By identifying specific application fingerprints in the TLS session establishment, the system can identify the client process and take appropriate action (allow/block).

EVE can identify over 5,000 client processes. The system maps a number of these processes to client applications for use as criteria in access control rules. This gives the system the ability to identify and control these applications without enabling TLS decryption. By using fingerprints of known malicious processes, EVE technology can also be used to identify and block encrypted malicious traffic without outbound decryption.

Through machine learning (ML) technology, Cisco processes over one billion TLS fingerprints and over 10000 malware samples daily to create and update EVE fingerprints. These updates are then delivered to customers using Cisco Vulnerability Database (VDB) package.

If EVE does not recognize a fingerprint, it identifies client application and estimates the threat score of the first flow using the destination details, such as IP address, port, and server name. At this point, the status of the fingerprints are randomized and the status can be viewed in the debug logs. For subsequent flows with the same fingerprint, EVE skips reanalysis and marks the fingerprint status as unlabeled. If you intend to block traffic based on EVE's Low or Very Low score thresholds, the initial flow is blocked. However, future flows will be allowed once the application's fingerprint is cached.

Indications of Compromise Events

The host's Indications of Compromise (IoC) events for encrypted visibility engine detection allows you to check connection events with a very high malware confidence level, as reported by EVE. IoC events are triggered for encrypted sessions generated from a host using a malicious client. You can view information, such as IP address, MAC address, and OS information of the malicious host, and the timestamp of the suspicious activity.

A session with Encrypted Visibility Threat Confidence score 'Very High' as seen in connection events genreates an IoC event. You must enable **Hosts** from **Policies** > **Network Discovery**. In the Firewall Management Center, you can view the IoC event existence from:

- **Analysis** > **Indications of Compromise**.
- **Analysis** > **Network Map** > **Indications of Compromise** > Choose the host that must be checked.

  You can view the process information of the session that generated the IoC on the **Connection Events** page. Click **Analysis** > **Connections Header** > **Events** to access the **Connection Events** page. Note that you must manually select the Encrypted Visibility fields and IoC field from the **Table View of Connection Events** tab.

QUIC Fingerprinting in EVE

Snort can identify client applications in Quick UDP Internet Connections (QUIC sessions) based on EVE. QUIC fingerprinting can:

- Detect applications over QUIC without enabling decryption.
- Identify malware without enabling decryption.
- Detect service applications. You can assign access control rules based on the service detected over the QUIC protocol.

Configure EVE

Procedure

Step 1 Choose **Policies** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy you want to edit.

Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Encrypted Visibility Engine (EVE)**.

Step 5 On the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.

Step 6 **Use EVE for Application Detection**—This toggle button is enabled by default, which means that EVE is allowed to assign client applications to processes.

EVE's fingerprint information is added in the **Encrypted Visibility Fingerprint** column header of the connection events or unified events. For further analysis of the EVE data collected, you can right-click the fingerprint information to open a dropdown menu. In the menu, click **View Encrypted Visibility Engine Process Analysis** to go to the Secure Firewall Application Detectors site and view details, such as the fingerprint, VDB version, and so on. Different rows with the same fingerprint string and potential process names associated with them and their prevalence are displayed. Prevalence indicates the frequency of a process associated with a particular fingerprint in the data collection system. You can choose the process names and click **Submit Request** to give feedback about any discrepancy in EVE's process detection. For example, you can submit requests if the process name that is detected does not match with the traffic that is being sent or if the process name is not detected at all for a particular fingerprint.

Access to view additional details on the Secure Firewall Application Detectors page is currently not available to users with non-Cisco email addresses.

If you disable the **Use EVE for Application Detection** toggle button:

- AppID-identified clients are assigned to processes and you can see the EVE process and score, but there is no mapping of EVE-detected processes to applications and no action is taken. You can see the details of the events under **Connection Events** or **Unified Events**. To see the difference in connection events (with and without application assignment), see the **Client Application** column header.
- The **Encrypted Visibility Fingerprint** field in the connection events or unified events is empty.

Step 7 Enable the **Block Malware Processes Based on Threat Confidence Level** toggle button to block malicious client processes with the prefix *malware_* based on EVE's threat confidence level.

The default block threshold is 99 percent, which means:

- If EVE detects the traffic to be malware with 99 percent confidence or more, the traffic is blocked.
- If EVE detects the traffic to be malware with less than 99 percent confidence, EVE takes no action.

Note
If EVE has blocked the traffic, the **Reason** column header on the **Connection Events** page displays **Encrypted Visiblity Block**.

Step 8 Use the slider to adjust the threshold for blocking based on EVE's threat confidence, which ranges from **Very Low** to **Very High**.

Step 9 For further granular control, enable the **Advanced Mode** toggle button. Now, you can assign a specific EVE Threat Confidence Level for blocking traffic. The default block threshold is 99 percent.

Caution
We recommend that you do not set a threshold below 50 percent to ensure optimal performance.

Step 10 Click **OK**.

Step 11 Click **Save**.

What to do next

Deploy configuration changes.

View Encrypted Visibility Engine Events

After enabling the **Encrypted Visibility Engine** and deploying your access control policy, you can start sending live traffic through your system. You can view the logged connection events on the **Connection Events** page or on the **Unified Events** page.

Perform this procedure to access the connection events in the Firewall Management Center.

Procedure

Step 1 Click **Analysis** > **Connections Header** > **Events**.

Step 2 Click the **Table View of Connection Events** tab.

You can also view the connection events in the **Unified Events** page. Click **Analysis** > **Unified Events** to access the **Unified Events** page.

The Encrypted Visibility Engine can identify the client process that initiated a connection and the operating system in the client, and indicate if the process contains malware or not.

On the **Connection Events** page, you must explicitly enable these columns that are added for the Encrypted Visibility Engine:

- **EVE Process Name**
- **EVE Process Confidence Score**
- **EVE Threat Confidence**
- **EVE Threat Confidence Score**
- **Detection Type**

For information about these fields, see Connection and Security-Related Connection Event Fields in the Cisco Secure Firewall Management Center Administration Guide.

Note
On the **Connection Events** page, if processes are assigned applications, the **Detection Type** column displays **Encrypted Visibility Engine**, indicating that the client application was identified by the Encrypted Visibility Engine. Without application assignments to process names, the **Detection Type** column displays **AppID**, indicating that the engine that identified the client application was AppID.

View EVE Dashboard

You can view the EVE analysis information in the following dashboards:

Before you begin

- In an access control policy, the **Encrypted Visisibility Engine (EVE)** must be enabled under the **Advanced Settings**.
- To view the **Connections with Detected Process** and **Malicious Processes** widgets, the devices must be running Firewall Threat Defense Version 7.7 or later.

Procedure

Step 1 Go to **Overview** > **Dashboards**, and click **Dashboard**.

Step 2 In the **Summary Dashboard** window, click the **Encrypted Visibility Engine** tab.

Step 3 You can view the following dashboards:

- **Discovered Processes**—Displays top client processes used in your network and the connection count. You can click the process name in the table to see the filtered view of the **Connection Events** page, which is filtered by the process name.
- **Threat Confidence**—Displays connections by the confidence levels. You can click the Threat confidence level in the table to see the filtered view of the **Connection Events** page, which is filtered by the confidence level.
- **Connections with Detected Process**—Displays total count of connections in which EVE identified the client processes.
- **Malicious Processes**—Displays count of malicious client processes identified by EVE with high and very high threat confidence levels.

Configure EVE Exception Rules

You can create an encrypted visibility engine (EVE) exception rule to ensure the continuity of trusted connections and services by bypassing the EVE's block action. You can add attributes such as process names, source and destination IP addresses/ FQDNs, and dynamic objects to the exception rule. For example, you may want to bypass EVE's block verdict for trusted networks. All the connections in the bypassed networks are exempted from EVE's block verdict based on the threat confidence level.

Procedure

Step 1 Choose **Policies** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy you want to edit.

Step 3 From the **More** drop-down arrow at the end of the packet flow line, choose **Advanced Settings**.

Step 4 Next to **Encrypted Visibility Engine (EVE)**, click **Edit** (✎).

Step 5 On the **Encrypted Visibility Engine** page, click the **Encrypted Visibility Engine (EVE)** toggle button to enable EVE.

Step 6 Enable the **Block based on EVE threat confidence level** toggle button to block traffic based on EVE's threat confidence level.

Step 7 Click **Add Exception Rule** and add one or more of the following attributes.

a) Under the **Process Name** tab, enter an EVE-identified process name, and click **Add to Process** on the right side of the window.

You can add multiple process names to the same exception rule. EVE exception list based on process names works only with EVE-identified process names, which are case- and space-sensitive.

b) Under the **Network Objects** tab, perform one of the following:

- Choose one or more IP addresses or FQDNs from the list and click either **Add to Source Network** or **Add to Destination Network**.
- Under **Selected Source Network** or **Selected Destination Network**, manually enter the IP address, and click the **Add** (+) icon to add it to the list of selected networks.

c) Under the **Dynamic Attributes** tab, choose the dynamic objects and add it to the **Selected Dynamic Objects** list.

For more information about creating dynamic objects or working with dynamic objects, see the *Create Dynamic Objects for the First Time* or *Work With Dynamic Objects* sections in Secure Firewall Management Center Device Configuration Guide.

d) (Optional) In the **Comment** field available on all the tabs, you can enter a reason for adding the required attributes to the EVE exception rule.

Step 8 Click **Save** to save the EVE exception rule.

Step 9 Save and deploy the access control policy on the devices.

Note When a connection matches an exception rule, it bypasses the EVE's block verdict. You can view EVE's action in the **Connection Events** or **Unified Events** page. The **Reason** column header displays **EVE Exempted** for identification of such EVE-bypassed traffic.

Add Exception Rule from Unified Events

Use the **Unified Events** page to add exception rules for connections that are blocked by EVE.

Before you begin

Exception list is supported only from threat defense Version 7.6.0 or later.

Procedure

Step 1 Click **Analysis** > **Unified Events**.

Step 2 In the **Reason** column with **Encrypted Visibility Block** as the reason, click the **Ellipsis**( ) icon inside the cell.

Step 3 Choose **Add EVE Exception Rule** from the drop-down list.

Step 4 In the **Encrypted Visibility Engine** window that is displayed, the rule is automatically added to the bottom of the exception list. You can review and make changes to the added rule before saving and deploying the configuration.

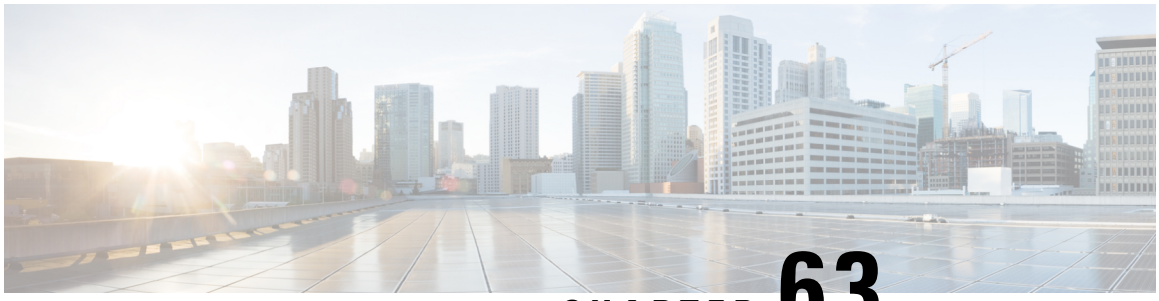
Event Enrichment

Context enrichment for MITRE ATT&CK occurs from the Talos taxonomy and the encrypted visibility engine (EVE). Both Talos and EVE enrichments are communicated using the Talos taxonomy. EVE enrichment works when EVE is enabled. For more information about enabling EVE, see Configure EVE, on page 2149.

On the **Connection Events** page, you can view the following column headers that are added as part of enriched eventing content. You must explicitly enable these columns.

- **MITRE ATT&CK**
- **Other Enrichment**

For information about these fields, see *Connection and Security-Related Connection Event Fields* in Cisco Secure Firewall Management Center Administration Guide.



CHAPTER 63

Elephant Flow Detection

Elephant flows are extremely large (in total bytes), continuous flows set up by a TCP (or other protocols) flow measured over a network link. By default, elephant flows are those larger than 1 GB/10 seconds. They can cause performance duress in Snort cores. Elephant flows are not numerous, but they can occupy a disproportionate share of the total bandwidth over a period of time. They can lead to problems, such as high CPU utilization, packet drops, and so on.

From Firewall Management Center 7.2.0 onwards (Snort 3 devices only), you can use the elephant flow feature to detect and remediate elephant flows, which helps to reduce system stress and resolve the mentioned issues.

- About Elephant Flow Detection and Remediation, on page 2155
- Elephant Flow Upgrade from Intelligent Application Bypass, on page 2155
- Configure Elephant Flow, on page 2156

About Elephant Flow Detection and Remediation

You can use the elephant flow detection feature to detect and remediate elephant flows. The following remediation actions can be applied:

- **Bypass elephant flow**–You can configure elephant flow to bypass Snort inspection. If this is configured, Snort does not receive any packet from that flow.
- **Throttle elephant flow**–You can apply rate-limit to the flow and continue to inspect flows. The flow rate is calculated dynamically and 10% of the flow rate is reduced. Snort sends the verdict (QoS flow with 10% less flow rate) to the firewall engine. If you choose to bypass all applications including unidentified applications, you cannot configure the throttle action (rate-limit) for any flow.

Note For the elephant flow detection to work, Snort 3 must be the detection engine.

Elephant Flow Upgrade from Intelligent Application Bypass

Intelligent Application Bypass (IAB) is deprecated from version 7.2.0 onwards for Snort 3 devices.

For devices running 7.2.0 or later, you must configure elephant flow settings under the **Elephant Flow Settings** section in the AC policy (Advanced settings tab).

Post-upgrade to 7.2.0 (or later), if you are using a Snort 3 device, the elephant flow configuration settings will be picked and deployed from the **Elephant Flow Settings** section and not from the **Intelligent Application Bypass Settings** section, so if you have not migrated to Elephant Flow configuration settings, your device will lose the elephant flow configuration upon the next deployment.

The following table shows the IAB or elephant flow configurations that can be applied to version 7.2.0 or later and to version 7.1.0 or earlier that are running Snort 3 or Snort 2 engines.

Firewall Management Center	Firewall Threat Defense	Elephant Flow or IAB Configuration
Firewall Management Center 7.0 or 7.1	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device	Configuration from IAB is applicable.
Firewall Management Center 7.2.0	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device (7.1.0 and earlier)	Configuration from IAB is applicable.
	Snort 3 device (7.2.0 and later)	Configuration from Elephant Flow is applicable.

Configure Elephant Flow

You can configure elephant flow to take actions on elephant flows, which helps resolve issues, such as system duress, high CPU utilization, packet drops, and so on.

Attention Elephant flow detection is not applicable for prefiltered, trusted, or fast-forwarded flows, which do not process through Snort. As elephant flows are detected by Snort, elephant flow detection is not applicable for encrypted traffic.

Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** (✎) next to **Elephant Flow Settings**.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Figure 447: Configure Elephant Flow Detection

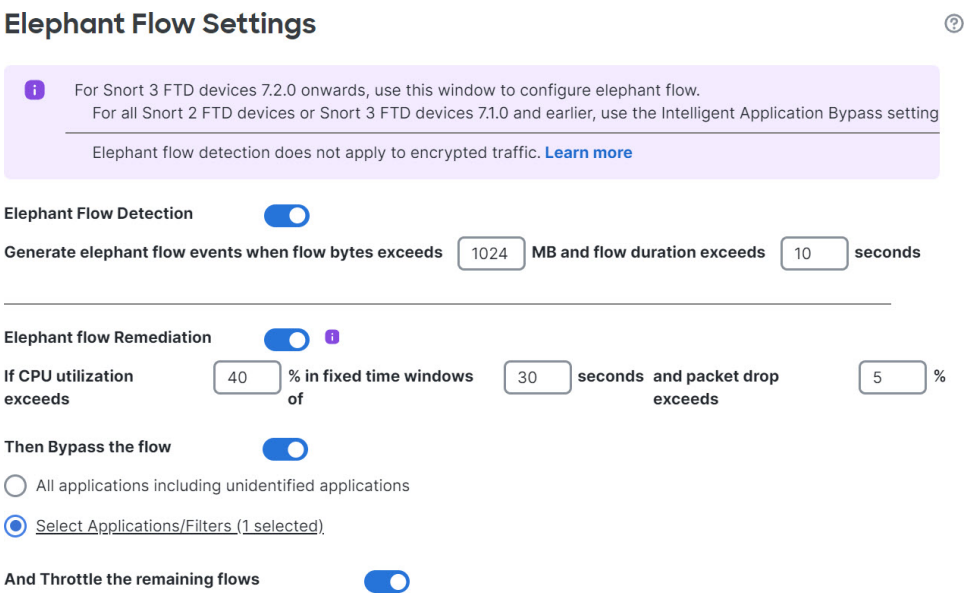


Figure 448: Configure Elephant Flow Detection

Step 2 The **Elephant Flow Detection** toggle button is enabled by default. You can configure the values for flow bytes and flow duration. When they exceed your configured values, elephant flow events are generated.

Step 3 To remediate elephant flows, enable the **Elephant Flow Remediation** toggle button.

Step 4 To set the criteria for remediation of the elephant flow, configure the values for CPU utilization %, duration of fixed time windows, and packet drop %.

CPU utilization is calculated per elephant flow and is derived from the flow latency. If the CPU utilization crosses the configured threshold and other configurations, such as fixed time windows and packet drops, are also matched, the elephant flow remediation actions are applied. Similarly, packet drop calculation is based on the packets dropped per CPU. After the packet drop percentage exceeds the configured value on a specific CPU, the remediation actions are applied. For example, consider that configurations are set to the default, that is, CPU utilization of 40%, fixed time window of 30 seconds, and packet drop of 5%. On a specific CPU, if more than 5% of packet drops are detected and the CPU utilization per flow exceeds 40% in the fixed time frame of 30 seconds, then the flows are either bypassed or throttled.

Step 5 You can perform the following actions for elephant flow remediation when it meets the configured criteria:

a. **Bypass the flow**—Enable this button to bypass Snort inspection for selected applications or filters. Choose from:

- **All applications including unidentified applications**—Select this option to bypass all the application traffic. If you configure this option, you cannot configure the throttle action (rate-limit) for any flow.
- **Select Applications/Filters**—Select this option to select the applications or filters whose traffic you want to bypass; see the topic **Configuring Application Conditions and Filters** in the **Access Control Rules** chapter in the Cisco Secure Firewall Management Center Device Configuration Guide.

b. **Throttle the flow**—Enable this button to apply rate-limit to the flow and continue to inspect flows. Note that you can select the applications or filters to bypass Snort inspection and throttle the remaining flows.

Note
Automatic removal of throttle from a throttled elephant flow occurs when the system is out of duress, that is, the percentage of Snort packet drops is lesser than your configured threshold. Consequently, rate limiting is also removed.

You can also manually remove throttling from a throttled elephant flow, using the following threat defense commands:

- **clear efd-throttle <5-tuple/all> bypass**—This command removes throttling from the throttled elephant flow and bypasses Snort inspection.
- **clear efd-throttle <5-tuple/all>**—This command removes throttling from the throttled elephant flow and Snort inspection continues. Elephant flow remediation is skipped after using this command.

  For more information about these commands, see the Cisco Secure Firewall Threat Defense Command Reference.

Step 6 In the **Remediation Exemption Rule** section, click **Add Rule** to configure L4 access control list (ACL) rules for flows that must be exempted from remediation.

Step 7 In the **Add Rule** window, use the **Networks** tab to add the network details, that is the source network and the destination network. Use the **Ports** tab to add the source port and the destination port.

If an elephant flow is detected and it matches the rules that are defined, an event is generated with the reason as **Elephant Flow Exempted** in the **Reason** column header of **Connection Events**.

Step 8 In the **Remediation Exemption Rule** section, you can view the flows that are exempt from the remediation action.

Step 9 Click **OK** to save the elephant flow settings.

Step 10 Click **Save** to save the policy.

What to do next

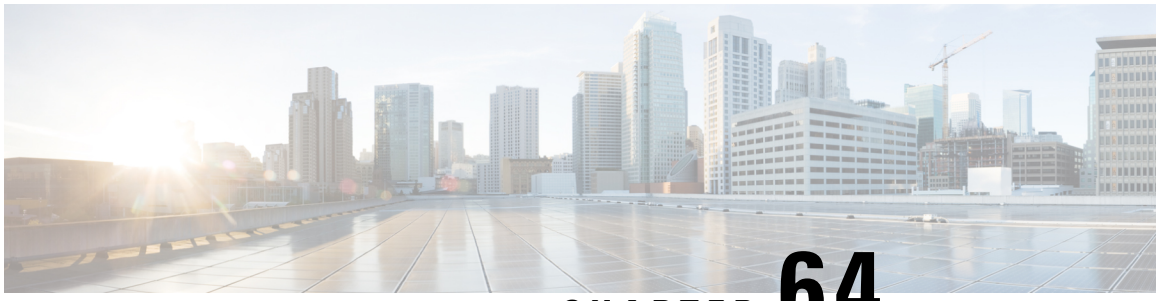
Deploy configuration changes; see Deploy Configuration Changes, on page 259.

After configuring your elephant flow settings, monitor your connection events to see if any flows are detected, bypassed, or throttled. You can view this in the **Reason** field of your connection event. The three reasons for elephant flow connections are:

- Elephant Flow
- Elephant Flow Throttled
- Elephant Flow Trusted

Attention Enabling elephant flow detection alone does not cause generation of connection events for elephant flows. If a connection event is already logged for another reason and the flow is also an elephant flow, then the **Reason** field contains this information. However, to ensure that you are logging all elephant flows, you must enable connection logging in the applicable access control rules.

Refer to Cisco Secure Firewall Elephant Flow Detection for more information.



CHAPTER 64

Use Case - Migrate from Snort 2 to Snort 3 In Secure Firewall Management Center

- Migrate from Snort 2 to Snort 3, on page 2159
- Benefits of Migrating to Snort 3, on page 2159
- Sample Business Scenario, on page 2160
- Best Practices for Migrating from Snort 2 to Snort 3, on page 2160
- Prerequisites, on page 2160
- End-to-End Migration Workflow, on page 2160
- Enable Snort 3 on Threat Defense, on page 2161
- Convert Snort 2 Rules of a Single Intrusion Policy to Snort 3, on page 2162
- Deploy Configuration Changes, on page 2167

Migrate from Snort 2 to Snort 3

Snort is an intrusion detection and prevention system that has undergone a significant change from Version 2 to Version 3. To leverage the enhanced features and capabilities of Snort 3, migration of the existing rule sets from Snort 2 becomes crucial. This migration process involves converting and adapting the Snort 2 rules to the Snort 3 rule syntax and optimizing them for improved detection and performance.

In some cases, organizations can have the threat defense devices managed by the Secure Firewall Management Center. Organizations can opt for a hybrid deployment approach during the migration from Snort 2 to Snort 3. This approach allows for a gradual transition and minimizes potential disruptions, if any.

Benefits of Migrating to Snort 3

- **Enhanced protocol support**—Snort 3 provides improved protocol support, allowing you to monitor and detect threats across a wide range of modern protocols, including encrypted traffic.
- **Streamlined rule management**—Snort 3 offers a more user-friendly rule language and rule management system, making it easier to create, modify, and manage rules effectively.
- **Improved performance**—Snort 3 has been optimized to handle higher traffic volumes more efficiently, reducing the risk of performance bottlenecks and ensuring timely threat detection.

Sample Business Scenario

Alice works as a security analyst in a large organization that heavily relies on the Snort inspection engine to monitor and protect their network infrastructure. The organization has been using Snort Version 2 for several years, but they have encountered some limitations and challenges.

Bob, the network administrator, is looking to migrate from Snort 2 to Snort 3 to overcome these issues and enhance his organization's network security capabilities.

This migration will also improve network security monitoring, enhance performance, and streamline rule management.

Best Practices for Migrating from Snort 2 to Snort 3

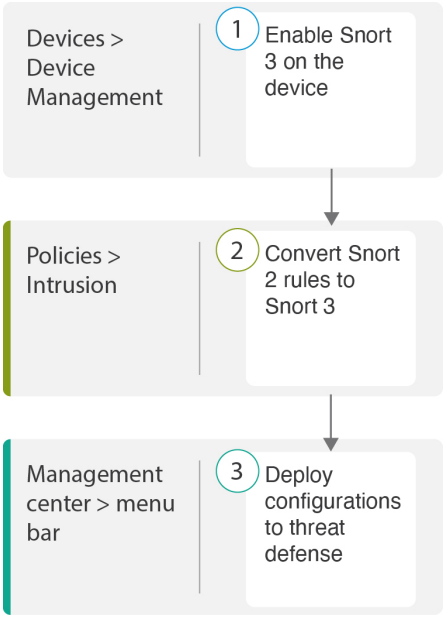
- Back up your intrusion policy before performing the migration. See the Export Configurations task in the *Cisco Secure Firewall Management Center Administration Guide*.
- Before upgrading a device to Snort 3, if changes are made in Snort 2, use the synchronize utility to include the latest synchronization from Snort 2 to Snort 3 so that you can start with a similar coverage. See Synchronize Snort 2 Rules with Snort 3 , on page 2054.
- Snort 2 custom rules are not automatically converted to Snort 3 and must be manually migrated. See Convert Snort 2 Custom IPS Rules to Snort 3, on page 2052.
- Synchronization does not migrate Snort 2 rules with thresholds or suppressions. These rules must be created again in Snort 3.

Prerequisites

- Have a working knowledge of Snort. To learn about the Snort 3 architecture, see Snort 3 Adoption.
- Back up your management center. See Backup the Management Center.
- Back up your intrusion policy. See Exporting Configurations.

End-to-End Migration Workflow

The following flowchart illustrates the workflow for migrating Snort 2 to Snort 3 in Secure Firewall Management Center.



Step	Description
1	Enable Snort 3 on the device. See Enable Snort 3 on Threat Defense, on page 2161.
2	Convert Snort 2 rules to Snort 3. See Convert Snort 2 Rules of a Single Intrusion Policy to Snort 3, on page 2162.
3	Deploy configuration. See Deploy Configuration Changes, on page 2055.

Enable Snort 3 on Threat Defense

Attention During the deployment process, there could be a momentary traffic loss because the current inspection engine needs to be shut down.

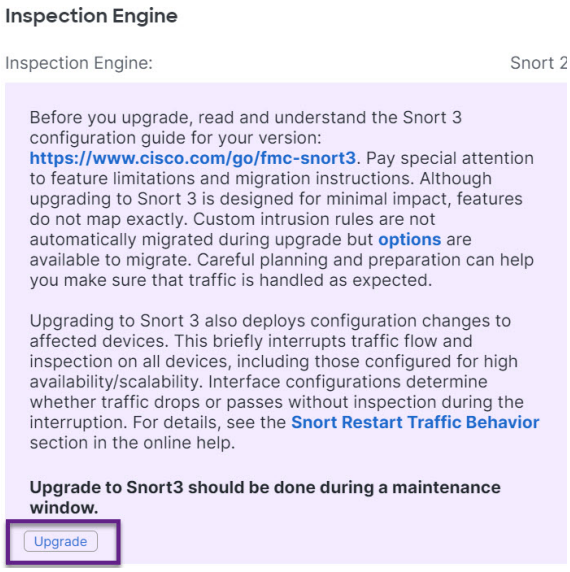
Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the corresponding device to go to the device home page.

Step 3 Click the **Device** tab.

Step 4 In the **Inspection Engine** section, click **Upgrade**.



Step 5 Click **Yes**.

What to do next

Deploy the changes on the device. See Deploy Configuration Changes, on page 2055.

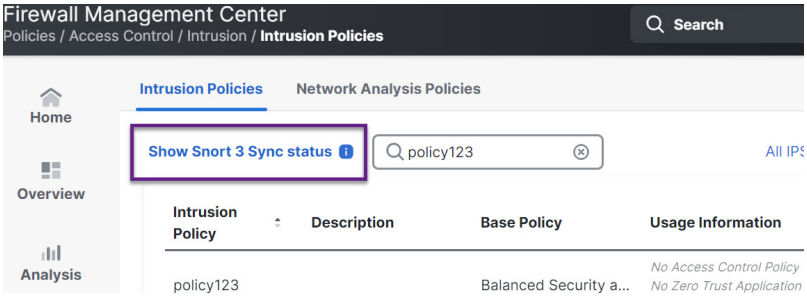
The system converts your policy configurations during the deployment process to make them compatible with the selected Snort version.

Convert Snort 2 Rules of a Single Intrusion Policy to Snort 3

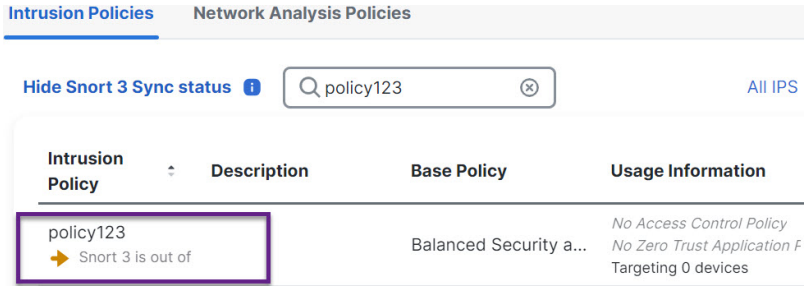
Procedure

Step 1 Choose **Policies** > **Intrusion**.

Step 2 In the **Intrusion Policies** tab, click **Show Snort 3 Sync status**.

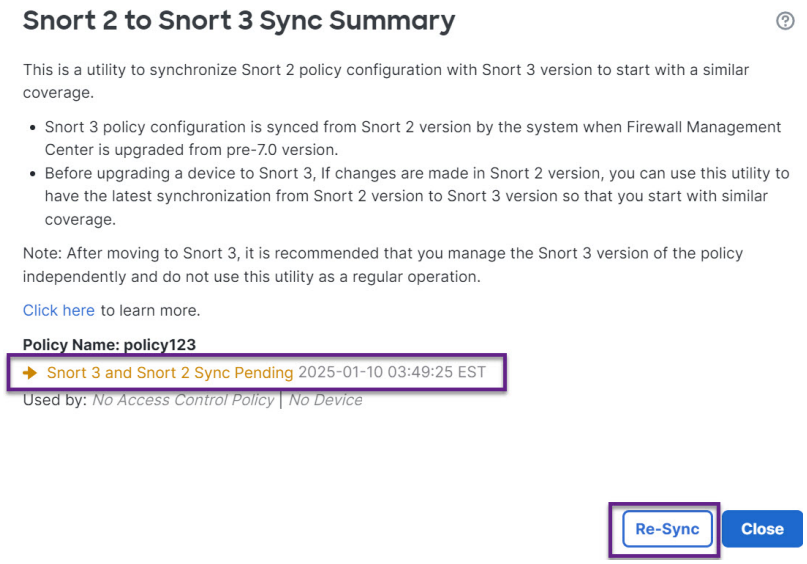


If your policy displays an orange arrow, it indicates that the Snort 2 and the Snort 3 versions of the intrusion policy are not synchronized.



Step 3 Click the orange arrow.

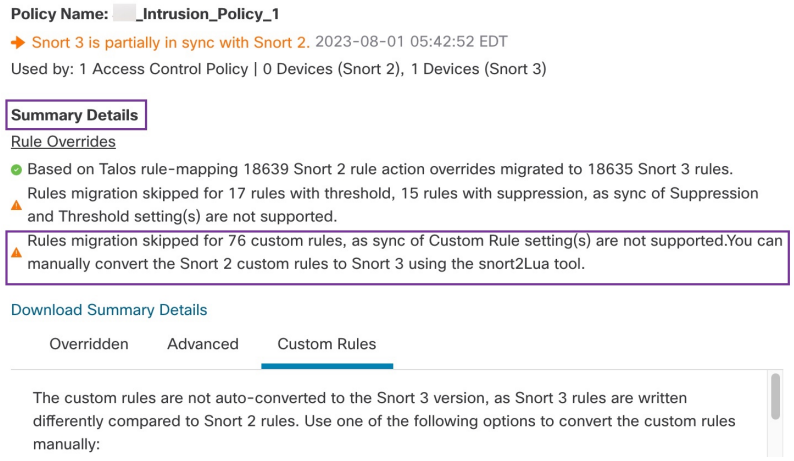
The **Snort 2 to Snort 3 Sync Summary** page displays that the Snort 2 to Snort 3 sync is pending.



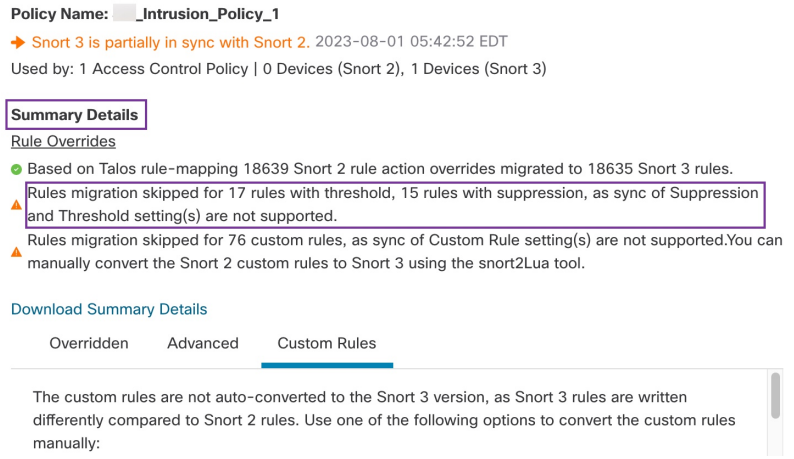
Step 4 Click **Re-Sync** to start the synchronization.

Note
When you click **Re-Sync**, the snort2Lua tool converts the rules from Snort 2 to Snort 3.

The **Summary Details** section lists the rules that were migrated or skipped. In our use case, there are 76 custom Snort 2 rules, 17 rules with thresholds, and 15 rules with suppression that were skipped during the sync process. To migrate the custom rules, go to the next step.



To migrate rules with thresholds and suppressions, go to Step 6.

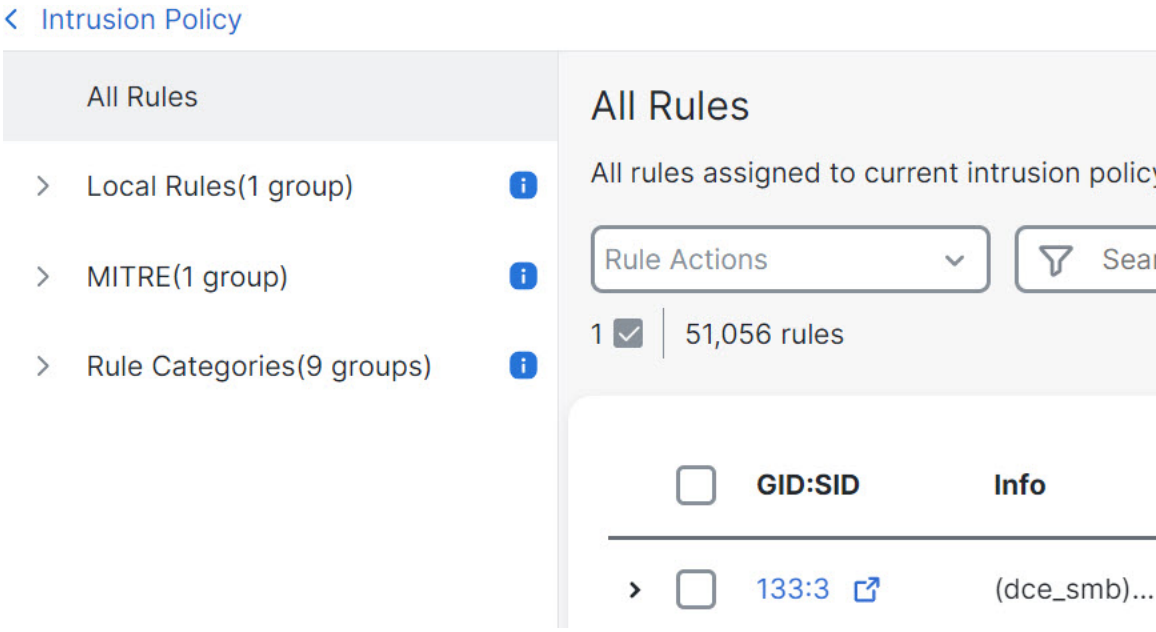


Step 5 To migrate the 76 custom rules, perform either one of these steps:

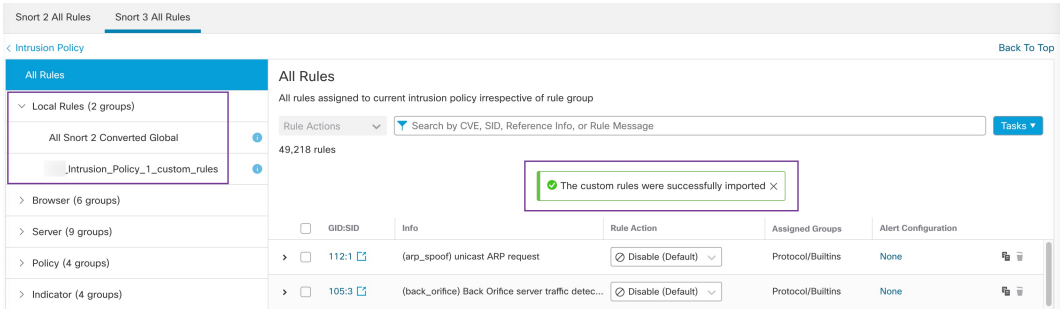
- In the **Custom Rules** tab, click the **Import** icon to convert and auto-import the local rules to the Snort 3 version of the policy.

  A confirmation message is displayed after the rules are successfully imported.

- Choose **Objects** > **Intrusion Rules** and click **Snort 3 All Rules**.
  a. Click **Local Rules** in the left panel to check if any rules have been migrated. Notice that no custom rules from Snort 2 have been migrated.
  b. From the **Tasks** drop-down list, choose **Convert Snort 2 rules and import**.

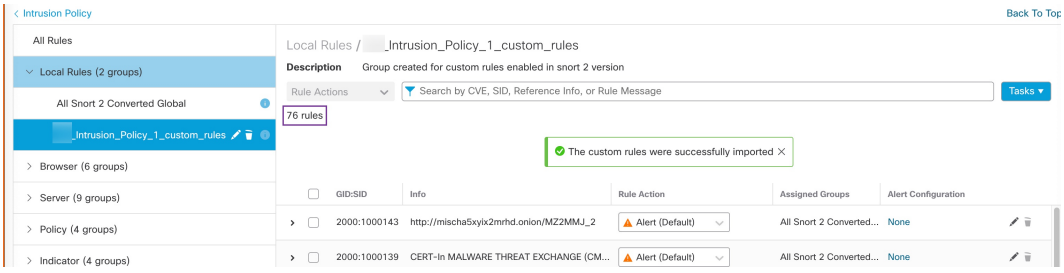


c. Click **OK**.



A newly created rule group (**All Snort 2 Converted Global**) is created under **Local Rules** in the left panel.

Notice that all 76 custom rules have been migrated, as shown in the following figure.



Alternatively, you can select the **Convert Snort 2 rules and download** in the previous step to save the rules file locally. You can review the converted rules in the downloaded file and later upload them using the **Upload Snort 3 rules** option.

Step 6 Click the **Download Summary Details** link to download the rules in .txt format.

The following is a sample of the summary that is displayed.

```
  "id": "00505691-15DC-0ed3-0000-004294988561",

  "type": "Threshold",
  "status": "ERROR",
  "description": "PSNG_TCP_FILTERED_DECOY_PORTSCAN"
},
{
  "id": "122:15",
  "type": "Threshold",
  "status": "ERROR",
  "description": "PSNG_IP_PORTSWEEP_FILTERED"
 },
{
  "id": "122:1",
  "type": "Threshold",
  "status": "ERROR",
  "description": "PSNG_TCP_PORTSCAN"
},
```

Step 7 Click **Close** to close the **Sync Summary** dialog box.

Step 8 To check the rules with status: ERROR, choose **Policies** > **Intrusion** and click the **Snort 2** version of the intrusion policy.

Step 9 Under **Policy Information**, click **Rules** and filter for the rule. For example, enter **PSNG_TCP_PORTSCAN** in the **Filter**field to find the rule.

Step 10 Click **Show Details** to view the detailed version of the rule.

Step 11 Create the rule again in Snort 3 using Snort 3 rule guidelines and save the file as a .txt or .rules file. For more information, see www.snort3.org.

Step 12 Upload the custom rule that you just created locally to the list of all the Snort 3 rules. See Add Custom Rules to Rule Groups.

What to do next

Deploy configuration changes. See Deploy Configuration Changes, on page 2055.

Deploy Configuration Changes

After you change configurations, deploy them to the affected devices.

Note This topic covers the basic steps involved in deploying configuration changes. We *strongly* recommend that you refer the *Deploy Configuration Changes* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide* to understand the prerequisites and implications of deploying the changes before proceeding with the steps.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic.

Procedure

Step 1 On the Secure Firewall Management Center menu bar, click **Deploy** and choose **Deployment**.

The GUI page lists the devices with out-of-date configurations having **Pending**status.

- The **Modified By** column lists the users who have modified the policies or objects. Expand the device listing to view the users who have modified the policies for each policy listing.

  Note
  Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption might occur in the device during deployment.

  If this column is blank for a device, it indicates that there will be no traffic inspection interruptions on that device during deployment.

- The **Last Modified Time** column specifies the last time you made configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment.

Step 2 Identify and choose the devices on which you want to deploy configuration changes.

- Search—Search for the device name, type, domain, group, or status in the search box.
- Expand—Click **Expand Arrow** (>) to view device-specific configuration changes to be deployed.

  When you check a check box adjacent to a device, all the changes made to the device and listed under the device, are pushed for deployment. However, you can use **Policy selection** ( ) to select individual policies or specific configurations to deploy while withholding the remaining changes without deploying them.

  Note
  - When the status in the **Inspect Interruption** column indicates (**Yes**) that deploying will interrupt inspection, and perhaps traffic, on a Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).
  - When there are changes to interface groups, security zones, or objects, the impacted devices are shown as out-of-date on the Firewall Management Center. To ensure that these changes take effect, the policies with these interface groups, security zones, or objects, also need to be deployed along with these changes. The impacted policies are shown as out-of-date on the **Preview**page on the Firewall Management Center.

Step 3 Click **Deploy**.

Step 4 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

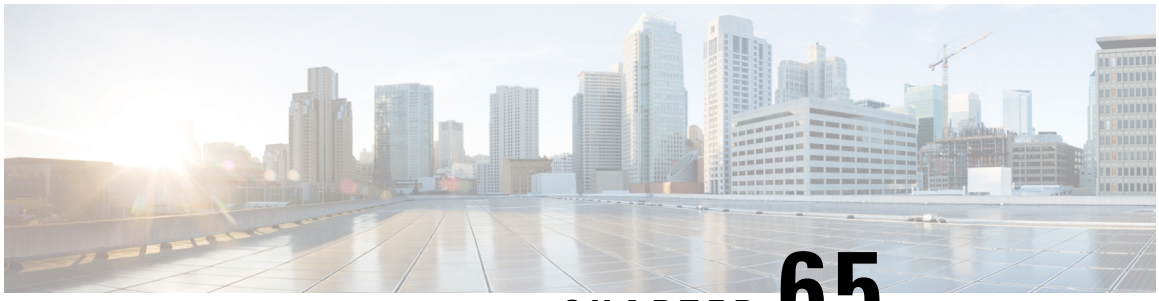
You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. You cannot proceed if the system identifies errors.

- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

What to do next

During deployment, if there is a deployment failure, there is a possibility that the failure may impact traffic. However, it depends on certain conditions. If there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For details, see the Deploy Configuration Changes topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.



CHAPTER 65

Use Case - Generate Snort 3 Recommendations In Secure Firewall Management Center

- Snort 3 Rule Recommendations, on page 2171
- Benefits, on page 2172
- Sample Business Scenario, on page 2172
- Best Practices, on page 2172
- Prerequisites, on page 2172
- Generate Snort 3 Recommendations, on page 2172
- Deploy Configuration Changes, on page 2175

Snort 3 Rule Recommendations

Rule recommendations automatically tune your intrusion policy with rules that are specific to the host environment. You can enable additional rules or tune the current rule set by disabling rules for the vulnerabilities that are not present in your network. For more information, see Overview of Secure Firewall Recommended Rules, on page 2093.

How does it work?

The management center builds a database of hosts on your network with details such as the IP address, hostname, operating system, services, users, and client applications through passive discovery. Based on this information, the system maps vulnerabilities to each discovered host. The Recommendations feature uses this host database to determine the rules that apply to your environment.

In Snort 3, there are four security levels, each corresponding to a specific Talos policy. They are:

- Level 1–Connectivity Over Security
- Level 2–Balanced Security and Connectivity
- Level 3–Security Over Connectivity
- Level 4–Maximum Detection

Check the **Accept Recommendations to Disable Rules** check box to disable rules for vulnerabilities not found on the hosts in your network. Check this option only if you have to trim your rule set because of a high number of alerts, or to improve inspection performance.

Benefits

- By configuring recommendations, you can tailor your intrusion policy to detect specific types of threats more effectively using rules that are specific to the host environment.
- Recommendations contribute to a more efficient and effective incident response process by reducing false positives and false negatives.

Sample Business Scenario

A large corporate network uses Snort 3 as its primary intrusion detection and prevention system. In a rapidly evolving threat landscape, robust network security measures must be adopted. The security team wants to enhance their incident response capabilities. One of the ways to do that is to generate recommendations or rule sets based on the vulnerabilites detected in the host network. This helps to optimize their intrusion policies, thereby safeguarding the network more effectively.

Best Practices

- You must have quality accurate host data.

  Because of the passive nature of Network Discovery, your threat defense devices must be positioned as close as possible to your protected hosts. This allows the threat defense devices to watch network traffic to and from these hosts, giving you an accurate data about applications, services, and vulnerabilities present on your network.
- Devices should have visibility to East-West as well as North-South traffic flows to build an accurate host profile.
- You can create a scheduled task to update recommendations automatically.

Prerequisites

- Ensure that hosts are present in the system to generate recommendations.
- Protected networks configured for recommendations should map to the hosts present in the system.

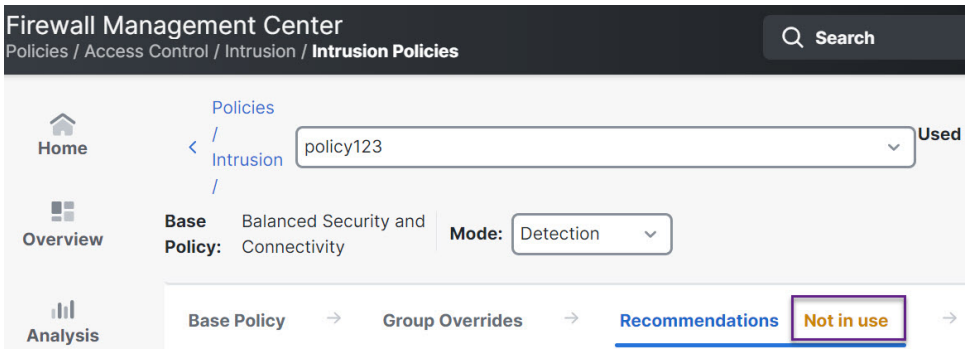
Generate Snort 3 Recommendations

Procedure

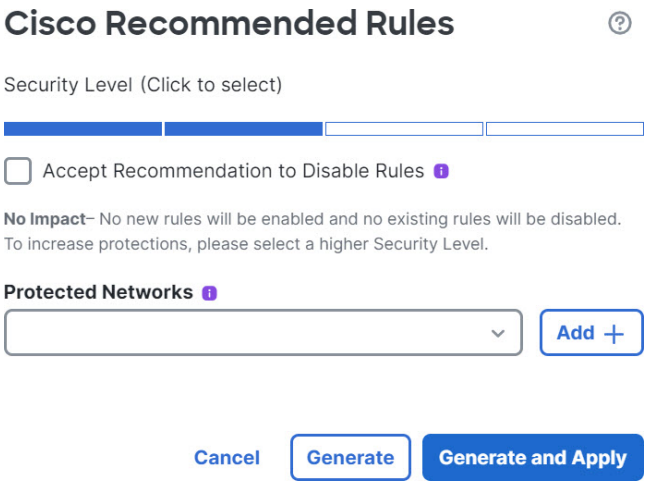
Step 1 Choose **Policies** > **Intrusion**.

Step 2 Click the **Snort 3 Version** button of the corresponding intrusion policy.

Step 3 Click the **Recommendations (Not in Use)** layer to configure the rule recommendations.



In the **Cisco Recommended Rules** window, you can set the security level.



Step 4 Click to select the security level.

Step 5 (Optional) Check the **Accept Recommendation to Disable Rules** check box to disable the rules written for vulnerabilities not found on the hosts in your network.

Use this option, only if you have to trim your rule set because of a high number of alerts or to improve inspection performance.

Step 6 From the **Protected Networks** drop-down list, choose the network objects that must be examined by the recommendations. By default, any IPv4 or IPv6 networks are selected if you do not make a selection.

Click **Add +** to create a new network object of type **Host** or **Network** and click **Save**.

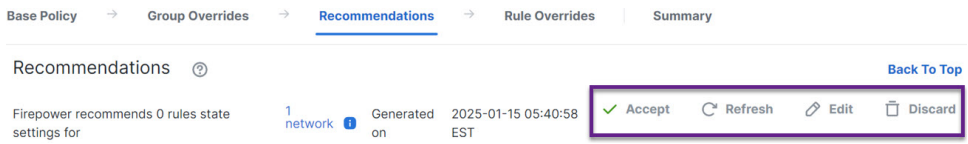
Step 7 Generate and apply recommendations:

- **Generate**—Generates the recommendations for an intrusion policy. This action lists the rules under **Recommended Rules (Not in use)**.
- **Generate and Apply**—Generates and applies the recommendations for an intrusion policy. This action lists the rules under **Recommended Rules (Not in use)**.

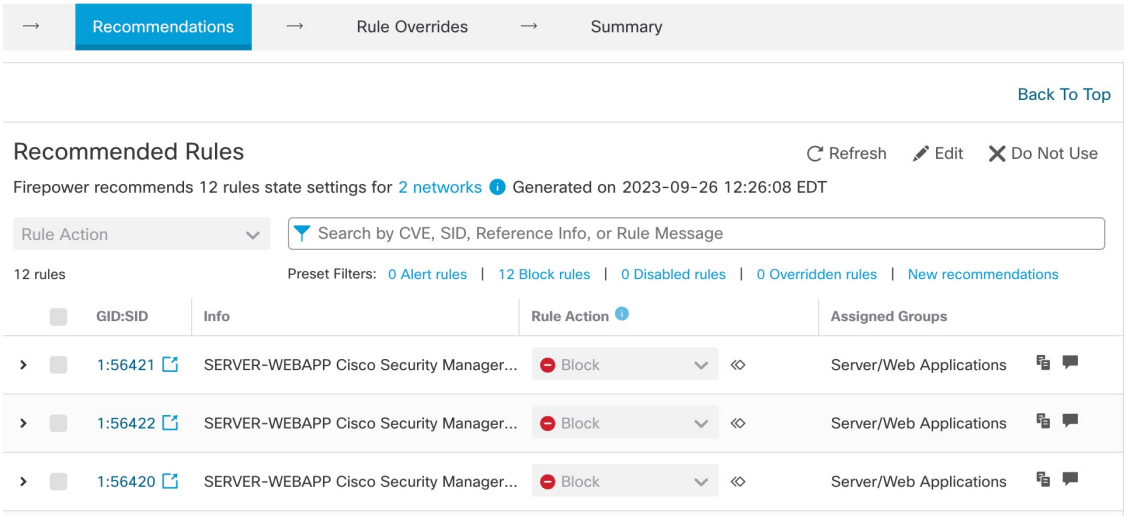
Recommendations are generated successfully. A new recommendation tab appears with all the recommended rules and their corresponding recommended actions. Rule action preset filters are also available for this tab, in addition to new recommendations.

Step 8 Verify the recommendations and then apply them accordingly:

- **Accept**—Applies the previously generated recommendations for an intrusion policy.
- **Refresh**—Regenerates and updates the rule recommendations for an intrusion policy.
- **Edit**—Opens the **Recommendations** dialog box where you can provide the recommendation input values and then generate the recommendations.
- **Discard**—Either reverts or removes the applied recommended rules from the policy; also removes the **Recommendations** tab.



Under **All Rules**, the Recommended Rules section displays the recommended rules.



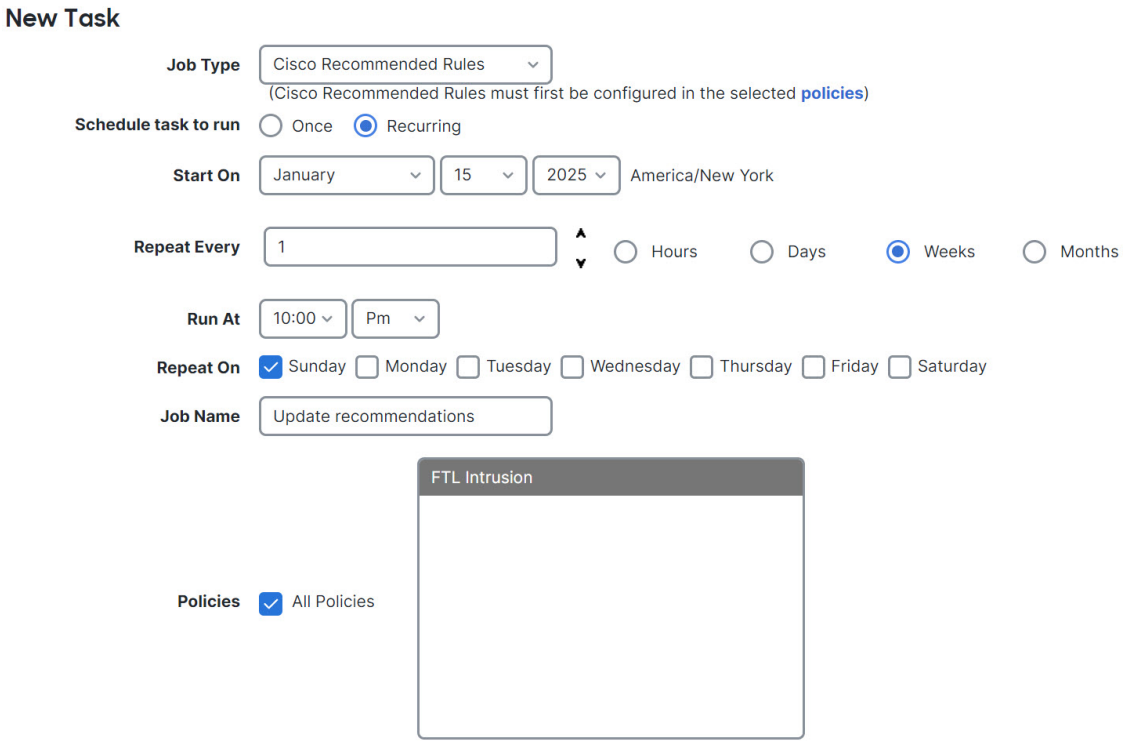
Step 9 To effectively use recommendations, they must be updated periodically. Follow these steps:

a. Choose **System** (⚙) > **Tools** > **Scheduling**.

b. Click **Add Task**.

c. Choose **Cisco Recommended Rules** from the **Job Type** drop-down list.

d. Update the required fields, as needed.



e. Click **Save**.

What to do next

Deploy configuration changes. See Deploy Configuration Changes, on page 2055.

Deploy Configuration Changes

After you change configurations, deploy them to the affected devices.

Note This topic covers the basic steps involved in deploying configuration changes. We *strongly* recommend that you refer the *Deploy Configuration Changes* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide* to understand the prerequisites and implications of deploying the changes before proceeding with the steps.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic.

Procedure

Step 1 On the Secure Firewall Management Center menu bar, click **Deploy** and choose **Deployment**.

The GUI page lists the devices with out-of-date configurations having **Pending**status.

- The **Modified By** column lists the users who have modified the policies or objects. Expand the device listing to view the users who have modified the policies for each policy listing.

  Note
  Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption might occur in the device during deployment.

  If this column is blank for a device, it indicates that there will be no traffic inspection interruptions on that device during deployment.

- The **Last Modified Time** column specifies the last time you made configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment.

Step 2 Identify and choose the devices on which you want to deploy configuration changes.

- Search—Search for the device name, type, domain, group, or status in the search box.
- Expand—Click **Expand Arrow** (>) to view device-specific configuration changes to be deployed.

  When you check a check box adjacent to a device, all the changes made to the device and listed under the device, are pushed for deployment. However, you can use **Policy selection** ( ) to select individual policies or specific configurations to deploy while withholding the remaining changes without deploying them.

  Note
  - When the status in the **Inspect Interruption** column indicates (**Yes**) that deploying will interrupt inspection, and perhaps traffic, on a Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).
  - When there are changes to interface groups, security zones, or objects, the impacted devices are shown as out-of-date on the Firewall Management Center. To ensure that these changes take effect, the policies with these interface groups, security zones, or objects, also need to be deployed along with these changes. The impacted policies are shown as out-of-date on the **Preview**page on the Firewall Management Center.

Step 3 Click **Deploy**.

Step 4 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

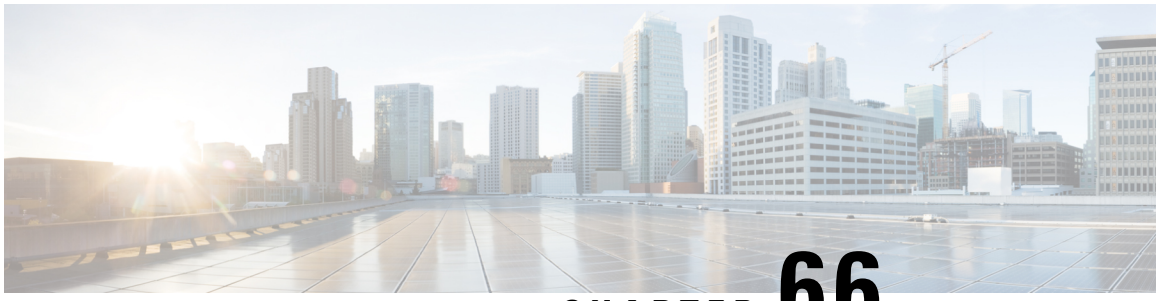
You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. You cannot proceed if the system identifies errors.

- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

What to do next

During deployment, if there is a deployment failure, there is a possibility that the failure may impact traffic. However, it depends on certain conditions. If there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For details, see the Deploy Configuration Changes topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.



CHAPTER 66

Use Case - Block Traffic Based on the EVE Threat Confidence Score

- About Encrypted Visibility Engine, on page 2179
- Benefits, on page 2179
- Sample Business Scenario, on page 2179
- Prerequisites, on page 2180
- High-Level Workflow, on page 2180
- Configure Block Thresholds in EVE, on page 2180
- Additional References, on page 2185

About Encrypted Visibility Engine

You can use the Encrypted Visibility Engine (EVE) to identify client applications and processes using Transport Layer Security (TLS) encryption. EVE provides more visibility into the encrypted sessions without decryption. Based on EVE's findings, administrators can enforce policy actions on the traffic within their environments. You can also use the EVE to identify and stop malware.

Benefits

Administrators can leverage and adjust EVE's threat score to block malicious encrypted traffic. If the probability that the incoming traffic is malicious, then based on the threat score, you can configure EVE to block the connection.

Sample Business Scenario

A large corporate network uses Snort 3 as its primary intrusion detection and prevention system. In a rapidly evolving threat landscape, adoption of robust network security measures is necessary and important. The security team uses EVE to enhance encrypted traffic inspection without the need to implement full man-in-the-middle (MITM) decryption. The EVE technology uses fingerprints of known malicious processes to identify and stop malware. Network administrators must have the flexibility to configure EVE's block traffic thresholds to block potentially malicious connections, which are based on their configured block thresholds.

Prerequisites

- You must be running management center 7.4.0 or later, and the managed threat defense must also be 7.4.0 or later.
- Ensure that you have a valid Intrusion Prevention System (IPS) license and Snort 3 is the detection engine.

High-Level Workflow

1. EVE analyzes the incoming traffic and gives a verdict on the probability of incoming traffic being malware or not.
2. If EVE detects incoming traffic to be malware with a certain level of confidence, you can configure EVE to block that traffic.
3. The packets are first checked for malware probability or threat score, and the threat score is compared with the block threshold that you have set.
4. If the threat score is higher than the configured threshold, EVE blocks the traffic.
5. If the threat score is lesser than the configured threshold, EVE takes no action.

Configure Block Thresholds in EVE

This procedure shows how to block potentially malicious traffic, based on the EVE threat confidence score of 90 percent or higher.

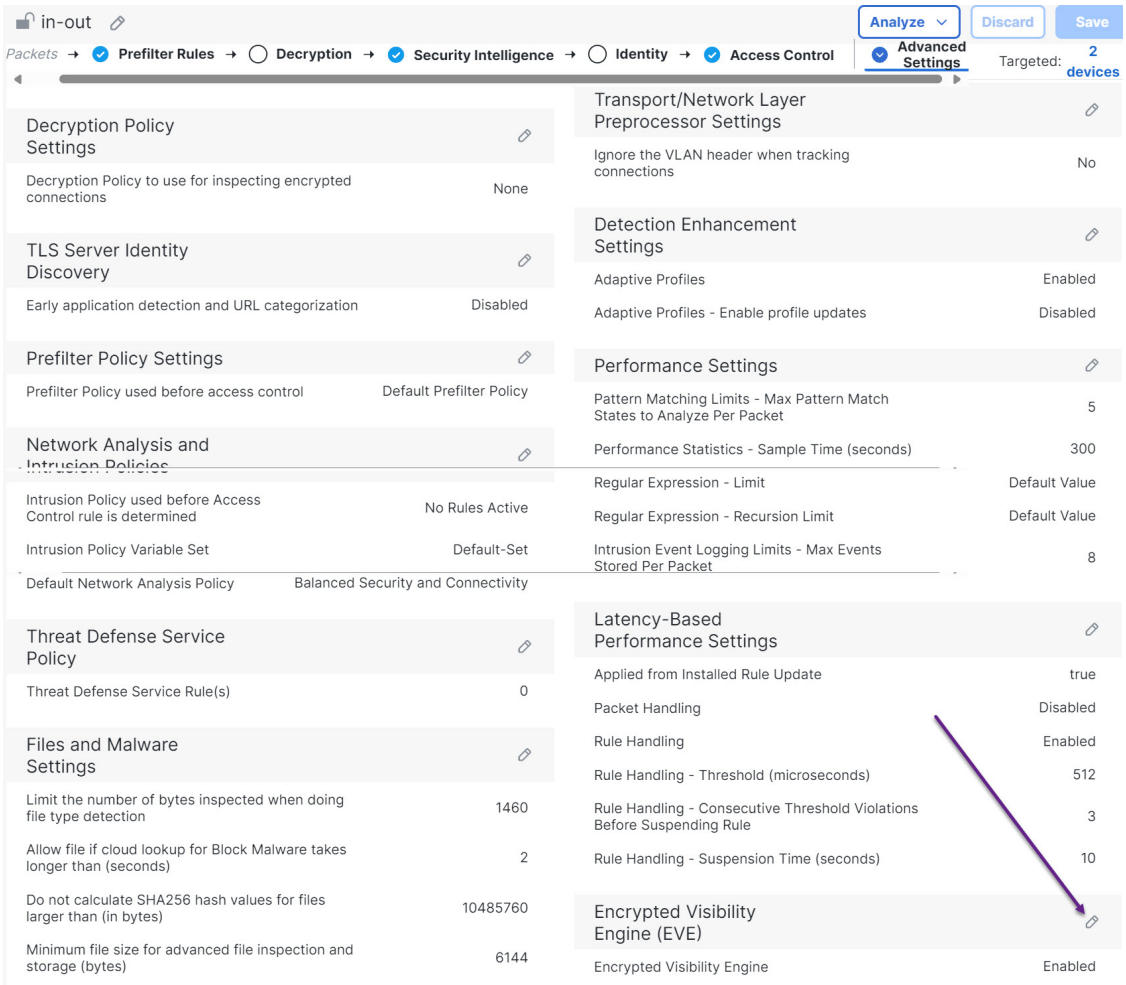
Procedure

Step 1 Choose **Policies** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy you want to edit.

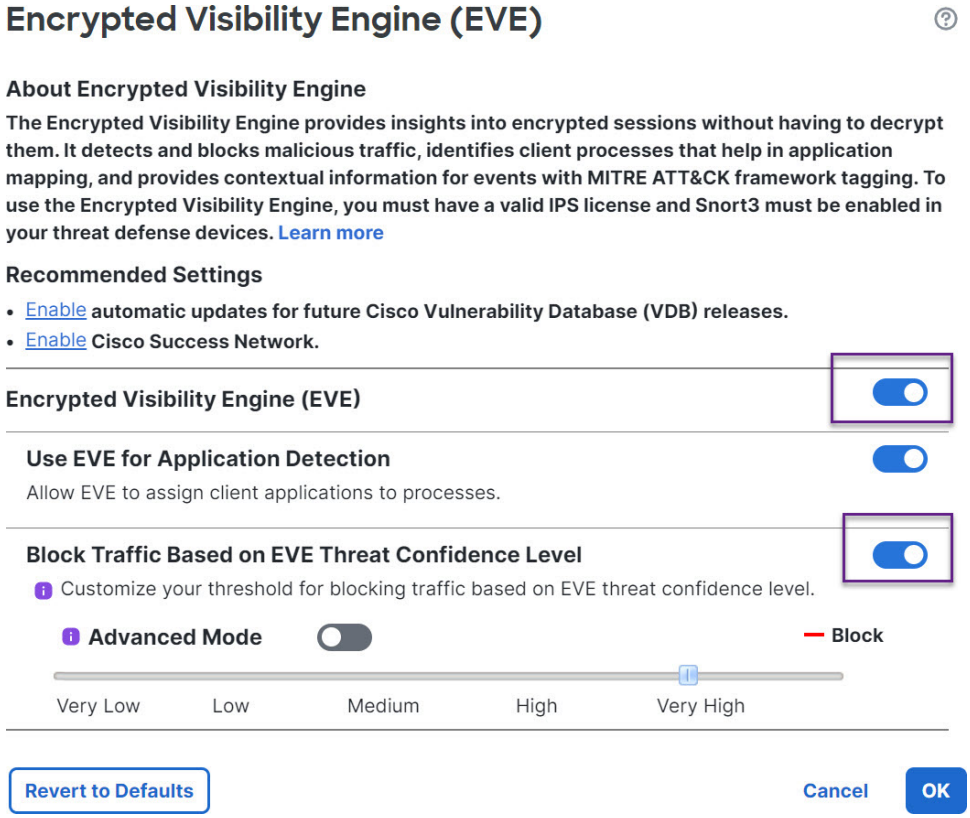
Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Encrypted Visibility Engine**.



Step 5 In the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.

Step 6 Enable the **Block Traffic Based on EVE Score** toggle button. Any incoming traffic that is a potential threat is blocked by default.

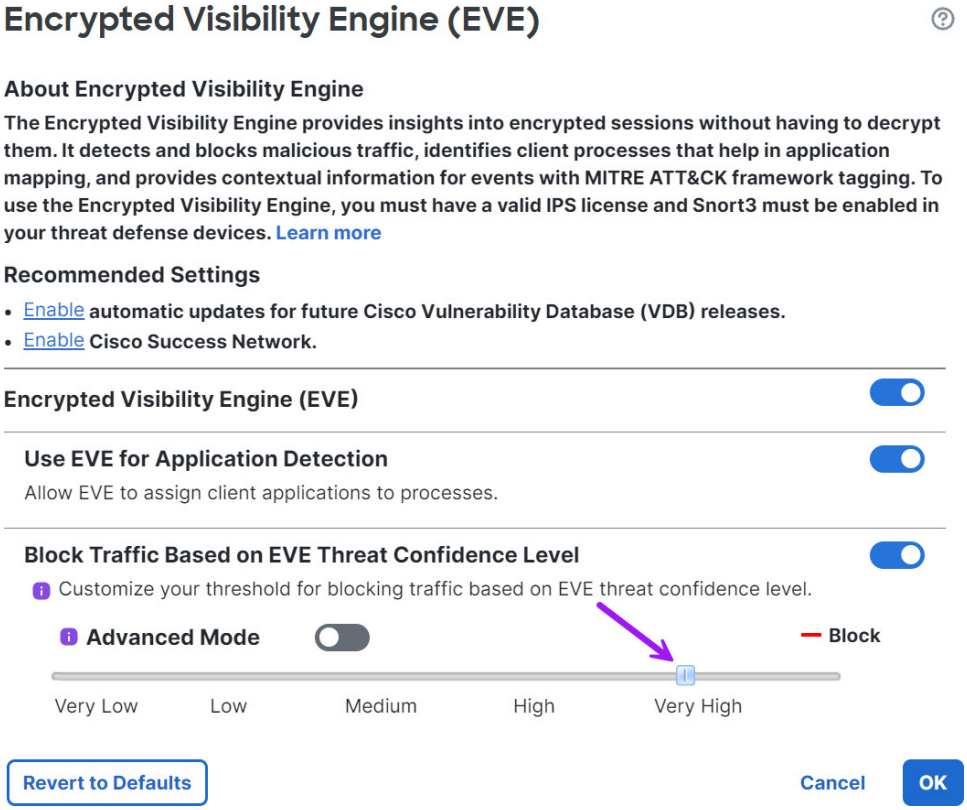


Note

By default, the threshold at which malware is blocked is 99 percent, which means:

- If EVE detects the traffic to be malware with 99 percent confidence or higher, EVE blocks the traffic.
- If EVE detects the traffic to be malware with less than 99 percent confidence, EVE takes no action.

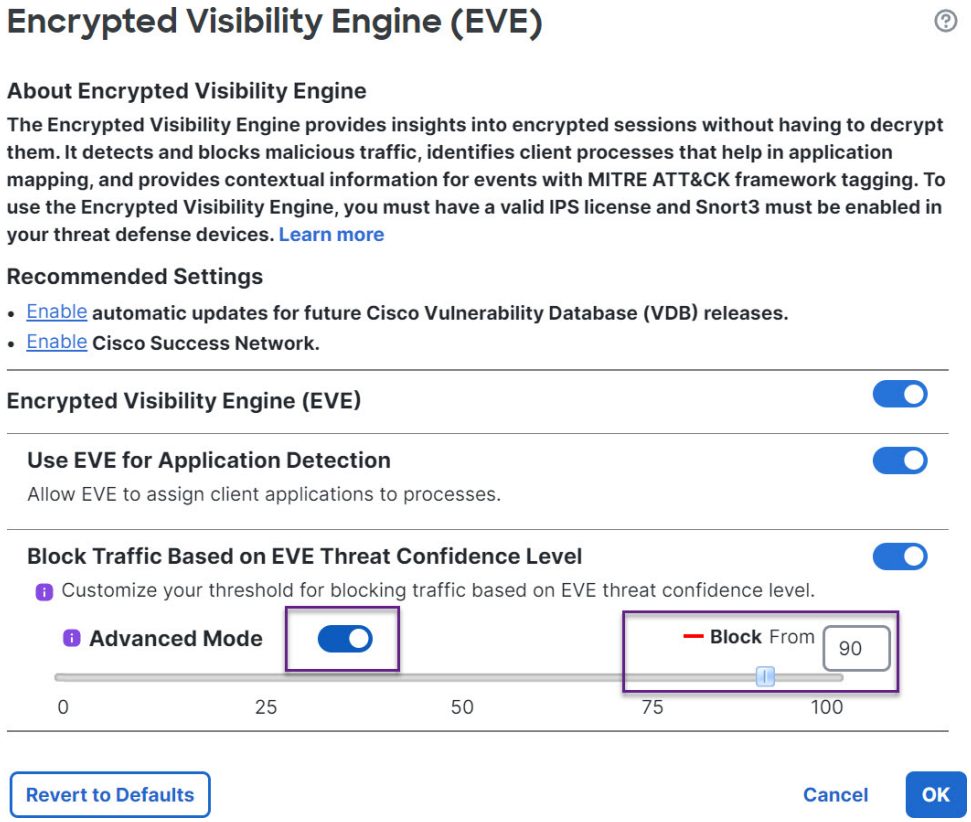
Step 7 Use the slider to adjust the threshold for blocking based on EVE threat confidence. This ranges from **Very Low** to **Very High**. In this example, the slider is set to **Very High**.



Step 8 For further granular control, enable the **Advanced Mode** toggle button. Now, you can assign a specific EVE Threat Confidence Score for blocking traffic. The default threshold is 99 percent.

Step 9 In this example, change the block threshold to **90** percent.

Attention
As a best practice, we recommend that you do not set the block threshold to below 50 percent to ensure optimum performance.



Step 10 Click **OK**.

Step 11 Click **Save**.

What to do next

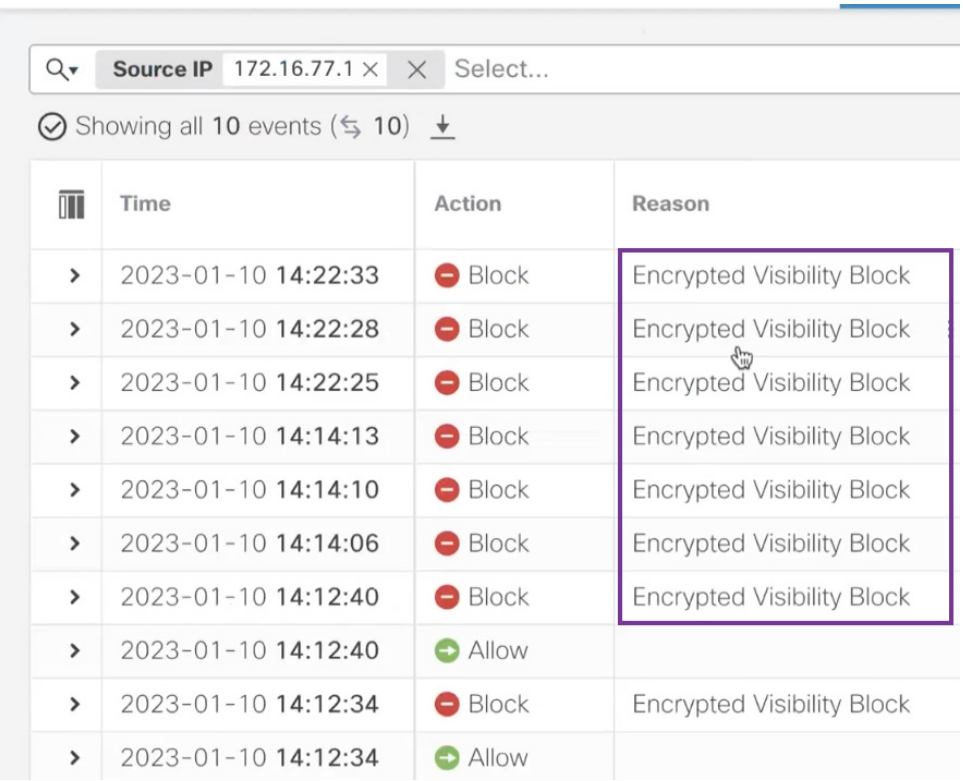
Deploy configuration changes. See Deploy Configuration Changes, on page 2055.

View EVE Events

Procedure

Step 1 To verify the block action, choose **Analysis** > **Connections**. You can also view the events from the **Unified Events** viewer.

Step 2 If you have configured EVE to block traffic, the **Reason** field shows **Encrypted Visibility Block**.



Step 3 The following is an example of the **Encrypted Visibility Process Name** as **test_malware**, **Encrypted Visibility Threat Confidence** as **Very High**, and **Encrypted Visibility Threat Confidence Score** as **90** percent.

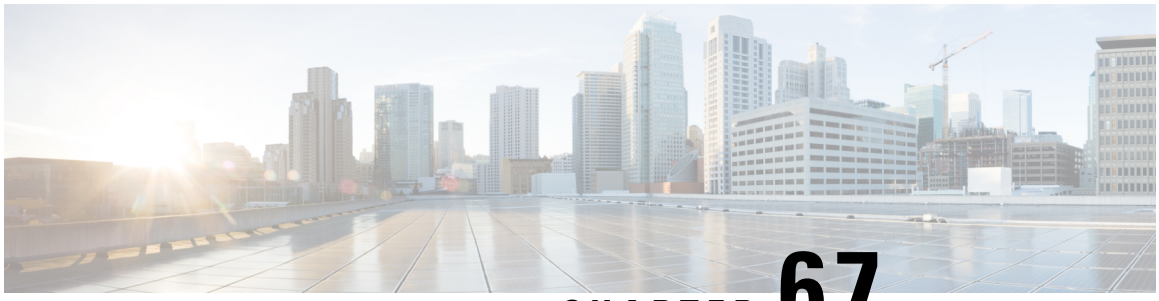
For detailed conceptual information, see the Encrypted Visibility Engine for Snort 3 chapter in this guide or the content in the following link:

Encrypted Visibility Engine



CHAPTER 67

Use Case - Configure Elephant Flow Detection Outcomes

- About Elephant Flows, on page 2187
- Benefits of Elephant Flow Detection and Remediation, on page 2187
- Elephant Flow Workflow, on page 2188
- Sample Business Scenario, on page 2188
- Prerequisites, on page 2189
- Configure Elephant Flow Parameters, on page 2189
- Configure Elephant Flow Remediation Exemption, on page 2193
- Additional References, on page 2196

About Elephant Flows

Elephant flows are extremely large (in total bytes), relative long-running network connections set up by a TCP (or other protocols) flow measured over a network link. By default, elephant flows are flows or connections that are larger than 1 GB per 10 seconds. They can cause performance duress or issues in Snort cores. Elephant flows are important because they can potentially consume an excessive amount of CPU resources and impact other competing flows for detection resources and cause issues, such as increased latency or packet drops.

Benefits of Elephant Flow Detection and Remediation

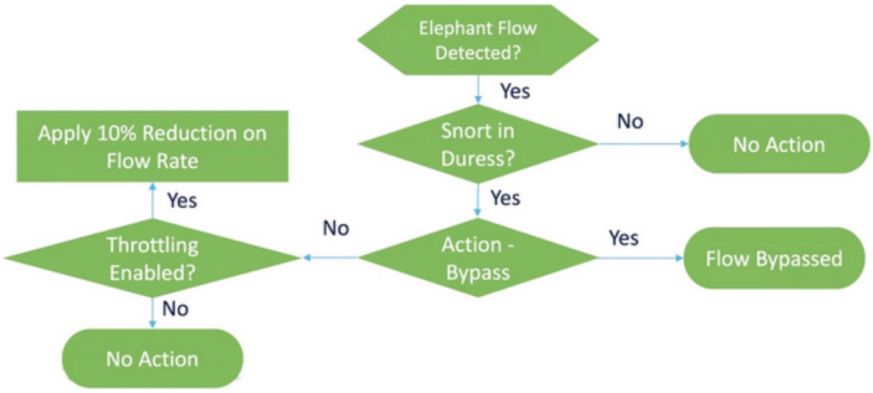
- Elephant flow configuration allows customization and the option to bypass or even throttle elephant flows.
- You can choose to bypass or throttle flows that are based on your chosen applications to provide Snort inspection of suspect traffic, while bypassing more trusted traffic.
- Elephant flow remediation helps prioritize and free up more bandwidth for your internal applications, depending on your specific requirements.

Elephant Flow Workflow

When an elephant flow is detected based on your configured parameters, you can choose to bypass or throttle the flow. When a flow is bypassed, the traffic is allowed to pass without Snort inspection. Throttling indicates that the flow throughput is reduced. The reduction on flow rate is done in 10 percent increments until the CPU utilization reduces to below the configured threshold. Bypassing or throttling happens after identifying the elephant flow and meeting the additional CPU and time window parameters. Prior to identification of the elephant flow, your intrusion policy processes the flow, assuming that you have configured this in an Allow rule. This means that elephant flows are not allowed to pass through the system completely uninspected because most of the attacks are detected very early in a connection.

To understand how flows are handled, see the following flow diagram.

Figure 449: Elephant Flow Workflow



No action is taken unless the system detects a Snort duress condition (performance issue). The system does not throttle or bypass a flow just because it is large. Also, the actions of throttle and bypass are mutually exclusive. This means that you can either bypass or throttle a flow, but not both.

If you do not want to bypass all the elephant flows causing duress, you can limit the bypass option to specific applications only. You can prioritize connectivity for the applications that you trust, without throttling performance. You can configure the applications that must be bypassed, but the remaining flows (causing duress) are throttled. This ensures that the other nontrusted application flows still receive full Snort inspection although their bandwidth is reduced.

Sample Business Scenario

In a data center, several activities are happening, such as replication of data between clusters, virtual machine integration, and database backup. Users in an organization could be watching videos on an OTT or downloading them. Bandwidth utilization for such activities might result in elephant flows, slow down the network, and impact the performance of important tasks. As a network administrator (and depending on your specific requirements), you want visibility into such large flows that are causing bandwidth issues and remediate them.

As an example, let us see how you can configure elephant flow parameters to bypass Snort inspection for WebEx traffic (which your organization uses for real-time video conferencing) and throttle the remaining applications or connections, including videos, movies, and so on.

Prerequisites

- Ensure that you are running management center 7.2.0 or later and that the managed threat defense is also 7.2.0 or later.
- Only enabling elephant flow detection does not generate additional connection events. Elephant flow detection adds the Elephant Flow notation to matching connections that are already being logged to the management center. **To log these events, you must enable connection logging in your access control policy.** You can do that for specific rules or add a Monitor rule that logs all connections, including elephant flows.

Configure Elephant Flow Parameters

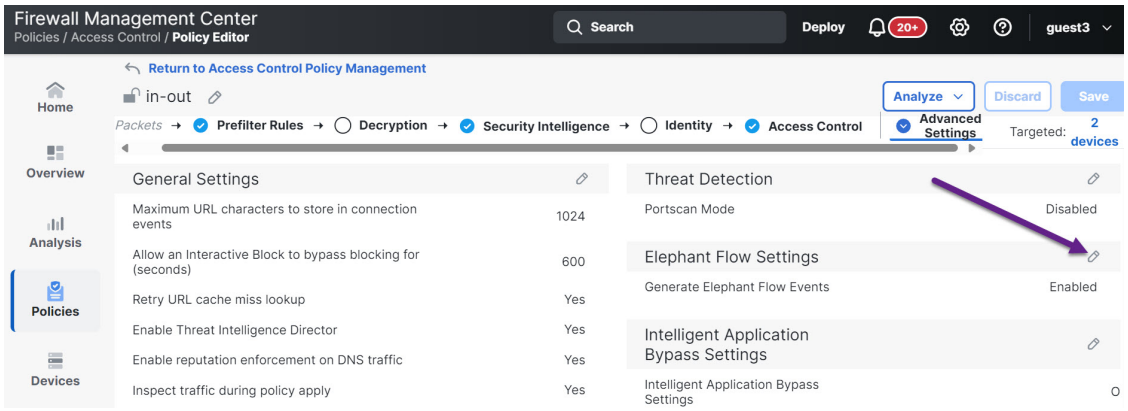
Procedure

Step 1 Choose **Policies** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy that you want to edit.

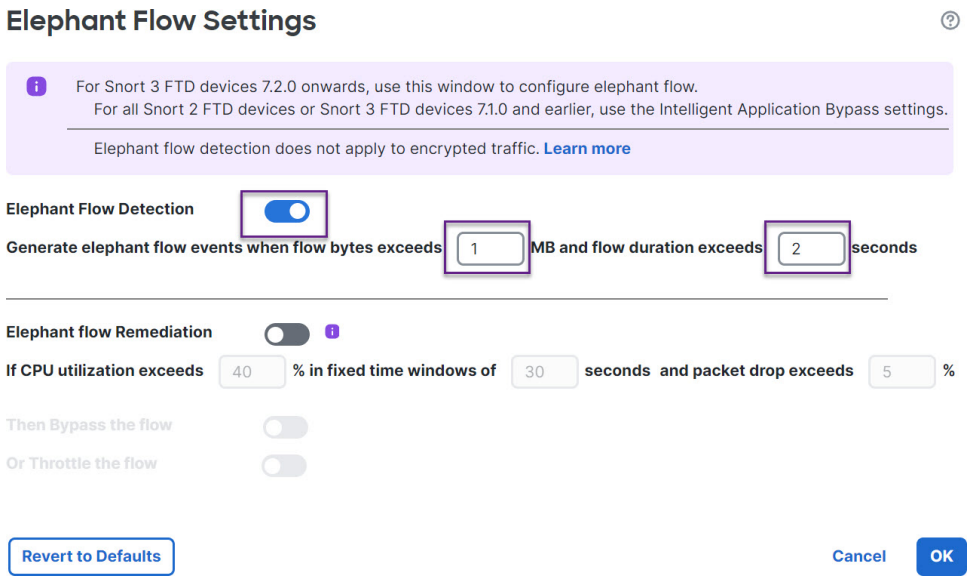
Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Elephant Flow Settings**.



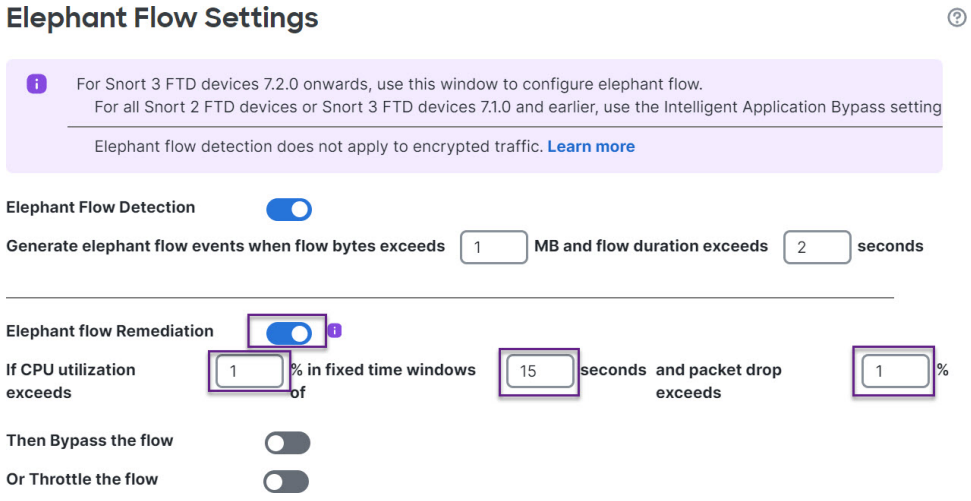
Step 5 The **Elephant Flow Detection** toggle button is enabled by default. The default setting enables detection only and no default action is configured. The detection settings allow you to adjust the flow bytes and duration so that you can identify the elephant flows in your system.

As a test setting, configure the flow bytes and duration parameters, as shown in the following figure.

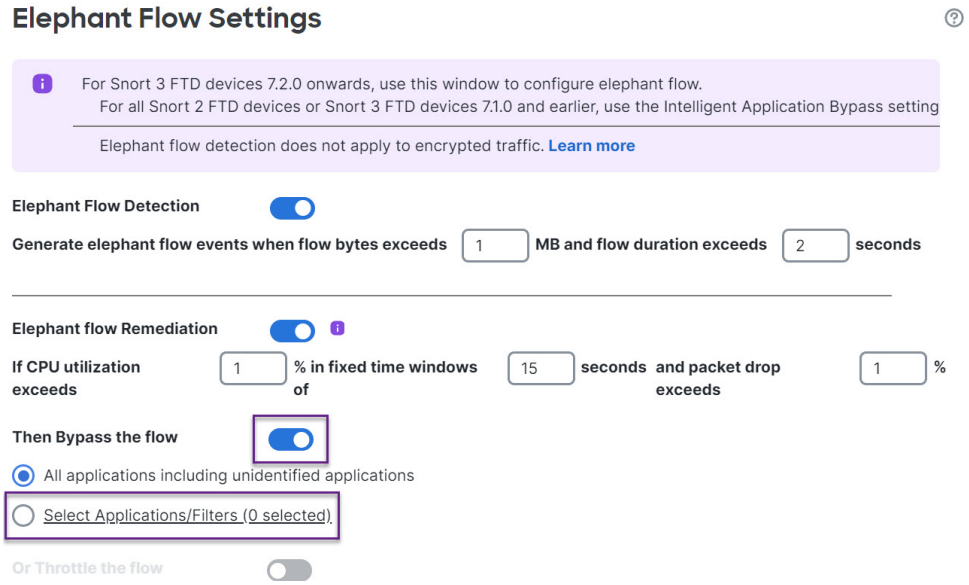


Step 6 Enable the **Elephant Flow Remediation** toggle button. When an elephant flow is detected, you can choose to bypass or throttle the flow. Bypassing a flow means that the traffic is allowed to pass without Snort inspection. Throttling indicates that the flow throughput is reduced. This rate reduction is done in 10 percent increments until the CPU utilization reduces to lesser than the configured threshold.

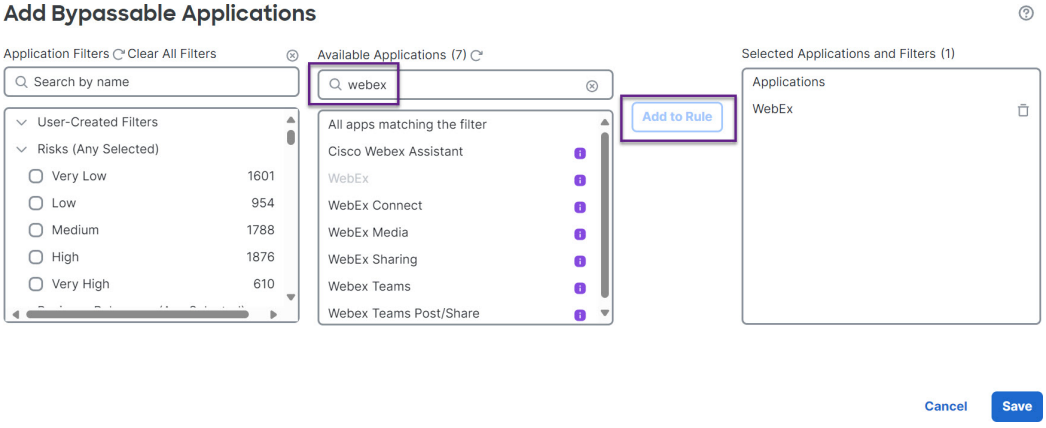
As a test setting, configure the elephant flow remediation parameters as shown in the following figure.



Step 7 Enable the **Bypass the flow** toggle button and click the **Select Applications/Filters** radio button.



Step 8 Under **Application Filters**, search for and select the **WebEx** application, add it to the rule, and click **Save**. This means that WebEx connections are trusted and prioritized and will skip Snort inspection if these WebEx connections are detected as elephant flows, based on the configured parameters.



Step 9 Enable the **Throttle** toggle button to throttle the remaining flows (causing duress). This ensures that all the other flows are slowed down in 10 percent increments until the Snort duress condition is met.

Step 10 Click **OK**.

Step 11 Click **Save**.

What to do next

Deploy configuration changes. See Deploy Configuration Changes, on page 2055.

View Events for Elephant Flows

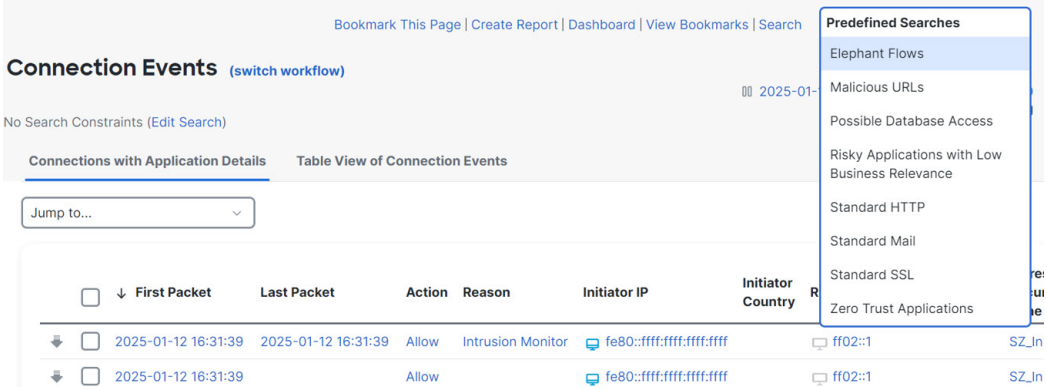
After configuring your elephant flow settings, monitor your connection events to see if any flows are detected, bypassed, or throttled. You can see this information in the **Reason** field of your connection events. The three types for elephant flow connections are:

- Elephant Flow
- Elephant Flow Throttled
- Elephant Flow Trusted

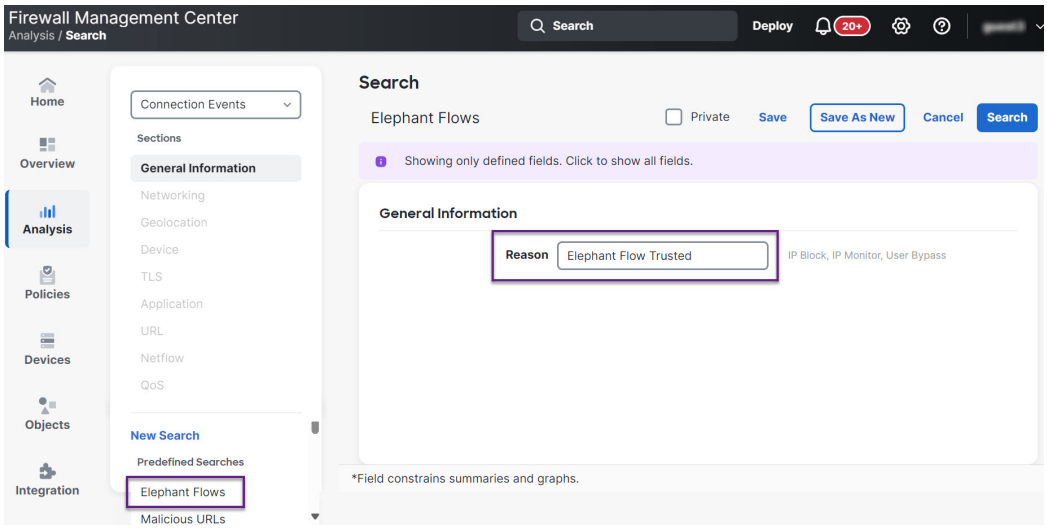
Procedure

Step 1 Choose **Analysis** > **Connections**. You can also view the events from the **Unified Events** viewer.

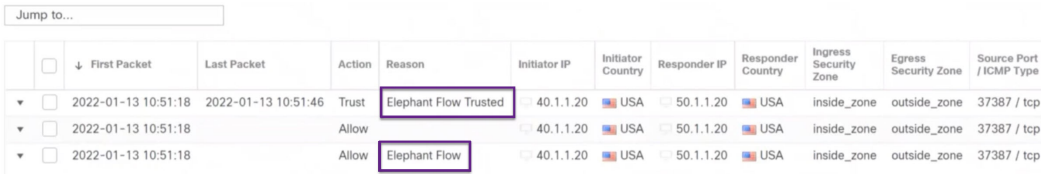
Step 2 In the **Connection Events** page, from the **Predefined Search** drop-down list, choose **Elephant Flows** to display elephant flow events.



Tip
To see **Elephant Flow Trusted** or **Elephant Flow Throttled** event types, click the **Edit Search** link on the top-left corner of the page and in the **Reason** field, choose **Elephant Flows** in the left panel. Enter **Elephant Flow Trusted** or **Elephant Flow Throttled**, depending on what you want to search.



Step 3 View the elephant flow that was detected mid-flow and the **Reason** field shows **Elephant Flow**. At the end of the flow, it was bypassed and the **Reason** field shows **Elephant Flow Trusted**.



Configure Elephant Flow Remediation Exemption

You can configure L4 access control list (ACL) rules for flows that must be exempted from remediation. If a flow is detected as an elephant flow and it matches the rules that are defined, that flow is exempted from the remediation action.

Before you begin

You must be running management center 7.4.0 or later and the managed threat defense must also be 7.4.0 or later.

Procedure

Step 1 Choose **Policies** > **Access Control**.

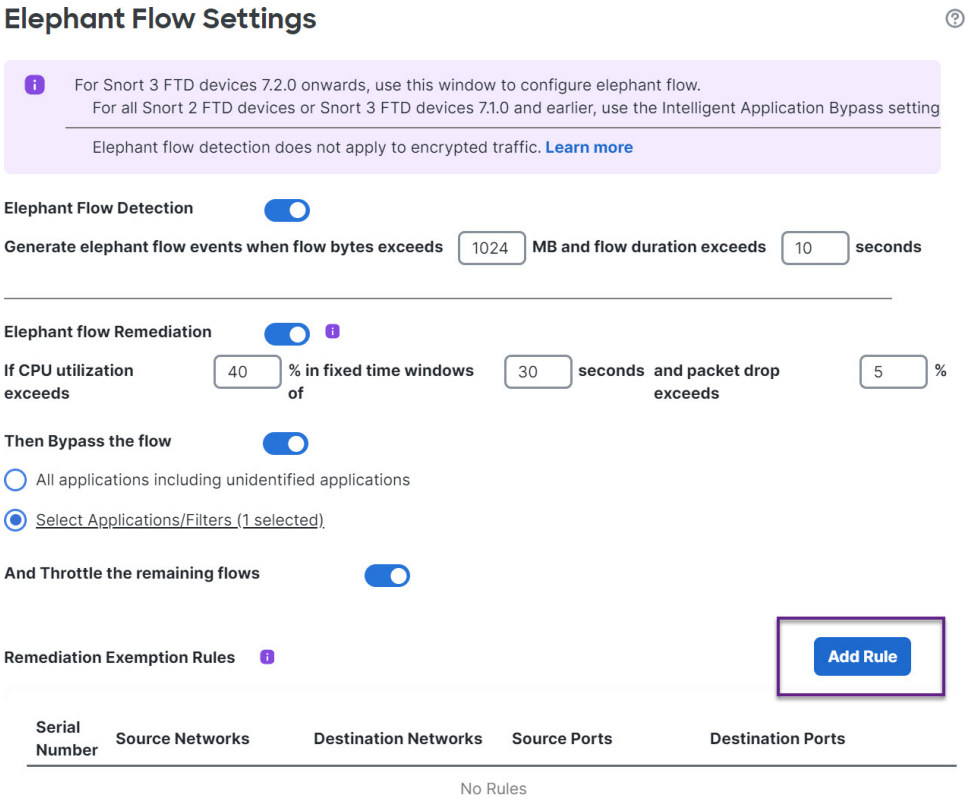
Step 2 Click **Edit** (✎) next to the access control policy you want to edit.

Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

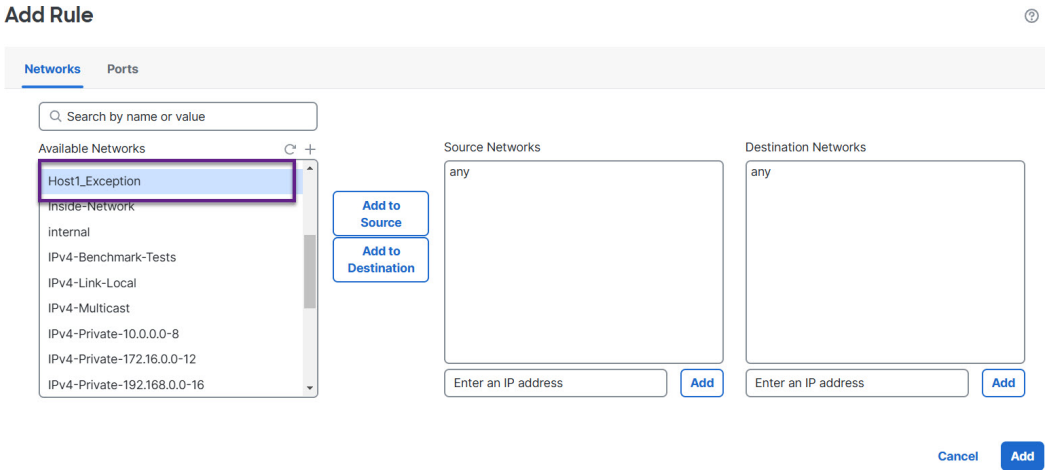
Step 4 Click **Edit** (✎) next to **Elephant Flow Settings**.

Step 5 Ensure that you have configured the elephant flow detection and remediation parameters. See Configure Elephant Flow Parameters, on page 2189.

Step 6 Click the **Add Rule** button next to **Remediation Exemption Rules**.



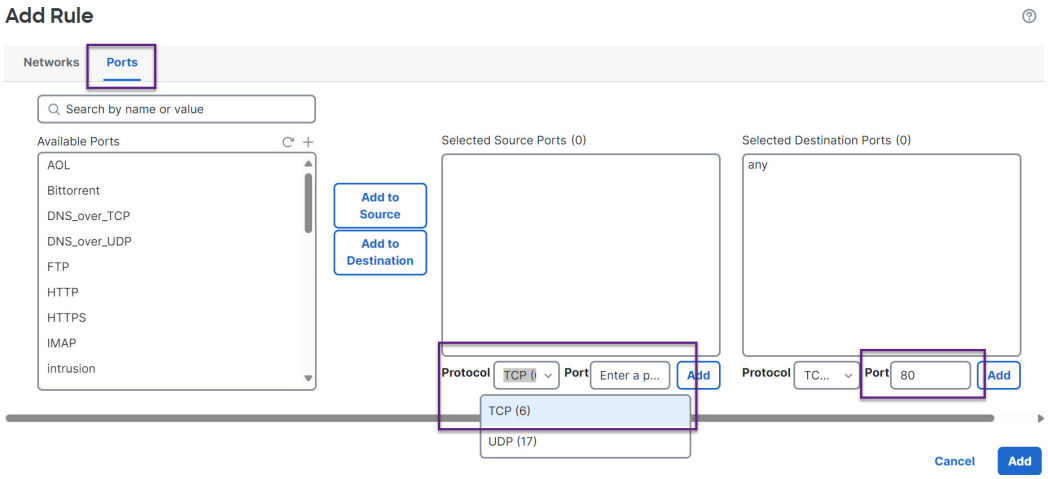
Step 7 From the list of **Available Networks**, choose the configured host to exempt from elephant flow remediation. For the purposes of this example, we have created a host called "Host1_Exception."



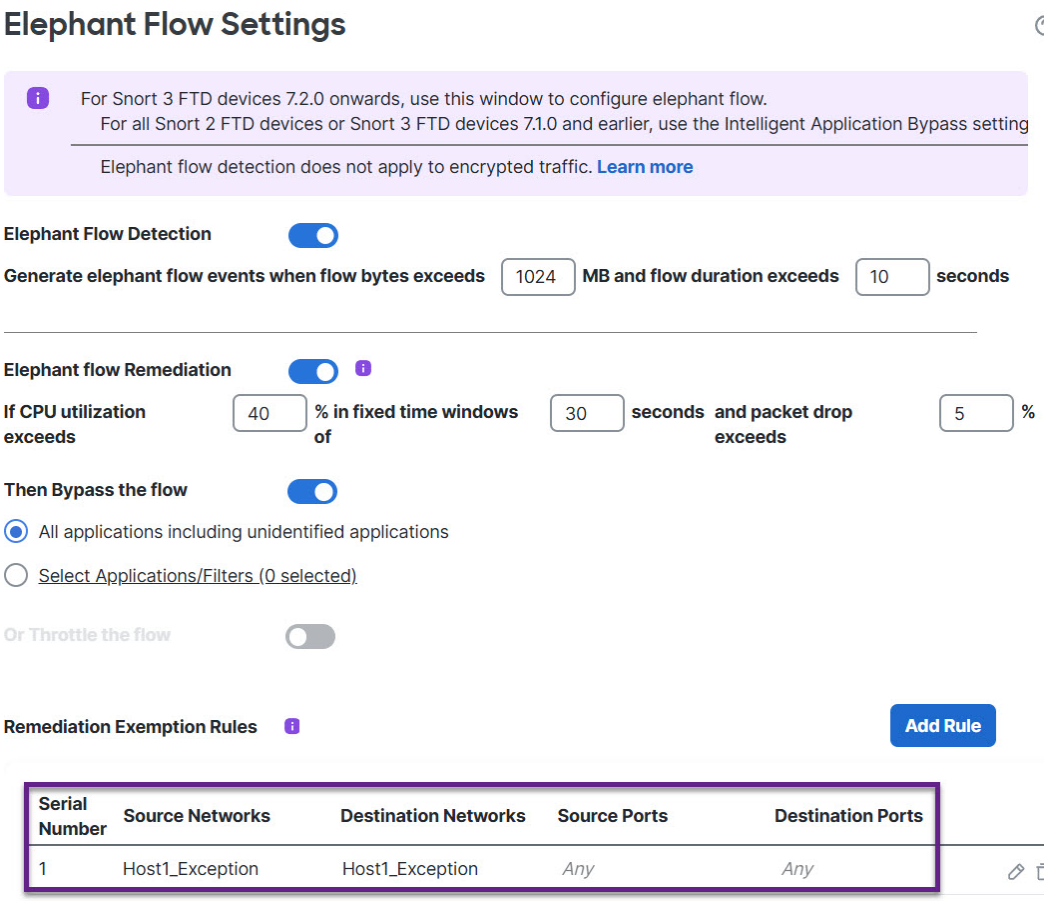
Step 8 Click **Add to Source** or **Add to Destination** (as required) to add this host to the source or destination.

Step 9 Click the **Ports** tab.

Step 10 For the source port, choose **Protocol** as TCP and enter **80** as the destination port, and click **Add**.



Step 11 Click **OK**.



Step 12 Click **Save**.

What to do next

Deploy configuration changes. See Deploy Configuration Changes, on page 2055.

View Events for Elephant Flow Remediation Exemption

Procedure

Step 1 Choose **Analysis** > **Connections**. You can also view the events from the **Unified Events** viewer.

Step 2 View the elephant flows that were exempted from remediation. The **Reason** field shows **Elephant Flow Exempted**.

CHAPTER 68

Mitigate Threats Using MITRE Framework in Snort 3 Intrusion Policies

- About MITRE ATT&CK Framework, on page 2197
- Benefits of MITRE Framework, on page 2198
- Sample Business Scenario for MITRE Network, on page 2198
- Prerequisites for MITRE Framework, on page 2198
- View and Edit Your Snort 3 Intrusion Policy, on page 2198
- View Intrusion Events, on page 2204
- Additional References, on page 2206

About MITRE ATT&CK Framework

The MITRE ATT&CK Framework is a comprehensive knowledge base that outlines the tactics, techniques, and procedures (TTPs) used by threat actors to compromise systems. It organizes these TTPs into matrices for different operating systems and platforms, mapping each attack stage (tactics) to specific methods (techniques). Each technique includes information about execution, procedures, defenses, detections, and real-world examples.

Note See https://attack.mitre.org for additional information about MITRE ATT&CK.

The management center uses the MITRE ATT&CK Framework to enhance threat detection and response, incorporating the following capabilities:

- Intrusion events include TTPs, allowing administrators to manage traffic with greater granularity by grouping rules according to vulnerability type, target system, or threat category.
- Select malware events use TTPs, enhancing the ability to detect and respond to threats.
- Unified and Classic Event Viewers display tactics, techniques, attack lifecycle graphs, and contextual enrichments from the Talos taxonomy. These enrichments include MITRE tags and a hierarchical view of associated tactics, techniques, and sub-techniques. You can also filter events using MITRE identifiers.

Benefits of MITRE Framework

- MITRE Tactics, Techniques, and Procedures (TTPs) are added to intrusion events, which enable administrators to act on traffic, based on the MITRE ATT&CK framework. This enables administrators to view and handle traffic with more granularity, and group rules by vulnerability type, target system, or threat category.
- You can organize intrusion rules according to the MITRE ATT&CK framework. This allows you to customize policies according to specific attacker tactics and techniques.

Sample Business Scenario for MITRE Network

A large corporate network uses Snort 3 as its primary intrusion detection and prevention system. In a rapidly evolving threat landscape, adoption of robust network security measures is necessary and important. Network administrators need to know if the configured policies are finding traffic of interest and if they are tracking a known attack group. For example, you may want to know if adversaries are attempting to take advantage of a weakness in your systems or applications in order to cause unanticipated behavior. The weakness in the system can be a bug, a glitch, or a design vulnerability. The applications may be websites, databases, standard services, such as Server Message Block (SMB) or Secure Shell (SSH), network device administration and management protocols or applications, such as web servers and related services.

The insights provided by the MITRE framework provides administrators with a more precise opportunity to specify protection for specific assets and protect their network from specific threat groups.

Prerequisites for MITRE Framework

- You must be running Secure Firewall Management Center and Secure Firewall Threat Defence Version 7.3.0 or later with Snort 3.
- You must have at least one intrusion policy. See Create a Custom Snort 3 Intrusion Policy , on page 2060.

View and Edit Your Snort 3 Intrusion Policy

Procedure

Step 1 Choose **Policies** > **Intrusion**.

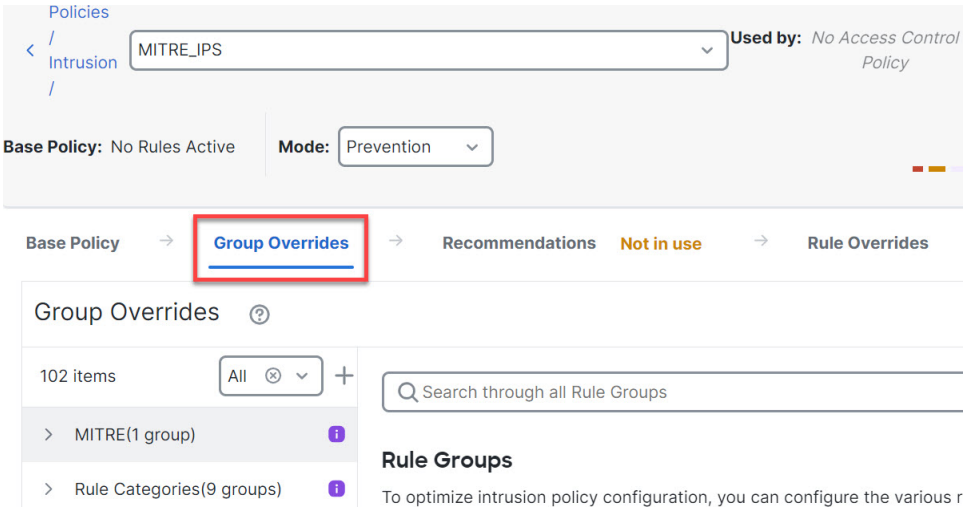
Step 2 Ensure that the **Intrusion Policies** tab is chosen.

Step 3 Click **Snort 3 Version** next to the intrusion policy that you want to view or edit.

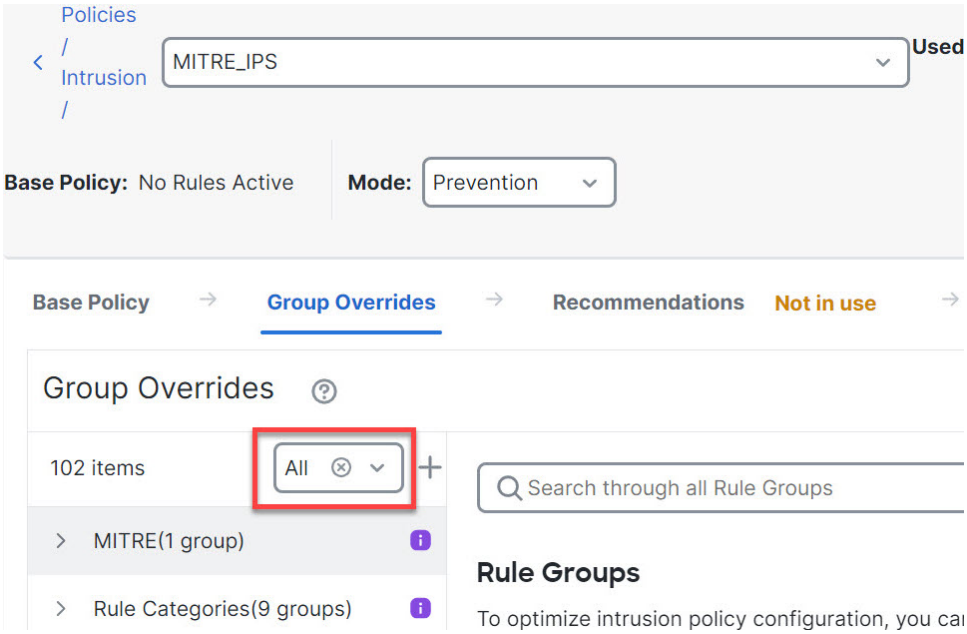
Step 4 Close the Snort helper guide that is displayed.

Step 5 Click the **Group Overrides** layer.

This layer lists all the categories of rule groups in an hierarchical structure. You can drill down to the last leaf rule group under each rule group.

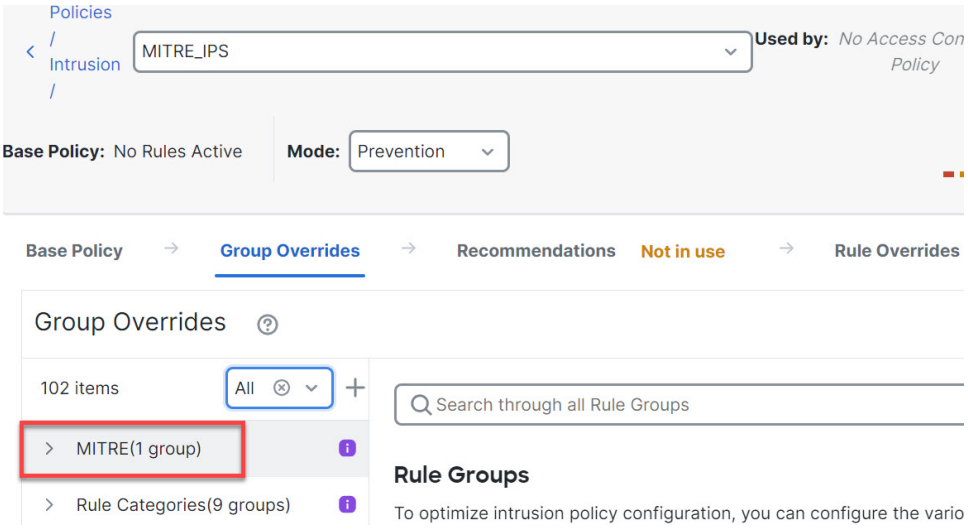


Step 6 Under **Group Overrides**, ensure that **All** is chosen in the drop-down list, so that all the rule groups for the corresponding intrusion policy are visible in the left pane.

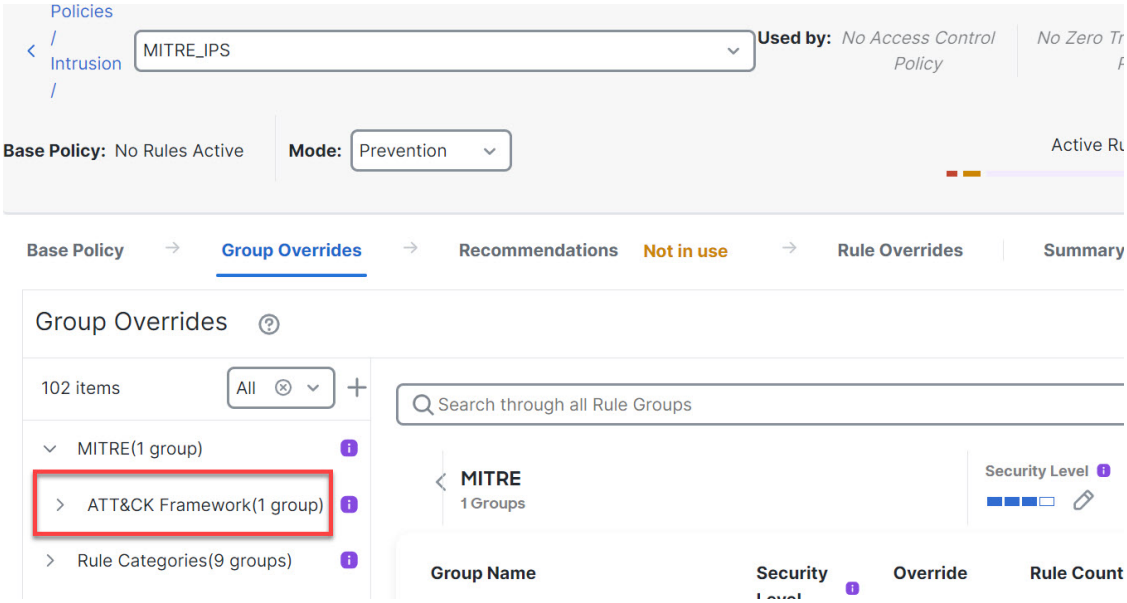


Step 7 Click **MITRE** in the left pane.

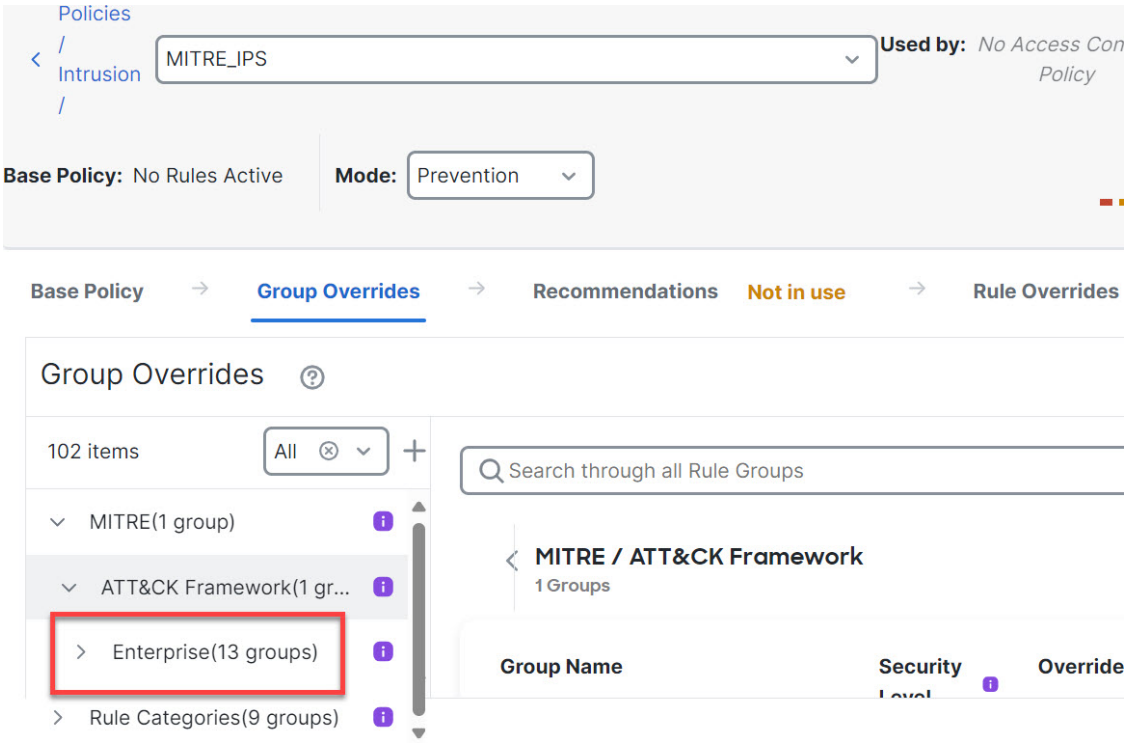
Note
Depending on your specific requirements, you can choose the **Rule Categories** rule group or any other rule group and subrule groups under it. All the rule groups use the MITRE framework.



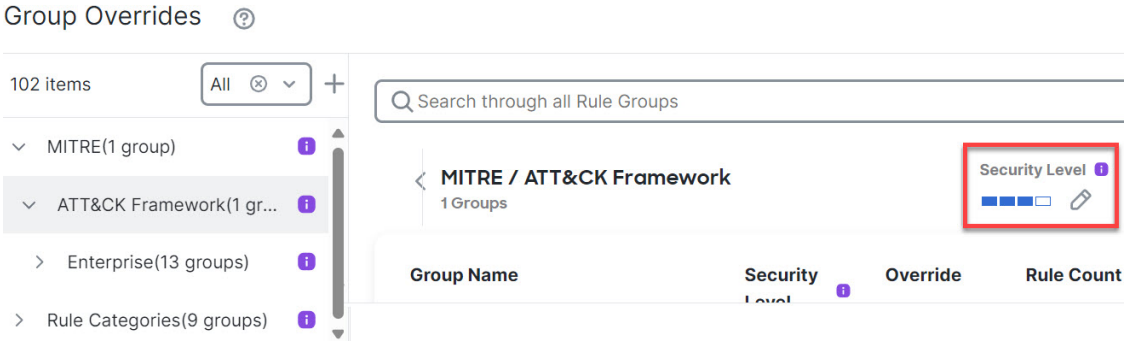
Step 8 Under **MITRE**, click **ATT&CK Framework** to drill down.



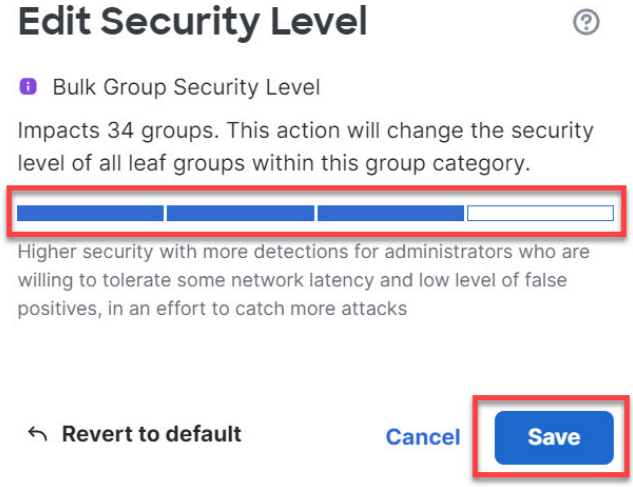
Step 9 Under **ATT&CK Framework**, click **Enterprise** to expand it.



Step 10 Click the **Edit** (✎) icon next to the **Security Level** of the rule group to make bulk changes to the security level of all the associated rule groups under the **Enterprise** rule group category.

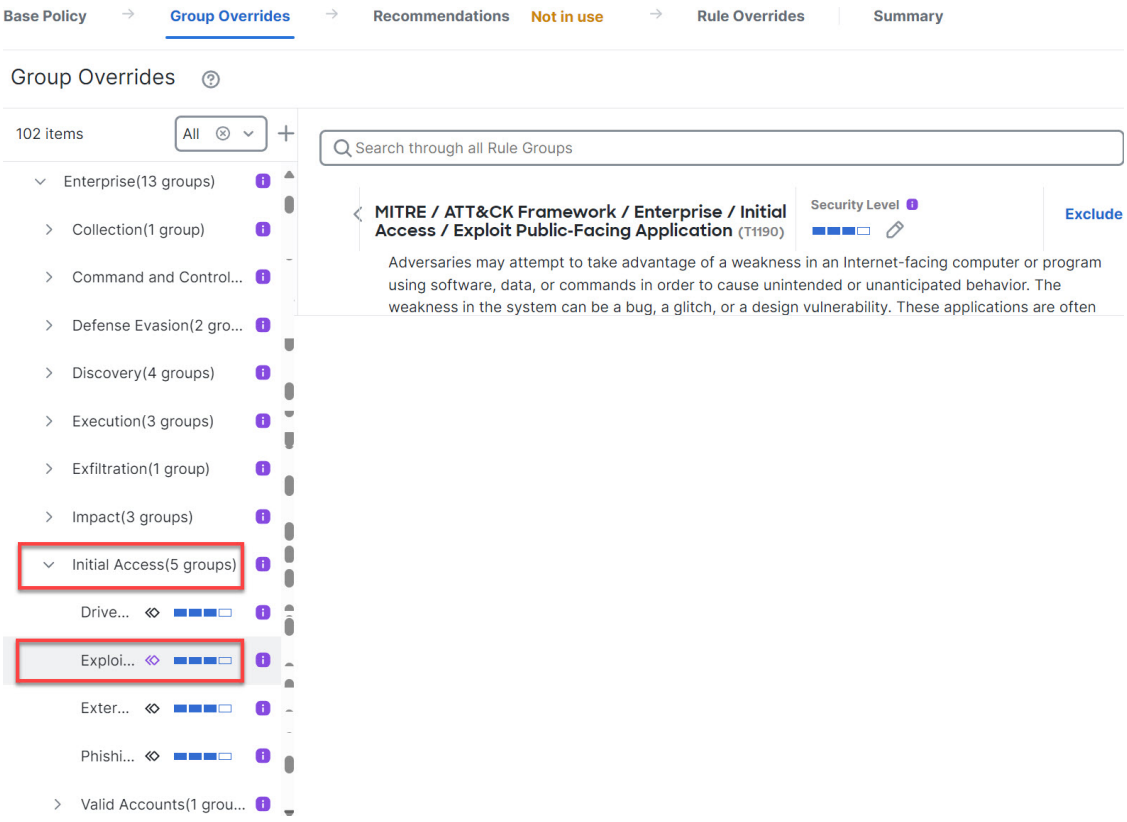


Step 11 In the **Edit Security Level** window, choose a **Security Level** (in this example, **3**), and click **Save**.

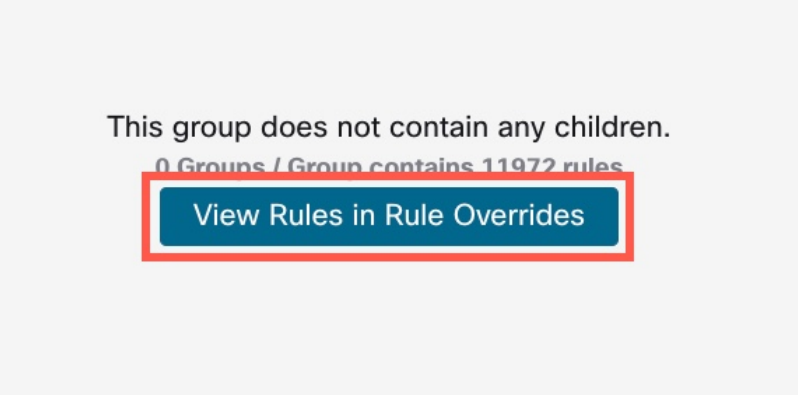


Step 12 Under **Enterprise**, click **Initial Access** to expand it.

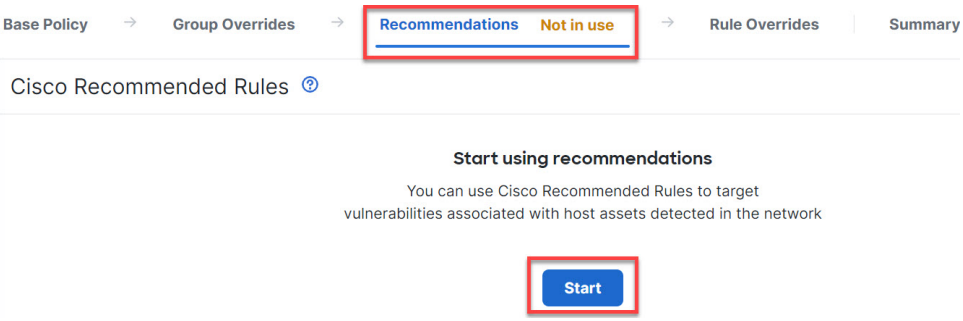
Step 13 Under **Initial Access**, click **Exploit Public-Facing Application**, which is the last leaf group.



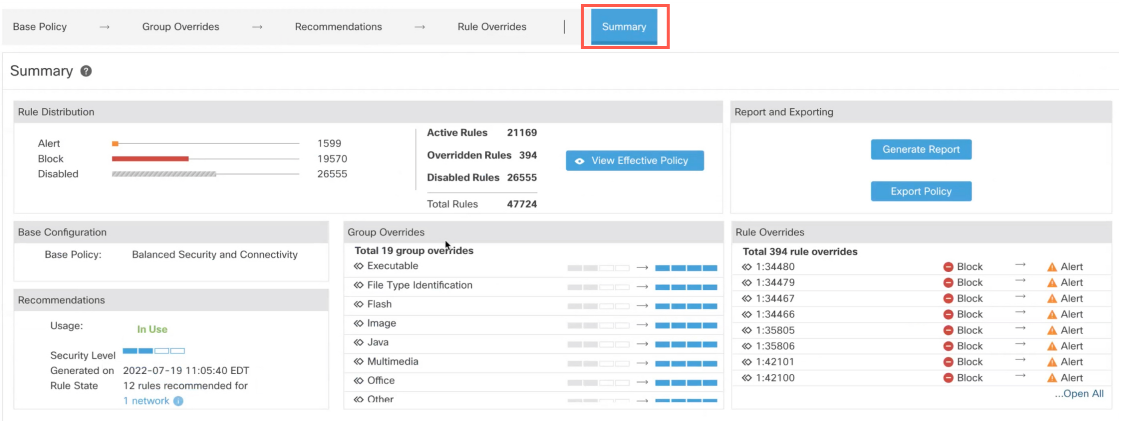
Step 14 Click **View Rules in Rule Overrides** to view the different rules, rule details, rule actions, and so on, for the different rules. You can change the rule actions for one or multiple rules in the **Rule Overrides** layer.



Step 15 Click the **Recommendations** layer and then click **Start** to start using Cisco-recommended rules. You can use the intrusion rule recommendations to target the vulnerabilities that are associated with the host assets detected in the network. For more information, see Generate New Secure Firewall Recommendations in Snort 3, on page 2095.



Step 16 Click the **Summary** layer for a holistic view of the current changes to the policy. Based on the rule overrides, security-level changes, and generation of Cisco-recommended rules, you can view the rule distribution of the policy, group overrides, rule overrides, rule recommendations, and so on, to verify your changes.



What to do next

Deploy your intrusion policy to detect and log events that are triggered by the Snort rules. See Deploy Configuration Changes, on page 2055.

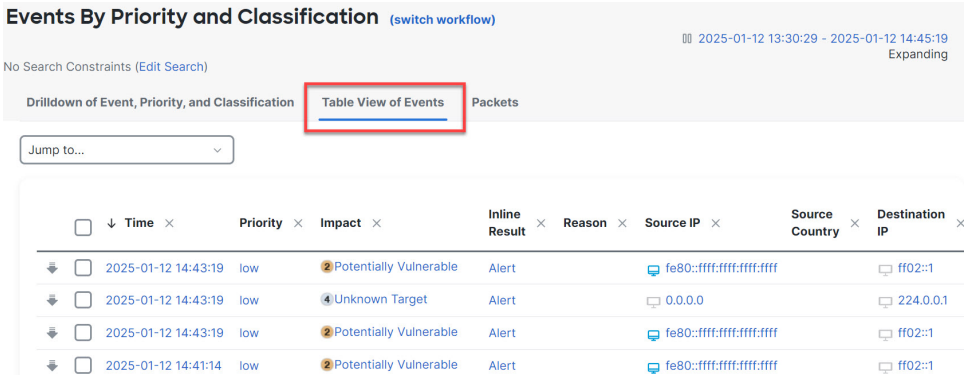
View Intrusion Events

You can view the MITRE ATT&CK techniques and rule groups in the intrusion events on the **Classic Event Viewer** and **Unified Event Viewer** pages. Talos provides mappings from Snort rules (GID:SID) to MITRE ATT&CK techniques and rule groups. These mappings are installed as part of the Lightweight Security Package (LSP).

Procedure

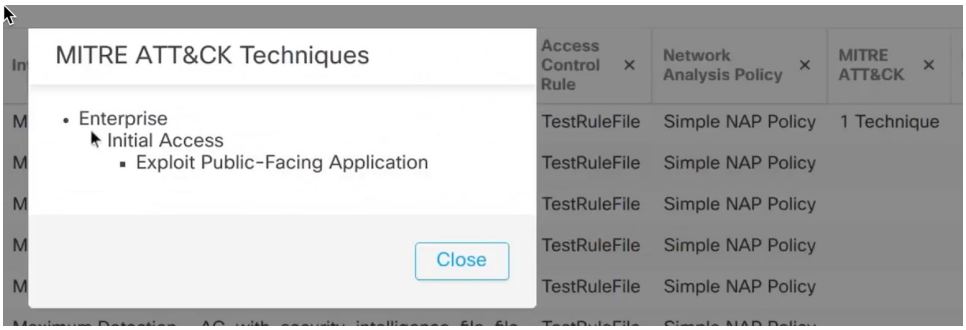
Step 1 Click **Analysis** and select **Events** under **Intrusions**.

Step 2 Click the **Table View of Events** tab.



Step 3 Under **MITRE ATT&CK**, you can see the techniques for an intrusion event. Click **1 Technique** to view the MITRE ATT&CK techniques.

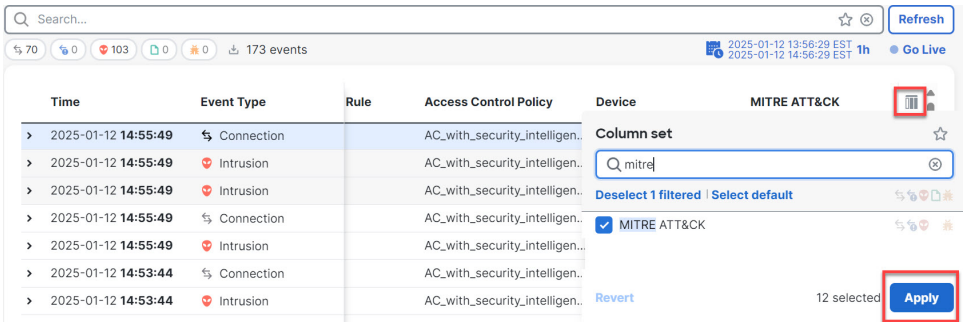
In this example, **Exploit Public-Facing Application** is the technique.



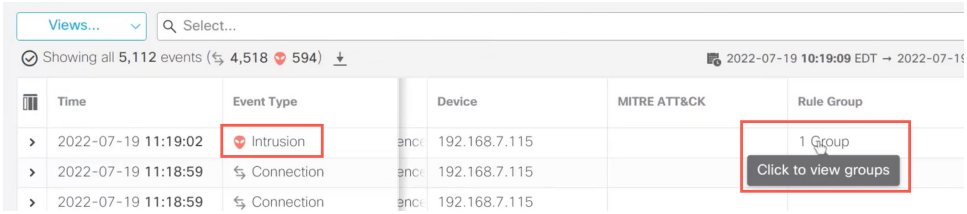
Step 4 Click **Close**.

Step 5 Click **Analysis** and select **Unified Events**.

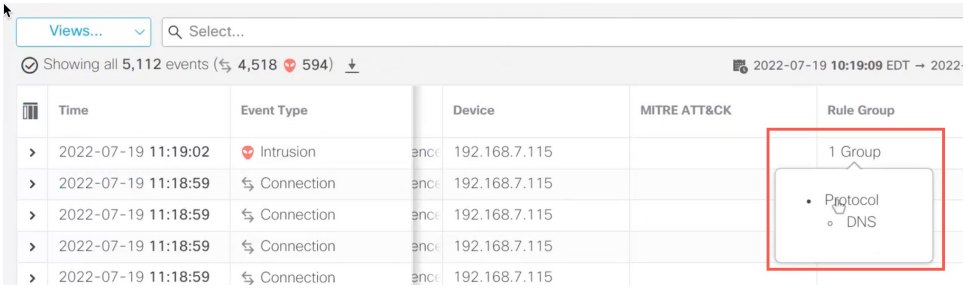
Step 6 If not enabled, click the column selector icon to enable the **MITRE ATT&CK** and **Rule Group** columns.



Step 7 In this example, the intrusion event is triggered by an event that is mapped to one rule group. Click **1 Group** under the **Rule Group** column.



Step 8 You can view **Protocol**, which is the parent rule group, and the DNS rule group under it. Choose **Protocol** > **DNS** to search for all the intrusion events that have at least one rule group that is .



The search results are displayed.

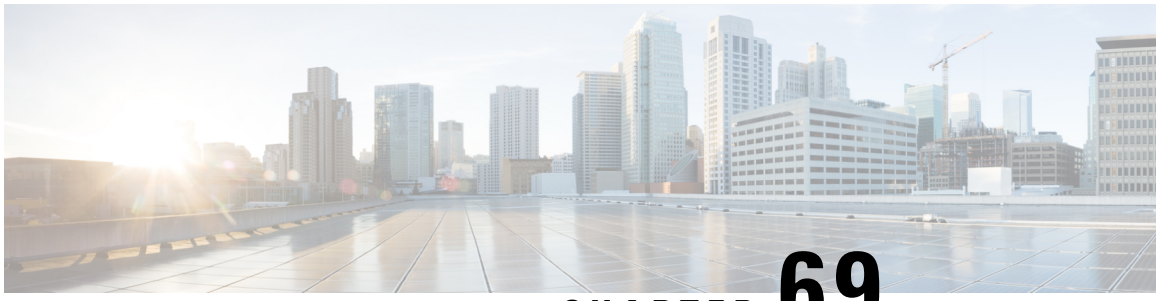
Network Malware Protection and File Policies

- Network Malware Protection and File Policies, on page 2209



CHAPTER 69

Network Malware Protection and File Policies

The following topics provide an overview of file control, file policies, file rules, Advanced Malware Protection (AMP), cloud connections, and dynamic analysis connections.

- About Network Malware Protection and File Policies, on page 2209
- Requirements and Prerequisites for File Policies, on page 2210
- License Requirements for File and Malware Policies, on page 2211
- Best Practices for File Policies and Malware Detection , on page 2211
- How to Configure Malware Protection, on page 2214
- Cloud Connections for Malware Protection, on page 2219
- File Policies and File Rules, on page 2228
- Retrospective Disposition Changes, on page 2243
- File and Malware Inspection Performance and Storage Options, on page 2243
- Tuning File and Malware Inspection Performance and Storage, on page 2244
- (Optional) Malware Protection with Secure Endpoint, on page 2245
- History for Network Malware Protection and File Policies, on page 2250

About Network Malware Protection and File Policies

To detect and block malware, use file policies. You can also use file policies to detect and control traffic by file type.

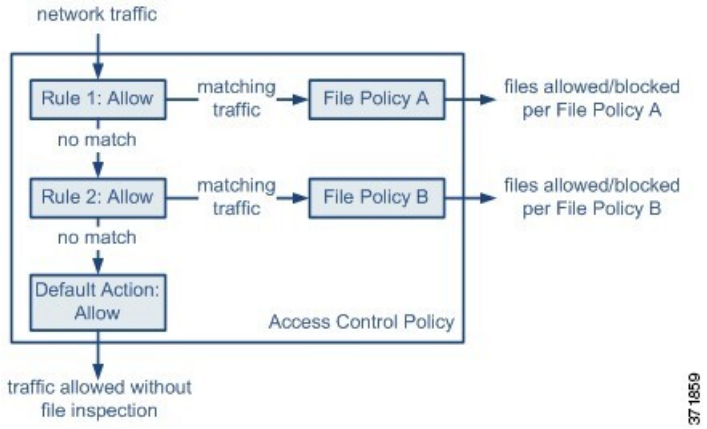
Advanced Malware Protection (AMP) for Firepower can detect, capture, track, analyze, log, and optionally block the transmission of malware in network traffic. In the Secure Firewall Management Center web interface, this feature is called *malware defense*, formerly called *AMP for Firepower*. Advanced Malware Protection identifies malware using managed devices deployed inline and threat data from the Cisco cloud.

You associate file policies with access control rules that handle network traffic as part of your overall access control configuration.

When the system detects malware on your network, it generates file and malware events. To analyze file and malware event data, see the *File/Malware Events and Network File Trajectory* chapter in the Cisco Secure Firewall Management Center Administration Guide .

File Policies

A file policy is a set of configurations that the system uses to perform malware protection and file control, as part of your overall access control configuration. This association ensures that before the system passes a file in traffic that matches an access control rule's conditions, it first inspects the file. Consider the following diagram of a simple access control policy in an inline deployment.



The policy has two access control rules, both of which use the Allow action and are associated with file policies. The policy's default action is also to allow traffic, but without file policy inspection. In this scenario, traffic is handled as follows:

- Traffic that matches `Rule 1` is inspected by `File Policy A`.
- Traffic that does not match `Rule 1` is evaluated against `Rule 2`. Traffic that matches `Rule 2` is inspected by `File Policy B`.
- Traffic that does not match either rule is allowed; you cannot associate a file policy with the default action.

By associating different file policies with different access control rules, you have granular control over how you identify and block files transmitted on your network.

Requirements and Prerequisites for File Policies

Model Support

Any

Supported Domains

Any

User Roles

- Admin
- Access Admin

License Requirements for File and Malware Policies

To Do This	License Required	File Rule Action
Block or allow all files of a particular type (for example, block all .exe files)	IPS (for Firewall Threat Defense devices) Protection (for Classic devices)	Allow, Block, Block with Reset
Selectively allow or block files based on a judgment that it contains or is likely to contain malware	IPS (for Firewall Threat Defense devices) Protection (for Classic devices) Malware Defense	Malware Cloud Lookup, Block Malware
Store files	IPS (for Firewall Threat Defense devices) Protection (for Classic devices) Malware Defense	Any file rule action with **Store Files** selected

For details about Malware Defense licenses, see:

- *Malware Defense Licenses* in the Cisco Secure Firewall Management Center Administration Guide

Best Practices for File Policies and Malware Detection

In addition to the items described below, follow the steps in How to Configure Malware Protection, on page 2214 and referenced topics.

File Rule Best Practices

Note the following guidelines and limitations when configuring file rules:

- A rule configured to block files in a passive deployment does not block matching files. Because the connection continues to transmit the file, if you configure the rule to log the beginning of the connection, you may see multiple events logged for this connection.
- A policy can include multiple rules. When you create the rules, ensure that no rule is "shadowed" by a previous rule.
- The file types supported for dynamic analysis are a subset of the file types supported for other types of analysis. To view the file types supported for each type of analysis, navigate to the file rule configuration page, select the **Block Malware** action, and select the checkboxes of interest.

To ensure that the system examines all file types, create separate rules (within the same policy) for dynamic analysis and for other types of analysis.

- If a file rule is configured with a **Malware Cloud Lookup** or **Block Malware** action and the Firewall Management Center cannot establish connectivity with the AMP cloud, the system cannot perform any configured rule action options until connectivity is restored.
- Cisco recommends that you enable **Reset Connection** for the **Block Files** and **Block Malware** actions to prevent blocked application sessions from remaining open until the TCP connection resets. If you do not reset connections, the client session will remain open until the TCP connection resets itself.
- If you are monitoring high volumes of traffic, do **not** store all captured files, or submit all captured files for dynamic analysis. Doing so can negatively impact system performance.
- You cannot perform malware analysis on all file types detected by the system. After you select values from the **Application Protocol**, **Direction of Transfer**, and **Action** drop-down lists, the system constrains the list of file types.

File Detection Best Practices

Consider the following notes and limitations for file detection:

- If adaptive profiling is not enabled, access control rules cannot perform file control, including AMP.
- If a file matches a rule with an application protocol condition, file event generation occurs after the system successfully identifies a file's application protocol. Unidentified files do not generate file events.
- FTP transfers commands and data over different channels. In a passive or inline tap mode deployment, the traffic from an FTP data session and its control session may not be load-balanced to the same internal resource.
- If the total number of bytes for all file names for files in a POP3, POP, SMTP, or IMAP session exceeds 1024, file events from the session may not reflect the correct file names for files that were detected after the file name buffer filled.
- When transmitting text-based files over SMTP, some mail clients convert newlines to the CRLF newline character standard. Since Mac-based hosts use the carriage return (CR) character and Unix/Linux-based hosts use the line feed (LF) character, newline conversion by the mail client can modify the size of the file. Note that some mail clients default to newline conversion when processing an unrecognizable file type.
- To detect ISO files, set the "Limit the number of bytes inspected when doing file type detection" option to a value greater than 36870, as described in File and Malware Inspection Performance and Storage Options, on page 2243.
- .Exe files inside some .rar archives cannot be detected, including possibly rar5.
- If the file disposition is Neutral, it is an unknown disposition.

File Blocking Best Practices

Consider the following notes and limitations for file blocking:

- If an end-of-file marker is not detected for a file, regardless of transfer protocol, the file will not be blocked by a **Block Malware** rule or the custom detection list. The system waits to block the file until the entire file has been received, as indicated by the end-of-file marker, and blocks the file after the marker is detected.
- If the end-of-file marker for an FTP file transfer is transmitted separately from the final data segment, the marker will be blocked and the FTP client will indicate that the file transfer failed, but the file will actually completely transfer to disk.
- File rules with **Block Files** and **Block Malware** actions block automatic resumption of file download via HTTP by blocking new sessions with the same file, URL, server, and client application detected for 24 hours after the initial file transfer attempt occurs.
- In rare cases, if traffic from an HTTP upload session is out of order, the system cannot reassemble the traffic correctly and therefore will not block it or generate a file event.
- If you transfer a file over NetBIOS-ssn (such as an SMB file transfer) that is blocked with a **Block Files** rule, you may see a file on the destination host. However, the file is unusable because it is blocked after the download starts, resulting in an incomplete file transfer.
- If you create file rules to detect or block files transferred over NetBIOS-ssn (such as an SMB file transfer), the system does not inspect the ongoing file transfers. However, the system inspects the new files that are transferred after you deploy an access control policy invoking the file policy.
- SMB has a functionality called multi-channel which creates multiple parallel sessions with the same IP address and different ports. For a given transaction over multi-channel, the file download is multiplexed across these sessions which is not inspected by the system as a single file.
- Files transferred concurrently in a single TCP or SMB session are not inspected.
- In a cluster environment, if an existing SMB session is moved to a new device due to a cluster role change or a device failure, then the files in any ongoing file transfers may not be inspected.
- Some SMB file transfers between Microsoft Windows systems use very high TCP window size for quick file transfers. To detect or block such file transfers, it is recommended that you increase the value of **Maximum Queued Bytes** and **Maximum Queued Segments** under **Network Analysis Policy** > **TCP Stream Configuration** > **Troubleshooting Options**.
- If you configure Firewall Threat Defense high availability, and failover occurs while the original active device is identifying the file, the file type is not synced. Even if your file policy blocks that file type, the new active device downloads the file.

File Policy Best Practices

Note the following general guidelines and limitations when configuring file policies.

- You can associate a single file policy with an access control rule whose action is **Allow**, **Interactive Block**, or **Interactive Block with reset**.
- You **cannot** use a file policy to inspect traffic handled by the access control default action.
- For a new policy, the web interface indicates that the policy is not in use. If you are editing an in-use file policy, the web interface tells you how many access control policies use the file policy. In either case, you can click the text to jump to the Access Control Policies page.

- For file blocking to work, the NAP policy you apply to the access control policy must be operating in Protection mode, also known as Inline mode.
- Based on your configuration, you can either inspect a file the first time the system detects it, and wait for a cloud lookup result, or pass the file on this first detection without waiting for the cloud lookup result.
- By default, file inspection of encrypted payloads is disabled. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has file inspection configured.

Attention The File Inpsect preprocessor with the following generator IDs (GIDs) are enabled by default for file/malware policy: GID: 146 and GID: 147.

- If you enable an access control policy with a file policy that uses either a Malware action or a Store Files option, the computing power and system performance of the device is reduced.

How to Configure Malware Protection

This topic summarizes the steps you must take to set up your system to protect your network from malicious software.

Procedure

Step 1 Plan and Prepare for Malware Protection, on page 2215

Step 2 Configure File Policies, on page 2216

Step 3 Add File Policies to Your Access Control Configuration, on page 2216

Step 4 Configure network discovery policies to associate file and malware events with hosts on your network.

(Do not simply turn on network discovery; you must configure it to discover hosts on your network to build a network map of your organization.)

See Network Discovery Policies, on page 2643 and subtopics.

Step 5 Deploy policies to managed devices.

See Deploy Configuration Changes, on page 259.

Step 6 Test your system to be sure it is processing malicious files as you expect it to.

Step 7 Set Up Maintenance and Monitoring of Malware Protection, on page 2218

What to do next

- (Optional) To further enhance detection of malware in your network, deploy and integrate Cisco's Secure Endpoint product. See (Optional) Malware Protection with Secure Endpoint, on page 2245 and subtopics.

- Understand how to investigate file and malware events.

  See *File/Malware Events and Network File Trajectory* in the Cisco Secure Firewall Management Center Administration Guide.

Plan and Prepare for Malware Protection

This procedure is the first set of steps in the complete process for configuring your system to provide malware protection.

Procedure

Step 1 Purchase and install licenses.

See License Requirements for File and Malware Policies, on page 2211 and *Licenses* in the Cisco Secure Firewall Management Center Administration Guide.

Step 2 Understand how file policies and malware protection fit into your access control plan.

See the chapter Access Control Overview, on page 1723.

Step 3 Understand the file analysis and malware protection tools.

See File Rule Actions, on page 2234 and subtopics.

Consider also Advanced and Archive File Inspection Options, on page 2229.

Step 4 Determine whether you will use public clouds or private (on-premises) clouds for malware protection (file analysis and dynamic analysis.)

See Cloud Connections for Malware Protection, on page 2219 and subtopics.

Step 5 If you will use private (on-premises) clouds for malware protection: Purchase, deploy, and test those products.

For information, contact your Cisco sales representative or authorized reseller.

Step 6 Configure your firewall to allow communications with your chosen clouds.

See *Security, Internet Access, and Communication Ports* in the Cisco Secure Firewall Management Center Administration Guide.

Step 7 Configure connections between Firepower and the malware protection clouds (public or private, as applicable).

- For the AMP cloud, see Change AMP Options, on page 2224.
- If you have deployed an on-premises Secure Malware Analytics Appliance, see Connect to an On-Premises Dynamic Analysis Appliance, on page 2225. (Access to the public Secure Malware Analytics Cloud does not require configuration.)

What to do next

Continue with the next step in the malware protection workflow:

See How to Configure Malware Protection, on page 2214.

Configure File Policies

Before you begin

Complete the tasks up to this point in the malware protection workflow:

See How to Configure Malware Protection, on page 2214.

Procedure

Step 1 Review file policy and file rule restrictions.

See Best Practices for File Policies and Malware Detection , on page 2211 and subtopics.

Step 2 Create a file policy.

See Create or Edit a File Policy, on page 2228.

Step 3 Create rules within your file policy.

See File Rules, on page 2233 and subtopics.

Step 4 Configure advanced options.

See Advanced and Archive File Inspection Options, on page 2229.

What to do next

Continue with the next step in the malware protection workflow:

See How to Configure Malware Protection, on page 2214.

Add File Policies to Your Access Control Configuration

An access control policy can have multiple access control rules associated with file policies. You can configure file inspection for any Allow or Interactive Block access control rule, which permits you to match different file and malware inspection profiles against different types of traffic on your network before it reaches its final destination.

Before you begin

Complete the tasks up to this point in the malware protection workflow:

See How to Configure Malware Protection, on page 2214.

Procedure

Step 1 Review guidelines for file policies in access control policies. (These are different from the file rule and file policy guidelines that you looked at previously.)

Review File and Intrusion Inspection Order, on page 1730.

Step 2 Associate the file policy with an access control policy.

See Configuring an Access Control Rule to Perform Malware Protection, on page 2217

Step 3 Assign the access control policy to managed devices.

See Assigning Devices to an Access Control Policy, on page 1755.

What to do next

Continue with the next step in the malware protection workflow:

See How to Configure Malware Protection, on page 2214.

Configuring an Access Control Rule to Perform Malware Protection

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Note Inline normalization is enabled automatically when a file policy is included in an access control rule. For more information, see https://www.cisco.com/go/snort3-inspectors.

Before you begin

- Adaptive profiling **must** be enabled (its default state) for access control rules to perform file control, including AMP.
- You must be an Admin, Access Admin, or Network Admin user to perform this task.

Procedure

Step 1 In the access control rule editor (from **Policies > Access Control)**, choose an **Action** of **Allow**, **Interactive Block**, or **Interactive Block with reset**.

Step 2 (Legacy UI only.) Click **Inspection**.

Step 3 Choose a **File Policy** to inspect traffic that matches the access control rule, or choose **None** to disable file inspection for matching traffic.

Step 4 (Optional) Disable logging of file or malware events for matching connections by clicking **Logging** and unchecking **Log Files**.

Note
Cisco recommends that you leave file and malware event logging enabled.

Step 5 Save the rule.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Related Topics

Create or Edit a File Policy, on page 2228
Snort Restart Scenarios, on page 252

Set Up Maintenance and Monitoring of Malware Protection

Ongoing maintenance is essential for protecting your network.

Before you begin

Configure your system to protect your network from malware.

See How to Configure Malware Protection, on page 2214 and referenced procedures.

Procedure

Step 1 Ensure that your system always has the most current and effective protection.

See Maintain Your System: File Types Eligible for Dynamic Analysis, on page 2227.

Step 2 Configure alerts for malware-related events and health monitoring.

See the Cisco Secure Firewall Management Center Administration Guide for information on *Configuring malware defense Alerting* and for information about the following modules:

- Local Malware Analysis

- Security Intelligence
- Threat Data Updates on Devices
- Intrusion and File Event Rate
- AMP for Firepower Status
- Secure Endpoint Status

What to do next

Review "What to do next items" in the malware protection workflow:

See How to Configure Malware Protection, on page 2214.

Cloud Connections for Malware Protection

Connections to public or private clouds are required in order to protect your network from malware.

AMP Clouds

The Advanced Malware Protection (AMP) cloud is a Cisco-hosted server that uses big data analytics and continuous analysis to provide intelligence that the system uses to detect and block malware on your network.

The AMP cloud provides dispositions for possible malware detected in network traffic by managed devices, as well as data updates for local malware analysis and file pre-classification.

If your organization has deployed Secure Endpoint and configured Firepower to import its data, the system imports this data from the AMP cloud, including scan records, malware detections, quarantines, and indications of compromise (IOC).

Cisco offers the following options for obtaining data from the Cisco cloud about known malware threats:

- **AMP public cloud**

  Your Secure Firewall Management Center communicates directly with the public Cisco cloud. There are three public AMP clouds, in the United States, Europe, and Asia.

- **An AMP private cloud**

  An AMP private cloud is deployed on your network and acts as a compressed, on-premises AMP cloud, as well as an anonymized proxy to connect to the public AMP cloud. For details, see Cisco AMP Private Cloud, on page 2221.

  If you integrate with Secure Endpoint, the AMP private cloud has some limitations. See Secure Endpoint and AMP Private Cloud, on page 2247.

Dynamic Analysis Cloud

- **Secure Malware Analytics Cloud**

  Public cloud that processes eligible files that you send for dynamic analysis, and provides threat scores and dynamic analysis reports. Firepower supports 200 samples/day for Secure Malware Analytics analysis.

- **On-premises Secure Malware Analytics Appliance**

  If your organization's security policy does not allow the system to send files outside of your network, you can deploy an on-premises appliance. This appliance does not contact the public Secure Malware Analytics Cloud.

  For more information, see Dynamic Analysis On-Premises Appliance (Cisco Secure Malware Analytics), on page 2225.

Configure Connections to AMP and Secure Malware Analytics Clouds

- AMP Cloud Connection Configurations, on page 2220
- Dynamic Analysis Connections, on page 2224

AMP Cloud Connection Configurations

The following topics describe AMP cloud connection configurations for different scenarios:

- Choose an AMP Cloud, on page 2221
- Connecting to an AMP Private Cloud, on page 2222
- Integrate Firepower and Secure Endpoint, on page 2247

The following topics are also relevant:

- Cisco AMP Private Cloud, on page 2221
- Requirements and Best Practices for AMP Cloud Connections, on page 2220
- Managing Connections to the AMP Cloud (Public or Private) , on page 2223

Requirements and Best Practices for AMP Cloud Connections

Requirements for AMP Cloud Connections

You must be an Admin user to set up the AMP cloud.

To ensure the Firewall Management Center can communicate with the AMP cloud, see *Security, Internet Access, and Communication Ports* in the Cisco Secure Firewall Management Center Administration Guide.

AMP and High Availability

Although they share file policies and related configurations, Firewall Management Centers in a high availability pair do not share AMP cloud connections, captured files, file events, and malware events. To ensure continuity of operations, and so that malware dispositions are the same on both Firewall Management Centers, both active and standby Firewall Management Centers must have access to the cloud.

These requirements apply to both public and private AMP clouds.

AMP Cloud Connections and Multitenancy

In a multidomain deployment, configure the malware defense connection at the Global level. Each Firewall Management Center can have only one malware defense connection.

Choose an AMP Cloud

By default, a connection to the United States (US) AMP public cloud is configured and enabled for your system. (This connection appears in the web interface as malware defense and sometimes AMP for Firepower.) You cannot delete or disable an malware defense cloud connection, but you can switch between different geographical AMP clouds, or configure an AMP private cloud connection.

Before you begin

- If you will use an AMP private cloud, see Connecting to an AMP Private Cloud, on page 2222 instead of this topic.
- Unless Firepower is integrated with Secure Endpoint, you can configure only one AMP cloud connection. This connection is labeled **AMP for Networks** or **AMP for Firepower**.
- If you have deployed Secure Endpoint and you want to add one or more AMP clouds to integrate that application with Firepower, see Integrate Firepower and Secure Endpoint, on page 2247.
- See Requirements and Best Practices for AMP Cloud Connections, on page 2220.

Procedure

Step 1 Choose **Integration** > **AMP** > **AMP Management**.

Step 2 Click pencil to edit the existing cloud connection.

Step 3 From the **Cloud Name** drop-down list, choose the regional cloud nearest to your Secure Firewall Management Center.

APJC is Asia/Pacific/Japan/China.

Step 4 Click **Save**.

What to do next

- If your deployment is a high-availability configuration, see Requirements and Best Practices for AMP Cloud Connections, on page 2220.
- (Optional) Change AMP Options, on page 2224.

Cisco AMP Private Cloud

The Firewall Management Center must connect to the AMP cloud for disposition queries for files detected in network traffic and receipt of retrospective malware events. This cloud can be public or private.

Your organization may have privacy or security concerns that make frequent or direct connections between your monitored network and the AMP cloud difficult or impossible. In these situations, you can set up a Cisco AMP Private Cloud, a proprietary Cisco product that acts as a compressed, on-premises version of the AMP cloud, as well as a secure mediator between your network and the AMP cloud. Connecting a Firewall Management Center to an AMP private cloud disables existing direct connections to the public AMP cloud.

All connections to the AMP cloud funnel through the AMP private cloud, which acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes disposition queries for files detected in network traffic, receiving of retrospective malware events, and so on. The AMP private cloud does not share any of your endpoint data over an external connection.

Note The AMP private cloud does **not** perform dynamic analysis, nor does it support anonymized retrieval of threat intelligence for other features that rely on Cisco Collective Security Intelligence (CSI), such as URL and Security Intelligence filtering.

For information about AMP private cloud (sometimes referred to as "AMPv"), see https://www.cisco.com/c/en/us/products/security/fireamp-private-cloud-virtual-appliance/index.html.

Connecting to an AMP Private Cloud

Before you begin

- Configure your Cisco AMP private cloud or clouds according to the directions in the documentation for that product. During configuration, note the private cloud host name. You will need this host name in order to configure the connection on the Firewall Management Center.
- Make sure the Firewall Management Center can communicate with the AMP private cloud, and confirm that the private cloud has internet access so it can communicate with the public AMP cloud. See the topics under *Security, Internet Access, and Communication Ports* in the Cisco Secure Firewall Management Center Administration Guide.
- Unless your deployment is integrated with Secure Endpoint, each Firewall Management Center can have only one AMP cloud connection. This connection is labeled **AMP for Networks** or **AMP for Firepower**.

  If you integrate with Secure Endpoint, you can configure multiple Secure Endpoint cloud connections.

Procedure

Step 1 Choose **Integration** > **AMP** > **AMP Management**.

Step 2 Click **Add AMP Cloud Connection**.

Step 3 From the **Cloud Name** drop-down list, choose **Private Cloud**.

Step 4 Enter a **Name**.

This information appears in malware events that are generated or transmitted by AMP private cloud.

Step 5 In the **Host** field, enter the private cloud host name that you configured when you set up the private cloud.

Step 6 Click **Browse** next to the **Certificate Upload Path** field to browse to the location of a valid TLS or SSL encryption certificate for the private cloud. For more information, see the AMP private cloud documentation.

Step 7 If you want to use this private cloud for both malware defense and Secure Endpoint, check the **Use for AMP for Firepower** check box.

If you configured a different private cloud to handle malware defense communications, you can clear this check box; if this is your only AMP private cloud connection, you cannot.

In a multidomain deployment, this check box appears only in the Global domain. Each Firewall Management Center can have only one malware defense connection.

Step 8 Click **Register**, confirm that you want to disable existing direct connections to the AMP cloud, and finally confirm that you want to continue to the AMP private cloud management console to complete registration.

Step 9 Log into the management console and complete the registration process. For further instructions, see the AMP private cloud documentation.

What to do next

In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.

Managing Connections to the AMP Cloud (Public or Private)

Use the Firewall Management Center to manage connections to public and private AMP clouds used for malware defense or Secure Endpoint or both.

You can delete a connection to a public or private AMP cloud if you no longer want to receive malware-related information from the cloud. Note that deregistering a connection using the Secure Endpoint or AMP private cloud management console does not remove the connection from the system. Deregistered connections display a failed state on the Secure Firewall Management Center web interface.

You can also temporarily disable a connection. When you reenable a cloud connection, the cloud resumes sending data to the system, including queued data from the disabled period.

Caution For disabled connections, the public or private AMP cloud can store malware events, indications of compromise, and so on until you re-enable the connection. In rare cases—for example, with a very high event rate or a long-term disabled connection—the cloud may not be able to store all information generated while the connection is disabled.

In a multidomain deployment, the system displays connections created in the current domain, which you can manage. It also displays connections created in ancestor domains, which you cannot manage. To manage connections in a lower domain, switch to that domain. Each Firewall Management Center can have only one malware defense connection, which belongs to the Global domain.

Procedure

Step 1 Select **Integration** > **AMP** > **AMP Management**.

Step 2 Manage your AMP cloud connections:

- Delete — Click **Delete** ( ), then confirm your choice.
- Enable or Disable — Click the slider, then confirm your choice.

What to do next

In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.

Change AMP Options

Procedure

Step 1 Choose **Integration** > **Other Integrations** > **Cloud Services**.

Step 2 Select options:

Table 118: AMP for Networks Options

Option	Description
Enable Automatic Local Malware Detection Updates	The local malware detection engine statically analyzes and preclassifies files using signatures provided by Cisco. If you enable this option, the Firewall Management Center checks for signature updates once every 30 minutes.
Share URI from Malware Events with Cisco	The system can send information about the files detected in network traffic to the AMP cloud. This information includes URI information associated with detected files and their SHA-256 hash values. Although sharing is opt-in, transmitting this information to Cisco helps future efforts to identify and track malware.

Step 3 Click **Save**.

Dynamic Analysis Connections

Requirements for Dynamic Analysis

You must be an Admin, Access Admin, or Network Admin user, and be in the global domain, to use dynamic analysis.

With the appropriate license, the system automatically has access to the Secure Malware Analytics Cloud.

Dynamic analysis requires that managed devices have direct or proxied access to the Secure Malware Analytics Cloud or an on-premises Secure Malware Analytics Appliance on port 443.

See also Which Files Are Eligible for Dynamic Analysis?, on page 2239.

If you will connect to an on-premises Secure Malware Analytics Appliance, see also the prerequisites in Connect to an On-Premises Dynamic Analysis Appliance, on page 2225.

Viewing the Default Dynamic Analysis Connection

By default, the Secure Firewall Management Center can connect to the public Secure Malware Analytics Cloud for file submission and report retrieval. You can neither configure nor delete this connection.

Procedure

Step 1 Choose **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 Click **Edit** ( ).

Note

For information about **Associate** ( ) on the **Integration** > **AMP** > **Dynamic Analysis Connections** page, see Enabling Access to Dynamic Analysis Results in the Public Cloud, on page 2226.

Dynamic Analysis On-Premises Appliance (Cisco Secure Malware Analytics)

If your organization has privacy or security concerns around submitting files to the public Secure Malware Analytics Cloud, you can deploy an on-premises Secure Malware Analytics Appliance. Like the public cloud, the on-premises appliance runs eligible files in a sandbox environment, and returns a threat score and dynamic analysis report to the system. However, the on-premises appliance does not communicate with the public cloud, or any other system external to your network.

For more information about on-premises Secure Malware Analytics Appliances, see https://www.cisco.com/c/en/us/products/security/threat-grid/index.html.

Connect to an On-Premises Dynamic Analysis Appliance

If you install an on-premises Secure Malware Analytics Appliance on your network, you can configure a dynamic analysis connection to submit files and retrieve reports from the appliance. When configuring the on-premises appliance dynamic analysis connection, you register the Secure Firewall Management Center to the on-premises appliance.

Before you begin

- Set up your on-premises Secure Malware Analytics Appliance.

  Documentation for this appliance is available from https://www.cisco.com/c/en/us/support/security/amp-threat-grid-appliances/tsd-products-support-series-home.html.

  For version requirements, see the *Cisco Firepower Compatibility Guide*.

- If your Secure Malware Analytics Appliance uses a self-signed public-key certificate, download the certificate from the Secure Malware Analytics Appliance; see the *Administrator's Guide* for your Secure Malware Analytics Appliance for information.

  If you use a certificate signed by a Certificate Authority (CA), the certificate must meet the following requirements:

  - The server key and signed certificate must be installed on the Secure Malware Analytics Appliance. Follow the upload instructions in the *Administrator's Guide* for your Secure Malware Analytics Appliance.
  - If there is a multi-level signing chain of CAs, all required intermediate certificates and the root certificate must be contained in a single file that will be uploaded to the Firewall Management Center.

- All certificates must be PEM-encoded.
- The file's newlines must be UNIX, not DOS.

- If you want to connect to the on-premises appliance using a proxy, configure the proxy; see *Modify Firewall Management Center Management Interfaces* in the Cisco Secure Firewall Management Center Administration Guide.
- Managed devices must have direct or proxied access to the Secure Malware Analytics Appliance on port 443.

Procedure

Step 1 Choose **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 Click **Add New Connection**.

Step 3 Enter a **Name**.

Step 4 Enter a **Host**.

Step 5 Next to **Certificate Upload**, click **Browse** to upload the certificate for the on-premises appliance.

If the Secure Malware Analytics Appliance will present a self-signed certificate, upload the certificate you downloaded from that appliance.

If the Secure Malware Analytics Appliance will present a CA-signed certificate, upload the file containing the certificate signing chain.

Step 6 If you want to use a configured proxy to establish the connection, check the check box of **Use Proxy When Available**.

Step 7 Click **Register**.

Step 8 Click **Yes** to display the on-premises Secure Malware Analytics Appliance login page.

Step 9 Enter your username and password to the on-premises Secure Malware Analytics Appliance.

Step 10 Click **Sign in**.

Step 11 You have the following options:

- If you previously registered the Secure Firewall Management Center to the on-premises appliance, click **Return**.
- If you did not register the Secure Firewall Management Center, click **Activate**.

Enabling Access to Dynamic Analysis Results in the Public Cloud

Secure Malware Analytics offers more detailed reporting on analyzed files than is available in the Firewall Management Center. If your organization has a Secure Malware Analytics Cloud account, you can access the Secure Malware Analytics portal directly to view additional details about files sent for analysis from your managed devices. However, for privacy reasons, file analysis details are available only to the organization that submitted the files. Therefore, before you can view this information, you must associate your Firewall Management Center with the files submitted by its managed devices.

Before you begin

You must have a Secure Malware Analytics Cloud account, and have your account credentials ready.

Procedure

Step 1 Select **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 Click **Associate** ( ) in the table row corresponding to the Secure Malware Analytics Cloud.

A Secure Malware Analytics portal window opens.

Step 3 Sign in to the Secure Malware Analytics Cloud.

Step 4 Click **Submit Query**.

Note
Do not change the default value in the **Devices** field.

If you have difficulties with this process, contact your Secure Malware Analytics representative at Cisco TAC.

It may take up to 24 hours for this change to take effect.

What to do next

After the association is activated, see *Viewing Dynamic Analysis Results in the Cisco Cloud* in the Cisco Secure Firewall Management Center Administration Guide .

Maintain Your System: File Types Eligible for Dynamic Analysis

The list of file types eligible for Dynamic Analysis is determined by the vulnerability database (VDB), which is updated periodically (but no more than once per day.) If you are an Admin user, you can update file types eligible for dynamic analysis.

The supported file types for automatic submission can vary in every release. The currently supported files for automatic submission are:

- PE Executable (32-bit Only)
- EXE
- DLL
- PDF
- MSOLE2 (Microsoft Object Linking and Embedding Compound File)
- DOCX, PPTX, XLSX

Note GZ and ZIP file types are not supported for automatic submission.

To ensure that your system has the current list:

Procedure

Step 1 Do one of the following:

- (Recommended) See *Vulnerability Database Update Automation* as discussed in the Cisco Secure Firewall Management Center Administration Guide
- Regularly check for new VDB updates, and *Manually Update the VDB* as discussed in the Cisco Secure Firewall Management Center Administration Guide when needed.

  If you choose this option, we recommend that you schedule regular reminders to do this.

Step 2 If your file policies specify individual file types instead of the **Dynamic Analysis Capable** file type category, update your file policies to use the newly supported file types.

Step 3 If the list of eligible file types changes, deploy to managed devices.

File Policies and File Rules

Create or Edit a File Policy

Before you begin

If you are configuring policies for malware protection, see all required procedures in Configure File Policies, on page 2216.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Create a new policy, or edit an existing policy.

If you are editing an existing policy: If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Tip

To make a copy of an existing file policy, click **Copy** ( ), then type a unique name for the new policy in the dialog box that appears. You can then modify the copy.

Step 3 Add one or more rules to the file policy as described in Creating File Rules, on page 2241.

Step 4 Optionally, select Advanced and configure advanced options as described in Advanced and Archive File Inspection Options, on page 2229.

Step 5 Save the file policy.

What to do next

- If you are configuring policies for malware protection, see other required procedures in Configure File Policies, on page 2216.
- Otherwise:
  - Add the file policy to an access control rule as described in Add File Policies to Your Access Control Configuration, on page 2216.
  - Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Advanced and Archive File Inspection Options

The Advanced Settings in the file policy editor has the following general options:

- **First Time File Analysis**—Select this option to analyze first-seen files while AMP cloud disposition is pending. The file must match a rule configured to perform a malware cloud lookup and Spero, local malware, or dynamic analysis. If you deselect this option, files detected for the first time are marked with an Unknown disposition
- **Enable Custom Detection List**—Block files on the custom detection list.
- **Enable Clean List**—If enabled, this policy will allow files that are on the clean list.
- **If AMP Cloud disposition is Unknown, override disposition based upon threat score**—Select an option:
  - If you select **Disabled,** the system will not override the disposition provided by the AMP Cloud.
  - If you set a threshold threat score, files with an AMP cloud verdict of Unknown are considered malware if their Dynamic Analysis score is equal to or worse than the threshold.
  - If you select a lower threshold value, you increase the number of files treated as malware. Depending on the action selected in your file policy, this can result in an increase of blocked files.
  - For numeric threat score ranges, see *Threat Scores and Dynamic Analysis Summary Reports* in the Cisco Secure Firewall Management Center Administration Guide.

The Advanced Settings in the file policy editor has the following archive file inspection options:

- **Inspect Archives**—Enables inspection of the contents of archive files, for archive files as large as the **Maximum file size to store** advanced access control setting.
- **Block Encrypted Archives**—Blocks password-protected archives.
- **Block Uninspectable Archives**—Blocks archive files with contents that the system is unable to inspect for reasons other than encryption. This usually applies to corrupted files, or those that exceed your specified maximum archive depth.
- **Max Archive Depth**—Blocks nested archive files that exceed the specified depth. The top-level archive file is not considered in this count; depth begins at 1 with the first nested file .

Archive Files

Archive files are files that contain other files, such as `.zip` or `.rar` files.

If any individual file in an archive matches a file rule with a block action, the system blocks the entire archive, not just the individual file.

For details about options for archive file inspection, see Advanced and Archive File Inspection Options, on page 2229.

Archive Files That Can Be Inspected

- **File types**

  A complete list of inspectable archive file types appears in the Firewall Management Center web interface on the file rule configuration page. To view that page, see Creating File Rules, on page 2241.

  Contained files that can be inspected appears in the same page.

- **File size**

  You can inspect archive files as large as the **Maximum file size to store** file policy advanced access control setting.

- **Nested archives**

  Archive files can contain other archive files, which can in turn contain archive files. The level at which a file is nested is its *archive file depth*. Note that the top-level archive file is not included in the depth count; depth begins at 1 with the first nested file.

  The system can inspect up to three levels of nested files beneath the outermost archive file (level 0). You can configure your file policy to block archive files that exceed that depth (or a lower maximum depth that you specify).

  If you choose not to block files that exceed the maximum archive file depth of 3, when archive files that contain some extractable contents and some contents nested at a depth of 3 or greater appear in monitored traffic, the system examines and reports data only for the files it was able to inspect.

  All features applicable to uncompressed files (such as dynamic analysis and file storage) are available for nested files inside archive files.

- **Encrypted files**

  You can configure the system to block archives whose contents are encrypted or otherwise cannot be inspected.

- **Archives that are not inspected**

  If traffic that contains an archive file is on a Security Intelligence Block list or Do Not Block list, or if the top-level archive file's SHA-256 value is on the custom detection list, the system does not inspect the contents of the archive file.

  If a nested file is blocked, the entire archive is blocked; however, if a nested file is allowed, the archive is not automatically passed (depending on any other nested files and characteristics).

  .Exe files inside some .rar archives cannot be detected, including possibly rar5.

Archive File Dispositions

Archive file dispositions are based on the dispositions assigned to the files inside the archive. **All** archives that contain identified malware files receive a disposition of `Malware`. Archives without identified malware files receive a disposition of `Unknown` if they contain any unknown files, and a disposition of `Clean` if they contain only clean files.

Table 119: Archive File Disposition by Contents

Archive File Disposition	Number of Unknown Files	Number of Clean Files	Number of Malware Files
`Unknown`	1 or more	Any	0
`Clean`	0	1 or more	0
`Malware`	Any	Any	1 or more

Archive files, like other files, may have dispositions of `Custom Detection` or `Unavailable` if the conditions for those dispositions apply.

Viewing Archive Contents and Details

If your file policy is configured to inspect archive file contents, you can use the context menu in a table on pages under the Analysis > Files menu, and the network file trajectory viewer to view information about the files inside an archive when the archive file appears in a file event, malware event, or as a captured file.

All file contents of the archive are listed in table form, with a short summary of their relevant information: name, SHA-256 hash value, type, category, and archive depth. A network file trajectory icon appears by each file, which you can click to view further information about that specific file.

Override File Disposition Using Custom Lists

If a file has a disposition in the AMP cloud that you know to be incorrect, you can add the file's SHA-256 value to a file list that overrides the disposition from the cloud:

- To treat a file as if the AMP cloud assigned a clean disposition, add the file to the *clean list*.
- To treat a file as if the AMP cloud assigned a malware disposition, add the file to the *custom detection list.*

On subsequent detection, the device either allows or blocks the file without reevaluating the file's disposition. You can use the clean list or custom detection list per file policy.

Note To calculate a file's SHA-256 value, you must configure a rule in the file policy to either perform a malware cloud lookup or block malware on matching files.

For complete information about using file lists in Firepower, see File List, on page 1392.

Alternatively, if applicable, use Centralized File Lists from Secure Endpoint, on page 2231.

Centralized File Lists from Secure Endpoint

If your organization has deployed Secure Endpoint, Firepower can use Block and Allow lists created in Secure Endpoint when it queries the AMP cloud for file dispositions.

Requirements:

- Your organization must be using the AMP public cloud.
- Your organization has deployed Secure Endpoint.

- You have registered your system to Secure Endpoint using the procedure in Integrate Firepower and Secure Endpoint, on page 2247.

To create and deploy these lists, see the documentation or online help for Secure Endpoint.

Note File lists created in Firepower override file lists created in Secure Endpoint.

Managing File Policies

The File Policies page displays a list of existing file policies along with their last-modified dates. You can use this page to manage your file policies.

Note The system checks for updates to the list of file types eligible for dynamic analysis (no more than once a day). If the list of eligible file types changes, this constitutes a change in the file policy; any access control policy using the file policy is marked out-of-date if deployed to any devices. You must deploy policies before the updated file policy can take effect on the device. See Maintain Your System: File Types Eligible for Dynamic Analysis, on page 2227.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Manage your file policies:

- Compare—Click **Compare Policies**; see Comparing policies.
- Create — To create a file policy, click **New File Policy** and proceed as described in Create or Edit a File Policy, on page 2228.
- Copy — To copy a file policy, click **Copy** ( ).

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Delete — If you want to delete a file policy, click **Delete** ( ), then click **Yes** and **OK** as prompted.

  If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Deploy—Choose **Deploy** > **Deployment**; see Deploy Configuration Changes, on page 259.
- Edit — If you want to modify an existing file policy, click **Edit** ( ).
- Report—Click **Report**( ); see Generate Current Policy Reports, on page 278.

File Rules

A file policy, like its parent access control policy, contains rules that determine how the system handles files that match the conditions of each rule. You can configure separate file rules to take different actions for different file types, application protocols, or directions of transfer.

For example, when a file matches a rule, the rule can:

- allow or block files based on simple file type matching
- block files based on disposition (whether or not evaluation indicates that it is malicious)
- store files to the device (For information, see Captured Files and File Storage, on page 2239)
- submit stored (captured) files for local malware, Spero, or dynamic analysis

In addition, the file policy can:

- automatically treat a file as if it is clean or malware based on entries in the clean list or custom detection list
- treat a file as if it is malware if the file's threat score exceeds a configurable threshold
- inspect the contents of archive files (such as `.zip` or `.rar`)
- block archive files whose contents are encrypted, nested beyond a specified maximum archive depth, or otherwise uninspectable

File Rule Components

Table 120: File Rule Components

File Rule Component	Description
application protocol	The system can detect and inspect files transmitted via FTP, HTTP, SMTP, IMAP, POP3, and NetBIOS-ssn (SMB). **Any**, the default, detects files in HTTP, SMTP, IMAP, POP3, FTP, and NetBIOS-ssn (SMB) traffic. To improve performance, you can restrict file detection to only one of those application protocols on a per-file rule basis.
direction of transfer	You can inspect incoming FTP, HTTP, IMAP, POP3, and NetBIOS-ssn (SMB) traffic for downloaded files; you can inspect outgoing FTP, HTTP, SMTP, and NetBIOS-ssn (SMB) traffic for uploaded files. **Tip** Use **Any** to detect files over multiple application protocols, regardless of whether users are sending or receiving.

File Rule Component	Description
file categories and types	The system can detect various types of files. These file types are grouped into basic categories, including multimedia (swf, mp3), executables (exe, torrent), and PDFs. You can configure file rules that detect individual file types, or on entire categories of file types. For example, you could block all multimedia files, or just ShockWave Flash (swf) files. Or, you could configure the system to alert you when a user downloads a BitTorrent (torrent) file. Note that executables include file types that can run macros and scripts, since these can contain malware. For a list of file types the system can inspect, select **Policies** > **Access Control heading** > **Malware & File** , create a temporary new file policy, then click **Add Rule**. Select a file type category and the file types that the system can inspect appear in the **File Types** list. **Note** Frequently triggered file rules can affect system performance. For example, detecting multimedia files in HTTP traffic (YouTube, for example, transmits significant Flash content) could generate an overwhelming number of events.
file rule action	A file rule's action determines how the system handles traffic that matches the conditions of the rule. Depending on the selected action, you can configure whether the system stores the file or performs Spero, local malware, or dynamic analysis on a file. If you select a Block action, you can also configure whether the system also resets the blocked connection. For descriptions of these actions and options, see File Rule Actions, on page 2234. File rules are evaluated in rule-action, not numerical, order. For details, see File Rule Actions: Evaluation Order, on page 2241.

File Rule Actions

File rules give you granular control over which file types you want to log, block, or scan for malware. Each file rule has an associated action that determines how the system handles traffic that matches the conditions of the rule. To be effective, a file policy must contain one or more rules. You can use separate rules within a file policy to take different actions for different file types, application protocols, or directions of transfer.

File Rule Actions

- *Detect Files* rules allow you to log the detection of specific file types to the database, while still allowing their transmission.
- *Block Files* rules allow you to block specific file types. You can configure options to reset the connection when a file transfer is blocked, and store captured files to the managed device.
- *Malware Cloud Lookup* rules allow you to obtain and log the disposition of files traversing your network, while still allowing their transmission.

- *Block Malware* rules allow you to calculate the SHA-256 hash value of specific file types, query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.

File Rule Action Options

Depending on the action you select, you have different options:

File Rule Action Option	Block Files capable?	Block Malware capable?	Detect Files capable?	Malware Cloud Lookup capable?
Spero Analysis* for MSEXE	no	yes, you can submit executable files	no	yes, you can submit executable files
Dynamic Analysis*	no	yes, you can submit executable files with Unknown file dispositions	no	yes, you can submit executable files with Unknown file dispositions
Capacity Handling	no	yes	no	yes
Local Malware Analysis*	no	yes	no	yes
Reset Connection	yes (recommended)	yes (recommended)	no	no
Store files	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select

* For complete information about these options, see Malware Protection Options (in File Rule Actions), on page 2235 and its subtopics.

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Malware Protection Options (in File Rule Actions)

The system applies several methods of file inspection and analysis to determine whether a file contains malware.

Depending on the options you enable in a file rule, the system inspects files using the following tools, in order:

1. Spero Analysis, on page 2237 and AMP Cloud Lookup, on page 2238
2. Local Malware Analysis, on page 2238

3. Dynamic Analysis, on page 2238

For a comparison of these tools, see Comparison of Malware Protection Options, on page 2236.

(You can also, if you choose, block all files based on their file type. For more information, see Block All Files by Type, on page 2241.)

See also information about Cisco's Secure Endpoint product at (Optional) Malware Protection with Secure Endpoint, on page 2245 and subtopics.

Comparison of Malware Protection Options

The following table details the benefits and drawbacks of each type of file analysis, as well as the way each malware protection method determines a file's disposition.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis	Structural analysis of executable files, submits Spero signature to the AMP Cloud for analysis	Less thorough than local malware analysis or dynamic analysis, only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.
Local malware analysis	Consumes fewer resources than dynamic analysis, and returns results more quickly, especially if the detected malware is common	Less thorough results than dynamic analysis	Disposition changes from Unknown to Malware only on positive identification of malware.
Dynamic analysis	Thorough analysis of unknown files using Secure Malware Analytics	Eligible files are uploaded to the public cloud or an on-premises appliance. It takes some time to complete analysis	Threat score determines maliciousness of a file. Disposition can be based on the threat score threshold configured in the file policy.
Spero analysis and local malware analysis	Consumes fewer resources than configuring local malware analysis and dynamic analysis, while still using AMP cloud resources to identify malware	Less thorough than dynamic analysis, Spero analysis only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis and dynamic analysis	Uses full capabilities of AMP cloud in submitting files and Spero signatures	Results obtained less quickly than if using local malware analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes based on configured threat score threshold in the file policy, and from Unknown to Malware if the Spero analysis identifies malware.
Local malware analysis and dynamic analysis	Thorough results in using both types of file analysis	Consumes more resources than either alone	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if local malware analysis identifies malware, or based on configured threat score threshold in the file policy.
Spero analysis, local malware analysis and dynamic analysis	Most thorough results	Consumes most resources in running all three types of file analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if Spero analysis or local malware analysis identifies malware, or based on configured threat score threshold in the file policy.
(Block transmission of all files of a specified file type)	Does not require a Malware Defense license (This option is not technically a malware protection option.)	Legitimate files will also be blocked	(No analysis is performed.)

Note Preclassification does not itself determine a file's disposition; it is merely one of the factors that determine whether a file is eligible for Dynamic Analysis.

Spero Analysis

Spero analysis examines structural characteristics such as metadata and header information in executable files. After generating a Spero signature based on this information, if the file is an eligible executable file, the device submits it to the Spero heuristic engine in the AMP cloud. Based on the Spero signature, the Spero engine determines whether the file is malware. You can also configure rules to submit files for Spero analysis without also submitting them to the AMP cloud.

Note that you cannot manually submit files for Spero analysis.

AMP Cloud Lookup

For files that are eligible for assessment using Advanced Malware Protection, the Firewall Management Center performs a *malware cloud lookup*, querying the AMP cloud for the file's disposition based on its SHA-256 hash value.

To improve performance, the system caches dispositions returned by the cloud and uses the cached disposition for known files rather than querying the AMP cloud. For more information about this cache, see Cached Disposition Longevity, on page 2238.

Local Malware Analysis

Local malware analysis allows a managed device to locally inspect executables, PDFs, office documents, and other types of files for the most common types of malware, using a detection rule set provided by the Talos Intelligence Group. Because local analysis does not query the AMP cloud, and does not run the file, local malware analysis saves time and system resources.

If the system identifies malware through local malware analysis, it updates the existing file disposition from Unknown to Malware. The system then generates a new malware event. If the system does not identify malware, it does not update the file disposition from Unknown to Clean. After the system runs local malware analysis, it caches file information such as SHA-256 hash value, timestamp, and disposition, so that if detected again within a certain period of time, the system can identify malware without additional analysis. For more information about the cache, see Cached Disposition Longevity, on page 2238.

Local malware analysis does not require establishing communications with the Secure Malware Analytics Cloud. However, you must configure communications with the cloud to submit files for dynamic analysis, and to download updates to the local malware analysis ruleset.

Cached Disposition Longevity

Dispositions returned from an AMP cloud query, associated threat scores, and dispositions assigned by local malware analysis, have a time-to-live (TTL) value. After a disposition has been held for the duration specified in the TTL value without update, the system purges the cached information. Dispositions and associated threat scores have the following TTL values:

- Clean — 4 hours
- Unknown — 1 hour
- Malware — 1 hour

If a query against the cache identifies a cached disposition that timed out, the system re-queries the local malware analysis database and the AMP cloud for a new disposition.

Dynamic Analysis

You can configure your file policy to automatically submit files for dynamic analysis using Secure Malware Analytics (formerly Threat Grid), Cisco’s file analysis and threat intelligence platform.

Devices submit eligible files to Secure Malware Analytics (either the public cloud or to an on-premises appliance, whichever you have specified) regardless of whether the device stores the file.

Secure Malware Analytics runs the file in a sandbox environment, analyzes the file's behavior to determine whether the file is malicious, and returns a threat score that indicates the likelihood that a file contains malware. From the threat score, you can view a dynamic analysis summary report with the reasons for the assigned

threat score. You can also look in Secure Malware Analytics to view detailed reports for files that your organization submitted, as well as scrubbed reports with limited data for files that your organization did not submit.

For more information about Cisco Secure Malware Analytics, see https://www.cisco.com/c/en/us/products/security/threat-grid/index.html

To configure your system to perform dynamic analysis, see the topics under Dynamic Analysis Connections, on page 2224.

Which Files Are Eligible for Dynamic Analysis?

A file's eligibility for dynamic analysis depends on:

- the file type
- the file size
- the file rule's action

Additionally:

- The system submits only files that match the file rules you configure.
- The file must have a malware cloud lookup disposition of Unknown or Unavailable at the time the file is sent for analysis.
- The system must preclassify the file as potential malware.

Dynamic Analysis and Capacity Handling

Capacity handling allows you to temporarily store files that are otherwise eligible for dynamic analysis if the system is temporarily unable to submit files to the cloud, either because the device cannot communicate with the cloud or because the maximum number of submissions has been reached. The system submits the stored files when the hindering condition has passed.

Some devices can store files on the device hard drive or in a malware storage pack. See also Malware Storage Pack, on page 2240.

Captured Files and File Storage

The file storage feature allows you to capture selected files detected in traffic, and automatically store a copy of the file temporarily to a device’s hard drive, or, if installed, to the malware storage pack.

After your device captures the files, you can:

- Store captured files on the device’s hard drive for later analysis.
- Download the stored file to a local computer for further manual analysis or archival purposes.
- Manually submit eligible captured files for AMP cloud lookup or dynamic analysis.

Note that once a device stores a file, it will not re-capture it if the file is detected in the future and the device still has that file stored.

Note When a file is detected for the first time on your network, you can generate a file event that represents the file's detection. However, if your file rule performs a malware cloud lookup, the system requires additional time to query the AMP cloud and return a disposition. Due to this delay, the system cannot store this file until the second time it is seen on your network, and the system can immediately determine the file's disposition.

Whether the system captures or stores a file, you can:

- Review information about the captured file from Analysis > Files > Captured Files, including whether the file was stored or submitted for dynamic analysis, file disposition, and threat score, allowing you to quickly review possible malware threats detected on your network.
- View the file's trajectory to determine how it traversed your network and which hosts have a copy.
- Add the file to the clean list or custom detection list to always treat the file as if it had a clean or malware disposition on future detection.

You configure file rules in a file policy to capture and store files of a specific type, or with a particular file disposition, if available. After you associate the file policy with an access control policy and deploy it to your devices, matching files in traffic are captured and stored. You can also limit the minimum and maximum file sizes to store.

Stored files are not included in system backups.

You can view captured file information under Analysis > Files > Captured Files, and download a copy for offline analysis.

Malware Storage Pack

Based on your file policy configuration, your device may store a substantial amount of file data to the hard drive. You can install a malware storage pack in the device; the system stores files to the malware storage pack, allowing more room on the primary hard drive to store events and configuration files. The system periodically deletes older files. If the device's primary hard drive does not have enough available space, and does not have an installed malware storage pack, you cannot store files.

Caution Do not attempt to install a hard drive that was not supplied by Cisco in your device. Installing an unsupported hard drive may damage the device. Malware storage pack kits are available for purchase **only** from Cisco. Contact Support if you require assistance with the malware storage pack.

Without a malware storage pack installed, when you configure a device to store files, it allocates a set portion of the primary hard drive's space to captured file storage. If you configure capacity handling to temporarily store files for dynamic analysis, the system uses the same hard drive allocation to store these files until it can resubmit them to the cloud.

When you install a malware storage pack in a device and configure file storage or capacity handling, the device allocates the entire malware storage pack for storing these files. The device cannot store any other information on the malware storage pack.

When the allocated space for captured file storage fills to capacity, the system deletes the oldest stored files until the allocated space reaches a system-defined threshold. Based on the number of files stored, you may see a substantial drop in disk usage after the system deletes files.

If a device has already stored files when you install a malware storage pack, the next time you restart the device, any captured files or capacity handling files stored on the primary hard drive are moved to the malware storage pack. Any future files the device stores are stored to the malware storage pack.

For more information on using MSP on the Firepower devices, see the Firepower Hardware Installation Guide for your device.

Block All Files by Type

If your organization wants to block not only the transmission of malware files, but all files of a specific type, regardless of whether the files contain malware, you can do so.

File control is supported for all file types where the system can detect malware, plus many additional file types. These file types are grouped into basic categories, such as multimedia (swf, mp3), executables (exe, torrent), and PDFs.

Blocking all files based on their type is not technically a malware protection feature; it does not require a Malware Defense license and does not query the AMP cloud.

File Rule Actions: Evaluation Order

A file policy will likely contain multiple rules with different actions for different situations. If more than one rule can apply to a particular situation, the evaluation order described in this topic applies. In general, simple blocking takes precedence over malware inspection and blocking, which takes precedence over simple detection and logging.

The order of precedence of file-rule actions is:

- *Block Files*
- *Block Malware*
- *Malware Cloud Lookup*
- *Detect Files*

If configured, TID also impacts action prioritization. For more information, see Threat Intelligence Director-Firewall Management Center Action Prioritization, on page 2757.

Creating File Rules

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Before you begin

If you are configuring rules for malware protection, see Configure File Policies, on page 2216.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Click the edit icon to modify an existing file policy.

Step 3 In the file policy editor, click **Add Rule**.

Step 4 Select an **Application Protocol** and **Direction of Transfer** as described in File Rule Components, on page 2233.

Step 5 Select one or more **File Types**.

The file types you see depend on the selected application protocol, direction of transfer, and action.

You can filter the list of file types in the following ways:

- Select one or more **File Type Categories**, then click **All types in selected Categories.**
- Search for a file type by its name or description. For example, type **`Windows`** in the **Search name and description** field to display a list of Microsoft Windows-specific files.

Tip
Hover your pointer over a file type to view its description.

Step 6 Select a file rule **Action** as described in File Rule Actions, on page 2234, with consideration for File Rule Actions: Evaluation Order, on page 2241.

The actions available to you depend on the licenses you have installed. See License Requirements for File and Malware Policies, on page 2211.

Step 7 Depending on the action you selected, configure options:

- reset the connection after blocking the file
- store files that match the rule
- enable Spero analysis*
- enable local malware analysis*
- enable dynamic analysis* and capacity handling

* For information about these options, see File Rule Actions, on page 2234 and Malware Protection Options (in File Rule Actions), on page 2235 and its subtopics.

Step 8 Click **Add.**

Step 9 Click **Save** to save the policy.

What to do next

- If you are configuring policies for malware protection, return to Configure File Policies, on page 2216.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Access Control Rule Logging for Malware Protection

When the system detects a prohibited file (including malware) according to the settings in the file policy, it automatically logs an event to the Secure Firewall Management Center database. If you do not want to log file or malware events, you can disable this logging on a per-access-control-rule basis.

The system also logs the end of the associated connection to the Secure Firewall Management Center database, regardless of the logging configuration of the invoking access control rule.

Retrospective Disposition Changes

File dispositions can change. For example, as new information is discovered, the AMP cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse—that a malware-identified file is actually clean. When the disposition changes for a file you queried in the past week, the AMP cloud notifies the system so it can automatically take action the next time it detects that file being transmitted. A changed disposition is called a *retrospective* disposition.

File and Malware Inspection Performance and Storage Options

Increasing the file sizes can affect the performance of the system.

Table 121: Advanced Access Control File and malware defense Options

Field	Description	Guidelines and Restrictions
Limit the number of bytes inspected when doing file type detection	Specifies the number of bytes inspected when performing file type detection.	0 - 4294967295 (4GB) 0 removes the restriction. The default value is the maximum segment size of a TCP packet (1460 bytes). In most cases, the system can identify common file types using the first packet. To detect ISO files, enter a value greater than 36870.
Allow file if cloud lookup for Block Malware takes longer than (seconds)	Specifies how long the system will hold the last byte of a file that matches a **Block Malware** rule and that does not have a cached disposition, while malware cloud lookup occurs. If the time elapses without the system obtaining a disposition, the file passes. Dispositions of Unavailable are not cached.	0 - 30 seconds Do *not* set this option to 0 without contacting Support. Cisco recommends that you use the default value to avoid blocking traffic because of connection failures.
Do not calculate SHA-256 hash values for files larger than (in bytes)	Prevents the system from storing files larger than a certain size, performing a malware cloud lookup on the files, or blocking the files if added to the custom detection list.	0 - 4294967295 (4GB) 0 removes the restriction. This value must be greater than or equal to **Maximum file size to store (bytes)** and **Maximum file size for dynamic analysis testing (bytes)**.

Field	Description	Guidelines and Restrictions

Minimum file size for advanced file inspection and storage (bytes)	These settings specify:
	• The file size that the system can inspect using the following detectors:
	  • Spero analysis
	  • Sandboxing and preclassification
	  • Local malware analysis/ClamAV
	  • Archive inspection
	• The file size that the system can store using a file rule.
		0 - 10485760 (10MB)
		0 disables file storage.
		Must be less than or equal to **Maximum file size to store (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**.

Maximum file size for advanced file inspection and storage (bytes)		0 - 10485760 (10MB) 0 disables file storage. Must be greater than or equal to **Minimum file size to store (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than (in bytes)**.
Minimum file size for dynamic analysis testing (bytes)	Specifies the minimum file size the system can submit to the AMP cloud for dynamic analysis.	0 -10485760 (10MB) Must be less than or equal to **Maximum file size for dynamic analysis testing (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**. The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis. The system checks the AMP cloud for updates to the minimum file size you can submit (no more than once a day). If the new minimum size is larger than your current value, your current value is updated to the new minimum, and your policy is marked out-of-date.
Maximum file size for dynamic analysis testing (bytes)	Specifies the maximum file size the system can submit to the AMP cloud for dynamic analysis.	0 -10485760 (10MB) Must be greater than or equal to **Minimum file size for dynamic analysis testing (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than (in bytes)**. The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis. The system checks the AMP cloud for updates to the maximum file size you can submit (no more than once a day). If the new maximum size is smaller than your current value, your current value is updated to the new maximum, and your policy is marked out-of-date.

Tuning File and Malware Inspection Performance and Storage

You must be an Admin, Access Admin, or Network Admin user to perform this task.

Procedure

Step 1 In the access control policy editor, click **Advanced Settings**.

Step 2 Click **Edit** (✎) next to **Files and Malware Settings**.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Set any of the options described in File and Malware Inspection Performance and Storage Options, on page 2243.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

(Optional) Malware Protection with Secure Endpoint

Cisco's Secure Endpoint is a separate malware-protection product that can supplement malware protection provided by the system and be integrated with your Firepower deployment.

Secure Endpoint is Cisco’s enterprise-class Advanced Malware Protection solution that runs as a lightweight connector on individual users' *endpoints* (computers and mobile devices) to discover, understand, and block advanced malware outbreaks, advanced persistent threats, and targeted attacks.

Benefits of Secure Endpoint include:

- Configure custom malware detection policies and profiles for your entire organization, as well as perform flash and full scans on all your users’ files
- Perform malware analysis, including view heat maps, detailed file information, network file trajectory, and threat root causes
- Configure multiple aspects of outbreak control, including automatic quarantines, application blocking to stop non-quarantined executables from running, and exclusion lists
- Create custom protections, block execution of certain applications based on group policy, and create custom Allowed Applications lists
- Use the Secure Endpoint management console to help you mitigate the effect of malware. The management console provides a robust, flexible web interface where you control all aspects of your Secure Endpoint deployment and manage all phases of an outbreak.

For detailed information about Secure Endpoint, see:

- https://www.cisco.com/c/en/us/products/security/amp-for-endpoints/index.html.
- Online help in the Secure Endpoint management console.

- Secure Endpoint documentation available from: http://docs.amp.cisco.com.

Comparison of Malware Protection: Firepower vs. Secure Endpoint

Table 122: Advanced Malware Protection Differences by Detecting Product

Feature	Firepower Malware Protection (malware defense)	Secure Endpoint
File type detection and blocking method (file control)	In network traffic, using access control and file policies	Not supported
Malware detection and blocking method	In network traffic, using access control and file policies	On individual endpoints (end-user computers and mobile devices), using a connector that communicates with the AMP cloud
Network traffic inspected	Traffic passing through a managed device	None; connectors installed on endpoints directly inspect files
Malware intelligence data source	AMP cloud (public or private)	AMP cloud (public or private)
Malware detection robustness	Limited file types	All file types
Malware analysis choices	Firewall Management Center-based, plus analysis in the AMP cloud	Firewall Management Center-based, plus additional options on the Secure Endpoint management console
Malware mitigation	Malware blocking in network traffic, Firewall Management Center-initiated remediations	Secure Endpoint-based quarantine and outbreak control options, Firewall Management Center-initiated remediations
Events generated	File events, captured files, malware events, and retrospective malware events	Malware events
Information in malware events	Basic malware event information, plus connection data (IP address, port, and application protocol)	In-depth malware event information; no connection data
Network file trajectory	Firewall Management Center-based	Firewall Management Center and the Secure Endpoint management console each have a network file trajectory. Both are useful.
Required licenses or subscriptions	Licenses required to perform file control and malware defense	Secure Endpoint subscription. No license is required to bring Secure Endpoint data into Firewall Management Center.

About Integrating Firepower with Secure Endpoint

If your organization has deployed Secure Endpoint, you can optionally integrate that product with your Firepower deployment.

Integration with Secure Endpoint does not require a dedicated Firepower license.

Benefits of Integrating Firepower and Secure Endpoint

Integrating your Secure Endpoint deployment with your system offers the following benefits:

- Centralized Blocked Applications and Allowed Applications lists configured in Secure Endpoint can determine verdicts for file SHAs sent from Firepower to the AMP cloud for disposition.

  See Centralized File Lists from Secure Endpoint, on page 2231.

- The system can import malware events detected by Secure Endpoint into Secure Firewall Management Center so you can manage these events along with malware events generated by the system. Imported data for these events includes scans, malware detections, quarantines, blocked executions, and cloud recalls, as well as indications of compromise (IOCs) that Firewall Management Center displays for hosts that it monitors.

  For more information, see *Malware Event Analysis with Secure Endpoint* in the Cisco Secure Firewall Management Center Administration Guide .

- You can view file trajectory and other details in the Secure Endpoint console.

  For details, see *Work with Event Data in the Secure Endpoint Console* in the Cisco Secure Firewall Management Center Administration Guide .

Important If you use a Cisco AMP Private Cloud, see limitations at Secure Endpoint and AMP Private Cloud, on page 2247.

Secure Endpoint and AMP Private Cloud

If you configure a Cisco AMP private cloud to collect Secure Endpoint data on your network, all Secure Endpoint connectors send data to the private cloud, which forwards that data to the Secure Firewall Management Center. The private cloud does not share any of your endpoint data over an external connection.

If your organization has deployed an AMP private cloud, all connections to the AMP cloud funnel through the private cloud, which acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes importing Secure Endpoint data. The private cloud does not share any of your endpoint data over an external connection.

The following integration features are not available if you use an AMP private cloud:

- Use of Blocked Applications and Allowed Applications lists configured in Secure Endpoint. (These lists are used to block or allow files.)
- Visibility in Secure Endpoint of malware events generated from Firepower.

You can configure multiple private clouds to support the capacity you require.

Integrate Firepower and Secure Endpoint

If your organization has deployed Cisco's Secure Endpoint product, you can integrate that application with Firepower to achieve the benefits described in Benefits of Integrating Firepower and Secure Endpoint, on page 2247.

When you integrate with Secure Endpoint, you must configure the Secure Endpoint connection even if you already have malware defense (AMP for Firepower) connections configured. You can configure multiple Secure Endpoint cloud connections.

Note Secure Endpoint connections that have not registered successfully do not affect malware defense.

Before you begin

- You must be an Admin user to perform this task.
- If your deployment uses Cisco AMP Private Cloud, see limitations at Secure Endpoint and AMP Private Cloud, on page 2247.
- Secure Endpoint must be set up and working properly on your network.
- The Firewall Management Center must have internet access.
- Make sure your Firewall Management Center and Secure Endpoint can communicate with each other. See the topics under *Security, Internet Access, and Communication Ports* in the Cisco Secure Firewall Management Center Administration Guide.
- If you are connecting to the AMP cloud after either reimaging or restoring your Firewall Management Center from backup, use the Secure Endpoint management console to remove the previous connection.
- You will need your Secure Endpoint credentials to log in to the Secure Endpoint console during this procedure.

Procedure

Step 1 Choose **Integration** > **AMP** > **AMP Management**.

Step 2 Click **Add AMP Cloud Connection**.

Step 3 From the **Cloud Name** drop-down list, choose the cloud you want to use.

- The AMP cloud closest to the geographical location of your Firewall Management Center.

  APJC is Asia/Pacific/Japan/China.

- For AMP private cloud (AMPv), choose **Private Cloud** and proceed as described in Cisco AMP Private Cloud, on page 2221.

Step 4 If you want to use this cloud for both malware defense and Secure Endpoint, select the **Use for AMP for Firepower** check box.

If you configured a different cloud to handle malware defense (AMP for Firepower) communications, you can clear this check box; if this is your only AMP cloud connection, you cannot.

Step 5 Click **Register**.

A **Spinning state** ( ) icon indicates that a connection is pending, for example, after you configure a connection on the Firewall Management Center, but before you authorize it using the Secure Endpoint management

console. A **Denied** ( ) icon indicates that the cloud denied the connection or the connection failed for another reason.

Step 6 Confirm that you want to continue to the Secure Endpoint management console, then log into the management console.

Step 7 Using the management console, authorize the AMP cloud to send Secure Endpoint data to Firewall Management Center.

Step 8 If you want to restrict the data that the Firewall Management Center receives, select specific groups within your organization for which you want to receive information.

By default, the AMP cloud sends data for all groups. To manage groups, choose **Management** > **Groups** on the Secure Endpoint management console. For detailed information, see the management console online help.

Step 9 Click **Allow** to enable the connection and start the transfer of data.

Clicking **Deny** returns you to the Firewall Management Center, where the connection is marked as denied. If you navigate away from the Applications page on the Secure Endpoint management console, and neither deny nor allow the connection, the connection is marked as pending on the Firewall Management Center's web interface. The health monitor does **not** alert you of a failed connection in either of these situations. If you want to connect to the AMP cloud later, delete the failed or pending connection, then recreate it.

Incomplete registration of the Secure Endpoint connection does not disable the malware defense connection.

Step 10 To verify that the connection is correctly configured:

a) On the **Integration** > **AMP** > **AMP Management** page, click the Cloud Name that includes Secure Endpoint in the **Cisco AMP Solution Type** column.
b) In the Secure Endpoint console window that displays, choose **Accounts > Applications**.
c) Verify that your Firewall Management Center is on the list.
d) In the Secure Endpoint console window, choose **Manage > Computers**.
e) Verify that your Firewall Management Center is on the list.

What to do next

- In the Secure Endpoint console window, configure settings as needed. For example, define group membership for your management center and assign policies. For information, see the Secure Endpoint online help or other documentation.
- In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.
- The default health policy warns you if the Firewall Management Center cannot connect to the Secure Endpoint portal after an initial successful connection, or if the connection is deregistered using the AMP portal.

  Verify that the **Secure Endpoint Status** monitor is enabled under **System > Health > Policy**.

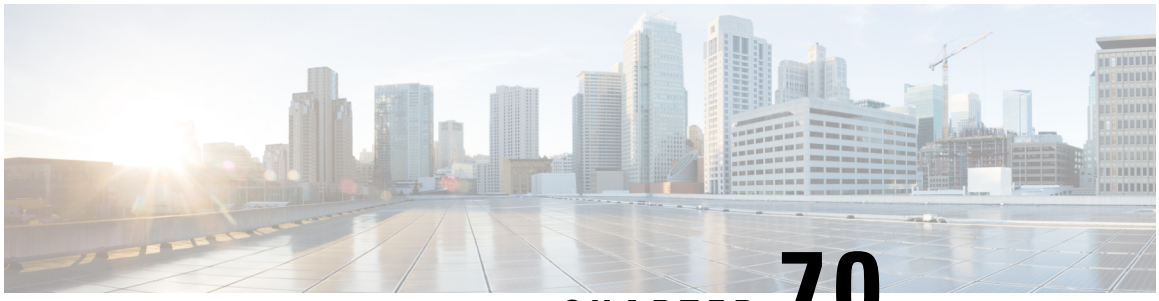
History for Network Malware Protection and File Policies

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Communication with AMP cloud	7.0	Any	Legacy port 32137 is no longer supported for communicating with the AMP public or private cloud. New/Modified screens: On the **System** > **Integration** > **Cloud Services** page, the **Use Legacy Port 32137 for AMP for Networks** option is no longer available.
Chapter restructure	Changes were made in 6.4 timeframe, but will appear in any version that is republished	Any	Restructured this chapter's content to reduce confusion. Some content was moved to or from the chapter for *File/Malware Events and Network File Trajectory* in the Cisco Secure Firewall Management Center Administration Guide .
Moved URL Filtering information to the new URL Filtering chapter	6.3	Any	Moved information about configuring cloud communications for URL Filtering to the new URL Filtering chapter. Made related changes to the structure of the Cisco CSI topics in the chapter.

PART XI

Encrypted Traffic Handling

- Traffic Decryption Overview, on page 2253
- Decryption Policies, on page 2279
- Decryption Rules, on page 2303
- Decryption Rules and Policy Example, on page 2351



CHAPTER 70

Traffic Decryption Overview

The following topics provide an overview of Transport Layer Security/Secure Sockets Layer (TLS/SSL) inspection, discuss the prerequisites for TLS/SSL inspection configuration, and detail deployment scenarios.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?

- Traffic Decryption Explained, on page 2253
- TLS/SSL Handshake Processing, on page 2255
- Decryption Rule and Policy Basics, on page 2260
- TLS Crypto Acceleration, on page 2268
- DTLS Crypto Acceleration, on page 2271
- How to Configure Decryption Policies and Rules, on page 2272
- History for Decryption Policy, on page 2273

Traffic Decryption Explained

Most traffic on the internet is encrypted and in most cases, you might choose not to decrypt it. You can glean some information from encrypted traffic and you can also block it from your network if desired.

Your choices are:

- Decrypt the traffic and subject it to the full array of deep inspection:
  - Advanced Malware Protection
  - Security intelligence
  - Threat Intelligence Director
  - Application detectors
  - URL and category filtering

- Leave the traffic encrypted and set up your access control and decryption policy to look for and potentially block:
  - Old protocol versions (such as Secure Sockets Layer)
  - Unsecure cipher suites
  - Applications with high risk and low business relevance
  - Untrusted issuer Distinguished Names

Access control policy

An access control policy is the main configuration that invokes subpolicies and other configurations, including a decryption policy. If you associate a decryption policy with access control, the system uses that decryption policy to handle encrypted sessions before it evaluates the sessions with access control rules. If you do not configure TLS/SSL inspection, or your devices do not support it, access control rules handle all encrypted traffic.

Access control rules also handle encrypted traffic when your TLS/SSL inspection configuration allows the traffic to pass. However, some access control rule conditions require unencrypted traffic, so encrypted traffic might match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improves performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Among the protocols we decrypt

Among the protocols we decrypt are the following:

- TLS versions up to 1.3 (if Snort 3 is enabled)
- DNS over HTTPS
- DNS over TLS (RFC 7858)
- FTPS, SMTPS, IMAPS, POP3S

Notes

Decryption rules require processing overhead that can impact performance. Before you decide to decrypt traffic, see When to Decrypt Traffic, When Not to Decrypt, on page 2261.

As long as your managed devices have Snort 3 enabled, the system supports decrypting TLS 1.3 traffic. You can enable TLS 1.3 decryption in an decryption policy's advanced options; for more information, see Decryption Policy Advanced Options, on page 2298.

The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign**, or **Decrypt - Known Key** decryption rule actions.

If you set the value of TCP maximum segment size (MSS) using FlexConfig, the observed MSS could be less than your setting. For more information, see About the TCP MSS, on page 878.

TLS/SSL Handshake Processing, on page 2255
Decryption Rule and Policy Basics, on page 2260

TLS/SSL Handshake Processing

In this documentation, the term *TLS/SSL handshake* represents the two-way handshake that initiates encrypted sessions in both the SSL protocol and its successor protocol, TLS.

In an inline deployment, the system processes the TLS/SSL handshake, potentially modifying the ClientHello message and acting as a TCP proxy server for the session.

The following figure shows an inline deployment.

After the client establishes a TCP connection with the server (after it successfully completes the TCP three-way handshake), the managed device monitors the TCP session for any attempt to initiate an encrypted session. The TLS/SSL handshake establishes an encrypted session using the exchange of specialized packets between client and server. In the SSL and TLS protocols, these specialized packets are called *handshake messages*. The handshake messages communicate which encryption attributes both the client and server support:

- ClientHello—The client specifies multiple supported values for each encryption attribute.
- ServerHello—The server specifies a single supported value for each encryption attribute, and the ServerHello response determines which encryption method the system uses during the secure session.

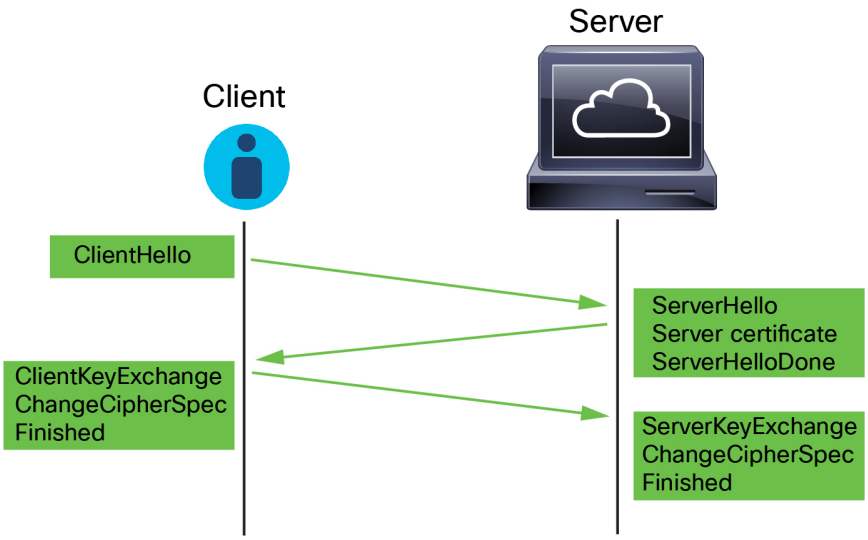
After a TLS/SSL handshake completes, the managed device caches encrypted session data, which allows session resumption without requiring the full handshake. The managed device also caches server certificate data, which allows faster handshake processing in subsequent sessions that use the same certificate.

ClientHello Message Handling

The client sends the ClientHello message to the server that acts as the packet destination if a secure connection can be established. The client sends the message to initiate the TLS/SSL handshake or in response to a ServerHello message from the destination server.

Overview

The following figure shows an example. Also see RFC 8446, sec. 4 . You can also consult a resource such as What Happens in a TLS Handshake? at cloudflare.com.



The process can be summarized as follows:

1. ClientHello initiates the process.

   The ClientHello message contains the Server Name Indication (SNI), which has the server's fully qualified domain name.

2. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server certificate message immediately follows the ServerHello message.

   The server certificate contains the Subject Alternative Name (SAN), which can have fully qualified domain names and IP addresses. For more information about the SAN, see Distinguished Name, on page 1382.

3. When the managed device receives these messages, it attempts to match them with decryption rules configured on the system. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on decryption rules' Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

The entire process is encrypted.

Data exchange

If you configure TLS/SSL decryption, when a managed device receives a ClientHello message, the system attempts to match the message to decryption rules that have the **Decrypt - Resign**, or **Decrypt - Known Key** action. The match relies on data from the ClientHello message and from cached server certificate data. Possible data includes:

Table 123: Data Availability for Decryption Rule Conditions

Decryption Rule Condition	Data Present In
Zones	ClientHello
Networks	ClientHello

Decryption Rule Condition	Data Present In
VLAN Tags	ClientHello
Ports	ClientHello
Users	ClientHello
Applications	ClientHello (Server Name Indicator extension)
Categories	ClientHello (Server Name Indicator extension)
Certificate	Server certificate (potentially cached)
Distinguished Names	Server certificate (potentially cached)
Certificate Status	Server certificate (potentially cached)
Cipher Suites	ServerHello
Versions	ServerHello

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

ClientHello modifications

If the ClientHello message matches a **Decrypt - Resign**, or **Decrypt - Known Key** rule, the system modifies the ClientHello message as follows:

- (TLS 1.2 only; TLS 1.3 does not support compression.) Compression methods—Strips the `compression_methods` element, which specifies the compression methods the client supports. The system cannot decrypt compressed sessions.
- Cipher suites—Strips cipher suites from the `cipher_suites` element if the system does not support them. If the system does not support any of the specified cipher suites, the system transmits the original, unmodified element. This modification reduces the Unknown Cipher Suite and Unsupported Cipher Suite types of undecryptable traffic.
- Session identifiers—Strips any value from the `Session Identifier` element and the SessionTicket extension (RFC 5077, sec 3.2) that does not match cached session data. If a ClientHello value matches cached data, an interrupted session can resume without the client and server performing the full TLS/SSL handshake. This modification increases the chances of session resumption and reduces the Session Not Cached type of undecryptable traffic.
- Elliptic curves—Strips elliptic curves from the Supported Elliptic Curves extension if the system does not support them. If the system does not support any of the specified elliptic curves, the managed device removes the extension and strips any related cipher suites from the `cipher_suites` element.
- ALPN extensions—Strips any value from the Application-Layer Protocol Negotiation (ALPN) extension that is unsupported in the system (for example, the HTTP/2 protocol).

- Other Extensions—Strips the Next Protocol Negotiation (NPN) and TLS Channel IDs extensions.

  Decryption rules with a **Decrypt - Resign**, or **Decrypt - Known Key** action now natively support the Extended Master Secret (EMS) extension during ClientHello negotiation, enabling more secure communications. The EMS extension is defined by RFC 7627.

After the system modifies the ClientHello message, it determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server.

If the ClientHello message does *not* match a **Decrypt - Resign**, **Decrypt - Replace Cert** or **Decrypt - Known Key** rule, the system does not modify the message. It then determines whether the message passes access control evaluation (which can include deep inspection). If the message passes inspection, the system transmits it to the destination server.

ClientHello is *not* modified if traffic matches a **Monitor** rule condition.

Man-in-the-middle

Direct communication between the client and server is no longer possible during the TLS/SSL handshake, because after message modification the Message Authentication Codes (MACs) computed by the client and server no longer match. For all subsequent handshake messages (and for the encrypted session once established), the managed device acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. As a result, each session contains different cryptographic session details.

Note The cipher suites that the system can decrypt are frequently updated and do not correspond directly to the cipher suites you can use in decryption rule conditions. For the current list of decryptable cipher suites, contact Cisco TAC.

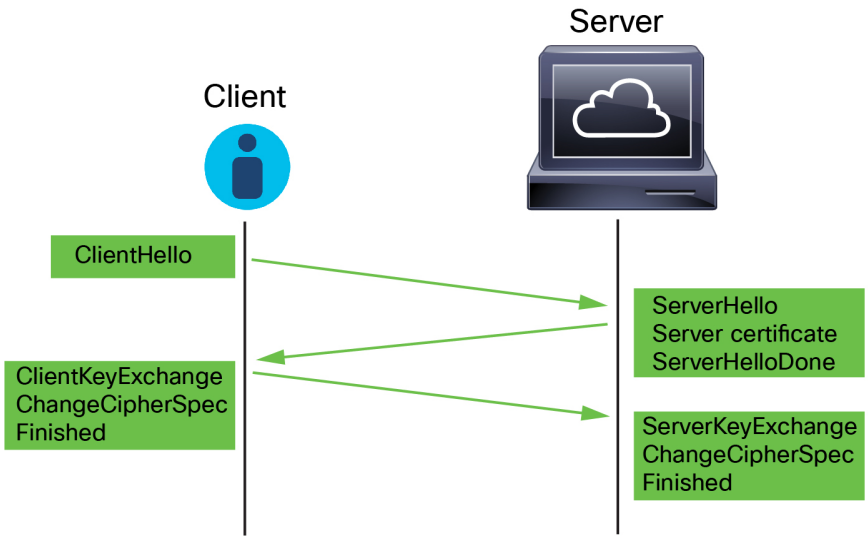
Default Handling Options for Undecryptable Traffic, on page 2296
ServerHello and Server Certificate Message Handling, on page 2258

ServerHello and Server Certificate Message Handling

Overview

The following figure shows an example. Also see RFC 8446, sec. 4 . You can also consult a resource such as What Happens in a TLS Handshake? at cloudflare.com.



The process can be summarized as follows:

1. ClientHello initiates the process.

   The ClientHello message contains the Server Name Indication (SNI), which has the server's fully qualified domain name.

2. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server certificate message immediately follows the ServerHello message.

   The server certificate contains the Subject Alternative Name (SAN), which can have fully qualified domain names and IP addresses. For more information about the SAN, see Distinguished Name, on page 1382.

3. When the managed device receives these messages, it attempts to match them with decryption rules configured on the system. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on decryption rules' Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

The entire process is encrypted.

Decryption Rule actions

If the messages do not match any decryption rules, the managed device performs the Decryption Policy Default Actions, on page 2295.

If the messages match a rule that belongs to a decryption policy associated with an access control policy, the managed device continues as appropriate:

Action: Monitor
The TLS/SSL handshake continues to completion. The managed device tracks and logs traffic but does not decrypt it.

Action: Block or Block with Reset
The managed device blocks the TLS/SSL session and, if configured, resets the TCP connection.

Action: Do Not Decrypt

The TLS/SSL handshake continues to completion. The managed device does not decrypt the application data exchanged during the TLS/SSL session.

Action: Decrypt - Known Key

The managed device attempts to match the server certificate data to an Internal Certificate object previously imported into the Secure Firewall Management Center . Because you cannot generate an Internal Certificate object, and you must possess its private key, we assume you own the server on which you're using known key decryption.

If the certificate matches a known certificate, the TLS/SSL handshake continues to completion. The managed device uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

If the server changes its certificate between the initial connection with the client and subsequent connections, you must import the new server certificate in the Secure Firewall Management Center for future connections to be decrypted.

Action: Decrypt - Resign

The managed device processes the server certificate message and re-signs the server certificate with the previously imported or generated certificate authority (CA). The TLS/SSL handshake continues to completion. The managed device then uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

Note The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign**, or **Decrypt - Known Key** decryption rule actions.

ClientHello Message Handling, on page 2255

Decryption Rule and Policy Basics

This section discusses information you should keep in mind when creating your decryption policies and rules.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?

The Case for Decryption

Traffic that is encrypted when it passes through the system can be allowed or blocked, but it *cannot* be subjected to deep inspection or the full range of policy enforcement (such as intrusion prevention).

All encrypted connections:

- Are sent through the decryption policy to determine if they should be decrypted or blocked.

  You can also configure decryption rules to block encrypted traffic of types you know you do not want on your network, such as traffic that uses the nonsecure SSL protocol or traffic with an expired or invalid certificate.

- If unblocked, whether or not decrypted, traffic goes through the access control policy for a final allow or block decision.

Only *decrypted* traffic takes advantage of the system's threat defense and policy enforcement features, including:

- Advanced Malware Protection
- Security intelligence
- Threat Intelligence Director
- Application detectors
- URL and category filtering

Keep in mind that decrypting and then re-encrypting traffic adds a processing load on the device, which can reduce overall system performance.

In summary:

- Encrypted traffic can be allowed or blocked by policy; encrypted traffic *cannot* be inspected
- Decrypted traffic is subject to threat defense and policy enforcement; decrypted traffic can be allowed or blocked by policy

Deep Inspection Using File and Intrusion Policies, on page 1728

When to Decrypt Traffic, When Not to Decrypt

This section provides guidelines on when you should decrypt traffic and when you should allow it to pass through the firewall encrypted.

When not to decrypt traffic

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information

- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

(Snort 3.) Decryption policy is *not* bypassed for any connections that match access control rules with actions of Trust, Block, or Block with Reset, unless the traffic is prefiltered. The encrypted traffic is first evaluated by decryption policy and then proceeds to the access control policy, where a final allow or block decision is made.

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- URL category and reputation
- Port
- User group

Decryption rules provide a **Do Not Decrypt** action for traffic you do not want to decrypt; for more information, see Decryption Rule Do Not Decrypt Action, on page 2335.

Note The related information links at the end of this topic explain how some aspects of rule evaluation work. Conditions such as URL and application filtering have limitations with respect to encrypted traffic. Make sure you understand those limitations.

For more information about using URL filtering in **Do Not Decrypt** rules, see Decryption Rule Do Not Decrypt Action, on page 2335.

When to decrypt traffic

All encrypted traffic must be decrypted to take advantage of the system's threat protection and policy enforcement features. If your managed device has sufficient memory and processing power to decrypt traffic, you should decrypt traffic that is not prohibited by law or regulation.

If you must decide what traffic to decrypt, base your decision on the risk of allowing the traffic on your network. The system provides a flexible framework for classifying traffic using rule conditions, which include URL reputation, cipher suite, protocol, and many other factors.

Decrypt and Resign (Outgoing Traffic)

This information applies only to rule-based decryption policies and rules.

The **Decrypt - Resign** decryption rule action enables the system to act as a man in the middle, intercepting, decrypting, and (if the traffic is allowed to pass) inspecting and re-encrypting it. The **Decrypt - Resign** rule action is used with outgoing traffic; that is, the destination server is outside your protected network.

The Firewall Threat Defense device negotiates with the client using an internal Certificate Authority (CA) object specified in the rule and builds a TLS/SSL tunnel between the client and the Firewall Threat Defense device. At the same time, the device connects to the destination web site and creates a TLS/SSL tunnel between the server and the Firewall Threat Defense device.

Thus, the client sees the CA certificate configured for the decryption rule instead of the certificate from the destination server. The client must trust the firewall's certificate to complete the connection. The Firewall Threat Defense device then performs decryption/re-encryption in both directions for traffic between the client and the destination server.

Prerequisite

To use the **Decrypt - Resign** rule action, you must create an internal CA object using a CA file and paired private key file. You can generate a CA and private key in the system if you don't already have them.

We simplify the process of configuring the **Decrypt - Resign** rule by automatically adding **Do Not Decrypt** rules to the decryption policy based on your choices for types of traffic to exempt from encryption, such as undecryptable applications. (Typically, these applications use certificate pinning so that decrypting the connection breaks the connection.) For more information, see Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281.

Note The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign**, or **Decrypt - Known Key** decryption rule actions.

Related Topics

Decryption Rule Decrypt Actions, on page 2337
External Certificate Objects, on page 1411

Known Key Decryption (Incoming Traffic)

This information applies only to rule-based decryption policies and rules.

The **Decrypt - Known Key** decryption rule action uses a server's private key to decrypt traffic. The **Decrypt - Known Key** rule action is used with incoming traffic; that is, the destination server is inside your protected network.

The main purpose of decrypting with a known key is to protect your servers from external attacks.

Prerequisite

To use the **Decrypt - Known Key** rule action, you must create an internal certificate object using the server's certificate file and paired private key file.

Note The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the Secure Firewall Management Center and use it for **Decrypt - Resign**, or **Decrypt - Known Key** decryption rule actions.

Other Decryption Rule Actions

This information applies only to rule-based decryption policies and rules.

The following sections discuss other decryption rule actions.

Related Topics

Decryption Rule Blocking Actions, on page 2336
Decryption Rule Monitor Action, on page 2334

Decryption Rule Components

This information applies only to rule-based decryption policies and rules.

Each decryption rule has the following components.

State

A rule can have either of two states: enabled or disabled. By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

Position

Rules in a decryption policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number.

Conditions

Conditions specify the specific traffic the rule handles. Conditions can match traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate subject or issuer, certificate status, cipher suite, or encryption protocol version. The use of conditions can depend on target device licenses.

Action

A rule's action determines how the system handles matching traffic. You can monitor, allow, block, or decrypt encrypted matching traffic. Decrypted traffic is subject to further inspection. Note that the system does *not* inspect blocked encrypted traffic.

Logging

A rule's logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. You can log a connection when the system blocks an encrypted session or allows it to pass without decryption, according to the settings in an decryption policy. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. You can log connections to the Secure Firewall Management Center database, as well as to the system log (syslog) or to an SNMP trap server.

For more information about logging, see Best Practices for Connection Logging in the Cisco Secure Firewall Management Center Administration Guide.

Tip Properly creating and ordering decryption rules is a complex task. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the decryption policy interface has a robust warning and error feedback system for rules.

Categories

For information about using decryption rule categories (such as Applications, Category, and Cert Status), see Decryption Rule Conditions, on page 2316.

Decryption Rule Order Evaluation

This information applies only to rule-based decryption policies and rules.

When you create a decryption rule in a decryption policy, you specify its position using the **Insert** list in the rule editor. Decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules. For more information about the OSI model, see this Wikipedia article.

Tip Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

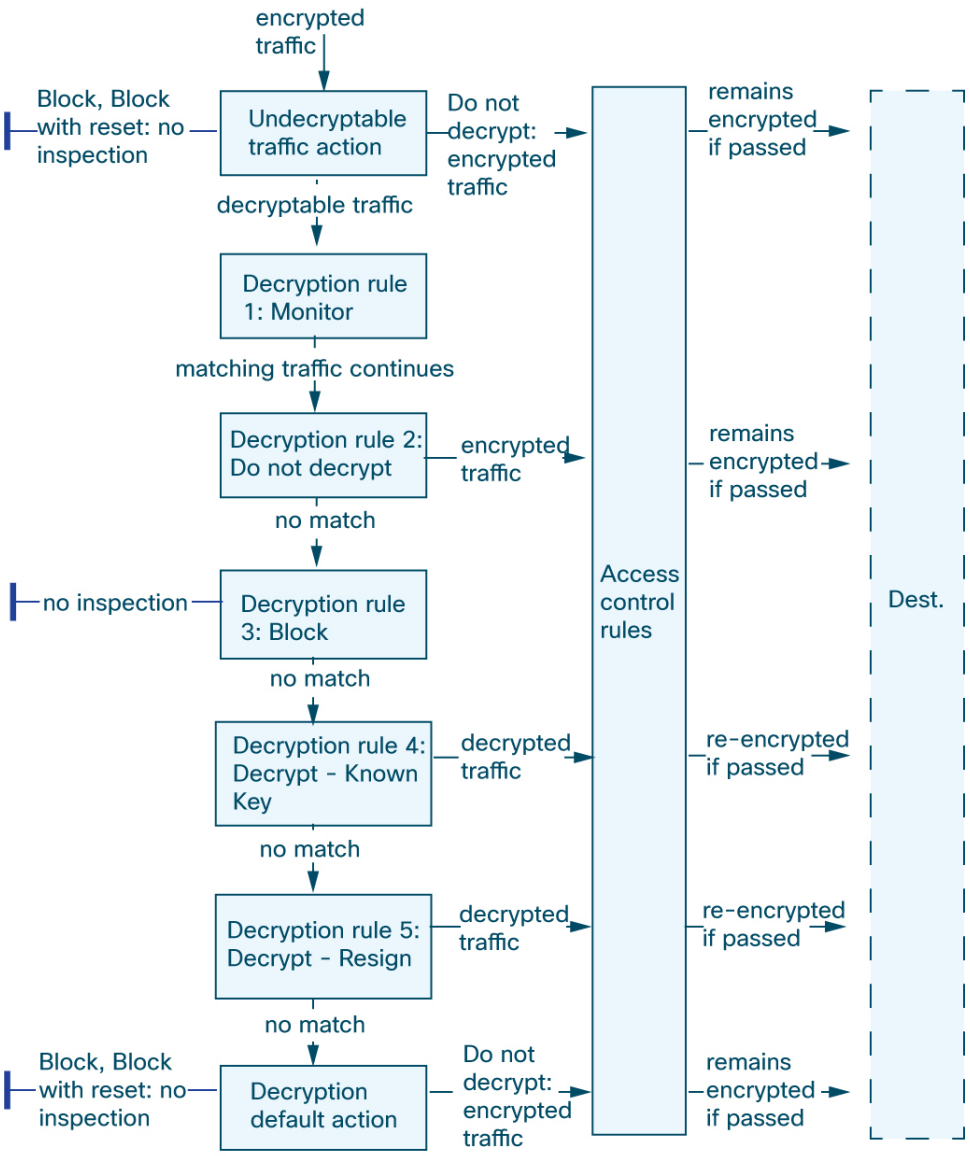
Best Practices for Access Control Rules, on page 1738
Default Handling Options for Undecryptable Traffic, on page 2296
Decryption Policy Rule Order

Multi-Rule Example

The following scenario summarizes the ways that decryption rules handle traffic in an inline deployment.



In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- **Decryption Rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- **Decryption Rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **Decryption Rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- **Decryption Rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- **Decryption Rule 5: Decrypt - Resign** is the final rule. If traffic matches this rule, the system re-signs the server certificate with an uploaded CA certificate, then acts as a man-in-the-middle to decrypt traffic. The decrypted traffic is then evaluated against access control rules. Access control rules treat decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule rule continues to the next rule.
- **Decryption policy Default Action** handles all traffic that does not match any of the decryption rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

TLS Crypto Acceleration

TLS crypto acceleration accelerates the following:

- TLS/SSL encryption and decryption
- VPN, including TLS/SSL and IPsec

Supported Hardware

The following hardware models support TLS crypto acceleration:

- Secure Firewall 3100
- Secure Firewall 4200
- Firepower 4100/9300

  For information about TLS crypto acceleration support on Firepower 4100/9300 Firewall Threat Defense container instances, see the *FXOS Configuration Guide*.

TLS crypto acceleration is *not* supported on any virtual appliances or on any hardware except for the preceding.

Note For more information about TLS crypto acceleration and the 4100/9300, see the *FXOS Configuration Guide*.

Features Not Supported by TLS crypto acceleration

Features *not* supported by TLS crypto acceleration include the following:

- Managed devices where Firewall Threat Defense container instance is enabled.

- If the inspection engine is configured to preserve connections and the inspection engine fails unexpectedly, TLS/SSL traffic is dropped until the engine restarts.

  This behavior is controlled by the **configure snort preserve-connection {enable | disable}** command.

TLS Crypto Acceleration Guidelines and Limitations

Keep the following in mind if your managed device has TLS crypto acceleration enabled.

HTTP-only performance

Using TLS crypto acceleration on a managed device that is not decrypting traffic can affect performance.

Federal Information Processing Standards (FIPS)

If TLS crypto acceleration and Federal Information Processing Standards (FIPS) are both enabled, connections with the following options fail:

- RSA keys less than 2048 bytes in size
- Rivest cipher 4 (RC4)
- Single Data Encryption Standard (single DES)
- Merkle–Damgard 5 (MD5)
- SSL v3

FIPS is enabled when you configure the Firewall Management Center and managed devices to operate in a security certifications compliance mode. To allow connections when operating in those modes, you can configure web browsers to accept more secure options.

For more information:

- Ciphers supported by FIPS: About SSL Settings, on page 980.
- Security Certifications Compliance Modes.
- Common Criteria.

TLS heartbeat

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

For more information, see Default Handling Options for Undecryptable Traffic, on page 2296.

To determine whether applications are using TLS heartbeat, see Troubleshoot TLS Heartbeat, on page 2342.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, see The SSL Preprocessor.

TLS/SSL oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions**:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

If a significant amount of oversubscription is occurring, you have the following options:

- Upgrade your managed devices to increase TLS/SSL processing capacity.
- Change your decryption policies to add **Do Not Decrypt** rules for traffic that is not a high priority to decrypt.

View the Status of TLS Crypto Acceleration

This topic discusses how you can determine if TLS crypto acceleration is enabled.

Perform the following task in the Firewall Management Center.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Devices** > **Device Management**.

Step 3 Click **Edit** (✎) to edit a managed device.

Step 4 Click **Device** page. TLS crypto acceleration status is displayed in the General section.

DTLS Crypto Acceleration

The Firewall Threat Defense, with the help of the FPGA and the Nitrox V crypto accelerator, supports DTLS cryptographic acceleration for the following models:

- Secure Firewall 3100
- Secure Firewall 4200

This feature improves the throughput of the DTLS-encrypted and DTLS-decrypted traffic. Both IPv4 and IPv6 traffic are supported.

The Firewall Threat Defense also performs optimization of the egress-encrypted packets to improve latency. The data path is optimized to enhance performance for single tunnel flows.

Both features are enabled by default and work only for DTLS 1.2.

These features are not supported with:

- Flows that use DTLS 1.0 or packet compression
- Rekeyed DTLS keys
- Clustering or multi-instance mode

You can disable DTLS crypto acceleration using FlexConfig and the **no flow-offload-dtls** and the **no flow-offload-dtls egress-optimization** commands..

Prerequisites for DTLS Crypto Acceleration

Supported License

- Management center Essentials (formerly Base) license must allow export-controlled functionality.

  Choose **System > Licenses > Smart Licenses** to verify this functionality in the management center.

Supported Devices

- Secure Firewall 3100
- Secure Firewall 4200

Monitoring DTLS Crypto Acceleration

Use the following CLI commands on the threat defense device to verify and monitor DTLS crypto acceleration and optimization of egress-encrypted packets.

- To verify the status of DTLS crypto acceleration and optimization of egress-encrypted packets, use the following command:

```
> show flow-offload-dtls info
  DTLS offload : Enabled
```

```
  Egress Optimization: Enabled
```

- To view the DTLS crypto acceleration statistics, use the following command:

```
> show flow-offload-dtls statistics
  Packet stats of Pipe 0
  ----------------------
  Rx Packet count : 975638666
  Tx Packet count : 975638666
  Error Packet count : 0
  Drop Packet count : 0

  CAM stats of Pipe 0
  ----------------------
  Option ID Table CAM Hit Count : 1145314723
  Option ID Table CAM Miss Count : 0
  Tunnel Table CAM Hit Count : 0
  Tunnel Table CAM Miss Count : 0
  6-Tuple CAM Hit Count : 975638666
  6-Tuple CAM Miss Count : 169676057
   NOTE: The counters displayed are cumulative counters
   for all offload applications and indicates the total packets
  offloaded
```

- To view the device's Nitrox V crypto accelerator statistics, use the following command:

```
> show crypto accelerator statistics

Crypto Accelerator Status

```

How to Configure Decryption Policies and Rules

This topic provides a high-level overview of tasks you must complete to configure decryption policies and decryption rules in those policies to block, monitor, or allow TLS/SSL traffic on your network.

You must be an Admin, Access Admin, or Network Admin to perform this task.

Procedure

Step 1 (Optional.) For **Decrypt - Known Key** decryption rules (to decrypt inbound traffic to an internal server), create an internal certificate object.

The internal certificate object uses your server's certificate and private key. See Internal Certificate Objects, on page 1412.

Step 2 (Optional.) For **Decrypt - Resign** decryption rules (to decrypt outbound traffic to a server outside of your network), create an internal certificate authority (CA) object.
The internal CA object uses a CA and private key. See Internal Certificate Authority Objects, on page 1405.

Step 3 For outbound protection policies (**Decrypt - Resign**) or inbound protection policies (**Decrypt - Known Key**), run the decryption policy wizard.

- Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281
- Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285

Step 4 For any other rule action (**Do Not Decrypt**, **Block**, **Block with Reset**, or **Monitor**), create a decryption policy and rules manually.
See Create a Create a Decryption Policy with Other Rule Actions, on page 2294.

What to do next

See one of the following:

- Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281
- Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285
- Create a Create a Decryption Policy with Other Rule Actions, on page 2294

History for Decryption Policy

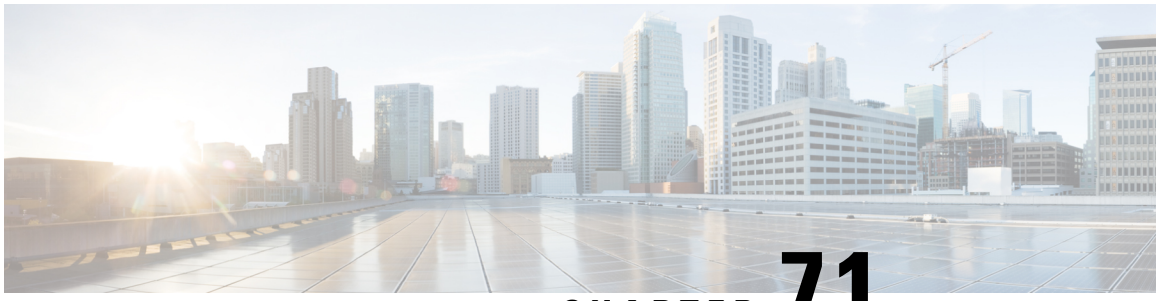
Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Hardware DTLS 1.2 crypto acceleration for the Secure Firewall 3100/4200.	7.6.0	7.6.0	The Secure Firewall 3100/4200 now supports DTLS 1.2 cryptographic acceleration and egress optimization, which improves throughput of DTLS-encrypted and decrypted traffic. This is automatically enabled on new and upgraded devices. To disable, use FlexConfig. New/modified FlexConfig commands: **flow-offload-dtls**, **flow-offload-dtls egress-optimization**, **show flow-offload-dtls**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
QUIC decryption.	7.6.0	7.6.0 with Snort 3	You can configure the decryption policy to apply to sessions running on the QUIC protocol. QUIC decryption is disabled by default. You can selectively enable QUIC decryption per decryption policy and write decryption rules to apply to QUIC traffic. By decrypting QUIC connections, the system can then inspect the connections for intrusion, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. We modified the decryption policy Advanced Settings to include the option to enable QUIC decryption.
Easily bypass decryption for sensitive and undecryptable traffic.	7.6.0	7.6.0	It is now easier to bypass decryption for sensitive and undecryptable traffic, which protects users and improves performance. New decryption policies now include predefined rules that, if enabled, can automatically bypass decryption for sensitive URL categories (such as finance or medical), undecryptable distinguished names, and undecryptable applications. Distinguished names and applications are undecryptable typically because they use TLS/SSL certificate pinning, which is itself not decryptable. For outbound decryption, you enable/disable these rules as part of creating the policy. For inbound decryption, the rules are disabled by default. After the policy is created, you can edit, reorder, or delete the rules entirely. New/modified screens: **Policies** > **Access Control** > **Decryption** > **Create Decryption Policy**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Decryption policy.	7.3.0	7.3.0	Feature renamed to *decryption policy* to better reflect what it does. We now enable you to configure a decryption policy with one or more **Decrypt - Resign** or **Decrypt - Known Key** rules at the same time. New/modified screens: • **Policies** > **Access Control heading** > **Decryption** (create new decryption policy) • The Create Decryption Policy dialog box now has two tab pages: **Outbound Connections** and **Inbound Connections**. Use the **Outbound Connections** tab page to configure one or more decryption rules with a **Decrypt - Resign** rule action. (You can either upload or generate certificate authorities at the same time). Each combination of a CA with networks and ports results in one decryption rule. Use the Inbound Connections tab page to configure one or more decryption rules with a Decrypt - Known Key rule action. (You can upload your server's certificate at the same time.) Each combination of a server certificate with networks and ports results in one decryption rule. • **Policies** > **Access Control heading** > **Decryption** (edit a decryption rule) **Advanced Settings** has new options discussed in TLS 1.3 Decryption Best Practices, on page 2300. • **Policies** > **Access Control Heading** > **Access Control** (edit an access control policy), click the word **Decryption** to associate a decryption policy with an access control policy.
TLS 1.3 decryption.	7.2.0	7.2.0	You can now enable TLS 1.3 decryption in an SSL policy's advanced actions. TLS 1.3 decryption requires the managed device run Snort 3. Other options are available as well; for more information, see TLS 1.3 Decryption Best Practices, on page 2300. New/modified screens: **SSL Policy** > **Advanced Settings**
SSL policy advanced settings.	7.2.0	7.1.0	SSL policy advanced settings New/modified screens: **SSL Policy** > **Advanced Settings**
Ability to specify handling of URLs having unknown reputation.	6.7.0	6.7.0	For details, see About URL Filtering with Category and Reputation, on page 1858.
ClientHello modification for **Decrypt - Known** key rules.	6.7.0	6.7.0	For details, see ClientHello Message Handling, on page 2255.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Ability to extract the certificate in TLS 1.3 traffic to enable traffic to match URL and application criteria in access control rules.	6.7.0	6.7.0	New/modified screens: **Policies** > **Access Control** > **(edit an access control policy)** > **Advanced** link. For details, see Decryption Policy Advanced Options, on page 2298.
Changes to category and reputation-based URL Filtering.	6.7.0	6.5.0	For details, see About URL Filtering with Category and Reputation, on page 1858.
TLS crypto acceleration cannot be disabled.	6.4.0	6.4.0	TLS crypto acceleration is enabled on all supported devices. On a managed device with native interfaces, TLS crypto acceleration cannot be disabled. Support for TLS crypto acceleration on Firewall Threat Defense container instances is limited as discussed in the next row of this table. Removed commands: • **system support ssl-hw-accel enable** • **system support ssl-hw-accel disable** • **system support ssl-hw-status**
Support for TLS crypto acceleration on one Firewall Threat Defense container instance on a Firepower 4100/9300 module/security engine.	6.4.0	6.4.0	You can now enable TLS crypto acceleration for one Firewall Threat Defense container instance on a module/security engine. TLS crypto acceleration is disabled for other container instances, but enabled for native instances. New/modified commands: • **config hwCrypto enable** • **show crypto accelerator status** replaces **system support ssl-hw-status**)
TLS/SSL hardware acceleration is now referred to as *TLS crypto acceleration*.	6.4.0	6.4.0	The name change reflects that TLS/SSL encryption and decryption acceleration is supported on more devices. Depending on the device, acceleration might be performed in software or in hardware. New/modified screens: **Devices** > **Device Management** > **Edit** > **Device** > **General** > **TLS Crypto Acceleration**
Extended Master Secret extension supported (see RFC 7627).	6.3.0.1	6.3.0.1	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of **Decrypt - Resign** or **Decrypt - Known Key**.
Extended Master Secret extension not supported.	6.3.0	6.3.0	The extension is stripped during ClientHello modification for **Decrypt - Resign** rules.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
TLS/SSL hardware acceleration enabled by default.	6.3.0	6.3.0	TLS/SSL hardware acceleration is enabled by default on all supported devices but can be disabled if desired.
Extended Master Secret extension supported (see RFC 7627).	6.2.3.9	6.2.3.9	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of **Decrypt - Resign** or **Decrypt - Known Key**.
Aggressive TLS 1.3 downgrade.	6.2.3.7	6.2.3.7	Using the **system support ssl-client-hello-enabled aggressive_tls13_downgrade {true|false}** CLI command, you can determine the behavior for downgrading TLS 1.3 traffic to TLS 1.2. For details, see the Cisco Secure Firewall Threat Defense Command Reference.
TLS/SSL hardware acceleration introduced.	6.2.3	6.2.3	Certain managed device models perform TLS/SSL encryption and decryption in hardware, improving performance. By default, the feature is enabled. Affected screen: To view the status of TLS/SSL hardware acceleration, **Devices** > **Device Management** > **Device**, General page.
Category and reputation conditions supported.	6.2.2	6.2.2	Access control rules or SSL rules with category/reputation conditions.
SafeSearch supported.	6.1.0	6.1.0	The system displays an HTTP response page for connections decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. In these cases, the system encrypts the response page and sends it at the end of the reencrypted SSL stream. SafeSearch filters objectionable content and stops people from searching adult sites.
TLS/SSL policy.	6.0.0	6.0.0	Feature introduced.



CHAPTER 71

Decryption Policies

The following topics provide an overview of decryption policy creation, configuration, management, and logging.

- About Decryption Policies, on page 2279
- Requirements and Prerequisites for Decryption Policies, on page 2281
- Create a Decryption Policy, on page 2281
- Decryption Policy Default Actions, on page 2295

About Decryption Policies

A decryption policy determines how the system handles encrypted traffic on your network. You can configure one or more decryption policies, associate a decryption policy with an access control policy, then deploy the access control policy to a managed device. When the device detects a TCP handshake, the access control policy first handles and inspects the traffic. If it subsequently identifies a TLS/SSL-encrypted session over the TCP connection, the decryption policy takes over, handling and decrypting the encrypted traffic.

Create a decryption policy using the wizard

You can use a wizard to create the following types of decryption policies:

- Outbound protection (**Decrypt - Resign** rule action). If traffic matches this rule, the system re-signs the server certificate with the CA certificate, then acts as a man-in-the-middle.

  Three rules with a **Do Not Decrypt** action are added to the policy at the same time, saving you the trouble of doing it later. These rules correspond to any decryption exclusions you configure when you create the policy (for example, you can choose to bypass decryption for applications that are known to use certificate pinning.

  For more information, see Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281.

- Inbound protection (**Decrypt - Known Key** rule action). You can associate one or more server certificates and paired private keys with the action. If traffic matches the rule, and the certificate used to encrypt the traffic matches the certificate associated with the action, the system uses the appropriate private key to obtain the session encryption and decryption keys.

Three rules with a **Do Not Decrypt** action are added to the policy at the same time but these rules are disabled by default. These rules correspond to any decryption exclusions you configure when you create the policy (for example, you can choose to bypass decryption for applications that are known to use certificate pinning.

For more information, see Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285.

- Any other decryption rule action (such as blocking or monitoring).

  For more information, see Create a Create a Decryption Policy with Other Rule Actions, on page 2294.

The wizard automatically creates a separate rule for each certificate you specify. For example, an inbound protection rule might specify one certificate for traffic coming to the Finance department internal network and a different certificate for traffic coming to the Engineering network.

The wizard creates additional rules for outbound and inbound protection policies as follows:

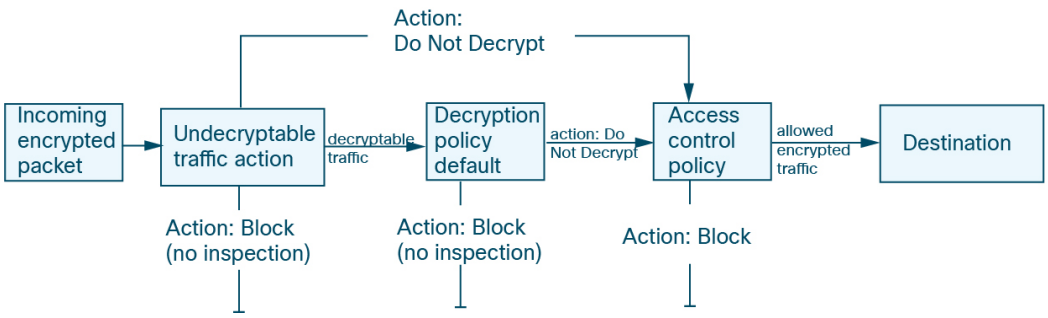
- Outbound protection (**Decrypt - Resign** rule action): The wizard creates Do Not Decrypt rules for traffic that matches exceptions you specify in the wizard. For example, you can choose to not decrypt traffic from undecryptable applications, typically those using certificate pinning.

  The Do Not Decrypt rules are placed first in the decryption policy so that traffic is passed through the firewall with minimal processing.

- Inbound protection (**Decrypt - Known Key** rule action): The wizard does not allow you to choose any exceptions but it adds the Do Not Decrypt rules to the policy and disables them; that way, you can enable those exceptions later if you need to.

Do Not Decrypt policy example

Following is an example decryption policy with a **Do Not Decrypt** rule action:



The simplest decryption policy, as shown in the following diagram, directs the device where it is deployed to handle encrypted traffic with a single default action. You can set the default action to block decryptable traffic without further inspection, or to inspect undecrypted decryptable traffic with access control. The system can then either allow or block the encrypted traffic. If the device detects undecryptable traffic, it either blocks the traffic without further inspection or does not decrypt it, inspecting it with access control.

To get started, see Create a Decryption Policy, on page 2281

Requirements and Prerequisites for Decryption Policies

Supported Domains

Any

User Roles

- Network Admin

Create a Decryption Policy

You can create any of the following types of decryption policies:

- *Outbound protection* policy with rules that protect outbound connections; that is, the destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action. We also create additional rules with a **Do Not Decrypt** action that excludes traffic you specify (such as traffic that uses certificate pinning).

  See Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281

- *Inbound protection* policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action. We also create additional rules with a **Do Not Decrypt** action that excludes traffic you specify (such as traffic that uses certificate pinning.) These rules are disabled initially but you can modify and enable them later if you wish.

  See Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285

- Other actions (including **Do Not Decrypt**, **Block**, and **Block with Reset**).

  See Create a Create a Decryption Policy with Other Rule Actions, on page 2294

Create a Create a Decryption Policy with Outbound Connection Protection

This task discusses how to create a decryption policy with a rule that protects outbound connections; that is, the destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules, multiple **Decrypt - Replace Cert** rules, and multiple **Decrypt - Resign** rules.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see Creating Change Management Tickets, on page 240 and Policies and Objects that Support Change Management, on page 235.

Before you begin

You can optionally must upload or generate an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal CAs** and referring to PKI, on page 1404.
- At the time you create this decryption policy.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

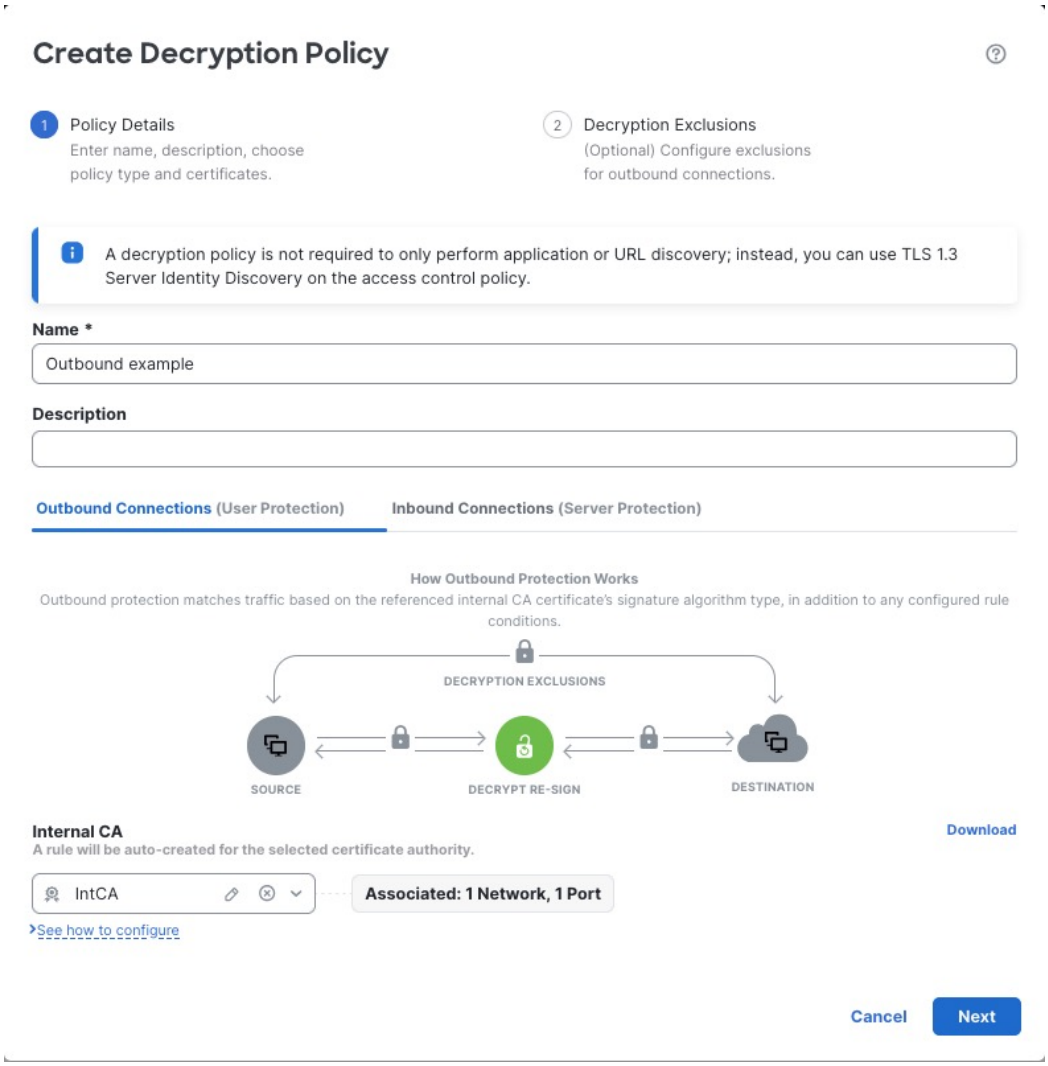
Step 3 Click **Create Decryption Policy**.

Step 4 Give the policy a unique **Name** and, optionally, a **Description**.

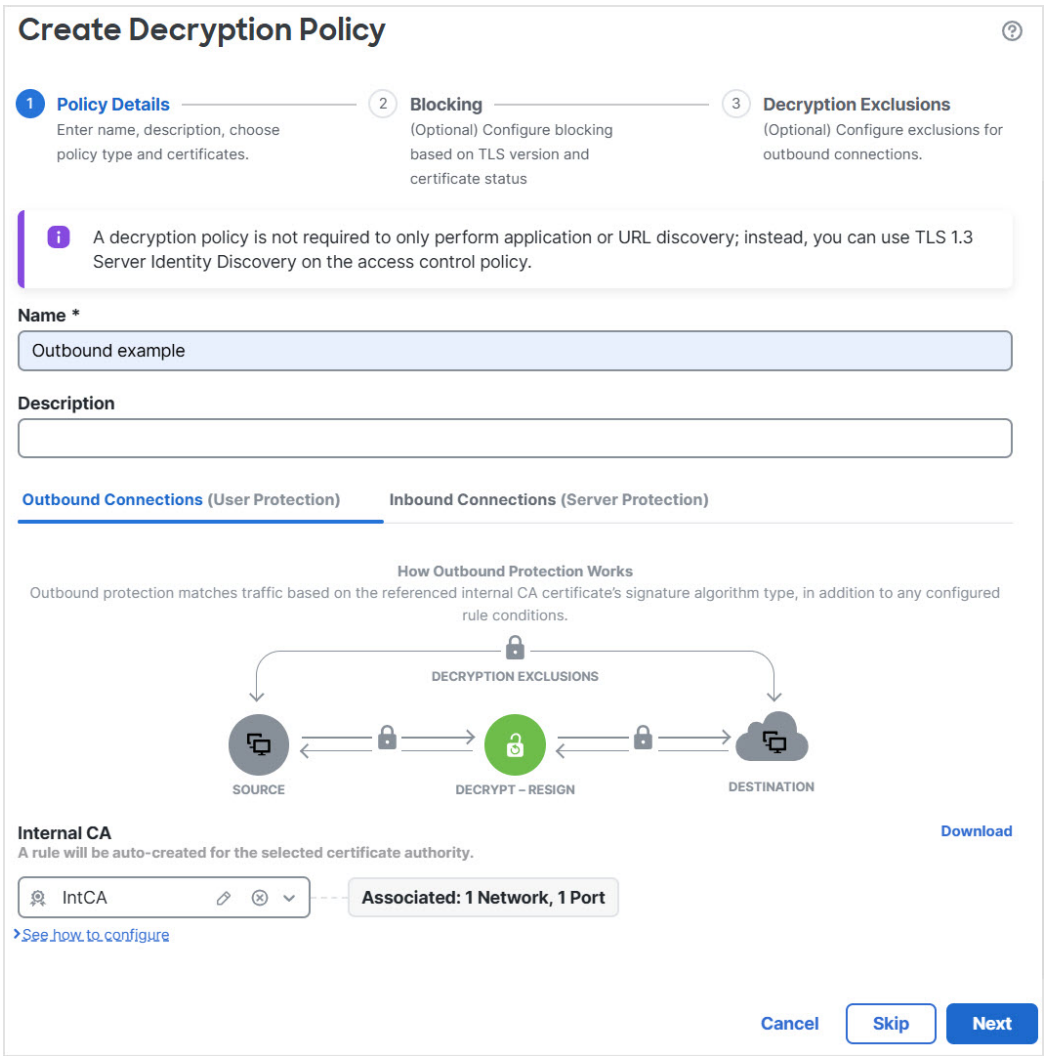
The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

Step 5 Click the **Outbound Connections** tab.



Step 6 Click the **Outbound Connections** tab.



Step 7 From the **Internal CA** list, upload or choose certificates for the rules.

For more information about internal certificates, see Generate an Internal CA for Outbound Protection, on page 2291 and Upload an Internal CA for Outbound Protection, on page 2292.

Step 8 (Optional.) Choose networks and ports.

For more information:

- Network Rule Conditions, on page 939
- Port Rule Conditions, on page 940

Step 9 Click **Next**.

Step 10 Continue with Decryption Policy Block Connections, on page 2287.

What to do next

- Add rule conditions: Decryption Rule Conditions, on page 2316
- Add a default policy action: Decryption Policy Default Actions, on page 2295
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the Cisco Secure Firewall Management Center Administration Guide .
- Set advanced policy properties: Decryption Policy Advanced Options, on page 2298.
- Associate the decryption policy with an access control policy as described in Associating Other Policies with Access Control, on page 1762.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Create a Create a Decryption Policy with Inbound Connection Protection

This task discusses how to create a decryption policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

Before you begin

You can optionally upload an internal certificate for your internal server before you can create a decryption policy that protects inbound connections. You can do this in any of the following ways:

- Create an internal certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal Certs** and referring to PKI, on page 1404.
- At the time you create this decryption policy.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see Creating Change Management Tickets, on page 240 and Policies and Objects that Support Change Management, on page 235.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

Step 4 Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

Step 5 From the **Internal Certificates** list, upload or choose certificates for the rules.

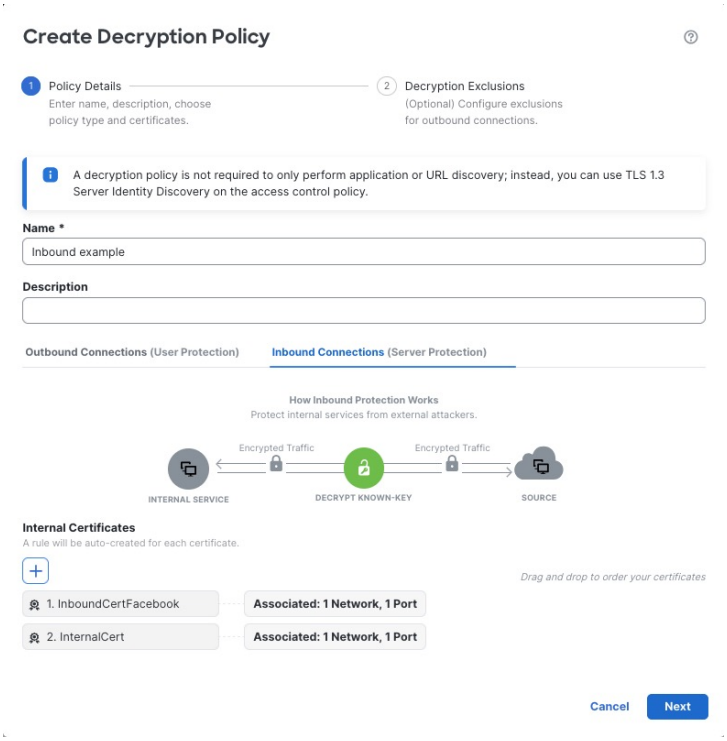
For more information about internal CA certificates, see Internal Certificate Authority Objects, on page 1405.

Step 6 (Optional.) Choose networks and ports.

For more information:

- Network Rule Conditions, on page 939
- Port Rule Conditions, on page 940

Step 7 Click the **Inbound Connections** tab.



Step 8 Click **Next**.

Step 9 Continue with Decryption Policy Block Connections, on page 2287

Step 10 Continue with Decryption Policy Exclusions, on page 2287.

What to do next

- Add rule conditions: Decryption Rule Conditions, on page 2316
- Add a default policy action: Decryption Policy Default Actions, on page 2295
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the Cisco Secure Firewall Management Center Administration Guide .
- Set advanced policy properties: Decryption Policy Advanced Options, on page 2298.

- Associate the decryption policy with an access control policy as described in Associating Other Policies with Access Control, on page 1762.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Decryption Policy Block Connections

This topic provides details about how to block connections to servers with unsecure TLS versions and server certificate statuses while creating a decryption policy. The **Block with Reset** rules are created in your decryption policy that are disabled by default.

Procedure

Step 1 Complete the tasks mentioned in:

- Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281
- Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285

Step 2 The **Blocking** page provides the following options. By default, all the options are *disabled* for decryption policy actions.

- **Block connections based on TLS version**—Check this check box to block connections to servers using unsecure TLS versions. By default, **SSL v3.0**, **TLS v1.0**, and **TLS v1.1** which are known to be vulnerable, are selected. You can choose other versions from the drop-down list.
- **Block connections based on server certificate status**—Check this check box to block connections to servers with unsecure server certificate statuses. By default, **Invalid Signature**, **Expired**, **Not Yet Valid**, and **Invalid Certificate** are selected. You can choose other statuses from the drop-down list.

Click **Delete** ( ) to remove the selections or click **Reset to default** to revert back to the default selections.

Step 3 Click **Next**.

What to do next

Continue with Decryption Policy Exclusions, on page 2287.

Decryption Policy Exclusions

This task discusses how to exclude certain types of traffic from decryption. We create **Do Not Decrypt** rules in your decryption policy for these although the rules are initially enabled only for an outbound decryption policy (that is, one that uses the **Decrypt - Resign** policy action).

Before you begin

You must upload an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal CAs** and referring to PKI, on page 1404.
- At the time you create this decryption policy.

Procedure

Step 1 Complete the tasks discussed in:

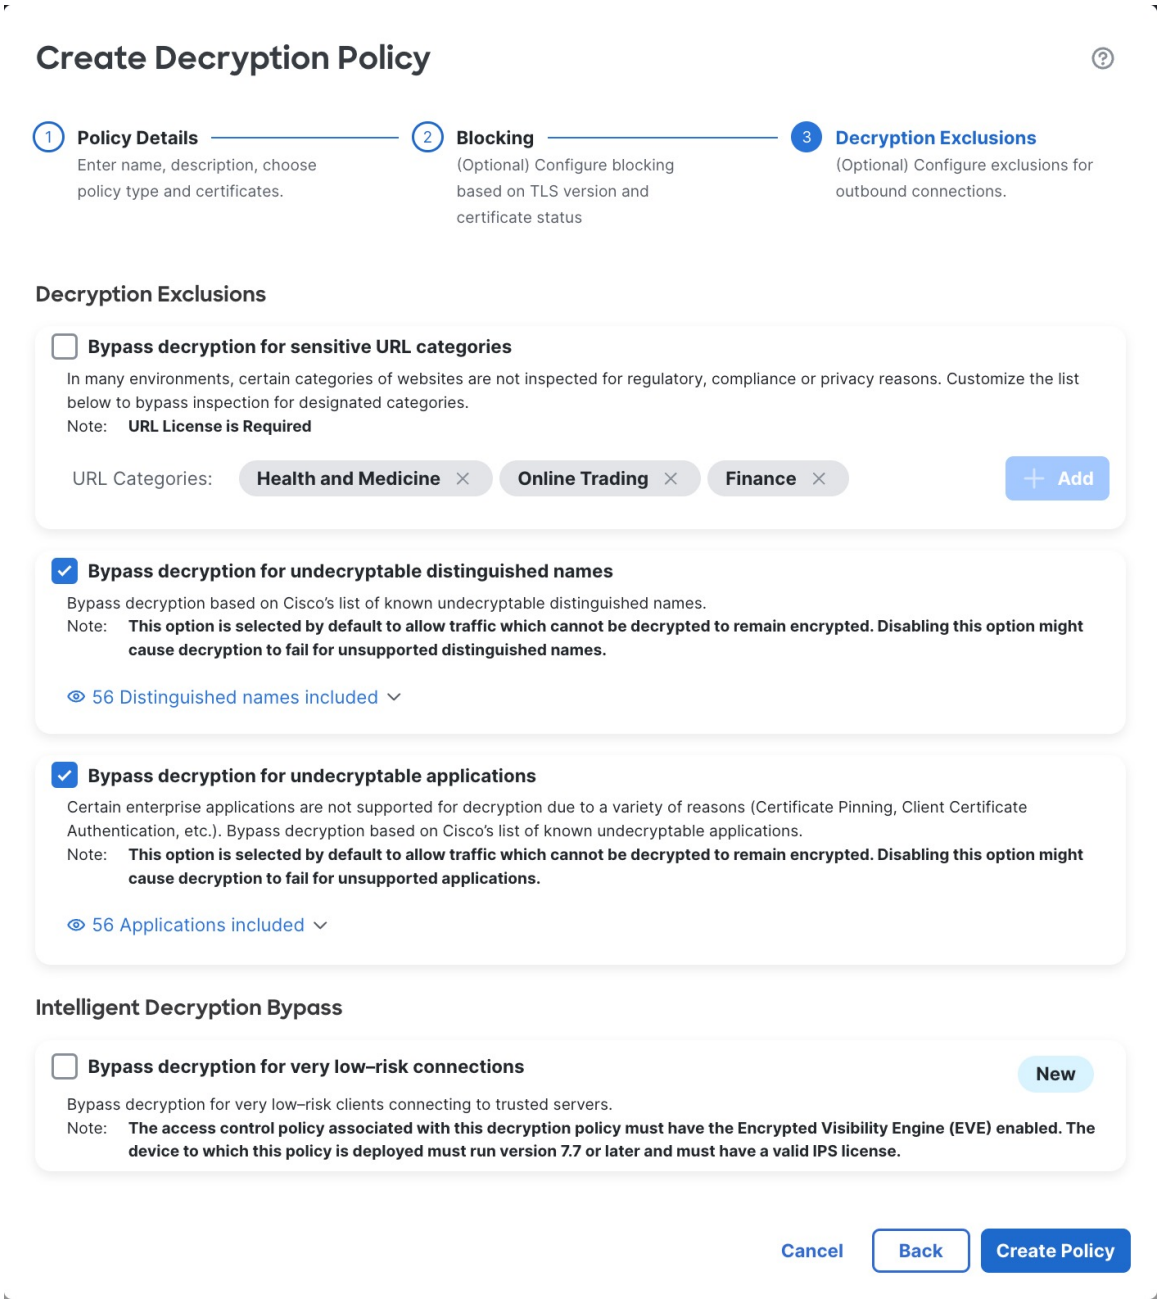
- Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281
- For more information, see Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285

Step 2 The exclusions page provides the following options. All options are *enabled* for an outbound protection policy (**Decrypt - Resign** rule action) and *disabled* for all other decryption policy actions.

Item	Description
Bypass decryption for sensitive URL categories	Check the box to not decrypt traffic from the indicated categories. Depending on the laws in your area, decryption certain traffic, such as finance or health-related, might be prohibited. Consult an authority in your area for more information. Click **Add** to add more categories. Click **Delete** (✕) to remove categories.
Bypass decryption for undecryptable distinguished names	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL Certificate Pinning Guidelines, on page 2310. The list of undecryptable distinguished names is maintained by Cisco.
Bypass decryption for undecryptable applications	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL Certificate Pinning Guidelines, on page 2310. Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the Secure Firewall Application Detectors page; the **undecryptable** tag identifies applications Cisco determines are undecryptable. The list of undecryptable applications is maintained by Cisco.

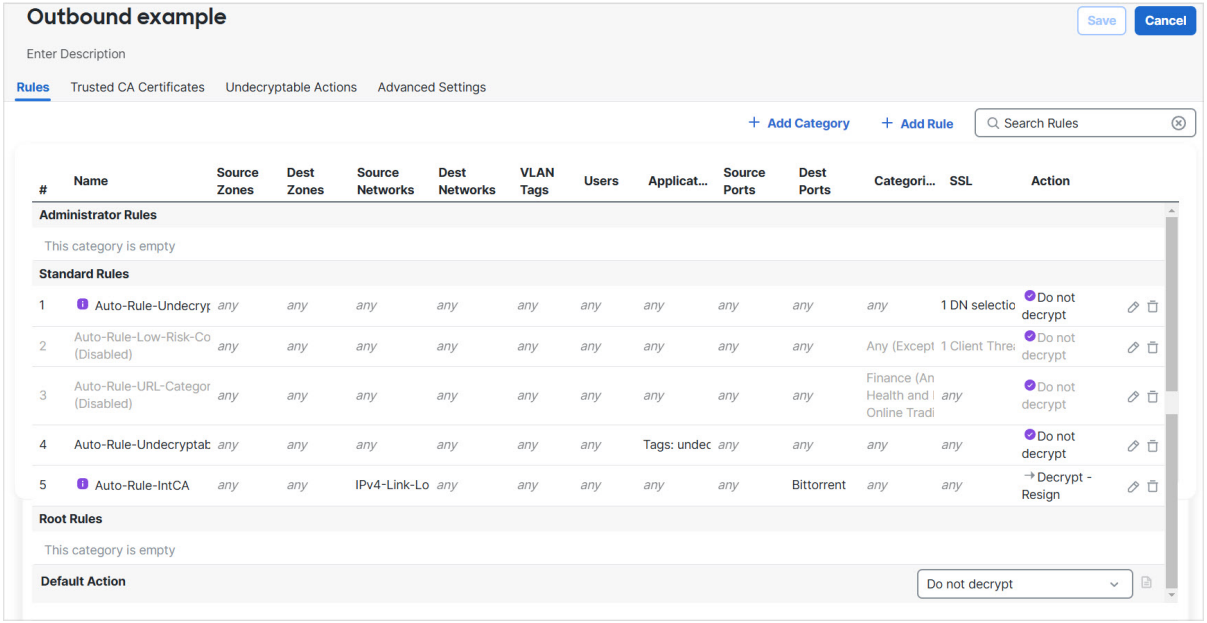
Item	Description
Bypass decryption for very low-risk connections	Check this check box to not decrypt traffic for very low-risk clients connecting to trusted servers, based on the threat confidence levels of clients which is determined by the Encrypted Visibility Engine (EVE) and the URL Category Reputation. An **Auto-Rule-Low-Risk-Connections** Do Not Decrypt rule is created and enabled in the new decryption policy. To use the **Bypass decryption for very low-risk connections** option, you must enable the EVE in the corresponding access control policy, and the managed devices must be running Version 7.7 or later with a valid IPS license.

The following figure shows the default options.



Step 3 Click **Create Policy**.

The following figure shows a sample outbound protection policy.



In the preceding example, the **Do Not Decrypt** rules corresponding to your choices for rule exclusions are automatically added before the **Decrypt - Resign** rule. The rule for sensitive URL categories is disabled because, by default, that exclusion is disabled. Had you selected the **Bypass decryption for sensitive URL categories** check box, the rule would have been enabled.

Step 4 Click **Create Policy**.

What to do next

- Add rule conditions: Decryption Rule Conditions, on page 2316
- Add a default policy action: Decryption Policy Default Actions, on page 2295
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the Cisco Secure Firewall Management Center Administration Guide .
- Set advanced policy properties: Decryption Policy Advanced Options, on page 2298.
- Associate the decryption policy with an access control policy as described in Associating Other Policies with Access Control, on page 1762.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Generate an Internal CA for Outbound Protection

This task discusses how you can optionally generate an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Uploading a Signed Certificate Issued in Response to a CSR, on page 1407.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal Certificate Authority Objects, on page 1405.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Create Decryption Policy (Rule-Based)**.

Step 4 Enter a name for the policy in the **Name** field and an optional description in the **Description** field.

Step 5 Click the **Outbound Connections** tab.

Step 6 From the **Internal CA** list, click **Create New** > **Generate CA**.

Step 7 Give the internal CA a **Name** and provide a two-letter **Country Name**.

Step 8 Click **Self-Signed** or **CSR**.

For more information about these options, see Internal Certificate Authority Objects, on page 1405.

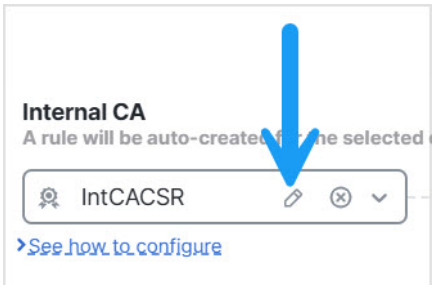
Step 9 Enter the requested information in the provided fields.

Step 10 Click **Save**.

Step 11 If you chose **CSR**, after the signing request has been completed, click **Install Certificate** as follows:

a) Repeat the preceding steps in this procedure.

b) Edit the CA from the **Internal CA** list as follows.



c) Click **Install Certificate**.

d) Follow the prompts on your screen to complete the task.

Step 12 Continue creating the policy as discussed in Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281.

Upload an Internal CA for Outbound Protection

This task discusses how you can optionally upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Uploading a Signed Certificate Issued in Response to a CSR, on page 1407.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal Certificate Authority Objects, on page 1405.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

Step 4 Enter a name for the policy in the **Name** field and an optional description in the **Description** field.

Step 5 Click the **Outbound Connections** tab.

Step 6 From the **Internal CA** list, click **Create New** > **Upload CA**.

Step 7 Give the internal CA a **Name**.

Step 8 Paste or browse to locate the certificate and its private key in the provided fields.

Step 9 If the CA has a password, select the **Encrypted** check box and enter the password in the adjacent field.

Step 10 Continue creating the policy as discussed in Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281.

Upload an Internal Certificate for Inbound Protection

This task discusses how to upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also upload the internal CA using **Objects** > **Object Management** as discussed in Importing a CA Certificate and Private Key, on page 1406.

Before you begin

Make sure you have an internal certificate authority in one of the formats discussed in Internal Certificate Authority Objects, on page 1405.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

Step 4 Enter a name for the policy in the **Name** field and an optional description in the **Description** field.

Step 5 Click the **Inbound Connections** tab.

Step 6 From the **Internal Certificates** list, click **Add** (+).

Step 7 If an internal certificate object exists, click its name.

Step 8 Otherwise, click **Upload**.

Step 9 Enter the required information.

See Adding Internal Certificate Objects, on page 1412.

Step 10 Continue creating the decryption policy as discussed in Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285.

Create a Create a Decryption Policy with Other Rule Actions

To create a decryption rule with a **Do Not Decrypt**, **Block**, **Block With Reset,** or **Monitor** rule action, create a decryption policy and edit the policy to add the rule.

When you create a decryption policy policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules, multiple **Decrypt - Replace Cert** rules, and multiple **Decrypt - Resign** rules.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see Creating Change Management Tickets, on page 240 and Policies and Objects that Support Change Management, on page 235.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

Step 4 Click **Next**.

Step 5 The bypass page is provided for your information only; you cannot bypass traffic for other types of decryption (such as **Block**).

Step 6 Click **Create Policy**.

Step 7 Wait for the policy to be created.

Step 8 Click **Edit** (✎) next to the decryption policy name.

Step 9 Click **Add Rule**.

Step 10 Give the rule a **Name**.

Step 11 From the **Action** list, click a rule action and see one of the following sections for more information:

- Decryption Rule Do Not Decrypt Action, on page 2335
- Decryption Rule Blocking Actions, on page 2336
- Decryption Rule Monitor Action, on page 2334

Step 12 Click **Save**.

What to do next

- Add rule conditions: Decryption Rule Conditions, on page 2316
- Add a default policy action: Decryption Policy Default Actions, on page 2295
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the Cisco Secure Firewall Management Center Administration Guide .
- Set advanced policy properties: Decryption Policy Advanced Options, on page 2298.
- Associate the decryption policy with an access control policy as described in Associating Other Policies with Access Control, on page 1762.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Decryption Policy Default Actions

The default action for a decryption policy determines how the system handles decryptable encrypted traffic that does not match any non-monitor rule in the policy. When you deploy a decryption policy that does not contain any decryption rules, the default action determines how all decryptable traffic on your network is handled. Note that the system does not perform any kind of inspection on encrypted traffic blocked by the default action.

To set the decryption policy default action:

1. Log in to the Secure Firewall Management Center if you haven't already done so.
2. Click **Policies** > **Access Control heading** > **Decryption**.
3. Click **Edit** (✎) next to the name of the decryption policy.
4. In the Default Action row, click one of the following actions from the list.

Table 124: Decryption Policy Default Actions

Default Action	Effect on Encrypted Traffic
Block	Block the TLS/SSL session without further inspection.
Block with reset	Block the TLS/SSL session without further inspection and reset the TCP connection. Choose this option if traffic uses a connectionless protocol like UDP. In that case, the connectionless protocol tries to reestablish the connection until it is reset. This action also displays a connection reset error in the browser so the user is informed that the connection is blocked.
Do not decrypt	Inspect the encrypted traffic with access control.

Default Handling Options for Undecryptable Traffic

Table 125: Undecryptable Traffic Types

Type	Description	Default Action	Available Action
Compressed Session	The TLS/SSL session applies a data compression method.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
SSLv2 Session	The session is encrypted with SSL version 2. Note that traffic is decryptable if the ClientHello message is SSL 2.0, and the remainder of the transmitted traffic is SSL 3.0.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unknown Cipher Suite	The system does not recognize the cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unsupported Cipher Suite	The system does not support decryption based on the detected cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Session not cached	The TLS/SSL session has session reuse enabled, the client and server reestablished the session with the session identifier, and the system did not cache that session identifier.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Handshake Errors	An error occurred during TLS/SSL handshake negotiation.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Decryption Errors	An error occurred during traffic decryption.	Block	Block Block with Reset

When you first create a decryption policy, logging connections that are handled by the default action is disabled by default. Because the logging settings for the default action also apply to undecryptable traffic handling, logging connections handled by the undecryptable traffic actions is disabled by default.

Note that if your browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. For more information, see Decryption Rule Guidelines and Limitations, on page 2304.

If a decryption policy is associated with an access control policy that uses TCP state bypass, matching traffic is acted on based on the policy's configured **Undecryptable Actions** for **Handshake Errors**.

For example, if a decryption policy's **Handshake Errors** is set to **Block**, traffic matching the rule is blocked and the connection event's action is reported as a handshake error.

For more information about TCP state bypass, see:

- Configure TCP State Bypass, on page 1945
- Bypass TCP State Checks for Asymetrical Routing (TCP State Bypass), on page 1943

Related Topics

Set Default Handling for Undecryptable Traffic, on page 2297

Set Default Handling for Undecryptable Traffic

You can set undecryptable traffic actions at the decryption policy level to handle certain types of encrypted traffic the system cannot decrypt or inspect. When you deploy a decryption policy that contains no decryption rules, the undecryptable traffic actions determine how all undecryptable encrypted traffic on your network is handled.

Depending on the type of undecryptable traffic, you can choose to:

- Block the connection.
- Block the connection, then reset it. This option is preferrable for connectionless protocols like UDP, which keep trying to connect until the connection is blocked.
- Inspect the encrypted traffic with access control.
- Inherit the default action from the decryption policy.

Procedure

Step 1 Log in to Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to the name of the decryption policy.

Step 4 In the decryption policy editor, click **Undecryptable Actions**.

Step 5 For each field, choose either the decryption policy's default action or another action you want to take on the type of undecryptable traffic. See Default Handling Options for Undecryptable Traffic, on page 2296 and Decryption Policy Default Actions, on page 2295 for more information.

Step 6 Click **Save** to save the policy.

What to do next

- Configure default logging for connections handled by the undecryptable traffic actions; see *Logging Connections with a Policy Default Action* in the Cisco Secure Firewall Management Center Administration Guide.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Decryption Policy Advanced Options

A decryption policy 's **Advanced Settings** page has global settings that are applied to all managed devices that are configured for Snort 3 to which the policy is applied.

A decryption policy advanced settings are all ignored on any managed device that runs:

- A version earlier than 7.1
- Snort 2

Block flows requesting ESNI

Encrypted Server Name Indication (ESNI (link to draft proposal)) is a way for a client to tell a TLS 1.3 server what the client is requesting. Because the SNI is encrypted, you can optionally block these connections because the system cannot determine what the server is.

Disable HTTP/3 advertisement

This option strips HTTP/3 (RFC 9114) from the ClientHello in TCP connections. HTTP/3 is part of the QUIC transport protocol, not the TCP transport protocol. Blocking clients from advertising HTTP/3 provides protection against attacks and evasion attempts potentially burried within QUIC connections.

Propagate untrusted server certificates to clients

This applies only to traffic matching a **Decrypt - Resign** rule action.

Enable this option to substitute the certificate authority (CA) on the managed device for the server's certificate in cases where the server certificate is untrusted. An *untrusted* server certificate is one that is not listed as a trusted CA in the Secure Firewall Management Center. (**Objects** > **Object Management** > **PKI** > **Trusted CAs**).

Enable TLS 1.3 Decryption

Whether to apply decryption rules to TLS 1.3 connections. If you do not enable this option, the decryption rules apply to TLS 1.2 or lower traffic only. See TLS 1.3 Decryption Best Practices, on page 2300.

Enable adaptive TLS server identity probe

Automatically enabled when TLS 1.3 decryption is enabled. A *probe* is a partial TLS connection with the server, the purpose of which is to obtain the server certificate and cache it. (If the certificate is already cached, the probe is never established.)

If TLS 1.3 Server Identity Discovery is disabled on the access control policy with which the decryption policy is associated, we attempt to use the Server Name Indication (SNI), which is not as reliable.

The adaptive TLS server identity probe occurs on any of the following conditions as opposed to on every connection as in earlier releases:

- Certificate Issuer—Matched when the value of **Issuer DNs** in a decryption rule's DN rule condition is matched.

  For more information, see Distinguished Name (DN) Rule Conditions, on page 2323.

- Certificate Status—Matched when any of the **Cert Status** conditions are matched in a decryption rule.

  For more information, see Certificate Status Decryption Rule Conditions, on page 2329.

- Internal/External Certificate—Internal certificates can be matched by the certificate used in **Decrypt - Known Key** rule actions; external certificates can be matched in **Certificates** rule conditions.

  For more information, see Known Key Decryption (Incoming Traffic), on page 2263 and Certificate Decryption Rule Conditions, on page 2322.

- Application ID—Can be matched by **Applications** rule conditions in either an access control policy or a decryption policy.

  For more information, see Application Rule Conditions, on page 939.

- URL Category—Can be matched by **URLs** rule conditions in an access control policy.

  For more information, see URL Rule Conditions, on page 942.

Note **Enable adaptive TLS server discovery mode** is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Secure Firewall Management Center, the connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.

Enable QUIC Decryption

Whether to apply decryption rules to connections that use the HTTP/3 over the QUIC protocol. When you decrypt QUIC connections, the system can inspect the contents of the sessions for intrusions, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. QUIC support is in line with RFC 9000, 9001, 9002, 9114, 9204.

Consider the following when implementing QUIC decryption:

- On high availability or clustered devices, QUIC decryption works only if the connection remains on the same node. If the connection fails over, or is forwarded to another node, the connection drops and must be re-established. Multi-instance is supported without restrictions.
- Rules that apply to QUIC traffic would include the UDP protocol with destination port 443.

- Access control rules that apply to QUIC traffic would include the HTTP/3 or QUIC protocols, either explicitly or by implication.

The following limitations apply to QUIC decryption:

- QUIC decryption applies to Firewall Threat Defense 7.6+ only. Devices running a lower release cannot decrypt QUIC connections.
- Connections from browsers using the Chromium stack (Google Chrome, Opera, Edge) cannot be decrypted for outbound traffic. But inbound traffic from the same browsers can be decrypted.
- Connection Migration as described in RFC 9000 is not supported. The concept of Connection ID in QUIC allows endpoints to retain the same connection in the event of address change.
- Key update, session resumption, and QUIC version 2 are not supported.
- Interactive Block and Interactive Block with Reset (in access control rules) is not supported. These actions will work as Block and Block with Reset.
- The active connection-ID per connection is limited to 5. If necessary, you can modify these limits using the **system support quic-tuning** and **system support quic-tuning-reset** commands in the device CLI.

TLS 1.3 Decryption Best Practices

Recommendation: When to enable advanced options

Both the decryption policy and the access control policy have advanced options that affect how traffic is handled, whether the traffic is being decrypted or not.

The advanced options are:

- Decryption policy:
  - TLS 1.3 decryption
  - TLS adaptive server identity probe
- Access control policy: TLS 1.3 Server Identity Discovery

  The access control policy setting takes precedence over the decryption policy setting.

Use the following table to decide which option to enable:

TLS adaptive server identity probe setting (decryption policy)	TLS 1.3 Server Identity Discovery setting (access control policy)	Result	Recommended when
Enabled	Disabled	Adaptive probe sent if decryption policy contains *any* rule conditions specified in Decryption Policy Advanced Options, on page 2298 *and* if the server certificate is not cached.	• You're not using application or URL conditions in access control rules • You're decrypting traffic

TLS adaptive server identity probe setting (decryption policy)	TLS 1.3 Server Identity Discovery setting (access control policy)	Result	Recommended when
Enabled	Enabled	Probe is always sent if the server certificate is not cached.	Use only if your access control rules have URL or application conditions
Disabled	Enabled	Probe is always sent if the server certificate is not cached.	Not recommended.
Disabled	Disabled	Probe is never sent.	Very limited usefulness; use only if not decrypting traffic and not using application or URL conditions in the access control rule

Note A cached TLS server's certificate is available to all Snort instances on a particular Firewall Threat Defense. The cache can be cleared with a CLI command and is automatically cleared when the device is rebooted.

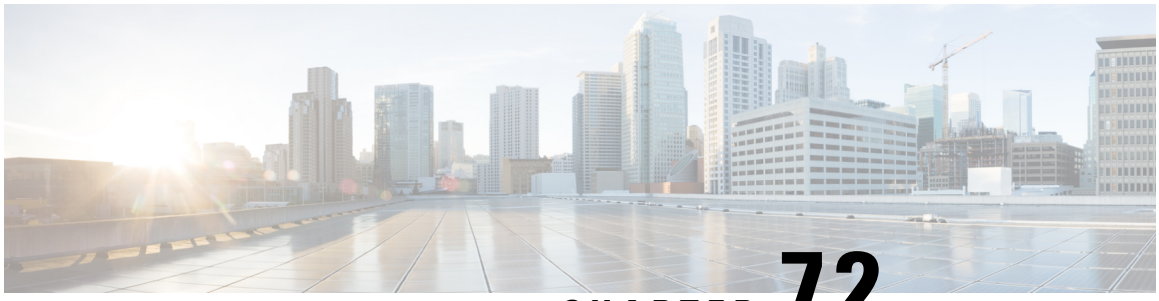
For more information, see the discussion of TLS server identity discovery on secure.cisco.com.



CHAPTER 72

Decryption Rules

The following topics provide an overview of creating, configuring, managing, and troubleshooting decryption rules:

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?

Decryption Rules Overview

Decryption rules provide a granular method of handling encrypted traffic across multiple managed devices, whether blocking the traffic without further inspection, not decrypting the traffic and inspecting it with access control, or decrypting the traffic for access control analysis.

Requirements and Prerequisites for Decryption Rules

Decryption Rule Guidelines and Limitations

Keep the following points in mind when setting up your decryption rules. Properly configuring decryption rules is a complex task, but one that is essential to building an effective deployment that handles encrypted traffic. Many factors influence how you configure rules, including certain application behavior that you cannot control.

In addition, rules can preempt each other, require additional licenses, or contain invalid configurations. Thoughtfully configured rules can also reduce the resources required to process network traffic. Creating overly complex rules and ordering rules the wrong way can adversely affect performance.

For detailed information, see Best Practices for Access Control Rules, on page 1738.

For guidelines related specifically to TLS crypto acceleration, see TLS Crypto Acceleration, on page 2268.

Guidelines for Using TLS/SSL Decryption

General guideline

decryption rules require processing overhead that can impact performance. Determine which traffic must be decrypted and subjected to deep inspection before you set up any policies or rules.

You cannot decrypt traffic on a device that uses any of the following:

- Passive interface
- Inline or inline tap interface

- TCP state bypass

Guidelines for undecryptable traffic

We can determine that certain traffic is not decryptable either because the website itself is not decryptable or because the website uses TLS/SSL pinning, which effectively prevents users from accessing a decrypted site without errors in their browser.

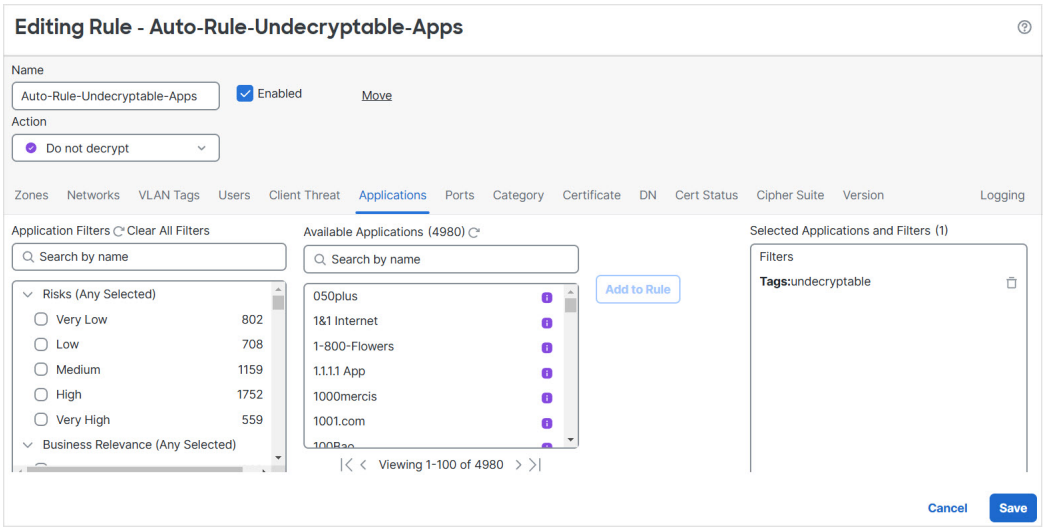
For more information about certificate pinning, see About TLS/SSL Pinning, on page 2343.

We maintain the list of these sites as follows:

- A Distinguished Name (DN) group named **Cisco-Undecryptable-Sites**
- The **pinned certificate** or **undecryptable** application filter

If you are decrypting traffic and you do not want users to see errors in their browsers when going to these sites, we recommend you set up a **Do Not Decrypt** rule toward the bottom of your decryption rules.

If you use the decryption policy wizard to create a policy for outbound traffic protection, a **Do Not Decrypt** rule for pinned certificates is created for you as the following example shows.



Decryption Rule Unsupported Features

RC4 cipher not unsupported

The Rivest Cipher 4 (also referred to as *RC4* or *ARC4* cipher is known to have vulnerabilities and is considered unsecure.

decryption policies identify the RC4 cipher suite as unsupported; you should configure the **Unsupported Cipher Suite** action in the decryption policies policy's **Undecryptable Actions** page to match your organization's requirements. For more information, see Default Handling Options for Undecryptable Traffic, on page 2296.

Passive, inline tap mode, and SPAN interfaces not supported

TLS/SSL traffic cannot be decrypted on passive, inline tap mode, or SPAN interfaces.

TLS/SSL Do Not Decrypt Guidelines

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

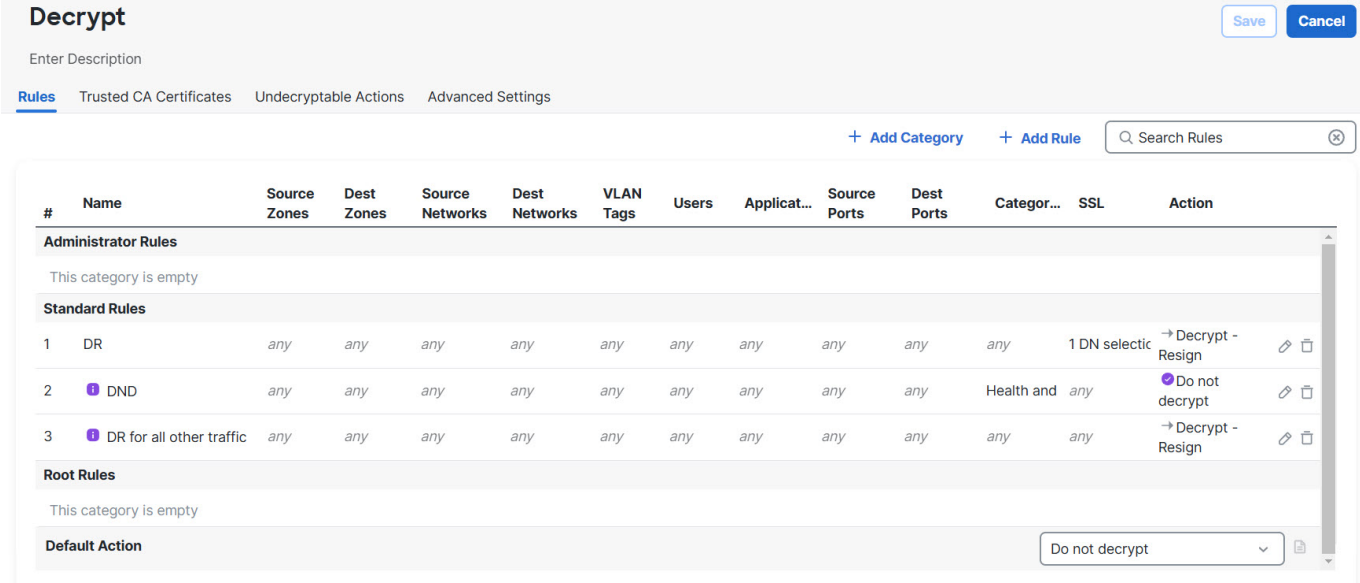
- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- URL category and reputation
- Port
- User group

Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for Using TLS/SSL Decryption, on page 2304.



Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Best Practices for Configuring Application Control, on page 1735.

TLS/SSL Decrypt - Resign Guidelines

You can associate one internal Certificate Authority (CA) certificate and private key with the **Decrypt - Resign** action. If traffic matches this rule, the system re-signs the server certificate with the CA certificate, then acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains different cryptographic session details, and allows the system to decrypt and reencrypt traffic.

Best practices

We recommend the following:

- Use the **Decrypt - Resign** rule action for decrypting *outgoing* traffic, as opposed to incoming traffic for which we recommend the **Decrypt - Known Key** rule action.

  For more information about **Decrypt - Known Key** , see TLS/SSL Decrypt - Known Key Guidelines, on page 2309.

- Always check the **Replace Key Only** check box when you set up a **Decrypt - Resign** rule action.

  When a user browses to a web site that uses a *self-signed* certificate, the user sees a security warning in the web browser and is aware that they are communicating with an unsecure site.

  When a user browses to a web site that uses a trusted certificate, the user does not see a security warning.

Details

If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's signature algorithm type, in addition to any configured rule conditions. Because you associate one CA certificate with a **Decrypt - Resign** action, you cannot create a decryption rule that decrypts multiple types of outgoing traffic encrypted with different signature algorithms. In addition, any external certificate objects and cipher suites you add to the rule must match the associated CA certificate encryption algorithm type.

For example, outgoing traffic encrypted with an elliptic curve (EC) algorithm matches a **Decrypt - Resign** rule only if the action references an EC-based CA certificate; you must add EC-based external certificates and cipher suites to the rule to create certificate and cipher suite rule conditions.

Similarly, a **Decrypt - Resign** rule that references an RSA-based CA certificate matches only outgoing traffic encrypted with an RSA algorithm; outgoing traffic encrypted with an EC algorithm does not match the rule, even if all other configured rule conditions match.

Guidelines and limitations

Also note the following:

Anonymous cipher suite unsupported

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

Do not use Version or Cipher Suite rule conditions

Important *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

Decrypt - Resign rule action and a Certificate Signing Request

To use a **Decrypt - Resign** rule action, you should create a Certificate Signing Request (CSR) and have it signed by a trusted certificate authority. (You can use the FMC to create a CSR: **Objects** > **Object Management** > **PKI** > **Internal Certs**.)

To be used in a **Decrypt - Resign** rule, your certificate authority (CA) must have at least one of the following extensions:

- **CA: TRUE**

  For more information, see the discussion of Basic Constraints in RFC3280, section 4.2.1.10.

- **KeyUsage=CertSign**

  For more information see RFC 5280, section 4.2.1.3.

To verify your CSR or CA has at least one of the preceding extensions, you can use the **openssl** command as discussed in a reference such as the openssl documentation.

This is necessary because for **Decrypt - Resign** inspection to work, the certificate that used in the decryption policy generates certificates on-the-fly and signs them so as to act as man-in-the middle and proxy all TLS/SSL connections.

Certificate pinning

If the customer's browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. To allow this traffic, configure a decryption rule with the **Do Not Decrypt** action to match the server certificate common name or distinguished name.

The decryption policy wizard creates such rules for you; see Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281 .

Non-matching cipher suite

The following error is displayed if you attempt to save a decryption rule with a cipher suite that does not match the certificate. To resolve the issue, see Verify TLS/SSL Cipher Suites, on page 2348.

```
Traffic cannot match this rule; none of your selected cipher suites contain a
signature algorithm that the resigning CA's signature algorithm
```

Untrusted Certificate Authority

If the client does not trust the Certificate Authority (CA) used to re-sign the server certificate, it warns the user that the certificate should not be trusted. To prevent this, import the CA certificate into the client trusted CA store. Alternatively, if your organization has a private PKI, you can issue an intermediate CA certificate signed by the root CA which is automatically trusted by all clients in the organization, then upload that CA certificate to the device.

HTTP proxy limitation

The system cannot decrypt traffic if an HTTP proxy is positioned between a client and your managed device, and the client and server establish a tunneled TLS/SSL connection using the CONNECT HTTP method. The **Handshake Errors** undecryptable action determines how the system handles this traffic.

Upload signed CA

If you create an internal CA object and choose to generate a certificate signing request (CSR), you cannot use this CA for a **Decrypt - Resign** action until you upload the signed certificate to the object.

Mismatched signature algorithm

If you configure a rule with the **Decrypt - Resign** action, and mismatch signature algorithm type for one or more external certificate objects or cipher suites, the policy editor displays an **Information**( ) next to the rule. If you mismatch signature algorithm type for all external certificate objects, or all cipher suites, the policy displays a warning icon **Warning** ( ) next to the rule, and you cannot deploy the access control policy associated with the decryption policy.

TLS/SSL Decrypt - Known Key Guidelines

When you configure the **Decrypt - Known Key** action, you can associate one or more server certificates and paired private keys with the action. If traffic matches the rule, and the certificate used to encrypt the traffic matches the certificate associated with the action, the system uses the appropriate private key to obtain the session encryption and decryption keys. Because you must have access to the private key, this action is best suited to decrypt traffic incoming to servers your organization controls.

Also note the following:

Anonymous cipher suite unsupported

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

Cannot match on Distinguished Name or Certificate

You cannot match on **Distinguished Name** or **Certificate** rule conditions when creating a decryption rule with a **Decrypt - Known Key** action. The assumption is that if this rule matches traffic, the certificate, subject DN, and issuer DN already match the certificate associated with the rule.

Do not use Version or Cipher Suite rule conditions

Important *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

Elliptic Curve Digital Signature Algorithm (*ECDSA*) certificate results in blocked traffic
(TLS 1.3 decryption enabled only.) If you use an ECDSA certificate with a **Decrypt - Known Key** rule action, matching traffic will be blocked. To avoid this, use a certificate with another type of certificate.

TLS/SSL Block Guidelines

If your decryption rule is associated with an access control policy that has a rule with an action of either **Interactive Block** or **Interactive Block with reset**, the system displays a customizable response page.

Provided you enabled logging in your rule, two connection events are displayed (in **Analysis** > **Connections**): One event for the interactive block and another event to indicate whether or not the user chose to continue to the site or not.

Related Topics

Configure HTTP Response Pages, on page 1873

TLS/SSL Certificate Pinning Guidelines

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

Because TLS/SSL pinning is used to avoid man-in-the-middle attacks, there is no way to prevent or work around it. We recommend adding a **Do Not Decrypt** rule before the **Decrypt - Resign** rule so pinning traffic is excluded from being decrypted. The decryption policy wizard does this for you.

- Create a **Do Not Decrypt** for those applications rule ordered before **Decrypt - Resign** rules.
- Instruct users to access the applications using a web browser.

For more information about rule ordering, see Decryption Policy Rule Order.

To determine whether applications are using TLS/SSL pinning, see Troubleshoot TLS/SSL Pinning, on page 2344.

TLS/SSL Heartbeat Guidelines

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, see The SSL Preprocessor.

For more information, see About TLS Heartbeat, on page 2341.

TLS/SSL Anonymous Cipher Suite Limitation

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

You can add an anonymous cipher suite to the **Cipher Suite** condition in a decryption rule, but the system automatically strips anonymous cipher suites during ClientHello processing. For the system to use the rule, you must also configure your decryption rules in an order that prevents ClientHello processing. For more information, see Decryption Policy Rule Order.

TLS/SSL Normalizer Guidelines

If you enable the **Normalize Excess Payload** option in the inline normalization preprocessor, when the preprocessor normalizes decrypted traffic, it might drop a packet and replace it with a trimmed packet. This does not end the TLS/SSL session. If the traffic is allowed, the trimmed packet is encrypted as part of the TLS/SSL session.

Other Decryption Rule Guidelines

Users and groups

If you add a group or user to a rule, then change your realm settings to exclude that group or user, the rule has no effect. (The same applies to disabling the realm.) For more information about realms, see Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Categories in decryption rules

If your decryption policy has a **Decrypt - Resign** action but web sites are not being decrypted, check **Category** page on rules associated with that policy.

In some cases, a web site redirects to another site for authentication or other purposes and the redirected site might have a different URL categorization than the site you're trying to decrypt. For example, `gmail.com` (**Web based email** category) redirects to `accounts.gmail.com` (**Internet Portals** category) for authentication. Be sure to include all relevant categories in the SSL rule.

Note In order to fully process traffic based on URL category, you must also configure URL filtering. See the URL Filtering, on page 1857 chapter.

Query for URLs not in the local database

If you create a **Decrypt - Resign** rule and users browse to a web site whose category and reputation are not in the local database, data might not be decrypted. Some web sites are not categorized in the local database and, if not, data from those web sites is not decrypted by default.

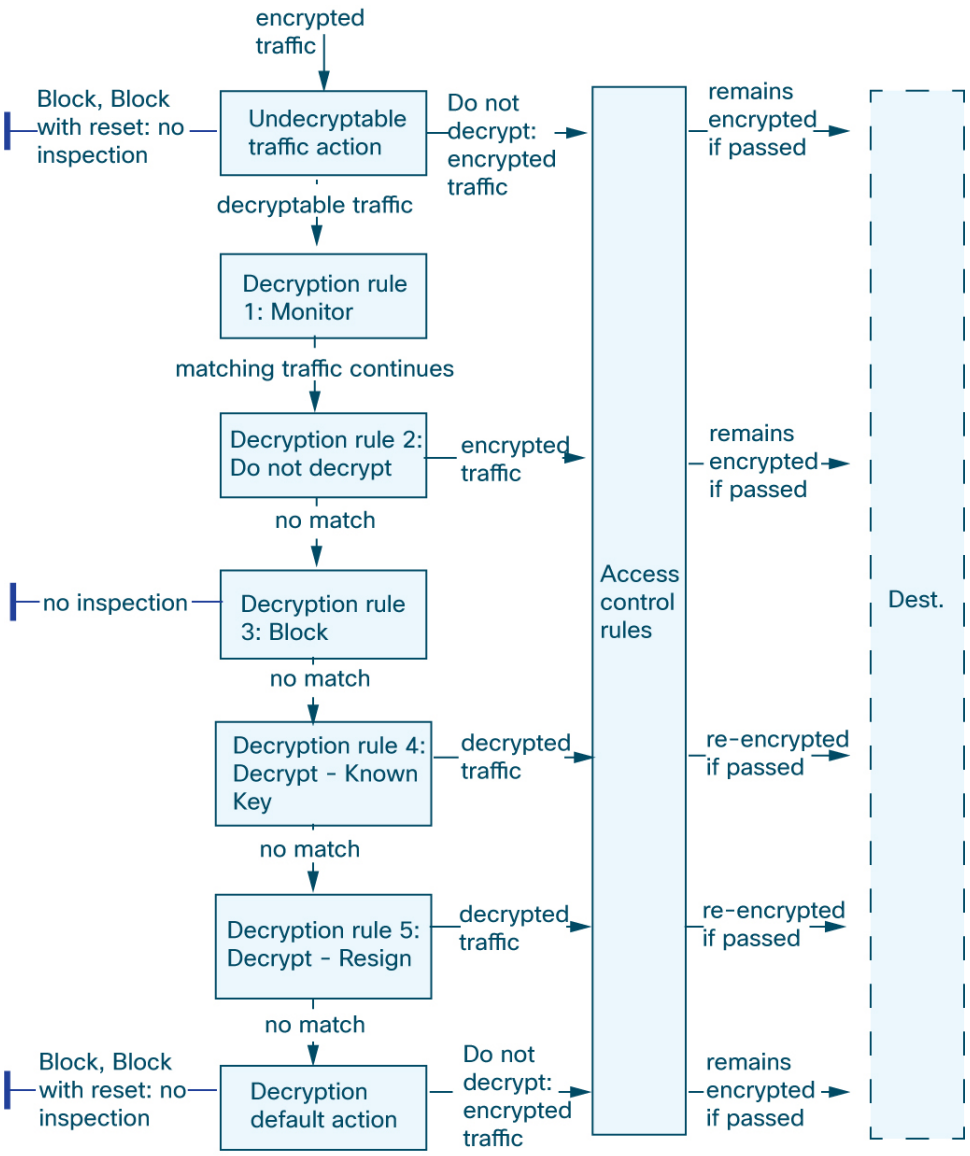
You can control this behavior with the **Query Cisco cloud for unknown URLs** setting in **Integration** > **Other Integrations** > **Cloud Services**

Decryption Rule Traffic Handling

The system matches traffic to decryption rules in the order you specify. In most cases, the system handles encrypted traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does inspect encrypted and undecryptable traffic with access control. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads.

The following scenario summarizes the ways that decryption rules handle traffic in an inline deployment.



In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- **Decryption Rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- **Decryption Rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **Decryption Rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- **Decryption Rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- **Decryption Rule 5: Decrypt - Resign** is the final rule. If traffic matches this rule, the system re-signs the server certificate with an uploaded CA certificate, then acts as a man-in-the-middle to decrypt traffic. The decrypted traffic is then evaluated against access control rules. Access control rules treat decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule rule continues to the next rule.
- **Decryption policy Default Action** handles all traffic that does not match any of the decryption rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

Encrypted Traffic Inspection Configuration

You must create reusable public key infrastructure (PKI) objects to control encrypted traffic based on encrypted session characteristics and decrypt encrypted traffic. You can add this information on the fly when uploading trusted certificate authority (CA) certificates to the a decryption policy and creating decryption rule, creating the associated object in the process. However, configuring these objects ahead of time reduces the chance of improper object creation.

Decrypting Encrypted Traffic with Certificates and Paired Keys

The system can decrypt incoming encrypted traffic if you configure an internal certificate object by uploading the server certificate and private key used to encrypt the session. If you reference that object in a decryption policy rule with an action of **Decrypt - Known Key** and traffic matches that rule, the system uses the uploaded private key to decrypt the session.

The system can also decrypt outgoing traffic if you configure an internal CA object by uploading a CA certificate and private key. If you reference that object in a decryption rule with an action of **Decrypt - Resign** and traffic matches that rule, the system re-signs the server certificate passed to the client browser, then acts as a man-in-the-middle to decrypt the session. You can optionally replace the self-signed certificate key only and not the entire certificate, in which case users see a self-signed certificate key notice in the browser.

Controlling Traffic Based on Encrypted Session Characteristics

The system can control encrypted traffic based on the cipher suite or server certificate used to negotiate the session. You can configure one of several different reusable objects and reference the object in a decryption rule condition to match traffic. The following table describes the different types of reusable objects you can configure:

If you configure...	You can control encrypted traffic based on whether...
A cipher suite list containing one or more cipher suites	The cipher suite used to negotiate the encrypted session matches a cipher suite in the cipher suite list

If you configure...	You can control encrypted traffic based on whether...
A trusted CA object by uploading a CA certificate your organization trusts	The trusted CA trusts the server certificate used to encrypt the session, whether: • The CA issued the certificate directly • The CA issued a certificate to an intermediate CA that issued the server certificate
An external certificate object by uploading a server certificate	The server certificate used to encrypt the session matches the uploaded server certificate
A distinguished name object containing a certificate subject or issuer distinguished name	The subject or issuer common name, country, organization, or organizational unit on the certificate used to encrypt the session matches the configured distinguished name

Distinguished Name, on page 1382
PKI, on page 1404

Decryption Rule Order Evaluation

This information applies only to rule-based decryption policies and rules.

When you create a decryption rule in a decryption policy, you specify its position using the **Insert** list in the rule editor. Decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules. For more information about the OSI model, see this Wikipedia article.

Tip Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

Related Topics

Best Practices for Access Control Rules, on page 1738
Default Handling Options for Undecryptable Traffic, on page 2296
Decryption Policy Rule Order

Decryption Rule Conditions

A decryption rule's conditions identify the type of encrypted traffic the rule handles. Conditions can be simple or complex, and you can specify more than one condition type per rule. Only if traffic meets all the conditions in a rule does the rule apply to the traffic.

If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a certificate condition but no version condition evaluates traffic based on the server certificate used to negotiate the session, regardless of the session SSL or TLS version.

Every decryption rule has an associated action that determines the following for matching encrypted traffic:

- Handling: Most importantly, the rule action governs whether the system will monitor, trust, block, or decrypt encrypted traffic that matches the rule's conditions
- Logging: The rule action determines when and how you can log details about matching encrypted traffic.

Your TLS/SSL inspection configuration handles, inspects, and logs decrypted traffic:

- The decryption policy's undecryptable actions handle traffic that the system cannot decrypt.
- The policy's default action handles traffic that does not meet the condition of any non-Monitor decryption rule.

You can log a connection event when the system blocks or trusts an encrypted session. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. Connection logs for encrypted sessions contain details about the encryption, such as the certificate used to encrypt that session. You can log only end-of-connection events, however:

- For blocked connections (Block, Block with reset), the system immediately ends the sessions and generates an event
- For Do Not Decrypt connections, the system generates an event when the session ends

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Security Zone Rule Conditions

Security zones segment your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices.

Security zones control or decrypt traffic by its source and destination security zones. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

Just as all interfaces in a zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Security Zone Conditions and Multitenancy

In a multidomain deployment, a zone created in an ancestor domain can contain interfaces that reside on devices in different domains. When you configure a zone condition in an descendant domain, your configurations apply to only the interfaces you can see.

Network Rule Conditions

Networks control or decrypt traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

VLAN Tags Rule Conditions

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

User Rule Conditions

Matches traffic based the user who initiates the connection, or the group to which the user belongs. For example, you could configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

You can configure user rule conditions for users in Microsoft Active Directory realms only.

In addition to configuring users and groups for configured realms, you can set policies for the following Special Identities users:

- Failed Authentication: User that failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified; for example, users that are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associating Other Policies with Access Control, on page 1762.

Client Threat Rule Conditions

The threat confidence levels of the client processes are determined by the Encrypted Visibility Engine (EVE), and represent the likelihood that the incoming traffic is malicious. The client threat confidence levels range from very low to very high, and the levels can be specified as rule conditions for decryption policy rules. When the client threat confidence levels and server URL category reputation are configured, they act as a powerful combination in decryption policies. We highly recommend that you specify a URL Category Reputation rule condition for rules that specify a Client Threat rule condition. When Client Threat and URL Category Reputation conditions are both specified for a decryption policy rule, the reputations of both the client and the server are utilized to make more accurate decryption policy decisions. We recommend that you do not specify a Client Threat rule condition alone without specifying a URL Category Reputation rule condition because this rule configuration only acts on information about the client and lacks information about the server.

Prerequisites for configuring client threat rule conditions

- The EVE must be enabled in the corresponding access control policy.
- The management center and threat defense devices must be Version 7.7.
- Snort 3 must be enabled on the device.
- Valid IPS and URL Filtering licenses must be installed on the managed device.

We recommend that you bypass decryption for very low-risk clients connecting to trusted servers based on the client threat determined by EVE and URL Category Reputation. To do so, create a new decryption policy rule, or edit an existing rule with the following configurations:

1. Choose the decryption policy rule action as **Do not decrypt**.
2. In the **Client Threat** tab, choose the client threat level as **Very Low**.
3. In the **Category** tab, choose the category as **All** and the reputation as **Trusted**.

Application Rule Conditions

When the system analyzes IP traffic, it can identify and classify the commonly used applications on your network. This discovery-based *application awareness* is the basis for *application control*—the ability to control application traffic.

System-provided *application filters* help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. You can create reuseable user-defined filters based on combinations of the system-provided filters, or on custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled for an application, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application. For more information about application detectors, see Application Detector Fundamentals, on page 2624.

You can use both application filters and individually specified applications to ensure complete coverage. However, understand the following note before you order your access control rules.

Benefits of Application Filters

Application filters help you quickly configure application control. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

Application Characteristics

The system characterizes each application that it detects using the criteria described in the following table. Use these characteristics as application filters.

Table 126: Application Characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email clients are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Best Practices for Configuring Application Control, on page 1735

Port Rule Conditions

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic.

Application filtering is also recommended for applications, like Firewall Threat Defense, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Category Rule Conditions

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

For more information, see URL Filtering Overview, on page 1857.

If you are using category rule conditions in decryption policies in a rule with the **Do Not Decrypt** rule action, see Decryption Rule Do Not Decrypt Action, on page 2335.

Server Certificate-Based Decryption Rule Conditions

decryption rules can handle and decrypt encrypted traffic based on server certificate characteristics. You can configure decryption rules based on the following server certificate attributes:

- Distinguished name conditions allow you to handle and inspect encrypted traffic based on the CA that issued a server certificate, or the certificate holder. Based on the issuer distinguished name, you can handle traffic based on the CA that issued a site's server certificate.

- Certificate conditions in decryption rules allow you to handle and inspect encrypted traffic based on the server certificate used to encrypt that traffic. You can configure a condition with one or more certificates; traffic matches the rule if the certificate matches any of the condition's certificates.
- Certificate status conditions in decryption rules allow you to handle and inspect encrypted traffic based on the status of the server certificate used to encrypt the traffic, including whether a certificate is valid, revoked, expired, not yet valid, self-signed, signed by a trusted CA, whether the Certificate Revocation List (CRL) is valid; whether the Server Name Indication (SNI) in the certificate matches the server in the request.
- Cipher suite conditions in decryption rules allow you to handle and inspect encrypted traffic based on the cipher suite used to negotiate the encrypted session.
- Session conditions in decryption rules allow you to inspect encrypted traffic based on the SSL or TLS version used to encrypt the traffic.

To detect multiple cipher suites in a rule, the certificate issuer, or the certificate holder, you can create reusable cipher suite list and distinguished name objects and add them to your rule. To detect the server certificate and certain certificate statuses, you must create external certificate and external CA objects for the rule.

Certificate Decryption Rule Conditions

When you build a certificate-based decryption rule condition, you can upload a server certificate; you save the certificate as an external certificate *object*, which is reusable and associates a name with a server certificate. Alternately, you can configure certificate conditions with existing external certificate objects and object groups.

You can search the **Available Certificates** field in the rule condition based for external certificate objects and object groups based on the following certificate distinguished name characteristics:

- Subject or issuer common name (CN), or if the URL is contained in the certificate's Subject Alternative Name (SAN)

  The URL the user enters in the browser matches the Common Name (CN)
- Subject or issuer organization (O)
- Subject or issuer organizational unit (OU)

You can choose to match against multiple certificates in a single certificate rule condition; if the certificate used to encrypt the traffic matches any of the uploaded certificates, the encrypted traffic matches the rule.

You can add a maximum of 50 external certificate objects and external certificate object groups to the **Selected Certificates** in a single certificate condition.

Note the following:

- You cannot configure a certificate condition if you also select the **Decrypt - Known Key** action. Because that action requires you to select a server certificate to decrypt traffic, the implication is that the certificate already matches the traffic.
- If you configure a certificate condition with an external certificate object, any cipher suites you add to a cipher suite condition, or internal CA objects you associate with the **Decrypt - Resign** action, must match the external certificate's signature algorithm type. For example, if your rule's certificate condition references an EC-based server certificate, any cipher suites you add, or CA certificates you associate with the **Decrypt - Resign** action, must also be EC-based. If you mismatch signature algorithm types in this case, the policy editor displays a warning next to the rule.
- The first time the system detects an encrypted session to a new server, certificate data is not available for ClientHello processing, which can result in an undecrypted first session. After the initial session, the managed device caches data from the server Certificate message. For subsequent connections from the same client, the system can match the ClientHello message conclusively to rules with certificate conditions and process the message to maximize decryption potential.

Distinguished Name (DN) Rule Conditions

This topic discusses how to use distinguished name conditions in a decryption rule. If you're not sure, you can find a certificate's Subject Alternative Name (SAN) and Common Name using a web browser, then you can add those values to a decryption rule as distinguished name conditions.

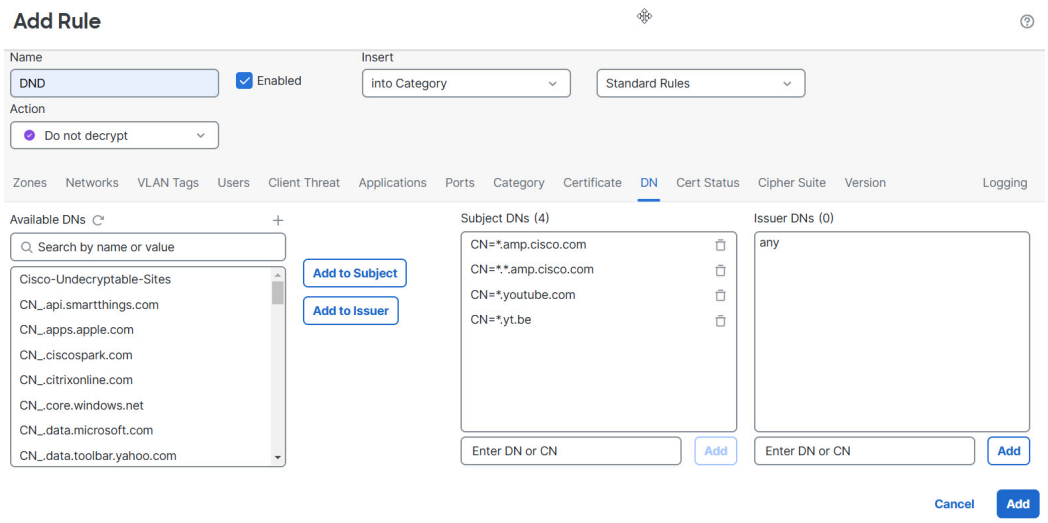
For detailed information about SANs, see RFC 528, section 4.2.1.6.

The following sections discuss:

- DN rule matching example
- How the system uses the SNIs and SANs
- How to find a certificate's Common Name and Subject Alternative Names
- How to add a DN rule condition

DN rule matching example

Following is an example of DN rule conditions in a Do Not Decrypt rule. Suppose you want to make sure to *not* decrypt traffic going to `amp.cisco.com` or to YouTube. You could set up your DN conditions as follows:



The preceding DN rule conditions would match the following URLs and therefore, the traffic would be undecrypted an earlier rule prevented it:

- www.amp.cisco.com
- auth.amp.cisco.com
- auth.us.amp.cisco.com
- www.youtube.com
- kids.youtube.com
- www.yt.be

The preceding DN rule conditions would *not* match any of the following URLs and therefore, the traffic would not match the Do Not Decrypt rule but might match any other decryption rules in the same decryption policy.

- amp.cisco.com
- youtube.com
- yt.be

To match any of the preceding host names, add more CNs to the rule (for example, adding `CN=yt.be` would match that URL.)

How the system uses the SNI and SANs

The host name portion of the URL in the client request is the Server Name Indication (SNI). The client specifies which hostname they want to connect to (for example, `auth.amp.cisco.com`) using the SNI extension in the TLS handshake. The server then selects the corresponding private key and certificate chain that are required to establish the connection while hosting all certificates on a single IP address.

If there's a match between the SNI and the CN or a SAN in the certificate, we use the SNI when comparing against the DNs listed in the rule. If there is no SNI or if it doesn't match the certificate, we use the certificate's CN when comparing against the DNs listed in the rule.

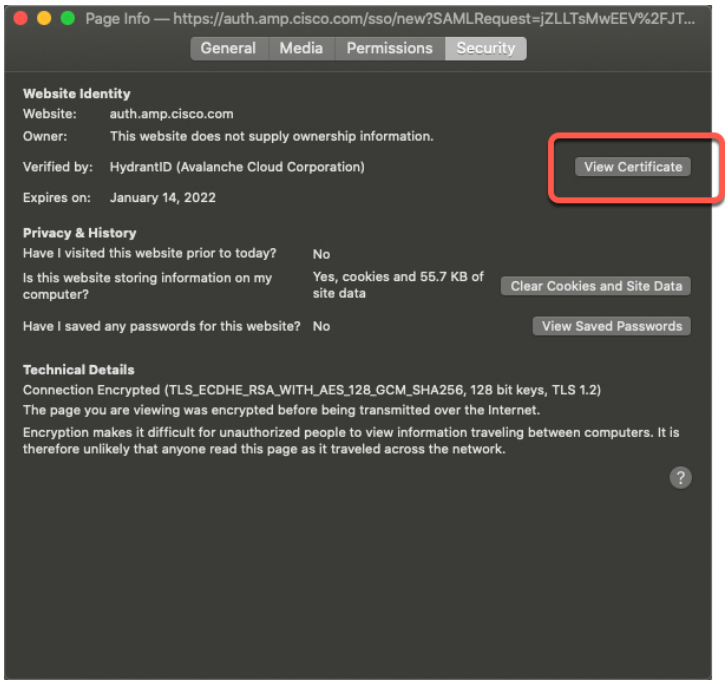
How to find a certificate's Common Name and subject alternative names

To find any certificate's Common Name, use the following steps. You can even use these steps to find the common name and SANs for a self-signed certificate.

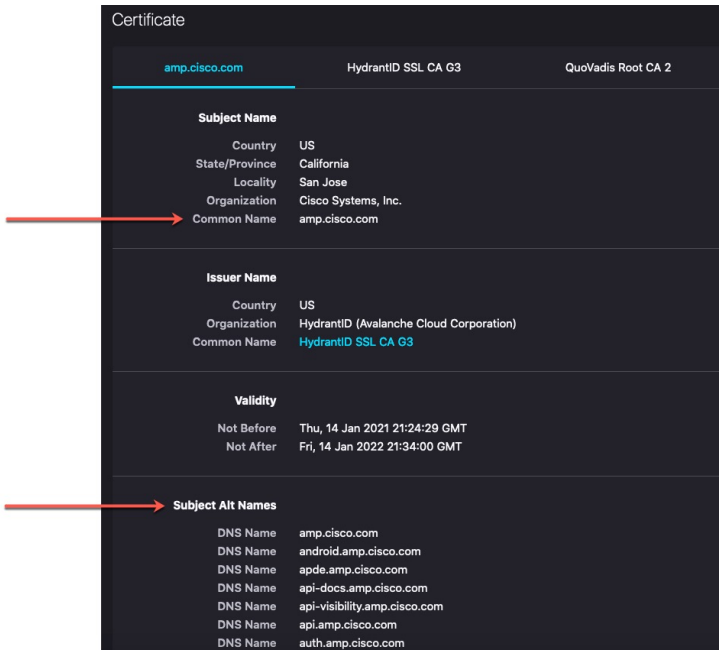
These steps are for Firefox but other browsers are similar. The following procedure uses `amp.cisco.com` as an example.

1. Browse to `amp.cisco.com` in Firefox.
2. In the browser's location bar, to the left of the URL, click .
3. Click **Connection secure** > **More Information**.

   (For a non-secure or self-signed certificate, click **Connection not secure** > **More Information**.)
4. On the Page Info dialog box, click **View Certificate**.



5. The next page shows certificate details.



Note the following:

- `CN=auth.amp.cisco.com`, if used as a DN rule condition, would match *only* that host name (that is, SNI). The SNI `amp.cisco.com` would *not* match.
- To match as many domain name fields as possible, use wildcards.

  For example, to match `auth.amp.cisco.com`, use `CN=*.amp.cisco.com`. To match `auth.us.amp.cisco.com`, use `CN=*.*.amp.cisco.com`.

  A DN like `CN=*.example.com` matches `www.example.com` but *not* `example.com`. To match both SNIs, use two DNs in the rule condition.
- Don't go overboard with wildcards though. For example, a DN object like `CN=*.google.com` matches a very large number of SANs. Instead of `CN=*.google.com`, use a DN object like `CN=*.youtube.com` as the DN object so it matches names like `www.youtube.com`.

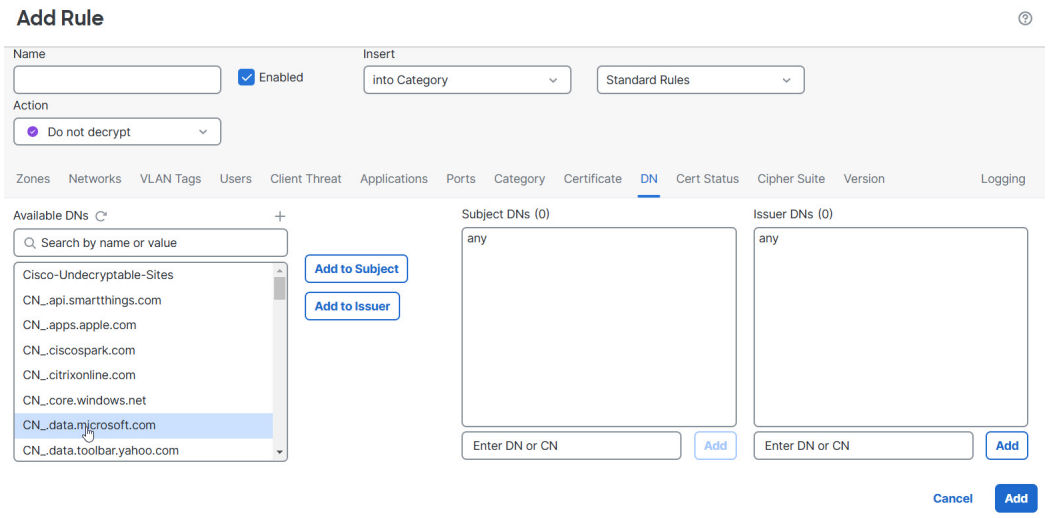
  You can also use variations of the SNI that match SANs like `CN=*.youtube.com`, `CN=youtu.be`, `CN=*.yt.be`, and so on.
- A self-signed certificate should work the same way. You can confirm it's a self-signed certificate by the fact the issuer DN is the same as the subject DN.

How to add a DN rule condition

After you know the CN you want to match, edit the decryption rule in one of the following ways:

- Use an existing DN.

  Click the name of a DN and then click either **Add to Subject** or **Add to Issuer**. (**Add to Subject** is much more common.) To view the value of a DN object, hover the mouse pointer over it.)



- Create a new DN object.

  Click **Add** (+) to the right of Available DNs. The DN object must consist of a name and a value.

- Add the DN directly.

  Enter the DN in the field at the bottom of the **Subject DNs** field or the **Issuer DNs** field. (**Subject DNs** is more common.) After you enter the DN, click **Add**.

Distinguished Name, on page 1382

Trusting External Certificate Authorities

You can trust CAs by adding root and intermediate CA certificates to your decryption policy, then use these trusted CAs to verify server certificates used to encrypt traffic.

If a trusted CA certificate contains an uploaded certificate revocation list (CRL), you can also verify whether a trusted CA revoked the encryption certificate.

Tip Upload all certificates in a root CA's chain of trust to the list of trusted CA certificates, including the root CA certificate and all intermediate CA certificates. Otherwise, it is more difficult to detect trusted certificates issued by intermediate CAs. Also, if you configure certificate status conditions to trust traffic based on the root issuer CA, all traffic within a trusted CA's chain of trust can be allowed without decryption, rather than unnecessarily decrypting it.

For more information, see Trusted CA Object, on page 1409.

Note When you create a decryption policy, the policy's **Trusted CA Certificate** tab page is populated with several trusted CA certificates, including the **Cisco-Trusted-Authorities** group, which is added to the **Select Trusted CAs** list.

Procedure

Step 1 Log in to the Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to the decryption policy to edit.

Step 4 Click **Add Rule** to add a new decryption rule or click **Edit** (✎) to edit an existing rule.

Step 5 Click the **Certificates** tab.

Step 6 Find the trusted CAs you want to add from the **Available Certificates**, as follows:

- To add a trusted CA object on the fly, which you can then add to the condition, click **Add** (+) above the **Available Certificates** list.
- To search for trusted CA objects and groups to add, click the **Search by name or value** prompt above the **Available Certificates** list, then enter either the name of the object, or a value in the object. The list updates as you type to display matching objects.

Step 7 To select an object, click it. To select all objects, right-click and then **Select All**.

Step 8 Click **Add to Rule**.

Tip
You can also drag and drop selected objects.

Step 9 Add or continue editing the rule.

What to do next

- Add a certificate status decryption rule condition to your SSL rule. See Matching Traffic on Certificate Status for more information.

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Certificate Status Decryption Rule Conditions

For each certificate status decryption rule you configure, you can match traffic against the presence or absence of a given status. You can select several statuses in one rule condition; if the certificate matches any of the selected statuses, the rule matches the traffic.

You can choose to match against the presence or absence of multiple certificate statuses in a single certificate status rule condition; the certificate needs to match only one of the criteria to match the rule.

You should consider, when setting this parameter, whether you're configuring a decrypt rule or a block rule. Typically, you should click **Yes** for a block rule and **No** for a decrypt rule. Examples:

- If you're configuring a **Decrypt - Resign** rule, the default behavior is to decrypt traffic with an expired certificate. To change that behavior, click **No** for **Expired** so traffic with an expired certificate is not decrypted and resigned.
- If you're configuring a **Block** rule, the default behavior is to allow traffic with an expired certificate. To change that behavior click **Yes** for **Expired** so traffic with an expired certificate is blocked.

The following table describes how the system evaluates encrypted traffic based on the encrypting server certificate's status.

Table 127: Certificate Status Rule Condition Criteria

Status Check	Status Set to Yes	Status Set to No
Revoked	The policy trusts the CA that issued the server certificate, and the CA certificate uploaded to the policy contains a CRL that revokes the server certificate.	The policy trusts the CA that issued the certificate, and the CA certificate uploa policy does not contain a CRL that rev certificate.
Self-signed	The detected server certificate contains the same subject and issuer distinguished name.	The detected server certificate contains subject and issuer distinguished names
Valid	All of the following are true: • The policy trusts the CA that issued the certificate. • The signature is valid. • The issuer is valid. • None of the policy's trusted CAs revoked the certificate. • The current date is between the certificate Valid From and Valid To date.	At least one of the following is true: • The policy does not trust the CA t certificate. • The signature is invalid. • The issuer is invalid. • A trusted CA in the policy revoke certificate. • The current date is before the cert From date. • The current date is after the certifi date.
Invalid signature	The certificate's signature cannot be properly validated against the certificate's content.	The certificate's signature is properly val the certificate's content.

Status Check	Status Set to Yes	Status Set to No
Invalid issuer	The issuer CA certificate is not stored in the policy's list of trusted CA certificates.	The issuer CA certificate is stored in the p of trusted CA certificates.
Expired	The current date is after the certificate Valid To date.	The current date is before or on the certific To date.
Not yet valid	The current date is before the certificate Valid From date.	The current date is after or on the certificat From date.
Invalid certificate	The certificate is not valid. At least one of the following is true: • Invalid or inconsistent certificate extension; that is, a certificate extension had an invalid value (for example, an incorrect encoding) or some value inconsistent with other extensions. • The certificate cannot be used for the specified purpose. • The Basic Constraints path length parameter has been exceeded. For more information, see RFC 5280, section 4.2.1.9. • The certificate's value for Not Before or Not After is invalid. These dates can be encoded as UTCTime or GeneralizedTime For more information, see RFC 5280 section 4.1.2.5. • The format of the name constraint is not recognized; for example, an email address format of a form not mentioned in RFC 5280, section 4.2.1.10. This could be caused by an improper extension or some new feature not currently supported. An unsupported name constraint type was encountered. OpenSSL currently supports only directory name, DNS name, email, and URI types. • The root certificate authority is not trusted for the specified purpose. • The root certificate authority rejects the specified purpose.	The certificate is valid. All of the followin • Valid certificate extension. • The certificate can be used for the spe purpose. • Valid Basic Constraints path length. • Valid values for Not Before and Not A • Valid name constraint. • The root certificate is trusted for the s purpose. • The root certificate accepts the specifie

Status Check	Status Set to Yes	Status Set to No
Invalid CRL	The Certificate Revocation List (CRL) digital signature is not valid. At least one of the following is true: • The value of the CRL's Next Update or Last Update field is invalid. • The CRL is not yet valid. • The CRL has expired. • An error occurred when attempting to verify the CRL path. This error occurs only if extended CRL checking is enabled. • CRL could not be found. • The only CRLs that could be found did not match the scope of the certificate.	The CRL is valid. All of the following • Next Update and Last Update fiel • The CRL's date is valid. • The path is valid. • The CRL was found. • The CRL matches the certificate's
Server mismatch	The server name does not match the server's Server Name Indication (SNI) name, which could indicate an attempt to spoof the server name.	The server name matches the SNI name to which the client is requesting access

Note that even though a certificate might match more than one status, the rule causes an action to be taken on the traffic only once.

Checking whether a CA issued or revoked a certificate requires uploading root and intermediate CA certificates and associated CRLs as objects. You then add these trusted CA objects to an decryption policy's list of trusted CA certificates.

Cipher Suite Decryption Rule Conditions

The system provides predefined cipher suites you can add to a cipher suite rule condition for Block or Block with Reset rule actions. You can also add cipher suite list objects containing multiple cipher suites.

Important Cipher suite rule conditions can be used only to *block* traffic, they cannot be used to *decrypt* traffic.

Note You cannot add new cipher suites. You can neither modify nor delete predefined cipher suites.

You can add a maximum of 50 cipher suites and cipher suite lists to the **Selected Cipher Suites** in a single cipher suite condition. The system supports adding the following cipher suites to a cipher suite condition:

- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_DES_CBC_SHA
- TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA

- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA256
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA256
- TLS_DHE_RSA_WITH_DES_CBC_SHA
- TLS_DH_Anon_WITH_AES_128_GCM_SHA256
- TLS_DH_Anon_WITH_AES_256_GCM_SHA384
- TLS_DH_Anon_WITH_CAMELLIA_128_CBC_SHA
- TLS_DH_anon_WITH_CAMELLIA_128_CBC_SHA256
- TLS_DH_Anon_WITH_CAMELLIA_256_CBC_SHA
- TLS_DH_anon_WITH_CAMELLIA_256_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_NULL_SHA
- TLS_ECDHE_ECDSA_WITH_RC4_128_SHA
- TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384

- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_NULL_SHA
- TLS_ECDHE_RSA_WITH_RC4_128_SHA
- TLS_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_128_GCM_SHA256
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA256
- TLS_RSA_WITH_AES_256_GCM_SHA384
- TLS_RSA_WITH_CAMELLIA_128_CBC_SHA
- TLS_RSA_WITH_CAMELLIA_128_CBC_SHA256
- TLS_RSA_WITH_CAMELLIA_256_CBC_SHA
- TLS_RSA_WITH_CAMELLIA_256_CBC_SHA256
- TLS_RSA_WITH_DES_CBC_SHA
- TLS_RSA_WITH_NULL_MD5
- TLS_RSA_WITH_NULL_SHA
- TLS_RSA_WITH_RC4_128_MD5
- TLS_RSA_WITH_RC4_128_SHA

Note the following:

- If you add cipher suites not supported for your deployment, you cannot deploy your configuration. For example, passive deployments do not support decrypting traffic with the any of the ephemeral Diffie-Hellman (DHE) or ephemeral elliptic curve Diffie-Hellman (ECDHE) cipher suites. Creating a rule with these cipher suites prevents you from deploying your access control policy.
- You can add an anonymous cipher suite to the **Cipher Suite** condition in decryption policy to use the rule, you must also configure your in an order that prevents ClientHello processing. For more information, see Decryption Policy Rule Order.
- When specifying a cipher suite as a rule condition, consider that the rule matches on the negotiated cipher suite in the ServerHello message, rather than on the full list of cipher suites specified in the ClientHello message. During ClientHello processing, the managed device strips unsupported cipher suites from the ClientHello message. However, if this results in all specified cipher suites being stripped, the system retains the original list. If the system retains unsupported cipher suites, subsequent evaluation results in an undecrypted session.

Encryption Protocol Version Decryption Rule Conditions

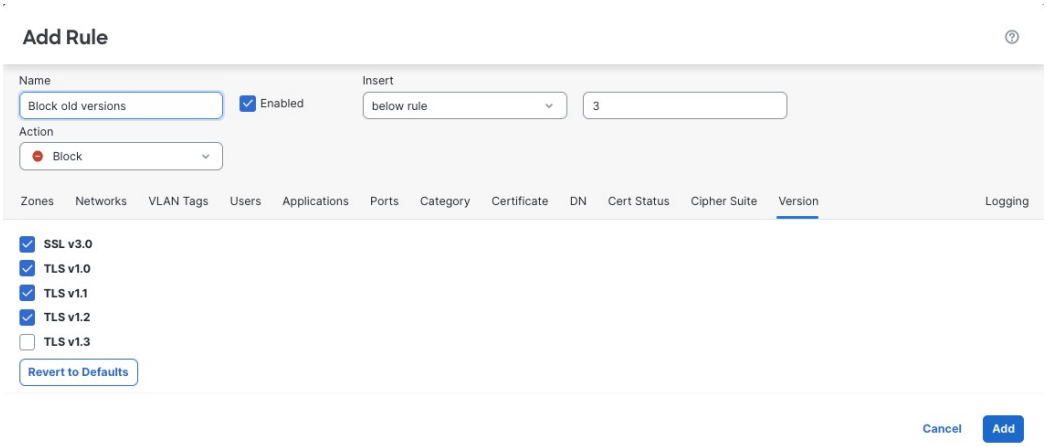
You can choose to match against traffic encrypted with SSL version 3.0, or TLS version 1.0, 1.1, or 1.2. By default, all protocol versions are selected when you create a rule; if you select multiple versions, encrypted traffic that matches any of the selected versions matches the rule. You must select at least one protocol version when saving the rule condition.

You can use SSL 3.0 in a Do Not Decrypt, Block, or Block with Reset rule action.

You *cannot* select SSL v2.0 in a version rule condition; the system does not support decrypting traffic encrypted with SSL version 2.0. You can configure an undecryptable action to allow or block this traffic without further inspection. For more information, see Set Default Handling for Undecryptable Traffic, on page 2297.

Important Protocol version rule conditions can be used *only* to *block* traffic, they cannot be used to *decrypt* traffic.

For example, to block all SSL v3.0, TLS v1.0, TLS v1.1, and TLS v1.2 traffic, set the options as follows:



Decryption Rule Actions

The following sections discuss the actions available with Decryption rules.

Decryption Rule Monitor Action

The **Monitor** action is not designed to permit or deny traffic. Rather, its primary purpose is to force connection logging, regardless of how matching traffic is eventually handled. The ClientHello message is not modified if traffic matches a **Monitor** rule condition.

Traffic is then matched against additional rules, if present, to determine whether to trust, block, or decrypt it. The first non-Monitor rule matched determines traffic flow and any further inspection. If there are no additional matching rules, the system uses the default action.

Because the primary purpose of Monitor rules is to track network traffic, the system automatically logs end-of connection events for monitored traffic to the Secure Firewall Management Center database, regardless of the logging configuration of the rule or default action that later handles the connection.

Decryption Rule Do Not Decrypt Action

The **Do Not Decrypt** action passes encrypted traffic for evaluation by the access control policy's rules and default action. Because some access control rule conditions require unencrypted traffic, this traffic might match fewer rules. The system cannot perform deep inspection on encrypted traffic, such as intrusion or file inspection.

Typical reasons for a **Do Not Decrypt** rule action include:

- When decrypting TLS/SSL traffic is prohibited by law.
- Sites you know you can trust.
- Sites you can disrupt by inspecting traffic (such as Windows Update).
- To view the values of TLS/SSL fields using connection events. (You do not need to decrypt traffic to view connection event fields.) For more information, see *Requirements for Populating Connection Event Fields* in the Cisco Secure Firewall Management Center Administration Guide.

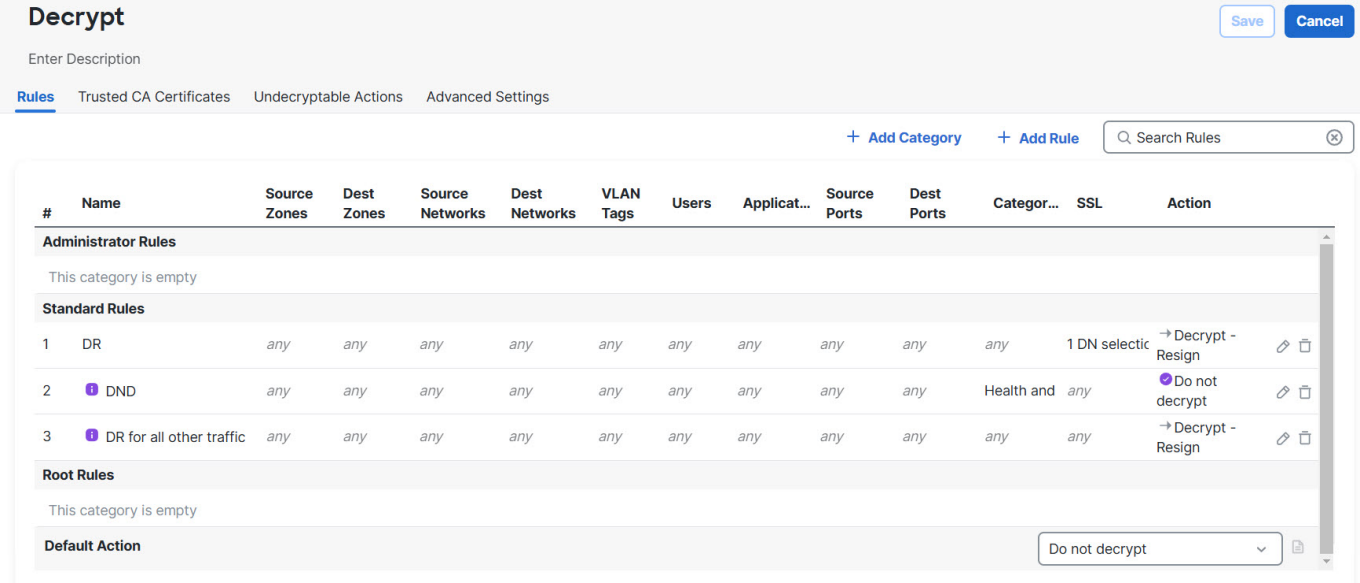
For more information, see Default Handling Options for Undecryptable Traffic, on page 2296

Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for Using TLS/SSL Decryption, on page 2304.



Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Best Practices for Configuring Application Control, on page 1735.

Decryption Rule Blocking Actions

The system provides the following decryption rule actions for traffic you do not want to pass through the system:

- **Block** to terminate the connection, resulting in an error in the client browser.

  The error message does not indicate the site was blocked due to policy. Instead, errors might indicate that there are no common encryption algorithms. It is not obvious from this message that you blocked the connection on purpose.

- **Block with reset** to terminate and reset the connection, resulting in an error in the client browser.

  The error indicates the connection was reset but does not indicate why.

Tip You cannot use the **Block** or **Block with reset** action in a passive or inline (tap mode) deployment because the device does not directly inspect the traffic. If you create a rule with the **Block** or **Block with reset** action that contains passive or inline (tap mode) interfaces within a security zone condition, the policy editor displays a warning (⚠) next to the rule.

Decryption Rule Decrypt Actions

The **Decrypt - Replace Cert**, **Decrypt - Known Key**, and **Decrypt - Resign** actions decrypt encrypted traffic. The system inspects decrypted traffic with access control. Access control rules handle decrypted and unencrypted traffic identically — you can inspect it for discovery data as well as detect and block intrusions, prohibited files, and malware. The system reencrypts allowed traffic before passing it to its destination.

We recommend you use a certificate from a trusted Certificate Authority (CA) to decrypt traffic. This prevents **Invalid Issuer** from being displayed in the SSL Certificate Status column in connection events.

For more information about adding trusted objects, see Trusted Certificate Authority Objects, on page 1409.

Related topic: TLS 1.3 Decryption Best Practices, on page 2300.

Related Topics

TLS 1.3 Decryption Best Practices, on page 2300

Select Internal Certificate Objects

Before you begin

To create a decryption rule with a **Decrypt - Known Key** action, you must add internal certificates for the servers to decrypt traffic. For more information, see Internal Certificate Authority Objects, on page 1405.

Procedure

Step 1 Click **Edit** (✎) in the field next to the decryption rule **Action**.

Step 2 In the Select Internal Certificate Objects dialog box, do the following:
Available Certificates list: Click the name of a certificate and click **Add to Rule** to use it in this rule. You can add one or more certificates to the rule.

Selected Certificates list: Displays internal certificates used in the rule. To remove a certificate, click **Delete** (🗑).

Step 3 To save these changes, click **OK**.

Monitor TLS/SSL Hardware Acceleration

The following topics discuss how to monitor the status of TLS/SSL

Informational Counters

If a system under load is working well, you should see large counts for the following counters. Because there are 2 sides to the tracker process per connection, you can see these counters increase by 2 per connection. The PRIV_KEY_RECV and SECU_PARAM_RECV counters are the most important, and are highlighted. The CONTEXT_CREATED and CONTEXT_DESTROYED counters relate to the allocation of cryptographic chip memory.

```
> show counters
Protocol      Counter                          Value   Context
SSLENC        CONTEXT_CREATED                 258225   Summary
SSLENC        CONTEXT_DESTROYED               258225   Summary
TLS_TRK       OPEN_SERVER_SESSION             258225   Summary
TLS_TRK       OPEN_CLIENT_SESSION             258225   Summary
TLS_TRK       UPSTREAM_CLOSE                  516450   Summary
TLS_TRK       DOWNSTREAM_CLOSE                516450   Summary
TLS_TRK       FREE_SESSION                    516450   Summary
TLS_TRK       CACHE_FREE                      516450   Summary
TLS_TRK       PRIV_KEY_RECV                   258225   Summary
TLS_TRK       NO_KEY_ENABLE                   258225   Summary
TLS_TRK       SECU_PARAM_RECV                 516446   Summary
TLS_TRK       DECRYPTED_ALERT                 258222   Summary
TLS_TRK       DECRYPTED_APPLICATION         33568976   Summary
TLS_TRK       ALERT_RX_CNT                    258222   Summary
TLS_TRK       ALERT_RX_WARNING_ALERT          258222   Summary
TLS_TRK       ALERT_RX_CLOSE_NOTIFY           258222   Summary
TCP_PRX       OPEN_SESSION                    516450   Summary
TCP_PRX       FREE_SESSION                    516450   Summary
TCP_PRX       UPSTREAM_CLOSE                  516450   Summary
TCP_PRX       DOWNSTREAM_CLOSE                516450   Summary
TCP_PRX       FREE_CONN                       258222   Summary
TCP_PRX       SERVER_CLEAN_UP                 258222   Summary
TCP_PRX       CLIENT_CLEAN_UP                 258222   Summary
```

Alert Counters

We implemented the following counters according to the TLS 1.2 specification. FATAL or BAD alerts could indicate issues; however, ALERT_RX_CLOSE_NOTIFY is normal.

For details, see RFC 5246 section 7.2.

```
TLS_TRK       ALERT_RX_CNT                       311   Summary
TLS_TRK       ALERT_TX_CNT                         2   Summary
TLS_TRK       ALERT_TX_IN_HANDSHAKE_CNT            2   Summary
TLS_TRK       ALERT_RX_IN_HANDSHAKE_CNT            2   Summary
TLS_TRK       ALERT_RX_WARNING_ALERT             308   Summary
TLS_TRK       ALERT_RX_FATAL_ALERT                 3   Summary
TLS_TRK       ALERT_TX_FATAL_ALERT                 2   Summary
TLS_TRK       ALERT_RX_CLOSE_NOTIFY              308   Summary
TLS_TRK       ALERT_RX_BAD_RECORD_MAC              2   Summary
TLS_TRK       ALERT_TX_BAD_RECORD_MAC              2   Summary
TLS_TRK       ALERT_RX_BAD_CERTIFICATE             1   Summary
```

Error Counters

These counters indicate system errors. These counts should be low on a healthy system. The BY_PASS counters indicate packets that have been passed directly to or from the inspection engine (Snort) process (which runs in software) without decryption. The following example lists some of the bad counters.

Counters with a value of 0 are not displayed. To view a complete list of counters, use the command **show counters description | include TLS_TRK**

```
> show counters
Protocol      Counter                          Value   Context
TCP_PRX       BYPASS_NOT_ENOUGH_MEM             2134   Summary
TLS_TRK       CLOSED_WITH_INBOUND_PACKET           2   Summary
TLS_TRK       ENC_FAIL                            82   Summary
```

```
TLS_TRK      DEC_FAIL                          211   Summary
TLS_TRK      DEC_CKE_FAIL                    43194   Summary
TLS_TRK      ENC_CB_FAIL                      4335   Summary
TLS_TRK      DEC_CB_FAIL                       909   Summary
TLS_TRK      DEC_CKE_CB_FAIL                   818   Summary
TLS_TRK      RECORD_PARSE_ERR                  123   Summary
TLS_TRK      IN_ERROR                        44948   Summary
TLS_TRK      ERROR_UPSTREAM_RECORD           43194   Summary
TLS_TRK      INVALID_CONTENT_TYPE              123   Summary
TLS_TRK      DOWNSTREAM_REC_CHK_ERROR          123   Summary
TLS_TRK      DECRYPT_FAIL                    43194   Summary
TLS_TRK      UPSTREAM_BY_PASS                  127   Summary
TLS_TRK      DOWNSTREAM_BY_PASS                127   Summary
```

Fatal Counters

The fatal counters indicate serious errors. These counters should be at or near 0 on a healthy system. The following example lists the fatal counters.

```
> show counters
Protocol     Counter                         Value   Context
CRYPTO       RING_FULL                           1   Summary
CRYPTO       ACCELERATOR_CORE_TIMEOUT            1   Summary
CRYPTO       ACCELERATOR_RESET                   1   Summary
CRYPTO       RSA_PRIVATE_DECRYPT_FAILED          1   Summary
```

The RING_FULL counter is not a fatal counter, but indicates how often the system overloaded the cryptographic chip. The ACCELERATOR_RESET counter is the number of times the TLS crypto acceleration process failed unexpectedly, which also causes the failure of pending operations, which are the numbers you see in ACCELERATOR_CORE_TIMEOUT and RSA_PRIVATE_DECRYPT_FAILED.

If you have persistent problems, disable TLS crypto acceleration (or **config hwCrypto disable**) and work with Cisco TAC to resolve the issues.

Note You can do additional troubleshooting using the **show snort tls-offload** and **debug snort tls-offload** commands. Use the **clear snort tls-offload** command to reset the counters displayed in the **show snort tls-offload** command to zero.

Troubleshoot Decryption Rules

The following topics discuss how to troubleshoot decryption rules.

About TLS/SSL Oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions**:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

Troubleshoot TLS/SSL Oversubscription

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are experiencing SSL oversubscription. You must add at least the **SSL Flow Flags** event to the table view of connection events.

Before you begin

- Configure a decryption policy with a setting for **Handshake Errors** on **Undecryptable Actions** page.

  For more information, see Set Default Handling for Undecryptable Traffic, on page 2297.

- Enable logging for your SSL rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Procedure

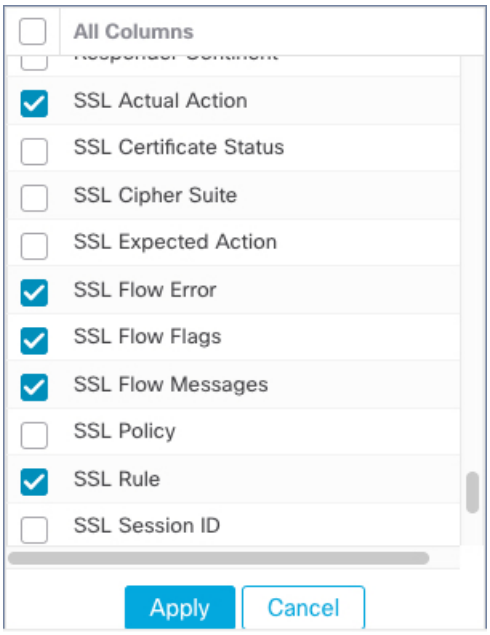
Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Analysis** > **Connections**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events. (Look in the Disabled Columns section of the dialog box.)



The columns are added in the order discussed in *Connection and Security Intelligence Event Fields* in the Cisco Secure Firewall Management Center Administration Guide .

Step 5 Click **Apply**.
TLS/SSL oversubscription is indicated by the values of `ERROR_EVENT_TRIGGERED` and `OVER_SUBSCRIBED` in the **SSL Flow Flags** column.

Step 6 If TLS/SSL oversubscription is occurring, log in to the managed device and enter any of the following commands:

Command	Result
show counters	If the value of **TCP_PRX BYPASS_NOT_ENOUGH_MEM** is large, consider upgrading your device to one with a larger capacity for SSL traffic or use **Do Not Decrypt** rules for lower priority encrypted traffic.
show snort tls-offload	If the value of **BYPASS_NOT_ENOUGH_MEM** is large, consider upgrading your device to one with a larger capacity for SSL traffic or use **Do Not Decrypt** rules for lower priority encrypted traffic.

About TLS Heartbeat

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

Related Topics

Troubleshoot TLS Heartbeat, on page 2342

Troubleshoot TLS Heartbeat

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are seeing traffic with the TLS heartbeat extension. You must add at least the **SSL Flow Messages** event to the table view of connection events.

Before you begin

SSL heartbeat is indicated by the value of `HEARTBEAT` in the **SSL Flow Messages** column in the table view of connection events. To determine if applications in your network use SSL heartbeat, first perform the following tasks:

- Configure an decryption policy with a setting for **Decryption Errors** on **Undecryptable Actions** page.

  For more information, see Set Default Handling for Undecryptable Traffic, on page 2297.

- Enable logging for your SSL rules as discussed in Secure Firewall Management Center and Threat Defense Management Network Administration.

Procedure

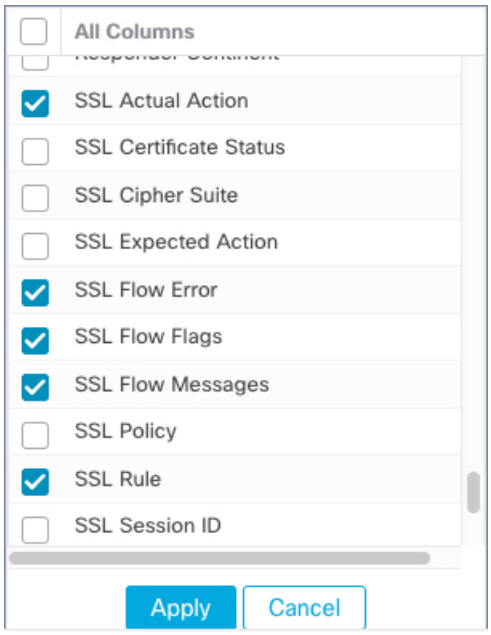
Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Analysis** > **Connections**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.



The columns are added in the order discussed in *Connection and Security Intelligence Event Fields* in the Cisco Secure Firewall Management Center Administration Guide .

Step 5 Click **Apply**.
TLS heartbeat is indicated by the value of `HEARTBEAT` in the **SSL Flow Messages** column.

Step 6 If applications in your network use SSL heartbeat, see Decryption Rule Guidelines and Limitations, on page 2304.

About TLS/SSL Pinning

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

To confirm that TLS/SSL pinning is occurring, attempt to log in to a mobile application like Facebook. If a network connection error is displayed, log in using a web browser. (For example, you *cannot* log in to a Facebook mobile application but *can* log in to Facebook using Safari or Chrome.) You can use Firepower Management Center connection events as further proof of TLS/SSL pinning

Note TLS/SSL pinning is not limited to mobile applications.

If applications in your network use SSL pinning, see TLS/SSL Certificate Pinning Guidelines, on page 2310.

Related Topics

Troubleshoot TLS/SSL Pinning, on page 2344

Troubleshoot TLS/SSL Pinning

You can view connection events to determine whether or not the devices are experiencing SSL pinning. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

Before you begin

- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.
- Log in to a mobile application like Facebook; if a network connection error displays, log in to Facebook using Chrome or Safari. If you *can* log in using a web browser but not the native application, SSL pinning is likely occurring.

Procedure

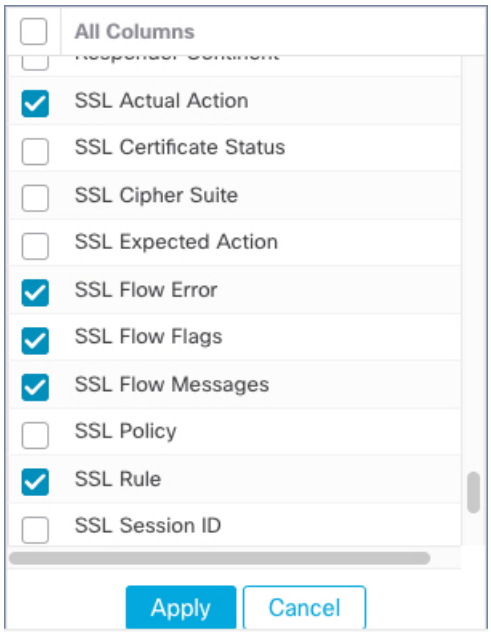
Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Analysis** > **Connections**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.



The columns are added in the order discussed in the section on connection and security intelligence event fields in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Step 5 Click **Apply**.

Step 6 The following paragraphs discuss how you can identify SSL pinning behavior.

Step 7 If you determine that applications in your network use SSL pinning, see Decryption Rule Guidelines and Limitations, on page 2304.

What to do next

You can use TLS/SSL connection events to confirm TLS/SSL pinning is occurring by looking for any of the following:

- Applications that send an SSL ALERT Message as soon as the client receives the SERVER_HELLO, SERVER_CERTIFICATE, SERVER_HELLO_DONE message from the server, followed by a TCP Reset, exhibit the following symptoms. (The alert, `Unknown CA (48)`, can be viewed using a packet capture.)
  - The SSL Flow Flags column displays `ALERT_SEEN` but *not* `APP_DATA_C2S` or `APP_DATA_S2C`.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: `CLIENT_ALERT`, `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`.
  - `Success` is displayed in the SSL Flow Error column.

- Applications that send no alerts but instead send TCP Reset after the SSL handshake is finished exhibit the following symptoms:
  - The SSL Flow Flags column does *not* display `ALERT_SEEN`, `APP_DATA_C2S`, or `APP_DATA_S2C`.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`, `CLIENT_KEY_EXCHANGE`, `CLIENT_CHANGE_CIPHER_SPEC`, `CLIENT_FINISHED`, `SERVER_CHANGE_CIPHER_SPEC`, `SERVER_FINISHED`.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`, `CLIENT_KEY_EXCHANGE`, `CLIENT_CHANGE_CIPHER_SPEC`, `CLIENT_FINISHED`,`SERVER_CHANGE_CIPHER_SPEC`, `SERVER_FINISHED`.
  - `Success` is displayed in the SSL Flow Error column.

Related Topics

Troubleshoot Unknown or Bad Certificates or Certificate Authorities, on page 2346

Troubleshoot Unknown or Bad Certificates or Certificate Authorities

You can view connection events to determine whether or not the devices are experiencing unknown certificate authorities, bad certificates, or unknown certificates. This procedure can also be used if a TLS/SSL certificate has been pinned. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

Before you begin

- Set up a decryption rule.
- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Procedure

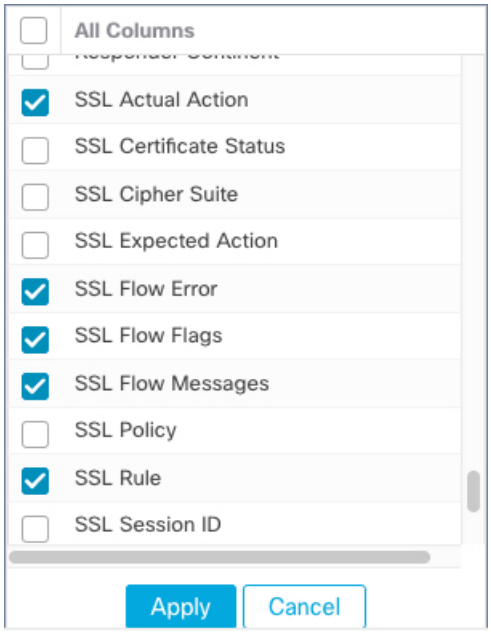
Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Analysis** > **Connections**.

Step 3 Click **Table View of Connection Events**.

Step 4 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.



The columns are added in the order discussed in the section on connection and security intelligence event fields in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Step 5 Click **Apply**.

Step 6 The following table discusses how you can determine if a certificate or certificate authority is bad or missing.

SSL flow flag	Meaning
CLIENT_ALERT_SEEN_UNKNOWN_CA	Indicates a valid certificate chain or partial chain was received by an SSL client application, but the certificate was not accepted because the CA certificate could not be located or could not be matched with a known, trusted CA. This message always indicates an unrecoverable error.
CLIENT_ALERT_SEEN_BAD_CERTIFICATE	A certificate was corrupt, contained signatures that did not verify correctly, or had other problems.
CLIENT_ALERT_SEEN_CERTIFICATE_UNKNOWN	Some other (unspecified) issue arose in processing the certificate, rendering it unacceptable.

Verify TLS/SSL Cipher Suites

Before you begin

This topic discusses actions you must take if you see the following error when saving a decryption rule that has cipher suite conditions:

```
Traffic cannot match this rule; none of your selected cipher suites contain a signature
algorithm that matches the resigning CA's signature algorithm
```

The error indicates that one or more of the cipher suites you chose for the decryption rule condition are incompatible with the certificate used in the decryption rule. To resolve the issue, you must have access to the certificate you're using.

Note The tasks in this topic assume knowledge of how TLS/SSL encryption works.

Procedure

Step 1 When you attempt to save a decryption rule rule with either **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** with specified cipher suites, the following error is displayed:

Example:

```
Traffic cannot match this rule; none of your selected cipher suites contain a
signature algorithm that the resigning CA's signature algorithm
```

Step 2 Locate the certificate you're using to decrypt traffic and, if necessary, copy the certificate to a system that can run openssl commands.

Step 3 Run the following command to display the signature algorithm used by the certificate:

openssl x509 -in *CertificateName* **-text -noout**

The first few lines of output are displayed similar to the following:

```
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 4105 (0x1009)
    Signature Algorithm: ecdsa-with-SHA256
```

Step 4 The **Signature algorithm** tells you the following:

- The cryptographic function used (in the preceding example, **ECDSA** means Elliptic Curve Digital Signature Algorithm).
- The hash function used to create a digest of the encrypted message (in the preceding example, **SHA256**).

Step 5 Search a resource such as *OpenSSL at University of Utah* for cipher suites that match those values. The cipher suite must be in RFC format.
You can also search a variety of other sites, such as Server Side TLS at the Mozilla wiki or Appendix C of RFC 5246. Cipher Suites in TLS/SSL (Schannel SSP) in Microsoft documentation has a detailed explanation of cipher suites.

Step 6 If necessary, translate the OpenSSL name to an RFC name that the Firepower Management System uses.

See the RFC mapping list on the on the `https://testssl.sh` site.

Step 7 The previous example, **ecdsa-with-SHA256**, can be found in the Modern Compatibility List on the Mozilla wiki.

a) Choose only cipher suites that have **ECDSA** and **SHA-256** in the name. These cipher suites follow:

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES128-SHA256
```

b) Find the corresponding RFC cipher suite on RFC mapping list. These cipher suites follow:

```
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
```

Step 8 Add the preceding cipher suites to your decryption rule.

Troubleshooting Using Crypto Archives

About Crypto Archives

Crypto issues are difficult to triage. Crypto archives help you to troubleshoot these issues. A crypto archive contains crypto session information about the crypto request, peer information, the component that sent the crypto request, and the timed-out crypto session information. Threat defense does not save keys and initialization vectors (IVs) for the session. For SSL and IPsec, you can also view the following information:

- For SSL: Session SSL version, source, destination IP addresses, and ports.
- For IPsec: IPsec security association information.

A ring can hold 2000 crypto command entries. Threat defense pushes the crypto command in one of the rings and pulls out the result after completing the crypto request. Crypto archive files now have the timed-out crypto request's ring and entry index. The ring and its entry index help in troubleshooting problematic crypto commands.

The crypto archive has two formats: a text file and a binary file. You can use the **debug menu ctm 103** command to decode the binary file. The crypto archive files are available at disk0:/crypto_archive.

For example:

```
FTD# debug menu ctm 103 crypto_eng0_arch_4.bin
[Nitrox V Archive Header v1.0 Info]
ASA Image Version: PIX (9.20) #0: Tue Mar 29 16:20:30 GMT 2022
...
SE SSL microcode: CNN5x-MC-SE-SSL-0011
AE microcode: CNN5x-MC-AE-MAIN-0002
Crypto Engine 0
Crash type: SE Ring Timeout
...
Core Soft Resets: 11
...
Timeout Ring (SE): 12
Timeout Entry: 642
SE TIMEOUT:

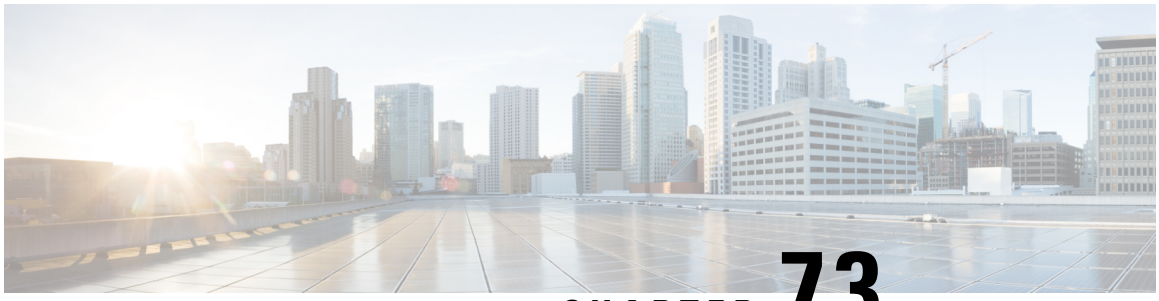
Source Port : 51915
Dest IP : 82.29.155.32
Dest Port : 443
```

In the above example, the highlighted information shows the timeout ring, the crash time (timeout entry), and SSL session information.

Supported Devices for Crypto Archives

The following devices with Nitrox V crypto accelerator support crypto archives:

- Cisco Firepower 3105, 3110, 3120, 3130, 3140
- Cisco Firepower 4112, 4115, 4125, 4145
- Cisco Firepower 9300 SM-40, SM-48 and SM-56
- Cisco Secure Firewall 4200



CHAPTER 73

Decryption Rules and Policy Example

This chapter builds on concepts discussed in this guide to provide a specific example of an SSL policy with decryption rules that follow our best practices and recommendations. You should be able to apply this example to your situation, adapting it to the needs of your organization.

In short:

- For trusted traffic (such as transferring a large compressed server backup), bypass inspection entirely, using prefiltering and flow offload.
- Put *first* any decryption rules that can be evaluated quickly, such as those that apply to specific IP addresses.
- Put *last* any decryption rules that require processing, **Decrypt - Resign**, and rules that block unsecure protocol versions and cipher suites.

- Decryption Rule Examples, on page 2351
- Run the Decryption Policy Wizard, on page 2351
- First Manual Do Not Decrypt Rule: Specific Traffic, on page 2356
- Next Manual Rule: Decrypt Specific Test Traffic, on page 2358
- Last Manual Decryption Rules: Block or Monitor Certificates and Protocol Versions, on page 2359
- Associate the Decryption Policy with an Access Control Policy and Advanced Settings, on page 2366
- Traffic to Prefilter, on page 2368
- Decryption Rule Settings, on page 2368

Decryption Rule Examples

This section provides an example of decryption rule that illustrate our best practices.

See one of the following sections for more information.

Run the Decryption Policy Wizard

This task discusses how to run the decryption policy wizard for outbound traffic protection. This policy has four rules:

1. **Do Not Decrypt** rule for distinguished names that are known to be undecryptable, most likely because they use TLS/SSL pinning.

2. **Do Not Decrypt** rule for URL categories that we classify as sensitive based on their content (for example, medical and financial).
3. **Do Not Decrypt** rule for applications that are known to be undecryptable, most likely because they use TLS/SSL pinning.
4. **Decrypt - Resign** rule that uses a certificate authority object named **IntCA** to decrypt the remainder of the traffic.

You can then edit the rules if you want and also manually add:

- **Decrypt - Resign** rules for traffic to monitor and determine whether the traffic should be blocked in the future.
- **Do Not Decrypt** rules for other types of traffic
- **Block** or **Block with Reset** rules for bad certificates and unsecure cipher suites.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see Creating Change Management Tickets, on page 240 and Policies and Objects that Support Change Management, on page 235.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

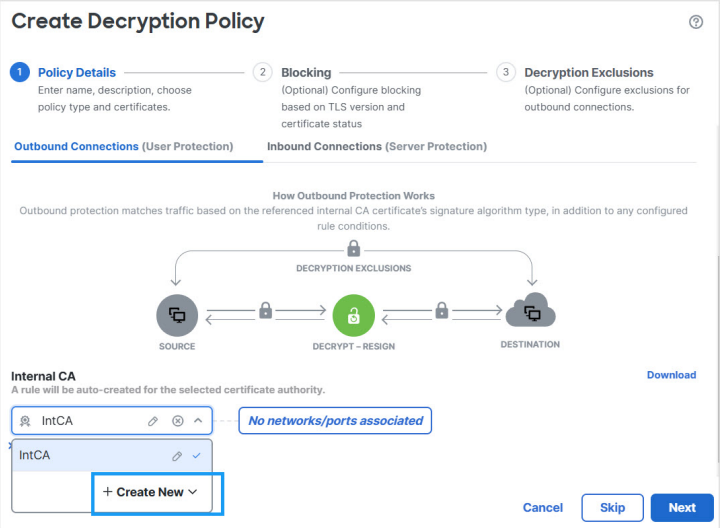
Step 3 Click **Create Decryption Policy**.

Step 4 Give the decryption policy a **Name** and optionally a **Description**.

Step 5 Click the **Outbound Protection** tab.

Step 6 From the **Internal CA** list, click the name of an internal certificate authority object or click **Create New** to upload or generate one.

The following figure shows an example.



For more information about creating or uploading an internal certificate authority object, see:

- Upload an Internal CA for Outbound Protection, on page 2292
- Generate an Internal CA for Outbound Protection, on page 2291

Step 7 (Optional.) To restrict traffic to source and destination networks, click **Click to assign networks and ports**.

Step 8 Click **Next**.

Step 9 Complete the wizard as discussed in Decryption Policy Exclusions, on page 2287.

Decryption Policy Exclusions

This task discusses how to exclude certain types of traffic from decryption. We create **Do Not Decrypt** rules in your decryption policy for these although the rules are initially enabled only for an outbound decryption policy (that is, one that uses the **Decrypt - Resign** policy action).

Before you begin

You must upload an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal CAs** and referring to PKI, on page 1404.
- At the time you create this decryption policy.

Procedure

Step 1 Complete the tasks discussed in:

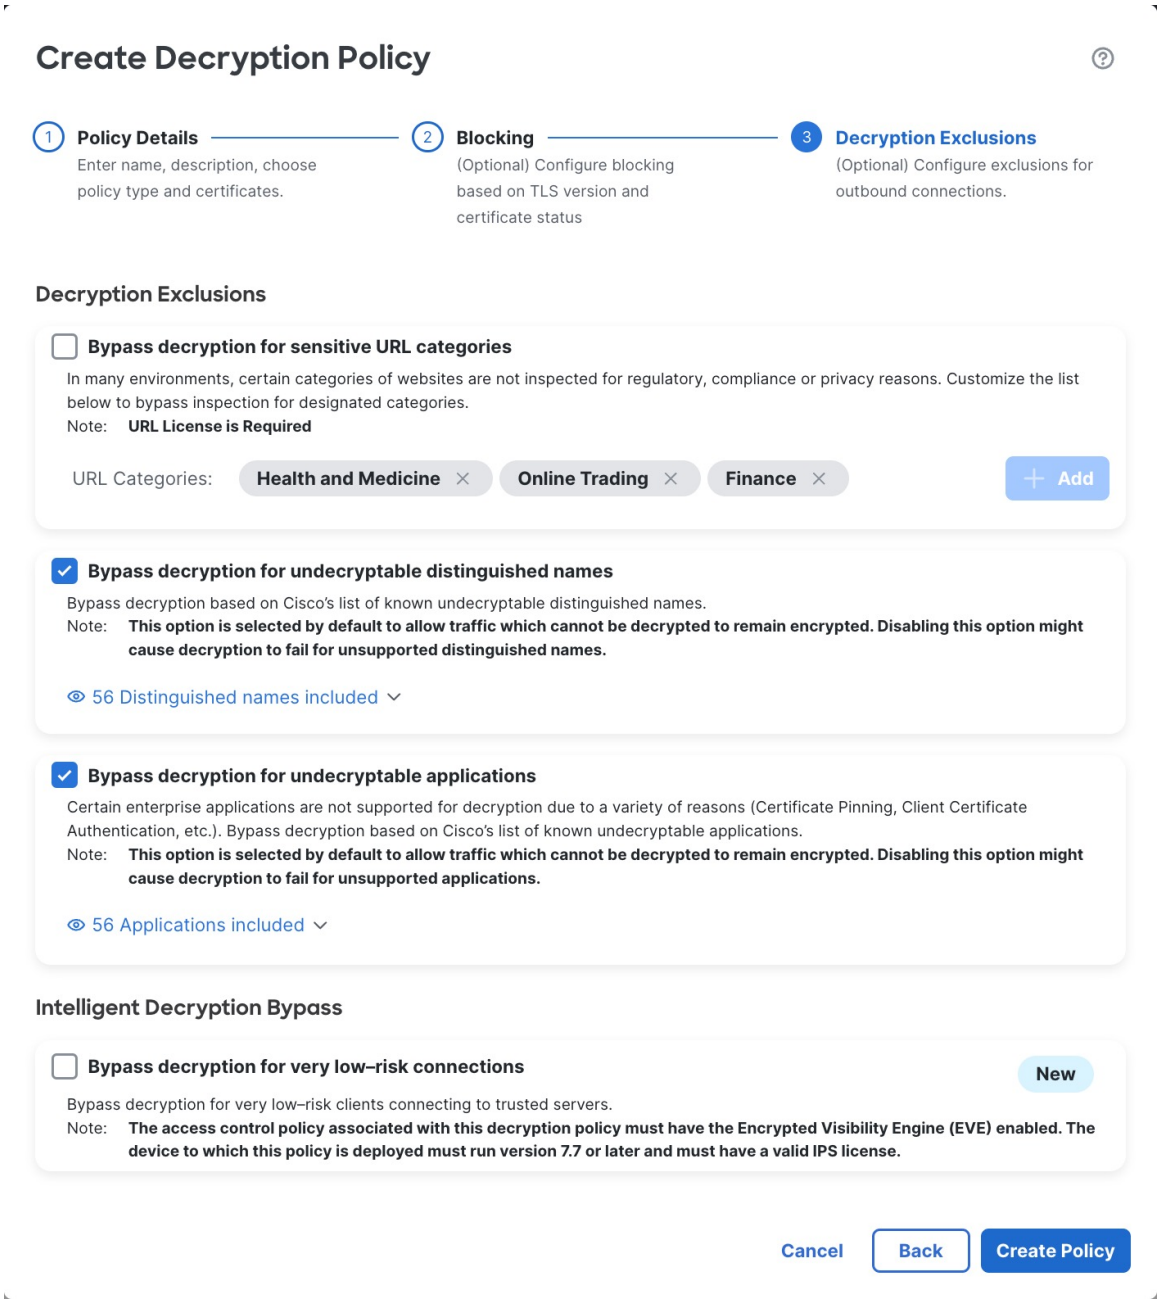
- Create a Create a Decryption Policy with Outbound Connection Protection, on page 2281

- For more information, see Create a Create a Decryption Policy with Inbound Connection Protection, on page 2285

Step 2 The exclusions page provides the following options. All options are *enabled* for an outbound protection policy (**Decrypt - Resign** rule action) and *disabled* for all other decryption policy actions.

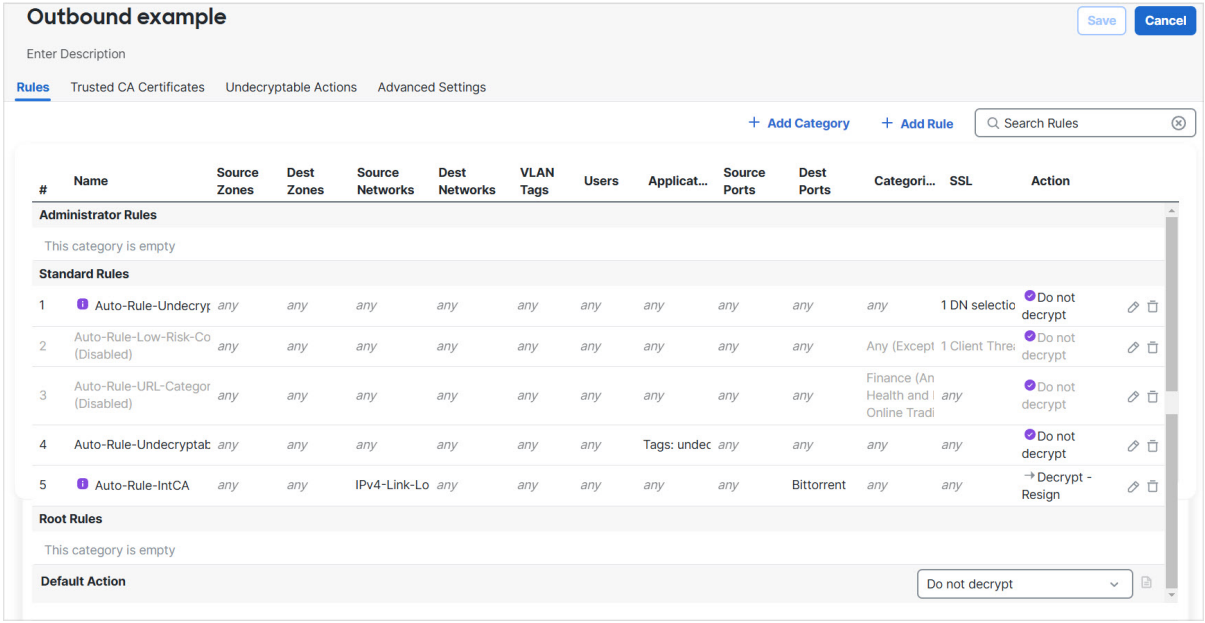
Item	Description
Bypass decryption for sensitive URL categories	Check the box to not decrypt traffic from the indicated categories. Depending on the laws in your area, decryption certain traffic, such as finance or health-related, might be prohibited. Consult an authority in your area for more information. Click **Add** to add more categories. Click **Delete** (✕) to remove categories.
Bypass decryption for undecryptable distinguished names	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL Certificate Pinning Guidelines, on page 2310. The list of undecryptable distinguished names is maintained by Cisco.
Bypass decryption for undecryptable applications	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL Certificate Pinning Guidelines, on page 2310. Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the Secure Firewall Application Detectors page; the **undecryptable** tag identifies applications Cisco determines are undecryptable. The list of undecryptable applications is maintained by Cisco.
Bypass decryption for very low-risk connections	Check this check box to not decrypt traffic for very low-risk clients connecting to trusted servers, based on the threat confidence levels of clients which is determined by the Encrypted Visibility Engine (EVE) and the URL Category Reputation. An **Auto-Rule-Low-Risk-Connections** Do Not Decrypt rule is created and enabled in the new decryption policy. To use the **Bypass decryption for very low-risk connections** option, you must enable the EVE in the corresponding access control policy, and the managed devices must be running Version 7.7 or later with a valid IPS license.

The following figure shows the default options.



Step 3 Click **Create Policy**.

The following figure shows a sample outbound protection policy.



In the preceding example, the **Do Not Decrypt** rules corresponding to your choices for rule exclusions are automatically added before the **Decrypt - Resign** rule. The rule for sensitive URL categories is disabled because, by default, that exclusion is disabled. Had you selected the **Bypass decryption for sensitive URL categories** check box, the rule would have been enabled.

Step 4 Click **Create Policy**.

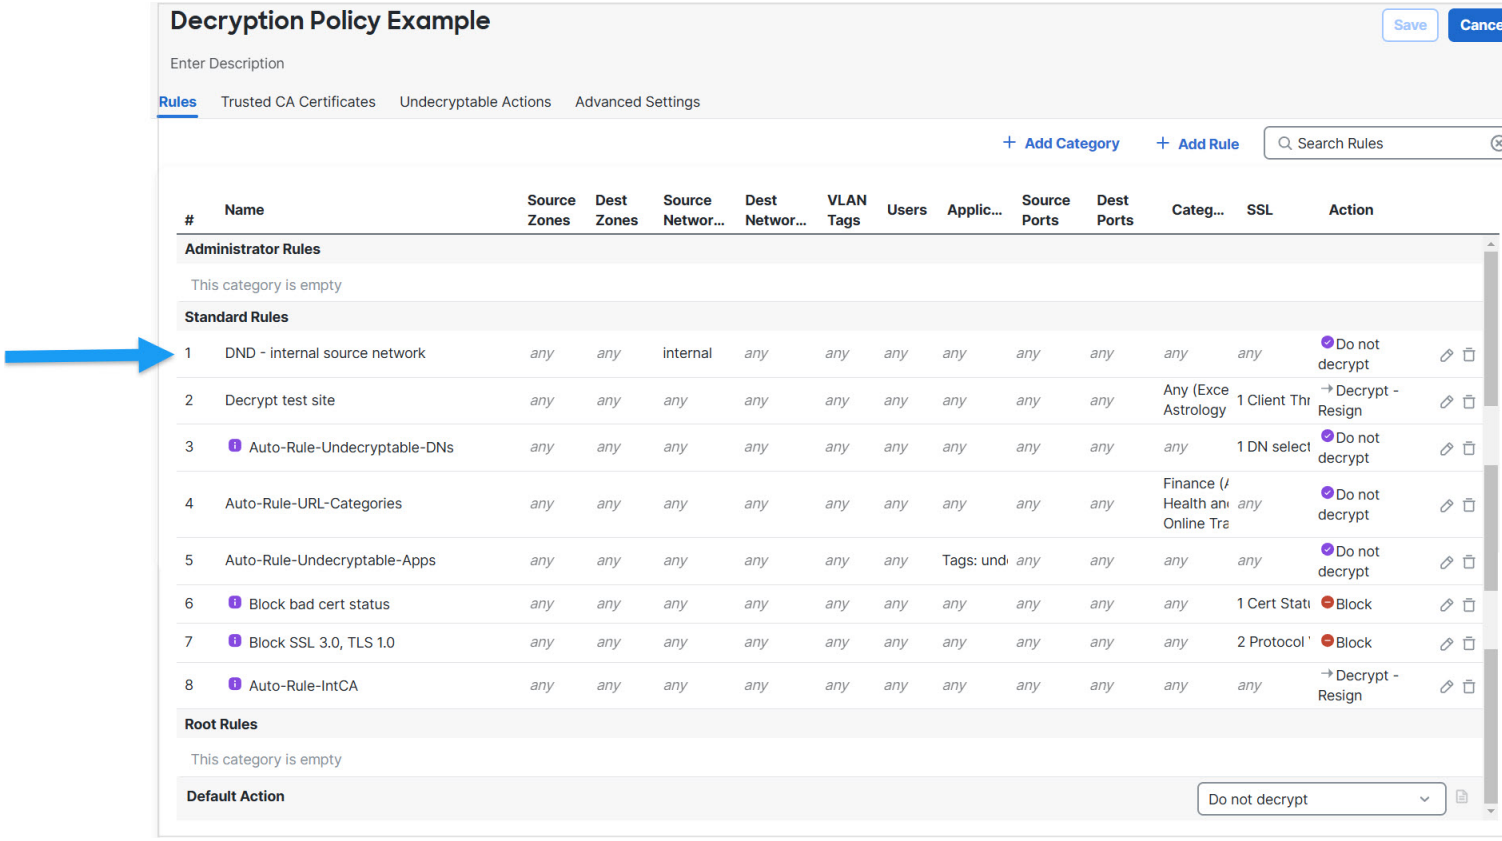
What to do next

- Add rule conditions: Decryption Rule Conditions, on page 2316
- Add a default policy action: Decryption Policy Default Actions, on page 2295
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the Cisco Secure Firewall Management Center Administration Guide .
- Set advanced policy properties: Decryption Policy Advanced Options, on page 2298.
- Associate the decryption policy with an access control policy as described in Associating Other Policies with Access Control, on page 1762.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

First Manual Do Not Decrypt Rule: Specific Traffic

The first decryption rule in the example does not decrypt traffic that goes to an internal network (defined as **internal**). **Do Not Decrypt** rule actions are matched during ClientHello so they are processed very fast.

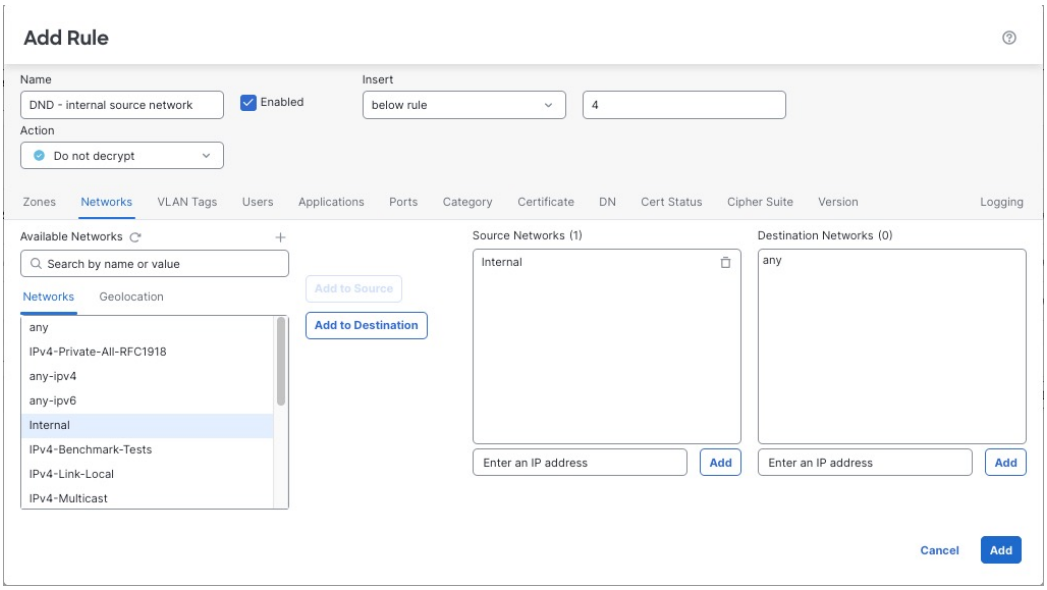
After you run the decryption policy wizard, edit the policy to add the following rule. Drag it to the top of the list of rules so it's evaluated first.



Note If you have traffic going from internal DNS servers to internal DNS resolvers (such as Cisco Umbrella Virtual Appliances), you can add **Do Not Decrypt** rules for them as well. You can even add those to prefiltering policies if the internal DNS servers do their own logging.

However, we strongly recommend you *do not* use **Do Not Decrypt** rules or prefiltering for DNS traffic that goes to the internet, such as internet root servers (for example, Microsoft internal DNS resolvers built into Active Directory). In those cases, you should fully inspect the traffic or even consider blocking it.

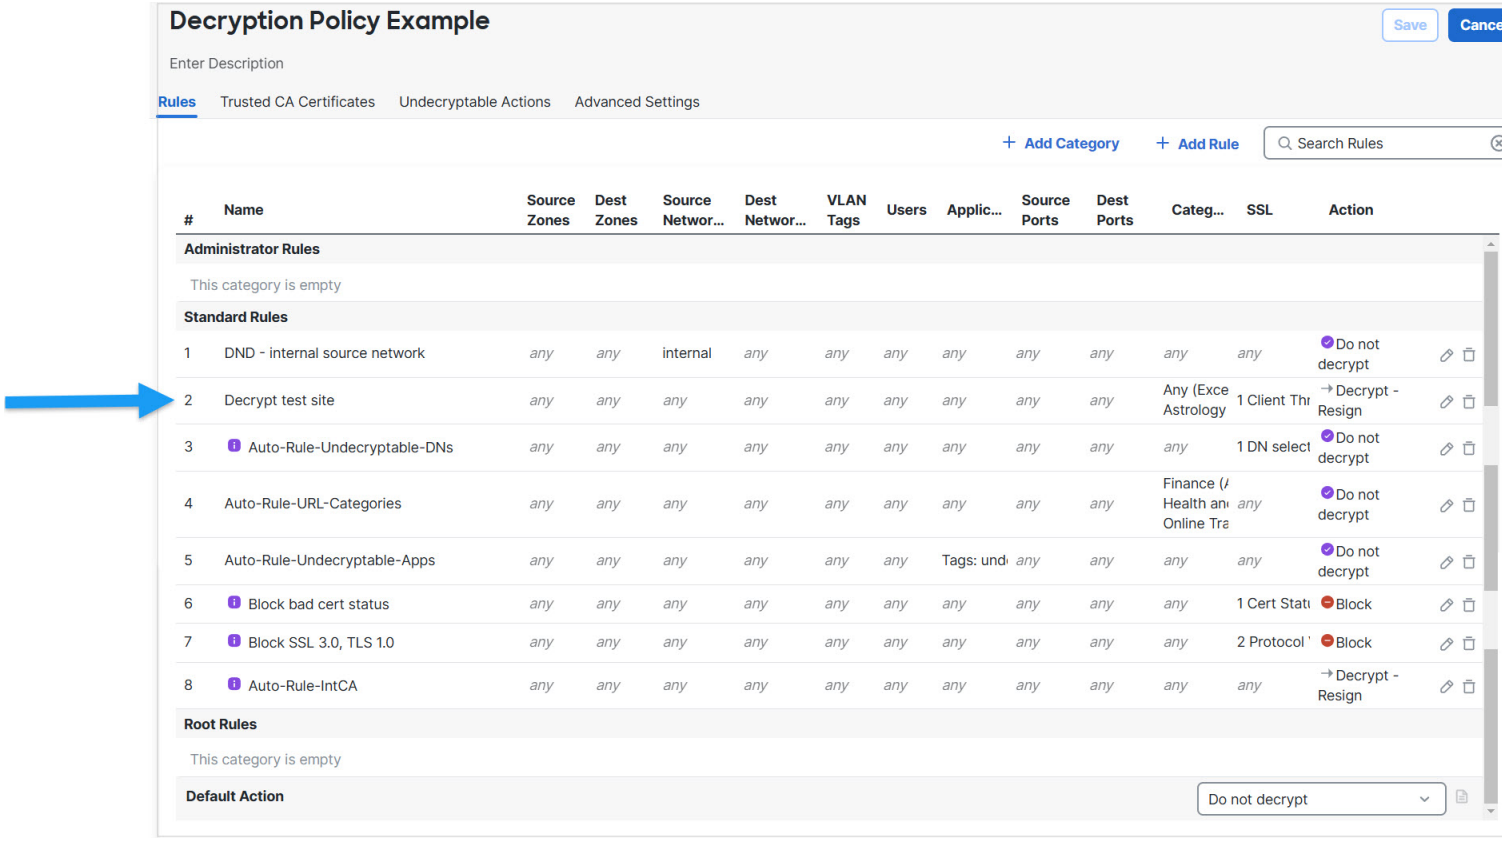
Rule detail:



Next Manual Rule: Decrypt Specific Test Traffic

The next rule is *optional* in the example; use it to decrypt and monitor limited types of traffic before determining whether or not to allow it on your network.

After you run the decryption policy wizard, edit the policy to add the following rule. Drag it to the second position in the list of rules.

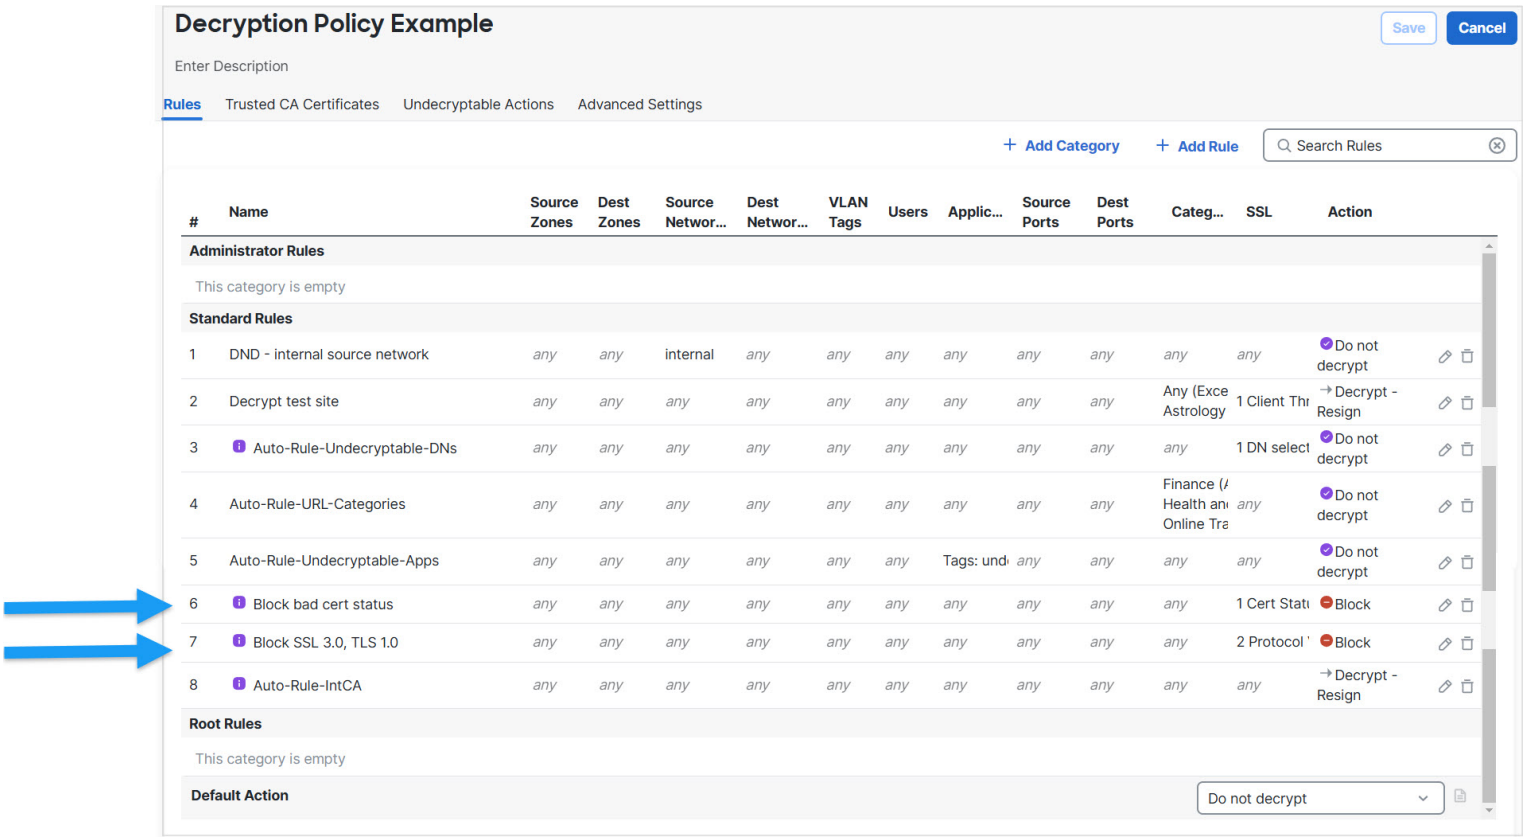


Rule detail:

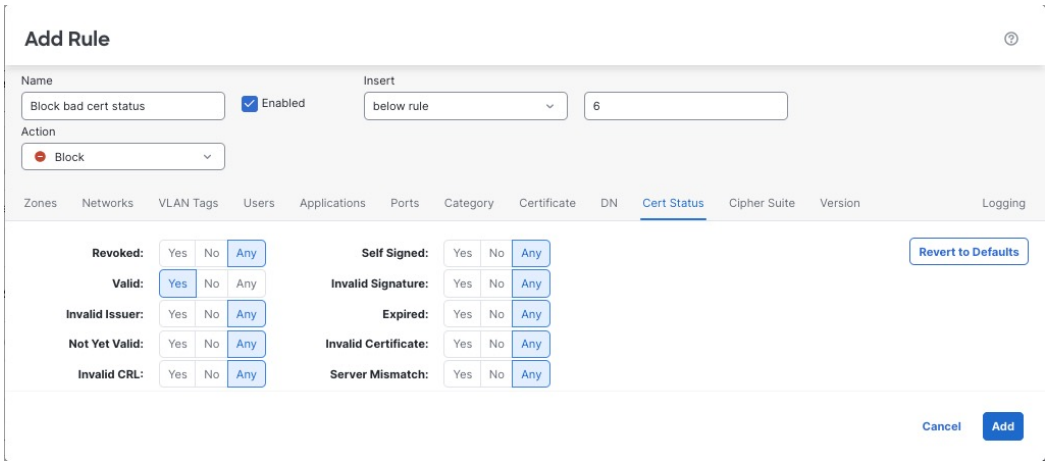
Last Manual Decryption Rules: Block or Monitor Certificates and Protocol Versions

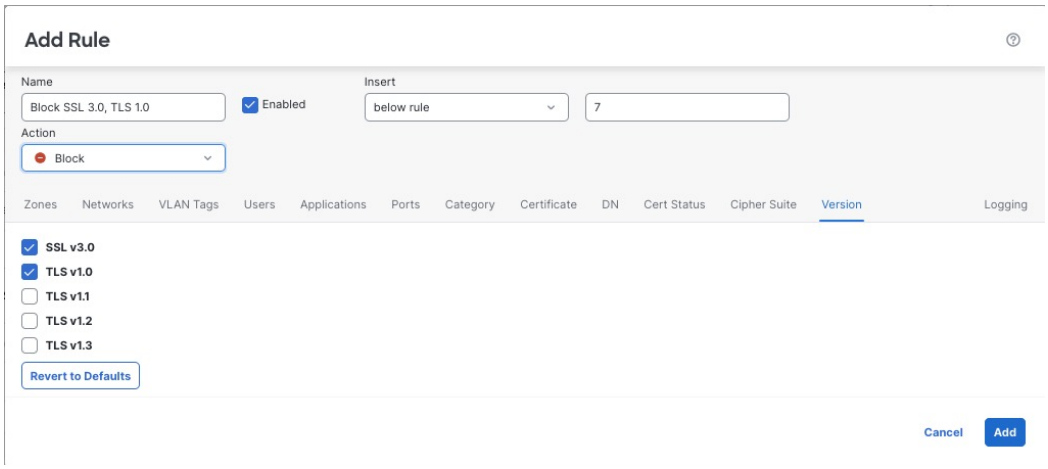
The last decryption rules, because they are the most specific and require the most processing, are rules that either monitor or block bad certificates and unsecure protocol versions.

After you run the decryption policy wizard, edit the policy to add the following rules. Drag them to a position *before* the **Decrypt - Resign** rule.



Rule details:





Example: Decryption Rule to Monitor or Block Certificate Status

The last decryption rules, because they are the most specific and require the most processing, are rules that either monitor or block bad certificates and unsecure protocol versions. The example in this section shows how to monitor or block traffic by certificate status.

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to your decryption policy.

Step 4 Click **Edit** (✎) next to a decryption rule.

Step 5 Click **Add Rule**.

Step 6 n the Add Rule dialog box, in the **Name** field, enter a name for the rule.

Step 7 Click **Cert Status**.

Step 8 For each certificate status, you have the following options:

- Click **Yes** to match against the *presence* of that certificate status.
- Click **No** to match against the *absence* of that certificate status.
- Click **Any** to skip the condition when matching the rule. In other words, choosing **Any** means the rule matches whether the certificate status is present or absent.

Step 9 From the **Action** list, click either **Monitor** to only monitor and log traffic that matches the rule or click **Block** or **Block with Reset** to block the traffic and optionally reset the connection.

Step 10 To save changes to the rule, at the bottom of the page, click **Add**.

Step 11 To save changes to the policy, at the top of the page, click **Save**.

Example

The organization trusts the Verified Authority certificate authority. The organization does not trust the Spammer Authority certificate authority. The system administrator uploads the Verified Authority certificate and an intermediate CA certificate issued by Verified Authority to the system. Because Verified Authority revoked a certificate it previously issued, the system administrator uploads the CRL that Verified Authority provided.

The following figure shows a certificate status rule condition checking for valid certificates, those issued by a Verified Authority, are not on the CRL, and still within the Valid From and Valid To date. Because of the configuration, traffic encrypted with these certificates is not decrypted and inspected with access control.

The following figure shows a certificate status rule condition checking for the absence of a status. In this case, because of the configuration, it matches against traffic encrypted with a certificate that has not expired.

In the following example, traffic would match this rule condition if the incoming traffic is using a certificate that has an invalid issuer, is self-signed, expired, and it is an invalid certificate.

The following graphic illustrates a certificate status rule condition that matches if the SNI of the request matches the server name or if the CRL is not valid.

Example: Decryption Rule to Monitor or Block Protocol Versions

This example shows how to block TLS and SSL protocols on your network that are no longer considered secure, such as TLS 1.0, TLS 1.1, and SSLv3. It's included to give you a little more detail about how protocol version rules work.

You should exclude nonsecure protocols from your network because they are all exploitable. In this example:

- You can block some protocols using **Version** page on the decryption rule.
- Because the system considers SSLv2 as undecryptable, you can block it using the **Undecryptable Actions** on the decryption policy.
- Similarly, because compressed TLS/SSL is not supported, you should block it as well.

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to your decryption policy.

Step 4 Click **Edit** (✎) next to a decryption rule.

Step 5 Click **Add Rule**.

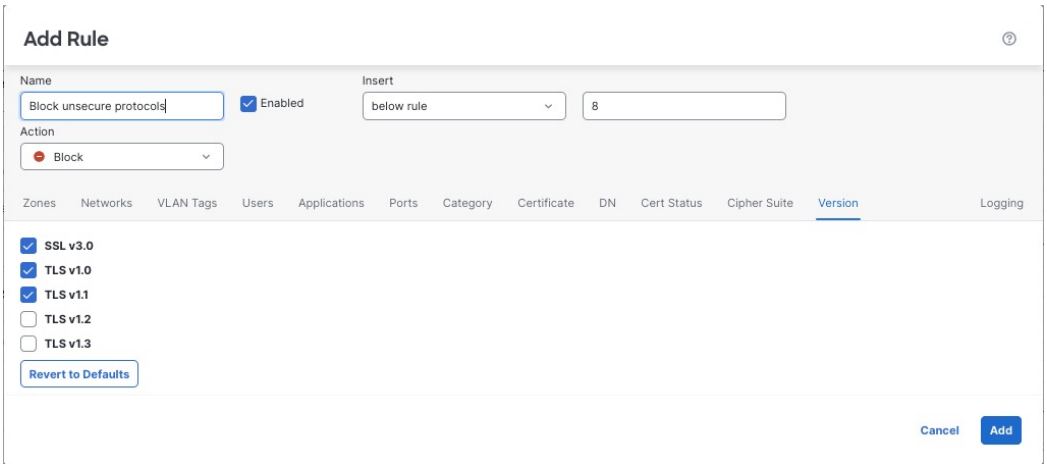
Step 6 In the Add Rule dialog box, in the **Name** field, enter a name for the rule.

Step 7 From the **Action** list, click **Block** or **Block with reset**.

Step 8 Click **Version** page.

Step 9 Check the check boxes for protocols that are no longer secure, such as **SSL v3.0**, **TLS 1.0**, and **TLS 1.1**. Clear the check boxes for any protocols that are still considered secure.

The following figure shows an example.



Step 10 Choose other rule conditions as needed.

Step 11 Click **Add**.

Optional Example: Manual Decryption Rule to Monitor or Block Certificate Distinguished Name

This rule is included to give you an idea about how to monitor or block traffic based on the server certificate's distinguishedname. It's included to give you a little more detail.

The distinguished name can consist of country code, common name, organization, and organizational unit, but typically consists of a common name only. For example, the common name in the certificate for `https://www.cisco.com` is `cisco.com`. (However, it's not always this simple; Distinguished Name (DN) Rule Conditions, on page 2323 shows how to find common names.)

The host name portion of the URL in the client request is the Server Name Indication (SNI). The client specifies which hostname they want to connect to (for example, `auth.amp.cisco.com`) using the SNI extension in the TLS handshake. The server then selects the corresponding private key and certificate chain that are required to establish the connection while hosting all certificates on a single IP address.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to your decryption policy.

Step 4 Click **Edit** (✎) next to a decryption rule.

Step 5 Click **Add Rule**.

Step 6 In the Add Rule dialog box, in the **Name** field, enter a name for the rule.

Step 7 From the **Action** list, click **Block** or **Block with reset**.

Step 8 Click **DN**.

Step 9 Find the distinguished names you want to add from the **Available DNs**, as follows:

- To add a distinguished name object on the fly, which you can then add to the condition, click **Add** (+) above the **Available DNs** list.
- To search for distinguished name objects and groups to add, click the **Search by name or value** prompt above the **Available DNs** list, then type either the name of the object, or a value in the object. The list updates as you type to display matching objects.

Step 10 To select an object, click it. To select all objects, right-click and then **Select All**.

Step 11 Click **Add to Subject** or **Add to Issuer**.

Tip
You can also drag and drop selected objects.

Step 12 Add any literal common names or distinguished names that you want to specify manually. Click the **Enter DN or CN** prompt below the **Subject DNs** or **Issuer DNs** list; then type a common name or distinguished name and click **Add**.

Although you can add a CN or DN to either list, it's more common to add them to the **Subject DNs** list.

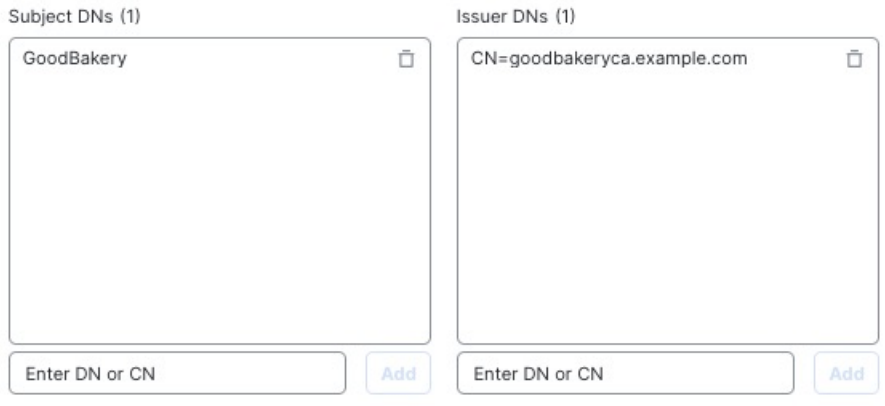
Step 13 Add or continue editing the rule.

Step 14 When you're done, to save changes to the rule, click **Add** at the bottom of the page.

Step 15 To save changes to the policy, click **Save** at the top of the page.

Example

The following figure shows a distinguished name rule condition searching for certificates issued to goodbakery.example.com or issued by goodca.example.com. Traffic encrypted with these certificates is allowed, subject to access control.



Associate the Decryption Policy with an Access Control Policy and Advanced Settings

This task discusses how to associate the decryption policy with an access control policy and setting recommended advanced settings for the access control policy.

For your decryption policy to be used by the system, you *must* associate it with an access control policy.

Before you begin

Create the sample decryption policy as discussed in this guide.

For more information about decryption policy advanced options, see Decryption Policy Advanced Options, on page 2298.

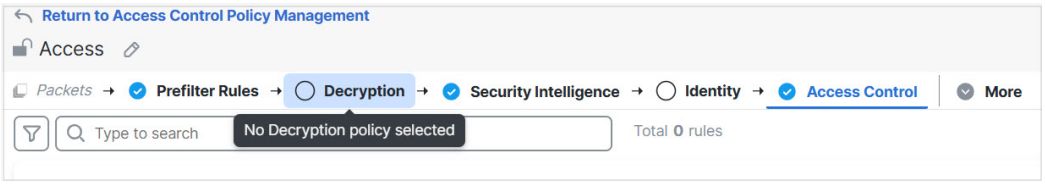
Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

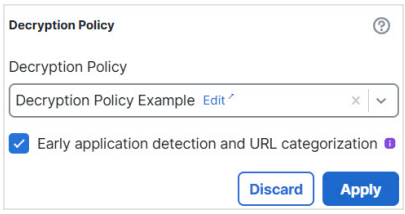
Step 2 Click **Policies** > **Access Control heading** > **Access Control**.

Step 3 Either create a new access control policy or click **Edit** (✎) to edit an existing one.

Step 4 Click the word Decryption as the following figure shows.

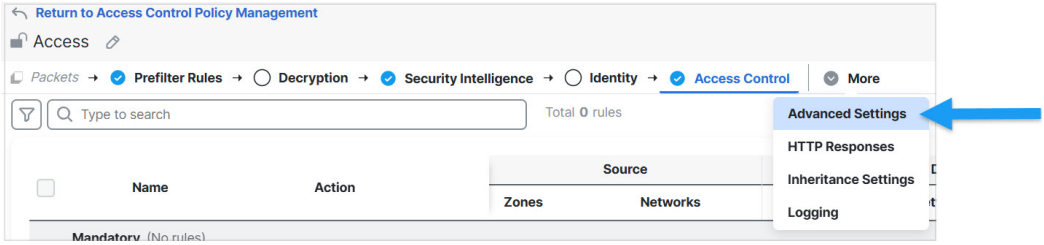


Step 5 From the list, click the name of your decryption policy and also check **Early application detection and URL categorization** as the following figure shows.



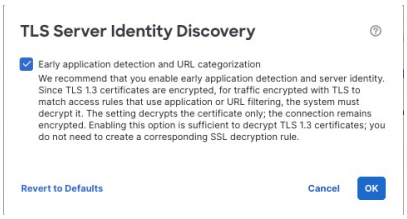
Step 6 Click **Apply**.

Step 7 Click **More** > **Advanced Settings** as the following figure shows.



Step 8 Click **Edit** (✎) next to **TLS Server Identity Discovery**.

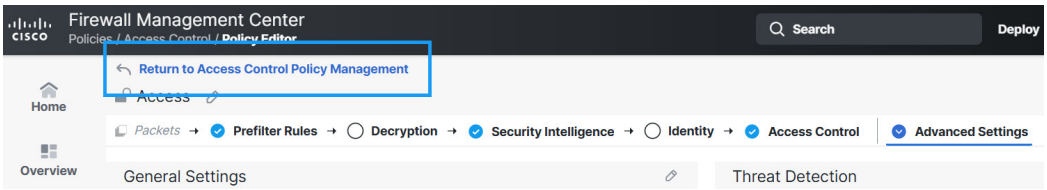
Step 9 Select the check box as the following figure shows.



Step 10 Click **OK**.

Step 11 At the top of the page, click **Save**.

Step 12 At the top of the page, click **Return to Access Control Policy Management**, as the following figure shows



Step 13 Click **Edit** (✎) to edit the access control rule.

Step 14 At the bottom of the page, next to the default action, click (Default Logging and Inspection).

Step 15 Check **Log at beginning of connection** and any other options you choose.

For more information, see Logging Settings for Access Control Policies, on page 1755Logging Settings for Access Control Policies in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

Step 16 Click **Apply**.

Step 17 At the top of the page, click **Save**.

What to do next

- Add rule conditions: Decryption Rule Conditions, on page 2316.
- Add a default policy action: Decryption Policy Default Actions, on page 2295.
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the Cisco Secure Firewall Management Center Administration Guide .

- Set advanced policy properties: Decryption Policy Advanced Options, on page 2298.
- Associate the decryption policy with an access control policy as described in Associating Other Policies with Access Control, on page 1762.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Traffic to Prefilter

Prefiltering is the first phase of access control, before the system performs more resource-intensive evaluation. Prefiltering is simple, fast, and early compared to subsequent evaluation, which uses inner headers and has more robust inspection capabilities.

Based on your security needs and traffic profile, you should consider prefiltering and therefore excluding from any policy and inspection the following:

- Common intraoffice applications such as Microsoft Outlook 365
- Elephant flows, such as server backups

Decryption Rule Settings

How to configure recommended best practice settings for your decryption rules.

Decryption rules: Enable logging for every rule except those with a **Do Not Decrypt** rule action. (It's up to you; if you want to see information about traffic that isn't decrypted, enable logging for those rules also.)

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **Edit** (✎) next to your decryption policy.

Step 4 Click **Edit** (✎) next to a decryption rule.

Step 5 Click the **Logging** tab.

Step 6 Click **Log at End of Connection**.

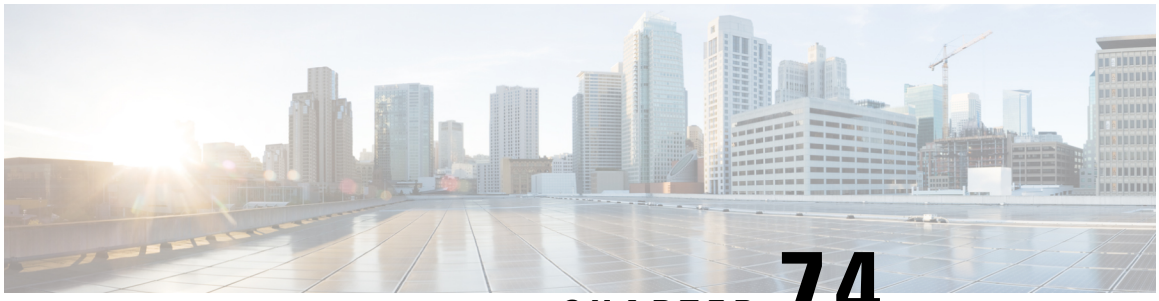
Step 7 Click **Save**.

Step 8 Click **Save** at the top of the page.

PART XII

User Identity

- User Identity Overview, on page 2371
- Realms, on page 2391
- User Control with the Passive Identity Agent, on page 2467
- User Control with ISE/ISE-PIC, on page 2499
- User Control with Captive Portal, on page 2525
- User Control with Remote Access VPN, on page 2545
- User Control with TS Agent, on page 2549
- User Identity Policies, on page 2553



CHAPTER 74

User Identity Overview

The following topics discuss user identity:

- About User Identity, on page 2371
- Host and User Limits, on page 2383
- Identity Realm Limit, on page 2387
- User Limits for Microsoft Azure Active Directory Realms, on page 2388

About User Identity

User identity information can help you to identify the source of policy breaches, attacks, or network vulnerabilities, and trace them to specific users. For example, you could determine:

- Who owns the host targeted by an intrusion event that has a Vulnerable (level 1: red) impact level.
- Who initiated an internal attack or portscan.
- Who is attempting unauthorized access to a specified host.
- Who is consuming an unreasonable amount of bandwidth.
- Who has not applied critical operating system updates.
- Who is using instant messaging software or peer-to-peer file-sharing applications in violation of company policy.
- Who is associated with each indication of compromise on your network.

Armed with this information, you can use other features of the system to mitigate risk, perform access control, and take action to protect others from disruption. These capabilities also significantly improve audit controls and enhance regulatory compliance.

After you configure user identity sources to gather user data, you can perform user awareness and user control.

For more information about identity sources, see About User Identity Sources, on page 2372.

Related Topics

Identity Terminology, on page 2372
About User Identity Sources, on page 2372
Identity Deployments, on page 2376
How to Set Up an Identity Policy, on page 2378

Identity Terminology

This topic discusses common terminology for user identity and user control.

User awareness

Identifying users on your network using *identity sources* (such as or TS Agent). User awareness enables you to identify users from both *authoritative* (such as Active Directory) and *non-authoritative* (application-based) sources. To use Active Directory as an identity source, you must configure a realm and directory. For more information, see About User Identity Sources, on page 2372.

User control

Configuring an *identity policy* that you associate with an *access control policy*. (The identity policy is then referred to as an access control *subpolicy*.) The identity policy specifies the identity source and, optionally, users and groups belonging to that source.

By associating the identity policy with an access control policy, you determine whether to monitor, trust, block, or allow users or user activity in traffic on your network. For more information, see Access Control Policies, on page 1745.

Authoritative identity sources

A trusted server validated the user login (for example, Active Directory). You can use the data obtained from authoritative logins to perform user awareness and user control. Authoritative user logins are obtained from passive and active authentications:

- *Passive authentications* occur when a user authenticates with Cisco ISE.
- *Active authentications* occur when a user authenticates through preconfigured managed devices. Captive portal is another name for active authentication. Active authentication generally uses the same user repositories as passive authentication (the exceptions being ISE/ISE-PIC, TS Agent, and the Passive Identity Agent, which are passive only).

Non-authoritative identity sources

An unknown or untrusted server validated the user login. Traffic-based detection is the only non-authoritative identity source supported by the system. You can use the data obtained from non-authoritative logins to perform user awareness.

About User Identity Sources

The following table provides a brief overview of the user identity sources supported by the system. Each identity source provides a store of users for user awareness. These users can then be controlled with identity and access control policies.

User Identity Source	Server Requirements	Login Type	Authentication Type	User Control	For more, see...
Captive portal	OpenLDAP Microsoft Active Directory Microsoft Azure Active Directory	Authoritative	Active	Yes	The Captive Portal Identity Source, on page 2525 Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal), on page 2412
Passive authentication	OpenLDAP Microsoft Active Directory	Non-authoritative	Active	Yes	Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426
Passive authentication	Microsoft Azure Active Directory	Passive	Passive	Yes	Configure Microsoft Entra ID for Passive Authentication, on page 2395
Passive authentication with the Passive Identity Agent	Microsoft Active Directory	Non-authoritative	Passive	Yes	The Passive Identity Agent Identity Source, on page 2467
Passive authentication with the TS Agent	Microsoft Windows Terminal Server	Authoritative	Passive	Yes	The Terminal Services (TS) Agent Identity Source, on page 2549
Remote Access VPN	OpenLDAP or Microsoft Active Directory	Authoritative	Active	Yes	The Remote Access VPN Identity Source, on page 2545
	RADIUS	Authoritative	Active	No, awareness only	
ISE/ISE-PIC	Microsoft Active Directory	Authoritative	Passive	Yes	The ISE/ISE-PIC Identity Source, on page 2499
Traffic-based detection (Configured in the network discovery policy.)	—	Non-authoritative	—	No, awareness only	The Traffic-Based Detection Identity Source, on page 2651

Consider the following when selecting identity sources to deploy:

- You must use traffic-based detection for non-LDAP user logins.
- You must use traffic-based detection or captive portal to record failed login or authentication activity. A failed login or authentication attempt does not add a new user to the list of users in the database.
- The captive portal identity source requires a managed device with a routed interface. You *cannot* use an inline (also referred to as tap mode) interface with captive portal.

Data from those identity sources is stored in the Secure Firewall Management Center's users database and the user activity database. You can configure Secure Firewall Management Center-server user downloads to automatically and regularly download new user data to your databases.

After you configure identity rules using the desired identity source, you must associate each rule with an access control policy and deploy the policy to managed devices for the policy to have any effect. For more information about access control policies and deployment, see Associating Other Policies with Access Control, on page 1762.

For general information about user identity, see About User Identity, on page 2371.

Best Practices for User Identity

We recommend you review the following information before you set up identity policies.

- Know user limits
- Health monitor
- Use latest version of ISE/ISE-PIC, two types of remediation
- User agent support drops in 6.7
- Captive portal requires routed interface, several individual tasks

Microsoft Active Directory and LDAP

The system supports Active Directory, LDAP, and other user repositories for user awareness and control. The association between an Active Directory or LDAP repository and the Secure Firewall Management Center is referred to as a *realm*. You should create one realm per LDAP server or Active Directory domain. For details about which versions are supported, see Supported Servers for Realms, on page 2434.

The only user identity source supported by LDAP is captive portal. To use other identity sources (with the exception of ISE/ISE-PIC), you must use Active Directory.

For Active Directory only:

- Create one *directory* per domain controller.

  For details, see Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426

- Users and groups in trust relationships between two domains are supported provided you add all Active Directory domains and domain controllers as realms and directories, respectively.

  For more information, see Realms and Trusted Domains, on page 2431.

Passive Identity Agent identity source

The passive identity agent software can monitor multiple Microsoft Active Directory servers and domain controllers and send user name and IP address information to the Secure Firewall Management Center.

For more information, see The Passive Identity Agent Identity Source, on page 2467.

Health monitor

The Secure Firewall Management Center health monitor provides valuable information about the status of various Secure Firewall Management Center functions, including:

- User/realm mismatches
- Snort memory usage
- ISE connection status

For more information about health modules, see *Health Modules* in the Cisco Secure Firewall Management Center Administration Guide.

To set up policies to monitor health modules, see *Creating Health Policies* in the Cisco Secure Firewall Management Center Administration Guide.

Device-specific user limits

Every physical or virtual Firewall Management Center device has limits to the number of users that can be downloaded. When the user limit is reached, the Firewall Management Center can run out of memory and can function unreliably as a result.

User limits are discussed in User Limits for Microsoft Active Directory, on page 2384.

If you use the ISE/ISE-PIC identity source, you can optionally limit the subnets the Firewall Management Center monitors to reduce memory usage using identity mapping filters as discussed in Create an Identity Policy, on page 2555.

Use the latest version of ISE/ISE-PIC

If you expect to use the ISE/ISE-PIC identity source, we strongly recommend you always use the latest version to make sure you get the latest features and bug fixes.

pxGrid 2.0 (which is used by version 2.6 patch 6 or later; or 2.7 patch 2 or later) also changes the remediation used by ISE/ISE-PIC from Endpoint Protection Service (EPS) to Adaptive Network Control (ANC). If you upgrade ISE/ISE-PIC, you must migrate your mediation policies from EPS to ANC.

More information about using ISE/ISE-PIC can be found in ISE/ISE-PIC Guidelines and Limitations, on page 2501.

To set up the ISE/ISE-PIC identity source, see How to Configure ISE/ISE-PIC for User Control, on page 2504.

Captive portal information

You can use captive portal active authentication with any of the following:

- LDAP

  For more information, see The Captive Portal Identity Source, on page 2525.

- Microsoft AD

For more information, see The Captive Portal Identity Source, on page 2525.

- Microsoft Azure AD (SAML)

  For more information, see Create a Microsoft Azure AD (SAML) Realm, on page 2392.

For more information about the captive portal identity source, see The Captive Portal Identity Source, on page 2525.

TS Agent information

The TS Agent user identity source is required to identify user sessions on a Windows Terminal Server. The TS Agent software must be installed on the Terminal Server machine as discussed in the *Cisco Terminal Services (TS) Agent Guide*. In addition, you must synchronize the time on your TS Agent server with the time on the Secure Firewall Management Center.

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.

For more information, see TS Agent Guidelines, on page 2550.

Associate the identity policy with an access control policy

After you configure your realm, directory, and user identity source, you must set up identity rules in an identity policy. To make the policy effective, you must associate the identity policy with an access control policy.

For more information about creating an identity policy, see Create an Identity Policy, on page 2555.

For more information about creating identity rules, see Create an Identity Rule, on page 2563.

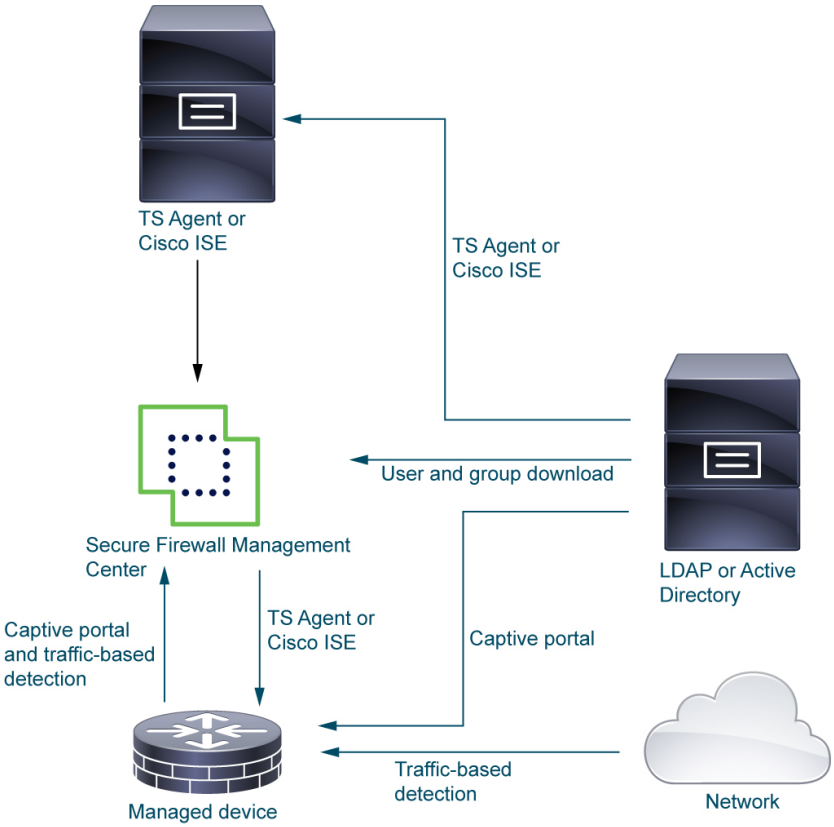
To associate an identity policy with an access control policy, see Associating Other Policies with Access Control, on page 1762.

Identity Deployments

When the system detects user data from a user login, from any identity source, the user from the login is checked against the list of users in the Secure Firewall Management Center user database. If the login user matches an existing user, the data from the login is assigned to the user. Logins that do not match existing users cause a new user to be created, unless the login is in SMTP traffic. Non-matching logins in SMTP traffic are discarded.

The group to which the user belongs is associated with the user as soon as the user is seen by the Secure Firewall Management Center.

The following diagram illustrates how the system collects and stores user data:



Sample identity deployments

In the preceding figure, Secure Firewall Management Center and one managed device are deployed to AWS and the other devices are located on premises. These devices can be either physical or virtual; they just need to be able to communicate with each other.

LDAP or Active Directory are needed only for TS Agent and captive portal, as the following paragraphs explain.

For more information about setting up a system like this, see How to Set Up an Identity Policy, on page 2378.

ISE/ISE-PIC identity source

When you deploy the ISE/ISE-PIC identity source, the ISE/ISE-PIC server sends users, groups, and subscriptions to the Secure Firewall Management Center.

You can optionally have an LDAP server in an ISE/ISE-PIC deployment but because it's optional, it isn't shown in the following figure.

For more information about ISE/ISE-PIC, see The ISE/ISE-PIC Identity Source, on page 2499.

Passive identity agent identity source

Software that monitors one or several Microsoft AD domain controllers, sending user name and IP address information to the Secure Firewall Management Center.

For more information, see The Passive Identity Agent Identity Source, on page 2467.

TS Agent identity source

The Terminal Services (TS) Agent software runs on a Microsoft Server and sends Secure Firewall Management Center user information based on the port range the users log in to the server with. TS Agent gets user identity information from LDAP or Active Directory and sends it to Secure Firewall Management Center.

For more information about the TS Agent identity source, see The Terminal Services (TS) Agent Identity Source, on page 2549.

Captive portal

You can use captive portal active authentication with any of the following:

- LDAP

  For more information, see The Captive Portal Identity Source, on page 2525.

- Microsoft AD

  For more information, see The Captive Portal Identity Source, on page 2525.

- Microsoft Azure AD (SAML)

  For more information, see Create a Microsoft Azure AD (SAML) Realm, on page 2392.

For more information about the captive portal identity source, see The Captive Portal Identity Source, on page 2525.

How to Set Up an Identity Policy

This topic provides a high-level overview of setting up an identity policy using any available user identity source: TS Agent, ISE/ISE-PIC, Microsoft Azure AD (SAML), captive portal.

Procedure

	Command or Action	Purpose
Step 1	Choose your identity source.	• To use Microsoft Active Directory or LDAP, continue with the next step. • To use a Microsoft Azure AD (SAML) realm, see Create a Microsoft Azure AD (SAML) Realm, on page 2392. • To use the Cisco ISE identity source, see Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512. • To use the passive identity agent identity source, see The Passive Identity Agent Identity Source, on page 2467.
Step 2	(Optional.) Create a realm and directory, one realm for every domain in the forest that contain users you want to use in user control.	Creating a realm, realm directory is optional if any of the following are true:

	Command or Action	Purpose
	Also create one directory for every domain controller. Only users and groups that have corresponding Firewall Management Center realms and directories can be used in identity policies..	• You use SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions. • You are using an identity policy only to filter network traffic. The *realm* is a trusted user and group store, typically a Microsoft Active Directory repository. The Firewall Management Center downloads users and groups at intervals you specify. You can include or exclude users and groups from being downloaded. See Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426. For details about the options to create a realm, see Realm Fields, on page 2436. A *directory* is an Active Directory domain controller that organizes information about a computer network's users and network shares. An Active Directory controller provides Directory Services for the realm. Active Directory distributes user and group objects across multiple domain controllers, which are peers that propagate local changes between each other by the use of Directory Services. For more information, see the Active Directory technical specification glossary on MSDN. You can specify more than one directory for a realm, in which case each domain controller is queried in the order listed on the realm's **Directory** tab page to match user and group credentials for user control. **Note** Configuring a realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions.
Step 3	Synchronize users and groups from the realm.	To be able to control users and groups, you must synchronize them with the Firewall Management Center. You can synchronize them with users and groups whenever you want or you can configure the system to synchronize them at a specified interval.

	Command or Action	Purpose
		When you synchronize users and groups, you can specify exceptions; for example, you can exclude the Engineering group from all user control for that realm, or you can exclude the user **joe.smith** from user controls that apply to the Engineering group. See Synchronize Users and Groups, on page 2445
Step 4	(Optional.) Create a realm sequence.	A realm sequence is an ordered list of realms that, when used in an identity policy, causes the system to search the realms in the specified order to find users to match the rule. See Create a Realm Sequence, on page 2446.
Step 5	Create a method to retrieve user and group data (the *identity source*).	Set up an identity source with its unique configuration to be able to control users and groups using data stored in the realm. Identity sources include TS Agent, captive portal, or Remote VPN. See one of the following: • How to Configure the Captive Portal for User Control, on page 2529 • Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512 • Configure RA VPN for User Control, on page 2546
Step 6	Create an identity policy.	An identity policy contains one or more identity rules, optionally organized in categories. See Create an Identity Policy, on page 2555. **Note** Configuring a realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.
Step 7	Create one or more identity rules.	Identity rules enable you to specify a number of matching criteria, including the type of authentication, network zones, networks or geolocation, realms, realm sequences, and so on. See Create an Identity Rule, on page 2563.
Step 8	Associate your identity policy with an access control policy.	An access control policy filters and optionally inspects traffic. An identity policy must be

	Command or Action	Purpose
		associated with an access control policy to have any effect. See Associating Other Policies with Access Control, on page 1762.
Step 9	Deploy the access control policy to at least one managed device.	To use your policy to control user activity, the policy must be deployed to the managed devices to which clients connect. See Deploy Configuration Changes, on page 259.
Step 10	Monitor user activity.	View a list of active sessions collected by user identity sources or a list of user information collected by user identity sources. See *Using Workflows* in the Cisco Secure Firewall Management Center Administration Guide . An identity policy is not required if all of the following are true: • You use the ISE/ISE-PIC identity source. • You do not use users or groups in access control policies. • You use Security Group Tags (SGT) in access control policies. For more information, see ISE SGT vs Custom SGT Rule Conditions.

Configuring Traffic-Based User Detection, on page 2653

The User Activity Database

The user activity database on the Secure Firewall Management Center contains records of user activity on your network detected or reported by all of your configured identity sources. The system logs events in the following circumstances:

- When it detects individual logins or logoffs.
- When it detects a new user.
- When a system administrator manually delete a user.
- When the system detects a user that is not in the database, but cannot add the user because you have reached your user limit.
- When you resolve an indication of compromise associated with a user, or enable or disable indication of compromise rules for a user.

Note If the TS Agent monitors the same users as another passive authentication identity source (such as the ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Firewall Management Center.

You can view user activity detected by the system using the Secure Firewall Management Center. (**Analysis** > **Users heading** > **User Activity**.)

The Users Database

The users database on the Secure Firewall Management Center contains a record for each user detected or reported by all of your configured identity sources. You can use data obtained from an authoritative source for user control.

See About User Identity Sources, on page 2372 for more information about the supported non-authoritative and authoritative identity sources.

The total number of users the Secure Firewall Management Center can store depends on the Secure Firewall Management Center model, as described in User Limits for Microsoft Active Directory, on page 2384. After the user limit is reached, the system prioritizes previously-undetected user data based on its identity source, as follows:

- If the new user is from a non-authoritative identity source, the system does not add the user to the database. To allow new users to be added, you must delete users manually or with a database purge.
- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period and adds the new user to the database.

If an identity source is configured to exclude specific user names, user activity data for those user names are not reported to the Secure Firewall Management Center. These excluded user names remain in the database, but are not associated with IP addresses. For more information about the type of data stored by the system, see *User Data* in the Cisco Secure Firewall Management Center Administration Guide.

If you have Firewall Management Center high availability configured and the primary fails, no logins reported by a captive portal, ISE/ISE-PIC, TS Agent, or Remote Access VPN device can be identified during failover downtime, even if the users were previously seen and downloaded to the Firewall Management Center. The unidentified users are logged as Unknown users on the Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

Note If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Firewall Management Center.

When the system detects a new user session, the user session data remains in the users database until one of the following occurs:

- A user on the Firewall Management Center manually deletes the user session.
- An identity source reports the logoff of that user session.

- A realm ends the user session as specified by the realm's **User Session Timeout: Authenticated Users**, **User Session Timeout: Failed Authentication Users**, or **User Session Timeout: Guest Users** setting.

Host and User Limits

Your Secure Firewall Management Center model determines how many individual hosts you can monitor with your deployment, as well as how many users you can monitor and use to perform user control.

Host Limit

The system adds a host to the network map when it detects activity associated with an IP address in your monitored network (as defined in your network discovery policy). The number of hosts a Secure Firewall Management Center can monitor, and therefore store in the network map, depends on its model.

Table 128: Host Limits by Secure Firewall Management Center Model

Firewall Management Center Model	Hosts
MC1000	50,000
MC1600	50,000
MC1700	50,000
MC2500	150,000
MC2600	150,000
MC2700	150,000
MC4500	600,000
MC4600	600,000
MC4700	600,000
virtual	50,000

You cannot view contextual data for hosts not in the network map. However, you can perform access control. For example, you can perform application control on traffic to and from a host not in the network map, even though you cannot use a compliance allow list to monitor the host's network compliance.

Note The system counts MAC-only hosts separately from hosts identified by both IP addresses and MAC addresses. All IP addresses associated with a host are counted together as one host.

Reaching the Host Limit and Deleting Hosts

The network discovery policy controls what happens when you detect a new host after you reach the host limit; you can drop the new host, or replace the host that has been inactive for the longest time. You can also set the period after which the system removes a host from the network map due to inactivity. Although you can manually delete a host, an entire subnet, or all of your hosts from the network map, if the system detects activity associated with a deleted host, it re-adds the host.

Network Discovery Data Storage Settings, on page 2659

User Limits for Microsoft Active Directory

About user limits

Your Firewall Management Center model determines how many individual users you can monitor. The user is added to the Firewall Management Center user database when:

- The user is downloaded from a realm.
- A captive portal or RA-VPN user logs in.
- A user is detected from any identity source (for example, TS Agent).

Only authoritative users are available for user control with access control policies.

Note the following:

- The maximum number of *downloaded* users depends on your Firewall Management Center model.
- The maximum number of *concurrent* user sessions (that is, logins) depends on your managed device model. A single user can have multiple sessions from different unique IP addresses.

Note The system downloads all user sessions to all Firewall Threat Defense devices. If you have devices with different user concurrent user session limits, the Firewall Threat Defense with the smallest limit reports health warnings when its memory reaches the configured limit. (For example, if your Firewall Management Center manages a Firepower 2110 and a 4125, the 2110 reports health warnings when the number of concurrent user sessions approaches its maximum of 64,000.)

User Limits for Microsoft Active Directory

Table 129: Maximum Concurrent User Login Limits by Firewall Threat Defense

Firewall Threat Defense Model	Maximum Concurrent User Logins per Realm
Firewall Threat Defense Virtual 5, 10, 20, 30, 50 (any supported hypervisor)	64,000

Firewall Threat Defense Model	Maximum Concurrent User Logins per Realm
Firepower 1010, 1120, 1140, 1150 Secure Firewall 1210, 1220, 1230, 1240, 1250 Firepower 2110, 2120, 2130 Secure Firewall 3105, 3110, 3120	64,000
Firepower 2140 Secure Firewall 3130, 3140 Firepower 4112, 4115, 4125	150,000
Firepower 4145 Firepower 9300	300,000
Secure Firewall 4215	300,000
Secure Firewall 4225, 4245	315,000

User limits are applied per Microsoft Active Directory realm. That is, if you attempt to download more than the maximum users in a *single* realm, the download stops after that many users and a health alert is displayed. If, however, you attempt to download more than the maximum number of users spread across *different* realms, the download succeeds (unless any one realm has more than 150,000 users, in which case the download fails for that realm).

Table 130: Maximum Downloaded Users by Firewall Management Center Model

Firewall Management Center Model	Maximum Downloaded Users
FMC 1000	50,000
FMC 1600	50,000
FMC 1700	50,000
FMC 2500	150,000
FMC 2600	150,000
FMC 2700	150,000
FMC 4500	600,000
FMC 4600	600,000
FMC 4700	600,000
Firewall Management Center Virtual (any supported hypervisor)	50,000
Firewall Management Center Virtual 300 (any supported hypervisor)	150,000

When the system detects a new, previously-undetected user after the limit has been reached, it prioritizes user data based on their identity source:

- If the new user is from a non-authoritative source, the system does not add the non-authoritative user to the database. To allow new users to be added, you must delete users manually or purge the database.
- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period of and adds the new authoritative user to the database.

  If there are only authoritative users, the system deletes the authoritative user who has remained inactive for the longest period of time and adds the new user to the database.

Troubleshooting information can be found in Troubleshoot User Control, on page 2573.

Tip Note that if you are using traffic-based detection, you can restrict user logging by protocol to help minimize username clutter and preserve space in the database. For example, you could prevent the system from adding users discovered in AIM, POP3, and IMAP traffic because you know it is traffic from specific contractors or visitors you do not want to monitor.

User Limits for Microsoft Azure Active Directory Realms

Microsoft Azure Active Directory User Limits

About user limits

Your Firewall Management Center model determines how many individual users you can monitor.

Note the following:

- The maximum number of *downloaded* users depends on your Firewall Management Center model.
- The maximum number of *concurrent* user sessions (that is, logins) depends on your managed device model. A single user can have multiple sessions from different unique IP addresses.

Note The system downloads all user sessions to all Firewall Threat Defense devices. If you have devices with different user concurrent user session limits, the Firewall Threat Defense with the smallest limit reports health warnings when its memory reaches the configured limit. (For example, if your Firewall Management Center manages a Firepower 2110 and a 4125, the 2110 reports health warnings when the number of concurrent user sessions approaches its maximum of 64,000.)

Refer to the following tables.

Table 131: Maximum Downloaded Users by Firewall Management Center Model[1]

Firewall Management Center Model	Number of Cisco Secure Dynamic Attributes Connector Connectors	Maximum Downloaded Users
FMC1600, FMC1700	10	50,000
FMC2600, FMC2700	20	150,000
FMC4600, FMC4700	30	600,000
Firewall Management Center Virtual (any supported hypervisor)	10	50,000
Firewall Management Center Virtual 300 (any supported hypervisor)	20	150,000

[1]—Firewall Management Center models are subject to end of life and end of sale. For more information, see End-Of-Life and End-Of-Sale Notices.

Table 132: Maximum Concurrent User Login Limits by Firewall Threat Defense

Firewall Threat Defense Model	Maximum Concurrent User Logins
Firewall Threat Defense Virtual 5, 10, 20, 30, 50 (any supported hypervisor)	50,000
Firepower 1010, 1120, 1140, 1150 Firepower 2110, 2120, 2130 Secure Firewall 3110, 3120, 3130, 3140	50,000
Firepower 2140 Secure Firewall 3130, 3140	150,000
Firepower 4140, 4145, 4150 Firepower 9300 Secure Firewall 4215	225,000
Secure Firewall 4225, 4245	300,000

Identity Realm Limit

We limit you to a maximum of 25 realms regardless of Firewall Threat Defense model; the same limit applies to the Cloud-Delivered Firewall Management Center.

The number of *users* you can download to a system is limited according to the information provided in:

User Limits for Microsoft Active Directory, on page 2384

User Limits for Microsoft Azure Active Directory Realms

Microsoft Azure Active Directory User Limits

About user limits

Your Firewall Management Center model determines how many individual users you can monitor.

Note the following:

- The maximum number of *downloaded* users depends on your Firewall Management Center model.
- The maximum number of *concurrent* user sessions (that is, logins) depends on your managed device model. A single user can have multiple sessions from different unique IP addresses.

Note The system downloads all user sessions to all Firewall Threat Defense devices. If you have devices with different user concurrent user session limits, the Firewall Threat Defense with the smallest limit reports health warnings when its memory reaches the configured limit. (For example, if your Firewall Management Center manages a Firepower 2110 and a 4125, the 2110 reports health warnings when the number of concurrent user sessions approaches its maximum of 64,000.)

Refer to the following tables.

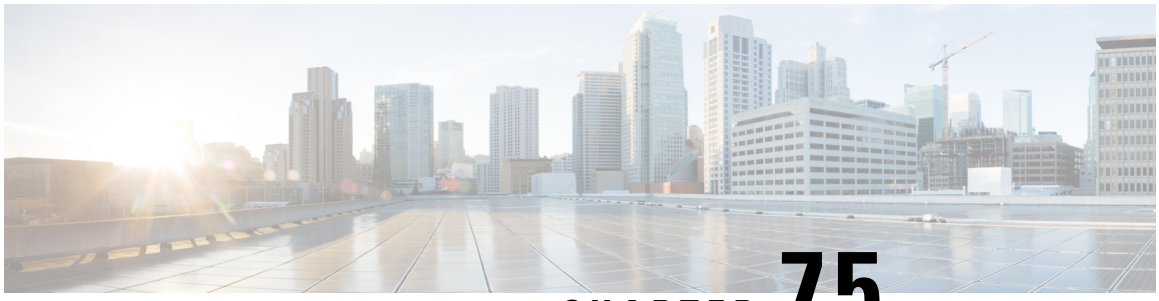
Table 133: Maximum Downloaded Users by Firewall Management Center Model[1]

Firewall Management Center Model	Number of Cisco Secure Dynamic Attributes Connector Connectors	Maximum Downloaded Users
FMC1600, FMC1700	10	50,000
FMC2600, FMC2700	20	150,000
FMC4600, FMC4700	30	600,000
Firewall Management Center Virtual (any supported hypervisor)	10	50,000
Firewall Management Center Virtual 300 (any supported hypervisor)	20	150,000

[1]—Firewall Management Center models are subject to end of life and end of sale. For more information, see End-Of-Life and End-Of-Sale Notices.

Table 134: Maximum Concurrent User Login Limits by Firewall Threat Defense

Firewall Threat Defense Model	Maximum Concurrent User Logins
Firewall Threat Defense Virtual 5, 10, 20, 30, 50 (any supported hypervisor)	50,000
Firepower 1010, 1120, 1140, 1150 Firepower 2110, 2120, 2130 Secure Firewall 3110, 3120, 3130, 3140	50,000
Firepower 2140 Secure Firewall 3130, 3140	150,000
Firepower 4140, 4145, 4150 Firepower 9300 Secure Firewall 4215	225,000
Secure Firewall 4225, 4245	300,000



CHAPTER 75

Realms

The following topics describe realms and identity policies:

- License Requirements for Realms, on page 2391
- Requirements and Prerequisites for Realms, on page 2391
- Create a Microsoft Azure AD (SAML) Realm, on page 2392
- Create a Microsoft Azure AD (SAML) Realm for Passive Authentication, on page 2417
- Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426
- Create a Realm Sequence, on page 2446
- Configure the Firewall Management Center for Cross-Domain-Trust: The Setup, on page 2447
- Manage a Realm, on page 2455
- Compare Realms, on page 2456
- Troubleshoot Realms and User Downloads, on page 2456
- History for Realms, on page 2464

License Requirements for Realms

Threat Defense License

Any

Requirements and Prerequisites for Realms

Model Support

Any.

Supported Domains

Any

User Roles

- Access Admin
- Network Admin

Create a Microsoft Azure AD (SAML) Realm

You can use a Microsoft Azure Active Directory (AD) (now called *Entra ID*) realm for either passive authentication or active authentication.

If you enabled Change Management, you must approve all certificates used in this procedure. Open a new ticket or edit an existing one. For more information, see Creating Change Management Tickets, on page 240 and .Policies and Objects that Support Change Management, on page 235

Passive authentication

Passive authentications occur when a user authenticates with Cisco ISE.

You have the following options, depending on your choice of user and group repository:

- To use Cisco ISE as a repository for users and to perform passive authentication using Entra ID. For more information, see:
  - About Entra ID and Cisco ISE with Resource Owned Password Credentials, on page 2394
  - About Entra ID and Cisco ISE with TEAP/EAP-TLS, on page 2394
- To download groups from Entra ID.

  For more information about setting up Entra ID, see Configure Microsoft Entra ID for Passive Authentication, on page 2395.

Active authentication

Active authentications occur when a user authenticates through preconfigured managed devices. Captive portal is another name for active authentication. Active authentication generally uses the same user repositories as passive authentication (the exceptions being ISE/ISE-PIC, TS Agent, and the Passive Identity Agent, which are passive only).

To use Microsoft Entra ID as a captive portal requires users to authenticate with Entra ID. We refer to the realm as a Security Assertion Markup Language (SAML) realm because SAML is used to establish a trust relationship between:

- A *service provider* (the Secure Firewall Threat Defense device or devices to which authentication requests are sent).
- An *identity provider* (Microsoft Entra ID).

SAML is an open standard developed by the OASIS standards body; for more information, see the SAML Overview.

For more information, see How to Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal), on page 2403.

How to Create a Microsoft Azure AD (SAML) for Passive Authentication

This topic discusses the high-level tasks of creating a Microsoft Azure AD (SAML) (now called *Entra ID*) realm for passive authentication use with the Secure Firewall Management Center.

Procedure

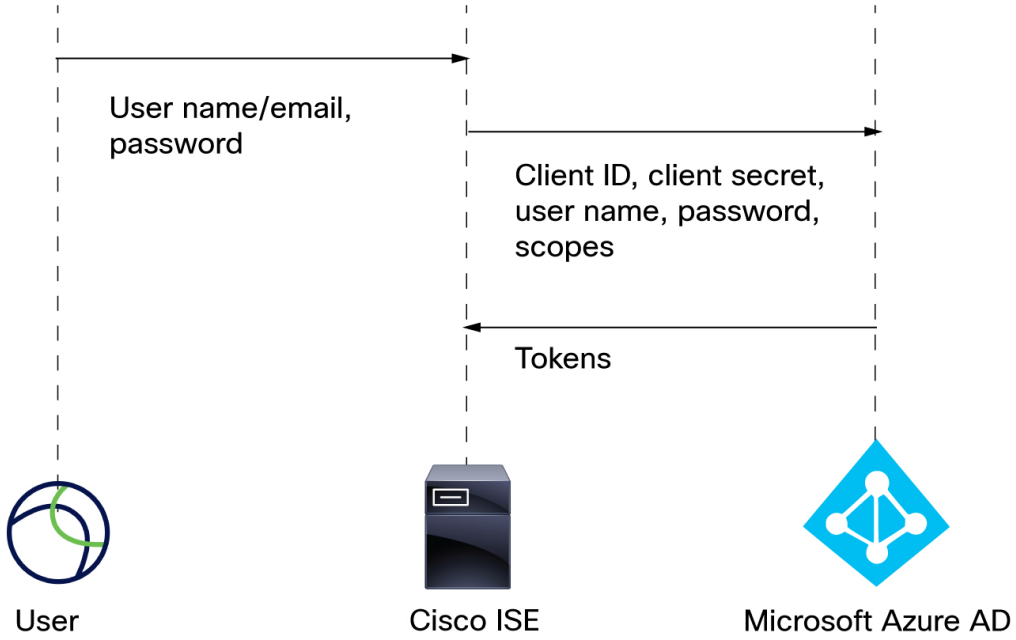
	Command or Action	Purpose
Step 1	Enable the Cisco Secure Dynamic Attributes Connector.	The Cisco Secure Dynamic Attributes Connector is required to use a Microsoft Azure AD (SAML) realm. You can do it first or you can enable it when you create the realm. For more information, see Enable the Cisco Secure Dynamic Attributes Connector, on page 1806.
Step 2	Configure Microsoft Entra ID.	Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log. See Configure Microsoft Entra ID for Passive Authentication, on page 2395.
Step 3	Configure Cisco ISE.	The way you configure ISE depends on how users authenticate with your system. For more information, see How to Configure ISE for Microsoft Azure AD (SAML), on page 2395.
Step 4	Create a Cisco ISE identity source.	The identity source enables ISE to communicate with the Secure Firewall Management Center.
Step 5	Get the information required to configure your Microsoft Azure AD (SAML) realm.	This information includes client and tenant IDs, client secret, and other information store in Microsoft Entra ID.
Step 6	Configure and verify your realm.	Test the realm's configuration before you start to use it in access control policies. Create a Microsoft Azure AD (SAML) realm as discussed in Create a Microsoft Azure AD (SAML) Realm, on page 2392
Step 7	Create access control policies and rules using your Microsoft Azure AD (SAML) realm.	Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy. See Creating a Basic Access Control Policy, on page 1748 and Create and Edit Access Control Rules, on page 1783.

What to do next

See About Entra ID and Cisco ISE with Resource Owned Password Credentials, on page 2394.

About Entra ID and Cisco ISE with Resource Owned Password Credentials

The following figure summarizes an Azure AD (now *called Entra ID*) realm with Cisco ISE and resource owned password credentials (ROPC):



With ROPC,

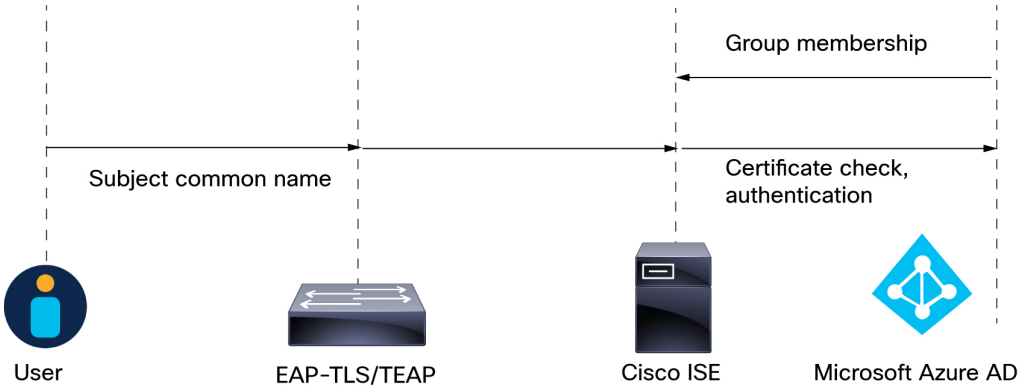
1. The user logs in with a user name (or email address) and password using a VPN client like Cisco Secure Client.
2. The client ID, client secret, user name, password, and scopes are sent to Entra ID.
3. Tokens are sent from Entra ID to Cisco ISE, which sends user sessions to the Secure Firewall Management Center.

For details about configuring Cisco ISE, see Configure ISE 3.0 REST ID with Azure Active Directory.

Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

About Entra ID and Cisco ISE with TEAP/EAP-TLS

Tunnel Extensible Authentication Protocol (TEAP) , defined by RFC7170, can be used with ISE and the Secure Firewall Management Center as follows:



The following is based on Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory:

1. The user's certificate is sent to ISE through EAP-TLS or TEAP with EAP-TLS as the inner method.
2. ISE evaluates the user's certificate (validity period, trusted certificate authority, certificate revocation list, and so on).
3. ISE takes the certificate subject name (CN) and performs a look-up to the Azure Graph API to fetch the user's groups and other attributes. This is referred to by Azure as User Principal name (UPN).
4. ISE authorization policies are evaluated against the user's attributes returned from Azure.

How to Configure ISE for Microsoft Azure AD (SAML)

In a Microsoft Azure AD (SAML) (now called *Entra ID*) realm, it's the responsibility of ISE to send user sessions (login, logout) to the Secure Firewall Management Center. This topic discusses how to set up ISE for use with an Azure AD realm.

Resource owned password credentials authentication

To use ISE with Microsoft Azure AD (SAML) implemented through Representational State Transfer (REST) Identity (ID) service with the help of Resource Owner Password Credentials (ROPC), see Configure ISE 3.0 REST ID with Azure Active Directory.

TEAP/EAP-TLS

To use ISE with authorization policies based on Azure AD group membership and other user attributes with EAP-TLS or TEAP as the authentication protocols, see Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory.

What to do next

Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398

Configure Microsoft Entra ID for Passive Authentication

This topic provides basic information about how to set up a Microsoft Entra ID (formerly caled *Microsoft Azure Active Directory (AD)*) as a realm you can use with the Secure Firewall Management Center. We expect you to already be familiar with Entra ID; if not, consult documentation or a support resource before you get started.

Give your application the Microsoft Graph permission

Grant your Entra ID application the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Secure Firewall Management Center to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Set up an event hub

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Secure Firewall Management Center uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Enable the audit log

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

Configure Cisco ISE for Entra ID

To send user session information to the Secure Firewall Management Center, configure Cisco ISE for Entra ID as discussed in Configure ISE 3.0 REST ID with Azure Active Directory.

What to do next

See How to Configure ISE for Microsoft Azure AD (SAML), on page 2395.

Configure Entra ID Basic Settings

Give your application the Microsoft Graph permission

Grant your Entra ID (formerly called *Azure AD*) application the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Firewall Management Center to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Firewall Management Center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Set up an event hub

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Firewall Management Center uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Enable the audit log

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

Get Required Information For Your Microsoft Azure AD (SAML) Realm

This task explains how to get the information required to set up a Microsoft Azure AD (SAML) (now called *Entra ID*) realm in the Secure Firewall Management Center. You might have already obtained this information when you set up Microsoft Entra ID as discussed in Configure Microsoft Entra ID for Passive Authentication, on page 2395.

Procedure

Step 1 Log in to https://portal.azure.com/ as a user with at least the Product Designer role.

Step 2 At the top of the page, click **Microsoft Entra ID**.

Step 3 In the left column, click **App Registrations**.

Step 4 If necessary, filter the list of displayed apps to show the one you want to use.

Step 5 Click the name of your app.

Step 6 Click **Copy** ( ) next to the following values on this page and paste those values to a text file.

- **Application (Client) ID**
- **Directory (tenant) ID**

Step 7 Click **Client Credentials**.

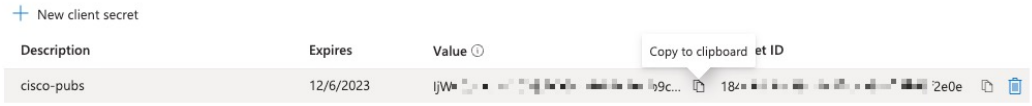
Step 8 Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

a) Click **New Client Secret**.

b) Enter the required information in the provided fields.

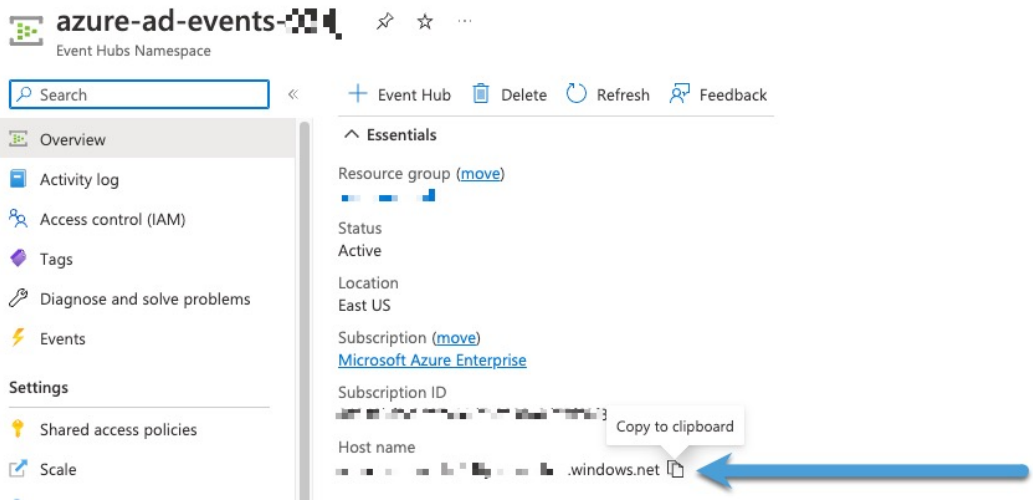
c) Click **Add**.

d) Click **Copy** ( ) next to Value as the following figure shows.



Step 9 From https://portal.azure.com/, click **Event Hubs** > **(name of an event hub)**.

Step 10 In the right pane, click **Copy** ( ) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.

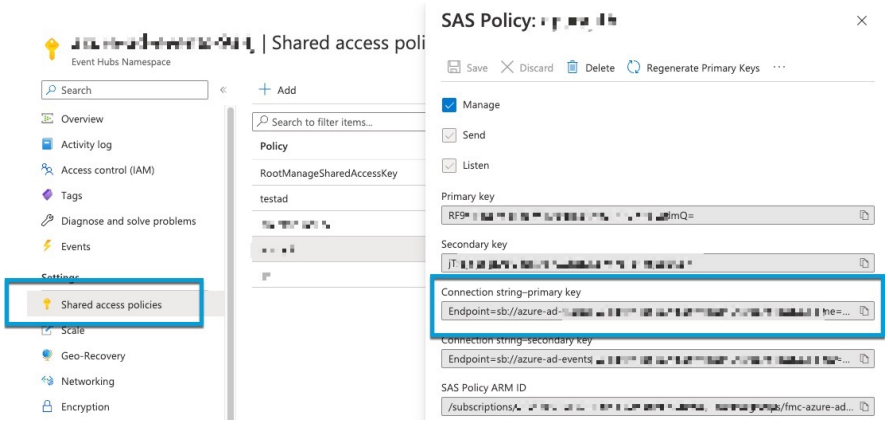


Step 11 Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).

Step 12 In the left pane, under Settings, click **Shared access policies**.

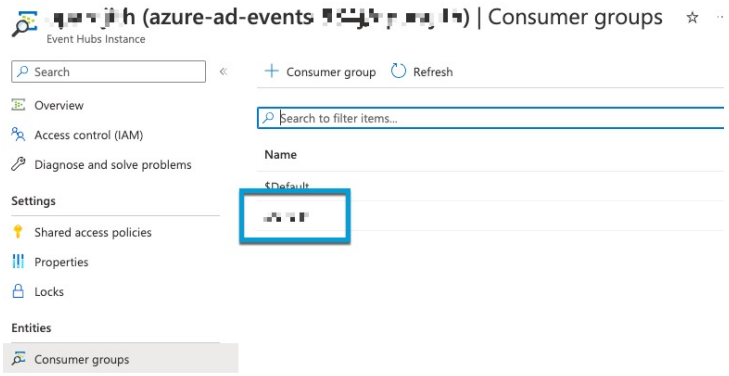
Step 13 Click the name of a policy.

Step 14 Click **Copy** (⧉) next to **Connection string-primary key**.



Step 15 Click **Overview** > **Entities** > **Event Hubs** > **(name of an event hub)** > **Entities** > **Consumer Groups**.

Write down the following value or copy it to the clipboard. This is your consumer group name.



Step 16 In the left pane, click **Overview**.

Step 17 Click **Copy** ( ) next to **Namespace**.

This is your event hubs topic name.

Create a Microsoft Azure AD (SAML) Realm for Passive Authentication

The following topics discuss how to run the multi-step wizard required to create a Microsoft Azure AD (SAML) (now called *Entra ID*) realm for passive authentication.

You can use a Microsoft Azure Active Directory (AD) realm with Cisco ISE to authenticate users and get user sessions for user control. We get groups from Entra ID and logged-in user session data from Cisco ISE.

You have the following options:

- Resource owned password credentials (ROPC): Enables users to log in with a client like Cisco Secure Client using a user name and password. ISE sends user sessions to the Secure Firewall Management Center. For more information, see About Entra ID and Cisco ISE with Resource Owned Password Credentials, on page 2394.

  Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

- Extensible Authentication Protocol (EAP) Chaining with Tunnel-based Extensible Authentication Protocol (TEAP) and Transport Layer Security (TLS), abbreviated EAP/TEAP-TLS: TEAP is a tunnel-based EAP method that establishes a secure tunnel and executes other EAP methods under the protection of that secured tunnel. ISE is used to validate user credentials and to send user sessions to the Secure Firewall Management Center. For more information, see About Entra ID and Cisco ISE with TEAP/EAP-TLS, on page 2394.

To configure the realm, complete all tasks in the following order:

1. Configure Entra ID Basic Settings, on page 2397.

2. Get required information for your realm as discussed in Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398.
3. Microsoft Azure AD (SAML) Realm: SAML Details, on page 2401.

Microsoft Azure AD (SAML) Realm: SAML Details

This task discusses the first step in a multi-step wizard that creates a Microsoft Azure AD (SAML) realm. You must complete all steps in the wizard to set up your realm. The steps are different depending on whether you create the realm for active or passive authentication.

Before you begin

Complete all of the following tasks before you create your realm:

- (Passive authentication with Cisco ISE only.) If you're using Cisco ISE as the repository for users and groups, set up ISE:
  - About Entra ID and Cisco ISE with Resource Owned Password Credentials, on page 2394
  - About Entra ID and Cisco ISE with TEAP/EAP-TLS, on page 2394
- To use Entra ID as the repository for users and groups, see Configure Microsoft Entra ID for Passive Authentication, on page 2395.
- Get required information for your realm as discussed in Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 Click **Add Realm** > **SAML - Azure AD**.

Step 4 Enter the following information.

Item	Description
Name	Unique name to identify the realm.
Description	(Optional.) Description of the realm.
Identity Provider	Always displays **Azure AD**.
Configuration Type	Click one of the following: • **Passive Authentication with ISE** for passive authentication. • **Passive authentication or captive portal with Azure AD** for to use Entra ID as a user store for either passive authentication or active authentication (that is, captive portal).

Step 5 Click **Next**.

What to do next

One of the following:

- Passive authentication: Microsoft Azure AD (SAML) Realm: Azure AD Details, on page 2402.
- Active authentication: Microsoft Azure AD (SAML) Realm: SAML Service Provider (SP) Metadata, on page 2414.

Microsoft Azure AD (SAML) Realm: Azure AD Details

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
Name	Enter a unique name to identify this realm.
Client Secret **Tenant ID** **Event Hubs Host Name** **Event Hub Name** **Event Hub Connection String**	Enter the information you found as discussed in:. • Passive authentication: How to Create a Microsoft Azure AD (SAML) for Passive Authentication, on page 2393 • Active authentication: Get Required Information For Your Microsoft Azure AD (SAML) Realm (Active Authentication Only), on page 2409
(Optional.) **User Groups**	Slide to **Slider enabled** ( ) to specify groups to include or exclude from policy.
(Optional.) **Excluded User Groups**	If you enter one or more group names in this field, all groups and users they contain *except* these are downloaded and available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive.
(Optional.) **Included User Groups**	If you enter one or more group names in this field, only those groups and users they contain are downloaded and user data is available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive.

Step 3 Click **Test**.
Make sure the test connection succeeds before you continue to the next step.

Step 4 Click **Next**.

Microsoft Azure AD (SAML) Realm: User Session Timeout

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

This option sets the number of seconds before an inactive session is terminated by the system.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
ISE users	Default is 1440 minutes (24 hours).
Captive portal users	Default is 1440 minutes (24 hours).

After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

Step 3 Click **Save**.

How to Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal)

This topic discusses the high-level tasks of creating a Microsoft Azure Active Directory (AD) realm (now called *Entra ID*) for use with the Secure Firewall Management Center.

Before you begin

If you enabled Change Management, you must open or edit, assign, and approve a ticket for each of the following objects before you can create the realm:

- Base URL
- Service provider certificate enrollment (PKCS12 format)
- Identity provider certificate enrollment (manual format)
- The realm itself (create and assign the ticket until realm creation is complete, then approve it)

For more information, see Opening a Ticket for Configuration Changes, on page 241 and Policies and Objects that Support Change Management, on page 235.

Procedure

	Command or Action	Purpose
Step 1	Create a fully-qualified host name (FQDN) using your DNS server and upload the Firewall Threat Defense's internal certificate to the Secure Firewall Management Center. You can consult a resource such as this one if you've never done it before. Specify the IP address of a routed interface on one of the devices managed by your Secure Firewall Management Center.	Consult a DNS server reference.
Step 2	Enable the Cisco Secure Dynamic Attributes Connector.	The Cisco Secure Dynamic Attributes Connector is required to use a Microsoft Azure AD realm. You can do it first or you can enable it when you create the realm. For more information, see Enable the Cisco Secure Dynamic Attributes Connector, on page 1806.
Step 3	Create a network object with an associated internal certificate.	See Creating Network Objects, on page 1403.
Step 4	Get a signed certificate and upload it to the Secure Firewall Threat Defense to which Entra ID authentication requests will be sent.	The certificate should be signed by a trusted Certificate Authority (CA) and delivered to you in **.p12** format (also referred to as PKCS#12; see also this article on ssl.com). For background, see the section on public key infrastructure in Cisco Secure Firewall Management Center Device Configuration Guide or stackoverflow.com. To upload the signed certificate, see Installing a Certificate Using a PKCS12 File, on page 1492.
Step 5	Configure Microsoft Entra ID basic settings.	Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log. See Configure Entra ID Basic Settings, on page 2397.
Step 6	Create a single sign-on (SSO) app in Entra ID.	The SSO app enables users that request access to a protected network resource to authenticate with Entra ID. The SSO app has both the federation XML that you can use to simplify realm creation as well as the identity provider

	Command or Action	Purpose
		certificate the Secure Firewall Threat Defense requires to security authenticate with Entra ID. See Configure a Single Sign-On (SSO) App in Entra ID, on page 2407.
Step 7	Get the information required to configure your Microsoft Azure AD (SAML) realm.	This information includes client and tenant IDs, client secret, and other information store in Microsoft Entra ID. See Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398.
Step 8	Configure a decryption policy with a **Decrypt - Resign** rule for the Azure Authentication Service so users can access web pages using the HTTPS protocol.	The Microsoft Azure AD (SAML) realm can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the realm. The Microsoft Azure AD (SAML) realm itself is seen by the system as the **Azure Authentication Service** application. Create a Decryption Rule with Decrypt - Resign Action, on page 2408.
Step 9	Create identity policy with an active authentication rule.	The identity policy enables selected users in your realm access resources after authenticating with the Microsoft Azure AD (SAML) realm. For more information, see Create an Identity Policy, on page 2555.
Step 10	Create access control policies and rules using your Microsoft Azure AD realm.	Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy. See Creating a Basic Access Control Policy, on page 1748 and Create and Edit Access Control Rules, on page 1783.
Step 11	Associate the identity and decryption policies with the access control policy from step 3.	This final step enables the system to authenticate users with the Microsoft Azure AD (SAML) realm. For more information, see Associating Other Policies with Access Control, on page 1762.

What to do next

See Configure Entra ID Basic Settings, on page 2397.

Configure Entra ID Basic Settings

Give your application the Microsoft Graph permission

Grant your Entra ID (formerly called *Azure AD*) application the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Firewall Management Center to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Firewall Management Center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Set up an event hub

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Firewall Management Center uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Enable the audit log

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

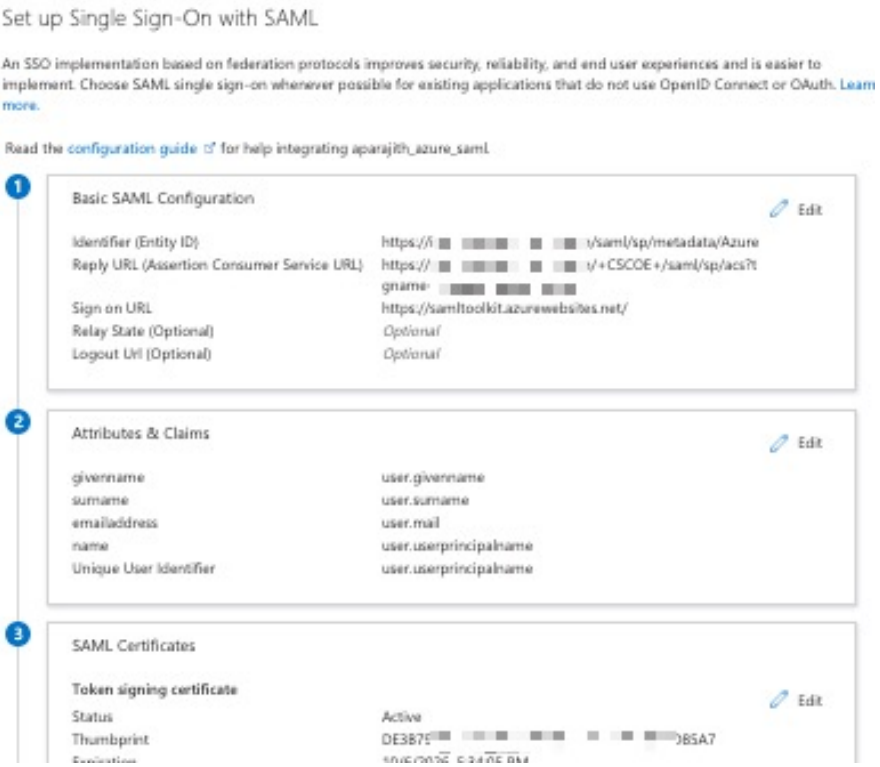
Configure a Single Sign-On (SSO) App in Entra ID

This topic discusses how to create an app in Microsoft Entra ID to handle single sign-on (SSO) from Entra ID when a network user attempts to access a protected network.

Create the app

In the Microsoft Entra ID portal, click **Enterprise Applications** on the home page and follow the instructions in Configure Microsoft Entra SSO on learn.microsoft.com.

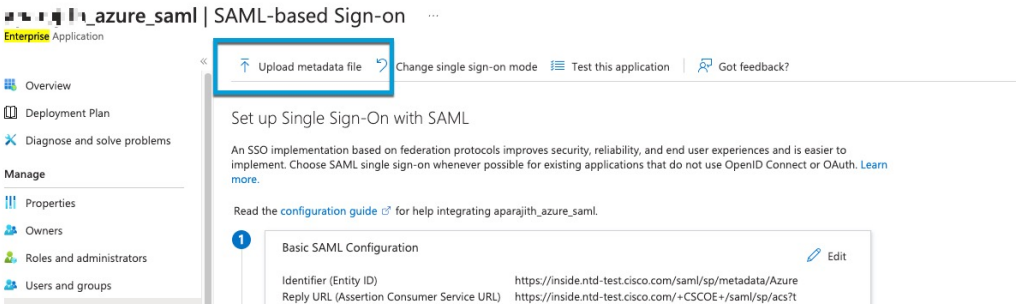
The following figure shows part of the SSO app configuration. You must provide some of the information on this page when you configure the Microsoft Azure AD (SAML) realm. For more information, see Get Required Information For Your Microsoft Azure AD (SAML) Realm (Active Authentication Only), on page 2409.



(Optional.) Upload the service provider metadata

If you already configured the Microsoft Azure AD (SAML) realm, click Upload metadata file at the top of the page to quickly provide configuration values for the SSO app.

The following figure shows an example.



Add users and groups to the SSO app

Add users and groups to your app as discussed in Add a user account to an enterprise application on learn.microsoft.com

What to do next

See Get Required Information For Your Microsoft Azure AD (SAML) Realm (Active Authentication Only), on page 2409.

Create a Decryption Rule with Decrypt - Resign Action

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the SAML realm. The realm can authenticate traffic only after it has been decrypted.

Procedure

Step 1 If you haven't done so already, log in to the Secure Firewall Management Center.

Step 2 If you haven't done so already, create an internal certificate authority object to decrypt TLS/SSL traffic as discussed in PKI, on page 1404.

Step 3 Click **Policies** > **Access Control heading** > **Decryption**.

Step 4 Click **New Policy**.

Step 5 Enter a **Name** and choose a **Default Action** for the policy. Default actions are discussed in Decryption Policy Default Actions, on page 2295.

Step 6 Click **Save**.

Step 7 Click **Add Rule**.

Step 8 Enter a **Name** for the rule.

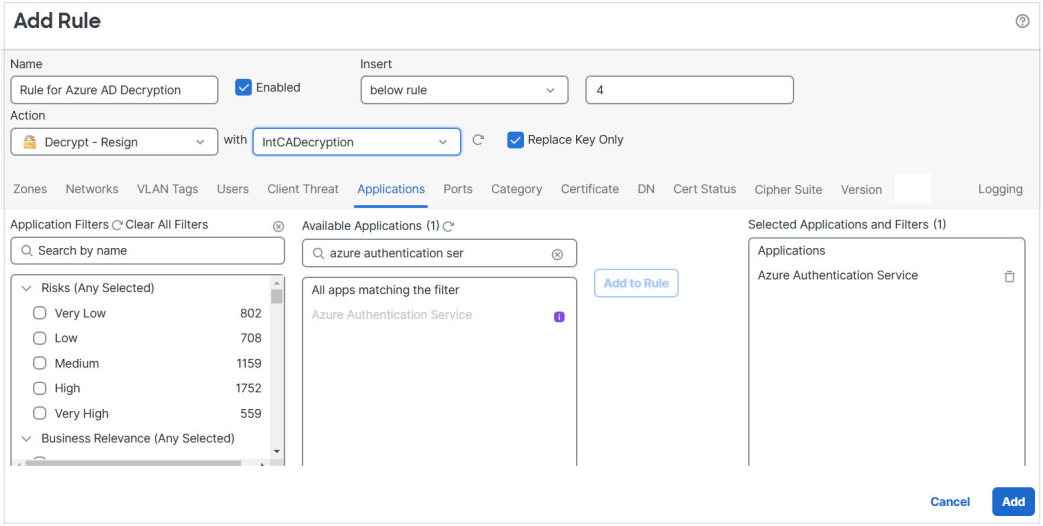
Step 9 From the **Action** list, choose **Decrypt - Resign**.

Step 10 From the **with** list, choose your service provider certificate object.

Step 11 Click the **Applications** tab page.

Step 12 In the Available Applications section, enter **Azure Authentication Service** in the search field.

Step 13 Click **Azure Authentication** and click **Add to Rule**.
The following figure shows an example.



Step 14 (Optional.) Set other options as discussed in Decryption Rule Conditions, on page 2316.

Step 15 Click **Add**.

Step 16 At the top of the page, click **Save**.

What to do next

Get Required Information For Your Microsoft Azure AD (SAML) Realm (Active Authentication Only)

This task explains how to get the information required to set up a Microsoft Azure AD (SAML) realm (now called *Entra ID*) in the Firewall Management Center.

Procedure

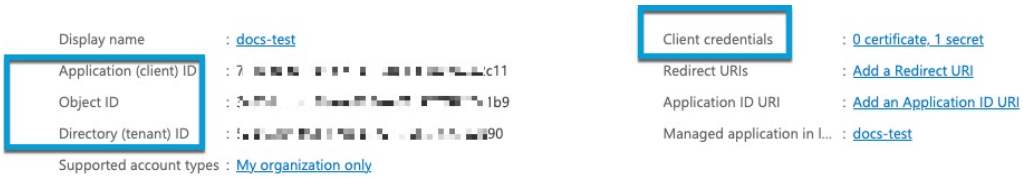
Step 1 Log in to https://portal.azure.com/ as a user with at least the Product Designer role.

Step 2 At the top of the page, click **Microsoft Entra ID**.

Step 3 In the left column, click **App Registrations**.

Step 4 If necessary, filter the list of displayed apps to show the one you want to use.

Step 5 Click the name of your app.



Step 6 Click **Copy** ( ) next to the following values on this page and paste those values to a text file.

- **Application (Client) ID**

- **Directory (tenant) ID**

Step 7 Click **Client Credentials**.

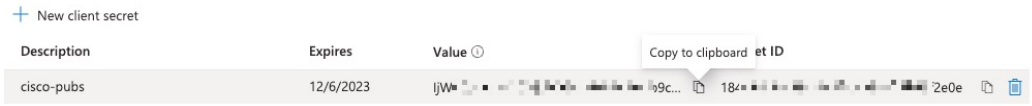
Step 8 Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

a) Click **New Client Secret**.

b) Enter the required information in the provided fields.

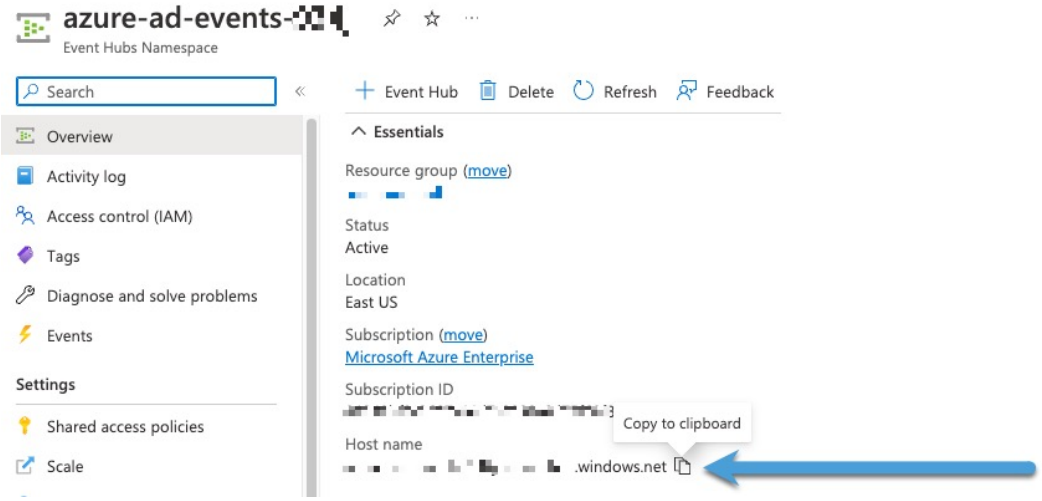
c) Click **Add**.

d) Click **Copy** (⧉) next to Value as the following figure shows.



Step 9 From https://portal.azure.com/, click **Event Hubs** > **(name of an event hub)**.

Step 10 In the right pane, click **Copy** (⧉) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.

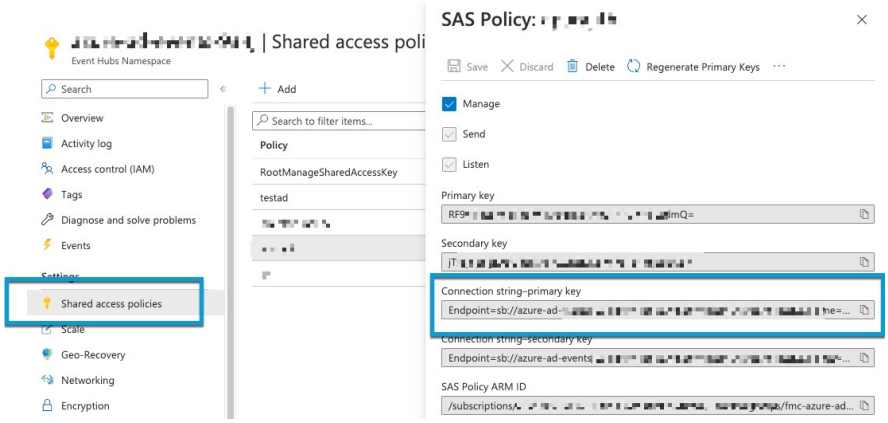


Step 11 Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).

Step 12 In the left pane, under Settings, click **Shared access policies**.

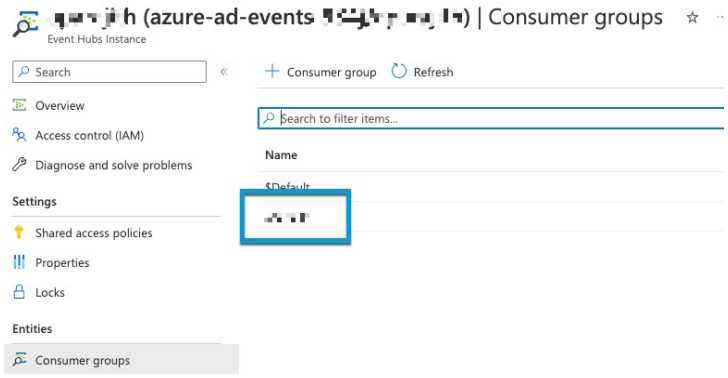
Step 13 Click the name of a policy.

Step 14 Click **Copy** (⧉) next to **Connection string-primary key**.



Step 15 Click **Overview** > **Entities** > **Event Hubs** > **(name of an event hub)** > **Entities** > **Consumer Groups**.

Write down the following value or copy it to the clipboard. This is your consumer group name.



Step 16 In the left pane, click **Overview**.

Step 17 Click **Copy** ( ) next to **Namespace**.

This is your event hubs topic name.

Step 18 Return to the home page and log in if necessary: https://portal.azure.com/#home.

Step 19 Click **Microsoft Entra ID**.

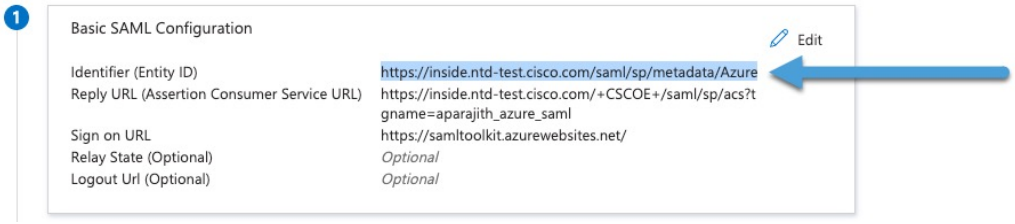
Step 20 In the left pane, click **Enterprise Applications.**

Step 21 If necessary, filter the list of applications to locate yours.

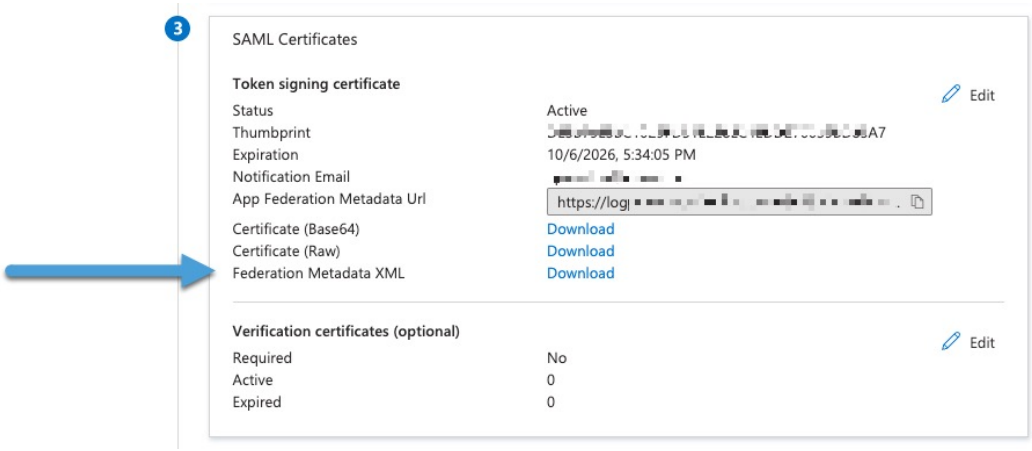
Step 22 Click the name of your enterprise application.

Step 23 Click **Get Started** under Set up single sign on.

Step 24 On your SSO app page, copy the value of Identifier (Entity ID) to the clipboard.
The following figure shows an example.

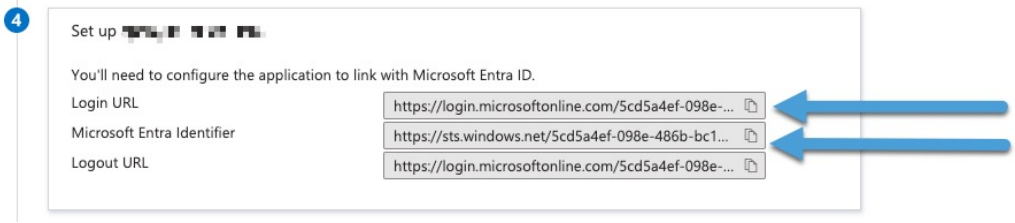


Step 25 On your SSO app page, click the **Download** link next to Federation Metadata XML, as the following figure shows.
The following figure shows an example.



Step 26 If you've already set up your SSO app, *you can stop here*. The Federation Metadata XML contains all the information required to configure the identity provider in the Secure Firewall Management Center.

Step 27 (Optional if you already downloaded the federation XML.) Click **Copy** ( ) next to both of the following values and save them to a text file.
The following figure shows an example.



What to do next

See Create a Decryption Rule with Decrypt - Resign Action, on page 2408.

Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal)

The following topics discuss how to run the multi-step wizard required to create a Microsoft Azure AD (SAML) realm (now called *Entra ID*) for active authentication.

In active authentication (also referred to as *captive portal*), Microsoft Entra ID is the user store. When a user tries to access a protected resource as defined in access control rules, the user must authenticate with Microsoft Entra ID first.

To configure the realm, complete all tasks in the following order:

1. Configure Entra ID Basic Settings, on page 2397.
2. Configure a Single Sign-On (SSO) App in Entra ID, on page 2407.
3. Get Required Information For Your Microsoft Azure AD (SAML) Realm (Active Authentication Only), on page 2409

Microsoft Azure AD (SAML) Realm: SAML Details

This task discusses the first step in a multi-step wizard that creates a Microsoft Azure AD (SAML) realm. You must complete all steps in the wizard to set up your realm. The steps are different depending on whether you create the realm for active or passive authentication.

Before you begin

Complete all of the following tasks before you create your realm:

- (Passive authentication with Cisco ISE only.) If you're using Cisco ISE as the repository for users and groups, set up ISE:
  - About Entra ID and Cisco ISE with Resource Owned Password Credentials, on page 2394
  - About Entra ID and Cisco ISE with TEAP/EAP-TLS, on page 2394
- To use Entra ID as the repository for users and groups, see Configure Microsoft Entra ID for Passive Authentication, on page 2395.
- Get required information for your realm as discussed in Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 Click **Add Realm** > **SAML - Azure AD**.

Step 4 Enter the following information.

Item	Description
Name	Unique name to identify the realm.
Description	(Optional.) Description of the realm.
Identity Provider	Always displays **Azure AD**.

Item	Description
Configuration Type	Click one of the following: • **Passive Authentication with ISE** for passive authentication. • **Passive authentication or captive portal with Azure AD** for to use Entra ID as a user store for either passive authentication or active authentication (that is, captive portal).

Step 5 Click **Next**.

What to do next

One of the following:

- Passive authentication: Microsoft Azure AD (SAML) Realm: Azure AD Details, on page 2402.
- Active authentication: Microsoft Azure AD (SAML) Realm: SAML Service Provider (SP) Metadata, on page 2414.

Microsoft Azure AD (SAML) Realm: SAML Service Provider (SP) Metadata

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Before you begin

Complete the tasks discussed in Microsoft Azure AD (SAML) Realm: SAML Details, on page 2401

Procedure

Step 1 Continue from Microsoft Azure AD (SAML) Realm: SAML Details, on page 2401.

Step 2 Enter the following information.

Item	Description
Base URL	From the list, click the network object you previously created. Network users are directed to this URL when they try to access protected network resources. You can also click **Add** (+) to create an object now.
Entity ID	Your SSO app's entity ID.
Assertion Consumer Services (ACS) URL	Automatically generated from the preceding values.

Item	Description
Service Provider Certificate	From the list, click the certificate to use to decrypt requests to the Secure Firewall Threat Defense. You can also click **Add** (+) to create an object now.
Download Service Provider Metadata	(Optional.) Download the metadata associated with the service provider (that is, managed device) to simplify configuring your Microsoft Entra ID SSO app.

Step 3 Click **Next**.

What to do next

Microsoft Azure AD (SAML) Realm: SAML Identity Provider (IdP) Metadata, on page 2415.

Microsoft Azure AD (SAML) Realm: SAML Identity Provider (IdP) Metadata

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Before you begin

Complete the tasks discussed in Microsoft Azure AD (SAML) Realm: SAML Service Provider (SP) Metadata, on page 2414.

Procedure

Step 1 Continue from Microsoft Azure AD (SAML) Realm: SAML Service Provider (SP) Metadata, on page 2414.

Step 2 If you previously downloaded the Entra ID SSO app's federation XML, click **Upload XML** and upload it now. You can then skip the next step.

Step 3 Enter the following information.

Item	Description
Entity ID	Enter your identity provider's entity ID.
Single Sign on (SSO) URL	Enter the app's SSO URL.
IdP Certificate	From the list, click the certificate to use to authenticate with Microsoft Entra ID. You can also click **Add** (+) to create an object now.

Step 4 Click **Next**.

What to do next

Microsoft Azure AD (SAML) Realm: SAML Details, on page 2401.

Microsoft Azure AD (SAML) Realm: Azure AD Details

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
Name	Enter a unique name to identify this realm.
Client Secret	Enter the information you found as discussed in:. • Passive authentication: How to Create a Microsoft Azure AD (SAML) for Passive Authentication, on page 2393 • Active authentication: Get Required Information For Your Microsoft Azure AD (SAML) Realm (Active Authentication Only), on page 2409
Tenant ID	
Event Hubs Host Name	
Event Hub Name	
Event Hub Connection String	
(Optional.) **User Groups**	Slide to **Slider enabled** ( ) to specify groups to include or exclude from policy.
(Optional.) **Excluded User Groups**	If you enter one or more group names in this field, all groups and users they contain *except* these are downloaded and available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive.
(Optional.) **Included User Groups**	If you enter one or more group names in this field, only those groups and users they contain are downloaded and user data is available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive.

Step 3 Click **Test**.
Make sure the test connection succeeds before you continue to the next step.

Step 4 Click **Next**.

Microsoft Azure AD (SAML) Realm: User Session Timeout

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

This option sets the number of seconds before an inactive session is terminated by the system.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
ISE users	Default is 1440 minutes (24 hours).
Captive portal users	Default is 1440 minutes (24 hours).

After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

Step 3 Click **Save**.

Create a Microsoft Azure AD (SAML) Realm for Passive Authentication

You can use a Microsoft Azure Active Directory (AD) realm with ISE to authenticate users and get user sessions for user control. We get groups from Azure AD and logged-in user session data from ISE.

You have the following options:

- Resource owned password credentials (ROPC): Enables users to log in with a client like AnyConnect using a user name and password. ISE sends user sessions to the Secure Firewall Management Center. For more information, see About Entra ID and Cisco ISE with Resource Owned Password Credentials, on page 2394.

  Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

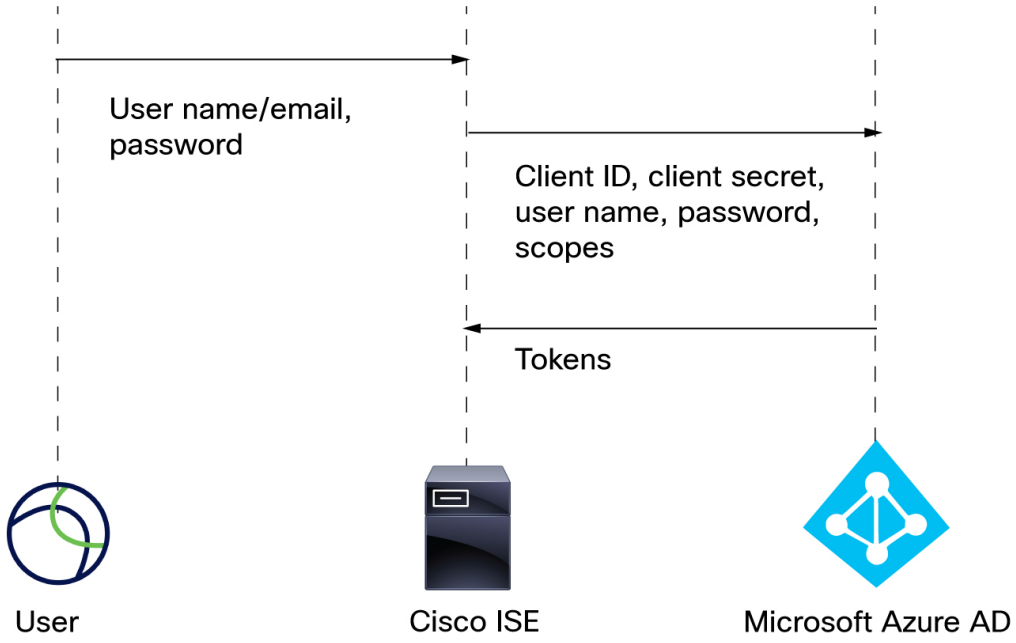
- Extensible Authentication Protocol (EAP) Chaining with Tunnel-based Extensible Authentication Protocol (TEAP) and Transport Layer Security (TLS), abbreviated EAP/TEAP-TLS: TEAP is a tunnel-based EAP method that establishes a secure tunnel and executes other EAP methods under the protection of that secured tunnel. ISE is used to validate user credentials and to send user sessions to the Secure Firewall Management Center. For more information, see About Entra ID and Cisco ISE with TEAP/EAP-TLS, on page 2394.

This type of authentication is *passive* authentication as opposed to active authentication used in Create a Microsoft Azure AD (SAML) Realm, on page 2392.

Note Before deploying policies related to a Microsoft Azure AD realm, see User Limits for Microsoft Azure Active Directory Realms, on page 2386.

About Entra ID and Cisco ISE with Resource Owned Password Credentials

The following figure summarizes an Azure AD (now *called Entra ID*) realm with Cisco ISE and resource owned password credentials (ROPC):



With ROPC,

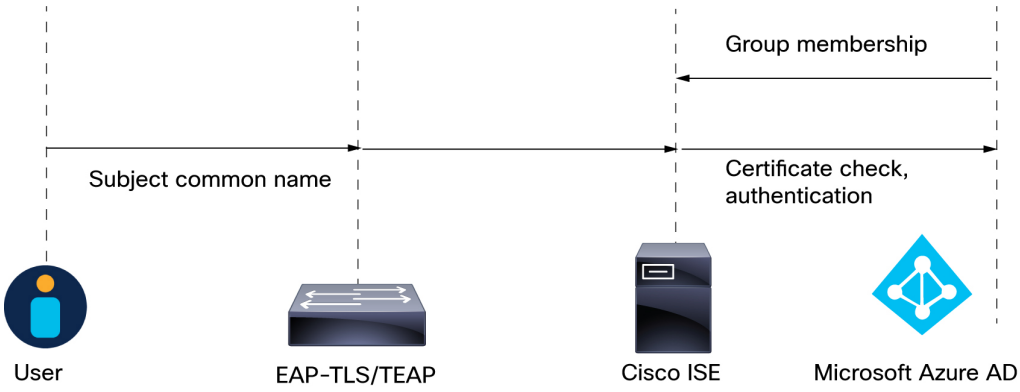
1. The user logs in with a user name (or email address) and password using a VPN client like Cisco Secure Client.
2. The client ID, client secret, user name, password, and scopes are sent to Entra ID.
3. Tokens are sent from Entra ID to Cisco ISE, which sends user sessions to the Secure Firewall Management Center.

For details about configuring Cisco ISE, see Configure ISE 3.0 REST ID with Azure Active Directory.

Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

About Entra ID and Cisco ISE with TEAP/EAP-TLS

Tunnel Extensible Authentication Protocol (TEAP) , defined by RFC7170, can be used with ISE and the Secure Firewall Management Center as follows:



The following is based on Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory:

1. The user's certificate is sent to ISE through EAP-TLS or TEAP with EAP-TLS as the inner method.
2. ISE evaluates the user's certificate (validity period, trusted certificate authority, certificate revocation list, and so on).
3. ISE takes the certificate subject name (CN) and performs a look-up to the Azure Graph API to fetch the user's groups and other attributes. This is referred to by Azure as User Principal name (UPN).
4. ISE authorization policies are evaluated against the user's attributes returned from Azure.

How to Create a Microsoft Azure AD (SAML) for Passive Authentication

This topic discusses the high-level tasks of creating a Microsoft Azure AD (SAML) (now called *Entra ID*) realm for passive authentication use with the Secure Firewall Management Center.

Procedure

	Command or Action	Purpose
Step 1	Enable the Cisco Secure Dynamic Attributes Connector.	The Cisco Secure Dynamic Attributes Connector is required to use a Microsoft Azure AD (SAML) realm. You can do it first or you can enable it when you create the realm. For more information, see Enable the Cisco Secure Dynamic Attributes Connector, on page 1806.
Step 2	Configure Microsoft Entra ID.	Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log. See Configure Microsoft Entra ID for Passive Authentication, on page 2395.

	Command or Action	Purpose
Step 3	Configure Cisco ISE.	The way you configure ISE depends on how users authenticate with your system. For more information, see How to Configure ISE for Microsoft Azure AD (SAML), on page 2395.
Step 4	Create a Cisco ISE identity source.	The identity source enables ISE to communicate with the Secure Firewall Management Center.
Step 5	Get the information required to configure your Microsoft Azure AD (SAML) realm.	This information includes client and tenant IDs, client secret, and other information store in Microsoft Entra ID.
Step 6	Configure and verify your realm.	Test the realm's configuration before you start to use it in access control policies. Create a Microsoft Azure AD (SAML) realm as discussed in Create a Microsoft Azure AD (SAML) Realm, on page 2392
Step 7	Create access control policies and rules using your Microsoft Azure AD (SAML) realm.	Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy. See Creating a Basic Access Control Policy, on page 1748 and Create and Edit Access Control Rules, on page 1783.

What to do next

See About Entra ID and Cisco ISE with Resource Owned Password Credentials, on page 2394.

Configure Microsoft Entra ID for Passive Authentication

This topic provides basic information about how to set up a Microsoft Entra ID (formerly caled *Microsoft Azure Active Directory (AD)*) as a realm you can use with the Secure Firewall Management Center. We expect you to already be familiar with Entra ID; if not, consult documentation or a support resource before you get started.

Give your application the Microsoft Graph permission

Grant your Entra ID application the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Secure Firewall Management Center to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Set up an event hub

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Secure Firewall Management Center uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Secure Firewall Management Center:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Enable the audit log

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

Configure Cisco ISE for Entra ID

To send user session information to the Secure Firewall Management Center, configure Cisco ISE for Entra ID as discussed in Configure ISE 3.0 REST ID with Azure Active Directory.

What to do next

See How to Configure ISE for Microsoft Azure AD (SAML), on page 2395.

How to Configure ISE for Microsoft Azure AD (SAML)

In a Microsoft Azure AD (SAML) (now called *Entra ID*) realm, it's the responsibility of ISE to send user sessions (login, logout) to the Secure Firewall Management Center. This topic discusses how to set up ISE for use with an Azure AD realm.

Resource owned password credentials authentication

To use ISE with Microsoft Azure AD (SAML) implemented through Representational State Transfer (REST) Identity (ID) service with the help of Resource Owner Password Credentials (ROPC), see Configure ISE 3.0 REST ID with Azure Active Directory.

TEAP/EAP-TLS

To use ISE with authorization policies based on Azure AD group membership and other user attributes with EAP-TLS or TEAP as the authentication protocols, see Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory.

What to do next

Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398

Get Required Information For Your Microsoft Azure AD (SAML) Realm

This task explains how to get the information required to set up a Microsoft Azure AD (SAML) (now called *Entra ID*) realm in the Secure Firewall Management Center. You might have already obtained this information when you set up Microsoft Entra ID as discussed in Configure Microsoft Entra ID for Passive Authentication, on page 2395.

Procedure

Step 1 Log in to https://portal.azure.com/ as a user with at least the Product Designer role.

Step 2 At the top of the page, click **Microsoft Entra ID**.

Step 3 In the left column, click **App Registrations**.

Step 4 If necessary, filter the list of displayed apps to show the one you want to use.

Step 5 Click the name of your app.

Step 6 Click **Copy** ( ) next to the following values on this page and paste those values to a text file.

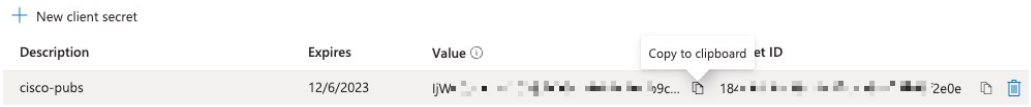
- **Application (Client) ID**
- **Directory (tenant) ID**

Step 7 Click **Client Credentials**.

Step 8 Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

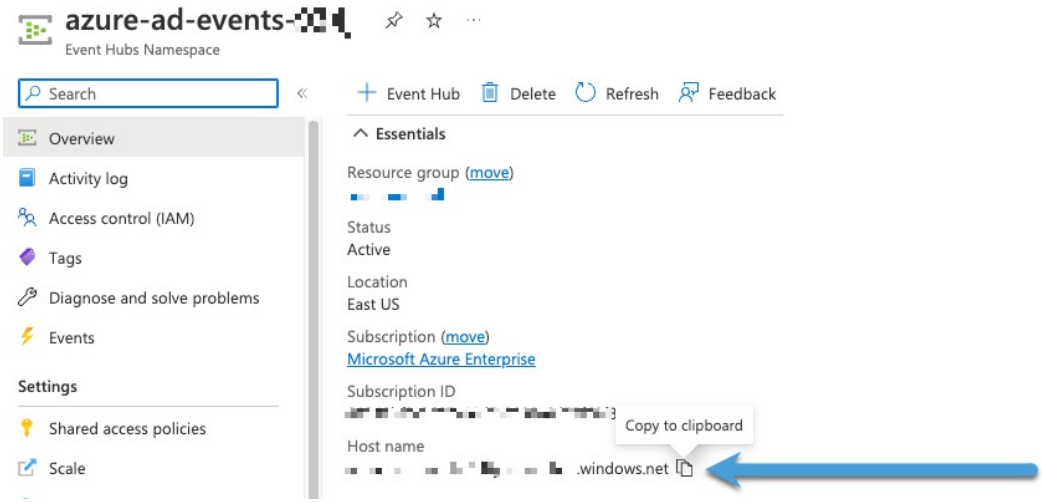
a) Click **New Client Secret**.
b) Enter the required information in the provided fields.
c) Click **Add**.

d) Click **Copy** (⧉) next to Value as the following figure shows.



Step 9 From https://portal.azure.com/, click **Event Hubs** > **(name of an event hub)**.

Step 10 In the right pane, click **Copy** (⧉) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.

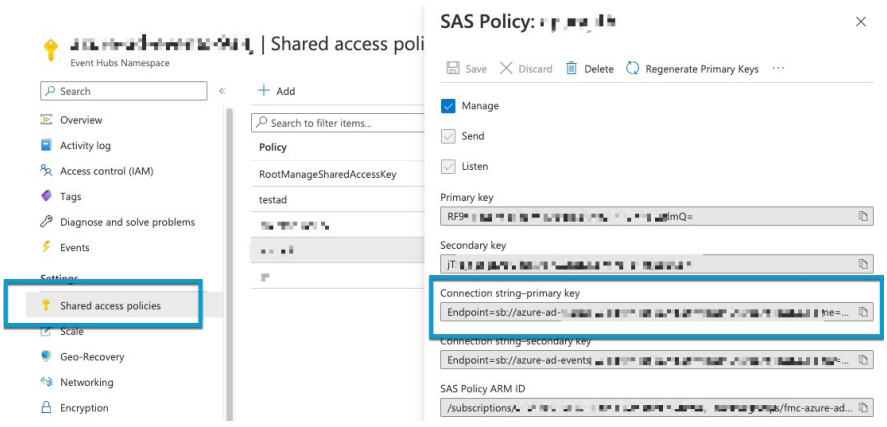


Step 11 Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).

Step 12 In the left pane, under Settings, click **Shared access policies**.

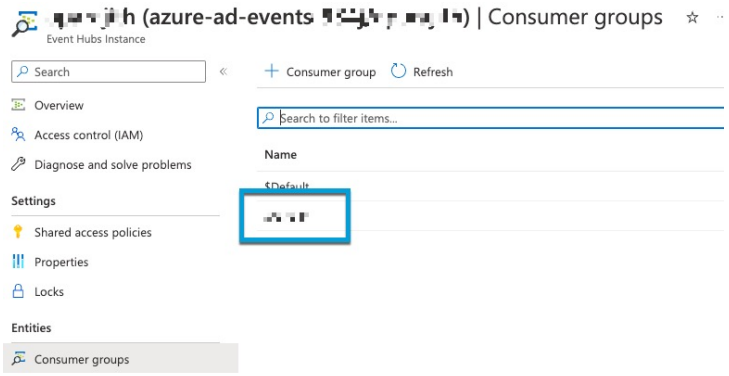
Step 13 Click the name of a policy.

Step 14 Click **Copy** (⧉) next to **Connection string-primary key**.



Step 15 Click **Overview** > **Entities** > **Event Hubs** > **(name of an event hub)** > **Entities** > **Consumer Groups**.

Write down the following value or copy it to the clipboard. This is your consumer group name.



Step 16 In the left pane, click **Overview**.

Step 17 Click **Copy** ( ) next to **Namespace**.

This is your event hubs topic name.

Create an Azure AD Realm

The following procedure enables you to create a *realm* (a connection between the Firewall Management Center and a Microsoft Azure AD realm).

Before you begin

Complete all of the following tasks:

- Configure ISE as discussed in How to Configure ISE for Microsoft Azure AD (SAML), on page 2395
- Create an ISE identity source as discussed in Configure ISE/ISE-PIC, on page 2506
- Enable the Cisco Secure Dynamic Attributes Connector as discussed in Enable the Cisco Secure Dynamic Attributes Connector, on page 1806 .
- Get values required for the Azure AD realm as discussed in Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398.
- Configure Azure AD as discussed in Configure Microsoft Entra ID for Passive Authentication, on page 2395

If you enabled Change Management, you must approve all certificates used in this procedure. Open a new ticket or edit an existing one. For more information, see Creating Change Management Tickets, on page 240 and .Policies and Objects that Support Change Management, on page 235

Note To perform user and identity control with an Azure AD realm, you need only an access control policy with an associated Azure AD realm. You do not need to create an identity policy.

Procedure

Step 1 Log in to Secure Firewall Management Center .

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 To create a new realm, click **Add Realm** > **Azure AD**.

Step 4 Enter the following information.

Item	Description
Name	
(Optional.) **Description**	
Client ID	Enter the information you found as discussed in Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398.
Client Secret	
Tenant ID	
Event Hubs Host Name	
Event Hub Name	
Event Hub Connection String	
(Optional.) **Excluded User Groups**	Enter one or more groups from which to *not* download users for identity control. Users in these groups will not be available for use in access control policies. Enter one group name per line followed by a line break. Group names are case-sensitive.

Step 5 To perform other tasks (such as enable, disable, or delete a realm), see Manage a Realm, on page 2455.

Step 6 Enter the values you found as discussed in Get Required Information For Your Microsoft Azure AD (SAML) Realm, on page 2398.

Step 7 Click **Test**.

Step 8 Fix any errors that are displayed in the test.

Step 9 Click **Save**.

What to do next

Create an access control policy and rule as discussed in Creating a Basic Access Control Policy, on page 1748.

Note Before deploying policies related to a Microsoft Azure AD realm, see User Limits for Microsoft Azure Active Directory Realms, on page 2386.

Azure AD (SAML) User Session Timeout

The Azure AD user session timeout for ISE/ISE-PIC is available on the **User Session Timeout** page when you edit an Azure AD realm.

The default value 1440 minutes (24 hours). After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

Create an LDAP Realm or an Active Directory Realm and Realm Directory

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the Secure Firewall Management Center. For more information, see Realm Fields, on page 2436.

The following procedure enables you to create a *realm* (a connection between the Firewall Management Center and an Active Directory realm) and a *directory* (a connection between the Firewall Management Center and an LDAP server or an Active Directory domain controller).

(Recommended.) To connect securely from the Firewall Management Center to your Active Directory server, first perform the following tasks:

- Export the Active Directory Server's Root Certificate, on page 2443
- Find the Active Directory Server's Name, on page 2442

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, see 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

For more information about realm and directory configuration fields, see Realm Fields, on page 2436 and Realm Directory and Synchronize fields, on page 2440.

A step-by-step example of setting up a realm with cross-domain trust is shown in Configure the Firewall Management Center for Cross-Domain-Trust: The Setup, on page 2447.

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, see Global Catalog on learn.microsoft.com.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the Secure Firewall Management Center. For more information, see Realm Fields, on page 2436.

Before you begin

If you're using Kerberos authentication for captive portal, see the following section before you begin: Prerequisites for Kerberos Authentication, on page 2436.

If you enabled Change Management, you must open or edit, assign, and approve a ticket for each of the following objects before you can create the realm:

- If you're connecting securely to Microsoft AD or LDAP, the server's trusted certificate authority
- The realm itself

For more information, see Opening a Ticket for Configuration Changes, on page 241 and Policies and Objects that Support Change Management, on page 235.

Important To reduce latency between the Secure Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Secure Firewall Management Center.

For example, if your Secure Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 To create a new realm, choose from **Add Realm** drop-down list.

Step 4 To perform other tasks (such as enable, disable, or delete a realm), see Manage a Realm, on page 2455.

Step 5 Enter realm information as discussed in Realm Fields, on page 2436.

Step 6 In the Directory Server Configuration section, enter directory information as discussed in Realm Directory and Synchronize fields, on page 2440.

Step 7 (Optional.) To configure another domain for this realm, click **Add another directory**.

Step 8 Click **Configure Groups and Users**.
Enter the following information:

Information	Description
AD Primary Domain	Domain for the Active Directory server where users should be authenticated. For additional information, see Realm Fields, on page 2436. You must create the realm with the original domain name of the domain and not any alternative user principal name (UPN) suffixes of the domain. Otherwise, users and groups fail to download and identity policies will not be enforced. For example, if the original domain is `domain.example.com` and the alternative UPN name is`domain2.mydomain.com`, you must configure the realm to use `domain.example.com`. For more information about configuring an alternative UPN suffix, see a resource like Configuring Alternate Login ID on learn.microsoft.com.
Base DN	The directory tree on the server where the Firewall Management Center should begin searching for user data.
Group DN	The directory tree on the server where the Firewall Management Center should begin searching for group data.
Load Groups	Click to load groups from the Active Directory server. If no groups are displayed, enter or edit information in the **AD Primary Domain**, **Base DN**, and **Group DN** fields and click **Load Groups**. For more information about those fields, see Realm Fields, on page 2436.
Available Groups section	Limit the groups to use in policy by moving them to either the **Included Groups and Users** or **Excluded Groups and Users** list. Moving one group to the **Included Groups and Users** list, for example, allows that group only to be used in policy but excludes all other groups. Groups in the **Excluded Groups and Users** and the users they contain are excluded from excluded from user awareness and control. All other groups and users *are* available. For more information, see Realm Directory and Synchronize fields, on page 2440.

Step 9 Click the **Realm Configuration** tab.

Step 10 Enter **Group Attribute**, and (if you use Kerberos authentication for captive portal) enter **AD Join Username** and **AD Join Password**. For more information, see Realm Directory and Synchronize fields, on page 2440.

Step 11 If you use Kerberos authentication, click **Test**. If the test fails, wait a short time and try again.

Step 12 Enter user session timeout values, in minutes, for **ISE/ISE-PIC Users**, **Terminal Server Agent Users**, **Captive Portal Users**, **Failed Captive Portal Users**, and **Guest Captive Portal Users**.

Step 13 When you're finished configuring the realm, click **Save**.

What to do next

- Configure the Firewall Management Center for Cross-Domain-Trust: The Setup, on page 2447

- Synchronize Users and Groups, on page 2445
- Edit, delete, enable, or disable a realm; see Manage a Realm, on page 2455.
- Compare Realms, on page 2456.
- Optionally, monitor the task status; see *Viewing Task Messages* in the Cisco Secure Firewall Management Center Administration Guide.

About Realms and Realm Sequences

Realms are connections between the Secure Firewall Management Center and the user accounts on the servers you monitor. They specify the connection settings and authentication filter settings for the server. Realms can:

- Specify the users and user groups whose activity you want to monitor.
- Query the user repository for user metadata on authoritative users, as well as some non-authoritative users: POP3 and IMAP users detected by traffic-based detection and users detected by traffic-based detection, a TS Agent, or ISE/ISE-PIC.

(Microsoft AD realm only.) A *realm sequence* is an ordered list of two or more Active Directory realms to use in identity policy. When you associate a realm sequence with an identity rule, the system searches the Active Directory domains in order from first to last as specified in the realm sequence.

You can add multiple domain controllers as directories in a realm, but they must share the same basic realm information. The directories in a realm must be exclusively LDAP or exclusively Active Directory (AD) servers. After you enable a realm, your saved changes take effect next time the Secure Firewall Management Center queries the server.

To perform user awareness, you must configure a realm for any of the supported server types. The system uses these connections to query the servers for data associated with POP3 and IMAP users, and to collect data about LDAP users discovered through traffic-based detection.

The system uses the email addresses in POP3 and IMAP logins to correlate with LDAP users on an Active Directory, Microsoft Azure Active Directory, or OpenLDAP. For example, if a managed device detects a POP3 login for a user with the same email address as an LDAP user, the system associates the LDAP user's metadata with that user.

To perform user control, you can configure any of the following:

- A realm or realm sequence for an Active Directory, Microsoft Azure Active Directory, server, or for ISE/ISE-PIC

Note Configuring a Microsoft AD realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.

Realm sequence is not available for Microsoft Azure AD realms.

- A realm or realm sequence for a Microsoft AD server for the TS Agent.
- For captive portal, an LDAP realm.

A realm sequence is not supported for LDAP.

You can nest Microsoft AD groups and the Secure Firewall Management Center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

About User Synchronization

You can configure a realm or realm sequence to establish a connection between the Firewall Management Center and an LDAP or Microsoft AD server to retrieve user and user group metadata for certain detected users:

- LDAP and Microsoft AD users authenticated by captive portal or reported by ISE/ISE-PIC. This metadata can be used for user awareness and user control.
- POP3 and IMAP user logins detected by traffic-based detection, if those users have the same email address as an LDAP or AD user. This metadata can be used for user awareness.

The Firewall Management Center obtains the following information and metadata about each user:

- LDAP user name
- First and last names
- Email address
- Department
- Telephone number

Important To reduce latency between the Secure Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Secure Firewall Management Center.

For example, if your Secure Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

About User Activity Data

User activity data is stored in the user activity database and user identity data is stored in the users database. The maximum number of users you can store and use in access control depends on your Firewall Management Center model. When choosing which users and groups to include, make sure the total number of users is less than your model limit. If your access control parameters are too broad, the Firewall Management Center obtains information on as many users as it can and reports the number of users it failed to retrieve in the Tasks tab page of the Message Center.

To optionally limit the subnets on which a managed device watches for user awareness data, you can use the **configure identity-subnet-filter** command as discussed in the Cisco Secure Firewall Threat Defense Command Reference.

Note If you remove a user that has been detected by the system from your user repository, the Firewall Management Center does *not* remove that user from its users database; you must manually delete it. However, your LDAP changes *are* reflected in access control rules when the Firewall Management Center next updates its list of authoritative users.

Realms and Trusted Domains

When you configure a Microsoft Active Directory (AD) *realm* in the Firewall Management Center, it is associated with a Microsoft Active Directory or LDAP *domain*.

A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B.

Note Trusted domains apply to Microsoft Active Directory domains only. They do *not* apply to either Microsoft Azure Active Directory or LDAP domains.

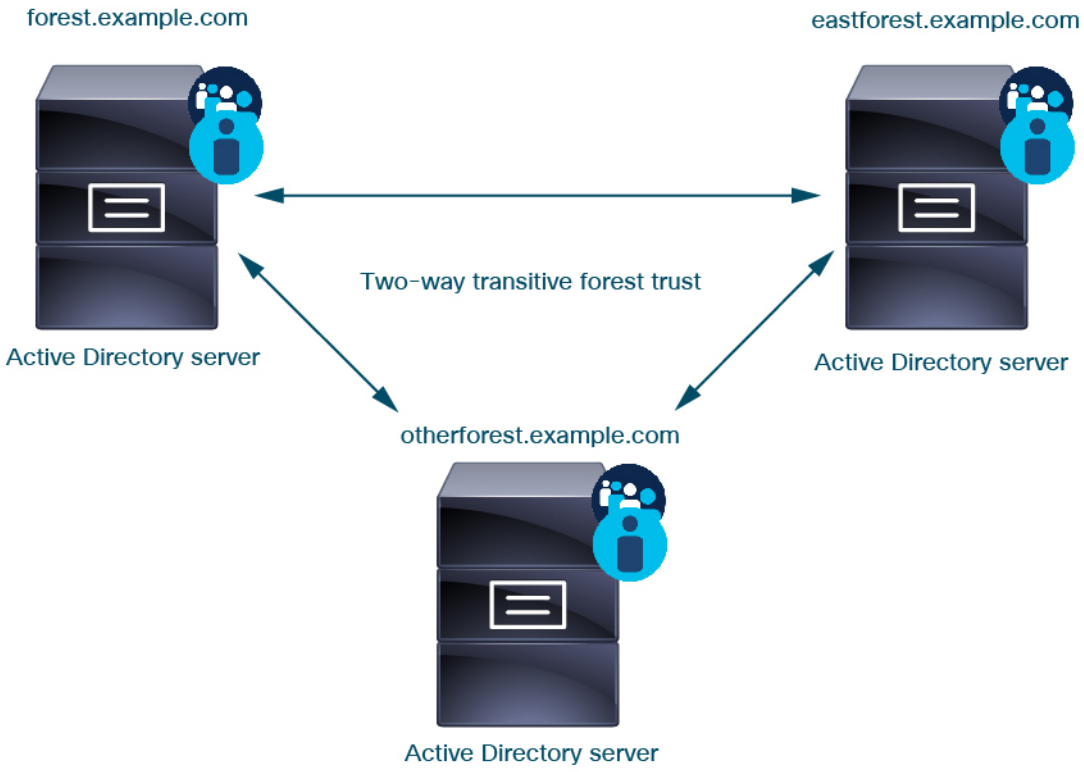
The system and trusted domains

The system supports AD forests that are configured in a trust relationship. There are several types of trust relationships; this guide discusses two-way, transitive forest trust relationships. The following simple example shows two forests: **forest.example.com** and **eastforest.example.com**. Users and groups in each forest can be authenticated by AD in the other forest, provided you configure the forests that way.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 foreign security principals (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.

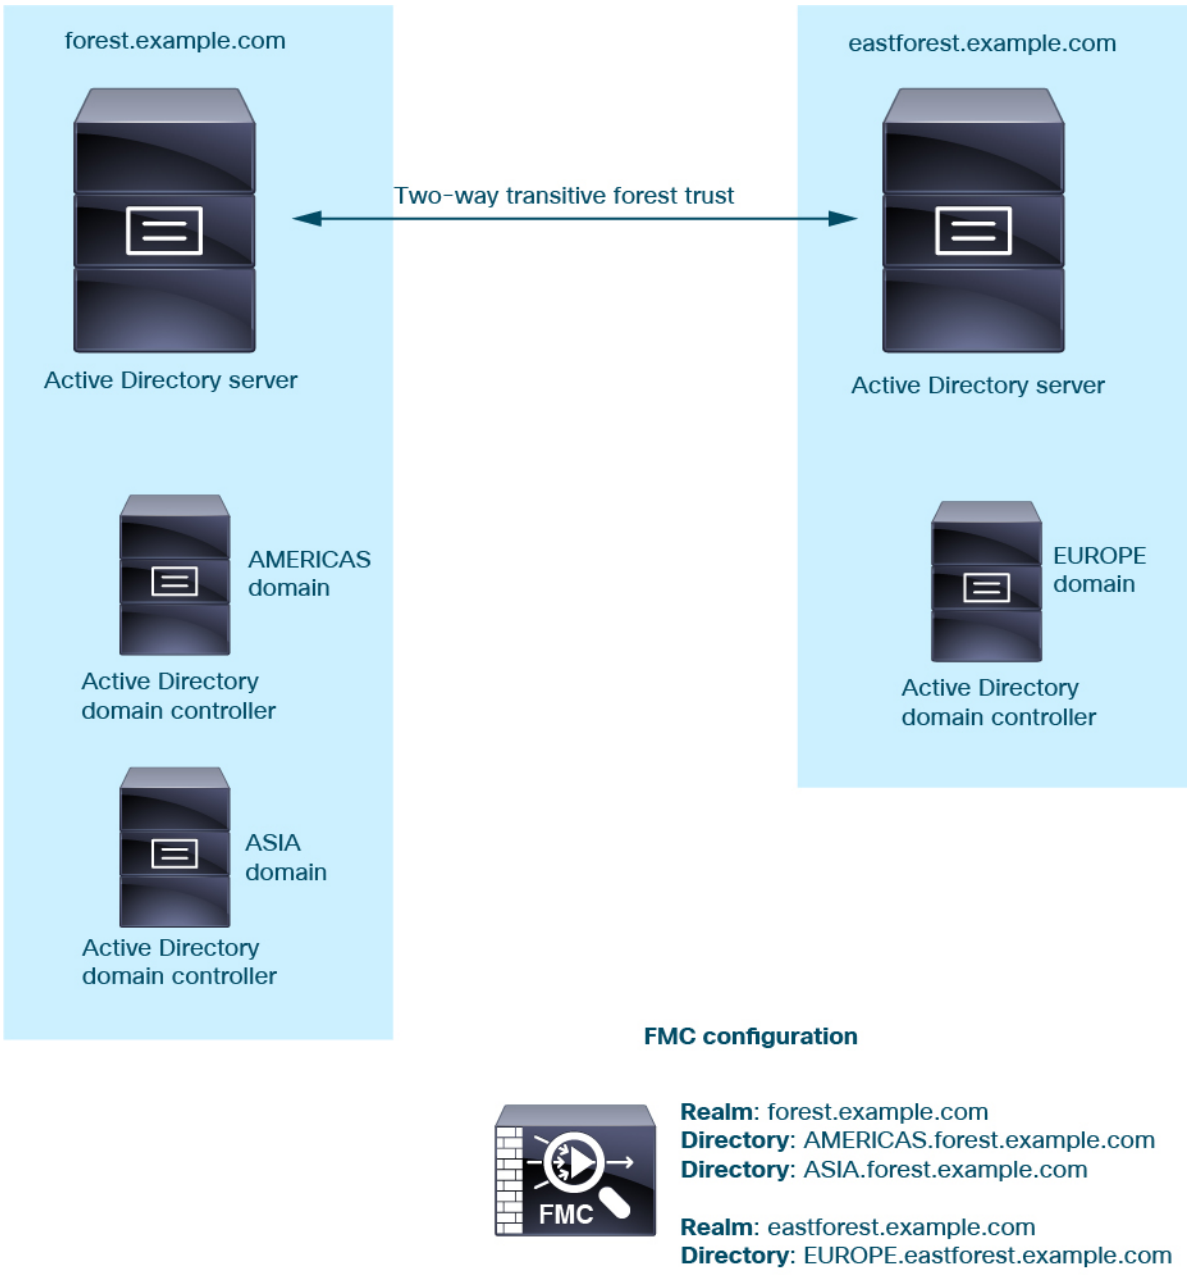
You need not configure a realm for any domain that has no users you wish to use in access control policies.

To continue the example, suppose you have three AD forests (one of which could be a subdomain or an independent forest), all set up as two-way transitive forest relationships, all users and groups are available in all three forests as well as in the system. (As in the preceding example, all three AD domains must be set up as realms and all domain controllers must be configured as directories in those realms.)



Finally, you can set up the Firewall Management Center to be able to enforce identity policies on users and groups in a two-forest system with two-way transitive forest trust. Suppose each forest has at least one domain controller, each of which authenticates different users and groups. For the Firewall Management Center to be able to enforce identity policies on those users and groups, you must set up each domain containing relevant users as Firewall Management Center realm and each domain controller as Firewall Management Center directory in the respective realm.

Failure to properly configure the Firewall Management Center prevents some of the users and groups from being able to be used in policies. You will see warnings when you try to synchronize users and groups in that case.



Using the preceding example, set up the Firewall Management Center as follows:

- Realm for any domain in **forest.example.com** that contains users you want to control with access control policies
  - Directory in the realm for **AMERICAS.forest.example.com**
  - Directory in the realm for **ASIA.forest.example.com**
- Realm for any domain in **eastforest.example.com** that contains users you want to control with access control policies

- Directory in the realm for **EUROPE.eastforest.example.com**

Note The Firewall Management Center uses the AD field **msDS-PrincipalName** to resolve references to find user and group names in each domain controller. **msDS-PrincipalName** returns a NetBIOS name.

Supported Servers for Realms

You can configure realms to connect to the following types of servers, providing they have TCP/IP access from the Firewall Management Center:

Server Type	Supported for ISE/ISE-PIC data retrieval?	Supported for TS Agent data retrieval?	Supported for captive portal data retrieval?
Microsoft Active Directory on Windows Server 2012, 2016, and 2019	Yes	Yes	Yes
Microsoft Azure AD	Yes	No	No
OpenLDAP on Linux	No	No	Yes

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, see Global Catalog on learn.microsoft.com.

Note If the TS Agent is installed on a Microsoft Active Directory Windows Server shared with another passive authentication identity source (ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Firewall Management Center.

Note the following about your server group configurations:

- To perform user control on user groups or on users in groups, you must configure user groups on the LDAP or Active Directory server.
- Group names cannot start with `s-` because it is used internally by LDAP.

  Neither group names nor organizational unit names can contain special characters like asterisk (*), equals (=), or backslash (\); otherwise, users in those groups or organizational units are not downloaded and are not available for identity policies.
- To configure an Active Directory realm that includes or excludes users who are members of a sub-group on your server, note that Microsoft recommends that Active Directory has no more than 5000 users per group in Windows Server 2012. For more information, see Active Directory Maximum Limits—Scalability on MSDN.

If necessary, you can modify your Active Directory server configuration to increase this default limit and accommodate more users.

- To uniquely identify the users reported by a server in your Remote Desktop Services environment, you must configure the Cisco Terminal Services (TS) Agent. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users. (Microsoft changed the name *Terminal Services* to *Remote Desktop Services*.)

  For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Supported Server Object Class and Attribute Names

The servers in your realms *must* use the attribute names listed in the following table for the Secure Firewall Management Center to retrieve user metadata from the servers. If the attribute names are incorrect on your server, the Secure Firewall Management Center cannot populate its database with the information in that attribute.

Table 135: Map of attribute names to Secure Firewall Management Center fields

Metadata	Firewall Management Center Attribute	LDAP ObjectClass	Active Directory Attribute	OpenLDAP Attribute
LDAP user name	Username	• user • inetOrgPerson	samaccountname	cn uid
first name	First Name		givenname	givenname
last name	Last Name		sn	sn
email address	Email		mail userprincipalname (if mail has no value)	mail
department	Department		department distinguishedname (if department has no value)	ou
telephone number	Phone		telephonenumber	telephonenumber

Note The LDAP ObjectClass for groups is `group`, `groupOfNames`, (`group-of-names` for Active Directory) or `groupOfUniqueNames`.

For more information about ObjectClasses and attributes, see the following references:

- Microsoft Active Directory:
  - ObjectClasses: All Classes on MSDN

- Attributes: All Attributes on MSDN

- OpenLDAP: RFC 4512

Prerequisites for Kerberos Authentication

If you're using Kerberos to authentication captive portal users, keep the following in mind.

Hostname character limit

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS response character limit

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Realm Fields

The following fields are used to configure a realm.

Realm Configuration Fields

These settings apply to all Active Directory servers or domain controllers (also referred to as *directories*) in a realm.

Name

A unique name for the realm.

- To use the realm in identity policies, the system supports alphanumeric and special characters.
- To use the realm in RA VPN configurations, the system supports alphanumeric, hyphen (-), underscore (_), and plus (+) characters.

Description

(Optional.) Enter a description of the realm.

Type

The type of realm, **AD** for Microsoft Active Directory, **LDAP** for other supported LDAP repositories, or **Local**. For a list of supported LDAP repositories, see Supported Servers for Realms, on page 2434. You can authenticate captive portal users with an LDAP repository; all others require Active Directory.

Note Only captive portal supports an LDAP realm.

The realm type **LOCAL** is used for configuring local user settings. The LOCAL realm is used in remote access user authentication.

Add the following Local User Information for the LOCAL realm:

- **Username**—Name of the local user.
- **Password**—Local user password.
- **Confirm Password**—Confirm the local user password.

Note **Click Add another local user** to add more users to the LOCAL realm.

You can add more users after creating the realm and update password for the local users. You can also create multiple LOCAL realms but cannot disable them.

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

AD Join Username and AD Join Password
(Available on the **Realm Configuration** tab page when you edit a realm.)

For Microsoft Active Directory realms intended for Kerberos captive portal active authentication, the distinguished username and password of any Active Directory user with appropriate rights to create a Domain Computer account in the Active Directory domain.

Keep the following in mind:

- DNS must be able to resolve the domain name to an Active Directory domain controller's IP address.
- The user you specify must be able to join computers to the Active Directory domain.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

If you choose **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Protocol** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

Directory Username and Directory Password

The distinguished username and password for a user with appropriate access to the user information you want to retrieve.

Note the following:

- For some versions of Microsoft Active Directory, specific permissions might be required to read users and groups. Consult the documentation provided with Microsoft Active Directory for details.
- For OpenLDAP, the user's access privileges are determined by the `<level>` parameter discussed in section 8 of the OpenLDAP specification. The user's `<level>` should be `auth` or better.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

Base DN

(Optional.) The directory tree on the server where the Secure Firewall Management Center should begin searching for user data. If you don't specify a **Base DN**, the system retrieves the top-level DN provided you can connect to the server.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of **`ou=security,dc=example,dc=com`**.

Group DN

(Optional.) The directory tree on the server where the Secure Firewall Management Center should search for users with the group attribute. A list of supported group attributes is shown in Supported Server Object Class and Attribute Names, on page 2435. If you don't specify a **Group DN**, the system retrieves the top-level DN provided you can connect to the server.

Note Following is the list of characters the system *supports* in users, groups, DNs in your directory server. Using any characters other than the following could result in the system failing to download users and groups.

Entity	Supported characters
User name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Group name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Base DN and Group DN	**a-z A-Z 0-9 ! @ $ % ^ & * ( ) _ - . ~ `**

A space is not supported anywhere in a user name, including at the end.

The following fields are available when you edit an existing realm.

User Session Timeout

(Available on the **Realm Configuration** tab page when you edit a realm.)

Enter the number of minutes before user sessions time out. The default is 1440 (24 hours) after the user's login event. After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Secure Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

In addition, if you set up ISE/ISE-PIC without a realm and the timeout is exceeded, a workaround is required. For more information, contact Cisco TAC.

You can set timeout values for the following:

- **User Agent and ISE/ISE-PIC Users**: Timeout for users tracked by the user agent or by ISE/ISE-PIC, which are types of passive authentication.

  The timeout value you specify does *not* apply to pxGrid SXP session topic subscriptions (for example, destination SGT mappings). Instead, session topic mappings are preserved as long as there is no delete or update message for a given mapping from ISE.

  For more information about ISE/ISE-PIC, see The ISE/ISE-PIC Identity Source, on page 2499.

- **Terminal Services Agent Users**: Timeout for users tracked by the TS Agent, which is a type of passive authentication. For more information, see The Terminal Services (TS) Agent Identity Source, on page 2549.

- **Captive Portal Users**: Timeout for users who successfully log in using the captive portal, which is a type of active authentication. For more information, see The Captive Portal Identity Source, on page 2525.

- **Failed Captive Portal Users**: Timeout for users who do not successfully log in using the captive portal. You can configure the **Maximum login attempts** before the user is seen by the Secure Firewall Management Center as Failed Auth User. A Failed Auth User can optionally be granted access to the network using access control policy and, if so, this timeout value applies to those users.

  For more information about failed captive portal logins, see Captive Portal Fields, on page 2539.

- **Guest Captive Portal Users**: Timeout for users who log in to the captive portal as a guest user. For more information, see The Captive Portal Identity Source, on page 2525.

Realm Directory and Synchronize fields

Realm Directory Fields

These settings apply to individual servers (such as Active Directory domain controllers) in a realm.

Hostname / IP Address

Fully qualified host name of the Active Directory domain controller machine. To find the fully qualified name, see Find the Active Directory Server's Name, on page 2442.

If you're using Kerberos for authenticating captive portal, also make sure you understand the following:

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Port

The server's port.

Encryption

(Strongly recommended.) The encryption method to use:

- **`STARTTLS`**—encrypted LDAP connection
- **`LDAPS`**—encrypted LDAP connection
- **`None`**—unencrypted LDAP connection (unsecured traffic)

To communicate securely with an Active Directory server, see Connect Securely to Active Directory or LDAP, on page 2442.

CA Certificate

The TLS/SSL certificate to use for authentication to the server. You must configure **`STARTTLS`** or **`LDAPS`** as the **Encryption** type to use a TLS/SSL certificate.

If you are using a certificate to authenticate, the name of the server in the certificate must match the server **Hostname / IP Address**. For example, if you use 10.10.10.250 as the IP address but **`computer1.example.com`** in the certificate, the connection fails.

Interface used to connect to Directory server

Required only for RA VPN authentication so the Secure Firewall Threat Defense can connect securely to your Active Directory server. This interface is not used for downloading users and groups, however.

You can choose only a routed interface group. For more information, see Interface, on page 1398.

Click one of the following:

- **Resolve via route lookup**: Use routing to connect to the Active Directory server.
- **Choose an interface**: Choose a specific managed device interface group to connect to the Active Directory server.

User Synchronize Fields

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

Enter query to look for users and groups

Base DN:

(Optional.) The directory tree on the server where the Firewall Management Center should begin searching for user data.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of `ou=security,dc=example,dc=com`.

Group DN:

(Optional.) The directory tree on the server where the Firewall Management Center should search for users with the group attribute. A list of supported group attributes is shown in Supported Server Object Class and Attribute Names, on page 2435.

Note Neither the group name nor the organizational unit name can contain special characters like asterisk (*), equals (=), backslash (\) because users in those groups are not downloaded and cannot be used in identity policies.

Load Groups

Enables you to download users and groups for user awareness and user control.

Available Groups, Add to Include, Add to Exclude

Limits the groups that can be used in policy.

- Groups that are displayed in the **Available Groups** field are available for policy unless you move groups to the **Included Groups and Users** or **Excluded Groups and Users** field.
- If you move groups to the **Included Groups and Users** field, only those groups and users they contain are downloaded and user data is available for user awareness and user control.
- If you move groups to the **Excluded Groups and Users** field, all groups and users they contain *except* these are downloaded and available for user awareness and user control.

- To include users from groups that are not included, enter the user name in the field below **User Inclusion** and click **Add**.
- To exclude users from groups that are not excluded, enter the user name in the field below **User Exclusion** and click **Add**.

Note The users that are downloaded to the Firewall Management Center is calculated using the formula **R = I - (E+e) + i**, where

- R is list of downloaded users
- I is included groups
- E is excluded groups
- e is excluded users
- i is included users

Synchronize Now
Click to synchronize groups and users with AD.

Begin automatic synchronization at
Enter the time and time interval at which to download users and groups from AD.

Connect Securely to Active Directory or LDAP

To create a secure connection between an Active Directory or LDAP server and the Secure Firewall Management Center (which we strongly recommend), you must perform all of the following tasks:

- Export the server's *root* certificate.
- Import the root certificate into the Secure Firewall Management Center as a trusted CA certificate (**Objects** > **Object Management** > **PKI** > **Trusted CAs**).
- Find the server's fully qualified name.
- Create the realm directory.

See one of the following tasks for more information.

Related Topics

Export the Active Directory Server's Root Certificate, on page 2443
Find the Active Directory Server's Name, on page 2442
Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426

Find the Active Directory Server's Name

To configure a realm directory in the Firewall Management Center, you must know the fully qualified server name, which you can find as discussed in the procedure that follows.

These tasks apply to Microsoft Active Directory only. If you use LDAP, consult an appropriate reference for the procedure.

Before you begin

You must log in to the Active Directory server as a user with sufficient privileges to view the computer's name.

Procedure

Step 1 Log in to the Active Directory server.

Step 2 Click **Start**.

Step 3 Right-click **This PC**.

Step 4 Click **Properties**.

Step 5 Click **Advanced System Settings**.

Step 6 Click the **Computer Name** tab.

Step 7 Note the value of **Full computer name**.
You must enter this exact name when you configure the realm directory in the Firewall Management Center.

What to do next

Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Related Topics

Export the Active Directory Server's Root Certificate, on page 2443

Export the Active Directory Server's Root Certificate

The task that follows discusses how to export the Active Directory server's root certificate, which is required to connect securely to the Firewall Management Center to obtain user identity information.

These tasks apply to Microsoft Active Directory only. If you use LDAP, consult an appropriate reference for the procedure.

Before you begin

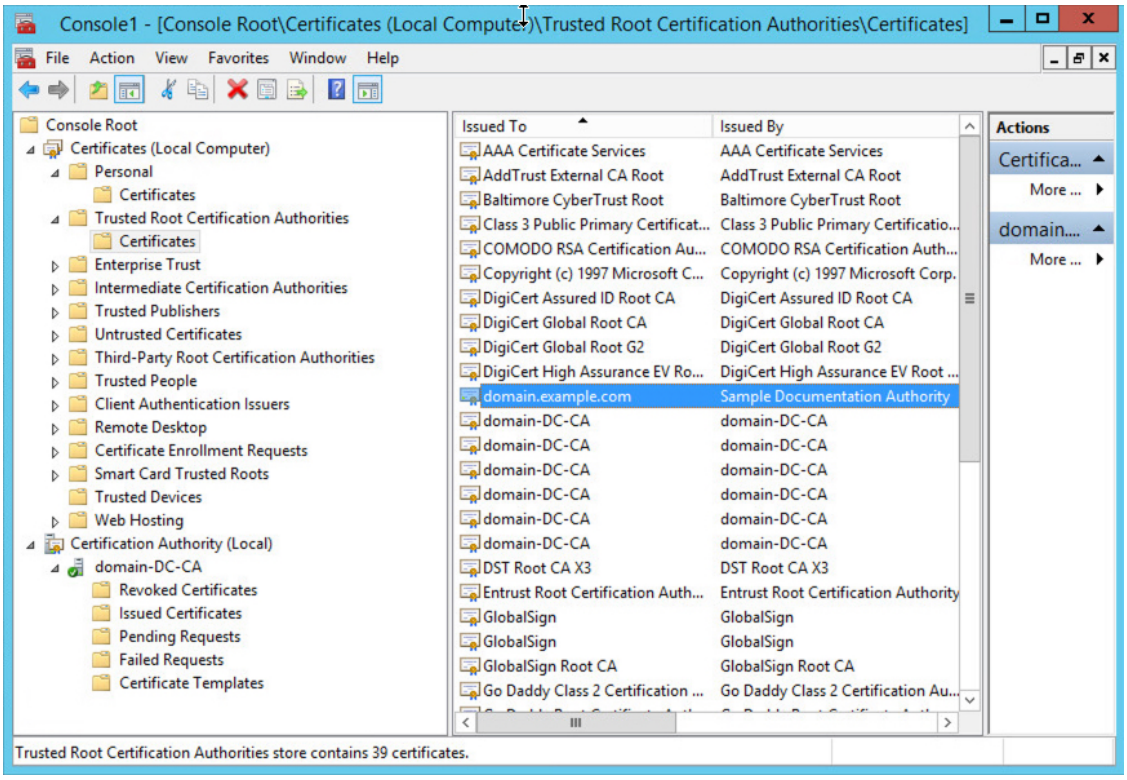
You must know the name of your Active Directory server's root certificate. The root certificate might have the same name as the domain or the certificate might have a different name. The procedure that follows shows one way you can find the name; there could be other ways, however.

Procedure

Step 1 Following is one way to find the name of the Active Directory Server's root certificate; consult Microsoft documentation for more information:

a) Log in to the Active Directory server as a user with privileges to run the Microsoft Management Console.
b) Click **Start** and enter **mmc**.
c) Click **File** > **Add/Remove Snap-in**
d) From the Available Snap-ins list in the left pane, click **Certificates (local)**.
e) Click **Add**.

f) At the Certificates snap-in dialog box, click **Computer Account** and click **Next**.
g) At the Select Computer dialog box, click **Local Computer** and click **Finish**.
h) *Windows Server 2012 only*. Repeat the preceding steps to add the Certification Authority snap-in.
i) Click **Console Root** > **Trusted Certification Authorities** > **Certificates**.
The server's trusted certificates are displayed in the right pane. The following figure is only an example for Windows Server 2012; yours will probably look different.



Step 2 Export the certificate using the **certutil** command.

This is only one way to export the certificate. It's a convenient way to export the certificate, especially if you can run a web browser and connect to the Firewall Management Center from the Active Directory server.

a) Click **Start** and enter **cmd**.
b) Enter the command **certutil -ca.cert** *certificate-name*.
The server's certificate is displayed on the screen.
c) Copy the entire certificate to the clipboard, starting with **-----BEGIN CERTIFICATE-----** and ending with **-----END CERTIFICATE-----** (including those strings).

What to do next

Import the Active Directory server's certificate into the Firewall Management Center as a Trusted CA Certificate as discussed in Adding a Trusted CA Object, on page 1409.

Related Topics

Find the Active Directory Server's Name, on page 2442

Synchronize Users and Groups

Synchronizing users and groups means the Firewall Management Center queries the realms and directories you configured for groups and users in those groups. All users the Firewall Management Center finds can be used in identity policies.

If issues are found, you most likely need to add a realm that contains users and groups the Firewall Management Center cannot load. For details, see Realms and Trusted Domains, on page 2431.

Before you begin

Create a Secure Firewall Management Center *realm* for each Active Directory domain and a Firewall Management Center *directory* for each Active Director domain controller in each forest. See Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Note Synchronizing users and groups is not necessary for Microsoft Azure AD realms.

You must create a realm only for domains that have users you want to use in user control.

You can nest Microsoft AD groups and the Secure Firewall Management Center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

You must create the realm with the original domain name of the domain and not any alternative user principal name (UPN) suffixes of the domain. Otherwise, users and groups fail to download and identity policies will not be enforced. For example, if the original domain is `domain.example.com` and the alternative UPN name is`domain2.mydomain.com`, you must configure the realm to use `domain.example.com`. For more information about configuring an alternative UPN suffix, see a resource like Configuring Alternate Login ID on learn.microsoft.com.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 Next to each realm, click **Download** ( ).

Step 4 To see the results, click the **Sync Results** tab.
The Realms column indicates whether or not there were issues synchronizing users and groups in Active Directory forests. Look for the following indicators next to each realm.

Indicator in Realms column	Meaning
(nothing)	All users and groups synchronized without error. No action is necessary.

Indicator in Realms column	Meaning
Yellow Triangle (⚠)	There were issues synchronizing users and groups. Make sure you added a realm for each Active Directory domain and a directory for each Active Directory domain controller. For more details, see Troubleshoot Cross-Domain Trust, on page 2461.

Create a Realm Sequence

The following procedure enables you to create a realm sequence, which is an ordered list of realms the system searches when it applies identity policy. You add a realm sequence to an identity rule exactly the same way as you add a realm; the difference is that the system searches all the realms in the order specified in the realm sequence when applying an identity policy.

Before you begin

You must create and enable at least two realms, each corresponding to a connection with an Active Directory server. You cannot create realm sequences for LDAP realms.

Create a realm as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realm Sequences**.

Step 3 Click the **Realm Sequences** tab.

Step 4 Click **Add Sequence**.

Step 5 In the **Name** field, enter a name to identify the realm sequence.

Step 6 (Optional.) In the **Description** field, enter a description for the realm sequence.

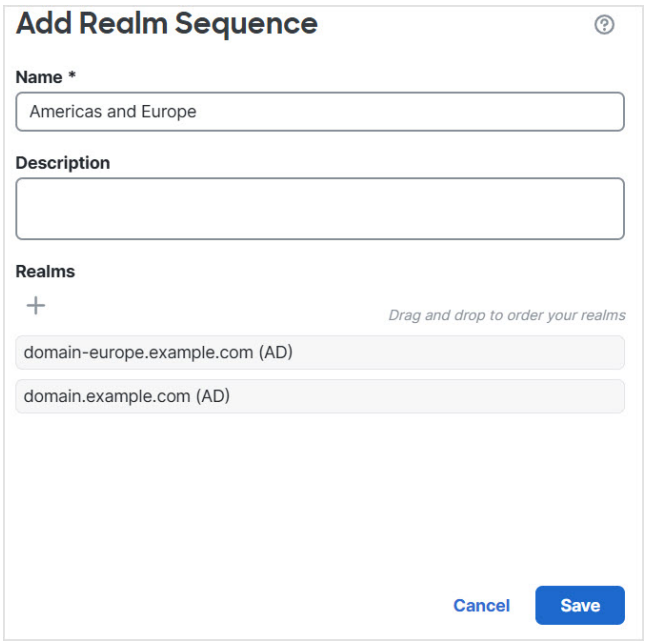
Step 7 Under Realms, click **Add** (+).

Step 8 Click the name of each realm to add to the sequence.

To narrow your search, enter all or part of a realm name in **Filter** field.

Step 9 Click **OK**.

Step 10 In the Add Realm Sequence dialog box, drag and drop the realms in the order in which you want the system to search for them.
The following figure shows an example of a realm sequence consisting of two realms. The **domain-europe.example.com** realm will be searched for users before the **domain.example.com** realm.



Step 11 Click **Save**.

What to do next

See Create an Identity Policy, on page 2555.

Configure the Firewall Management Center for Cross-Domain-Trust: The Setup

This is an introduction to several topics that walk you through configuring the Firewall Management Center with two realms with cross-domain trust.

This step-by-step example involves two forests: **forest.example.com** and **eastforest.example.com**. The forests are configured so that certain users and groups in each forest can be authenticated by Microsoft AD in the other forest.

Note This topic applies to Microsoft AD realms only. It does *not* apply to Microsoft Azure AD realms.

Following is the example setup used in this example.

Using the preceding example, you would set up the Firewall Management Center as follows:

- Realm and directory for any domain in **forest.example.com** that contains users you want to control with access control policy
- Realm and directory for any domain in **eastforest.example.com** that contains users you want to control with access control policy

Each realm in the example has one domain controller, which is configured in the Firewall Management Center as a directory. The directories in this example are configured as follows:

- **forest.example.com**
  - Base distinguished name (DN) for users: **ou=UsersWest,dc=forest,dc=example,dc=com**
  - Base DN for groups: **ou=EngineringWest,dc=forest,dc=example,dc=com**
- **eastforest.example.com**
  - Base DN for users: **ou=EastUsers,dc=eastforest,dc=example,dc=com**
  - Base DN for groups: **ou=EastEngineering,dc=eastforest,dc=example,dc=com**

Related Topics

Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories, on page 2448

Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories

This is the first task in a step-by-step procedure that explains how to configure the Firewall Management Center to recognize Active Directory servers configured in a cross-domain trust relationship, which is an increasingly common configuration for enterprise organizations. For an overview of this sample configuration, see Configure the Firewall Management Center for Cross-Domain-Trust: The Setup, on page 2447.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 foreign security principals (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.

Before you begin

You must configure Microsoft Active Directory servers in a cross-domain trust relationship; see Realms and Trusted Domains, on page 2431 for more information.

If you authenticate users with LDAP or Microsoft Azure AD, you *cannot* use this procedure.

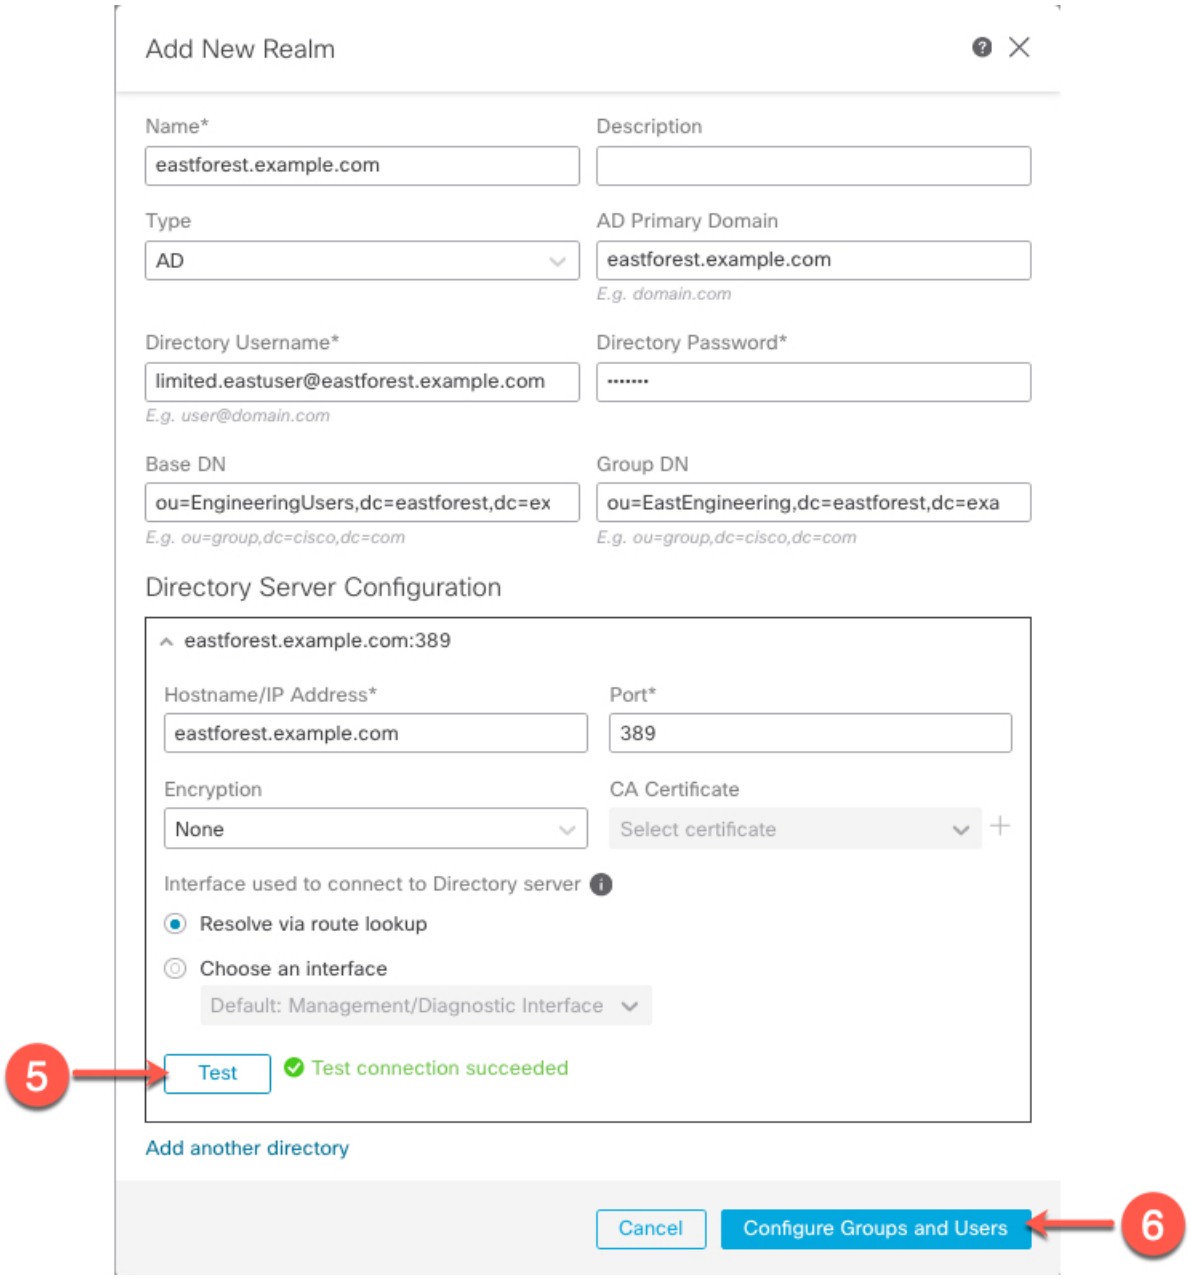
Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 Click **Add Realm** > **Active Directory/LDAP**.

Step 4 Enter the following information to configure **forest.example.com**.



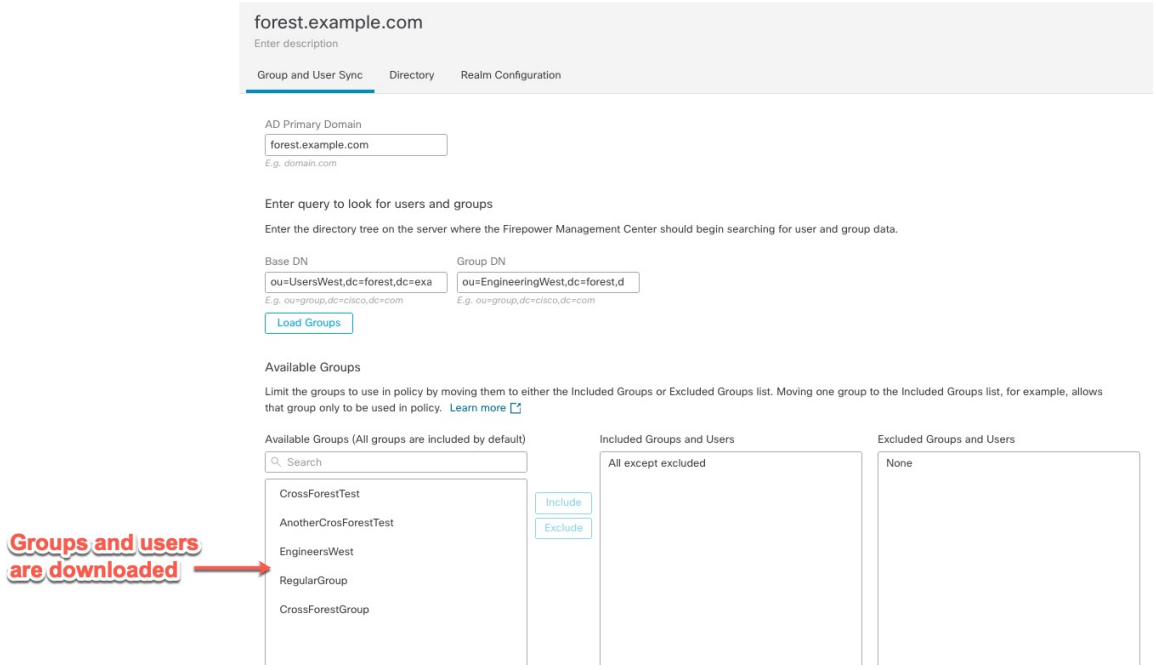
Note
The **Directory Username** can be any user in the Active Directory domain; no special permissions are required.

The **Interface used to connect to Directory server** can be any interface that can connect to the Active Directory server.

Step 5 Click **Test** and make sure the test succeeds before you continue.

Step 6 Click **Configure Groups and Users**.

Step 7 If your configuration was successful, the next page is displayed similar to the following.



Note
If groups and users were not downloaded, verify the values in the **Base DN** and **Groups DN** fields and click **Load Groups**.

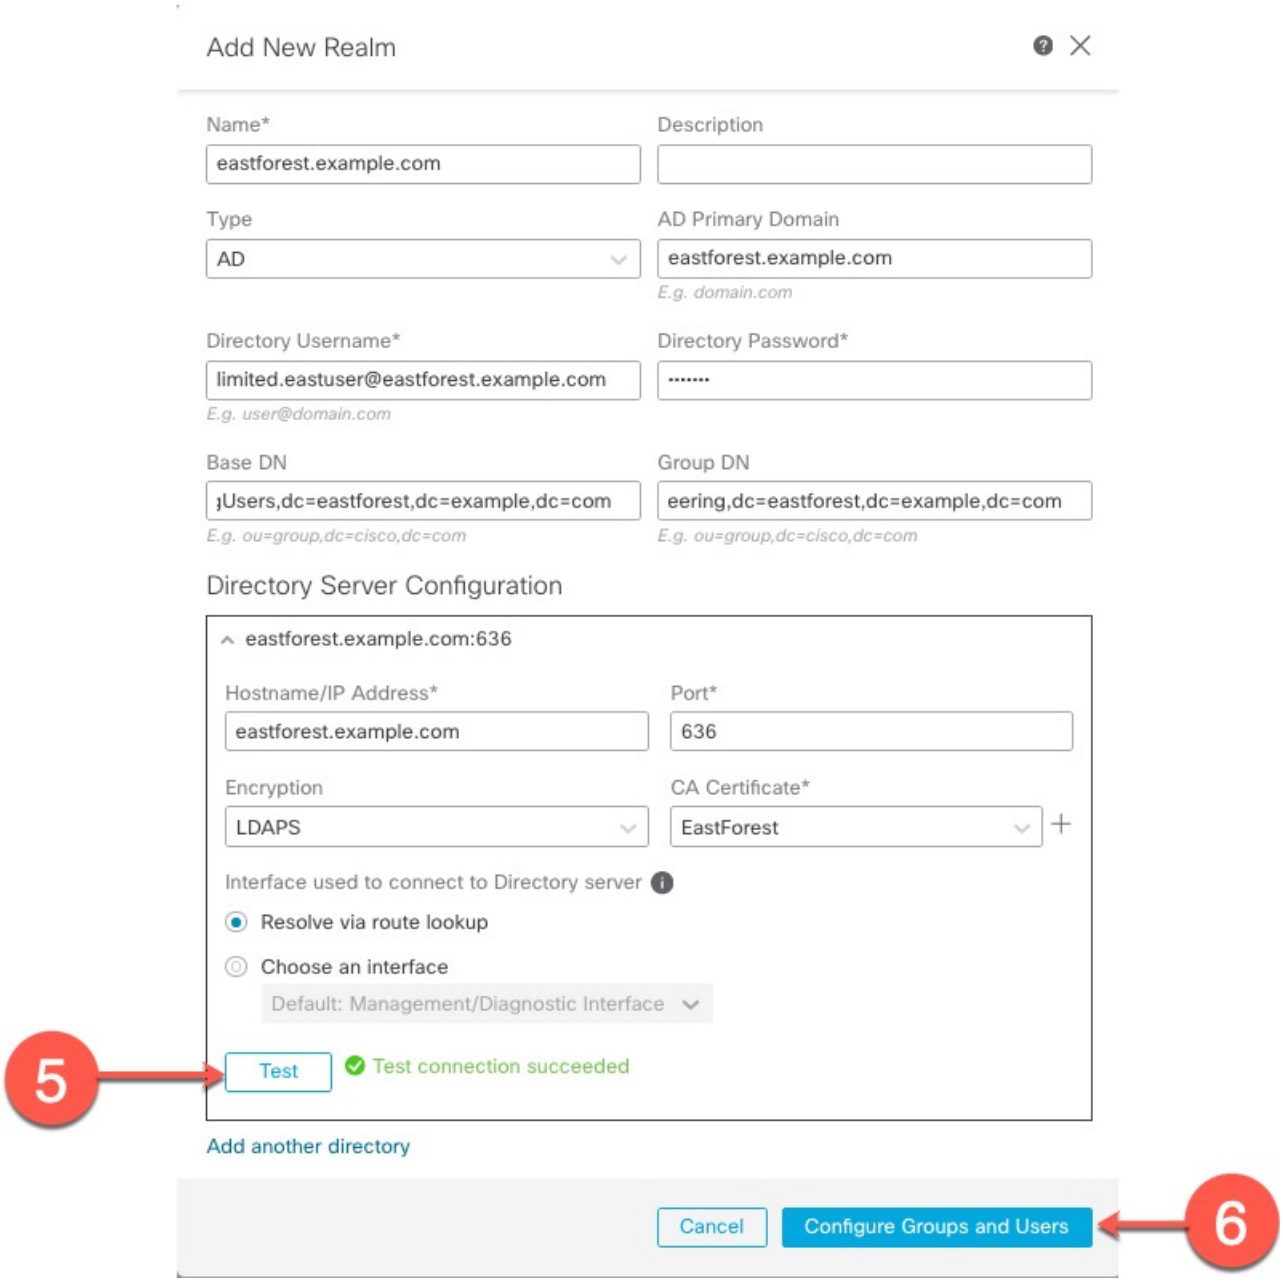
There are other optional configurations available on this page; for more information about them, see Realm Fields, on page 2436 and Realm Directory and Synchronize fields, on page 2440.

Step 8 If you made changes on this page or tab pages, click **Save**.

Step 9 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 10 Click **Add Realm**.

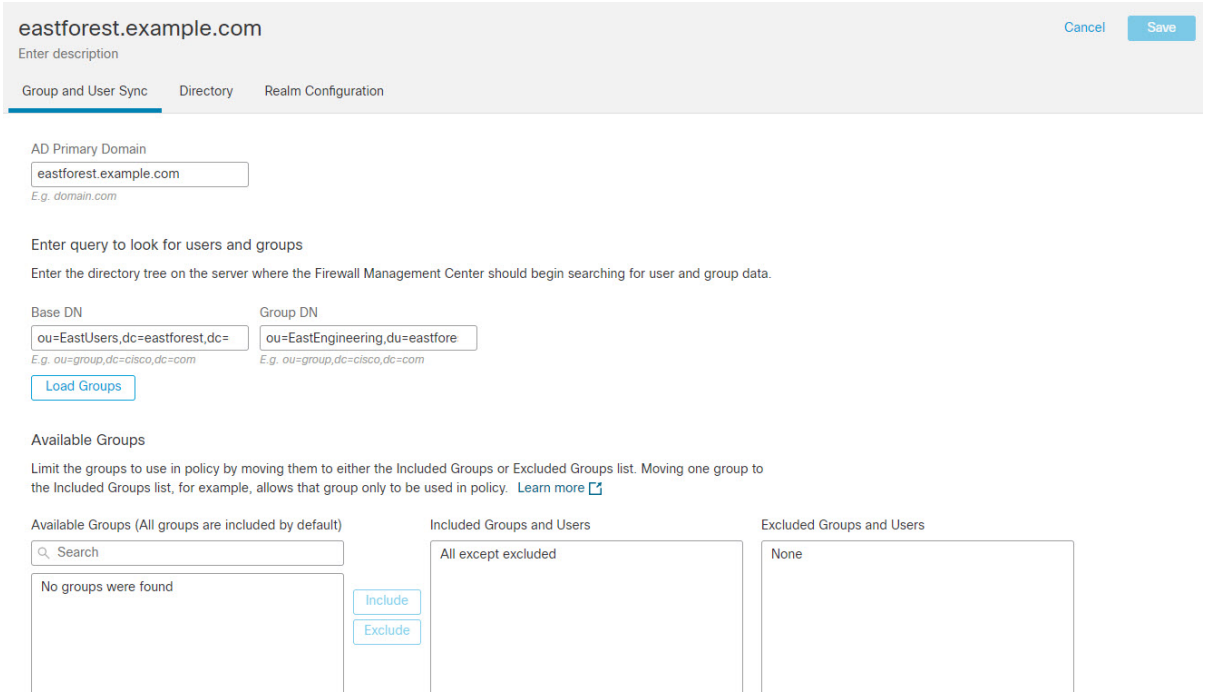
Step 11 Enter the following information to configure **eastforest.example.com**.



Step 12 Click **Test** and make sure the test succeeds before you continue.

Step 13 Click **Configure Groups and Users**.

Step 14 If your configuration was successful, the next page is displayed similar to the following.



Related Topics

Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 2: Synchronize Users and Groups, on page 2453

Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 2: Synchronize Users and Groups

After you configure two or more Active Directory servers that have a cross-domain trust relationship, you must download users and groups. That process exposes possible issues with the Active Directory configuration (for example, groups or users downloaded for one Active Directory domain but not the other).

Before you begin

Make sure you have performed the tasks discussed in Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories, on page 2448.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 At the end of the row of any realm in the cross-domain trust, click **Download Now**(), then click **Yes**.

Step 4 Click **Check Mark** () (Notifications) > **Tasks**.

If groups and users fail to download, try again. If subsequent attempts fail, review your realm and directory setup as discussed in Realm Fields, on page 2436 and Realm Directory and Synchronize fields, on page 2440.

Step 5 Click **Integration** > **Other Integrations** > **Realms** > **Sync Results**.

Related Topics

Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 3: Resolve Issues, on page 2454

Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 3: Resolve Issues

The final step in setting up cross-domain trust in the Firewall Management Center is to make sure users and groups are downloaded without errors. A typical reason why users and groups do not download properly is that the realms to which they belong have not been downloaded to the Firewall Management Center.

This topic discusses how to diagnose that a group referred in one forest to cannot be downloaded because the realm is not configured to find the group in the domain controller hierarchy.

Before you begin

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

In the Realms column, if **Yellow Triangle** (⚠) is displayed next to the name of a realm, you have issues that must be resolved. If not, your results are configured properly and you can quit.

Step 3 Download users and groups again from the realms that display issues.

a) Click the **Realms** tab.

b) Click ⤓ (Download Now), then click **Yes**.

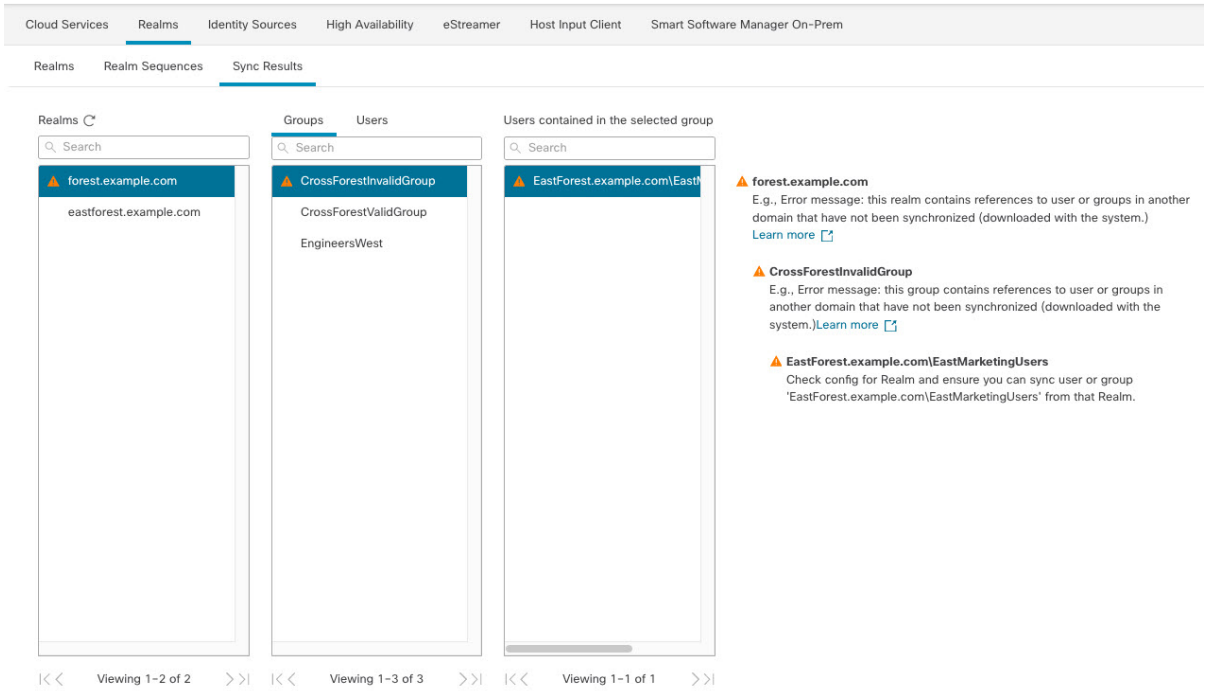
Step 4 Click the **Sync Results** tab page.

If the **Yellow Triangle** (⚠) is displayed in the Realms column, click **Yellow Triangle** (⚠) next to the realm that has issues.

Step 5 In the middle column, click either **Groups** or **Users** to find more information.

Step 6 In the Groups or Users tab page, click **Yellow Triangle** (⚠) to display more information.

The right column should display enough information you can isolate the source of the issue.



In the preceding example, **forest.example.com** includes a cross-domain group **CrossForestInvalidGroup** that contains another group **EastMarketingUsers** that was not downloaded by the Firewall Management Center. If, after synchronizing the **eastforest.example.com** realm again, the error does not resolve, it likely means that the Active Directory domain controller does not include **EastMarketingUsers**.

To resolve this issue, you can:

- Remove the **EastMarketingUsers** from **CrossForestInvalidGroup**, synchronize the **forest.example.com** realm again, and recheck.
- Remove the **ou=EastEngineering** value from the **Group DN** of the **eastforest.example.com** realm, which causes the Firewall Management Center to retrieve groups from the highest level in the Active Directory hierarchy, synchronize **eastforest.example.com**, and recheck.

Manage a Realm

This section discusses how to perform various maintenance tasks for a realm using controls on the Realms page:

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 To delete a realm, click **Delete** ( ).

Step 4 To edit a realm, click **Edit** ( ) next to the realm and make changes as described in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Step 5 To enable a realm, slide **State** to the right; to disable a realm, slide it to the left.

Step 6 To download users and user groups, click **Download** ( ).

Step 7 To copy a realm, click **Copy** ( ).

Step 8 To compare realms, see Compare Realms, on page 2456.

Compare Realms

You must be an Admin, Access Admin, Network Admin, or Security Approver to perform this task.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 Click **Compare Realms**.

Step 4 Choose **Compare Realm** from the **Compare Against** list.

Step 5 Choose the realms you want to compare from the **Realm A** and **Realm B** lists.

Step 6 Click **OK**.

Step 7 To navigate individually through changes, click **Previous** or **Next** above the title bar.

Step 8 (Optional.) Click **Comparison Report** to generate the realm comparison report.

Step 9 (Optional.) Click **New Comparison** to generate a new realm comparison view.

Troubleshoot Realms and User Downloads

If you notice unexpected server connection behavior, consider tuning your realm configuration, device settings, or server settings. For other related troubleshooting information, see:

- Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues, on page 2521
- Troubleshoot the TS Agent Identity Source, on page 2550
- Troubleshoot the Captive Portal Identity Source, on page 2541

- Troubleshoot the Remote Access VPN Identity Source, on page 2546
- Troubleshoot User Control, on page 2573

Symptom: Realms and groups reported but not downloaded

The Secure Firewall Management Center's health monitor informs you of user or realm mismatches, which are defined as:

- User mismatch: A user is reported to the Secure Firewall Management Center without being downloaded.

  A typical reason for a user mismatch is that the user belongs to a group you have excluded from being downloaded to the Secure Firewall Management Center. Review the information discussed in Cisco Secure Firewall Management Center Device Configuration Guide.

- Realm mismatch: A user logs into a domain that corresponds to a realm not known to the Firewall Management Center.

For example, if you defined a realm that corresponds to a domain named **domain.example.com** in the Firewall Management Center but a login is reported from a domain named **another-domain.example.com**, this is a *realm mismatch*. Users in this domain are identified by the Firewall Management Center as Unknown.

You set the mismatch threshold as a percentage, above which a health warning is triggered. Examples:

- If you use the default mismatch threshold of 50%, and there are two mismatched realms in eight incoming sessions, the mismatch percentage is 25% and no warning is triggered.
- If you set the mismatch threshold to 30% and there are three mismatched realms in five incoming sessions, the mismatch percentage is 60% and a warning is triggered.

Unknown users that do not match identity rules have no policies applied to them. (Although you can set up identity rules for Unknown users, we recommend keeping the number of rules to a minimum by identifying users and realms correctly.)

For more information, see Detect Realm or User Mismatches, on page 2460.

Symptom: Users are not downloaded

Possible causes follow:

- If you have the realm **Type** configured incorrectly, users and groups cannot be downloaded because of a mismatch between the attribute the system expects and what the repository provides. For example, if you configure **Type** as **LDAP** for a Microsoft Active Directory realm, the system expects the `uid` attribute, which is set to `none` on Active Directory. (Active Directory repositories use `sAMAccountName` for the user ID.)

  Solution: Set the realm **Type** field appropriately: **AD** for Microsoft Active Directory or **LDAP** for another supported LDAP repository.

- Users in Active Directory groups that have special characters in the group or organizational unit name might not be available for identity policy rules. For example, if a group or organizational unit name contains the characters asterisk (`*`), equals (`=`), or backslash (`\`), users in those groups are not downloaded and can't be used for identity policies.

  Solution: Remove special characters from the group or organizational unit name.

Important To reduce latency between the Secure Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Secure Firewall Management Center.

For example, if your Secure Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

Symptom: Not all users in a realm are downloaded

Possible causes follow:

- If you attempt to download more than the maximum number of users in any one realm, the download stops at the maximum number of users and a health alert is displayed. User download limits are set per Secure Firewall Management Center model. For more information, see User Limits for Microsoft Active Directory, on page 2384.
- Every user must be a member of a group. Users that are members of no groups do not get downloaded.

Symptom: Access control policy doesn't match group membership

This solution applies to an AD domain that is in a trust relationship with other AD domains. In the following discussion, *external domain* means a domain other than the one to which the user logs in.

If a user belongs to a group defined in a trusted external domain, the Secure Firewall Management Center doesn't track membership in the external domain. For example, consider the following scenario:

- Domain controllers 1 and 2 trust each other
- Group A is defined on domain controller 2
- User `mparvinder` in controller 1 is a member of Group A

Even though user `mparvinder` is in Group A, the Secure Firewall Management Center access control policy rules specifying membership Group A don't match.

Solution: Create a similar group in domain controller 1 that contains has all domain 1 accounts that belong to group A. Change the access control policy rule to match any member of Group A or Group B.

Symptom: Access control policy doesn't match child domain membership

If a user belongs to a domain that is child of parent domain, Firepower doesn't track the parent/child relationships between domains. For example, consider the following scenario:

- Domain `child.parent.com` is child of domain `parent.com`
- User `mparvinder` is defined in `child.parent.com`

Even though user `mparvinder` is in a child domain, the Firepower access control policy matching the `parent.com` don't match `mparvinder` in the `child.parent.com` domain.

Solution: Change the access control policy rule to match membership in either `parent.com` or `child.parent.com`.

Symptom: Realm or realm directory test fails

The **Test** button on the directory page sends an LDAP query to the hostname or IP address you entered. If it fails, check the following:

- The **Hostname** you entered resolves to the IP address of an LDAP server or Active Directory domain controller.
- The **IP Address** you entered is valid.

The **Test AD Join** button on the realm configuration page verifies the following:

- DNS resolves the **AD Primary Domain** to an LDAP server or Active Directory domain controller's IP address.
- The **AD Join Username** and **AD Join Password** are correct.

  AD Join Username must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).
- The user has sufficient privileges to create a computer in the domain and join the Secure Firewall Management Center to the domain as a Domain Computer.

Symptom: User timeouts are occurring at unexpected times

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC server is synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC, or TS Agent server is synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

Symptom: User data for previously-unseen ISE/ISE-PIC users is not displaying in the web interface

After the system detects activity from an ISE/ISE-PIC or TS Agent user whose data is not yet in the database, the system retrieves information about them from the server. In some cases, the system requires additional time to successfully retrieve this information from Microsoft Windows servers. Until the data retrieval succeeds, activity seen by the ISE/ISE-PIC, or TS Agent user is *not* displayed in the web interface.

Note that this can also prevent the system from handling the user's traffic using access control rules.

Symptom: User data in events is unexpected

If you notice user or user activity events contain unexpected IP addresses, check your realms. The system does not support configuring multiple realms with the same **AD Primary Domain** value.

Symptom: Users originating from terminal server logins are not uniquely identified by the system

If your deployment includes a terminal server and you have a realm configured for one or more servers connected to the terminal server, you must deploy the Cisco Terminal Services (TS) Agent to accurately report user logins in terminal server environments. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users in the web interface.

For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Detect Realm or User Mismatches

This section discusses how to detect realm or user *mismatches*, which are defined as:

- User mismatch: A user is reported to the Secure Firewall Management Center without being downloaded.

  A typical reason for a user mismatch is that the user belongs to a group you have excluded from being downloaded to the Secure Firewall Management Center. Review the information discussed in Cisco Secure Firewall Management Center Device Configuration Guide.

- Realm mismatch: A user logs into a domain that corresponds to a realm not known to the Firewall Management Center.

For additional details, see Troubleshoot Realms and User Downloads, on page 2456.

Unknown users that do not match identity rules have no policies applied to them. (Although you can set up identity rules for Unknown users, we recommend keeping the number of rules to a minimum by identifying users and realms correctly.)

Procedure

Step 1 Enable detection of realm or user mismatches:

a) Log in to the Firewall Management Center if you have not already done so.
b) Click **System** (⚙) > **Health** > **Policy**.
c) Create a new health policy or edit an existing one.
d) On the Editing Policy page, set a **Policy Runtime Interval**.
This is the frequency at which all health monitor tasks run.
e) In the left pane, click **Realm**.
f) Enter the following information:

- **Enabled**: Click **On**
- **Warning Users match threshold %**: The percentage of either realm mismatches or user mismatches that triggers a warning in the Health Monitor. For more information, see Troubleshoot Realms and User Downloads, on page 2456.

g) At the bottom of the page, click **Save Policy & Exit**.
h) Apply the health policy to managed devices as discussed in *Applying Health Policies* in the Cisco Secure Firewall Management Center Administration Guide.

Step 2 View user and realm mismatches in any of the following ways:

- If the warning threshold is exceeded, click **Warning** > **Health** in the top navigation of the Firewall Management Center. This opens the Health Monitor.
- Click **System** (⚙) > **Health** > **Monitor**.

Step 3 On the Health Monitor page, in the Display column, expand **Realm: Domain** or **Realm: User** to view details about the mismatch.

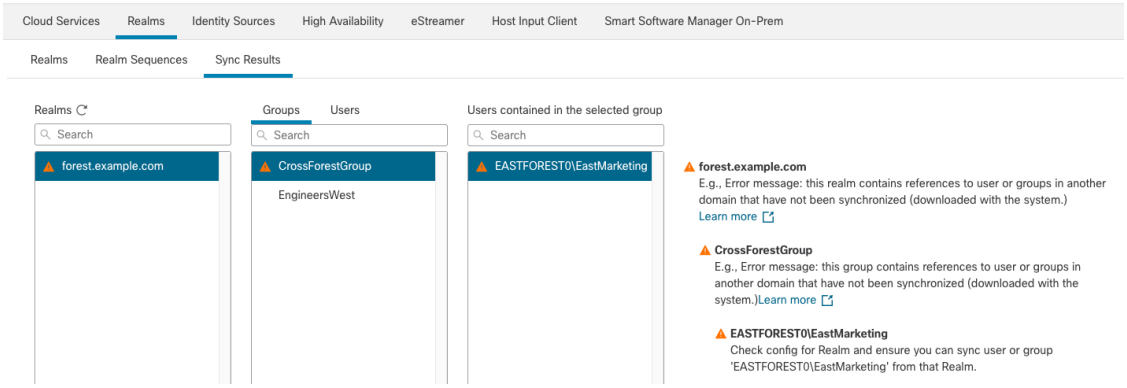
Troubleshoot Cross-Domain Trust

Typical issues with troubleshooting the Firewall Management Center configuration for cross-domain trust include the following:

- Not adding realms or directories for all forests that have shared groups.
- Configure a realm to exclude users from being downloaded and those users are referenced in a group in a different realm.
- Certain temporary issues.

Understand the issues

If there are issues with the Firewall Management Center being able to synchronize users and groups with your Active Directory forests, the Sync Results tab page is displayed similar to the following.



The following table explains how to interpret the information.

Column	Meaning
Realms	Displays all realms configured in the system. Click **Refresh** ( ) to update the list of realms. **Yellow Triangle** ( ) is displayed to indicate issues in the realm. Nothing is displayed next to a realm if all users and groups synchronized successfully.
Groups	Click **Groups** to display all groups in the realm. As with realms, **Yellow Triangle** ( ) is displayed to indicate issues. Click **Yellow Triangle** ( ) to see more detail about the issue.
Users	Click **Users** to display all users, sorted by group.
Users contained in the selected group	Displays all users in the group you selected in the Groups column. Clicking **Yellow Triangle** ( ) displays more information to the right of the table.

Column	Meaning
Groups that contain selected user	Displays all groups the selected user belongs to. Clicking **Yellow Triangle** ( ) displays more information to the right of the table.
Error detail information (displayed to the right of the table).	The system displays the NetBIOS forest name and group name it could not synchronize. Typical reasons the system cannot synchronize these users and groups follow: • **Problem**: The forest containing the groups and users do not have corresponding realms configured in the Firewall Management Center. **Solution**: Add a realm for the forest that contains the group as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426. • **Problem**: You excluded groups from being downloaded to the Firewall Management Center. **Solution**: Click the **Realms** tab page, click **Edit** ( ), then move the indicated group or user from the **Excluded Groups and Users** list.

Try downloading users and groups again

If there is a possibility the issues are temporary, download users and groups for all realms.

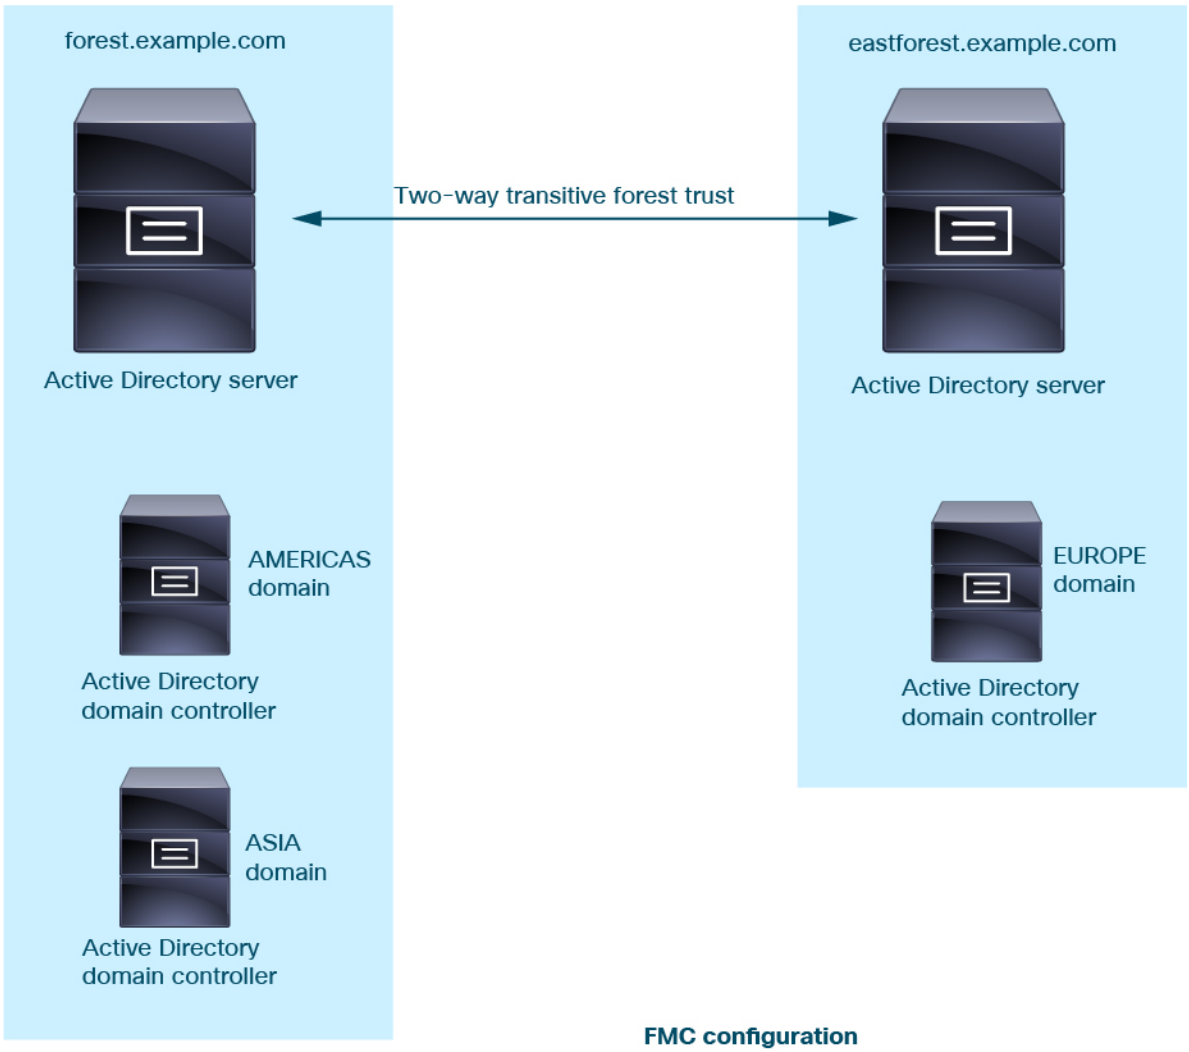
1. If you haven't done so already, log in to the Firewall Management Center.
2. Click **Integration** > **Other Integrations** > **Realms** > **Realms**.
3. Click **Download** ( ).
4. Click the **Sync Results** tab page.
5. If no indicator is displayed for entries in the Realms column, the issues have been resolved.

Add a realm for all forests

Make sure you configured:

- Firewall Management Center realm for each forest that has users you want to use in identity policies.
- Firewall Management Center directory for each domain controller in that forest with users you want to use in identity polices.

The following figure shows an example.



FMC configuration

Realm: forest.example.com
Directory: AMERICAS.forest.example.com
Directory: ASIA.forest.example.com

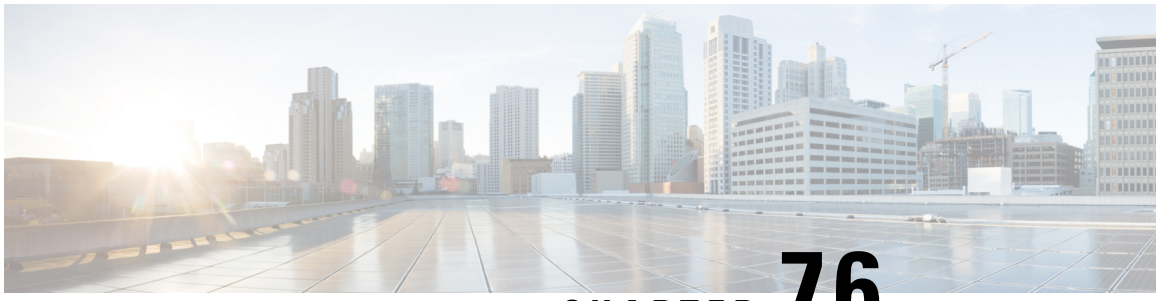
Realm: eastforest.example.com
Directory: EUROPE.eastforest.example.com

History for Realms

Table 136:

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Microsoft Azure Active Directory (SAML) realms.	7.6.0	7.4.0	You can now use Microsoft Azure Active Directory (AD) realms for active and passive authentication: • Active authentication using Azure AD: Use Azure AD as a captive portal. • Passive authentication using Cisco ISE (introduced in Version 7.4.0): The Firewall Management Center gets groups from Azure AD and logged-in user session data from ISE. We use SAML (Security Assertion Markup Language) to establish a trust relationship between a service provider (the devices that handle authentication requests) and an identity provider (Azure AD). **Upgrade impact**. If you had a Microsoft Azure AD realm configured before the upgrade, it is displayed as a SAML - Azure AD realm configured for passive authentication. All previous user session data is preserved. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Add Realm** > **SAML - Azure AD** New/modified CLI commands: none
Microsoft Azure Active Directory (AD) realms.	7.4.0	7.4.0	You can use a Microsoft Azure Active Directory (AD) realm with ISE to authenticate users and get user sessions for user control. New/modified screens: **System** > **Integration** > **Realms** > **Add Realm** > **Azure AD**
Proxy sequences.	7.2.0	7.2.0	Similar to a realm sequence, a proxy sequence is one or more managed devices that can communicate with Cisco Security Cloud Control in the event Cisco Security Cloud Control cannot communicate with the LDAP or Active Directory server. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Proxy Sequence**
Cross-domain trust for Active Directory domains.	7.2.0	7.0.0	A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B. The Firewall Management Center can get users from Active Directory forests for identity rules.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Realm sequences.	7.2.0	6.7.0	A *realm sequence* is an ordered list of two or more realms to which to apply identity rules. When you associate a realm sequence with an identity policy, the Firepower System searches the Active Directory domains in order from first to last as specified in the realm sequence. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Realm SequencesSystem** > **Integration** > **Realms** > **Realm Sequences**
Realms for user control.	7.2.0	Any	A realm is a connection between the Firewall Management Center either an Active Directory or LDAP user repository.



CHAPTER 76

User Control with the Passive Identity Agent

The following topics discuss how to configure and use the passive identity agent.

- The Passive Identity Agent Identity Source, on page 2467
- Deploy the Passive Identity Agent, on page 2469
- How to Create a Passive Identity Agent Identity Source, on page 2474
- Configure the Passive Identity Agent , on page 2476
- Monitor the Passive Identity Agent, on page 2491
- Manage the Passive Identity Agent, on page 2493
- Troubleshoot the Passive Identity Agent, on page 2494
- Security Requirements for the Passive Identity Agent, on page 2495
- Internet Access Requirements for the Passive Identity Agent, on page 2496
- History for the Passive Identity Agent, on page 2497

The Passive Identity Agent Identity Source

The passive identity agent identity source sends session data from Microsoft Active Directory (AD) to the Secure Firewall Management Center. All you need is a supported Microsoft AD setup as discussed in About Realms and Realm Sequences, on page 2429.

The passive identity agent version 1.0 sends IPv4 user sessions only but Version 1.1 sends IPv4 and IPv6 user sessions.

Note You do not need to configure the Cisco Identity Services Engine (ISE) to use this identity source.

Passive identity agent roles

The passive identity agent supports the following roles:

- Standalone: A passive identity agent that is not part of a redundant pair. A standalone agent can download users and groups from multiple Active Directory servers and domain controllers, provided the software is installed on all of them.
- Primary: (Primary agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

Handles all communication with the Secure Firewall Management Center unless it stops communicating, in which case communication is handled by secondary agents.

- Secondary: (Secondary, or backup, agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

  Monitors the health of the primary agent and takes over if the primary agent stops communicating with the Secure Firewall Management Center.

Passive identity agent system requirements

The passive identity agent requires the following:

- If you install the passive identity agent on a Windows Active Directory server, the server must run Windows Server 2008 or later.
- If you install it on a Windows client attached to the domain, the client must run Windows 8 or later.
- The system clock on all systems must be synchronized. We strongly recommend using the same NTP servers on all of them. This means:
  - The Secure Firewall Management Center.

    For more information, see Time Synchronization, on page 1002.
  - All Windows Active Directory servers and domain controllers.
  - The machine on which the passive identity agent is installed.
- Secure Firewall Management Center must run 7.6 or later.
- Any Secure Firewall Threat Defense managed by the Secure Firewall Management Center must run 7.1 or later.
- You must enable Snort 3 on the Secure Firewall Threat Defense devices.

Passive identity agent limitations

The passive identity agent the following limitations:

- Up to 10 agents simultaneously
- One passive identity agent identity source can monitor up to 50 AD directories
- Up to 300,000 concurrent user sessions
- IPv6 addresses are *not* supported (passive identity agent 1.0)
- IPv6 addresses are supported (passive identity agent 1.1)

Deploy the passive identity agent

For information about deployment options, see Deploy the Passive Identity Agent, on page 2469.

Note We recommend you use the latest version of the passive identity agent. To see the available versions, go to software.cisco.com. To upgrade the passive identity agent, see Upgrade the Passive Identity Agent Software, on page 2491

Deploy the Passive Identity Agent

You can install the Passive Identity Agent software on any machine that is part of a Microsoft Active Directory (AD) domain you want to use for user awareness and control. In other words, you can install it on any of the following:

- The Microsoft Active Directory server
- A domain controller
- A client connected to the network that is neither the directory server nor a domain controller

Any particular passive identity agent can monitor one or several Active Directory domain controllers in the same domain.

The machine on which the passive identity agent must communicate with the Secure Firewall Management Center using the TLS/SSL protocol. For more information, see Internet Access Requirements for the Passive Identity Agent, on page 2496.

Types of agents

You can configure the following types of agents on the Microsoft AD directory server, domain controller, or on any client connected to the domain:

- Standalone agent: One agent that can monitor one or several Active Directory domain controllers in the same domain.
- Primary agent and secondary agent that can monitor one or several AD domain controllers in the same domain: To provide redundancy, you can install a primary and secondary agent on different machines. The primary is responsible for communicating with the Secure Firewall Management Center but if communication fails, the secondary agent takes over.

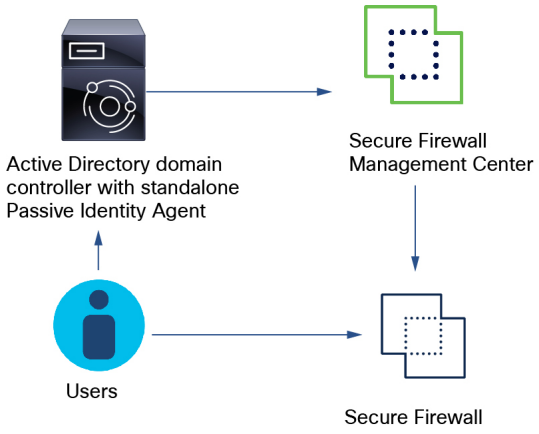
See one of the following topics for more information.

Related Topics

Simple Passive Identity Agent Deployment, on page 2469
Single Passive Identity Agent Monitoring Multiple Domain Controllers, on page 2470
Multiple Passive Identity Agents Monitoring Multiple Domain Controllers, on page 2471
Passive Identity Agent Primary/Secondary Agent Deployments, on page 2473

Simple Passive Identity Agent Deployment

The following diagram shows the simplest passive identity agent deployment.

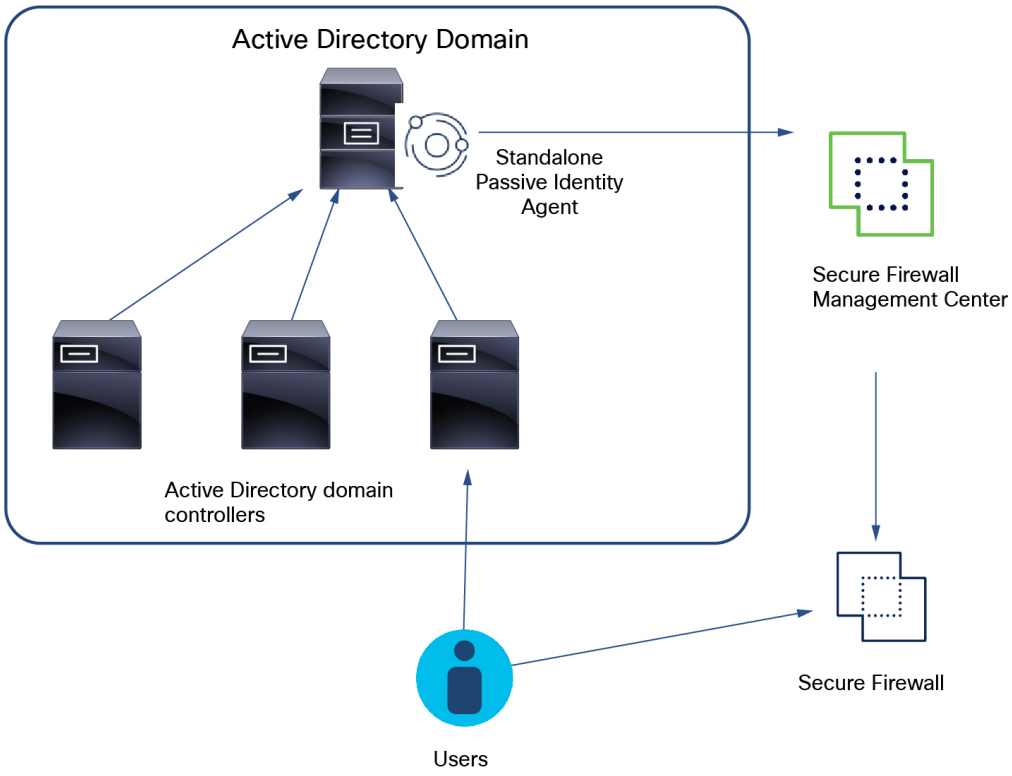


In the preceding example, a standalone passive identity agent is installed on the AD domain controller. Users log in and out of the AD domain and the agent sends user name and IP address information to the Secure Firewall Management Center. As users access the network, access control and identity policies deployed to the Secure Firewall Threat Defense determine whether or not, and how, access is allowed.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

Single Passive Identity Agent Monitoring Multiple Domain Controllers

The following diagram shows a standalone passive identity agent that monitors several AD domain controllers.



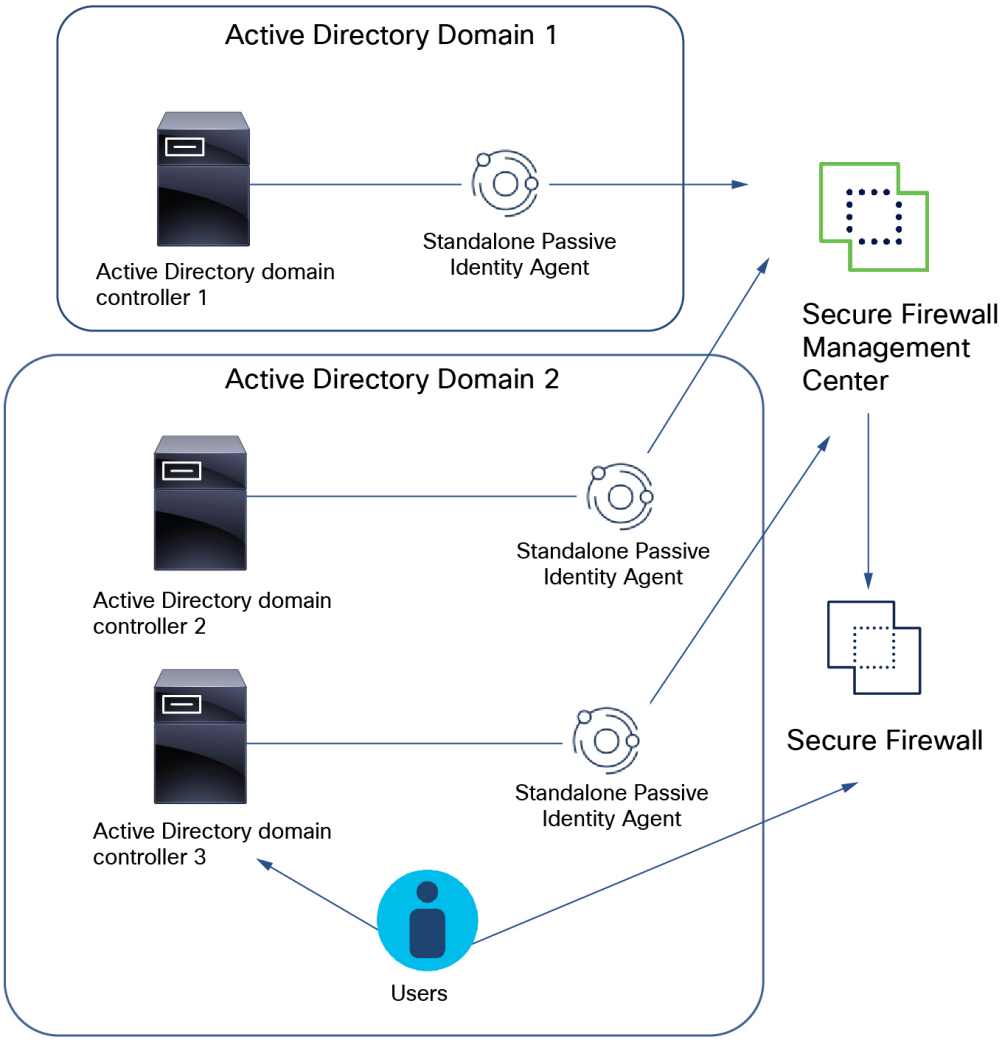
In the preceding diagram, the standalone passive identity agent is installed on a client attached to the AD domain (or on the domain controller itself). Users log in to any domain controller and the agent sends user and IP address information to the Secure Firewall Management Center. As users access the network, access control and identity policies deployed to the Secure Firewall Threat Defense determine whether or not, and how, access is allowed.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

Multiple Passive Identity Agents Monitoring Multiple Domain Controllers

The following figure shows standalone monitoring multiple AD domain controllers:

- In AD domain 1, a standalone passive identity agent installed on a machine attached to AD domain controller 1 sends user and IP address mapping data to the Secure Firewall Management Center.
- In AD domain 2, standalone agents installed on AD domain controllers 1 and 2 send user and IP address mapping data to the Secure Firewall Management Center.



You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

The preceding figure shows three passive identity agents, each configured as a standalone. To do this:

1. Create two Microsoft AD realms: one for each AD domain.

   See Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

2. For AD domain 2, create two directories, one for each domain controller.

3. Install the Passive Identity Agent software on a client that can log in to the domain.

   Configure each passive identity agent individually to communicate with the Secure Firewall Management Center on which you configure the passive identity agent source.

   See Install the Passive Identity Agent Software, on page 2487.

4. Create the passive identity agent identity source.

   See Create a Primary or Secondary Passive Identity Agent Identity Source, on page 2479.

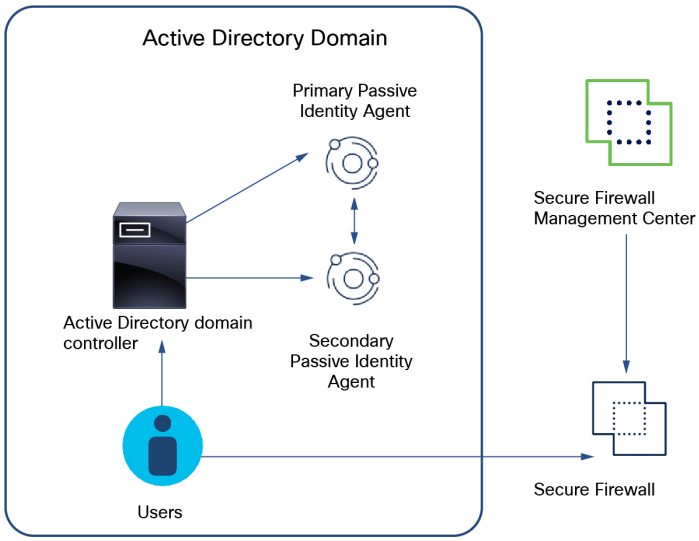
Passive Identity Agent Primary/Secondary Agent Deployments

To provide redundancy and to avoid a single point of failure, you can configure primary and secondary passive identity agents in any of the ways shown in this topic.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

Single AD domain controller with primary and secondary agents

The following figure shows how to set up primary and secondary passive identity agents on one AD domain controller. If the primary agent fails, the secondary takes over.



To set this up:

1. Create a Microsoft AD realm that has one directory for the domain controller.

   See Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

2. Install the passive identity agent software on any two network machines connected to the domain controller.

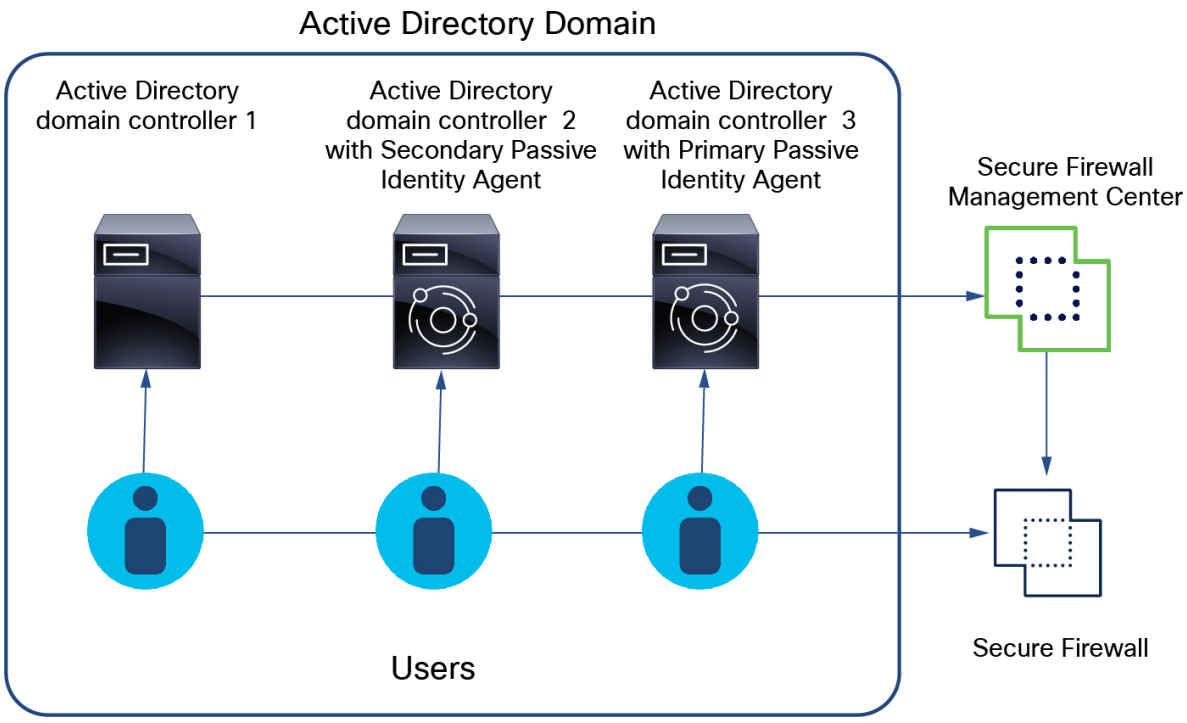
   Configure each passive identity agent individually to communicate with the Secure Firewall Management Center on which you configure the passive identity agent source.

   See Install the Passive Identity Agent Software, on page 2487.

3. Create the identity source.

   See Create a Primary or Secondary Passive Identity Agent Identity Source, on page 2479.

Multiple AD domain controllers, primary and secondary agents



The preceding figure shows how to configure primary and secondary agents to monitor three AD domain controllers. If the primary agent fails, the secondary agent takes over.

To set this up:

1. Create a Microsoft AD realm that has one directory for the domain controller.

   See Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

2. Install the passive identity agent software on any machine connected to the domain controller.

   Configure each passive identity agent individually to communicate with the Secure Firewall Management Center on which you configure the passive identity agent source.

   See Install the Passive Identity Agent Software, on page 2487.

3. Create the identity source.

   See Create a Primary or Secondary Passive Identity Agent Identity Source, on page 2479.

How to Create a Passive Identity Agent Identity Source

The following provides high-level tasks required to configure the passive identity agent identity source in the Secure Firewall Management Center and to deploy agent software to your Microsoft Active Directory (AD) servers.

Procedure

	Command or Action	Purpose
Step 1	Create a realm for your Microsoft AD domain and domain controllers.	*Realms* are connections between the Secure Firewall Management Center and the user accounts on the servers you monitor. They specify the connection settings and authentication filter settings for the server. For more information, see Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
Step 2	Create a passive identity agent identity source.	The identity source allows the Secure Firewall Management Center and passive identity agent to communicate with each other. Create standalone, primary, or secondary agents, depending on your needs. For more information, see: • About Passive Identity Agent Roles, on page 2481 • Create a Passive Identity Agent Identity Source, on page 2476
Step 3	Create a passive identity agent user on the Secure Firewall Management Center.	We provide a role sufficient for the agent and manager to communicate with each other. We recommend using that role and no other for the passive identity agent user.
Step 4	Install the passive identity agent software.	The way you install the agent depends on your deployment. You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor. For more information, see: • Deploy the Passive Identity Agent, on page 2469 • Install the Passive Identity Agent Software, on page 2487

What to do next

Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Configure the Passive Identity Agent

The following topics discuss how to configure the passive identity agent.

Related Topics

Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426
Create a Passive Identity Agent Identity Source, on page 2476
Install the Passive Identity Agent Software, on page 2487
Create a Secure Firewall Management Center User for the Passive Identity Agent, on page 2482

Create a Microsoft Active Directory Realm

The passive identity agent requires you to create a Microsoft Active Directory (AD) realm and directories in the Secure Firewall Management Center as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Create a Passive Identity Agent Identity Source

This task discusses how to create a passive identity agent that sends user session activity to the Secure Firewall Management Center.

Before you begin

Complete the following:

- Review passive identity agent roles as discussed in About Passive Identity Agent Roles, on page 2481.
- Create a Microsoft AD realm as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

Procedure

Step 1 Log in to the Secure Firewall Management Center as an administrator.

Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.

Step 3 **Integration** > **Other Integrations** > **Identity Sources**.

Step 4 Click **Passive Identity Agent**.

Step 5 If the Cisco Secure Dynamic Attributes Connector has not been enabled yet, you are prompted to do so.

For more information about enabling the dynamic attributes connector, see Enable the Cisco Secure Dynamic Attributes Connector, on page 1806.

Step 6 Click **Create Agent**.

Step 7 In the Configure Agent dialog box, enter the following information:

Item	Description
Name	Enter a unique name to identify this passive identity agent.

Item	Description
Description	Enter an optional description.
Role	Click one of the following: • **Primary**: The agent responsible for communicating with the Secure Firewall Management Center. Not available if you choose **Standalone**. • **Secondary**: Becomes the primary if the primary loses contact with the Secure Firewall Management Center. Not available if you choose **Standalone**. • **Standalone**: If there is only one passive identity agent. For more information about roles, see About Passive Identity Agent Roles, on page 2481.

Step 8 Continue with:

- Create a Standalone Passive Identity Agent Identity Source, on page 2477
- Create a Primary or Secondary Passive Identity Agent Identity Source, on page 2479

Create a Standalone Passive Identity Agent Identity Source

This task discusses how to configure a standalone passive identity agent.

Before you begin

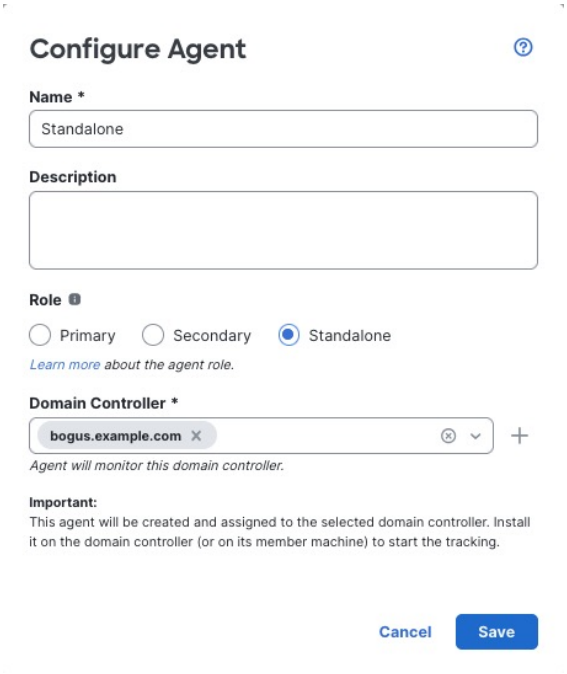
Complete the tasks discussed in Create a Passive Identity Agent Identity Source, on page 2476.

Procedure

Step 1 In the Configure Agent dialog box, enter the following information:

Item	Description
Role	Click **Standalone**.
Domain Controller	From the list, select the check box next to each domain controller that has a passive identity agent you wish to use for identity management and user control. (Optional.) Click **Add** (+) to add a new one.

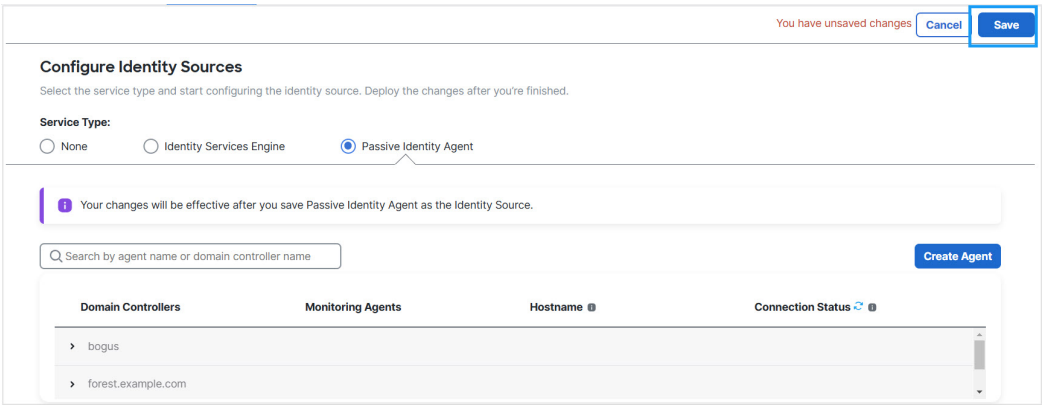
The following figure shows an example of a standalone passive identity agent identity source.



Step 2 In the Configure Agent dialog box, click **Save**.

Step 3 In the top right corner of the page, click **Save**.

The following figure shows an example.



Note
The passive identity agent won't be active until you create a user and install the software.

What to do next

- See Create a Secure Firewall Management Center User for the Passive Identity Agent, on page 2482
- See About Passive Identity Agent Installation, on page 2485

Create a Primary or Secondary Passive Identity Agent Identity Source

The following task continues from Create a Passive Identity Agent Identity Source, on page 2476.

Before you begin

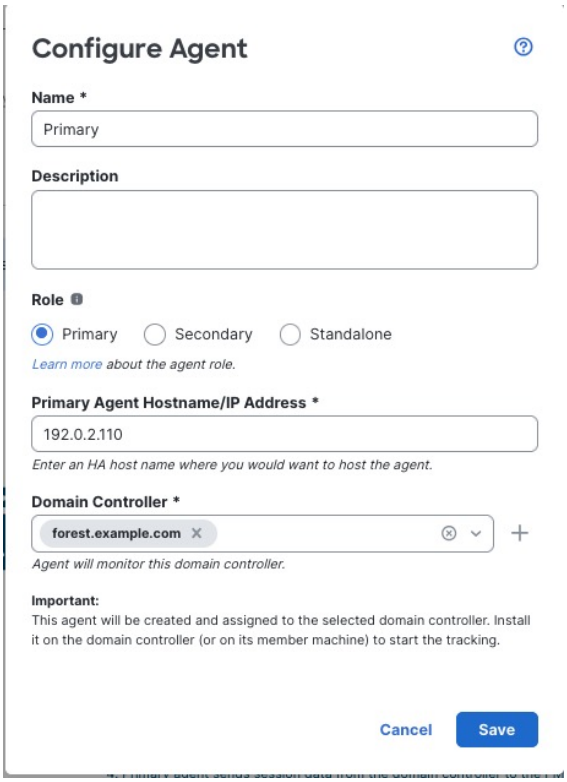
Complete the tasks discussed in Create a Passive Identity Agent Identity Source, on page 2476.

Procedure

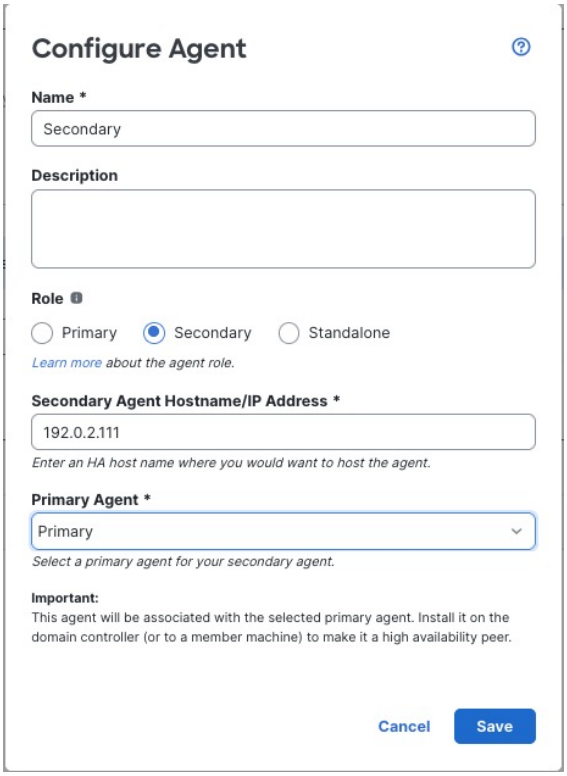
Step 1 In the Configure Agent dialog box, enter the following information:

Item	Description
Role	Click one of the following: • **Primary**: The agent responsible for communicating with the Secure Firewall Management Center. • **Secondary**: Becomes the primary if the primary loses contact with the Secure Firewall Management Center. For more information about roles, see About Passive Identity Agent Roles, on page 2481.
Primary Agent Hostname/IP Address	(Primary agent only.) Enter the fully qualified domain name or IP address of the server on which the primary passive identity agent is installed. The passive identity agent version 1.0 supports IPv4 addresses and fully qualified domain names only. Version 1.1 supports IPv4, IPv6, and fully qualified domain names.
Secondary Agent Hostname/IP Address	(Secondary agent only.) Enter the fully qualified host name or IP address of the server on which the secondary passive identity agent is installed. The passive identity agent version 1.0 supports IPv4 addresses and fully qualified domain names only. Version 1.1 supports IPv4, IPv6, and fully qualified domain names.
Primary Agent	(Secondary agent only.) From the list, click the name of the primary passive identity agent.
Domain Controller	(Primary agent only.) From the list, select the check box next to each domain controller that has a passive identity agent you wish to use for identity management and user control.

The following figure shows an example of a primary agent:



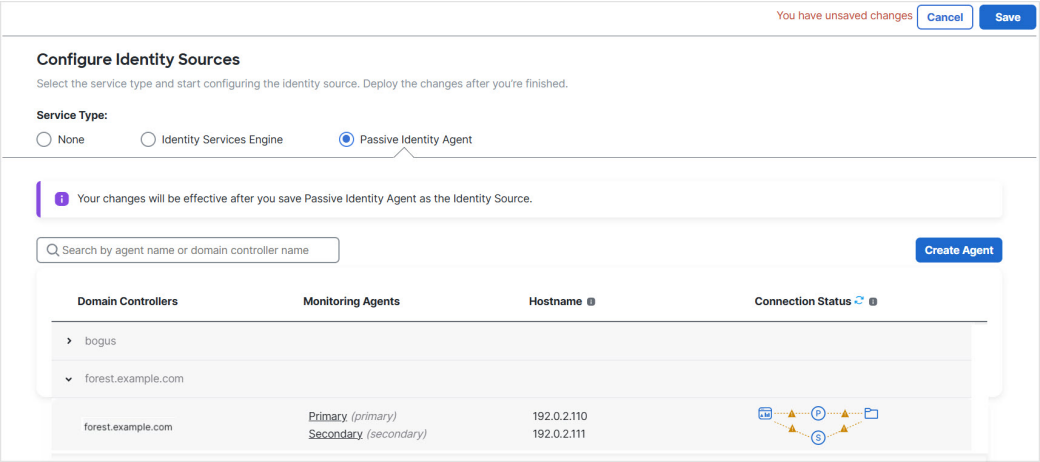
The following figure shows an example of a secondary agent:



Step 2 In the Configure Agent dialog box, click **Save**.

Step 3 In the top right corner of the page, click **Save**.

The following figure shows an example.



Note
The passive identity agent won't be active until you create a user and install the software.

What to do next

- See Create a Secure Firewall Management Center User for the Passive Identity Agent, on page 2482
- See About Passive Identity Agent Installation, on page 2485

About Passive Identity Agent Roles

The passive identity agent has the following roles:

- Standalone: A passive identity agent that is not part of a redundant pair. A standalone agent can download users and groups from multiple Active Directory servers and domain controllers, provided the software is installed on all of them.
- Primary: (Primary agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

  Handles all communication with the Secure Firewall Management Center unless it stops communicating, in which case communication is handled by secondary agents.
- Secondary: (Secondary, or backup, agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

  Monitors the health of the primary agent and takes over if the primary agent stops communicating with the Secure Firewall Management Center.

The can monitor several AD domain controllers that art part of the same domain.

Create a Secure Firewall Management Center User for the Passive Identity Agent

This task discusses how to create a Secure Firewall Management Center user with sufficient permissions to communicate with the passive identity agent. This user has limited privileges to perform other tasks; the user is expected only to enable communication with the passive identity agent.

Note Use *only* the **Passive Identity User** role for the passive identity agent user. In particular, *do not* use the **Administrator** role for the passive identity agent because **Administrator** will be logged off at a regular basis as the passive identity agent communicates with the Secure Firewall Management Center.

Before you begin

Complete the tasks discussed in Create a Passive Identity Agent Identity Source, on page 2476.

Note You *cannot* use external authentication with the Passive Identity Agent user.

Procedure

Step 1 Log in to the Secure Firewall Management Center as an administrator.

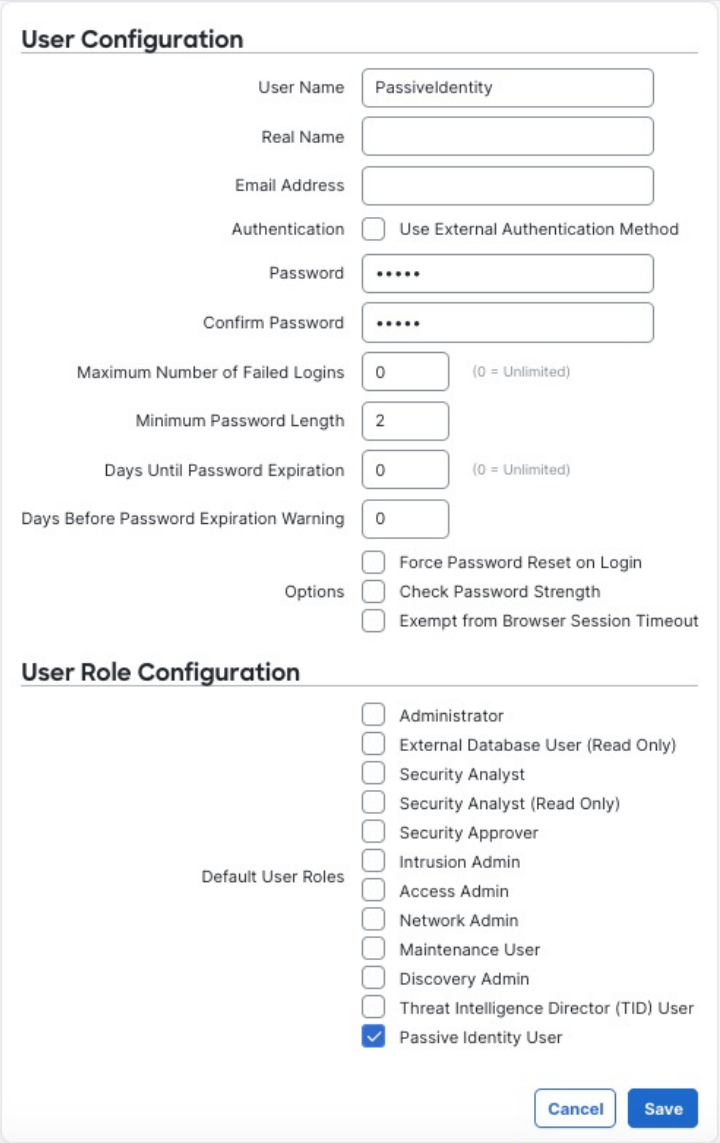
Step 2 Click **System** (⚙) > **Users** > **Users**.

Step 3 Click **Create User**.

Step 4 Create the user as discussed in Add or Edit an Internal User in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 5 Select the **Passive Identity User** role.

The following figure shows an example.



Note
Do not choose a role for the passive identity agent user other than **Passive Identity User** because the agent will not function properly.

Step 6 Click **Save**.

What to do next

About Passive Identity Agent Installation, on page 2485.

Troubleshoot the Passive Identity Agent

This topic discusses how you can troubleshoot the passive identity agent software on your Windows AD domain controller or directory server.

(Optional.) Set the log level

By default, the passive identity agent logs at the INFO level. To optionally change the log level, open **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config** in a text editor, save the file, and restart the Cisco Passive Identity Agent service.

Do not rename the logging service

Do not rename **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config**; otherwise, the passive identity agent will stop generating log files. Do not remove or change the **.exe.config** file extension.

Generate troubleshooting files

To generate a .zip containing troubleshooting files:

1. Log in to the Microsoft Active Directory domain controller.
2. Start the passive identity agent software.
3. Click the Troubleshooting button in the top right corner of the window.

   The following figure shows an example.

   A confirmation message is displayed.

Your troubleshoot logs are saved to your system's Downloads folder; the file name starts with **TroubleshootLogs**.

Manually view log files

Passive identity agent log files are stored in plain text format in the agent's installation directory: **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent**.

Use Notepad or another text editor to view these files. Log files rotate after reaching 10MB in size.

Use the Microsoft Active Directory event viewer

In the event you are not seeing user sessions in the Secure Firewall Management Center, you can look on your Microsoft Active Directory server's event viewers for the following Kerberos-related events:

- 4770
- 4768

For general information about audit policy, see Audit Policy Recommendations on learn.microsoft.com.

For more information about Windows Group Policy Object settings, see Group Policy Objects on learn.microsoft.com.

About Passive Identity Agent Installation

The following topics discuss prerequisites and tasks required to install the passive identity agent.

Note We recommend you use the latest version of the passive identity agent. To see the available versions, go to software.cisco.com. To upgrade the passive identity agent, see Upgrade the Passive Identity Agent Software, on page 2491

Related Topics

Prerequisites to Installing the Passive Identity Agent, on page 2485
Install the Passive Identity Agent Software, on page 2487

Prerequisites to Installing the Passive Identity Agent

The following task shows how to configure Windows Group Policy Object (GPO) security settings to enable the passive identity agent to log successful and unsuccessful Kerberos authentication attempts. This setting is required for the passive identity agent to function properly.

For more information, see Audit Policy Recommendations on learn.microsoft.com.

Before you begin

Make sure your systems meet the following requirements:

- If you install the passive identity agent on a Windows Active Directory server, the server must run Windows Server 2008 or later.
- If you install it on a Windows client attached to the domain, the client must run Windows 8 or later.
- The system clock on all systems must be synchronized. We strongly recommend using the same NTP servers on all of them. This means:
  - The Secure Firewall Management Center.

For more information, see Time Synchronization, on page 1002.

- All Windows Active Directory servers and domain controllers.
- The machine on which the passive identity agent is installed.

- Secure Firewall Management Center must run 7.6 or later.
- Any Secure Firewall Threat Defense managed by the Secure Firewall Management Center must run 7.1 or later.
- You must enable Snort 3 on the Secure Firewall Threat Defense devices.

Procedure

Step 1 Log in to the Active Directory Server as an administrator.

Step 2 As Administrator, open a DOS command prompt.

Step 3 Enter `gpmc.msc` to start the Group Policy Management Editor.

Step 4 If necessary, create a new GPO; if one already exists, edit it.

For more information about creating a GPO, see a resource like Create a Group Policy Object on learn.microsoft.com.

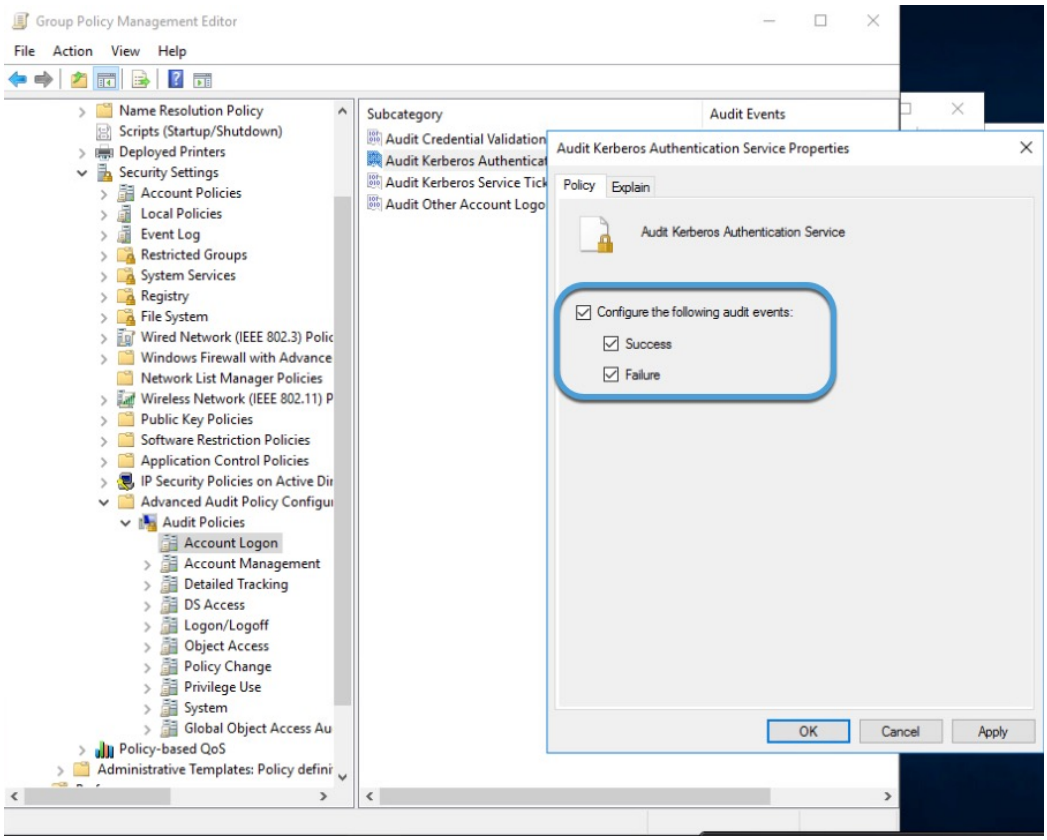
Step 5 In your GPO, expand **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Advanced Policy Configuration** > **Audit Policies**.

Step 6 Click **Account Logon**.

Step 7 In the right pane, double-click **Audit Kerberos Authentication Service**.

Step 8 In the dialog box that is displayed, select all checkboxes which enables the system to log successes and failures.

The following figure shows an example.



Step 9 Follow the prompts on your screen to save the changes.

Step 10 (Optional.) To update GPO immediately, enter **`gpupdate /force`** in your DOS command prompt window.

What to do next

See Install the Passive Identity Agent Software, on page 2487.

Install the Passive Identity Agent Software

This task discusses how to install the passive identity agent software. For a simple installation, you can install it on your Microsoft Active Directory (AD) domain controller; for other options, see Deploy the Passive Identity Agent, on page 2469.

Note We recommend you use the latest version of the passive identity agent. To see the available versions, go to software.cisco.com. To upgrade the passive identity agent, see Upgrade the Passive Identity Agent Software, on page 2491

Before you begin

See Prerequisites to Installing the Passive Identity Agent, on page 2485.

Procedure

Step 1 Download the passive identity agent from software.cisco.com.

Step 2 Log in as a member of the Administrators group to the machine on which to install the passive identity agent.

Step 3 Double-click **CiscoPassiveIdentityAgentInstaller-1.1.msi**.

Step 4 Click **Next**.

Step 5 Choose a folder in which to install the passive identity agent and click **Next**.

The default installation folder is **Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent**.

Step 6 Click **Next**.

Step 7 Click **Install**.

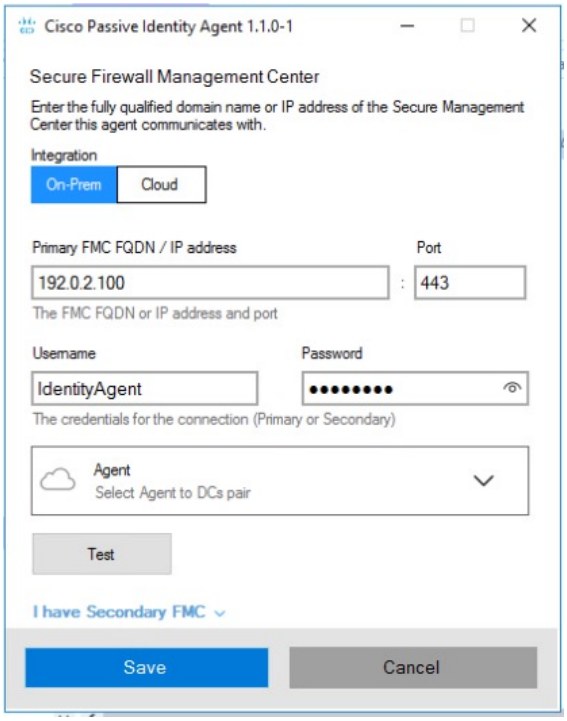
Step 8 When the installation is done, click **Finish** and optionally check the box to start the passive identity agent.

Step 9 When the passive identity agent starts, click the **On-Prem** tab if you are using the agent with an on-premises Secure Firewall Management Center (physical or virtual) or click the **Cloud** tab if you are using the agent with Cloud-Delivered Firewall Management Center.

Step 10 In the Cisco Passive Agent dialog box, enter the following information:

Item	Description
FMC FQDN / IP Address	Enter the address of the Secure Firewall Management Center on which you created the passive identity agent identity source. The passive identity agent version 1.0 supports IPv4 addresses and fully qualified domain names only. Version 1.1 supports IPv4, IPv6, and fully qualified domain names.
Port	Enter the Secure Firewall Management Center listen port (by default, 443).
Username	Enter the username of the user you created in Create a Secure Firewall Management Center User for the Passive Identity Agent, on page 2482.
Password	Enter the user's password.
Agent	Click the list to locate the domain controller of the passive identity agent you created previously on the Secure Firewall Management Center.

The following figure shows an example.

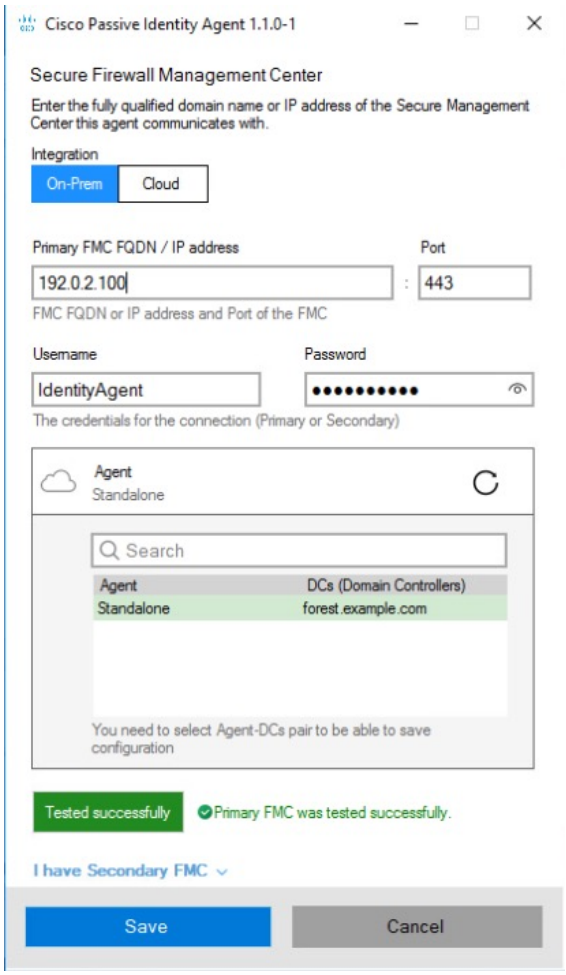


Step 11 Click the **Agent** list.

Step 12 From the list, click the name of the domain controller to monitor.

Step 13 Click **Test**.

The following figure shows an example.



Step 14 If you have a high availability pair, click **I have Secondary FMC** and enter the secondary's IP address or fully qualified host name and its listen port.

Step 15 Only if the test succeeds, click **Save**.

What to do next

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2555.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1762.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 259.
- Monitor user activity as discussed in *Using Workflows* in the Cisco Secure Firewall Management Center Administration Guide.

Uninstall the Passive Identity Agent Software

This task discusses how to uninstall the passive identity agent software from your Microsoft AD servers.

Procedure

Step 1 Log in as an administrator to the machine on which the passive identity agent is installed.

Step 2 Search for Add or Remove Programs.

Step 3 Click **Cisco Passive Identity Agent**.

Step 4 Click **Uninstall**.

Step 5 You are required to confirm the uninstallation.

Upgrade the Passive Identity Agent Software

To upgrade to a newer version of the passive identity agent, you must uninstall the earlier version the install the later version.

See the following information:

- Uninstall the Passive Identity Agent Software, on page 2491
- About Passive Identity Agent Installation, on page 2485

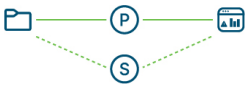
Monitor the Passive Identity Agent

The passive identity agent indicates whether or not it can communicate with the Secure Firewall Management Center and other agents if it's configured as primary-secondary. You can view the status at **Integration** > **Other Integrations** > **Identity Sources**.

Deployments

A standalone passive identity agent is represented as follows.

A primary-secondary pair is represented as follows.



The following table explains the meaning of the indicators.

Object	Meaning
	Secure Firewall Management Center

Object	Meaning
	Standalone Passive Identity Agent
	Active Directory domain controller
	Primary agent
	Secondary agent

Status indicators and colors

The passive identity agent indicates status using lines (that indicate whether communication with the Secure Firewall Management Center is active or standby) and colors (that indicate whether or not communication is successful).

The following table shows the meanings of lines and colors:

Object	Meaning
Solid line	The agent that is responsible for communicating with the Secure Firewall Management Center.
Dashed line	Primary/secondary configuration only. The agent that is acting as the backup agent. In the event of a communication failure between the active (solid line) agent, this agent communicates with the Secure Firewall Management Center.
Blue	Agent communication is normal.
Amber	Agent has never successfully communicated with the Secure Firewall Management Center. A newly created agent line is amber and remains so until configuration is complete.
Red	Communication is failing. To resolve the issues: • Check sure the network connections between agents and the Secure Firewall Management Center. • Make sure you have completed configuring the system (Microsoft AD server, domain controllers, and the Secure Firewall Management Center). For more information, see How to Create a Passive Identity Agent Identity Source, on page 2474.

Manage the Passive Identity Agent

The following topics discuss how to edit or delete passive identity agents you previously configured on the Secure Firewall Management Center.

Related Topics

Edit Passive Identity Agents, on page 2493
Delete a Standalone Passive Identity Agent, on page 2493
Delete Primary and Secondary Passive Identity Agents, on page 2494
Uninstall the Passive Identity Agent Software, on page 2491

Edit Passive Identity Agents

This task discusses how to edit passive identity agents you previously configured in the Secure Firewall Management Center.

Procedure

Step 1 Log in to the Secure Firewall Management Center as an administrator.
Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.
Step 3 Click **Passive Identity Agent**.
Step 4 Click **Edit** (✎) next to the agent to edit.
Step 5 Make the desired changes.
Step 6 Click **Save**.

Delete a Standalone Passive Identity Agent

This task discusses how to delete a standalone passive identity agent.

Procedure

Step 1 Log in to the Secure Firewall Management Center as an administrator.
Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.
Step 3 Click **Passive Identity Agent**.
Step 4 Click **Edit** (✎) next to the agent to delete.
Step 5 Click **Delete**.
Step 6 You are required to confirm the action.

Delete Primary and Secondary Passive Identity Agents

This task discusses how to delete primary and secondary passive identity agents. You must delete a secondary agent before you can delete a primary agent.

Procedure

Step 1 Log in to the Secure Firewall Management Center as an administrator.

Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.

Step 3 Click **Passive Identity Agent**.

Step 4 Click **Edit** (✎) next to a secondary agent to delete.

Step 5 Click **Delete**.

Step 6 You are required to confirm the action.

Step 7 If you wish to delete a primary agent, first delete all secondary agents.

Troubleshoot the Passive Identity Agent

This topic discusses how you can troubleshoot the passive identity agent software on your Windows AD domain controller or directory server.

(Optional.) Set the log level

By default, the passive identity agent logs at the INFO level. To optionally change the log level, open **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config** in a text editor, save the file, and restart the Cisco Passive Identity Agent service.

Do not rename the logging service

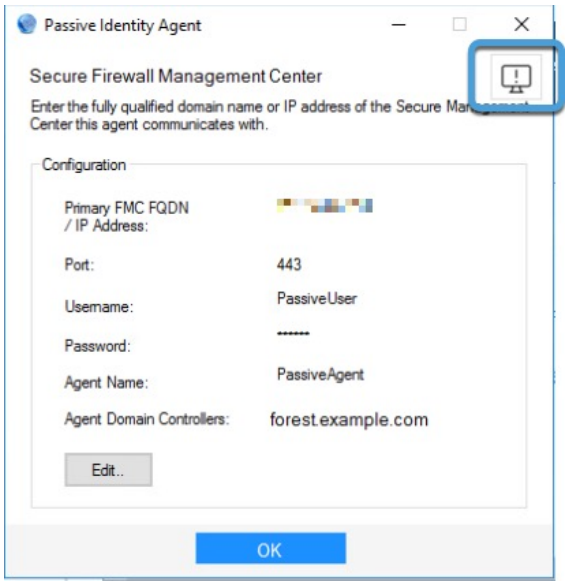
Do not rename **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config**; otherwise, the passive identity agent will stop generating log files. Do not remove or change the **.exe.config** file extension.

Generate troubleshooting files

To generate a .zip containing troubleshooting files:

1. Log in to the Microsoft Active Directory domain controller.
2. Start the passive identity agent software.
3. Click the Troubleshooting button in the top right corner of the window.

   The following figure shows an example.



A confirmation message is displayed.

Your troubleshoot logs are saved to your system's Downloads folder; the file name starts with **TroubleshootLogs**.

Manually view log files

Passive identity agent log files are stored in plain text format in the agent's installation directory: **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent**.

Use Notepad or another text editor to view these files. Log files rotate after reaching 10MB in size.

Use the Microsoft Active Directory event viewer

In the event you are not seeing user sessions in the Secure Firewall Management Center, you can look on your Microsoft Active Directory server's event viewers for the following Kerberos-related events:

- 4770
- 4768

For general information about audit policy, see Audit Policy Recommendations on learn.microsoft.com.

For more information about Windows Group Policy Object settings, see Group Policy Objects on learn.microsoft.com.

Security Requirements for the Passive Identity Agent

To safeguard the system, you should install the passive identity agent on a protected internal network. Although the passive identity agent is configured to have only the necessary services and ports available, you must make sure that attacks cannot reach it.

If the passive identity agent and the Secure Firewall Management Center reside on the same network, you can connect the Secure Firewall Management Center to the same protected internal network as the passive identity agent.

Regardless of how you deploy your appliances, inter-system communication is encrypted. However, you must still take steps to ensure that communications between appliances cannot be interrupted, blocked, or tampered with; for example, with a distributed denial of service (DDoS) or man-in-the-middle attack.

Internet Access Requirements for the Passive Identity Agent

By default, the passive identity agent is configured to communicate with the Firepower System over the internet using HTTPS on port 443/tcp (HTTPS). If you do not want the passive identity agent to have direct access to the internet, you can configure a proxy server.

The following information informs you of the ports the passive identity agent use to communicate with each other, with the Secure Firewall Management Center , and with Microsoft Active Directory.

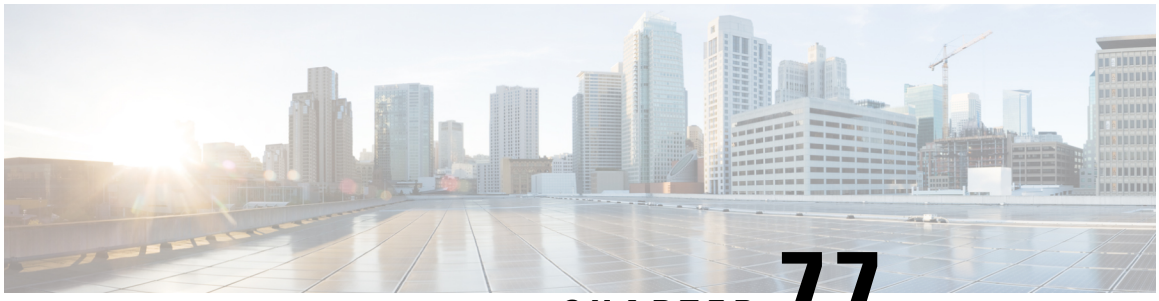
Table 137: Passive Identity Agent port requirements

Port	Reason
443	Communicate with the Secure Firewall Management Center .
135	Communicate with Microsoft Active Directory using the MSRPC protocol.
9095	Communicate with each other using the UDP protocol.

History for the Passive Identity Agent

Table 138: History for the Passive Identity Agent

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Passive Identity Agent	7.6	7.1	This feature is introduced. Passive Identity Agent version 1.1 is compatible with 7.6.0 and later and adds the following: • You can use either FQDN, IPv4, or IPv6 to connect from the Passive Identity Agent to the Secure Firewall Management Center or Cisco Security Cloud Control. • Sends both IPv4 and IPv6 user sessions from Microsoft Active Directory (AD) to the Firewall Management Center. • You can zip troubleshooting logs. • When you start the Passive Identity Agent software, a list of prerequisites is displayed. The Passive Identity Agent identity source sends session data from Microsoft Active Directory (AD) to the Firewall Management Center. Passive identity agent software is supported on: • Microsoft AD server (Windows Server 2008 or later) • Microsoft AD domain controller (Windows Server 2008 or later) • Any client connected to the domain you want to monitor (Windows 8 or later)



CHAPTER 77

User Control with ISE/ISE-PIC

The following topics discuss how to perform user awareness and user control with ISE/ISE-PIC:

- The ISE/ISE-PIC Identity Source, on page 2499
- License Requirements for ISE/ISE-PIC, on page 2501
- Requirements and Prerequisites for ISE/ISE-PIC, on page 2501
- ISE/ISE-PIC Guidelines and Limitations, on page 2501
- How to Configure ISE/ISE-PIC for User Control, on page 2504
- Configure ISE/ISE-PIC, on page 2506
- Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512
- Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues, on page 2521
- History for ISE/ISE-PIC, on page 2523

The ISE/ISE-PIC Identity Source

You can integrate your Cisco Identity Services Engine (ISE) or ISE Passive Identity Connector (ISE-PIC) deployment with the system to use ISE/ISE-PIC for passive authentication.

ISE/ISE-PIC is an authoritative identity source, and provides user awareness data for users who authenticate using Active Directory (AD), LDAP, RADIUS, or RSA. Additionally, you can perform user control on Active Directory users. ISE/ISE-PIC does not report failed login attempts or the activity of ISE Guest Services users.

In addition to user awareness and control, if you use ISE Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects. For more information, see Configure Dynamic Attributes Conditions. Also see ISE/ISE-PIC Guidelines and Limitations, on page 2501.

Note The system does not parse IEEE 802.1x machine authentication but it *does* parse 802.1x user authentication. If you are using 802.1x with ISE, you must include user authentication. 802.1x machine authentication will not provide a user identity to the Firewall Management Center that can be used in policy.

For more information on Cisco ISE/ISE-PIC, see the Cisco Identity Services Engine Passive Identity Connector Administrator Guide or the Cisco Identity Services Engine Administrator Guide.

Note We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set and the most number of issue fixes.

Source and Destination Security Group Tag (SGT) Matching

If you use Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects. For more information, see Configure Dynamic Attributes Conditions.

Matching on SGT tags provides the following benefits:

- The Firewall Management Center can subscribe to Security Group Tag eXchange Protocol (SXP) mappings from ISE.

  ISE uses SXP to propagate the IP-to-SGT mapping database to managed devices. When you configure Firewall Management Center to use an ISE server, you enable the option to listen to the SXP topic from ISE. This causes the Firewall Management Center to learn about the security group tags and mappings directly from ISE. The Firewall Management Center then publishes SGTs and mappings to managed devices.

  The SXP Topic receives security group tags based on static and dynamic mappings learned through the SXP protocol between ISE and other SXP compliant devices (like switches).

  You can create security group tags in ISE and assign host or network IP addresses to each tag. You can also assign SGTs to user accounts, and the SGT is assigned to the user's traffic. If the switches and routers in the network are configured to do so, these tags then get assigned to packets as they enter the network controlled by ISE, the Cisco TrustSec cloud.

  SXP is *not* supported by ISE-PIC.

- The Firewall Management Center and managed devices can learn about SGT mappings without deploying additional policy. (In other words, you can view connection events for SGT mappings without deploying an access control policy.)

- Supports Cisco TrustSec, which enables you to segment your network to protect critical business assets.

- When a managed device evaluates SGT as a traffic matching criteria for a rule, it uses the following priority:

  1. The source SGT tag defined in the packet, if any.

     For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

     For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

  2. The SGT assigned to the user session, as downloaded from the ISE session directory. The SGT can be matched to source or destination.

  3. The SGT-to-IP address mapping downloaded using SXP. If the IP address is in the range for an SGT, then the traffic matches the rule that uses the SGT. The SGT can be matched to source or destination.

Examples:

- In ISE, create an SGT tag named Guest Users and associate it with the 192.0.2.0/24 network.

  For example, you could use Guest Users as a source SGT condition in your access control rule and restrict access to certain URLs, web site categories, or networks from anyone who accesses your network.

- In ISE, create an SGT tag named Restricted Networks and associate it with the 198.51.100.0/8 network.

  For example, you could use Restricted Networks as a destination SGT rule condition and block access from Guest Users and other networks that have users who are not authorized to access the network.

ISE/ISE-PIC Guidelines and Limitations

Use the guidelines discussed in this section when configuring ISE/ISE-PIC.

ISE/ISE-PIC Version and Configuration Compatibility

Your ISE/ISE-PIC version and configuration affects its integration and interaction with the Secure Firewall Management Center, as follows:

- We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set.
- Synchronize the time on the ISE/ISE-PIC server and the Secure Firewall Management Center. Otherwise, the system might perform user timeouts at unexpected intervals.

- To implement user control using ISE or ISE-PIC data, configure and enable a realm for the ISE server assuming the pxGrid persona as described in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
- Each Secure Firewall Management Center host name that connects to an ISE server must be unique; otherwise, the connection to one of the Secure Firewall Management Centers will be dropped.
- If you configure ISE/ISE-PIC to monitor a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected.

  For any device running version 6.7 or later, you can optionally use the **configure identity-subnet-filter** command to limit the subnets that the managed device monitors. For more information, see the Cisco Secure Firewall Threat Defense Command Reference.

  Alternatively, you can configure a network object and apply that object as an Identity Mapping Filter in the identity policy. See Create an Identity Policy, on page 2555.

For the specific versions of ISE/ISE-PIC that are compatible with this version of the system, see the Cisco Firepower Compatibility Guide.

IPv6 support

- Compatible versions of ISE/ISE-PIC version 2.x include support for IPv6-enabled endpoints.
- Version 3.0 (patch 2) and later of ISE/ISE-PIC enables IPv6 communication between ISE/ISE-PIC and the Firewall Management Center.

Approve clients in ISE

Before a connection between the ISE server and the Firewall Management Center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the *Cisco Identity Services Engine Administrator Guide*.

Unreachable sessions are removed

If a user session in ISE/ISE-PIC is reported as unreachable, the > prunes that session so another user with the same IP cannot match the unreachable user's identity rules.
You can control this behavior in ISE/ISE-PIC by going to **Providers** > **Endpoint Probes** and clicking one of the following:

- **Enabled** to cause ISE/ISE-PIC to monitor endpoint connections and therefore to cause the Secure Firewall Management Center prune a session from an unreachable user.
- **Disabled** to cause ISE/ISE-PIC to ignore endpoint connections.

Security Group Tags (SGT)

A Security Group Tag (SGT) specifies the privileges of a traffic source within a trusted network. Cisco ISE and Cisco TrustSec use a feature called Security Group Access (SGA) to apply SGT attributes to packets as they enter the network. These SGTs correspond to a user's assigned security group within ISE or TrustSec. If you configure ISE as an identity source, the Firepower System can use these SGTs to filter traffic.

Security Group Tags can be used both as source and destination matching criteria in access control rules.

Note To implement user control using only the ISE SGT attribute tag, you do not need to configure a realm for the ISE server. ISE SGT attribute conditions can be configured in policies with or without an associated identity policy.

Note In some rules, custom SGT conditions can match traffic tagged with SGT attributes that were *not* assigned by ISE. This is not considered user control, and works only if you are not using ISE/ISE-PIC as an identity source; see Custom SGT Conditions.

To match destination SGT tags in addition to source SGT tags, the following apply:

Required ISE version: 2.6 patch 6 or later, 2.7 patch 2 or later

Router support: Any Cisco router that supports SGT inline tagging over Ethernet. For more information, consult a reference such as the Cisco Group Based Policy Platform and Capability Matrix Release

Limitations:

- Quality of Service (QoS) policy uses source SGT matching only; it does *not* use destination SGT matching
- RA-VPN does not receive SGT mappings directly through RADIUS

ISE and High Availability

When the primary ISE/ISE-PIC server fails, the following occurs:

As a result of the integration with pxGrid v2, the Secure Firewall Management Center round-robins between both configured ISE hosts until one accepts the connection.

If the connection is lost, the Secure Firewall Management Center resumes round-robin attempts to the connected hosts.

Endpoint Location (or Location IP)

An Endpoint Location attribute is the IP address of the network device that used ISE to authenticate the user, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Location (Location IP)**.

ISE Attributes

Configuring an ISE connection populates the Secure Firewall Management Center database with ISE attribute data. You can use the following ISE attributes for user awareness and user control. This is not supported with ISE-PIC.

Endpoint Profile (or Device Type)

An Endpoint Profile attribute is the user's endpoint device type, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Profile (Device Type)**.

How to Configure ISE/ISE-PIC for User Control

You can use ISE/ISE-PIC in any of the following configurations:

- With a realm, identity policy, and associated access control policy.

  Use a realm to control *user* access to network resources in policy. You can still use ISE/ISE-PIC Security Group Tags (SGT) metadata in your policies.

- With an access control policy only. No realm or identity policy are necessary.

  Use this method to control network access using SGT metadata alone.

Related Topics

How to Configure ISE/ISE-PIC Without a Realm, on page 2504
How to Configure ISE/ISE-PIC for User Control Using a Realm, on page 2505

How to Configure ISE/ISE-PIC Without a Realm

This topic provides a high-level overview of tasks you must complete to configure ISE to be able to allow or block access to the network using SGT tags.

Procedure

	Command or Action	Purpose
Step 1	SGT matching: Enable SXP on ISE.	This enables the Secure Firewall Management Center to receive updates from ISE when SGT metadata changes.
Step 2	Create the ISE/ISE-PIC identity source.	The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC. See Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512.
Step 3	Create an access control rule.	The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Introduction to Access Control Rules, on page 1773.
Step 4	Deploy the access control policy to managed devices.	Before your policy can take effect, it must be deployed to managed devices. See Deploy Configuration Changes, on page 259.

What to do next

Export Certificates from the ISE/ISE-PIC Server for Use in the Firewall Management Center, on page 2509

How to Configure ISE/ISE-PIC for User Control Using a Realm

Before you begin

This topic provides a high-level overview of tasks you must complete to configure ISE/ISE-PIC for user control and to be able to allow or block user or group access to the network. Users and groups can be stored in any server listed in Supported Servers for Realms, on page 2434.

Procedure

	Command or Action	Purpose
Step 1	Destination SGT only: Enable SXP on ISE.	This enables the Secure Firewall Management Center to receive updates from ISE when SGT metadata changes.
Step 2	Create a realm.	You must create a realm only to control access to the network by the users and groups you choose. See Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
Step 3	Download users and groups, and enable the realm.	Downloading users and groups enables you to use them in access control rules. See Synchronize Users and Groups, on page 2445.
Step 4	Create the ISE/ISE-PIC identity source.	The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC. See Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512.
Step 5	Create an identity policy.	An identity policy is a container for one or more identity rules. See Create an Identity Policy, on page 2555.
Step 6	Create an identity rule.	An identity rule specifies how a realm is used to control access to the network by users and groups. See Create an Identity Rule, on page 2563.
Step 7	Associate the identity policy with an access control policy.	This enables the access control policy to use users and groups in the realm.
Step 8	Create an access control rule.	The access control rule specifies an action to take (for example, allow or block) if traffic

	Command or Action	Purpose
		matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Introduction to Access Control Rules, on page 1773.
Step 9	Deploy the access control policy to managed devices.	Before your policy can take effect, it must be deployed to managed devices. See Deploy Configuration Changes, on page 259.

What to do next

Export Certificates from the ISE/ISE-PIC Server for Use in the Firewall Management Center, on page 2509

Configure ISE/ISE-PIC

The following topics discuss how to configure the ISE/ISE-PIC server for use with identity policies in the Firewall Management Center.

The topics discuss how to:

- (Cisco ISE advanced configuration only.) Export certificates from the ISE/ISE-PIC server to authenticate with the Firewall Management Center.
- Publish SXP topics so the Firewall Management Center can be updated with Security Group Tags (SGT) on the ISE server.

Related Topics

Configure Security Groups and SXP Publishing in ISE, on page 2506
Export Certificates from the ISE/ISE-PIC Server for Use in the Firewall Management Center, on page 2509

Configure Security Groups and SXP Publishing in ISE

There is a lot of configuration that you must do in Cisco Identity Services Engine (ISE) to create the TrustSec policy and security group tags (SGT). Please look at the ISE documentation for more complete information on implementing TrustSec.

The following procedure picks out the highlights of the core settings you must configure in ISE for the Firewall Threat Defense device to be able to download and apply static SGT-to-IP address mappings, which can then be used for source and destination SGT matching in access control rules. See the ISE documentation for detailed information.

The screen shots in this procedure are based on ISE 2.4. The exact paths to these features might change in subsequent releases, but the concepts and requirements will be the same. Although ISE 2.4 or later is recommended, and preferably 2.6 or later, the configuration should work starting with ISE 2.2 patch 1.

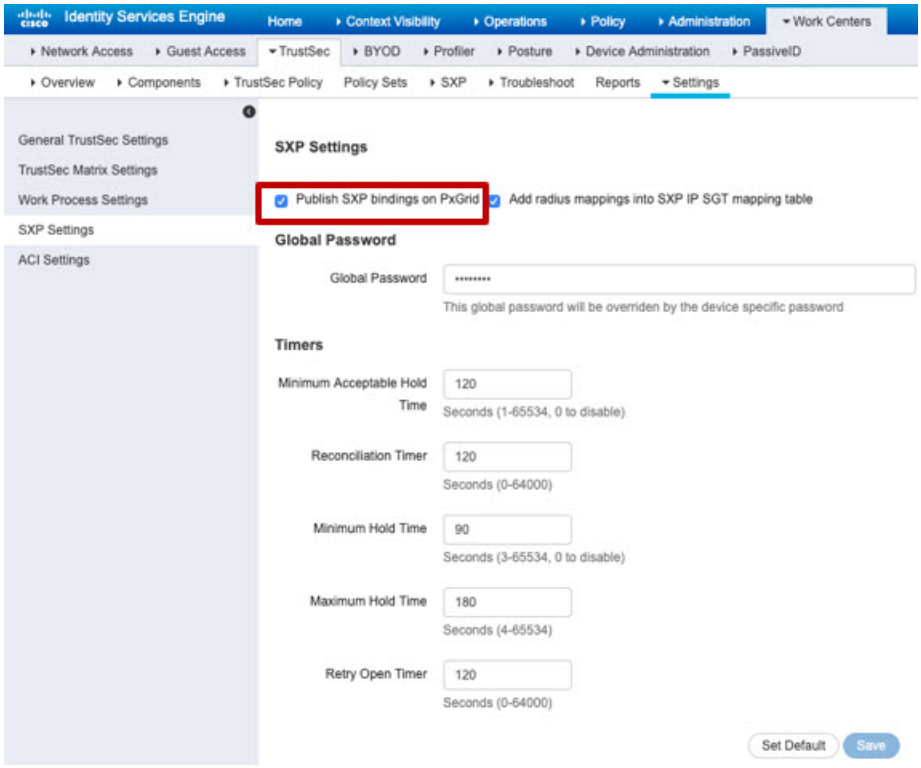
Before you begin

You must have the ISE Plus license to publish SGT-to-IP address static mappings and to get user session-to-SGT mappings so that the Firewall Threat Defense device can receive them.

Procedure

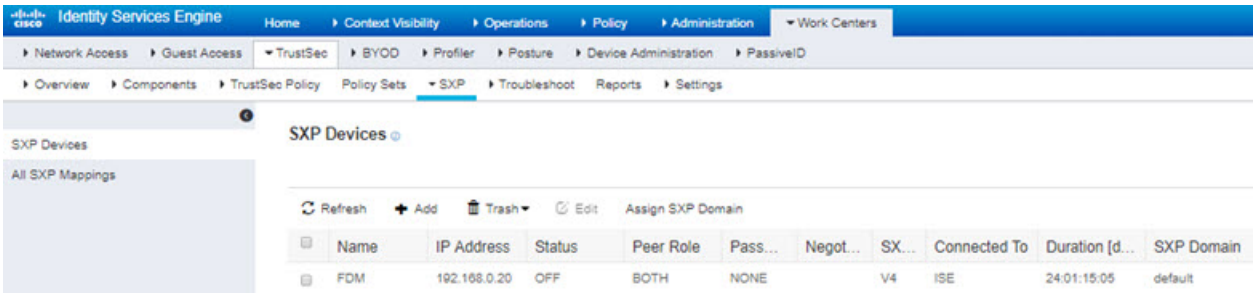
Step 1 Choose **Work Centers** > **TrustSec** > **Settings** > **SXP Settings**, and select the **Publish SXP Bindings on PxGrid** option.

This option makes ISE send the SGT mappings out using SXP. You must select this option for the Firewall Threat Defense device to "hear" anything from listing to the SXP topic. This option must be selected for the Firewall Threat Defense device to get static SGT-to-IP address mapping information. It is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

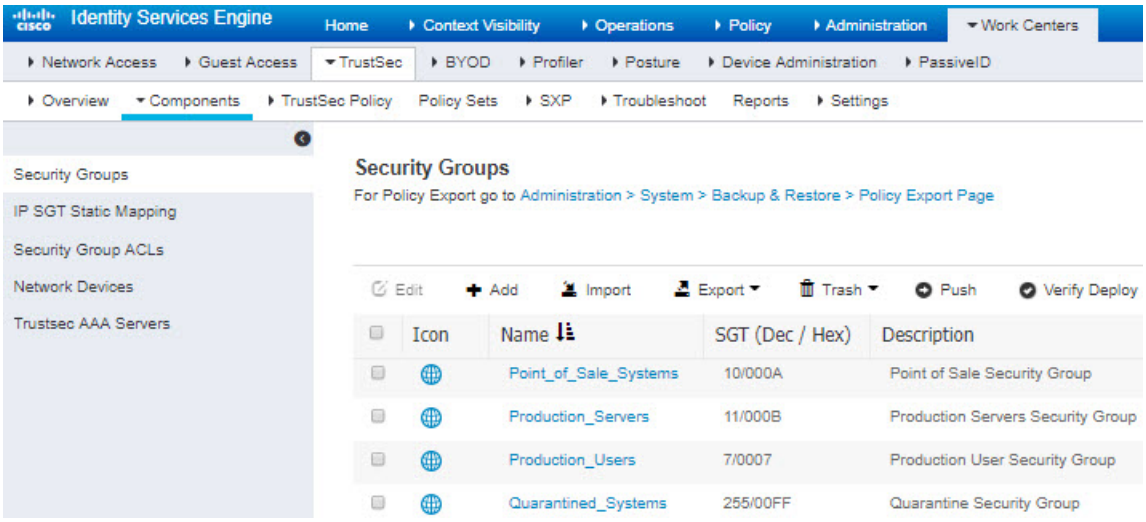


Step 2 Choose **Work Centers** > **TrustSec** > **SXP** > **SXP Devices**, and add a device.

This does not have to be a real device, you can even use the management IP address of the Firewall Threat Defense device. The table simply needs at least one device to induce ISE to publish the static SGT-to-IP address mappings. This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

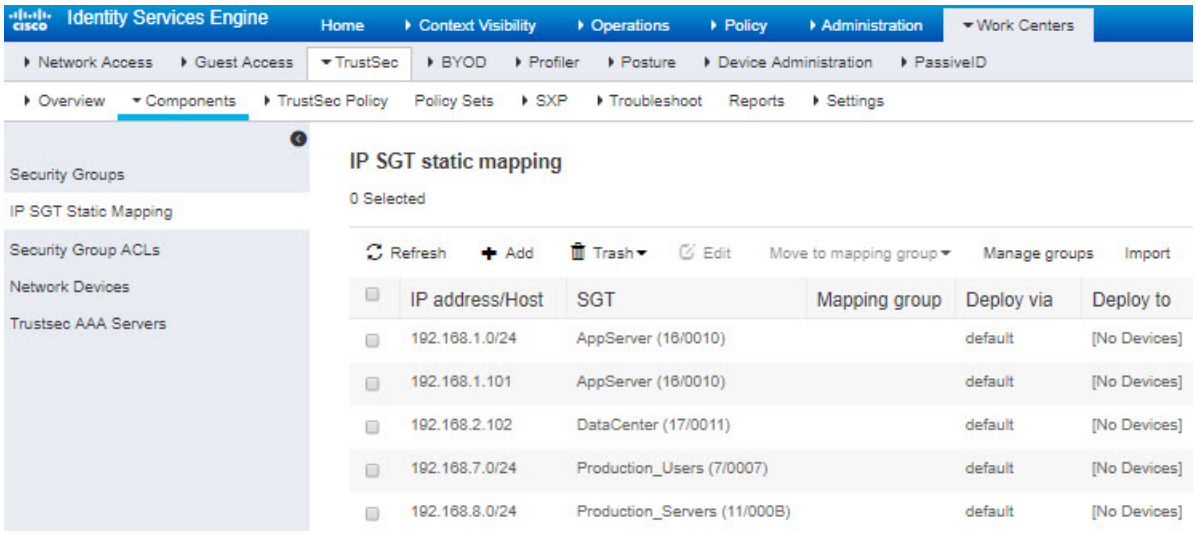


Step 3 Choose **Work Centers** > **TrustSec** > **Components** > **Security Groups** and verify there are security group tags defined. Create new ones as necessary.



Step 4 Choose **Work Centers** > **TrustSec** > **Components** > **IP SGT Static Mapping** and map host and network IP addresses to the security group tags.

This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.



Export Certificates from the ISE/ISE-PIC Server for Use in the Firewall Management Center

The following sections discuss how to:

- Export system certificates from the ISE/ISE-PIC server.

  These certificates are required to securely connect to the ISE/ISE-PIC server. You might need to export one, or as many as three, certificates, depending on how your ISE system is set up:

  - One certificate for the pxGrid server
  - One certificate for the monitoring (MNT) server
  - One certificate, including the private key, for the pxGrid client (that is, the Firewall Management Center)

    Unlike the first two certificates, this is a self-signed certificate.

- Import these certificates into the Firewall Management Center:
  - pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
  - pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
  - MNT certificate: trusted CA

Related Topics

Export a System Certificate
Import ISE/ISE-PIC Certificates, on page 2511

Export a System Certificate

You can export a system certificate or a certificate and its associated private key. If you export a certificate and its private key for backup purposes, you can reimport them later if needed.

Before you begin

To perform the following task, you must be a Super Admin or System Admin.

Procedure

Step 1 In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration** > **System** > **Certificates** > **System Certificates**.

Step 2 Check the check box next to the certificate that you want to export and click **Export**.

Step 3 Choose whether to export only the certificate, or the certificate and its associated private key.

Tip
We do not recommend exporting the private key that is associated with a certificate because its value may be exposed. If you must export a private key (for example, when you export a wildcard system certificate to be imported into the other Cisco ISE nodes for inter-node communication), specify an encryption password for the private key. You must specify this password while importing this certificate into another Cisco ISE node to decrypt the private key.

Step 4 Enter the password if you have chosen to export the private key. The password should be at least eight characters long.

Step 5 Click **Export** to save the certificate to the file system that is running your client browser.

If you export only the certificate, the certificate is stored in the PEM format. If you export both the certificate and private key, the certificate is exported as a .zip file that contains the certificate in the PEM format and the encrypted private key file.

Generate a Self-Signed Certificate

Add a new local certificate by generating a self-signed certificate. Cisco recommends that you only employ self-signed certificates for your internal testing and evaluation needs. If you plan to deploy Cisco ISE in a production environment, use CA-signed certificates whenever possible to ensure more uniform acceptance around a production network.

Note If you use a self-signed certificate and you want to change the hostname of your Cisco ISE node, log in to the administration portal of the Cisco ISE node, delete the self-signed certificate that has the old hostname, and generate a new self-signed certificate. Otherwise, Cisco ISE continues to use the self-signed certificate with the old hostname.

Before you begin

To perform the following task, you must be a Super Admin or System Admin.

Procedure

Step 1 In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration** > **System** > **Certificates** > **System Certificates**.

To generate a self-signed certificate from a secondary node, choose **Administration** > **System** > **Server Certificate**.

Step 2 In the ISE-PIC GUI, click the **Menu** icon (☰) and choose **Certificates** > **System Certificates**.

Step 3 Click **Generate Self Signed Certificate** and enter the details in the window displayed.

Step 4 Check the check boxes in the **Usage** area based on the service for which you want to use this certificate.

Step 5 Click **Submit** to generate the certificate.

To restart the secondary nodes, from the CLI, enter the following commands in the following order:

a) **application stop ise**
b) **application start ise**

Import ISE/ISE-PIC Certificates

This procedure is optional. You can also import the certificates automatically by providing login credentials to your ISE server as discussed in Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512.

Import the certificates as followed:

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Before you begin

(Optional.) Export certificates from the ISE/ISE-PIC server as discussed in Export a System Certificate, on page 2510. The certificates and key must be present on the machine from which you log in to the Secure Firewall Management Center.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you have not already done so.

Step 2 Click **Objects** > **Object Management** > **PKI** > **Internal Certs**.

Step 3 Click **Add Internal Cert**.

Step 4 Follow the prompts on your screen to import the certificate and private key.

Step 5 Click **Trusted CAs**.

Step 6 Click **Add Trusted CA**.

Step 7 Follow the prompts on your screen to import the pxGrid server certificate.

Step 8 Repeat the preceding steps, if necessary, to import the MNT server's trusted CA.

What to do next

Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512

Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source

You can configure the Cisco ISE identity source in any of the following ways:

- Quick configuration (new): *Cisco ISE only; not supported for ISE-PIC*. Enter the user name and password of a user in at least the External RESTful Services (ERS) Operator group. The Secure Firewall Management Center logs into the Cisco ISE Primary Authentication Node (PAN), downloads the certificates, and configures the identity source. You have the option of saving the ISE configuration for later use.

  For more information about groups, see the section on Cisco ISE Administrator Groups in the Cisco Identity Services Engine Administrator Guide.

  For details, see Quick Configuration, on page 2514.

- Advanced configuration (old): Same as previous Secure Firewall Management Center releases and works for both Cisco ISE and ISE-PIC. You must get certificates and other information from your ISE/ISE-PIC server as discussed in Configure ISE/ISE-PIC, on page 2506.

  For details about advanced configuration, see Cisco ISE Advanced Configuration, on page 2518.

Related Topics

About Cisco ISE Quick Configuration, on page 2512
Cisco ISE Advanced Configuration, on page 2518

About Cisco ISE Quick Configuration

Complete these tasks first: Prerequisites for ISE Quick Configuration, on page 2513.

You must have the following information:

- Fully qualified domain name or IP address of the policy administration node (PAN).
- User name and password of a user in at least the External RESTful Services (ERS) Operator group.

Note the following about SGT-to-IP mappings and SXP:

- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:
  - To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in Create and Edit Access Control Rules, on page 1783. Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.

- To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.

Quick Configuration, on page 2514
About Cisco ISE Quick Configuration, on page 2512
Cisco ISE Advanced Configuration, on page 2518

Prerequisites for ISE Quick Configuration

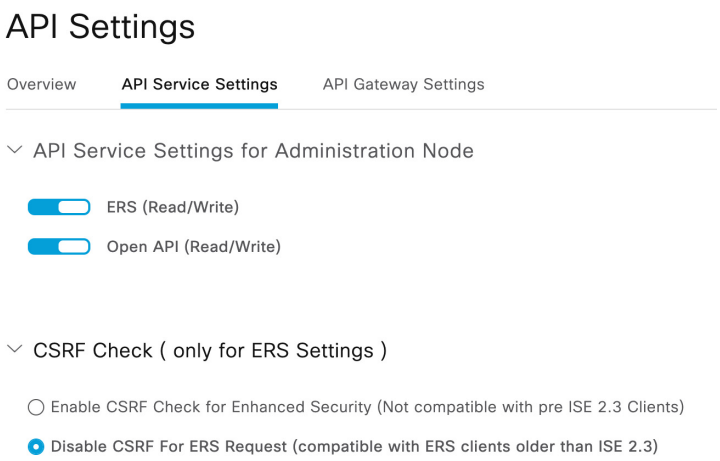
For ISE quick configuration to succeed, you mst do both of the following as an ISE administrator:

- Enable External RESTful Services (ERS) (read/write), Open API (read/write), and *disable* the Cross-Site Request Forgery (CSRF) check

  Go to > **Administration** > **System** > **Settings** > **API Settings** > **API Service Settings**

  For more information, see Enable API Service in the Cisco Identity Services Engine Administrator Guide.

  The following figure shows an example.



- Slide **ERS (Read/Write)** to **Enabled**.
- Enable the certificate authority

  Go to > **Administration** > **System** > **Certificates** > **Certificate Authority** > **Internal CA Settings**

  For more information, see Internal CA Settings in the Cisco Identity Services Engine Administrator Guide.

  The following figure shows an example.

Cisco ISE Advanced Configuration, on page 2518

Quick Configuration

This task discusses how to configure Cisco ISE (but not ISE-PIC) by entering a user name and password. The Secure Firewall Management Center then logs in to ISE and downloads the necessary certificates to authenticate the two applications.

Firewall Threat Defense Feature History:

7.6—This feature is introduced.

Before you begin

See the following topics first:

- About Cisco ISE Quick Configuration, on page 2512
- Prerequisites for ISE Quick Configuration, on page 2513

Procedure

Step 1 Log in to the Secure Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.

Step 3 Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.

Note
To disable the connection, click **None**.

Step 4 Click **Quick Configuration (New)**.

Step 5 In the **Primary PAN FQDN/IP Address** field, enter the fully qualified domain name or IP address of the policy administration node (PAN). Do *not* enter a scheme (such as **https://**).

Step 6 In the **Username** field, enter the user name of a user in at least the ERS Operator group.

For more information about groups, see the section on Cisco ISE Administrator Groups in the Cisco Identity Services Engine Administrator Guide.

Step 7 In the **Password** field, enter the user's password.

Step 8 (Optional.) Enter an **ISE Network Filter** using CIDR block notation.

Step 9 In the Subscribe To section, check the following:

- **Session Directory Topic** to receive ISE user session information from the ISE server.
- **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.

Step 10 To test the connection, click **Test**.

Connection and integration results are discussed in Cisco Identity Services Engine (Cisco ISE) Quick Configuration Results, on page 2515.

Step 11 (Optional.) After a successful trest, click **Save this Config** at the top of the page to save the configuration on the Secure Firewall Management Center.

What to do next

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2555.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1762.
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.

  For more information, see Configure Dynamic Attributes Conditions.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 259.
- Monitor user activity as discussed in *Using Workflows* in the Cisco Secure Firewall Management Center Administration Guide.

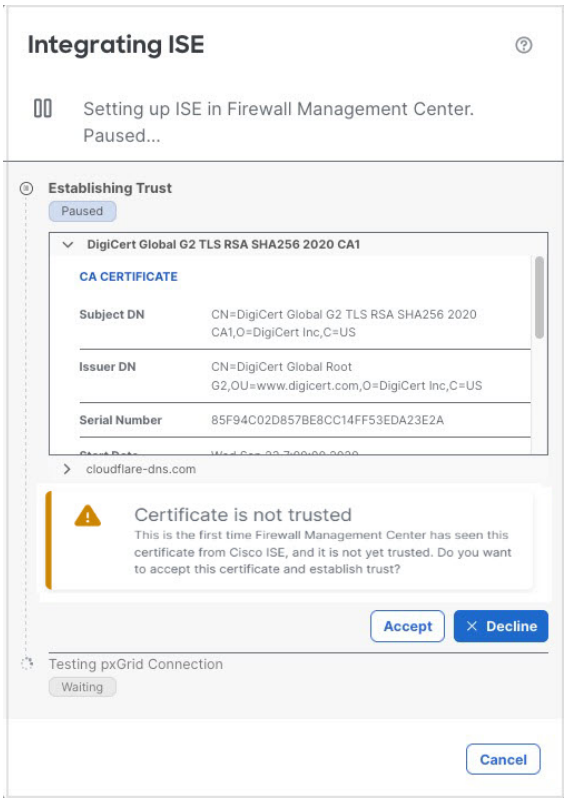
Cisco Identity Services Engine (Cisco ISE) Quick Configuration Results

Initial information page for an untrusted certificate

When you enter required information in the **Quick Configuration (New)** tab page, the system first checks to see if the certificate was signed by a trusted authority. If not, a page similar to the following is displayed.



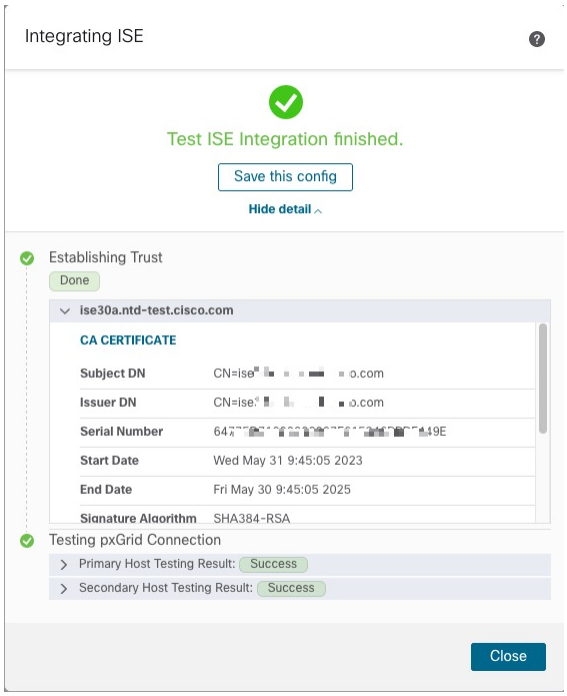
You have the following options:

- Click **Accept** for the > to trust the certificate and continue authenticating with ISE.
- Click **Decline** to quit without authenticating with ISE.

  You can then verify the ISE configuration on the **Quick Configuration (New)** tab page and try again.

Successful ISE integration

If the Secure Firewall Management Center was able to authenticate successfully with the information you provided, a page similar to the following is displayed.

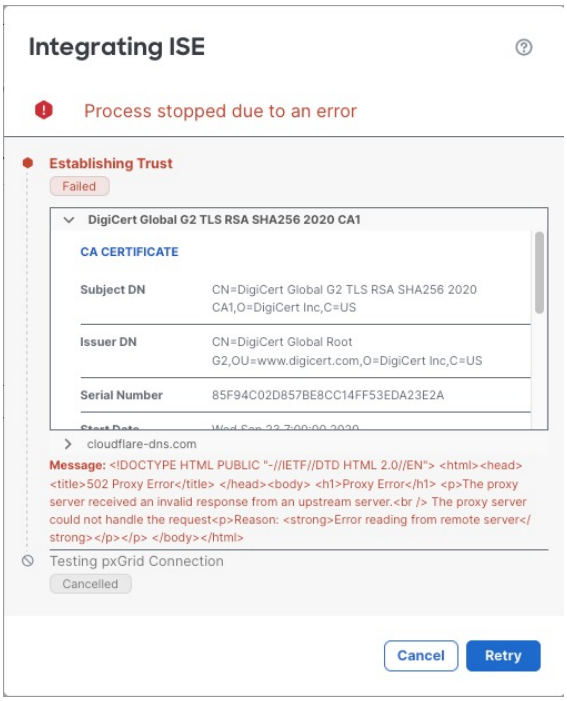


Click **Save this Config** to save it and be able to use the identity source in the future.

Optionally expand one of the lists under Testing pxGrid Connection to display certificates downloaded from those sources.

Unsuccessful ISE integration

If the Secure Firewall Management Center fails to authenticate with ISE for any reason, a page similar to the following is displayed.



The error messages are displayed in red text.

You have the following options:

- If the error is temporary (for example, a temporarily network issue), click **Retry**.
- To try again with different ISE credentials, click **Cancel**.

Cisco ISE Advanced Configuration

The following procedure discusses how to configure the ISE/ISE-PIC identity source. You must be in the global domain to perform this task.

Before you begin

- To get user sessions from a Microsoft Active Directory Server or supported LDAP server, configure and enable a realm for the Cisco ISE server, assuming the pxGrid persona, as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:
  - To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in Create and Edit Access Control Rules, on page 1783. Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.

- To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.

- (Advanced configuration only.) Export certificates from the ISE/ISE-PIC server and optionally import them into the Secure Firewall Management Center as discussed in Export Certificates from the ISE/ISE-PIC Server for Use in the Firewall Management Center, on page 2509.
- To publish SXP topics so the Secure Firewall Management Center can be updated with Security Group Tags (SGT) on the ISE server, see Configure ISE/ISE-PIC, on page 2506.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.

Step 3 Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.

Note
To disable the connection, click **None**.

Step 4 Enter a **Primary Host Name/IP Address** and, optionally, a **Secondary Host Name/IP Address**.

Step 5 Click the appropriate certificate authorities from the **pxGrid Server CA** and **MNT Server CA** lists, and the appropriate certificate from the **pxGrid Client Certificate** list. You can also click **Add** (+) to add a certificate.

Note
The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

Step 6 (Optional.) Enter an **ISE Network Filter** using CIDR block notation.

Step 7 In the Subscribe To section, check the following:

- **Session Directory Topic** to receive ISE user session information from the ISE server.
- **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.

Step 8 To test the connection, click **Test**.

If the test fails, click **Additional Logs** for more information about the connection failure.

Note
If you set up load balancing with ISE, the node that responds to the test should be the currently active node. For more information, see Cisco pxGrid Node.

What to do next

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2555.

- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1762.
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.

  For more information, see Configure Dynamic Attributes Conditions.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 259.
- Monitor user activity as discussed in *Using Workflows* in the Cisco Secure Firewall Management Center Administration Guide.

ISE/ISE-PIC Configuration Fields

The following fields are used to configure a connection to /ISE-PIC.

Primary and Secondary Host Name/IP Address

The hostname or IP address for the primary and, optionally, the secondary pxGrid ISE servers.

The ports used by the host names you specify must be reachable by both ISE and the Secure Firewall Management Center.

pxGrid Server CA

The trusted certificate authority for the pxGrid framework. If your deployment includes a primary and a secondary pxGrid node, the certificates for both nodes must be signed by the same certificate authority.

MNT Server CA

The trusted certificate authority for the ISE certificate when performing bulk downloads. If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

pxGrid Client Certificate

The internal certificate and key that the Secure Firewall Management Center must provide to /ISE-PIC to connect to /ISE-PIC or to perform bulk downloads.

Note The **pxGrid Client Certificate** must include the clientAuth extended key usage value, or it must not include any extended key usage values.

ISE Network Filter

An optional filter you can set to restrict the data that ISE reports to the Secure Firewall Management Center. If you provide a network filter, ISE reports data from the networks within that filter. You can specify a filter in the following ways:

- Leave the field blank to specify **`any`**.
- Enter a single IPv4 address block using CIDR notation.

- Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

Note This version of the system does not support filtering using IPv6 addresses, regardless of your ISE version.

Subscribe to:

Session Directory Topic: Check this box to subscribe to user session information from the ISE server. Includes SGT and endpoint metadata.

Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues

Troubleshoot Cisco TrustSec issues

A device interface can be configured to propagate Security Group Tags (SGTs) either from ISE/ISE-PIC or from a Cisco device on the network (referred to as Cisco TrustSec.) On the device management page (**Devices** > **Device Management**), the **Propagate Security Group Tag** check box for an interface is disabled by default. If you want the interface to propagate TrustSec data, check the box.

Troubleshoot ISE/ISE-PIC issues

For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2456 and Troubleshoot User Control, on page 2573.

If you experience issues with the ISE or ISE-PIC connection, check the following:

- The pxGrid Identity Mapping feature in ISE must be enabled before you can successfully integrate ISE with the system.
- When the primary server fails, you must manually promote the secondary to primary; there is no automatic failover.
- Before a connection between the ISE server and the Firewall Management Center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

  You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the Cisco Identity Services Engine Administrator Guide.
- The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.
- The time on your ISE server must be synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

- If your deployment includes a primary and a secondary pxGrid node,
  - The certificates for both nodes must be signed by the same certificate authority.
  - The ports used by the host name must be reachable by both the ISE server and by the Secure Firewall Management Center.
- If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

To exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE, use the **configure identity-subnet-filter** {**add** | **remove**} command. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

If you experience issues with user data reported by ISE or ISE-PIC, note the following:

- After the system detects activity from an ISE user whose data is not yet in the database, the system retrieves information about them from the server. Activity seen by the ISE user is *not* handled by access control rules, and is *not* displayed in the web interface until the system successfully retrieves information about them in a user download.
- You cannot perform user control on ISE users who were authenticated by an LDAP, RADIUS, or RSA domain controller.
- The Secure Firewall Management Center does not receive user data for ISE Guest Services users.
- If ISE monitors the same users as TS Agent, the Secure Firewall Management Center prioritizes the TS Agent data. If the TS Agent and ISE report identical activity from the same IP address, only the TS Agent data is logged to the Secure Firewall Management Center.
- Your ISE version and configuration impact how you can use ISE in the system. For more information, see The ISE/ISE-PIC Identity Source, on page 2499.
- If you have Secure Firewall Management Center high availability configured and the primary fails, see the section on ISE and high availability in ISE/ISE-PIC Guidelines and Limitations, on page 2501.
- ISE-PIC does not provide ISE attribute data.
- ISE-PIC cannot perform ISE ANC remediations.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

If you experience issues with supported functionality, see The ISE/ISE-PIC Identity Source, on page 2499 for more information about version compatibility.

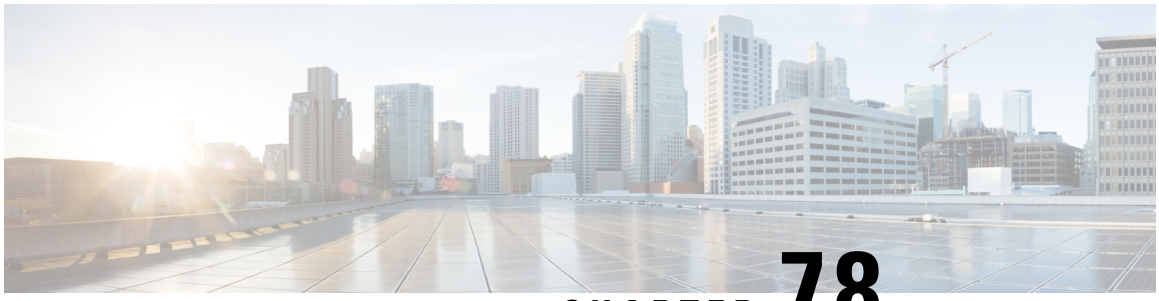
ISE/ISE-PIC user timeout

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the Secure Firewall Management Center. For more information, see Realm Fields, on page 2436.

History for ISE/ISE-PIC

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Quick configuration	7.6	7.6.0	You can optionally configure ISE using only the user name and password of a user in the External RESTful Services (ERS) Operator group. (*This feature is available for ISE only, not ISE-PIC.*) **Upgrade impact**. Any ISE or ISE-PIC identity source you created before upgrade is still available on the **Advanced Configuration (Old)** tab page. Quick configuration affects only new ISE identity sources created after the upgrade. New/modified screens: **Integration** > **Other Integrations** > **Identity Sources** > **Identity Services Engine**. There are two tab pages: **Quick Configuration (New)** and **Advanced Configuration (Old)**. New/modified CLI commands: none
pxGrid 2.0 is the default for supported ISE/ISE-PIC versions	6.7.0	6.7.0	Note the following: • Supported ISE/ISE-PIC versions: 2.6 patch 6 or later, 2.7 patch 2 or later • Adaptive Network Control (ANC) policies replace Endpoint Protection Service (EPS) remediations. If you have EPS policies configured in the Firewall Management Center, you must migrate them to use ANC.
Optionally exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.	6.7.0	6.7.0	New command: **configure identity-subnet-filter** {**add** | **remove**}

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Destination Security Group Tag matching (SGT)	6.5.0	6.5.0	Feature introduced. Enables you to use ISE SGT tags for both source and destination matching criteria in access control rules. SGT tags are tag-to-host/network mappings obtained by ISE. New/modified screens: • New options to configure Destination SGT matching: **System** > **Integration** > **Identity Sources** > **ISE/ISE-PIC** • **Session Directory Topic**: Subscribe to ISE user session information. • **SXP Topic**: Subscribe to SGT tag updates on the ISE server. • New and renamed columns in **Analysis** > **Connections** > **Events** • Renamed: Security Groups Tags renamed to Source SGT • New: Destination SGT
Integration with ISE-PIC	6.2.1	6.2.1	You can now use data from ISE-PIC.
SGT tags for user control.	6.2.1	6.2.0	You no longer need to create a realm or identity policy to perform user control based on ISE Security Group Tag (SGT) data.
Integration with ISE.	6.0	6.0	Feature introduced. By subscribing to Cisco's Platform Exchange Grid (PxGrid), the Firepower Management Center can download additional user data, device type data, device location data, and Security Group Tags (SGTs) —a method used by ISE to provide network access control).



CHAPTER 78

User Control with Captive Portal

- The Captive Portal Identity Source, on page 2525
- License Requirements for Captive Portal, on page 2526
- Requirements and Prerequisites for Captive Portal, on page 2526
- Captive Portal Guidelines and Limitations, on page 2526
- How to Configure the Captive Portal for User Control, on page 2529
- Troubleshoot the Captive Portal Identity Source, on page 2541
- History for Captive Portal, on page 2543

The Captive Portal Identity Source

Captive portal is one of the authoritative identity sources supported by the system. Captive portal is an active authentication method where users authenticate onto the network using a managed device. (RA-VPN is another type of active authentication.) Active authentication differs from passive authentication in that the user is presented with a login page by the managed device, whereas passive authentication queries the authentication realm (for example, Microsoft AD) to authenticate the user.

You typically use captive portal to require authentication to access the internet or to access restricted internal resources; you can optionally configure guest access to resources. After the system authenticates captive portal users, it handles their user traffic according to access control rules. Captive portal performs authentication on HTTP and HTTPS traffic only.

Note To use a Microsoft Azure AD (SAML) realm for captive portal, see Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal), on page 2412.

Note HTTPS traffic must be decrypted before captive portal can perform authentication.

Captive portal also records failed authentication attempts. A failed attempt does not add a new user to the list of users in the database. The user activity type for failed authentication activity reported by captive portal is **Failed Auth User**.

The authentication data gained from captive portal can be used for user awareness and user control.

Related Topics

How to Configure the Captive Portal for User Control, on page 2529

About Hostname Redirect

(Snort 3 only.) An active authentication identity rule redirects to the captive portal port using its configured interface. Because the redirect is typically done to an IP address, the user gets an untrusted certificate error and because this behavior is similar to a man-in-the-middle attack, users might be reluctant to accept the untrusted certificate.

To avoid this problem, you can configure the captive portal to use the managed device's fully-qualified domain name (FQDN). With a properly configured certificate, users will not get an untrusted certificate error, and the authentication will be more seamless and appear to be more secure.

Captive Portal Guidelines and Limitations

When you configure and deploy captive portal in an identity policy, users from specified realms authenticate using Firewall Threat Defense to access your network.

Note When a remote access VPN user has already actively authenticated through a managed device acting as a secure gateway, captive portal active authentication will not occur, even if configured in an identity policy.

Captive portal and policies

You configure captive portal in your identity policy and invoke active authentication in your identity rules. Identity policies are associated with access control policies and access control policies define access to resources in the network. For example, you might exclude users in the US-West/Finance group to access Engineering servers or you can prohibit users from accessing nonsecure applications on the network.

You configure some captive portal identity policy settings on the identity policy's **Active Authentication** tab page and configure the rest in the identity rule associated with the access control policy.

An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected. In each case the system transparently enables or disables TLS/SSL decryption, which restarts the Snort process.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

For more information about synchronizing users and groups, see Synchronize Users and Groups, on page 2445.

Routed interface required

Captive portal active authentication can be performed only by a device with a routed interface configured. If you are configuring an identity rule for captive portal and your captive portal device contains inline and routed interfaces, you must configure interface rule conditions in the access control policy to target only the routed interfaces on the device.

If the identity policy associated with your access control policy contains one or more captive portal identity rules and you deploy the policy on the Secure Firewall Management Center that manages one or more devices with routed interfaces configured, the policy deployment succeeds and the routed interfaces perform active authentication.

Required certificate and certificate authorities

Before you can use the captive portal for user control and awareness, you must have all of the following:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Secure Firewall Management Center as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

You can create the internal certificate and internal certificate authority at the time you create a decryption policy.

Captive portal requirements and limitations

Note the following requirements and limitations:

- Captive portal does not support HTTP/3 QUIC connections.
- The system supports up to 20 captive portal logins per second.
- There is a maximum five minute limit between failed login attempts for a failed login attempt to be counted toward the count of maximum login attempts. The five minute limit is not configurable.

  (Maximum login attempts are displayed in connection events: **Analysis** > **Connections**.)

  If more than five minutes elapse between failed logins, the user is redirected to captive portal for authentication and will not be designated a failed login user or a guest user, and will not be reported to the Secure Firewall Management Center.
- Captive portal does not negotiate TLS v1.0 connections.

  Only TLS v1.1, v1.2, and TLS 1.3 connections are supported.
- To securely log a user out of captive portal and prevent the user from logging in again, an administrator can close their session: **Analysis** > **Users heading** > **Active Sessions**. If the user closes their browser, the browser does not reauthenticate automatically.
- If a realm is created for a parent domain and the managed device detects a login to a child of that parent domain, the user's subsequent logout is not detected by the managed device.
- Your access control rule must allow traffic destined for the IP address and port of the device you plan to use for captive portal.
- To perform captive portal active authentication on HTTPS traffic, you must use a decryption policy to decrypt the traffic from the users you want to authenticate. You cannot decrypt the traffic in the connection between a captive portal user's web browser and the captive portal daemon on the managed device; this connection is used to authenticate the captive portal user.
- To limit the amount of non-HTTP or HTTPS traffic that is allowed through the managed device, you should enter typical HTTP and HTTPS ports in the identity policy's **Ports** tab page.

  The managed device changes a previously unseen user from **`Pending`** to **`Unknown`** when it determines that the incoming request does not use the HTTP or HTTPS protocol. As soon as the managed device changes a user from **`Pending`** to another state, access control, Quality of Service, and decryption policies can be applied to that traffic. If your other policies don't permit non-HTTP or HTTPS traffic, configuring ports on the captive portal identity policy can prevent undesired traffic from being allowed through the managed device.

Kerberos prerequisites

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

How to Configure the Captive Portal for User Control

Before you begin

To use the captive portal for active authentication, you must set up an LDAP realm; or a Microsoft AD realm or realm sequence; Microsoft Azure AD (SAML) realm; access control policy; an identity policy; a decryption policy; and associate the identity and decryption policies with the same access control policy. Finally, you must deploy the policies to managed devices. This topic provides a high-level summary of those tasks.

Note To use a Microsoft Azure AD (SAML) realm as a captive portal, see How to Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal), on page 2403.

Perform the following tasks first:

- Confirm that your Secure Firewall Management Center manages one or more devices with a *routed* interface configured.
- To use encrypted authentication with the captive portal, either create a PKI object for the authenticating managed device or have your certificate data and key available on the machine from which you're accessing the Secure Firewall Management Center. To create a PKI object, see PKI, on page 1404.

Procedure

Step 1 Create and enable an LDAP realm; or a Microsoft AD realm and optionally realm sequence as discussed in the following topics:

- Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426
- Synchronize Users and Groups, on page 2445

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

For more information, see Synchronize Users and Groups, on page 2445.

Step 2 Get required certificates and certificate authorities.
You must have all of the following:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Secure Firewall Management Center as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

You can create the internal certificate and internal certificate authority at the time you create a decryption policy.

Step 3 Create a network object with an associated trusted certificate authority.

See Configure the Captive Portal Part 1: Create a Network Object, on page 2531.

Step 4 Create identity policy with an active authentication rule.

The identity policy enables selected users in your realm access resources after authenticating with the captive portal.

For more information, see Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2532.

Step 5 Configure an access control rule for the captive portal that allows traffic on the captive portal port (by default, TCP 885).

You can choose any available TCP port for the captive portal to use. Whatever your choice, you must create a rule that allows traffic on that port.

For more information, see Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2534.

Step 6 Add another access control rule to allow users in the selected realm or realm sequence to access resources using the captive portal.

For more information, see Configure the Captive Portal Part 4: Create a User Access Control Rule, on page 2535.

Step 7 Configure a decryption policy with a **Decrypt - Resign** rule for the **Unknown** user so captive portal users can access web pages using the HTTPS protocol.

The captive portal can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the captive portal. The captive portal itself is seen by the system as the **Unknown** user.

Captive Portal Example: Create a Decryption Policy with an Outbound Rule, on page 2536

Step 8 Associate the identity and decryption policies with the access control policy from step 3.

This final step enables the system to authenticate users with the captive portal.

For more information, see Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy, on page 2538.

What to do next

See Configure the Captive Portal Part 1: Create a Network Object, on page 2531.

Related Topics

Exclude Applications from Captive Portal, on page 2540
PKI, on page 1404
Troubleshoot the Captive Portal Identity Source, on page 2541
Snort Restart Scenarios, on page 252

Configure the Captive Portal Part 1: Create a Network Object

This task discusses how to start configuring the captive portal as an identity source.

Before you begin

(Snort 3 only.) Create a fully-qualified host name (FQDN) using your DNS server and upload the Firewall Threat Defense's internal certificate to the Firewall Management Center. You can consult a resource such as this one if you've never done it before. Specify the IP address of a routed interface on one of the devices managed by your Firewall Management Center.

For more information about the network object, see Redirect to Host Name Network Rule Conditions, on page 2558.

Procedure

Step 1 If you haven't already done so, log in to your Firewall Management Center.

Step 2 Click **Objects** > **Object Management**.

Step 3 Expand **PKI**.

Step 4 Click **Internal Certs**.

Step 5 Click **Add Internal Cert**.

Step 6 In the **Name** field, enter a name to identify the internal cert (for example, **`MyCaptivePortal`**).

Step 7 In the **Certificate Data** field, either paste the certificate or use the **Browse** button to locate it.

The certificate Common Name must exactly match the FDQN with which you want captive portal users to authenticate.

Step 8 In the **Key** field, either paste the certificate's private key or use the **Browse** button to locate it.

Step 9 If the certificate is encrypted, select the **Encrypted** check box and enter the password in the adjacent field.

Step 10 Click **Save**.

Step 11 Click **Network**.

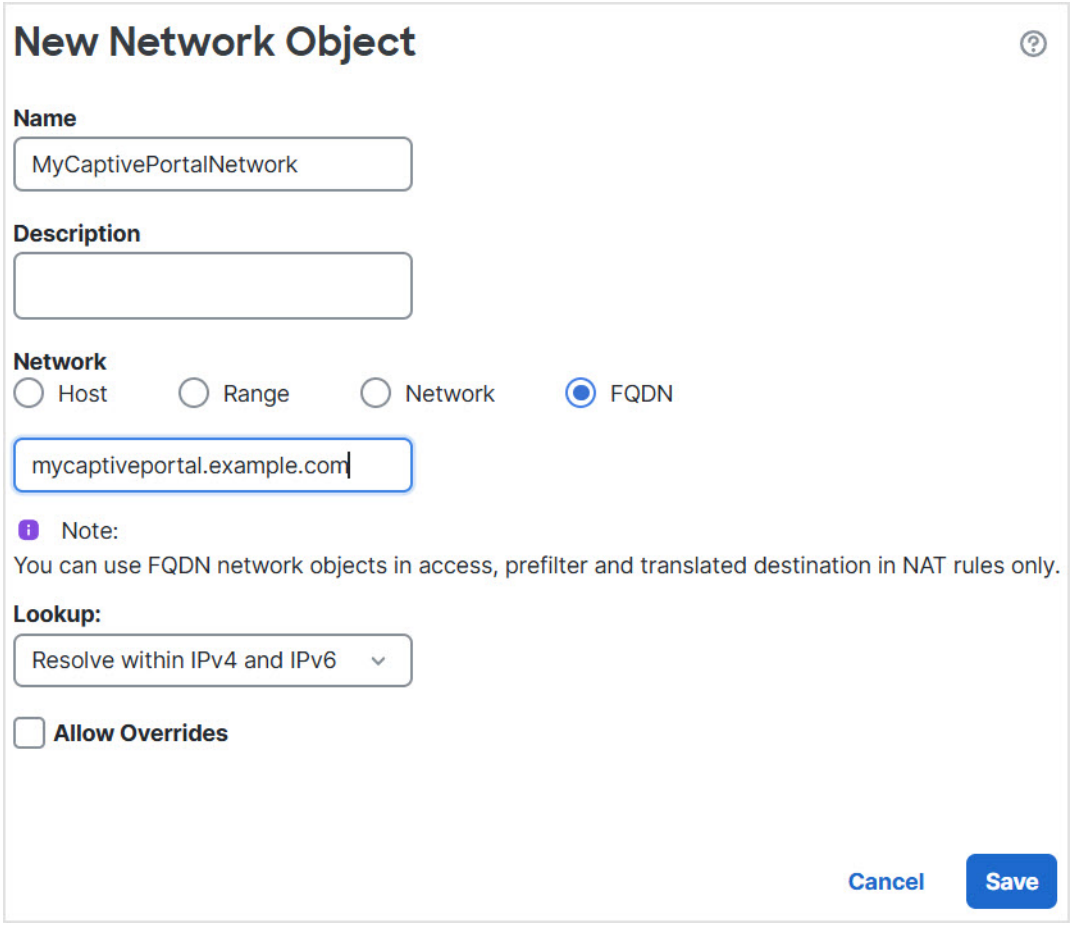
Step 12 Click **Add Network** > **Add Object**.

Step 13 In the **Name** field, enter a name to identify the object (for example, **`MyCaptivePortalNetwork`**).

Step 14 Click **FDQN** and, in the field, enter the name of the captive portal's FDQN.

Step 15 Click an option for **Lookup**.

The following figure shows an example.



Step 16 Click **Save**.

What to do next

Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2532

Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule

Before you begin

This multi-part procedure shows how to set up the captive portal using the default TCP port 885 and using a Firewall Management Center server certificate for both the captive portal and for TLS/SSL decryption. Each part of this example explains one task required to enable the captive portal to perform active authentication.

If you follow all the steps in this procedure, you can configure captive portal to work for users in your domains. You can optionally perform additional tasks, which are discussed in each part of the procedure.

For an overview of the entire procedure, see How to Configure the Captive Portal for User Control, on page 2529.

Procedure

Step 1 Log in to the Firewall Management Center if you have not already done so.

Step 2 Click **Policies** > **Access Control heading** > **Identity** and create or edit an identity policy.

Step 3 (Optional.) Click **Add Category** to add a category for the captive portal identity rules and enter a **Name** for the category.

Step 4 Click the **Active Authentication** tab.

Step 5 Choose the appropriate *root* **Server Certificate** from the list or click **Add** (+) to add a certificate.

For more information, see Connect Securely to Active Directory or LDAP, on page 2442.

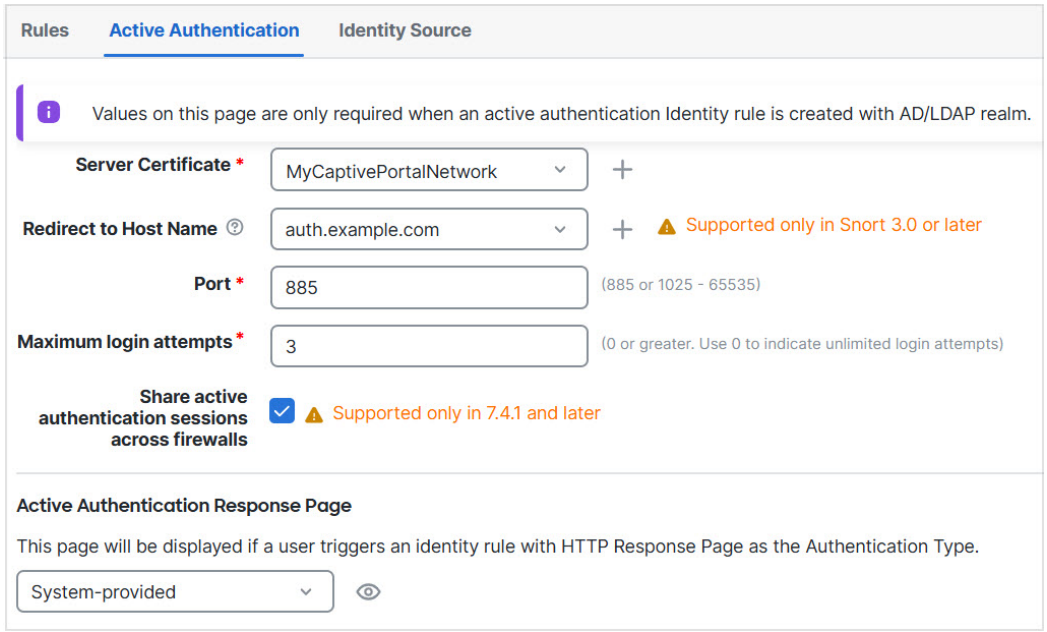
Note
Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

Step 6 From the **Redirect to Host Name** field, click the network object you previously created or click **Add** (+).

Step 7 Enter **885** in the **Port** field and specify the **Maximum login attempts**.

Step 8 Uncheck **Share active authentication across firewalls** to enable the Firewall Management Center to require users to reauthenticate every time they access your network using a different managed device than the last time.
For more information about this option, see Captive Portal Fields, on page 2539.

Step 9 (Optional.) Choose an **Active Authentication Response Page** as described in Captive Portal Fields, on page 2539.



Step 10 (If you upgraded to version 7.4.1 from an earlier version only and you authenticate users with a realm sequence.) Click **Edit** (✎) and see Update a Custom Authentication Form, on page 2534.

Step 11 Click **Save**.

Step 12 Click **Rules**.

Step 13 Click **Add Rule** to add a new captive portal identity policy rule, or click **Edit** (✎) to edit an existing rule.

Step 14 Enter a **Name** for the rule.

Step 15 From the **Action** list, choose **Active Authentication**.

Step 16 Click **Realm & Settings**.

Step 17 From the **Realms** list, choose a realm or realm sequence to use for user authentication.

Step 18 (Optional.) Check **Identify as Guest if authentication cannot identify user**. For more information, see Captive Portal Fields, on page 2539.

Step 19 Choose an **Authentication Protocol** from the list.

You *cannot* authenticate users with a realm sequence if you choose **NTLM**, **Kerberos**, or **HTTP Negotiate** authentication protocols. Choose **HTTP Basic** or **HTTP Response Page** instead.

Step 20 (Optional.) To exempt specific application traffic from captive portal, see Exclude Applications from Captive Portal, on page 2540.

Step 21 Add conditions to the rule (port, network, and so on) as discussed in Identity Rule Conditions, on page 2557.

Step 22 Click **Add**.

Step 23 At the top of the page, click **Save**.

What to do next

Continue with Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2534.

Update a Custom Authentication Form

After you upgrade to version 7.4.1 (or later) from an earlier release, you must add the following line to a custom authentication form for users to see a list of domains when they authenticate with captive portal. (This task is always required if you use the HTTP Response Page authentication type; if users authenticate with a realm using another authentication type, this task is optional.)

On the **Active Authentication** tab page of your identity rule, click **Edit** (✎) and enter the following in the part of the form that requires the user to log in:

```
<select name="realm" id="realm"></select>
```

Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule

This part of the procedure shows how to create an access control rule that allows the captive portal to communicate with clients using TCP port 885, which is the captive portal's default port. You can choose another port if you wish, but the port must match the one you chose in Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2532.

Before you begin

For an overview of the entire captive portal configuration, see How to Configure the Captive Portal for User Control, on page 2529.

Procedure

Step 1 Log in to the Firewall Management Center if you have not already done so.

Step 2 If you haven't done so already, create a certificate for the captive portal as discussed in PKI, on page 1404.

Step 3 Click **Policies** > **Access Control heading** > **Access Control** and create or edit an access control policy.

Step 4 Click **Add Rule**.

Step 5 Enter a **Name** for the rule.

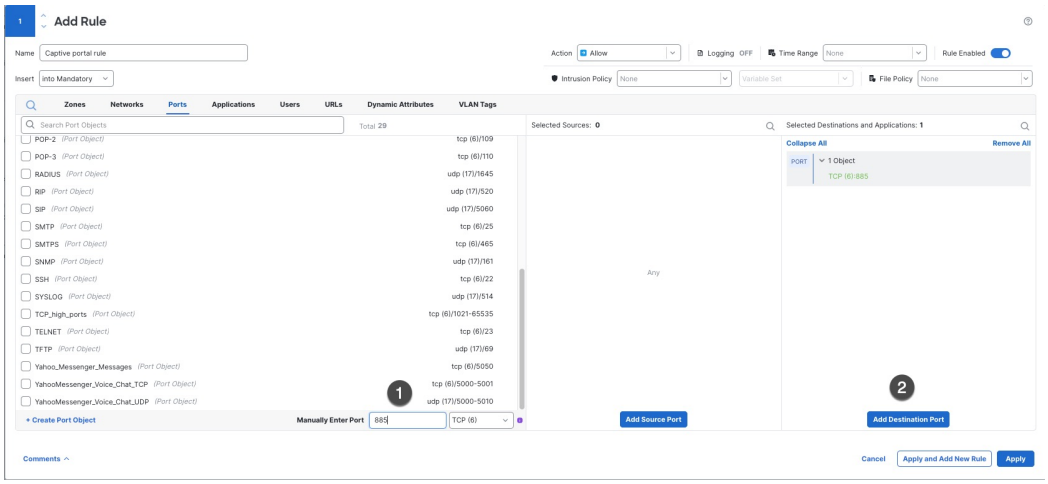
Step 6 Choose **Allow** from the **Action** list.

Step 7 Click **Ports**.

Step 8 From the **Protocol** list under the **Selected Destination Ports** field, choose **TCP**.

Step 9 In the **Port** field, enter **885**.

Step 10 Click **Add** next to the **Port** field.
The following figure shows an example.



Step 11 Click **Add** at the bottom of the page.

What to do next

Continue with Configure the Captive Portal Part 4: Create a User Access Control Rule, on page 2535.

Configure the Captive Portal Part 4: Create a User Access Control Rule

This part of the procedure discusses how to add an access control rule that enables users in a realm to authenticate using captive portal.

Before you begin

For an overview of the entire captive portal configuration, see How to Configure the Captive Portal for User Control, on page 2529.

Procedure

Step 1 In the rule editor, click **Add Rule**.

Step 2 Enter a **Name** for the rule.

Step 3 Choose **Allow** from the **Action** list.

Step 4 Click **Users**.

Step 5 In the **Available Realms** list, click the realms to allow.

Step 6 If no realms display, click **Refresh** ( ).

Step 7 In the **Available Users** list, choose the users to add to the rule and click **Add to Rule**.

Step 8 (Optional.) Add conditions to the access control policy as discussed in Identity Rule Conditions, on page 2557.

Step 9 Click **Add**.

Step 10 On the access control rule page, click **Save**.

Step 11 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

What to do next

Captive Portal Example: Create a Decryption Policy with an Outbound Rule, on page 2536

Captive Portal Example: Create a Decryption Policy with an Outbound Rule

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal. The captive portal can authenticate traffic only after it has been decrypted.

Before you begin

You must have an internal certificate authority (CA) for your outbound server; in other words, the managed device that decrypts the traffic for captive portal users to authenticate. This certificate must be different from the *internal certificate* you use to authenticate the captive portal with the managed device.

Procedure

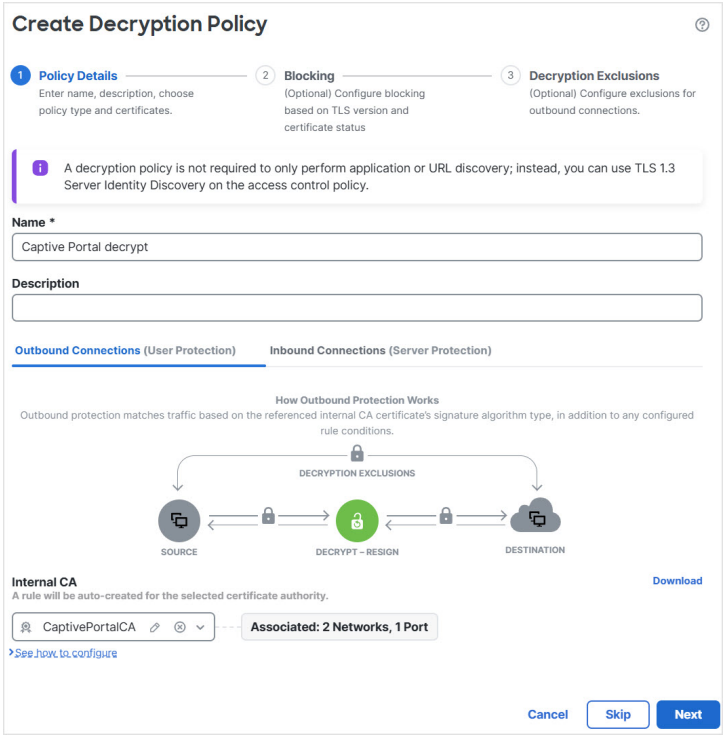
Step 1 Log in to the Firewall Management Center if you haven't already done so.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **New Policy**.

Step 4 Give the policy a unique **Name** and, optionally, a **Description**.

Step 5 Click the **Outbound Connections** tab.



Step 6 Upload or choose certificates for the rules.

The system creates one rule per combination of CA and networks/ports.

Step 7 (Optional.) Choose networks and ports.

For more information:

- Decryption Rule Conditions, on page 2316
- Network Rule Conditions, on page 939
- Port Rule Conditions, on page 940

Step 8 Click **Save**.

Step 9 Click **Edit** (✎) next to the decryption policy you just created.

Step 10 Click **Edit** (✎) next to the decryption rule for captive portal.

Step 11 Click **Users**.

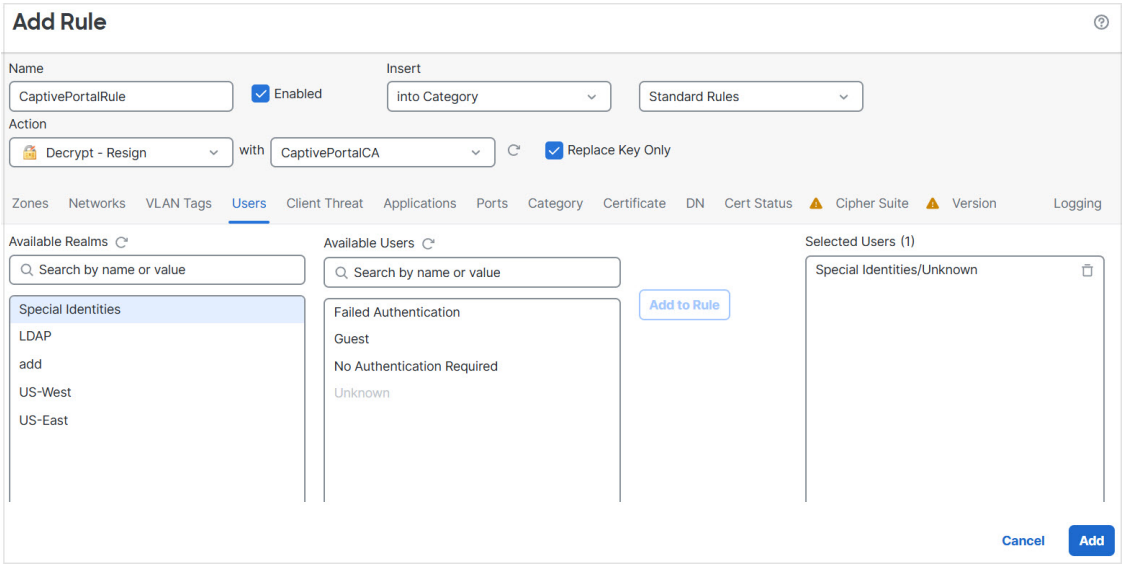
Step 12 Above the **Available Realms** list, click **Refresh** (↻).

Step 13 In the **Available Realms** list, click **Special Identities**.

Step 14 In the **Available Users** list, click **Unknown**.

Step 15 Click **Add to Rule**.

The following figure shows an example.



Step 16 (Optional.) Set other options as discussed in Decryption Rule Conditions, on page 2316.

Step 17 Click **Add**.

What to do next

Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy, on page 2538

Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy

This part of the procedure discusses how to associate the identity policy and TLS/SSL **Decrypt - Resign** rule with the access control policy you created earlier. After this, users can authenticate using the captive portal.

Before you begin

For an overview of the entire captive portal configuration, see How to Configure the Captive Portal for User Control, on page 2529.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Access Control** and edit the access control policy you created as discussed in Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2534. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Either create a new access control policy or edit an existing policy.

Step 3 At the top of the page, click the word **Identity**.

Step 4 From the list, choose the name of your identity policy and, at the top of the page, click **Save**.

Step 5 Repeat the preceding steps to associate your captive portal decryption policy with the access control policy.

Step 6 If you haven't done so already, target the policy at managed devices as discussed in Assigning Devices to an Access Control Policy, on page 1755.

What to do next

- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 259.
- Monitor user activity as discussed in *Using Workflows* in the Cisco Secure Firewall Management Center Administration Guide.

Captive Portal Fields

Use the following fields to configure captive portal on the **Active Authentication** tab page of your identity policy. See also Identity Rule Fields, on page 2564 and Exclude Applications from Captive Portal, on page 2540.

Server Certificate

An internal certificate presented by the captive portal daemon.

Note Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

Port

The port number to use for the captive portal connection. You must set up your access control rule with a TCP port to use for the captive portal, then associate the identity policy with that access control policy. For more information, see Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2534.

Maximum login attempts

The maximum allowed number of failed login attempts before the system denies a user's login request.

Share active authentication sessions across firewalls

Determines whether or not users are required to authenticate when their authentication session is sent to a different managed device than one they previously connected to. If your organization requires users to authenticate every time they change locations or sites, you should *disable* this option.

- (Default, which continues previous behavior.) Check the box to allow users to authenticate with any managed device associated with the active authentication identity rule.
- Uncheck the box to require the user to authenticate with a different managed device, even if they have already authenticated with another managed device to which the active authentication rule is deployed. Use this option if your organization requires authentication per location or site and a managed device is deployed per site.

Managed devices are either clustered or are in a high availability pair act as if they are the same device; in particular,

- Managed devices in the same cluster or high availability pair: Saves the user session to maintain consistency across the pair. On failover, the secondary has the current user session data.
- Managed devices in a different cluster or high availability pair: User session data is not shared with and therefore not stored on these devices.

Active Authentication Response Page

The system-provided or custom HTTP response page you want to display to captive portal users. After you select an **Active Authentication Response Page** in your identity policy active authentication settings, you also must configure one or more identity rules with **`HTTP Response Page`** as the **Authentication Protocol**.

The system-provided HTTP response page includes **Username** and **Password** fields, a list of realms if you chose to authenticate with a realm sequence, as well as a **Login as guest** button to allow users to access the network as guests. To display a single login method, configure a custom HTTP response page.

An example of what users see when logging in with a response page is shown in Create a Sample Identity Policy with an Active Authentication Rule, on page 2568.

Choose the following options:

- To use a generic response, click **System-provided**. You can click **View** ( ) to view the HTML code for this page.
- To create a custom response, click **Custom**. A window with system-provided code is displayed that you can replace or modify. When you are done, save your changes. You can edit a custom page by clicking **Edit** ( ).

Related Topics

Internal Certificate Objects, on page 1412

Exclude Applications from Captive Portal

You can select applications (identified by their HTTP `User-Agent` strings) and exempt them from captive portal active authentication. This allows traffic from the selected applications to pass through the identity policy without authenticating.

Note Only applications with the **`User-Agent Exclusion`** **Tag** are displayed in this list.

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** .

Step 3 Edit the identity policy that contains the captive portal rule.

Step 4 On **Realm & Settings** tab page, expand **HTTP User Agent Exclusions**.

- In the first column, select the check box next to each item to filter applications, then one or more applications, and click **Add to Rule**.

  Check boxes are ANDed together.

- To narrow the filters that are displayed, type a search string in the **Search by name** field; this is especially useful for categories and tags. To clear the search, click **Clear** ( ).
- To refresh the filters list and clear any selected filters, click **Reload** ( ).

Note
The list displays 100 applications at a time.

Step 5 Choose the applications that you want to add to the filter from the **Available Applications** list:

- To narrow the individual applications that appear, enter a search string in the **Search by name** field. To clear the search, click **Clear** ( ).
- Use paging at the bottom of the list to browse the list of individual available applications.
- To refresh the applications list and clear any selected applications, click **Reload** ( ).

Step 6 Add the selected applications to exclude from external authentication. You can click and drag, or you can click **Add to Rule**. The result is the combination of the application filters you selected.

What to do next

- Continue configuring the identity rule as described in Create an Identity Rule, on page 2563.

Troubleshoot the Captive Portal Identity Source

For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2456 and Troubleshoot User Control, on page 2573.

If you experience issues with captive portal, check the following:

- The time on your captive portal managed device must be synchronized with the time on the Firewall Management Center.
- If you have DNS resolution configured and you create an identity rule to perform **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) captive portal, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the hostname you provided when configuring DNS.

  For more information, see About Hostname Redirect, on page 2526.

- If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

- DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.
- If the captive portal is configured correctly but the redirect to an IP address or fully-qualified domain name (FQDN) fails, disable endpoint security software. This type of software can interfere with the redirection.
- If you select **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Type** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.
- If you select **`HTTP Basic`** as the **Authentication Type** in an identity rule, users on your network might not notice their sessions time out. Most web browsers cache the credentials from **`HTTP Basic`** logins and use the credentials to seamlessly begin a new session after an old session times out.
- If the connection between your Firewall Management Center and a managed device fails, no captive portal logins reported by the device can be identified during the downtime, unless the users were previously seen and downloaded to the Firewall Management Center. The unidentified users are logged as Unknown users on the Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.
- If the device you want to use for captive portal contains both inline and routed interfaces, you must configure a zone condition in your captive portal identity rules to target only the routed interfaces on the captive portal device.
- The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.
- To securely log a user out of captive portal and prevent the user from logging in again, an administrator can close their session: **Analysis** > **Users heading** > **Active Sessions**. If the user closes their browser, the browser does not reauthenticate automatically.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.
- When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

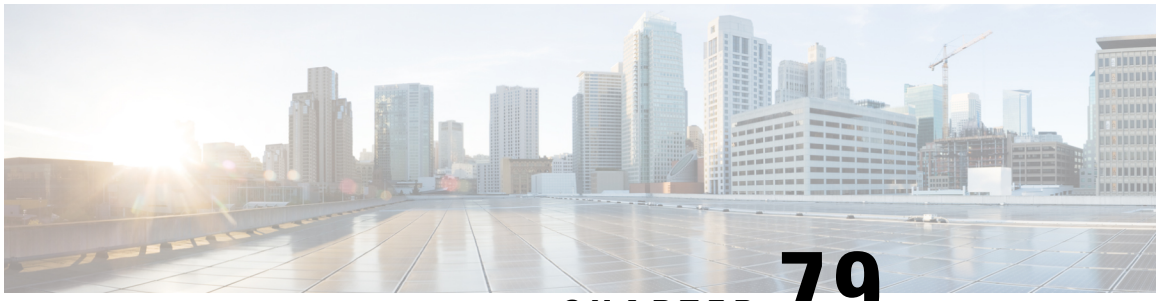
  To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

  For more information, see Synchronize Users and Groups, on page 2445.

History for Captive Portal

Feature	Minimum Firewall Management CenterFirewall Management Center	Minimum Firewall Threat Defense	Details
Authentication using a realm or realm sequence.	7.4.1	7.4.1	You can configure active authentication for either an LDAP realm; or a Microsoft Active Directory realm or a realm sequence. In addition, you can configure a passive authentication rule to fall back to active authentication using either a realm or a realm sequence. You can optionally share sessions between managed devices that share the same identity policy in access control rules. In addition, you have the option to require users to authenticate again when they access the system using a different managed device than they accessed previously. Microsoft Azure Active Directory cannot be used with captive portal. New/modified screens: • **Policies** > **Identity** > **(edit policy)** > **Active Authentication** > **Share active authentication sessions across firewalls** • **Identity policy** > **(edit)** > **Add Rule** > **Passive Authentication** > **Realms & Settings** > **Use active authentication if passive or VPN identity cannot be established** • **Identity policy** > **(edit)** > **Add Rule** > **Active Authentication** > **Realms & Settings** > **Use active authentication if passive or VPN identity cannot be established**
Share active authentication sessions across firewalls.	7.4.1	7.4.1	Determines whether or not users are required to authenticate when their authentication session is sent to a different managed device than one they previously connected to. If your organization requires users to authenticate every time they change locations or sites, you should *disable* this option. • (Default.) Enable to allow users to authenticate with any managed device associated with the active authentication identity rule. • Disable to require the user to authenticate with a different managed device, even if they have already authenticated with another managed device to which the active authentication rule is deployed. New/modified screens: **Policies** > **Identity** > **(edit policy)** > **Active Authentication** > **Share active authentication sessions across firewalls**
Hostname redirect.	7.1.0	7.1.0 with Snort 3	You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.

Feature	Minimum Firewall Management CenterFirewall Management Center	Minimum Firewall Threat Defense	Details
Guest login.	6.1.0	6.1.0	Users can log in as guest using captive portal.
Captive portal.	6.0.0	6.0.0	Feature introduced. You can use the captive portal to require users to enter their credentials when prompted in a browser window. The mapping also allows policies to be based on a user or group of users.



CHAPTER 79

User Control with Remote Access VPN

The following topics discuss how to perform user awareness and user control with Remote Access VPN:

- The Remote Access VPN Identity Source, on page 2545
- Configure RA VPN for User Control, on page 2546
- Troubleshoot the Remote Access VPN Identity Source, on page 2546
- History for RA VPN, on page 2548

The Remote Access VPN Identity Source

Secure Client is the only client supported on endpoint devices for remote VPN connectivity to Firewall Threat Defense devices.

When you set up a secure VPN gateway as discussed in Create a New Remote Access VPN Policy, on page 1584, you can set up an identity policy for those users and associate the identity policy with an access control policy, provided your users are in an Active Directory repository.

Note If you use remote access VPN with User Identity and RADIUS as the identity source, you must configure the realm (**Objects** > **Object Management** > **AAA Server** > **RADIUS Server Group**).

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Secure Firewall Threat Defense secure gateway.

Note If users authenticate with remote access VPN using Active Directory as the authentication source, users must log in using their username; the format `domain\username` or `username@domain` fails. (Active Directory refers to this username as the *logon name* or sometimes as `sAMAccountName`.) For more information, see User Naming Attributes on MSDN.

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

Once authenticated via a VPN connection, the remote user takes on a *VPN Identity*. This VPN Identity is used by *identity policies* on the Secure Firewall Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that the remote user blocked or allowed to access your network resources.

Guidelines and Limitations for Remote Access VPNs, on page 1580
Create a New Remote Access VPN Policy, on page 1584

Configure RA VPN for User Control

Before you begin

- Create a realm as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
- To use authentication, authorization, and auditing (AAA), set up a RADIUS server group as discussed in Add a RADIUS Server Group, on page 1364.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Devices** > **VPN** > **Remote Access**.

Step 3 See Create a New Remote Access VPN Policy, on page 1584.

What to do next

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2555.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1762.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 259.
- Monitor VPN user traffic as discussed in VPN Session and User Information, on page 1710.

Troubleshoot the Remote Access VPN Identity Source

- For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2456 and Troubleshoot User Control, on page 2573.

- If you experience issues with Remote Access VPN, check the connection between your Firewall Management Center and a managed device. If the connection fails, all Remote Access VPN logins reported by the device cannot be identified during the downtime, unless the users were previously seen and downloaded to the Firewall Management Center.

  The unidentified users are logged as Unknown users on the Firewall Management Center. After the downtime, the Unknown users are re identified and processed according to the rules in your identity policy.

- The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.

- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

Not Observing Correct Settings for VPN Statistics

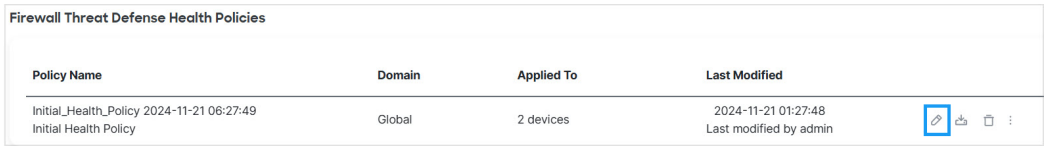
This task discusses steps you must take after either enabling or disabling the **VPN Statistics** setting in a health policy. Failure to perform this task means managed devices have a health policy with incorrect settings.

Procedure

Step 1 Log in to the Secure Firewall Management Center if you haven't already done so.

Step 2 Click **System** (⚙) > **Health** > **Policy**.

Step 3 Under Firewall Threat Defense Health Policies, click **Edit** (✎) next to a policy to edit.



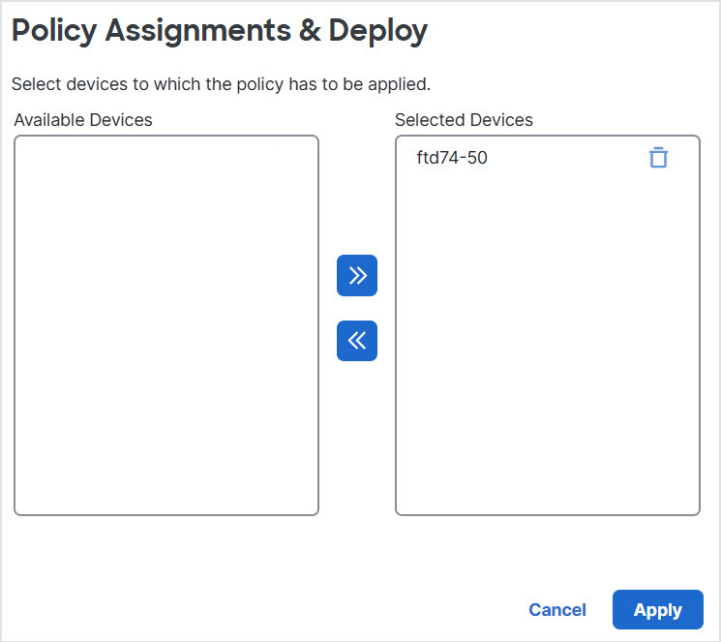
Step 4 On the **Health Modules** tab page, scroll down to locate **VPN Statistics**.

Step 5 Verify the VPN statistics setting is correct or change it if necessary.

Step 6 If you changed the setting, click **Save**, then click **Cancel** to return to the health policy.

Step 7 Under Firewall Threat Defense Health Policies, click **Deploy health policy** (⬆) to apply the policy.

Step 8 In the **Policy Assignments & Deploy** dialog box, move the devices to which to deploy the health policy to the **Selected Devices** field.



Step 9 Click **Apply**.
A message is displayed when the health policy is deployed.

Step 10 After the health policy has finished deploying, click **Policies** > **Access Control heading** > **Access Control** to edit an access control policy.

Step 11 Click **Edit** (✎) next to a policy to edit.

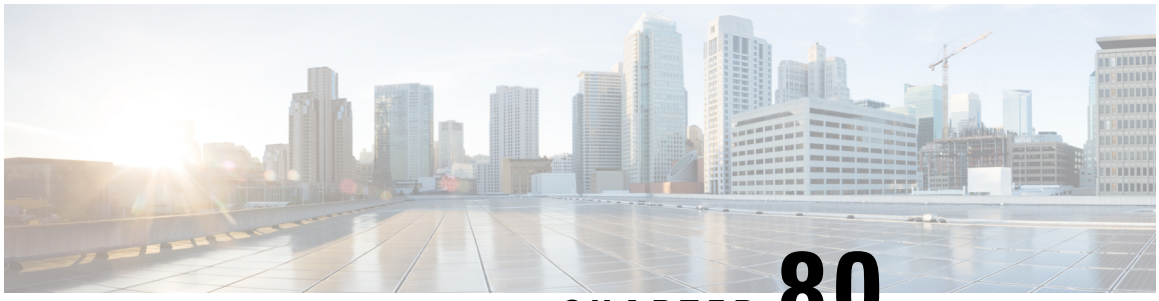
Step 12 Make a minor change to the policy, such as changing its name.

Step 13 Save the access control policy.

Step 14 Deploy configuration changes; see Deploy Configuration Changes, on page 259..

History for RA VPN

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Remote Access VPN	6.2.1	Any	Feature introduced. RA VPN allows individual users to connect to a private business network from a remote location using a laptop or desktop computer connected to the internet, or an Android or Apple iOS mobile device. Remote users transfer data securely and confidentially using encryption techniques crucial for data being transferred over shared mediums and the Internet.



CHAPTER 80

User Control with TS Agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the Cisco Terminal Services (TS) Agent Guide.

What to do next:

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2555.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1762.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 259.
- Monitor user activity as discussed in *Using Workflows* in the Cisco Secure Firewall Management Center Administration Guide .

- The Terminal Services (TS) Agent Identity Source, on page 2549
- TS Agent Guidelines, on page 2550
- User Control with TS Agent, on page 2550
- Troubleshoot the TS Agent Identity Source, on page 2550
- History for TS Agent, on page 2551

The Terminal Services (TS) Agent Identity Source

The TS Agent is a passive authentication method and one of the authoritative identity sources supported by the system. A Windows Terminal Server performs the authentication, and the TS Agent reports it to a standalone or high availability Firewall Management Center.

When installed on Windows Terminal Servers, the TS Agent assigns a unique port range to individual users as they log in or log out of a monitored network. The Firewall Management Center uses the unique port to identify individual users in the system. You can use one TS Agent to monitor user activity on one Windows Terminal Server and send encrypted data to a Firewall Management Center.

The TS Agent does not report failed login attempts. The data gained from the TS Agent can be used for user awareness and user control.

TS Agent Guidelines

The TS Agent requires a multi-step configuration, and includes the following:

1. A Windows Terminal Server with the TS Agent installed and configured.
2. One or more identity realms targeting the users your server is monitoring.

You install the TS Agent on a Microsoft Windows Terminal Server. For detailed information about the multi-step TS Agent installation and configuration and a complete discussion of the server and system requirements, see the Cisco Terminal Services (TS) Agent Guide.

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.

Note If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive identity source report activity by the same IP address, only the TS Agent data is logged to the Firewall Management Center.

User Control with TS Agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the Cisco Terminal Services (TS) Agent Guide.

What to do next:

- Specify users to control and other options using an identity policy as described in Create an Identity Policy, on page 2555.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associating Other Policies with Access Control, on page 1762.
- Deploy your identity and access control policies to managed devices as discussed in Deploy Configuration Changes, on page 259.
- Monitor user activity as discussed in *Using Workflows* in the Cisco Secure Firewall Management Center Administration Guide .

Troubleshoot the TS Agent Identity Source

For other related troubleshooting information, see Troubleshoot Realms and User Downloads, on page 2456 and Troubleshoot User Control, on page 2573.

If you experience issues with the TS Agent integration, check:

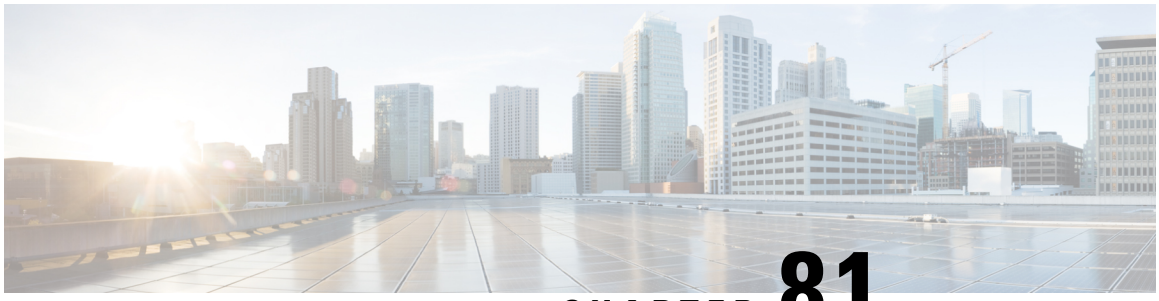
- You must synchronize the time on your TS Agent server with the time on the Firewall Management Center.

- If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Firewall Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Firewall Management Center.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

For more troubleshooting information, see the Cisco Terminal Services (TS) Agent Guide.

History for TS Agent

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
TS Agent for user control.	7.2.0	6.2.0	Feature introduced. Firepower now provides the ability to better identify individual users in shared environments, such as Citrix's Virtual Desktop Infrastructure (VDI), to accurately enforce user-based policy rules on the firewall. Users are identified by ports used. The TS Agent software is updated independently of the Firepower Management Center. For more information, see: • *Cisco Terminal Services (TS) Agent Guide* available on cisco.com • Cisco Firepower Compatibility Guide



CHAPTER 81

User Identity Policies

The following topics discuss how to create and manage identity rules and identity policies:

- About Identity Policies, on page 2553
- License Requirements for Identity Policies, on page 2554
- Requirements and Prerequisites for Identity Policies, on page 2554
- Create an Identity Policy, on page 2555
- Identity Rule Conditions, on page 2557
- Create an Identity Rule, on page 2563
- Sample Identity Policies and Rules, on page 2565
- Manage an Identity Policy, on page 2572
- Manage an Identity Rule, on page 2573
- Troubleshoot User Control, on page 2573

About Identity Policies

Identity policies contain identity rules. Identity rules associate sets of traffic with a realm and an authentication method: passive authentication, active authentication, or no authentication.

With the exception noted in the following paragraphs, you must configure realms and authentication methods you plan to use before you can invoke them in your identity rules:

- You configure realms outside of your identity policy, at **Integration** > **Other Integrations** > **Realms** > **Realms**. For more information, see Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
- You configure ISE/ISE-PIC, a passive authentication identity source, at **Integration** > **Other Integrations** > **Identity Sources**. For more information, see Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512.
- You configure the TS Agent, a passive authentication identity source, outside the system. For more information, see the *Cisco Terminal Services (TS) Agent Guide*.
- You configure captive portal, an active authentication identity source, within the identity policy. For more information, see How to Configure the Captive Portal for User Control, on page 2529.
- You configure Remote Access VPN, an active authentication identity source, in Remote Access VPN policies. For more information, see Remote Access VPN Authentication, on page 1576.

After you add multiple identity rules to a single identity policy, order the rules. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles the traffic.

You can also filter traffic by network object, which limits the network each device monitors in the event your devices are at or near their memory limits.

After you configure one or more identity policies, you must associate one identity policy with your access control policy. When traffic on your network matches the conditions in your identity rule, the system associates the traffic with the specified realm and authenticates the users in the traffic using the specified identity source.

If you do not configure an identity policy, the system does not perform user authentication.

Exception to creating an identity policy

An identity policy is not required if all of the following are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies. For more information, see ISE SGT vs Custom SGT Rule Conditions.

Create an Identity Policy

This task discusses how to create an identity policy.

Before you begin

An identity policy is required to use users and groups in a realm in access control policies. Create and enable one or more realms as described in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.

(Optional.) If a particular managed device monitors a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected. Provided the devices run version 6.7 or later, you can configure the identity rule to monitor traffic by one network or network group object only. To create a network object, see Creating Network Objects, on page 1403.

An identity policy is not required if all of the following are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies. For more information, see ISE SGT vs Custom SGT Rule Conditions.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** and click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

Step 5 To add a rule to the policy, click **Add Rule** as described in Create an Identity Rule, on page 2563.

Step 6 To create a rule category, click **Add Category**.

Step 7 To configure captive portal active authentication, click **Active Authentication** and see Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2532.

Step 8 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 9 Click **Save** to save the identity policy.

What to do next

- Add rules to your identity policy that specify which users to match and other options; see Create an Identity Rule, on page 2563.
- Associate the identity policy with an access control policy to allow or block selected users from accessing specified resources; see Associating Other Policies with Access Control, on page 1762.

- (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see Deploy Configuration Changes, on page 259.

If you encounter issues, see Troubleshoot User Control, on page 2573.

Related Topics

Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2532
Captive Portal Fields, on page 2539
Troubleshoot User Control, on page 2573
Create an Identity Mapping Filter, on page 2556

Create an Identity Mapping Filter

An identity mapping filter can be used to limit the networks to which an identity rule applies. For example, if your Firewall Management Center manages FTDs that have a limited amount of memory, you can limit the networks they monitor.

You must create separate identity mapping filters for IPv4 and IPv6 addresses.

You can also optionally exclude subnets from the following:

- Receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE.
- Receiving user-to-IP mappings from the passive identity agent.

You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

Before you begin

Perform the following tasks:

1. Create a realm, which is required for an identity policy. See Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
2. Create an identity policy. See Create an Identity Policy, on page 2555.
3. Create a network object or network group object as discussed in Creating Network Objects, on page 1403. The network object or group you create should define the network you want managed devices to monitor in identity policies.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** .

Step 3 Click **Edit** ( ).

Step 4 Click the **Identity Source** tab.

Step 5 From the **Identity Mapping Filter** list, choose the name of a network object to use as a filter .

To create a new network object, see Creating Network Objects, on page 1403.

Note
To restrict traffic to IPv6 addresses, you must add at least one address, network, or group to the filter.

Step 6 Click **Save**.

Step 7 (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see Deploy Configuration Changes, on page 259.

What to do next

(Not required for Microsoft Azure AD realms.) Associate the identity policy with an access control policy as discussed in Associating Other Policies with Access Control, on page 1762.

To check or change ISE identity mapping filters (also referred to as *subnet filters*), use the following commands:

```
show identity-subnet-filter
configure identity-subnet-filter { add | remove } subnet
```

Identity Rule Conditions

Rule conditions enable you to fine-tune your identity policy to target the users and networks you want to control. See one of the following sections for more information.

Related Topics

Security Zone Rule Conditions, on page 1905
Network Rule Conditions, on page 939
VLAN Tags Rule Conditions, on page 1787
Port Rule Conditions, on page 940
Realm & Settings Rule Conditions, on page 2561

Security Zone Rule Conditions

Security zones segment your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices.

Security zones control or decrypt traffic by its source and destination security zones. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

Just as all interfaces in a zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Security Zone Conditions and Multitenancy

In a multidomain deployment, a zone created in an ancestor domain can contain interfaces that reside on devices in different domains. When you configure a zone condition in an descendant domain, your configurations apply to only the interfaces you can see.

Network Rule Conditions

Networks control or decrypt traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

Redirect to Host Name Network Rule Conditions

(Snort 3.0 only.)—You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.

The FQDN must resolve to the IP address of one of the interfaces on a managed device. By using an FQDN, you can assign a certificate for active authentication that the client will recognize, thus avoiding the untrusted certificate warning users get when being redirected to a managed device's IP address.

The certificate can specify one FQDN, a wildcard FQDN, or multiple FQDNs in the Subject Alternate Names (SAN) in the certificate.

If an identity rule requires active authentication for a user, but you do not specify a redirect FQDN, the user is redirected to the captive portal port on the managed device interface to which they are connected.

If you do not supply a Redirect to Host Name FQDN, the HTTP Basic, HTTP Response Page, and NTLM authentication methods redirect the user to the captive portal using the IP address of the interface. However, for HTTP Negotiate, the user is redirected using the fully-qualified DNS name *firewall-hostname.directory-server-domain-name*. To use HTTP Negotiate without a Redirect to Host Name FQDN, you must also update your DNS server to map this name to the IP addresses of all inside interfaces where you are requiring active authentication. Otherwise, the redirection cannot complete, and users cannot authenticate.

We recommend that you always provide a Redirect to Host Name FQDN to ensure consistent behavior regardless of authentication method.

VLAN Tags Rule Conditions

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

Port Rule Conditions

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic.

Application filtering is also recommended for applications, like Firewall Threat Defense, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Port, Protocol, and ICMP Code Rule Conditions

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of the following:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—You can control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic. Note that application filtering is not available in prefilter rules.

Application filtering is also recommended for applications, like FTP, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although you can configure port conditions to match non-TCP traffic, there are some restrictions:

- Access control rules—For Classic devices, you can match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, you can add only network-based conditions: zone, IP address, port, and VLAN tag. Also, the system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support TCP port conditions only.

- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies sent in response to ICMP echo requests are ignored. For a rule to match on any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Realm & Settings Rule Conditions

The **Realm & Settings** tab page enables you to choose a realm or realm sequence to which to apply the identity rule. If you are using captive portal, you have additional options.

Authentication Realm

From the **Realm** list, click a realm or realm sequence.

The realm or realm sequence containing the users you want to perform the specified **Action** on. You must fully configure a realm or realm sequence before selecting it as the realm in an identity rule.

Note If remote access VPN is enabled and your deployment is using a RADIUS server group for VPN authentication, make sure you specify the realm associated with this RADIUS server group.

Active authentication only: other options

If you either choose **Active Authentication** as the authentication type or if you check the box, **Use active authentication if passive or VPN identity cannot be established**, you have the following options.

Use active authentication if passive or VPN identity cannot be established

(Passive authentication rule only.) Selecting this option authenticates users using captive portal active authentication if a passive or a VPN authentication fails to identify them. You must configure an Active Authentication rule in your identity policy in order to select this option. (That is, users must authenticate using the captive portal.)

If you disable this option, users that do not have a VPN identity or that passive authentication cannot identify are identified as Unknown.

Also see the discussion of the **Authentication Realm** list later in this topic,

Identify as Special Identities/Guest if authentication cannot identify user

Selecting this option allows users who fail captive portal active authentication the specified number of times to access your network as a guest. These users appear in the Firewall Management Center identified by their username (if their username exists on the AD or LDAP server) or by **Guest** (if their user name is unknown). Their realm is the realm specified in the identity rule. (By default, the number of failed logins is 3.)

This field is displayed only if you configure **Active Authentication** (that is, captive portal authentication) as the rule **Action**.

Authentication Protocol

The method to use to perform captive portal active authentication. An example of what users see when logging in with a response page is shown in Create a Sample Identity Policy with an Active Authentication Rule, on page 2568.

The selections vary depending on the type of realm, LDAP or AD:

- Choose **HTTP Basic** if you want to authenticate users using an unencrypted HTTP Basic Authentication (BA) connection. Users log in to the network using their browser's default authentication pop-up window.

  Most web browsers cache the credentials from **HTTP Basic** logins and use the credentials to seamlessly begin a new session after an old session times out.

- Choose **NTLM** to authenticate users using a NT LAN Manager (NTLM) connection. This selection is available only when you select an AD realm. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication pop-up window.
- Choose **Kerberos** to authenticate users using a Kerberos connection. This selection is available only when you select an AD realm for a server with secure LDAP (LDAPS) enabled. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication pop-up window.

Note The **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform Kerberos captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the host name you provided when configuring DNS.

For Firewall Threat Defense devices, the FQDN must resolve to the IP address of the routed interface used for captive portal.

- Choose **HTTP Negotiate** to allow the captive portal server to choose between HTTP Basic, Kerberos, or NTLM for the authentication connection. This type is available only when you select an AD realm.

Note The **Realm** you choose must be configured with an **AD Join Username** and **AD Join Password** for **HTTP Negotiate** to choose Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform **HTTP Negotiate** captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN of the device you are using for captive portal must match the hostname you provided when configuring DNS.

- Choose **HTTP Response Page** to enable users to choose a realm to log in to.

You can optionally customize the response page; for example, to conform to company style standards.

Active Authentication Realm

(Passive authentication rule only.) If you clicked **Use active authentication if passive or VPN identity cannot be established**, you must click the name of a realm or realm sequence. The availability of a realm or realm sequence is determined by your choice for Authentication Protocol as follows:

- **HTTP Basic** or **HTTP Response Page** authentication protocol: You can choose either a realm or a realm sequence.
- **NTLM**, **Kerberos**, or **HTTP Negotiate** authentication protocol: You can choose a realm only. You *cannot* choose a realm sequence.

Create an Identity Rule

For details about configuration options for identity rules, see Identity Rule Fields, on page 2564.

Before you begin

You must create and enable a realm or realm sequence.

- Create a Microsoft Active Directory realm and realm directory as discussed in Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2426.
- (Microsoft AD realm only.) Download users and groups and enable the realm as discussed in Synchronize Users and Groups, on page 2445.
- Create a Microsoft Azure AD (SAML) realm as discussed in Create a Microsoft Azure AD (SAML) Realm, on page 2392.
- (Optional.) Create a realm sequence as discussed in Create a Realm Sequence, on page 2446.
- Rules are evaluated top-down. For a connection that matches the specified network criteria of a given rule, the user is evaluated against the identity realm specified in the rule. If the user is not part of that realm, they will be marked as unknown, and no further rules in the identity policy will be evaluated. Thus, if you have more than one realm that needs to be evaluated, be sure to use realm sequences instead of a single realm.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** .

Step 3 Click **Edit** (✎) next to the identity policy to which to add the identity rule.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add Rule**.

Step 5 Enter a **Name**.

Step 6 If the Specified rule is applicable, check the check box of **Enabled**.

Step 7 To add the rule to an existing category, indicate where you want to **Insert** the rule. To add a new category, click **Add Category**.

Step 8 Choose a rule **Action** from the list.

Step 9 If you're configuring captive portal, see How to Configure the Captive Portal for User Control, on page 2529.

Step 10 (Optional) To add conditions to the identity rule, see Identity Rule Conditions, on page 2557.

Step 11 Click **Add**.

Step 12 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 13 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Identity Rule Fields

Use the following fields to configure identity rules.

Enabled

Enabling this option enables the identity rule in the identity policy. Unselecting this option disables the identity rule.

Action

Specify the type of authentication you want to perform on the users in the specified realm: **Passive Authentication** (default), **Active Authentication**, or **No Authentication**. You must fully configure the authentication method, or *identity source*, before selecting it as the action in an identity rule.

Additionally, if VPN is enabled (configured on at least one managed device), remote access VPN sessions are actively authenticated by VPN. Other sessions use the rule action. This means that, if VPN is enabled, VPN identity determination is performed first for all sessions regardless of the selected action. If a VPN

identity is found on the specified realm, this is the identity source used. No additional captive portal active authentication is done, even if selected.

If the VPN identity source is not found, the process continues according to the specified action. You cannot restrict the identity policy to VPN authentication only because if the VPN identity is not found, the rule is applied according to the selected action.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include an SSL policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

For information about which passive and active authentication methods are supported in your version of the system, see About User Identity Sources, on page 2372.

Sample Identity Policies and Rules

The following sections provide examples of configuring an identity policy with either a passive authentication rule or an active authentication rule. In addition, because you can authenticate users with active authentication using either realms or realm sequences, separate examples are provided.

Active authentication means the user authenticates using the captive portal; the user enters network credentials before being allowed to access allowed resources. (RA-VPN is another type of active authentication but it cannot be used together with captive portal authentication. For more information, see The Remote Access VPN Identity Source, on page 2545.)

Passive authentication covers all other types. Passive authentication includes using Microsoft Active Directory realms, Microsoft Azure Active Directory realms, Cisco Identity Services Engine, and others.

You can use a Microsoft Azure Active Directory realm to authenticate users a different way that is not discussed here. For more information, see Create a Microsoft Azure AD (SAML) Realm, on page 2392.

Assumptions

The examples use the following assumptions:

- Microsoft Active Directory (AD) realm named forest.example.com with two child domains configured in a trust relationship:
  - US-West
  - US-East
- A realm sequence named US that includes both realms
- Passive authentication rule that authenticates users with a realm sequence
- Two active authentication rules:

- One rule that authenticates users with a realm and uses the NTLM authentication protocol
- One rule that authenticates users with a realm sequence and uses the HTTP Response Page authentication protocol

- Each sample identity rule is associated with a different identity policy

Passive authentication identity rules

When you configure a Passive Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use. For an example, see Create an Identity Policy with a Passive Authentication Rule, on page 2566.

Active authentication identity rules

When you configure an Active Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use.

You can also authenticate users with a Microsoft Active Directory realm sequence except for the following authentication types:

- NTLM
- Kerberos
- HTTP Negotiate

For an example, see Create a Sample Identity Policy with an Active Authentication Rule, on page 2568.

Create an Identity Policy with a Passive Authentication Rule

This task discusses how to create an identity policy with a passive authentication rule that authenticates users using the US realm sequence. If a user is not found in the first realm in the sequence, the system searches the other realms in the sequence in the order listed in the realm sequence. If a user is still not found in the realm or realm sequence, the user is identified as Unknown.

You can optionally authenticate a user with the captive portal (that is, active authentication) if the user is not found in any realm in the sequence. For more information, see Captive Portal Guidelines and Limitations, on page 2526.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** .

Step 3 Click **New Policy**.

Step 4 Enter a **Name** for the policy and an optional **Description**.

Step 5 Click **Save**.

Step 6 Click **Add Rule**.

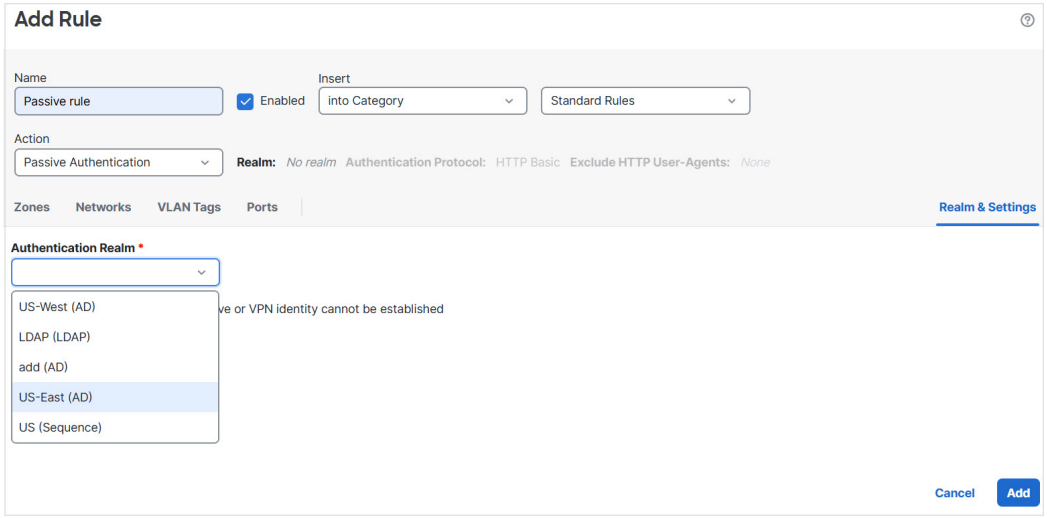
Step 7 Enter a **Name** for the rule.

Step 8 From the list, click **Passive Authentication**.

Step 9 Click the **Realms & Settings** tab page.

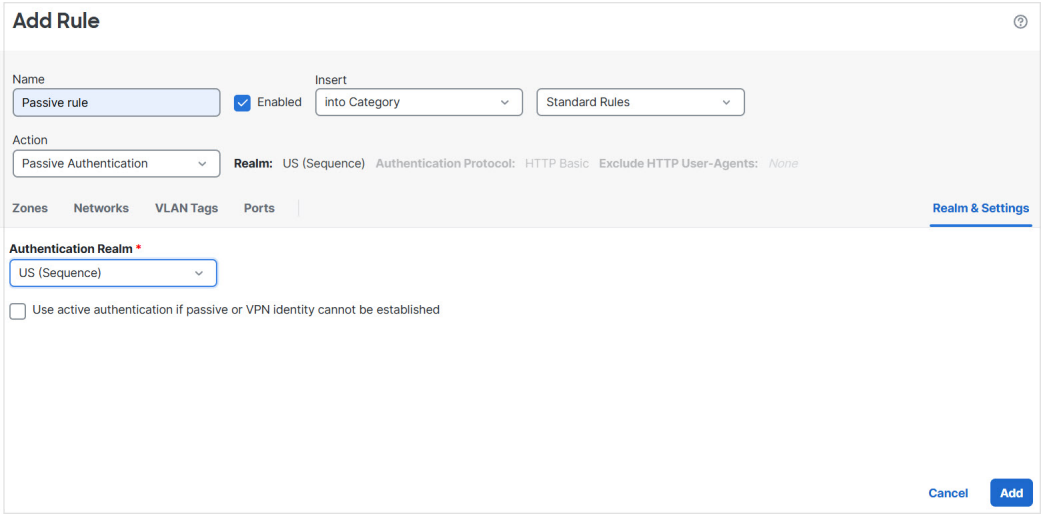
Step 10 From the list, click the name of a realm or realm sequence.

The following figure shows an example.



- If you choose a realm (such as **US-East** in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.
- If you choose a realm sequence (**US (Sequence)** in the example), users are searched in every realm in the sequence in the order specified in the sequence. If the user is not found, the user is identified as Unknown.
- You can also choose an LDAP realm.
- For additional ways to authenticate the user, check **Use active authentication if passive or VPN identity cannot be established**. For more information, see Captive Portal Guidelines and Limitations, on page 2526.

The following figure shows a sample passive identity policy configured to search for users in the US realm sequence.



Step 11 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 12 Set identity rule conditions as discussed in Identity Rule Conditions, on page 2557.

Step 13 Associate the identity rule with an access control rule as discussed in Associating Other Policies with Access Control, on page 1762.

Step 14 Deploy configuration changes to managed devices; see Deploy Configuration Changes, on page 259.

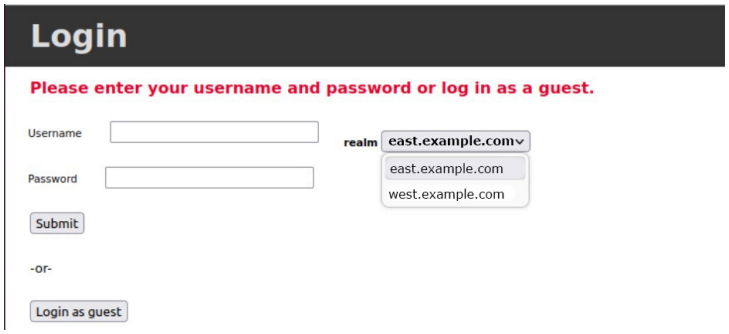
Create a Sample Identity Policy with an Active Authentication Rule

The associated tasks show an examples of configuring an identity policy with an **Active Authentication** rule where authentication is performed using either a realm or a realm sequence.

The differences follow:

- *Realm* enables you to use any supported authentication type (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).
- *Realm sequence* limits you to only the **HTTP Basic** or **HTTP Response Page** authentication types.

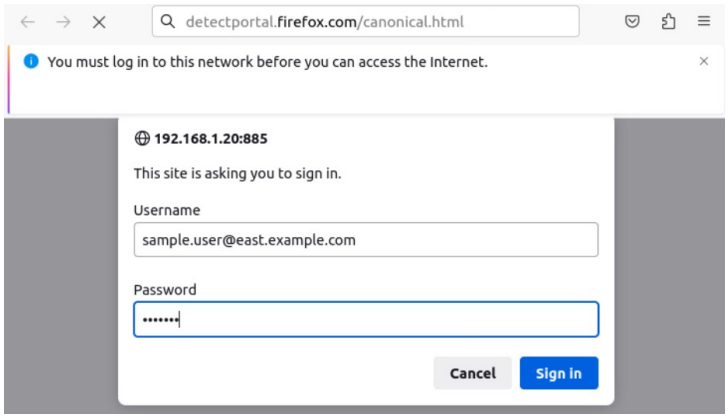
  Users who authenticate with a realm sequence and the HTTP Response Page authentication type see the following by default:



The user can authenticate in any of the following ways:

- If a list of realms in the realm sequence is displayed (as shown), the user must enter their user name and password in the provided fields and click the name of their realm from the list.
- If realms are not displayed in a list, the user can enter their credentials in `username@domain` format.

Users who authenticate with a realm and the HTTP Basic authentication page see the following:



The user must enter their user name in `username@domain` format.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** .

Step 3 Click **New Policy**.

Step 4 Enter a **Name** for the policy and an optional **Description**.

Step 5 Click **Save**.

Step 6 Click the **Active Authentication** tab.

Step 7 Enter the following information:

- **Server Certificate**: From the list, click an internal certificate object to use for secure connection to the Firewall Threat Defense device, or click **Add** (+) to add one.
- **Redirect to Host Name**: (Optional.) From the list, click a network object to which to redirect captive portal requests. If you omit this value, requests redirect to the IP address of the managed device. You can click **Add** (+) to create a new network object. For more information, see Redirect to Host Name Network Rule Conditions, on page 2558.

  Managed devices must have Snort 3 enabled to use this option.
- **Port**: Enter a port for the captive portal to use. This port must be unique for the captive portal and must match an access control rule you set up as discussed in Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2534. (Default is 885.)

- **Maximum login attempts**: Enter the maximum number of login attempts before login fails. (Default is 3.)
- **Share active authentication sessions across firewalls**: Uncheck to enable the Firewall Management Center to force users to reauthenticate every time they access your network using a different managed device than the last time.

  For more information about this option, see Captive Portal Fields, on page 2539.
- **Active Authentication Response Page**: Choose a system-provided or custom login page for captive portal users. For more information about your options, see Captive Portal Fields, on page 2539.

Step 8 Click **Save** to save your changes to the identity policy.

Step 9 Click the **Rules** tab.

Step 10 Click **Add Rule**.

Step 11 Enter a **Name** for the rule.

Step 12 From the list, click **Active Authentication**.

Step 13 Click the **Realms & Settings** tab page and continue with one of the following sections.

What to do next

Continue with one of the following sections:

- Active Authentication Using a Realm, on page 2570
- Active Authentication Using a Realm Sequence, on page 2571

Active Authentication Using a Realm

This task discusses how to authenticate captive portal users with a realm and any available authentication protocol (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).

Before you begin

Complete the task discussed in Create a Sample Identity Policy with an Active Authentication Rule, on page 2568.

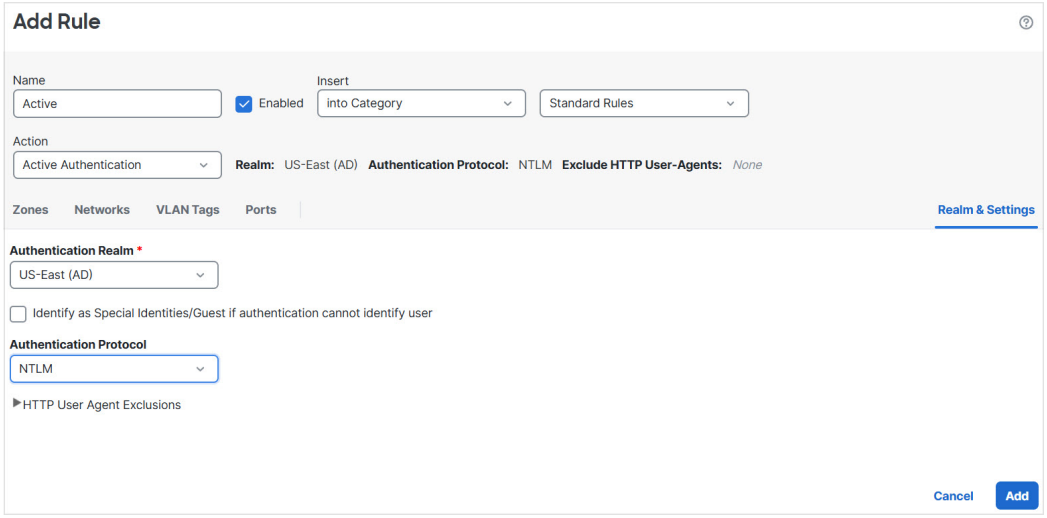
Procedure

Step 1 Continue from Create a Sample Identity Policy with an Active Authentication Rule, on page 2568.

Step 2 On the **Realms & Settings** tab page, click **US-East**.

Step 3 From the **Authentication Protocol** list, click **NTLM**.

The following figure shows an example.



If you choose a realm (such as in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.

Step 4 Click **Add**.

Step 5 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 6 Set identity rule conditions as discussed in Identity Rule Conditions, on page 2557.

Step 7 Associate the identity rule with an access control rule as discussed in Associating Other Policies with Access Control, on page 1762.

Step 8 Deploy configuration changes to managed devices; see Deploy Configuration Changes, on page 259.

Active Authentication Using a Realm Sequence

This task discusses how to authenticate captive portal users with a realm sequence, which restricts you to the **HTTP Basic** or **HTTP Response Page** authentication protocols.

Before you begin

Complete the task discussed in Create a Sample Identity Policy with an Active Authentication Rule, on page 2568.

Procedure

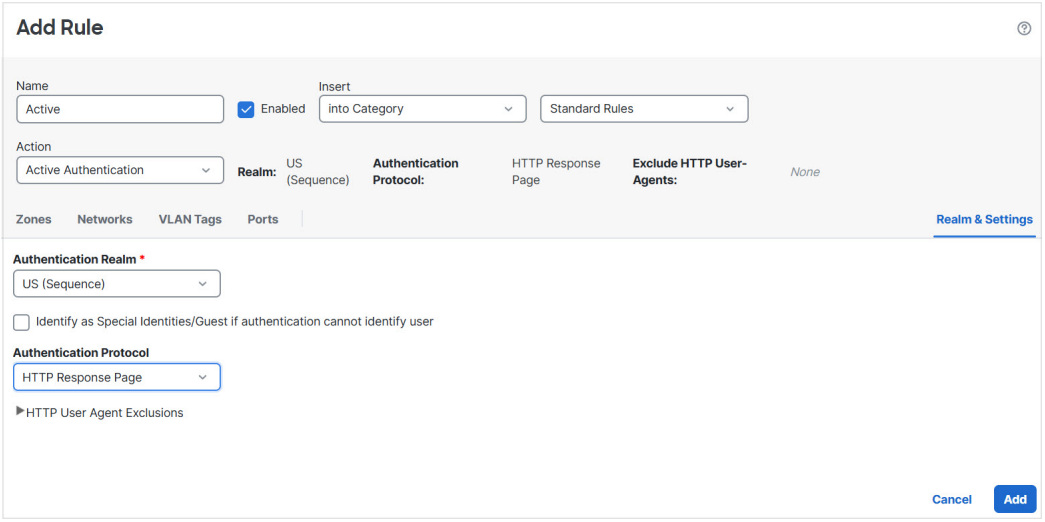
Step 1 Continue from Create a Sample Identity Policy with an Active Authentication Rule, on page 2568.

Step 2 On the **Realms & Settings** tab page, click the name of a realm from the list.

Step 3 From the list, click **US-East**.

Step 4 From the **Protocol** list, click **HTTP Response Page**.

The following figure shows an example.



If you choose a realm sequence (such as in the example), the system searches realms in the sequence in the order specified in the realm sequence. The first realm in the sequence can be referred to as the *default* realm; it's the realm that is used if the user does not change it. If a user is not found, the user is identified as Unknown.

(Only if you upgraded to version 7.4.1 from an earlier version.) Edit the HTTP response page so it shows the list of realms in the sequence as discussed in Update a Custom Authentication Form, on page 2534.

Step 5 Click **Add**.

Step 6 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 7 Set identity rule conditions as discussed in Identity Rule Conditions, on page 2557.

Step 8 Associate the identity rule with an access control rule as discussed in Associating Other Policies with Access Control, on page 1762.

Step 9 Deploy configuration changes to managed devices; see Deploy Configuration Changes, on page 259.

Manage an Identity Policy

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** .

Step 3 To delete a policy, click **Delete** (). If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit a policy, click **Edit** () next to the policy and make changes as described in Create an Identity Policy, on page 2555. If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 5 To copy a policy, click **Copy** ().

Step 6 To generate a report for the policy, click **Report** ( ) as described in Generate Current Policy Reports, on page 278.

Step 7 To compare policies, see Compare Policies, on page 277.

Step 8 To create a folder in which to organize policies, click **Add Category**.

What to do next

Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Manage an Identity Rule

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** .

Step 3 Click **Edit** ( ) next to the policy you want to edit. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit an identity rule, click **Edit** ( ) and make changes as described in Create an Identity Policy, on page 2555.

Step 5 To delete an identity rule, click **Delete** ( ).

Step 6 To create a rule category, click **Add Category** and choose the position and the rule.

Step 7 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Troubleshoot User Control

If you notice unexpected user rule behavior, consider tuning your rule, identity source, or realm configurations. For other related troubleshooting information, see:

- Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues, on page 2521
- Troubleshoot the TS Agent Identity Source, on page 2550
- Troubleshoot the Captive Portal Identity Source, on page 2541
- Troubleshoot Realms and User Downloads, on page 2456

Rules targeting realms, users, or user groups are not matching traffic

If you configure a TS Agent or ISE/ISE-PIC device to monitor a large number of user groups, or if you have a very large number of users mapped to hosts on your network, the system may drop user records due to your Firewall Management Center user limit. As a result, rules with user conditions may not match traffic as expected.

Rules targeting user groups or users within user groups are not matching traffic as expected

If you configure a rule with a user group condition, your LDAP or Active Directory server must have user groups configured. The system cannot perform user group control if the server organizes the users in basic object hierarchy.

Rules targeting users in secondary groups are not matching traffic as expected

If you configure a rule with a user group condition that includes or excludes users who are members of a secondary group on your Active Directory server, your server may be limiting the number of users it reports.

By default, Active Directory servers limit the number of users they report from secondary groups. You must customize this limit so that all of the users in your secondary groups are reported to the Firewall Management Center and eligible for use in rules with user conditions.

Rules are not matching users when seen for the first time

After the system detects activity from a previously-unseen user, the system retrieves information about them from the server. Until the system successfully retrieves this information, activity seen by this user is *not* handled by matching rules. Instead, the user session is handled by the next rule it matches (or the policy's default action, if applicable).

For example, this might explain when:

- Users who are members of user groups are not matching rules with user group conditions.
- Users who were reported by a TS Agent or ISE device are not matching rules, when the server used for user data retrieval is an Active Directory server.

Note that this might also cause the system to delay the display of user data in event views and analysis tools.

Rules are not matching all ISE/ISE-PIC users

This is expected behavior. You can perform user control on ISE/ISE-PIC users who were authenticated by an Active Directory domain controller. You cannot perform user control on ISE/ISE-PIC users who were authenticated by an LDAP, RADIUS, or RSA domain controller.

Users and groups using too much memory

If processing users and groups is using too much memory, health alerts are displayed. Remember that all user sessions are propagated to all devices managed by the Firewall Management Center. If your Firewall Management Center manages devices with different amounts of memory, the device with the least amount of memory determines the number of user sessions the system can handle without errors.

It's not possible to tune memory allocated to identity processes; even if a device has available memory, it can report out-of-memory issues. If issues persist, you have the following options:

- Segregate lower capacity managed devices on subnets and configure ISE/ISE-PIC to not report passive authentication data to those subnets.

See the chapter on managing network devices in the *Cisco Identity Services Engine Administrator Guide*.

- Unsubscribe from Security Group Tags (SGTs).

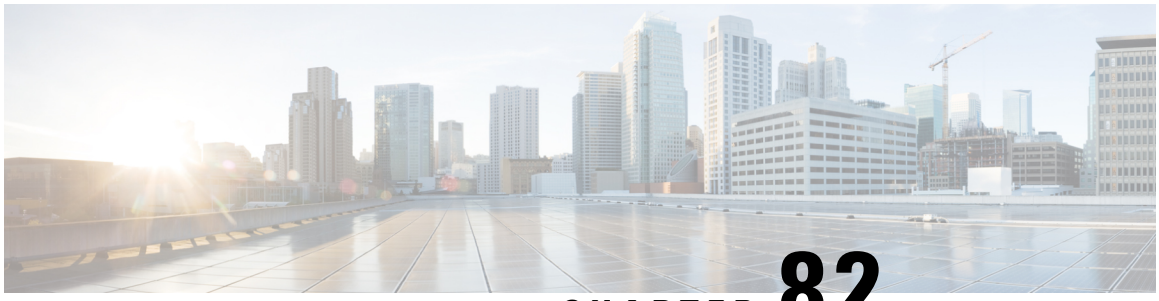
  For more information, see Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source, on page 2512.

- Upgrade your managed device to a model with more memory.

PART XIII

Network Discovery

- Network Discovery Overview, on page 2579
- Host Identity Sources, on page 2587
- Application Detection, on page 2623
- Network Discovery Policies, on page 2643



CHAPTER 82

Network Discovery Overview

The following topics discuss network discovery:

- About Detection of Host, Application, and User Data, on page 2579
- Host and Application Detection Fundamentals, on page 2580

About Detection of Host, Application, and User Data

The system uses *network discovery* and *identity* policies to collect host, application, and user data for traffic on your network. You can use certain types of discovery and identity data to build a comprehensive map of your network assets, perform forensic analysis, behavioral profiling, access control, and mitigate and respond to the vulnerabilities and exploits to which your organization is susceptible.

Host and Application Data

Host and application data is collected by host identity sources and application detectors according to the settings in your network discovery policy. Managed devices observe traffic on the network segments you specify.

For more information, see Host and Application Detection Fundamentals, on page 2580.

User Data

User data is collected by user identity sources according to the settings in your network discovery and identity policies. You can use the data for user awareness and user control.

For more information, see About User Identity, on page 2371.

Logging discovery and identity data allows you to take advantage of many features in the system, including:

- Viewing the network map, which is a detailed representation of your network assets and topology that you can view by grouping hosts and network devices, host attributes, application protocols, or vulnerabilities.
- Performing application and user control; that is, writing access control rules using application, realm, user, user group, and ISE attribute conditions.
- Viewing host profiles, which are complete views of all the information available for your detected hosts.
- Viewing dashboards, which (among other capabilities) can provide you with an at-a-glance view of your network assets and user activity.
- Viewing detailed information on the discovery events and user activity logged by the system.

- Associating hosts and any servers or clients they are running with the exploits to which they are susceptible.

  This enables you to identify and mitigate vulnerabilities, evaluate the impact that intrusion events have on your network, and tune intrusion rule states so that they provide maximum protection for your network assets

- Alerting you by email, SNMP trap, or syslog when the system generates either an intrusion event with a specific impact flag, or a specific type of discovery event
- Monitoring your organization's compliance with an allow list of allowed operating systems, clients, application protocols, and protocols
- Creating correlation policies with rules that trigger and generate correlation events when the system generates discovery events or detects user activity
- Logging and using NetFlow connections, if applicable.

Host and Application Detection Fundamentals

You can configure your network discovery policy to perform host and application detection.

For more information, see Overview: Host Data Collection, on page 2587 and Overview: Application Detection, on page 2623.

Passive Detection of Operating System and Host Data

Passive detection is the system's default method of populating the network map by analyzing network traffic (and any exported NetFlow data). Passive detection provides contextual information about your network assets, such as operating systems and running applications.

If traffic from a monitored host does not offer conclusive evidence of the host's operating system, the network map displays the most likely operating system. For example, a NAT device may appear to be running several operating systems because of the hosts "behind" the NAT device. To make this most-likely determination, the system uses a confidence value it assigns to each detected operating system, and the amount of corroborating data among detected operating systems.

Note The system does not consider reported "`unknown`" applications and operating systems in its determination.

If passive detection inaccurately identifies your network assets, consider the placement of your managed devices. You can also augment the system's passive detection capabilities with custom operating-system fingerprints and custom application detectors. Or, you can use *active detection*, which is not based on traffic analysis, but instead allows you to directly update the network map using scan results or other information sources.

Active Detection of Operating System and Host Data

Active detection adds host information collected by active sources to network maps. For example, you can use the Nmap scanner to actively scan the hosts that you target on your network. Nmap discovers operating systems and applications on hosts.

In addition, the host input feature allows you to actively add *host input data* to network maps. There are two different categories of host input data:

- *user input data*—Data added through the system user interface. You can modify a host's operating system or application identity through this interface.
- *host import input data*—Data imported using a command line utility.

The system retains one identity for each active source. When you run an Nmap scan instance, for example, the results of the previous scan are replaced with the new scan results. However, if you run an Nmap scan and then replace those results with data from a client whose results are imported through the command line, the system retains both the identities from the Nmap results and the identities from the import client. The system then uses the priorities set in the network discovery policy to determine which active identity to use as the current identity.

Note that user input is considered one source, even if it comes from different users. As an example, if UserA sets the operating system through the host profile, and then UserB changes that definition through the host profile, the definition set by UserB is retained, and the definition set by UserA is discarded. In addition, note that user input overrides all other active sources and is used as the current identity if it exists.

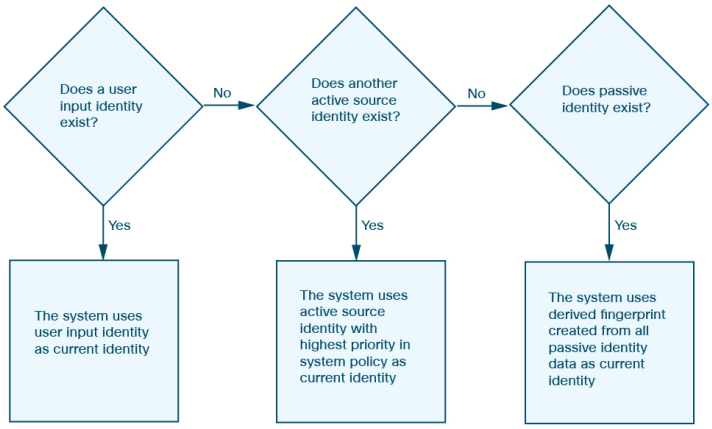
Current Identities for Applications and Operating Systems

The *current identity* for an application or an operating system on a host is the identity that the system finds most likely to be correct.

The system uses the current identity for an operating system or application for the following purposes:

- to assign vulnerabilities to a host
- for impact assessment
- when evaluating correlation rules written against operating system identifications, host profile qualifications, and compliance allow lists
- for display in the Hosts and Servers table views in workflows
- for display in the host profile
- to calculate the operating system and application statistics on the Discovery Statistics page

The system uses source priorities to determine which active identity should be used as the current identity for an application or operating system.



For example, if a user sets the operating system to Windows 2003 Server on a host, Windows 2003 Server is the current identity. Attacks which target Windows 2003 Server vulnerabilities on that host are given a higher impact, and the vulnerabilities listed for that host in the host profile include Windows 2003 Server vulnerabilities.

The database may retain information from several sources for the operating system or for a particular application on a host.

The system treats an operating system or application identity as the current identity when the source for the data has the highest source priority. Possible sources have the following priority order:

1. user

2. scanner and application (set in the network discovery policy)

3. managed devices

4. NetFlow records

A new higher priority application identity will not override a current application identity if it has less detail than the current identity.

In addition, when an identity conflict occurs, the resolution of the conflict depends on settings in the network discovery policy or on your manual resolution.

Current User Identities

When the system detects multiple logins to the same host by different users, the system assumes that only one user is logged into any given host at a time, and that the current user of a host is the last authoritative user login. If only non-authoritative user logins have been logged into the host, the last non-authoritative user login is considered the current user. If multiple users are logged in through remote sessions, the last user reported by the server is the user reported to the Firewall Management Center.

When the system detects multiple logins to the same host by the same user, the system records the first time that a user logs into a specific host and disregards subsequent logins. If an individual user is the only person who logs into a specific host, the only login that the system records is the original login.

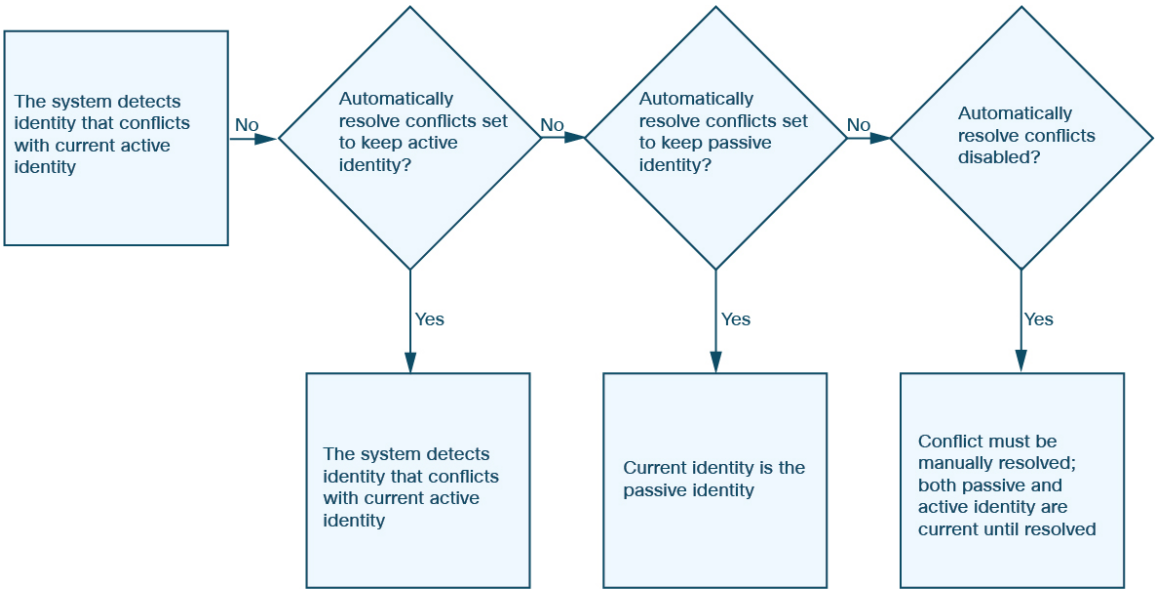
If another user logs into that host, however, the system records the new login. Then, if the original user logs in again, his or her new login is recorded.

Application and Operating System Identity Conflicts

An *identity conflict* occurs when the system reports a new passive identity that conflicts with the current active identity and previously reported passive identities. For example, the previous passive identity for an operating system is reported as Windows 2000, then an active identity of Windows XP becomes current. Next, the system detects a new passive identity of Ubuntu Linux 8.04.1. The Windows XP and the Ubuntu Linux identities are in conflict.

When an identity conflict exists for the identity of the host's operating system or one of the applications on the host, the system lists both conflicting identities as current and uses both for impact assessment until the conflict is resolved.

A user with Administrator privileges can resolve identity conflicts automatically by choosing to always use the passive identity or always use the active identity. Unless you disable automatic resolution of identity conflicts, identity conflicts are always automatically resolved.



A user with Administrator privileges can also configure the system to generate an event when an identity conflict occurs. That user can then set up a correlation policy with a correlation rule that uses an Nmap scan as a correlation response. When an event occurs, Nmap scans the host to obtain updated host operating system and application data.

NetFlow Data

NetFlow is a Cisco IOS application that provides statistics on packets flowing through a router. It is available on Cisco networking devices and can also be embedded in Juniper, FreeBSD, and OpenBSD devices.

When NetFlow is enabled on a network device, a database on the device (the NetFlow cache) stores records of the flows that pass through the router. A flow, called a *connection* in the system, is a sequence of packets that represents a session between a source and destination host, using specific ports, protocol, and application protocol. The network device can be configured to export this NetFlow data. In this documentation, network devices configured in this way are called *NetFlow exporters*.

Managed devices can be configured to collect records from NetFlow exporters, generate unidirectional end-of-connection events based on the data in those records, and finally send those events to the Firewall

Management Center to be logged in the connection event database. You can also configure the network discovery policy to add host and application protocol information to the database based on the information in NetFlow connections.

You can use this discovery and connection data to supplement the data gathered directly by your managed devices. This is especially useful if you have NetFlow exporters monitoring networks that your managed devices cannot monitor.

Requirements for Using NetFlow Data

Before you configure the system to analyze NetFlow data, you must enable the NetFlow feature on the routers or other NetFlow-enabled network devices you plan to use, and configure the devices to broadcast NetFlow data to a destination network where the sensing interface of a managed device is connected.

The system can parse both NetFlow version 5 and NetFlow version 9 records. NetFlow exporters **must** use one of those versions if you want to export the data to the system. In addition, the system requires that specific fields be present in the exported NetFlow templates and records. If your NetFlow exporters are using version 9, which you can customize, you **must** make sure that the exported templates and records contain the following fields, in any order:

- IN_BYTES (1)
- IN_PKTS (2)
- PROTOCOL (4)
- TCP_FLAGS (6)
- L4_SRC_PORT (7)
- IPV4_SRC_ADDR (8)
- L4_DST_PORT (11)
- IPV4_DST_ADDR (12)
- LAST_SWITCHED (21)
- FIRST_SWITCHED (22)
- IPV6_SRC_ADDR (27)
- IPV6_DST_ADDR (28)

Because the system uses managed devices to analyze NetFlow data, your deployment must include at least one managed device that can monitor NetFlow exporters. At least one sensing interface on that managed device must be connected to a network where it can collect the exported NetFlow data. Because the sensing interfaces on managed devices do not usually have IP addresses, the system does not support the direct collection of NetFlow records.

Note that the Sampled NetFlow feature available on some network devices collects NetFlow statistics on only a subset of packets that pass through the devices. Although enabling this feature can improve CPU utilization on the network device, it may affect the NetFlow data you are collecting for analysis by the system.

Differences between NetFlow and Managed Device Data

The traffic represented by NetFlow data is not directly analyzed. Instead, it converts exported NetFlow records into connection logs and host and application protocol data.

As a result, there are several differences between converted NetFlow data and the discovery and connection data gathered directly by your managed devices. You should keep these differences in mind when performing analysis that requires:

- Statistics on the number of detected connections
- Operating system and other host-related information (including vulnerabilities)
- Application data, including client information, web application information, and vendor and version server information
- Knowing which host in a connection is the initiator and which is the responder

Network Discovery Policy versus Access Control Policy

You configure NetFlow data collection, including connection logging, using rules in the network discovery policy. Contrast this with connection logging for connections detected by managed devices, which you configure per access control rule.

Types of Connection Events

Because NetFlow data collection is linked to networks rather than access control rules, you do not have granular control over which NetFlow connections the system logs.

NetFlow data cannot generate Security Intelligence events.

NetFlow-based connection events can be stored in the connection event database only; you cannot send them to the system log or an SNMP trap server.

Number of Connection Events Generated Per Monitored Session

For connections detected directly by managed devices, you can configure the access control rule to log a bidirectional connection event at the beginning or end of a connection, or both.

In contrast, because exported NetFlow records contain unidirectional connection data, the system generates at least two connection events for each NetFlow record it processes. This also means that a summary's connection count is incremented by two for every connection based on NetFlow data, providing an inflated count of the number of connections that are actually occurring on your network.

Because the NetFlow exporter outputs records at a fixed interval even if a connection is still ongoing, long-running sessions can result in multiple exported records, each of which generates a connection event. For example, if the NetFlow exporter exports every five minutes, and a particular connection lasts twelve minutes, the system generates six connection events for that session:

- One pair of events for the first five minutes
- One pair for the second five minutes
- A final pair when the connection is terminated

Host and Operating System Data

Hosts added to the network map from NetFlow data do not have operating system, NetBIOS, or host type (host vs network device) information. You can, however, manually set a host’s operating system identity using the host input feature.

Application Data

For connections detected directly by managed devices, the system can identify application protocols, clients, and web applications by examining the packets in the connection.

When the system processes NetFlow records, the system uses a port correlation in `/etc/sf/services` to extrapolate application protocol identity. However, there is no vendor or version information for those application protocols, nor do connection logs contain information on client or web applications used in the session. You can, however, manually provide this information using the host input feature.

Note that a simple port correlation means that application protocols running on non-standard ports may be unidentified or misidentified. Additionally, if no correlation exists, the system marks the application protocol as `unknown` in connection logs.

Vulnerability Mappings

The system cannot map vulnerabilities to hosts monitored by NetFlow exporters, unless you use the host input feature to manually set either a host's operating system identity or an application protocol identity. Note that because there is no client information in NetFlow connections, you cannot associate client vulnerabilities with hosts created from NetFlow data.

Initiator and Responder Information in Connections

For connections detected directly by managed devices, the system can identify which host is the initiator, or source, and which is the responder, or destination. However, NetFlow data does not contain initiator or responder information.

When the System processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known:

- If both or neither port being used is a well-known port, the system considers the host using the lower-number port to be the responder.
- If only one of the hosts is using a well-known port, the system considers that host to be the responder.

For this purpose, a well-known port is any port that is either numbered from 1 to 1023, or that contains application protocol information in `/etc/sf/services` on the managed device.

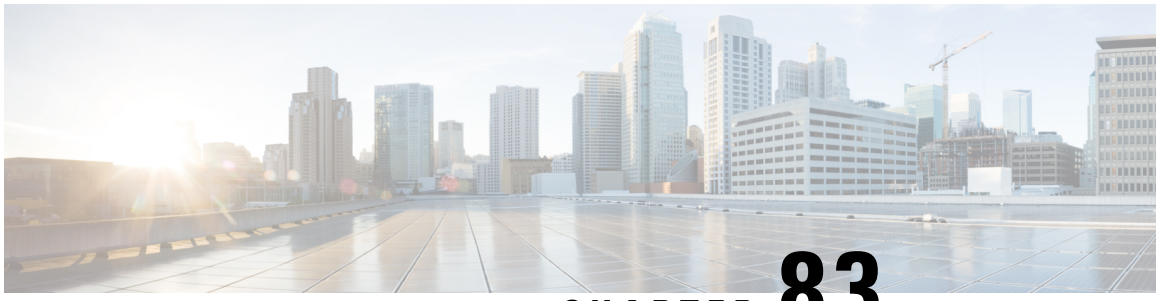
In addition, for connections detected directly by managed devices, the system records two byte counts in the corresponding connection event:

- The **Initiator Bytes** field records bytes sent.
- The **Responder Bytes** field records bytes received.

Connection events based on unidirectional NetFlow records contain only one byte count, which the system assigns to either **Initiator Bytes** or **Responder Bytes**, depending on the port-based algorithm. The system sets the other field to 0. Note that if you are viewing connection summaries (aggregated connection data) of NetFlow records, both fields may be populated.

NetFlow-only Connection Event Fields

A small number of fields are present only in connection events generated from NetFlow records; see *Information Available in Connection Event Fields* in the Cisco Secure Firewall Management Center Administration Guide.



CHAPTER 83

Host Identity Sources

The following topics provide information on host identity sources:

- Overview: Host Data Collection, on page 2587
- Requirements and Prerequisites for Host Identity Sources, on page 2588
- Determining Which Host Operating Systems the System Can Detect, on page 2588
- Identifying Host Operating Systems, on page 2588
- Custom Fingerprinting, on page 2589
- Host Input Data, on page 2597
- Nmap Scanning, on page 2604
- History for Host Identity Sources, on page 2622

Overview: Host Data Collection

As the system passively monitors the traffic that travels through your network, it compares specific packet header values and other unique data from network traffic against established definitions (called *fingerprints*) to determine information about the hosts on your network, including:

- the number and types of hosts (including network devices such as bridges, routers, load balancers, and NAT devices)
- basic network topology data, including the number of hops from the discovery point on the network to the hosts
- the operating systems running on the hosts
- applications on the hosts and users associated with these applications

If the system cannot identify a host's operating system, you can create custom client or server fingerprints. The system uses these fingerprints to identify new hosts. You can map fingerprints to systems in the vulnerability database (VDB) to allow the appropriate vulnerability information to be displayed whenever a host is identified using the custom fingerprint.

Note In addition to collecting host data from monitored network traffic, the system can collect host data from exported NetFlow records, and you can actively add host data using Nmap scans and the host input feature.

Requirements and Prerequisites for Host Identity Sources

Model Support

Any.

Supported Domains

Any, with the exception of custom fingerprinting, which is Leaf only.

User Roles

- Admin
- Discovery Admin, except for third-party data and custom mappings.

Determining Which Host Operating Systems the System Can Detect

To learn which exact operating systems the system can fingerprint, view the list of available fingerprints that is shown during the process of creating a custom OS fingerprint.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Create Custom Fingerprint**.

Step 4 View the lists of options in the drop-down lists in the **OS Vulnerability Mappings** section. These options are the operating systems that the system can fingerprint.

What to do next

As needed, see Identifying Host Operating Systems, on page 2588.

Identifying Host Operating Systems

If the system does not correctly identify a host's operating system (for example, it shows in the Host Profile as Unknown or is incorrectly identified), try the strategies below.

Procedure

Try one of the following strategies:

- Check the Network Discovery Identity Conflict Settings.
- Create a custom fingerprint for the host.
- Run an Nmap scan against the host.
- Import data into the network map, using the host input feature.
- Manually enter operating system information.

Custom Fingerprinting

The system includes operating system *fingerprints* that the system uses to identify the operating system on each host it detects. However, sometimes the system cannot identify a host operating system or misidentifies it because no fingerprints exist that match the operating system. To correct this problem, you can create a *custom fingerprint,* which provides a pattern of operating system characteristics unique to the unknown or misidentified operating system, to supply the name of the operating system for identification purposes.

If the system cannot match a host's operating system, it cannot identify the vulnerabilities for the host, because the system derives the list of vulnerabilities for each host from its operating system fingerprint. For example, if the system detects a host running Microsoft Windows, the system has a stored Microsoft Windows vulnerability list that it adds to the host profile for that host based on the detected Windows operating system.

As an example, if you have several devices on your network running a new beta version of Microsoft Windows, the system cannot identify that operating system or map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for Microsoft Windows, you may want to create a custom fingerprint for one of the hosts to help identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for Microsoft Windows in the fingerprint to associate that list with each host that matches the fingerprint.

When you create a custom fingerprint, the Firewall Management Center lists the set of vulnerabilities associated with that fingerprint for any hosts running the same operating system. If the custom fingerprint you create does not have any vulnerabilities mappings in it, the system uses the fingerprint to assign the custom operating system information you provide in the fingerprint. When the system sees new traffic from a previously detected host, the system updates the host with the new fingerprint information. the system also uses the new fingerprint to identify any new hosts with that operating system the first time they are detected.

Before creating a custom fingerprint, you should determine why the host is not being identified correctly to decide whether custom fingerprinting is a viable solution.

You can create two types of fingerprints with the system:

- Client fingerprints, which identify operating systems based on the SYN packet that the host sends when it connects to a TCP application running on another host on the network.

- Server fingerprints, which identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application.

Note If both a client and server fingerprint match the same host, the client fingerprint is used.

After creating fingerprints, you must activate them before the system can associate them with hosts.

Related Topics

Creating a Custom Fingerprint for Clients, on page 2592
Creating a Custom Fingerprint for Servers, on page 2594

Managing Fingerprints

After a fingerprint is created and activated, you can edit a fingerprint to make changes or add vulnerability mappings.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**. If the system is awaiting data to create a fingerprint, it automatically refreshes the page every 10 seconds until the fingerprint is created.

Step 3 Manage your custom fingerprints:

- Activate/Deactivate — Activate or deactivate a fingerprint as described in Activating and Deactivating Fingerprints, on page 2590.
- Create — Create fingerprints as described in Creating a Custom Fingerprint for Clients, on page 2592 and Creating a Custom Fingerprint for Servers, on page 2594.
- Edit — Edit a fingerprint as described in Editing an Active Fingerprint, on page 2591 and Editing an Inactive Fingerprint, on page 2591.
- Delete — Click **Delete** ( ) next to the fingerprint you want to delete, and click **OK** to confirm. You can only delete deactivated fingerprints.

Activating and Deactivating Fingerprints

You must activate a custom fingerprint before the system can use it to identify hosts. After the new fingerprint is activated, the system uses it to re-identify previously discovered hosts and discover new hosts.

If you want to stop using a fingerprint, you can deactivate it. Deactivating a fingerprint causes a fingerprint to no longer be used, but allows it to remain on the system. When you deactivate a fingerprint, the operating system is marked as unknown for hosts that use the fingerprint. If the hosts are detected again and match a different active fingerprint, they are then identified by that active fingerprint.

Deleting a fingerprint removes it from the system completely. After deactivating a fingerprint, you can delete it.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click the slider next to the fingerprint you want to activate or deactivate.

Note
The activate option is only available if the fingerprint you created is valid. If the slider is not available, try creating the fingerprint again.

Editing an Active Fingerprint

If a fingerprint is *active*, you can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

You can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**

Step 3 Click **Edit** (✎) next to the fingerprint you want to edit.

Step 4 Modify the fingerprint name, description, and custom OS display, if necessary.

Step 5 If you want to delete a vulnerability mapping, click **Delete** next to the mapping in the **Pre-Defined OS Product Maps** section of the page.

Step 6 If you want to add additional operating systems for vulnerability mapping, choose the **Product** and, if applicable, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** and then click **Add OS Definition**.

The vulnerability mapping is added to the **Pre-Defined OS Product Maps** list.

Step 7 Click **Save**.

Editing an Inactive Fingerprint

If a fingerprint is *inactive*, you can modify all elements of the fingerprint and resubmit it to the Secure Firewall Management Center. This includes all properties you specified when creating the fingerprint, such as fingerprint type, target IP addresses and ports, vulnerability mappings, and so on. When you edit an inactive fingerprint and submit it, it is resubmitted to the system and, if it is a client fingerprint, you must resend traffic to the appliance before activating it. Note that you can choose only a single vulnerability mapping for an inactive fingerprint. After you activate the fingerprint, you can map additional operating systems and versions to its vulnerabilities list.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Edit** (✎) next to the fingerprint you want to edit.

Step 4 Make changes to the fingerprint as necessary:

- If you are modifying a client fingerprint, see Creating a Custom Fingerprint for Clients, on page 2592.
- If you are modifying a server fingerprint, see Creating a Custom Fingerprint for Servers, on page 2594.

Step 5 Click **Save**.

What to do next

- If you modified a client fingerprint, remember to send traffic from the host to the appliance gathering the fingerprint.

Creating a Custom Fingerprint for Clients

Client fingerprints identify operating systems based on the SYN packet a host sends when it connects to a TCP application running on another host on the network.

If the Firewall Management Center does not have direct contact with monitored hosts, you can specify a device that is managed by the Firewall Management Center and is closest to the host you intend to fingerprint when specifying client fingerprint properties.

Before you begin the fingerprinting process, obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the Firewall Management Center or the device you use to obtain the fingerprint. (Cisco strongly recommends that you directly connect the Firewall Management Center or the device to the same subnet that the host is connected to.)
- The network interface (on the Firewall Management Center or the device) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- Access to the host in order to generate client traffic.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Create Custom Fingerprint**.

Step 4 From the **Device** drop-down list, choose the Firewall Management Center or the device that you want to use to collect the fingerprint.

Step 5 Enter a **Fingerprint Name**.

Step 6 Enter a **Fingerprint Description**.

Step 7 From the **Fingerprint Type** list, choose **Client**.

Step 8 In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.

Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).

Step 9 In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.

Caution
This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

Step 10 From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.

Note
Use the management interface or any other available network interfaces that is configured as the sensing interface on your device to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

Step 11 If you want to display custom information in the host profile for fingerprinted hosts (or if the host you want to fingerprint does not reside in the **OS Vulnerability Mappings** section), choose **Use Custom OS Display** and provide the values you want to display for the following:

- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

Step 12 In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.

You must specify **Vendor** and **Product** values in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.

To map vulnerabilities for all versions of an operating system, specify only the **Vendor** and **Product** values.

Note
Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

Example:

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the major version.

Example:

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

Step 13 Click **Create**.

The status briefly shows `New`, then switches to `Pending`, where it remains until traffic is seen for the fingerprint. Once traffic is seen, it switches to `Ready`.

The Custom Fingerprint status page refreshes every ten seconds until it receives data from the host in question.

Step 14 Using the IP address you specified as the target IP address, access the host you are trying to fingerprint and initiate a TCP connection to the appliance.

To create an accurate fingerprint, traffic **must** be seen by the appliance collecting the fingerprint. If you are connected through a switch, traffic to a system other than the appliance may not be seen by the system.

Example:

Access the web interface of the Firewall Management Center from the host you want to fingerprint or SSH into the Firewall Management Center from the host. If you are using SSH, use the command below, where localIPv6address is the IPv6 address specified in step 7 that is currently assigned to the host and DCmanagementIPv6address is the management IPv6 address of the Firewall Management Center. The Custom Fingerprint page should then reload with a “Ready” status.

```
ssh -b localIPv6address DCmanagementIPv6address
```

What to do next

- Activate the fingerprint as described in Activating and Deactivating Fingerprints, on page 2590.

Creating a Custom Fingerprint for Servers

Server fingerprints identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application. Before you begin, you should obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the appliance you use to obtain the fingerprint. Cisco strongly recommends that you directly connect an unused interface on the appliance to the same subnet that the host is connected to.
- The network interface (on the appliance) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- An IP address that is not currently in use and is authorized on the network where the host is located.

Tip If the Firewall Management Center does not have direct contact with monitored hosts, you can specify a managed device that is closest to the host you intend to fingerprint when specifying server fingerprint properties.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Custom Operating Systems**.

Step 3 Click **Create Custom Fingerprint**.

Step 4 From the **Device** list, choose the Firewall Management Center or the managed device that you want to use to collect the fingerprint.

Step 5 Enter a **Fingerprint Name**.

Step 6 Enter a **Fingerprint Description**.

Step 7 From the **Fingerprint Type** list, choose **Server** to display the server fingerprinting options.

Step 8 In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.

Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).

Caution
You can capture IPv6 fingerprints only with appliances running Version 5.2 and later.

Step 9 In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.

Caution
This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.

Step 10 From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.

Caution
Cisco recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.

Step 11 Click **Get Active Ports**.

Step 12 In the **Server Port** field, enter the port that you want the device chose to collect the fingerprint to initiate contact with, or choose a port from the **Get Active Ports** drop-down list.

You can use any server port that you know is open on the host (for instance, 80 if the host is running a web server).

Step 13 In the **Source IP Address** field, enter an IP address that should be used to attempt to communicate with the host.

You should use a source IP address that is authorized for use on the network but is not currently being used, for example, a DHCP pool address that is currently not in use. This prevents you from temporarily knocking another host offline while you create the fingerprint.

You should exclude that IP address from monitoring in your network discovery policy while you create the fingerprint. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address.

Step 14 In the **Source Subnet Mask** field, enter the subnet mask for the IP address you are using.

Step 15 If the **Source Gateway** field appears, enter the default gateway IP address that should be used to establish a route to the host.

Step 16 If you want to display custom information in the host profile for fingerprinted hosts or if the fingerprint name you want to use does not exist in the OS Definition section, choose **Use Custom OS Display** in the Custom OS Display section.

Provide the values you want to appear in host profiles for the following:

- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

Step 17 In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.

You must specify a Vendor and Product name in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.

To map vulnerabilities for all versions of an operating system, specify only the vendor and product name.

Note
Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

Example:

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Example:

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

Step 18 Click **Create**.
The Custom Fingerprint status page refreshes every ten seconds and should reload with a "Ready" status.

Note
If the target system stops responding during the fingerprinting process, the status shows an `ERROR: No Response` message. If you see this message, submit the fingerprint again. Wait three to five minutes (the time period may vary depending on the target system), click **Edit** () to access the Custom Fingerprint page, and then click **Create**.

What to do next

- Activate the fingerprint as described in Activating and Deactivating Fingerprints, on page 2590.

Host Input Data

You can augment the network map by importing network map data from third parties. You can also use the host input feature by modifying operating system or application identities or deleting application protocols, protocols, host attributes, or clients using the web interface.

The system may reconcile data from multiple sources to determine the current identity of an operating system or application.

All data except third-party vulnerabilities is discarded when the affected host is removed from the network map. For more information on setting up scripts or import files, see the *Firepower System Host Input API Guide*.

To include imported data in impact correlations, you must map the data to the operating system and application definitions in the database.

Requirements for Using Third-Party Data

You can import discovery data from third-party systems on your network. However, to enable features where intrusion and discovery data are used together, such as Cisco recommendations, adaptive profile updates, or impact assessment, you should map as many elements of it as possible to corresponding definitions. Consider the following requirements for using third-party data:

- If you have a third-party system that has specific data on your network assets, you can import that data using the host input feature. However, because third parties may name the products differently, you must map the third-party vendor, product, and versions to the corresponding Cisco product definition. After you map the products, you must enable vulnerability mappings for impact assessment in the Firewall Management Center configuration to allow impact correlation. For versionless or vendorless application protocols, you need to map vulnerabilities for the application protocols in the Firewall Management Center configuration.
- If you import patch information from a third party and you want to mark all vulnerabilities fixed by that patch as invalid, you must map the third-party fix name to a fix definition in the database. All vulnerabilities addressed by the fix will then be removed from hosts where you add that fix.
- If you import operating system and application protocol vulnerabilities from a third party and you want to use them for impact correlation, you must map the third-party vulnerability identification string to vulnerabilities in the database. Note that although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities. After the vulnerabilities are mapped, you must enable third-party vulnerability mappings for impact assessment in the Firewall Management Center configuration. To cause application protocols without vendor or version information to map to vulnerabilities, an administrative user must also map vulnerabilities for the applications in the Firewall Management Center configuration.
- If you import application data and you want to use that data for impact correlation, you must map the vendor string for each application protocol to the corresponding Cisco application protocol definition.

Related Topics

Mapping Third-Party Products, on page 2598
Mapping Third-Party Product Fixes, on page 2599
Mapping Third-Party Vulnerabilities, on page 2600
Creating Custom Product Mappings, on page 2601

Third-Party Product Mappings

When you add data from third parties to the network map through the user input feature, you must map the vendor, product, and version names used by the third party to the Cisco product definitions. Mapping the products to Cisco definitions assigns vulnerabilities based on those definitions.

Similarly, if you are importing patch information from a third party, such as a patch management product, you must map the name for the fix to the appropriate vendor and product and the corresponding fix in the database.

Mapping Third-Party Products

If you import data from a third party, you must map the Cisco product to the third-party name to assign vulnerabilities and perform impact correlation using that data. Mapping the product associates Cisco vulnerability information with the third-party product name, which allows the system to perform impact correlation using that data.

If you import data using the host input import feature, you can also use the AddScanResult function to map third-party products to operating system and application vulnerabilities during the import.

For example, if you import data from a third party that lists Apache Tomcat as an application and you know it is version 6 of that product, you could add a third-party map where:

- **Vendor Name** is set to `Apache`.
- **Product Name** is set to `Tomcat`.
- **Apache** is chosen from the **Vendor** drop-down list.
- **Tomcat** is chosen from the **Product** drop-down list.
- **6** is chosen from the **Version** drop-down list

This mapping would cause any vulnerabilities for Apache Tomcat 6 to be assigned to hosts with an application listing for Apache Tomcat.

Note that for versionless or vendorless applications, you must map vulnerabilities for the application types in the Secure Firewall Management Center configuration. Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities.

Tip If you have already created a third-party mapping on another Secure Firewall Management Center, you can export it and then import it onto this Firewall Management Center. You can then edit the imported mapping to suit your needs.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new map set, click **Create Product Map Set**.
- Edit — To edit an existing map set, click **Edit** () next to the map set you want to modify. If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Mapping Set Name**.

Step 5 Enter a **Description**.

Step 6 You have two choices:

- Create — To map a third-party product, click **Add Product Map**.
- Edit — To edit an existing third-party product map, **Edit** () next to the map set you want to modify. If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 7 Enter the **Vendor String** used by the third-party product.

Step 8 Enter the **Product String** used by the third-party product.

Step 9 Enter the **Version String** used by the third-party product.

Step 10 In the Product Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping from the **Vendor**, **Product**, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** fields.

Example:

If you want a host running a product whose name consists of third-party strings to use the vulnerabilities from Red Hat Linux 9, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 11 Click **Save**.

Mapping Third-Party Product Fixes

If you map a fix name to a particular set of fixes in the database, you can then import data from a third-party patch management application and apply the fix to a set of hosts. When the fix name is imported to a host, the system marks all vulnerabilities addressed by the fix as invalid for that host.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new map set, click **Create Product Map Set**.

- Edit — To edit an existing map set, click **Edit** (✎) next to the map set you want to modify. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Enter a **Mapping Set Name**.

Step 5 Enter a **Description**.

Step 6 You have two choices:

- Create — To map a third-party product, click **Add Fix Map.**
- Edit — To edit an existing third-party product map, click **Edit** (✎) next to it. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 7 Enter the name of the fix you want to map in the **Third-Party Fix Name** field.

Step 8 In the **Product Mappings** section, choose the operating system, product, and versions you want to use for fix mapping from the following fields:

- **Vendor**
- **Product**
- **Major Version**
- **Minor Version**
- **Revision Version**
- **Build**
- **Patch**
- **Extension**

Example:

If you want your mapping to assign the fixes from Red Hat Linux 9 to hosts where the patch is applied, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

Step 9 Click **Save** to save the fix map.

Mapping Third-Party Vulnerabilities

To add vulnerability information from a third party to the VDB, you must map the third-party identification string for each imported vulnerability to any existing SVID, Bugtraq, or SID. After you create a mapping for the vulnerability, the mapping works for all vulnerabilities imported to hosts in the network map and allows impact correlation for those vulnerabilities.

You must enable impact correlation for third-party vulnerabilities to allow correlation to occur. For versionless or vendorless applications, you must also map vulnerabilities for the application types in the Secure Firewall Management Center configuration.

Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot use third-party client vulnerabilities for impact assessment.

Tip If you have already created a third-party mapping on another Secure Firewall Management Center, you can export it and then import it onto this Firewall Management Center. You can then edit the imported mapping to suit your needs.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **User Third-Party Mappings**.

Step 3 You have two choices:

- Create — To create a new vulnerability set, click **Create Vulnerability Map Set**.
- Edit — To edit an existing vulnerability set, click **Edit** ( ) next to the vulnerability set. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add Vulnerability Map**.

Step 5 Enter the third-party identification for the vulnerability in the **Vulnerability ID** field.

Step 6 Enter a **Vulnerability Description**.

Step 7 Optionally:

- Enter a Snort ID in the **Snort Vulnerability ID Mappings** field.
- Enter a legacy vulnerability ID in the **SVID Mappings** field.
- Enter a Bugtraq identification number in the **Bugtraq Vulnerability ID Mappings** field.

Step 8 Click **Add**.

Related Topics

Enabling Network Discovery Vulnerability Impact Assessment, on page 2657

Custom Product Mappings

You can use product mappings to ensure that servers input by a third party are associated with the appropriate Cisco definitions. After you define and activate the product mapping, all servers or clients on monitored hosts that have the mapped vendor strings use the custom product mappings. For this reason, you may want to map vulnerabilities for all servers in the network map with a particular vendor string instead of explicitly setting the vendor, product, and version for the server.

Creating Custom Product Mappings

If the system cannot map a server to a vendor and product in the VDB, you can manually create the mapping. When you activate a custom product mapping, the system maps vulnerabilities for the specified vendor and product to all servers in the network map where that vendor string occurs.

Note Custom product mappings apply to all occurrences of an application protocol, regardless of the source of the application data (such as Nmap, the host input feature, or the system itself). However, if third-party vulnerability mappings for data imported using the host input feature conflicts with the mappings you set through a custom product mapping, the third-party vulnerability mapping overrides the custom product mapping and uses the third-party vulnerability mapping settings when the input occurs.

You create lists of product mappings and then enable or disable use of several mappings at once by activating or deactivating each list. When you specify a vendor to map to, the system updates the list of products to include only those made by that vendor.

After you create a custom product mapping, you must activate the custom product mapping list. After you activate a list of custom product mappings, the system updates all servers with occurrences of the specified vendor strings. For data imported through the host input feature, vulnerabilities update unless you have already explicitly set the product mappings for this server.

If, for example, your company modifies the banner for your Apache Tomcat web servers to read `Internal Web Server`, you can map the vendor string `Internal Web Server` to the vendor **Apache** and the product **Tomcat**, then activate the list containing that mapping, all hosts where a server labeled `Internal Web Server` occurs have the vulnerabilities for Apache Tomcat in the database.

Tip You can use this feature to map vulnerabilities to local intrusion rules by mapping the SID for the rule to another vulnerability.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**

Step 3 Click **Create Custom Product Mapping List**.

Step 4 Enter a **Custom Product Mapping List Name**.

Step 5 Click **Add Vendor String**.

Step 6 In the **Vendor String** field, enter the vendor string that identifies the applications that should map to the chosen vendor and product values.

Step 7 Choose the vendor you want to map to from the **Vendor** drop-down list.

Step 8 Choose the product you want to map to from the **Product** drop-down list.

Step 9 Click **Add** to add the mapped vendor string to the list.

Step 10 Optionally, repeat steps 4 to 8 as needed to add additional vendor string mappings to the list.

Step 11 Click **Save**.

What to do next

- Activate the custom product mapping list. For more information, see Activating and Deactivating Custom Product Mappings, on page 2603.

Editing Custom Product Mapping Lists

You can modify existing custom product mapping lists by adding or removing vendor strings or changing the list name.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**.

Step 3 Click **Edit** (✎) next to the product mapping list you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Make changes to the list as described in Creating Custom Product Mappings, on page 2601.

Step 5 When you finish, click **Save**.

Activating and Deactivating Custom Product Mappings

You can enable or disable use of an entire list of custom product mappings at once. After you activate a custom product mapping list, each mapping on that list applies to all applications with the specified vendor string, whether detected by managed devices or imported through the host input feature.

Procedure

Step 1 Choose **Policies** > **Application Detectors**.

Step 2 Click **Custom Product Mappings**.

Step 3 Click the slider next to the custom product mapping list to activate or deactivate it.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Configuring the Host Input Client

The host input feature allows you to update the Firewall Management Center's network map from a client program running on another appliance. For example, you can add or delete hosts from the network map, or update the host OS and service information. For more information, see *Firepower System Host Input API Guide*.

Before you can run a remote client, you must add the client to the Firewall Management Center’s peers database from the Host Input Client page. You must also copy the authentication certificate generated by the Firewall Management Center to the client. After completing these steps the client can connect to the Firewall Management Center.

In a multidomain deployment, you can create a client in any domain. The authentication certificate allows the client to submit network map updates for any leaf domains associated with the client certificate's domain. If you create a certificate for an ancestor domain (or if your certificate domain later becomes an ancestor domain after adding descendant domains), any clients using that certificate must specify a target leaf domain with every transaction, as described in the *Firepower System Host Input API Guide*.

The Host Input Client shows only clients associated the current domain, so if you want to download or revoke a certificate, switch to the domain where the client was created.

This connection uses TLS 1.2.

Procedure

Step 1 Choose **Integration** > **Other Integrations**.

Step 2 Click **Host Input Client**.

Step 3 Click **Create Client**.

Step 4 In the **Hostname** field, enter the host name or IP address of the host running the host input client.

Note
If you have not configured DNS resolution, use an IP address.

Step 5 If you want to encrypt the certificate file, enter a password in the **Password** field.

Step 6 Click **Save**.
The host input service allows the host to access port 8307 on the Firewall Management Center and creates an authentication certificate to use during client-server authentication.

Step 7 Click **Download** ( ) next to the certificate file.

Step 8 Save the certificate file to the directory used by your client for SSL/TLS authentication.

Step 9 To revoke access for a client, click **Delete** ( ) next to the host you want to remove.

Nmap Scanning

The system builds network maps through passive analysis of traffic on your network. Information obtained through this passive analysis can occasionally be incomplete, depending on system conditions. However, you can actively scan a host to obtain complete information. For example, if a host has a server running on an open port but the server has not received or sent traffic during the time that the system has been monitoring your network, the system does not add information about that server to the network map. If you directly scan that host using an active scanner, however, you can detect the presence of the server.

The system integrates with Nmap™, an open source active scanner for network exploration and security auditing.

When you scan a host using Nmap, the system:

- Adds servers on previously undetected open ports to the Servers list in the host profile for that host. The host profile lists any servers detected on filtered or closed TCP ports or on UDP ports in the Scan Results section. By default, Nmap scans more than 1660 TCP ports.

  If the system recognizes a server identified in an Nmap scan and has a corresponding server definition, the system maps the names Nmap uses for servers to the corresponding Cisco server definitions.

- Compares the results of the scan to over 1500 known operating system fingerprints to determine the operating system and assigns scores to each. The operating system assigned to the host is the operating system fingerprint with the highest score.

The system maps Nmap operating system names to Cisco operating system definitions.

- Assigns vulnerabilities to the host for the added servers and operating systems.

Note:

- A host must exist in the network map before Nmap can append its results to the host profile.
- If the host is deleted from the network map, any Nmap scan results for that host are discarded.

Tip Some scanning options (such as portscans) may place a significant load on networks with low bandwidths. Schedule scans like these to run during periods of low network use.

For more information on the underlying Nmap technology used to scan, refer to the Nmap documentation at http://insecure.org/.

Nmap Remediation Options

You define the settings for an Nmap scan by creating an Nmap remediation. An Nmap remediation can be used as a response in a correlation policy, run on demand, or scheduled to run at a specific time.

Note that Nmap-supplied server and operating system data remain static until you run another Nmap scan. If you plan to scan a host for operating system and server data using Nmap, you may want to set up regularly scheduled scans to keep any Nmap-supplied operating system and server data up-to-date.

The following table explains the options configurable in Nmap remediations.

Table 139: Nmap Remediation Options

Option	Description	Corresponding Nmap Option
Scan Which Address(es) From Event?	When you use an Nmap scan as a response to a correlation rule, select one of the following options to control which address in the event is scanned, that of the source host, the destination host, or both: • **Scan Source and Destination Addresses** scans the hosts represented by the source IP address and the destination IP address in the event. • **Scan Source Address Only** scans the host represented by the event's source IP address. • **Scan Destination Address Only** scans the host represented by the event's destination IP address.	N/A

Option	Description	Corresponding Nmap Option
Scan Types	Select how Nmap scans ports: • The **TCP Syn** scan connects quickly to thousand of ports without using a complete TCP handshake. This options allows you to scan quickly in stealth mode on hosts where the `admin` account has raw packet access or where IPv6 is not running, by initiating TCP connections but not completing them. If a host acknowledges the Syn packet sent in a TCP Syn scan, Nmap resets the connection. • The **TCP Connect** scan uses the `connect()` system call to open connections through the operating system on the host. You can use the TCP Connect scan if the `admin` user on the Firewall Management Center or managed device does not have raw packet privileges on a host or you are scanning IPv6 networks. In other words, use this option in situations where the TCP Syn scan cannot be used. • The **TCP ACK** scan sends an ACK packet to check whether ports are filtered or unfiltered. • The **TCP Window** scan works in the same way as a TCP ACK scan but can also determine whether a port is open or closed. • The **TCP Maimon** scan identifies BSD-derived systems using a FIN/ACK probe.	**TCP Syn**: `-sS` **TCP Connect**: `-sT` **TCP ACK**: `-sA` **TCP Window**: `-sW` **TCP Maimon**: `-sM`
Scan for UDP ports	Enable to scan UDP ports in addition to TCP ports. Note that scanning UDP ports may be time-consuming, so avoid using this option if you want to scan quickly.	`-sU`
Use Port From Event	If you plan to use the remediation as a response in a correlation policy, enable to cause the remediation to scan only the port specified in the event that triggers the correlation response. • Select **On** to scan the port in the correlation event, rather than the ports you specify during Nmap remediation configuration. If you scan the port in the correlation event, note that the remediation scans the port on the IP addresses that you specify during Nmap remediation configuration. These ports are also added to the remediation's dynamic scan target. • Select **Off** to scan only the ports you specify Nmap remediation configuration. You can also control whether Nmap collects information about operating system and server information. Enable the **Use Port From Event** option to scan the port associated with the new server.	N/A

Option	Description	Corresponding Nmap Option
Scan from reporting detection engine	Enable to scan a host from the appliance where the detection engine that reported the host resides. • To scan from the appliance running the reporting detection engine, select **On**. • To scan from the appliance configured in the remediation, select **Off**.	N/A
Fast Port Scan	Enable to scan only the TCP ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings. Note that you cannot use this option with the **Port Ranges and Scan Order** option. • To scan only the ports listed in the `nmap-services` file located in the `/var/sf/nmap/share/nmap/nmap-services` directory on the device that does the scanning, ignoring other port settings, select **On**. • To scan all TCP ports, select **Off**.	`-F`
Port Ranges and Scan Order	Set the specific ports you want to scan, using Nmap port specification syntax, and the order you want to scan them. Note that you cannot use this option with the **Fast Port Scan** option.	`-p`
Probe open ports for vendor and version information	Enable to detect server vendor and version information. If you probe open ports for server vendor and version information, Nmap obtains server data that it uses to identify servers. It then replaces the Cisco server data for that server. • Select **On** to scan open ports on the host for server information to identify server vendors and versions. • Select **Off** to continue using Cisco server information for the host.	`-sV`
Service Version Intensity	Select the intensity of Nmap probes for service versions. • To use more probes for higher accuracy with a longer scan, select a higher number. • To use fewer probes for less accuracy with a faster scan, select a lower number.	`--version-intensity` <intensity>
Detect Operating System	Enable to detect operating system information for the host. If you configure detection of the operating system for a host, Nmap scans the host and uses the results to create a rating for each operating system that reflects the likelihood that the operating system is running on the host. • Select **On** to scan the host for information to identify the operating system. • Select **Off** to continue using Cisco operating system information for the host.	`-o`

Option	Description	Corresponding Nmap Option
Treat All Hosts As Online	Enable to skip the host discovery process and run a port scan on every host in the target range. Note that when you enable this option, Nmap ignores settings for **Host Discovery Method** and **Host Discovery Port List**. • To skip the host discovery process and run a port scan on every host in the target range, select **On**. • To perform host discovery using the settings for **Host Discovery Method** and **Host Discovery Port List** and skip the port scan on any host that is not available, select **Off**.	`-PN`
Host Discovery Method	Select to perform host discovery for all hosts in the target range, over the ports listed in the **Host Discovery Port Lis**t, or if no ports are listed, over the default ports for that host discovery method. Note that if you also enabled **Treat All Hosts As Online**, however, the **Host Discovery Method** option has no effect and host discovery is not performed. Select the method to be used when Nmap tests to see if a host is present and available: • The **TCP SYN** option sends an empty TCP packet with the SYN flag set and recognizes the host as available if a response is received. TCP SYN scans port 80 by default. Note that TCP SYN scans are less likely to be blocked by a firewall with stateful firewall rules. • The **TCP ACK** option sends an empty TCP packet with the ACK flag set and recognizes the host as available if a response is received. TCP ACK also scans port 80 by default. Note that TCP ACK scans are less likely to be blocked by a firewall with stateless firewall rules. • The **UDP** option sends a UDP packet and assumes host availability if a port unreachable response comes back from a closed port. UDP scans port 40125 by default.	**TCP SYN**: `-PS` **TCP ACK**: `-PA` **UDP**: `-PU`
Host Discovery Port List	Specify a customized list of ports, separated by commas, that you want to scan when doing host discovery.	port list for host discovery method
Default NSE Scripts	Enable to run the default set of Nmap scripts for host discovery and server and operating system and vulnerability detection. See https://nmap.org/nsedoc/categories/default.html for the list of default scripts. • To run the default set of Nmap scripts, select **On**. • To skip the default set of Nmap scripts, select **Off**.	`-sC`

Option	Description	Corresponding Nmap Option
Timing Template	Select the timing of the scan process; the higher the number you select, the faster and less comprehensive the scan.	**0**: `T0` (paranoid) **1**: `T1` (sneaky) **2**: `T2` (polite) **3**: `T3` (normal) **4**: `T4` (aggressive) **5**: `T5` (insane)

Nmap Scanning Guidelines

While active scanning can obtain valuable information, overuse of a tool such as Nmap may overload your network resources or even crash important hosts. When using any active scanner, you should create a scanning strategy following these guidelines to make sure that you are scanning only the hosts and ports that you need to scan.

Selecting Appropriate Scan Targets

When you configure Nmap, you can create scan targets that identify which hosts you want to scan. A scan target includes a single IP address, a CIDR block or octet range of IP addresses, an IP address range, or a list of IP addresses or ranges to scan, as well as the ports on the host or hosts.

You can specify targets in the following ways:

- For IPv6 hosts:
  - an exact IP address (for example, `2001:DB8:1::178:ABCD`)
- For IPv4 hosts:
  - an exact IP address (for example, `192.168.1.101`) or a list of IP addresses separated by commas or spaces
  - an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive).
  - an IP address range using octet range addressing (for example, `192.168.0-255.1-254` scans all addresses in the 192.168.x.x range, except those that end in .0 and or .255)
  - an IP address range using hyphenation (for example, `192.168.1.1 - 192.168.1.5` scans the six hosts between 192.168.1.1 and 192.168.1.5, inclusive)
  - a list of addresses or ranges separated by commas or spaces (for example, for example, `192.168.1.0/24, 194.168.1.0/24` scans the 254 hosts between 192.168.1.1 and 192.168.1.254, inclusive and the 254 hosts between 194.168.1.1 and 194.168.1.254, inclusive)

Ideal scan targets for Nmap scans include hosts with operating systems that the system is unable to identify, hosts with unidentified servers, or hosts recently detected on your network. Remember that Nmap results cannot be added to the network map for hosts that do not already exist in the network map.

Caution

- Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans.
- If a host is deleted from the network map, any Nmap scan results are discarded.
- Make sure you have permission to scan your targets. Using Nmap to scan hosts that do not belong to you or your company may be illegal.

Selecting Appropriate Ports to Scan

For each scan target you configure, you can select the ports you want to scan. You can designate individual port numbers, port ranges, or a series of port numbers and port ranges to identify the exact set of ports that should be scanned on each target.

By default, Nmap scans TCP ports 1 through 1024. If you plan to use the remediation as a response in a correlation policy, you can cause the remediation to scan only the port specified in the event that triggers the correlation response. If you run the remediation on demand or as a scheduled task, or if you do not use the port from the event, you can use other port options to determine which ports are scanned. You can choose to scan only the TCP ports listed in the `nmap-services` file, ignoring other port settings. You can also scan UDP ports in addition to TCP ports. Note that scanning for UDP ports may be time-consuming, so avoid using that option if you want to scan quickly. To select the specific ports or range of ports to scan, use Nmap port specification syntax to identify ports.

Setting Host Discovery Options

You can decide whether to perform host discovery before starting a port scan for a host, or you can assume that all the hosts you plan to scan are online. If you choose not to treat all hosts as online, you can choose what method of host discovery to use and, if needed, customize the list of ports scanned during host discovery. Host discovery does not probe the ports listed for operating system or server information; it uses the response over a particular port only to determine whether a host is active and available. If you perform host discovery and a host is not available, Nmap does not scan ports on that host.

Example: Using Nmap to Resolve Unknown Operating Systems

This example walks through an Nmap configuration designed to resolve unknown operating systems. For a complete look at Nmap configuration, see Managing Nmap Scanning, on page 2612.

If the system cannot determine the operating system on a host on your network, you can use Nmap to actively scan the host. Nmap uses the information it obtains from the scan to rate the possible operating systems. It then uses the operating system that has the highest rating as the host operating system identification.

Using Nmap to challenge new hosts for operating system and server information deactivates the system's monitoring of that data for scanned hosts. If you use Nmap to discover host and server operating system for hosts the system marks as having unknown operating systems, you may be able to identify groups of hosts that are similar. You can then create a custom fingerprint based on one of them to cause the system to associate the fingerprint with the operating system you know is running on the host based on the Nmap scan. Whenever possible, create a custom fingerprint rather than inputting static data through a third-party source like Nmap because the custom fingerprint allows the system to continue to monitor the host operating system and update it as needed.

In this example, you would:

1. Configure a scan instance as described in Adding an Nmap Scan Instance, on page 2613.
2. Create an Nmap remediation using the following settings:
   - Enable **Use Port From Event** to scan the port associated with the new server.
   - Enable **Detect Operating System** to detect operating system information for the host.
   - Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
   - Enable **Treat All Hosts as Online**, because you know the host exists.
3. Create a correlation rule that triggers when the system detects a host with an unknown operating system. The rule should trigger when **a discovery event occurs** and **the OS information for a host has changed** and it meets the following conditions: **OS Name is unknown**.
4. Create a correlation policy that contains the correlation rule.
5. n the correlation policy, add the Nmap remediation you created in step 2 as a response to the rule you created in step 3.
6. Activate the correlation policy.
7. Purge the hosts on the network map to force network discovery to restart and rebuild the network map.
8. After a day or two, search for events generated by the correlation policy. Analyze the Nmap results for the operating systems detected on the hosts to see if there is a particular host configuration on your network that the system does not recognize.
9. If you find hosts with unknown operating systems whose Nmap results are identical, create a custom fingerprint for one of those hosts and use it to identify similar hosts in the future.

Creating a Custom Fingerprint for Clients, on page 2592

Example: Using Nmap to Respond to New Hosts

This example walks through an Nmap configuration designed to respond to new hosts. For a complete look at Nmap configuration, see Managing Nmap Scanning, on page 2612.

When the system detects a new host in a subnet where intrusions may be likely, you may want to scan that host to make sure you have accurate vulnerability information for it.

You can accomplish this by creating and activating a correlation policy that detects when a new host appears in this subnet, and that launches a remediation that performs an Nmap scan on the host.

To do this, you would:

1. Configure a scan instance as described in Adding an Nmap Scan Instance, on page 2613.
2. Create an Nmap remediation using the following settings:
   - Enable **Use Port From Event** to scan the port associated with the new server.
   - Enable **Detect Operating System** to detect operating system information for the host.

- Enable **Probe open ports for vendor and version information** to detect server vendor and version information.
- Enable **Treat All Hosts as Online**, because you know the host exists.

3. Create a correlation rule that triggers when the system detects a new host on a specific subnet. The rule should trigger when **a discovery event occurs** and **a new host is detected**.
4. Create a correlation policy that contains the correlation rule.
5. In the correlation policy, add the Nmap remediation you created in step 2 as a response to the rule you created in step 3.
6. Activate the correlation policy.
7. When you are notified of a new host, check the host profile to see the results of the Nmap scan and address any vulnerabilities that apply to the host.

After you activate the policy, you can periodically check the remediation status view (**Analysis** > **Correlation** > **Status**) to see when the remediation launched. The remediation's dynamic scan target should include the IP addresses of the hosts it scanned as a result of the server detection. Check the host profile for those hosts to see if there are vulnerabilities that need to be addressed for the host, based on the operating system and servers detected by Nmap.

Caution If you have a large or dynamic network, detection of a new host may be too frequent an occurrence to respond to using a scan. To prevent resource overload, avoid using Nmap scans as a response to events that occur frequently. In addition, note that using Nmap to challenge new hosts for operating system and server information deactivates Cisco monitoring of that data for scanned hosts.

Creating an Nmap Remediation, on page 2616

Managing Nmap Scanning

To use Nmap scanning, you must, at minimum, configure an Nmap scan instance and an Nmap remediation. Configuring an Nmap scan target is optional.

Procedure

Step 1 Configure the Nmap scan:

- Add an Nmap scan instance as described in Adding an Nmap Scan Instance, on page 2613.
- Create an Nmap remediation as described in Creating an Nmap Remediation, on page 2616.
- Optionally, add an Nmap scan target as described in Adding an Nmap Scan Target, on page 2615.

Step 2 Run the Nmap scan:

- Run an on-demand Nmap scan as described in Running an On-Demand Nmap Scan, on page 2619.
- Configure automatic Nmap scans as described in *Nmap Scan Automation* in the Cisco Secure Firewall Management Center Administration Guide.

- Schedule automatic Nmap scans as described in *Scheduling an Nmap Scan* in the Cisco Secure Firewall Management Center Administration Guide.

What to do next

- Monitor the Nmap scan in progress by viewing the related task; see *Viewing Task Messages* in the Cisco Secure Firewall Management Center Administration Guide.
- Optionally, refine the scan:
  - Edit an Nmap scan instance as described in Editing an Nmap Scan Instance, on page 2614.
  - Edit an Nmap scan target as described in Editing an Nmap Scan Target, on page 2616.
  - Edit an Nmap remediation as described in Editing an Nmap Remediation, on page 2618.

Adding an Nmap Scan Instance

You can set up a separate scan instance for each Nmap module that you want to use to scan your network for vulnerabilities. You can set up scan instances for the local Nmap module on the Secure Firewall Management Center and for any devices you want to use to run scans remotely. The results of each scan are always stored on the Firewall Management Center where you configure the scan, even if you run the scan from a remote device. To prevent accidental or malicious scanning of mission-critical hosts, you can create a blacklist for the instance to indicate the hosts that should never be scanned with the instance.

You cannot add a scan instance with the same name as any existing scan instance.

Procedure

Step 1 Access the list of Nmap scan instances using either of the following methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Add the remediation:

- If you accessed the list via the first method above, locate the Add a New Instance section, choose the Nmap Remediation module from the drop-down list, and click **Add**.
- If you accessed the list via the second method above, click **Add Nmap Instance**.

Step 3 Enter an **Instance Name**.

Step 4 Enter a **Description**.

Step 5 Optionally, in the **Exempted hosts** field, specify any hosts or networks that should *never* be scanned with this scan instance, using the following syntax:

- For IPv6 hosts, an exact IP address (for example, `2001:DB8::fedd:eeff`)
- For IPv4 hosts, an exact IP address (for example, `192.168.1.101`) or an IP address block using CIDR notation (for example, `192.168.1.0/24` scans the 254 hosts between `192.168.1.1` and `192.168.1.254`, inclusive)

- Note that you cannot use an exclamation mark (!) to negate an address value.

Note
If you specifically target a scan to a host that is in a blacklisted network, that scan will not run.

Step 6 Optionally, to run the scan from a remote device instead of the Firewall Management Center, specify the IP address or name of the device as it appears in the Information page for the device in the Firewall Management Center web interface, in the **Remote Device Name** field.

Step 7 Click **Create**.
When the system is done creating the instance, it displays it in edit mode.

Step 8 Optionally, add an Nmap remediation to the instance. To do so, locate the Configured Remediations section of the instance, click **Add**, and create a remediation as described in Creating an Nmap Remediation, on page 2616.

Step 9 Click **Cancel** to return to the list of instances.

Note
If you accessed the list of Nmap scan instances via the **Scanners** option, the system does not display the instance you added unless you also added a remediation to the instance. To view any instances to which you have not yet added remedations, use the **Instances** menu option to access the list.

Editing an Nmap Scan Instance

When you edit a scan instance, you can view, add, and delete remediations associated with the instance. Delete an Nmap scan instance when you no longer want to use the Nmap module profiled in the instance. Note that when you delete the scan instance, you also delete any remediations that use that instance.

Procedure

Step 1 Access the list of Nmap scan instances using either of the following methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Click **View** ( ) next to the instance you want to edit.

Step 3 Make changes to the scan instance settings as described in Adding an Nmap Scan Instance, on page 2613.

Step 4 Click **Save**.

Step 5 Click **Done**.

What to do next

- Optionally, add a new remediation to the scan instance; see Creating an Nmap Remediation, on page 2616
- Optionally, edit a remediation associated with the instance; see Editing an Nmap Remediation, on page 2618.

- Optionally, delete a remediation associated with the instance; see Running an On-Demand Nmap Scan, on page 2619.
- Optionally, delete the scan instance by clicking **Delete** ( ) next to it.

Adding an Nmap Scan Target

When you configure an Nmap module, you can create and save scan targets that identify the hosts and ports you want to target when you perform an on-demand or a scheduled scan, so that you do not have to construct a new scan target every time. A scan target includes a single IP address or a block of IP addresses to scan, as well as the ports on the host or hosts. For Nmap targets, you can also use Nmap octet range addressing or IP address ranges. For more information on Nmap octet range addressing, refer to the Nmap documentation at http://insecure.org.

Note:

- Scans for scan targets containing a large number of hosts can take an extended period of time. As a workaround, scan fewer hosts at a time.
- Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Targets**.

Step 3 Click **Create Scan Target**.

Step 4 In the **Name** field, enter the name you want to use for this scan target.

Step 5 In the **IP Range** text box, specify the host or hosts you want to scan using the syntax described in Nmap Scanning Guidelines, on page 2609.

Note
If you use a comma in a list of IP addresses or ranges in a scan target, the comma converts to a space when you save the target.

Step 6 In the **Ports** field, specify the ports you want to scan.

You can enter any of the following, using values from 1 to 65535:

- a port number
- a list of ports separated by commas
- a range of port numbers separated by a dash
- ranges of port numbers separated by dashes, separated by commas

Step 7 Click **Save**.

Editing an Nmap Scan Target

Tip You might want to edit a remediation's dynamic scan target if you do not want to use the remediation to scan a specific IP address, but the IP address was added to the target because the host was involved in a correlation policy violation that launched the remediation.

Delete a scan target if you no longer want to scan the hosts listed in it.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Targets**.

Step 3 Click **Edit** () next to the scan target you want to edit.

If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Make modifications as necessary. For more information, see Adding an Nmap Scan Target, on page 2615.

Step 5 Click **Save**.

Step 6 Optionally, delete the scan target by clicking **Delete** () next to it.

Creating an Nmap Remediation

An Nmap remediation can only be created by adding it to an existing Nmap scan instance. The remediation defines the settings for the scan. It can be used as a response in a correlation policy, run on demand, or run as a scheduled task at a specific time.

Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.

For general information about Nmap functionality, refer to the Nmap documentation at http://insecure.org.

Before you begin

- Add an Nmap scan instanceas described in Adding an Nmap Scan Instance, on page 2613 .

Procedure

Step 1 Choose **Policies** > **Actions** > **Instances**.

Step 2 Click **View** () next to the instance to which you want to add the remediation.

Step 3 In the Configured Remediations section, click **Add**.

Step 4 Enter a **Remediation Name**.

Step 5 Enter a **Description**.

Step 6 If you plan to use this remediation in response to a correlation rule that triggers on an intrusion event, a connection event, or a user event, configure the **Scan Which Address(es) From Event?** option.

Tip
If you plan to use this remediation in response to a correlation rule that triggers on a discovery event or a host input event, by default the remediation scans the IP address of the host involved in the event; you do not need to configure this option.

Note
Do **not** assign an Nmap remediation as a response to a correlation rule that triggers on a traffic profile change.

Step 7 Configure the **Scan Type** option.

Step 8 Optionally, to scan UDP ports in addition to TCP ports, choose **On** for the **Scan for UDP ports** option.

Tip
A UDP portscan takes more time than a TCP portscan. To speed up your scans, leave this option disabled.

Step 9 If you plan to use this remediation in response to correlation policy violations, configure the **Use Port From Event** option.

Step 10 If you plan to use this remediation in response to correlation policy violations and want to run the scan using the appliance running the detection engine that detected the event, configure the **Scan from reporting detection engine** option.

Step 11 Configure the **Fast Port Scan** option.

Step 12 In the **Port Ranges and Scan Order** field, enter the ports you want to scan by default, using Nmap port specification syntax, in the order you want to scan those ports.

Use the following format:

- Specify values from 1 to 65535.
- Separate ports using commas or spaces.
- Use a hyphen to indicate a port range.
- When scanning for both TCP and UDP ports, preface the list of TCP ports you want to scan with a T and the list of UDP ports with a U.

Note
The **Use Port From Event** option overrides this setting when the remediation is launched in response to a correlation policy violation, as described in step 8.

Example:

To scan ports 53 and 111 for UDP traffic, then scan ports 21-25 for TCP traffic, enter `U:53,111,T:21-25`.

Step 13 To probe open ports for server vendor and version information, configure **Probe open ports for vendor and version information**.

Step 14 If you choose to probe open ports, set the number of probes used by choosing a number from the **Service Version Intensity** drop-down list.

Step 15 To scan for operating system information, configure **Detect Operating System** settings.

Step 16 To determine whether host discovery occurs and whether port scans are only run against available hosts, configure **Treat All Hosts As Online**.

Step 17 To set the method you want Nmap to use when it tests for host availability, choose a method from the **Host Discovery Method** drop-down list.

Step 18 If you want to scan a custom list of ports during host discovery, enter a list of ports appropriate for the host discovery method you chose, separated by commas, in the **Host Discovery Port List** field.

Step 19 Configure the **Default NSE Scripts** option to control whether to use the default set of Nmap scripts for host discovery and server, operating system, and vulnerability discovery.

Tip
See http://nmap.org/nsedoc/categories/default.html for the list of default scripts.

Step 20 To set the timing of the scan process, choose a timing template number from the **Timing Template** drop-down list.

Choose a higher number for a faster, less comprehensive scan and a lower number for a slower, more comprehensive scan.

Step 21 Click **Create**.
When the system is done creating the remediation, it displays it in edit mode.

Step 22 Click **Done** to return to the related instance.

Step 23 Click **Cancel** to return to the instance list.

Related Topics

Nmap Remediation Options, on page 2605

Editing an Nmap Remediation

Modifications you make to Nmap remediations do not affect scans in progress. The new settings take effect when the next scan starts. Delete an Nmap remediation if you no longer need it.

Procedure

Step 1 Access the list of Nmap scan instances using either of the following methods:

- Choose **Policies** > **Actions** > **Instances**.
- Choose **Policies** > **Actions** > **Scanners**.

Step 2 Access the remediation you want to edit:

- If you accessed the list via the first method above, click **View** ( ) next to the relevant instance, and then click it again next to the remediation you want to edit in the Configured Remediations section.
- If you accessed the list via the second method above, click **View** ( ) next to the remediation you want to edit.

Step 3 Make modifications as necessary as described in Creating an Nmap Remediation, on page 2616.

Step 4 Click **Save** if you want to save your changes, or **Done** if you want to exit without saving.

Step 5 Optionally, delete the remediation by clicking **Delete** ( ) next to it.

Running an On-Demand Nmap Scan

You can launch on-demand Nmap scans whenever needed. You can specify the target for an on-demand scan by entering the IP addresses and ports you want to scan or by choosing an existing scan target.

Nmap-supplied server and operating system data remains static until you run another Nmap scan. If you plan to scan a host using Nmap, regularly schedule scans. If a host is deleted from the network map, any Nmap scan results are discarded.

Before you begin

- Optionally, add an Nmap scan target; see Adding an Nmap Scan Target, on page 2615.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 Next to the Nmap remediation you want to use to perform the scan, click **Scan** ( ).

Step 3 Optionally, to scan using a saved scan target, choose a target from the **Saved Targets** drop-down list, and click **Load**.

Step 4 In the **IP Range(s)** field, specify the IP address for hosts you want to scan or modify the loaded list.

Note:

- For hosts with IPv4 addresses, you can specify multiple IP addresses separated by commas or use CIDR notation. You can also negate IP addresses by preceding them with an exclamation point (!).
- For hosts with IPv6 addresses, use an exact IP address. Ranges are not supported.

Step 5 In the **Ports** field, specify the ports you want to scan or modify the loaded list.

You can enter a port number, a list of ports separated by commas, or a range of port numbers separated by a dash.

Step 6 Click **Scan Now**.

What to do next

- Optionally, monitor the task status; see *Viewing Task Messages* in the Cisco Secure Firewall Management Center Administration Guide.

Nmap Scan Results

You can monitor Nmap scans in progress, import results from scans previously performed through the system or results preformed outside the system, and view and analyze scan results.

You can view scan results that you create using the local Nmap module as a rendered page in a pop-up window. You can also download the Nmap results file in raw XML format.

You can also view operating system and server information detected by Nmap in host profiles and in the network map. If a scan of a host produces server information for servers on filtered or closed ports, or if a scan collects information that cannot be included in the operating system information or the servers section, the host profile includes those results in an Nmap Scan Results section.

Viewing Nmap Scan Results

When an Nmap scan is complete, you can view a table of scan results.

You can manipulate the results view depending on the information you are looking for. The page you see when you access scan results differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of scan results. You can also create a custom workflow that displays only the information that matches your specific needs.

You can download and view the Nmap results using the Nmap Version 1.01 DTD, available at http://insecure.org.

You can also clear scan results.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

Step 2 On the toolbar, click **Scan Results**.

Step 3 You have the following choices:

- Adjust the time range as described in *Event Time Constraints* in the Cisco Secure Firewall Management Center Administration Guide.
- To use a different workflow, including a custom workflow, click **(switch workflows)** by the workflow title.
- To view the scan results as a rendered page in a pop-up window, click **View** next to the scan job.
- To save a copy of the scan results file so that you can view the raw XML code in any text editor, click **Download** next to the scan job.
- To sort scan results, click the column title. Click the column title again to reverse the sort order.
- To constrain the columns that appear, click **Close** (✕) in the column heading that you want to hide. In the pop-up window that appears, click **Apply**.

  Tip
  To hide or show other columns, check or clear the appropriate check boxes before you click **Apply**. To add a disabled column back to the view, Click the expand arrow to expand the search constraints, then click the column name under **Disabled Columns**.

- To drill down to the next page in the workflow, see *Using Drill-Down Pages* in the Cisco Secure Firewall Management Center Administration Guide.
- To configure scan instances and remediations, click **Scanners** in the toolbar and see Managing Nmap Scanning, on page 2612.
- To navigate within and between workflow pages, see *Workflow Page Navigation Tools* in the Cisco Secure Firewall Management Center Administration Guide.
- To navigate to other event views to view associated events, choose the name of the event view you want to see from the **Jump to** drop-down list.

- To search for scan results, enter your search criteria in the appropriate fields.

Related Topics

Nmap Scan Results Fields, on page 2621

Nmap Scan Results Fields

When you run an Nmap scan, the Firewall Management Center collects the scan results in a database. The following table describes the fields in the scan results table that can be viewed and searched.

Table 140: Scan Results Fields

Field	Description
Start Time	The date and time that the scan that produced the results started.
End Time	The date and time that the scan that produced the results ended.
Target	The IP address (or host name, if DNS resolution is enabled) of the scan target for the scan that produced the results.
Scan Type	Either `Nmap` or the name of the third-party scanner to indicate the type of the scan that produced the results.
Scan Mode	The mode of the scan that produced the results: • `On Demand` — results from scans run on demand. • `Imported` — results from scans on a different system and imported onto the Firewall Management Center. • `Scheduled` — results from scans run as a scheduled task.
Results	The results of the scan.
Domain	The domain of the scan target. This field is only present in a multidomain deployment.

Importing Nmap Scan Results

You can import XML results files created by an Nmap scan performed outside of the system. You can also import XML results files that you previously downloaded from the system. To import Nmap scan results, the results file must be in XML format and adhere to the Nmap Version 1.01 DTD. For more information on creating Nmap results and on the Nmap DTD, refer to the Nmap documentation at http://insecure.org.

A host must already exist in the network map before Nmap can append its results to the host profile.

Procedure

Step 1 Choose **Policies** > **Actions** > **Scanners**.

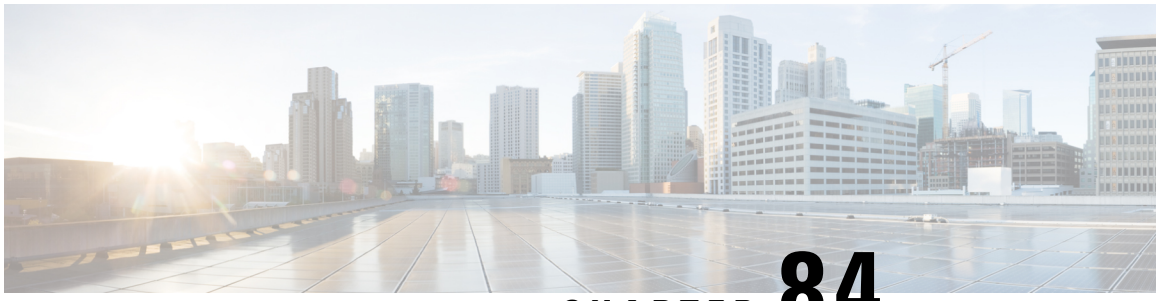
Step 2 On the toolbar, click **Import Results**.

Step 3 Click **Browse** to navigate to the results file.

Step 4 After you return to the Import Results page, click **Import** to import the results.

History for Host Identity Sources

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Security improvement to the host input data feature	6.5	Any	TLS 1.2 is now used for communication between your Firewall Management Center and the host input client. The topic Configuring the Host Input Client, on page 2603has been updated with this information.



CHAPTER 84

Application Detection

The following topics describe application detection:

- Overview: Application Detection, on page 2623
- Requirements and Prerequisites for Application Detection, on page 2629
- Custom Application Detectors, on page 2629
- Viewing or Downloading Detector Details, on page 2638
- Sorting the Detector List, on page 2638
- Filtering the Detector List, on page 2638
- Navigating to Other Detector Pages, on page 2640
- Activating and Deactivating Detectors, on page 2640
- Editing Custom Application Detectors, on page 2641
- Deleting Detectors, on page 2642

Overview: Application Detection

When the system analyzes IP traffic, it attempts to identify the commonly used applications on your network. Application awareness is crucial to application control.

There are three types of applications that the system detects:

- *application protocols* such as HTTP and SSH, which represent communications between hosts
- *clients* such as web browsers and email clients, which represent software running on the host
- *web applications* such as MPEG video and Facebook, which represent the content or requested URL for HTTP traffic

The system identifies applications in your network traffic according to the characteristics specified in the detector. For example, the system can identify an application by an ASCII pattern in the packet header. In addition, Secure Socket Layers (SSL) protocol detectors use information from the secured session to identify the application from the session.

There are two sources of application detectors:

- *System-provided detectors* detect web applications, clients, and application protocols.

  The availability of system-provided detectors for applications (and operating systems) depends on the version of the system software and the version of the VDB you have installed. Release notes and advisories

contain information on new and updated detectors. You can also import individual detectors authored by Professional Services.

- *Custom application protocol detectors* are user-created and detect web applications, clients, and application protocols.

You can also detect application protocols through *implied application protocol detection*, which infers the existence of an application protocol based on the detection of a client.

The system identifies only those application protocols running on hosts in your monitored networks, as defined in the network discovery policy. For example, if an internal host accesses an FTP server on a remote site that you are not monitoring, the system does not identify the application protocol as FTP. On the other hand, if a remote or internal host accesses an FTP server on a host you are monitoring, the system can positively identify the application protocol.

If the system can identify the client used by a monitored host to connect to a non-monitored server, the system identifies the client's corresponding application protocol, but does not add the protocol to the network map. Note that client sessions must include a response from the server for application detection to occur.

The system characterizes each application that it detects; see Application Characteristics, on page 1736. The system uses these characteristics to create groups of applications, called *application filters*. Application filters are used to perform access control and to constrain search results and data used in reports and dashboard widgets.

You can also supplement application detector data using exported NetFlow records, Nmap active scans, and the host input feature.

Related Topics

Best Practices for Configuring Application Control, on page 1735
Application Detector Fundamentals, on page 2624

Application Detector Fundamentals

The system uses *application detectors* to identify the commonly used applications on your network. Use the Detectors page (**Policies** > **Application Detectors**) to view the detector list and customize detection capability.

Whether you can modify a detector or change its state (active or inactive) depends on its type. The system uses only active detectors to analyze application traffic.

Note Cisco-provided detectors may change with system and VDB updates. See the release notes and advisories for information on updated detectors.

Note For Firepower application identification, the ports are not listed intentionally. The application's associate ports are not reported for any of Cisco's applications because most of the applications are port-agnostic. Our platform's detection capabilities can identify services running at any port in the network.

Cisco-Provided Internal Detectors

Internal detectors are a special category of detectors for client, web application, and application protocol traffic. Internal detectors are delivered with system updates and are always on.

If an application matches against internal detectors designed to detect client-related activity and no specific client detector exists, a generic client may be reported.

Cisco-Provided Client Detectors

Client detectors detect client traffic and are delivered via VDB or system update, or are provided for import by Cisco Professional Services. You can activate and deactivate client detectors. You can export a client detector only if you import it.

Cisco-Provided Web Application Detectors

Web application detectors detect web applications in HTTP traffic payloads and are delivered via VDB or system update. Web application detectors are always on.

Cisco-Provided Application Protocol (Port) Detectors

Port-based application protocol detectors use well-known ports to identify network traffic. They are delivered via VDB or system update, or are provided for import by Cisco Professional Services. You can activate and deactivate application protocol detectors, and view a detector definition to use it as the basis for a custom detector.

Cisco-Provided Application Protocol (Firepower) Detectors

Firepower-based application protocol detectors analyze network traffic using Firepower application fingerprints and are delivered via VDB or system update. You can activate and deactivate application protocol detectors.

Custom Application Detectors

Custom application detectors are pattern-based. They detect patterns in packets from client, web application, or application protocol traffic. You have full control over imported and custom detectors.

Identification of Application Protocols in the Web Interface

The following table outlines how the system identifies detected application protocols:

Table 141: System Identification of Application Protocols

Identification	Description
application protocol name	The Firewall Management Center identifies an application protocol with its name if the application protocol was: • positively identified by the system • identified using NetFlow data and there is a port-application protocol correlation in `/etc/sf/services` • manually identified using the host input feature • identified by Nmap or another active source

Identification	Description
`pending`	The Firewall Management Center identifies an application protocol as `pending` if the system can neither positively nor negatively identify the application. Most often, the system needs to collect and analyze more connection data before it can identify a pending application. In the Application Details and Servers tables and in the host profile, the `pending` status appears only for application protocols where specific application protocol traffic was detected (rather than inferred from detected client or web application traffic).
`unknown`	The Firewall Management Center identifies an application protocol as `unknown` if: • the application does not match any of the system's detectors. • the application protocol was identified using NetFlow data, but there is no port-application protocol correlation in `/etc/sf/services`. • Snort has closed the session but it still persists in the device. Here, the traffic is allowed to pass through the firewall, but the application is not detected.
blank	All available detected data has been examined, but no application protocol was identified. In the Application Details and Servers tables and in the host profile, the application protocol is left blank for non-HTTP generic client traffic with no detected application protocol.

Implied Application Protocol Detection from Client Detection

If the system can identify the client used by a monitored host to access a non-monitored server, the Firewall Management Center infers that the connection is using the application protocol that corresponds with the client. (Because the system tracks applications only on monitored networks, connection logs usually do not include application protocol information for connections where a monitored host is accessing a non-monitored server.)

This process, or *implied application protocol detection*, has the following consequences:

- Because the system does not generate a New TCP Port or New UDP Port event for these servers, the server does not appear in the Servers table. In addition, you cannot trigger either discovery event alerts or correlation rules using the detection of these application protocol as a criterion.
- Because the application protocol is not associated with a host, you cannot view its details in host profiles, set its server identity, or use its information in host profile qualifications for traffic profiles or correlation rules. In addition, the system does not associate vulnerabilities with hosts based on this type of detection.

You can, however, trigger correlation events on whether the application protocol information is present in a connection. You can also use the application protocol information in connection logs to create connection trackers and traffic profiles.

Host Limits and Discovery Event Logging

When the system detects a client, server, or web application, it generates a discovery event unless the associated host has already reached its maximum number of clients, servers, or web applications.

Host profiles display up to 16 clients, 100 servers, and 100 web applications per host.

Note that actions dependent on the detection of clients, servers, or web applications are unaffected by this limit. For example, access control rules configured to trigger on a server will still log connection events.

Special Considerations for Application Detection

SFTP

In order to detect SFTP traffic, the same rule must also detect SSH.

Squid

The system positively identifies Squid server traffic when either:

- the system detects a connection from a host on your monitored network to a Squid server where proxy authentication is enabled, or
- the system detects a connection from a Squid proxy server on your monitored network to a target system (that is, the destination server where the client is requesting information or another resource).

However, the system cannot identify Squid service traffic if:

- a host on your monitored network connects to a Squid server where proxy authentication is disabled, or
- the Squid proxy server is configured to strip Via: header fields from its HTTP responses

SSL Application Detection

The system provides application detectors that can use session information from a Secure Socket Layers (SSL) session to identify the application protocol, client application, or web application in the session.

When the system detects an encrypted connection, it marks that connection as either a generic HTTPS connection or as a more specific secure protocol, such as SMTPS, when applicable. When the system detects an SSL session, it adds `SSL client` to the **Client** field in connection events for the session. If it identifies a web application for the session, the system generates discovery events for the traffic.

For SSL application traffic, managed devices can also detect the common name from the server certificate and match that against a client or web application from an SSL host pattern. When the system identifies a specific client, it replaces `SSL client` with the name of the client.

Because the SSL application traffic is encrypted, the system can use only information in the certificate for identification, not application data within the encrypted stream. For this reason, SSL host patterns can sometimes only identify the company that authored the application, so SSL applications produced by the same company may have the same identification.

In some instances, such as when an HTTPS session is launched from within an HTTP session, managed devices detect the server name from the client certificate in a client-side packet.

To enable SSL application identification, you must create access control rules that monitor responder traffic. Those rules must have either an application condition for the SSL application or URL conditions using the URL from the SSL certificate. For network discovery, the responder IP address does not have to be in the networks to monitor in the network discovery policy; the access control policy configuration determines whether the traffic is identified. To identify detections for SSL applications, you can filter by the `SSL protocol` tag, in the application detectors list or when adding application conditions in access control rules.

Referred Web Applications

Web servers sometimes refer traffic to other websites, which are often advertisement servers. To help you better understand the context for referred traffic occurring on your network, the system lists the web application that referred the traffic in the **Web Application** field in events for the referred session. The VDB contains a list of known referred sites. When the system detects traffic from one of those sites, the referring site is stored with the event for that traffic. For example, if an advertisement accessed via Facebook is actually hosted on Advertising.com, the detected Advertising.com traffic is associated with the Facebook web application. The system can also detect referring URLs in HTTP traffic, such as when a website provides a simple link to another site; in this case, the referring URL appears in the HTTP Referrer event field.

In events, if a referring application exists, it is listed as the web application for the traffic, while the URL is that for the referred site. In the example above, the web application for the connection event for that traffic would be Facebook, but the URL would be Advertising.com. A referred application may appear as the web application if no referring web application is detected, if the host refers to itself, or if there is a chain of referrals. In the dashboard, connection and byte counts for web applications include sessions where the web application is associated with traffic referred by that application.

Note that if you create a rule to act specifically on referred traffic, you should add a condition for the referred application, rather than the referring application. To block Advertising.com traffic referred from Facebook, for example, add an application condition to your access control rule for the Advertising.com application.

Application Detection in Snort 3

Note Snort 3 is now at parity with Snort 2, with respect to enabling AppID inspection exclusively on particular network subnets that are defined in the Network Discovery policy filters **if** no other configuration in the AC policy requires AppID to monitor all traffic.

In Snort 3, application detection is always enabled for all networks by default. To disable application detection, do the following:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**, click edit policy and delete the application rules.

Step 2 Choose **Policies** > **Access Control heading** > **Decryption**, click delete to delete the SSL policy.

Step 3 Choose **Policies** > **Network Discovery**, click delete to delete the network discovery policy.

Step 4 Choose **Policies** > **Access Control heading** > **Access Control**, click **Edit** (✎) to the policy you want to edit and then click the **Security Intelligence** > **URLs** tab to delete the URLs Allow or Block list.

Step 5 As you cannot delete default DNS rules, choose **Policies** > **Access Control heading** > **DNS**, click edit and uncheck the enabled box to disable the DNS policy.

Step 6 In the access control policy, under the **Advanced** settings, disable the *Enable Threat Intelligence Director* and *Enable reputation enforcement on DNS traffic* options.

Step 7 Save and deploy the access control policy.

Custom Application Detectors

If you use a custom application on your network, you can create a custom web application, client, or application protocol detector that provides the system with the information it needs to identify the application. The type of application detector is determined by your selections in the **Protocol**, **Type**, and **Direction** fields.

Client sessions must include a responder packet from the server for the system to begin detecting and identifying application protocols in server traffic. Note that, for UDP traffic, the system designates the source of the responder packet as the server.

If you have already created a detector on another Firewall Management Center, you can export it and then import it onto this Firewall Management Center. You can then edit the imported detector to suit your needs. You can export and import custom detectors as well as detectors provided by Cisco Professional Services. However, you **cannot** export or import any other type of Cisco-provided detectors.

Custom Application Detector and User-Defined Application Fields

You can use the following fields to configure custom application detectors and user-defined applications.

Custom Application Detector Fields: General

Use the following fields to configure basic and advanced custom application detectors.

Application Protocol

The application protocol you want to detect. This can be a system-provided application or a user-defined application.

If you want the application to be available for exemption from active authentication (configured in your identity rules), you must select or create an application protocol with the **`User-Agent Exclusion`** tag.

Description

A description for the application detector.

Name

A name for the application detector.

Detector Type

The type of detector, **Basic** or **Advanced**. Basic application detectors are created in the web interface as a series of fields. Advanced application detectors are created externally and uploaded as custom .lua files.

Custom Application Detector Fields: Detection Patterns

Use the following fields to configure the detection patterns for basic custom application detectors.

Direction

The source of the traffic the detector should inspect, **Client** or **Server**.

Offset

The location in a packet, in bytes from the beginning of the packet payload, where the system should begin searching for the pattern.

Because packet payloads start at byte 0, calculate the offset by subtracting 1 from the number of bytes you want to move forward from the beginning of the packet payload. For example, to look for the pattern in the fifth bit of the packet, type `4` in the **Offset** field.

Pattern

The pattern string associated with the **Type** you selected.

Ports

The port of the traffic the detector should inspect.

Protocol

The protocol you want to detect. Your protocol selection determines whether the **Type** or the **URL** field displays.

The protocol (and, in some cases, your subsequent selections in the **Type** and **Direction** fields) determine the type of application detector you create: web application, client, or application protocol.

Detector Type	Protocol	Type or Direction
Web Application	HTTP	**Type** is **Content Type** or **URL**
	RTMP	Any
	SSL	Any
Client	HTTP	**Type** is **User Agent**
	SIP	Any
	TCP or UDP	**Direction** is **Client**
Application Protocol	TCP or UDP	**Direction** is **Server**

Type

The type of pattern string you entered. The options you see are determined by the **Protocol** you selected. If you selected **RTMP** as the protocol, the **URL** field displays instead of the **Type** field.

Note If you select **User Agent** as the **Type**, the system automatically sets the **Tag** for the application to **User-Agent Exclusion**.

Type Selection	String Characteristics
Ascii	The string is ASCII encoded.
Common Name	The string is the value in the commonName field within the server response message.
Content Type	The string is the value in the content-type field within the server response header.
Hex	The string is in hexadecimal notation.
Organizational Unit	The string is the value in the organizationName field within the server response message.
SIP Server	The string is the value in the From field within the message header.
SSL Host	The string is the value in the server_name field within the ClientHello message.
URL	The string is a URL. **Note** The detector assumes that the string you enter is a complete section of the URL. For example, entering **cisco.com** would match **www.cisco.com/support** and **www.cisco.com**, but not **www.wearecisco.com**.
User Agent	The string is the value in the user-agent field within the GET request header. It is also available for the SIP protocol and indicates that the string is the value in the User-Agent field within the SIP message header.

URL

Either a full URL or a section of a URL from the swfURL field within the C2 message of a RTMP packet. This field displays instead of the **Type** field when you select **RTMP** as the **Protocol**.

Note The detector assumes that the string you enter is a complete section of the URL. For example, entering **cisco.com** would match **www.cisco.com/support** and **www.cisco.com**, but not **www.wearecisco.com**.

User-Defined Application Fields

Use the following fields to configure user-defined applications within basic and advanced custom application detectors.

Business Relevance

The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.

Categories

A general classification for the application that describes its most essential function.

Description

A description for the application.

Name

A name for the application.

Risk

The likelihood that the application is used for purposes that might be against your organization's security policy: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.

Tags

One or more predefined tags that provide additional information about the application. If you want an application to be available for exemption from active authentication (configured in your identity rules), you must add the **User-Agent Exclusion** tag to your application.

Configuring Custom Application Detectors

You can configure basic or advanced custom application detectors.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Create Custom Detector**.

Step 3 Enter a **Name** and a **Description**.

Step 4 Choose an **Application Protocol** from the application drop-down list. You have the following options:

- If you are creating a detector for an existing application protocol (for example, if you want to detect a particular application protocol on a non-standard port), select the application protocol from the drop-down list.
- If you are creating a detector for a user-defined application, follow the procedure outlined in Create a User-Defined Application, on page 2633.

Step 5 Click **Detector Type** as **Basic** or **Advanced**.

Step 6 Click **OK**.

Step 7 Configure **Detection Patterns** or **Detection Criteria** or **Encrypted Visibility Engine Process Assignments**:

- If you are configuring a basic detector, specify preset **Detection Patterns** as described in Specifying Detection Patterns in Basic Detectors, on page 2634.
- If you are configuring an advanced detector, specify custom **Detection Criteria** as described in Specifying Detection Criteria in Advanced Detectors, on page 2635.
- If you are configuring an encrypted visibility engine (EVE) detector, specify custom EVE process assignments as described in *Specifying EVE Process Assignments* section in this chapter.

Caution
Advanced custom detectors are complex and require outside knowledge to construct valid .lua files. Incorrectly configured detectors could have a negative impact on performance or detection capability.

Step 8 Optionally, use **Packet Captures** to test the new detector as described in Testing a Custom Application Protocol Detector, on page 2637.

Step 9 Click **Save**.

Note
If you include the application in an access control rule, the detector is automatically activated and cannot be deactivated while in use.

What to do next

- Activate the detector as described in Activating and Deactivating Detectors, on page 2640.

Related Topics

Custom Application Detector and User-Defined Application Fields, on page 2629

Create a User-Defined Application

Applications, categories, and tags created here are available in access control rules and in the application filter object manager as well.

Caution Creating a user-defined application immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Before you begin

- Begin configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632.

Procedure

Step 1 On the **Create A Custom Application Detector** dialog box, click **Add** (+) next to the **Application** field.

Step 2 Type a **Name**.

Step 3 Type a **Description**.

Step 4 Select a **Business Relevance**.

Step 5 Select a **Risk**.

Step 6 Click **Add** next to Categories to add a category and type a new category name, or select an existing category from the **Categories** drop-down list.

Step 7 Click **Add** next to Tags to add a tag and type a new tag name, or select an existing tag from the **Tags** drop-down list.

Note
To associate the customized application detector domain for Policy Based Routing, you must select NSG from the **Tags** list.

Step 8 Click **OK**.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Custom Application Detector and User-Defined Application Fields, on page 2629

Specifying Detection Patterns in Basic Detectors

You can configure a custom application protocol detector to search application protocol packet headers for a particular pattern string. You can also configure detectors to search for multiple patterns; in that case the application protocol traffic must match all of the patterns for the detector to positively identify the application protocol.

Application protocol detectors can search for ASCII or hexadecimal patterns, using any offset.

Before you begin

- Begin configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632.

Procedure

Step 1 On the **Create Detector** page, in the **Detection Patterns** section, click **Add**.

Step 2 Choose protocol type from the **Application** drop-down list.

Step 3 Choose pattern type from the **Type** drop-down list.

Step 4 Type a **Pattern** string that matches the **Type** you specified.

Step 5 Optionally, type the **Offset** (in bytes).

Step 6 Optionally, to identify application protocol traffic based on the port it uses, type a port from 1 to 65535 in the **Port(s)** field. To use multiple ports, separate them by commas.

Step 7 Click a **Direction**: `Client` or `Server`.

Step 8 Click **OK**.

Tip

If you want to delete a pattern, click **Delete** ( ) next to the pattern you want to delete.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Specifying Detection Criteria in Advanced Detectors, on page 2635

Specifying Detection Criteria in Advanced Detectors

Caution Advanced custom detectors are complex and require outside knowledge to construct valid .lua files. Incorrectly configured detectors could have a negative impact on performance or detection capability.

Caution Do not upload .lua files from untrusted sources.

Custom .lua files contain your custom application detector settings. Creating custom .lua files requires advanced knowledge of the lua programming language and experience with Cisco's C-lua API. Cisco strongly recommends you use the following to prepare .lua files:

- third-party instruction and reference material for the lua programming language
- The Open Source Detectors Developers Guide: https://www.snort.org/downloads
- OpenAppID Snort community resources: http://blog.snort.org/search/label/openappid

Note The system does not support .lua files that reference system calls or file I/O.

Before you begin

- Begin configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632.
- Prepare to create a valid .lua file by downloading and studying the .lua files for comparable detectors. For more information about downloading detector files, see Viewing or Downloading Detector Details, on page 2638.
- Create a valid .lua file that contains your custom application detector settings.

Procedure

Step 1 On the **Create Detector** page for an advanced custom application detector, in the **Detection Criteria** section, click **Add**.

Step 2 Click **Browse...** to navigate to the `.lua` file and upload it.

Step 3 Click **OK**.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632. You must save and activate the detector before the system can use it to analyze traffic.

Related Topics

Specifying Detection Patterns in Basic Detectors, on page 2634

Specifying EVE Process Assignments

You can configure your own custom application detectors to map processes detected by the encrypted visibility engine (EVE) to new or existing applications.

Before you begin

- Begin configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632.

Procedure

Step 1 On the Create Detector page, in the Encrypted Visibility Engine Process Assignments section, click **Add**.

Step 2 Enter the **Process Name** and **Minimum Process Confidence** value.

Note
You can enter text in the **Process Name** field and this is case-sensitive. The value should match the exact process name detected by EVE. The **Minimum Process Confidence** can be any number from 0 to 100. This is the number displayed in the **Encrypted Visibility Process Confidence Score** field in Connection Events.

For information about the **Encrypted Visibility Process Confidence Score** field, see the section *Connection and Security Intelligence Event Fields* in the Cisco Firepower Management Center Administration Guide.

Step 3 Click **Save**.

Step 4 In the Application Detector listing page, activate the detector that you created. For more information, see Activating and Deactivating Detectors, on page 2640. When you activate the detector, the detector files are pushed to all the FTDs registered on the Firewall Management Center.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632. You must save and activate the detector before the system can use it to analyze traffic.

Testing a Custom Application Protocol Detector

If you have a packet capture (pcap) file that contains packets with traffic from the application protocol you want to detect, you can test a custom application protocol detector against that pcap file. Cisco recommends using a simple, clean pcap file without unnecessary traffic.

Pcap files must be 256 KB or smaller; if you try to test your detector against a larger pcap file, the Firewall Management Center automatically truncates it and tests the incomplete file. You must fix the unresolved checksums in a pcap before using the file to test a detector.

Before you begin

- Configure your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632.

Procedure

Step 1 On the Create Detector page, in the Packet Captures section, click **Add**.

Step 2 Browse to the pcap file in the pop-up window and click **OK**.

Step 3 To test your detector against the contents of the pcap file, click evaluate next to the pcap file. A message indicates whether the test succeeded.

Step 4 Optionally, repeat steps 1 to 3 to test the detector against additional pcap files.

Tip

To delete a pcap file, click **Delete** ( ) next to the file you want to delete.

What to do next

- Continue configuring your custom application protocol detector as described in Configuring Custom Application Detectors, on page 2632. You must save and activate the detector before the system can use it to analyze traffic.

Viewing or Downloading Detector Details

You can use the detectors list to view application detector details (all detectors) and download detector details (custom application detectors only).

Procedure

Step 1 To view application detector details, do one of the following:

- See the *Cisco Firepower Application Detector Reference* for the relevant VDB version at https://www.cisco.com/c/en/us/support/security/defense-center/products-technical-reference-list.html
- a. Select **Policies** > **Application Detectors**.

  b. Filter the list to find a particular detector.

  c. Click **Information**( )

Step 2 To download detector details for a custom application detector, click **Download** ( ).

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have the necessary permissions.

Sorting the Detector List

By default, the Detectors page lists detectors alphabetically by name. An up or down arrow next to a column heading indicates that the page is sorted by that column in that direction.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click the appropriate column heading.

Filtering the Detector List

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Expand one of the filter groups described in Filter Groups for the Detector List, on page 2639 and select the check box next to a filter. To select all filters in a group, right-click the group name and select **Check All**.

Step 3 If you want to remove a filter, click **Remove** (✕) in the name of the filter in the **Filters** field or disable the filter in the filter list. To remove all filters in a group, right-click the group name and select **Uncheck All**.

Step 4 If you want to remove all filters, click **Clear all** next to the list of filters applied to the detectors.

Filter Groups for the Detector List

You can use several filter groups, separately or in combination, to filter the list of detectors.

Name

Finds detectors with names or descriptions containing the string you type. Strings can contain any alphanumeric or special character.

Custom Filter

Finds detectors matching a custom application filter created on the object management page.

Author

Finds detectors according to who created the detector. You can filter detectors by:

- any individual user who has created or imported a custom detector
- Cisco, which represents all Cisco-provided detectors *except* individually imported add-on detectors (you are the author for any detector that you import)
- **Any User**, which represents all detectors not provided by Cisco

State

Finds detectors according to their state, that is, **Active** or **Inactive**.

Type

Finds detectors according to the detector type, as described in Application Detector Fundamentals, on page 2624.

Protocol

Finds detectors according to which traffic protocol the detector inspects.

Category

Finds detectors according to the categories assigned to the application they detect.

Tag

Finds detectors according to the tags assigned to the application they detect.

Risk

Finds detectors according to the risks assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

Business Relevance

Finds detectors according to the business relevance assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

Navigating to Other Detector Pages

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 If you want to view the next page, click **Right Arrow** ( ).

Step 3 If you want to view the previous page, click **Left Arrow** ( ).

Step 4 If you want to view a different page, type the page number and press Enter.

Step 5 If you want to jump to the last page, click **Right End Arrow** ( ).

Step 6 If you want to jump to the first page, click **Left End Arrow** ( ).

Activating and Deactivating Detectors

You must activate a detector before you can use it to analyze network traffic. By default, all Cisco-provided detectors are activated.

You can activate multiple application detectors for each port to supplement the system's detection capability.

When you include an application in an access control rule in a policy and that policy is deployed, if there is no active detector for that application, one or more detectors automatically activate. Similarly, while an application is in use in a deployed policy, you cannot deactivate a detector if deactivating leaves no active detectors for that application.

Tip For improved performance, deactivate any application protocol, client, or web application detectors you do not intend to use.

Caution Activating or deactivating a system or custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click the slider next to the detector you want to activate or deactivate. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Note
Some application detectors are required by other detectors. If you deactivate one of these detectors, a warning appears to indicate that the detectors that depend on it are also disabled.

Editing Custom Application Detectors

Use the following procedure to modify custom application detectors.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Edit** (✎) next to the detector you want to modify. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Make changes to the detector as described in Configuring Custom Application Detectors, on page 2632.

Step 4 You have the following saving options, depending on the state of the detector:

- To save an inactive detector, click **Save**.
- To save an inactive detector as a new, inactive detector, click **Save as New**.
- To save an active detector and immediately start using it, click **Save and Reactivate**.

Caution
Saving and reactivating a custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

- To save an active detector as a new, inactive detector, click **Save as New**.

Deleting Detectors

You can delete custom detectors as well as individually imported add-on detectors provided by Cisco Professional Services. You cannot delete any of the other Cisco-provided detectors, though you can deactivate many of them.

Note While a detector is in use in a deployed policy, you cannot delete the detector.

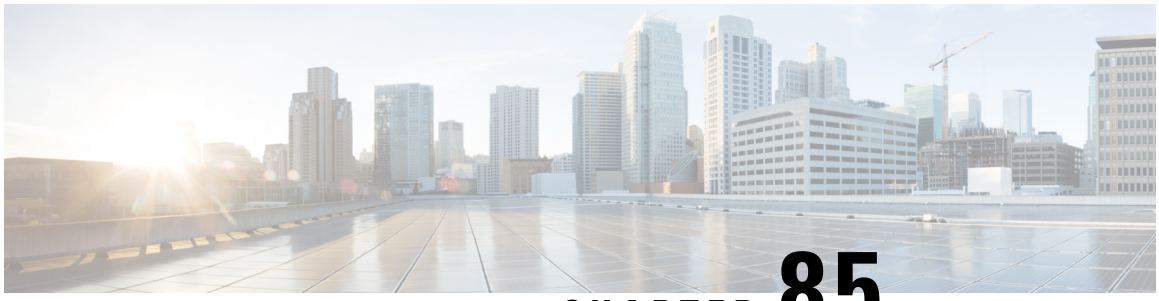
Caution Deleting an activated custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Procedure

Step 1 Select **Policies** > **Application Detectors**.

Step 2 Click **Delete** ( ) next to the detector you want to delete. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **OK**.



CHAPTER 85

Network Discovery Policies

The following topics describe how to create, configure, and manage network discovery policies:

- Overview: Network Discovery Policies, on page 2643
- Requirements and Prerequisites for Network Discovery Policies, on page 2644
- Network Discovery Customization, on page 2644
- Network Discovery Rules, on page 2645
- Configuring Advanced Network Discovery Options, on page 2654
- Troubleshooting Your Network Discovery Strategy, on page 2662

Overview: Network Discovery Policies

The network discovery policy on the Firewall Management Center controls how the system collects data on your organization's network assets and which network segments and ports are monitored.

Discovery rules within the policy specify which networks and ports the system monitors to generate discovery data based on network data in traffic, and the zones to which the policy is deployed. Within a rule, you can configure whether hosts, applications, and non-authoritative users are discovered. You can create rules to exclude networks and zones from discovery. You can configure discovery of data from NetFlow exporters and restrict the protocols for traffic where user data is discovered on your network.

The network discovery policy has a single default rule in place, configured to discover applications from all observed traffic. The rule does not exclude any networks, zones, or ports, host and user discovery is not configured, and the rule is not configured to monitor a NetFlow exporter. This policy is deployed by default to any managed devices when they are registered to the Firewall Management Center. To begin collecting host or user data, you must add or modify discovery rules and re-deploy the policy to a device.

If you want to adjust the scope of network discovery, you can create additional discovery rules and modify or remove the default rule.

Remember that the access control policy for each managed device defines the traffic that you permit for that device and, therefore, the traffic you can monitor with network discovery. If you block certain traffic using access control, the system cannot examine that traffic for host, user, or application activity. For example, if an access control policy blocks access to social networking applications, the system cannot provide any discovery data on those applications.

If you enable traffic-based user detection in your discovery rules, you can detect non-authoritative users through user login activity in traffic over a set of application protocols. You can disable discovery in particular protocols across all rules if needed. Disabling some protocols can help avoid reaching the user limit associated with your Firewall Management Center model, reserving available user count for users from the other protocols.

Advanced network discovery settings allow you to manage what data is logged, how discovery data is stored, what indications of compromise (IOC) rules are active, what vulnerability mappings are used for impact assessment, and what happens when sources offer conflicting discovery data. You can also add sources for host input and NetFlow exporters to monitor.

Network Discovery Customization

The information about your network traffic collected by the system is most valuable to you when the system can correlate this information to identify the hosts on your network that are most vulnerable and most important.

As an example, if you have several devices on your network running a customized version of SuSE Linux, the system cannot identify that operating system and so cannot map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for SuSE Linux, you may want to create a custom fingerprint for one of the hosts that can then be used to identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for SuSE Linux in the fingerprint to associate that list with each host that matches the fingerprint.

The system also allows you to input host data from third-party systems directly into the network map, using the host input feature. However, third-party operating system or application data does not automatically map to vulnerability information. If you want to see vulnerabilities and perform impact correlation for hosts using third-party operating system, server, and application protocol data, you must map the vendor and version information from the third-party system to the vendor and version listed in the vulnerability database (VDB). You also may want to maintain the host input data on an ongoing basis. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

If the system cannot identify application protocols running on hosts on your network, you can create user-defined application protocol detectors that allow the system to identify the applications based on a port or a pattern. You can also import, activate, and deactivate certain application detectors to further customize the application detection capability.

You can also replace detection of operating system and application data using scan results from the Nmap active scanner or augment the vulnerability lists with third-party vulnerabilities. The system may reconcile data from multiple sources to determine the identity for an application.

Configuring the Network Discovery Policy

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Configure the following components of your policy:

- Discovery rules — See Configuring Network Discovery Rules, on page 2646.
- Traffic-based detection for users — See Configuring Traffic-Based User Detection, on page 2653.
- Advanced network discovery options — See Configuring Advanced Network Discovery Options, on page 2654.
- Custom operating system definitions (fingerprints) — See Creating a Custom Fingerprint for Clients, on page 2592 and Creating a Custom Fingerprint for Servers, on page 2594.

Network Discovery Rules

Network discovery rules allow you to tailor the information discovered for your network map to include only the specific data you want. Rules in your network discovery policy are evaluated sequentially. You can create rules with overlapping monitoring criteria, but doing so may affect your system performance.

When you exclude a host or a network from monitoring, the host or network does not appear in the network map and no events are reported for it. However, when the host discovery rules for the local IP are disabled, the detection engine instances are impacted by a higher processing load, as it builds data from each flow afresh rather than using the existing host data.

We recommend that you exclude load balancers (or specific ports on load balancers) and NAT devices from monitoring. These devices may create excessive and misleading events, filling the database and overloading the Firewall Management Center. For example, a monitored NAT device might exhibit multiple updates of its operating system in a short period of time. If you know the IP addresses of your load balancers and NAT devices, you can exclude them from monitoring.

Tip The system can identify many load balancers and NAT devices by examining your network traffic.

In addition, if you need to create a custom server fingerprint, you should temporarily exclude from monitoring the IP address that you are using to communicate with the host you are fingerprinting. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address. After you create the fingerprint, you can configure your policy to monitor that IP address again.

Cisco also recommends that you **not** monitor the same network segment with NetFlow exporters and managed devices. Although ideally you should configure your network discovery policy with non-overlapping rules, the system does drop duplicate connection logs generated by managed devices. However, you **cannot** drop duplicate connection logs for connections detected by both a managed device and a NetFlow exporter.

Configuring Network Discovery Rules

You can configure discovery rules to tailor the discovery of host and application data to your needs.

Tip In most cases, we recommend restricting discovery to the addresses in RFC 1918.

Before you begin

- Make sure you are logging connections for the traffic where you want to discover network data ; see *Best Practices for Connection Logging* in the Cisco Secure Firewall Management Center Administration Guide.
- If you want to collect exported NetFlow records, add a NetFlow Exporter as described in Adding NetFlow Exporters to a Network Discovery Policy, on page 2658.
- If you will want to view discovery performance graphs, you must enable hosts, users, and applications in your discovery rule. Note that this may impact system performance.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Set the **Action** for the rule as described in Actions and Discovered Assets, on page 2646.

Step 4 Set optional discovery parameters:

- Restrict the rule action to specific networks; see Restricting the Monitored Network, on page 2648.
- Restrict the rule action to traffic in specific zones; see Configuring Zones in Network Discovery Rules, on page 2651.
- Exclude ports from monitoring; see Excluding Ports in Network Discovery Rules, on page 2650.
- Configure the rule for NetFlow data discovery; see Configuring Rules for NetFlow Data Discovery, on page 2648.

Step 5 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Actions and Discovered Assets

When you configure a discovery rule, you must select an action for the rule. The effect of that action depends on whether you are using the rule to discover data from a managed device or from a NetFlow exporter.

The following table describes what assets are discovered by rules with the specified action settings in those two scenarios.

Table 142: Discovery Rule Actions

Action	Option	Managed Device	NetFlow Exporter
Exclude	--	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.
Discover	Hosts	Adds hosts to the network map based on discovery events. (Optional, unless user discovery is enabled, then required.)	Adds hosts to the network map and logs connections based on NetFlow records. (Required)
Discover	Applications	Adds applications to the network map based on application detectors. Note that you cannot discover hosts or users in a rule without also discovering applications. (Required)	Adds application protocols to the network map based on NetFlow records and the port-application protocol correlation in `/etc/sf/services`. (Optional)
Discover	Users	Adds users to the users table and logs user activity based on traffic-based detection on the user protocols configured in the network discovery policy. (Optional)	n/a
Log NetFlow Connections	--	n/a	Logs NetFlow connections only. Does not discover hosts or applications.

If you want the rule to monitor managed device traffic, application logging is required. If you want the rule to monitor users, host logging is required. If you want the rule to monitor exported NetFlow records, you cannot configure it to log users, and logging applications is optional.

Note The system detects connections in exported NetFlow records based on the **Action** settings in the network discovery policy. The system detects connections in managed device traffic based on access control policy settings.

Monitored Networks

A discovery rule causes discovery of monitored assets only in traffic to and from hosts in the specified networks. For a discovery rule, discovery occurs for connections that have at least one IP address within the networks specified, with events generated only for IP addresses within the networks to monitor. The default discovery rule discovers applications from all observed traffic (`0.0.0.0/0` for all IPv4 traffic, and `::/0` for all IPv6 traffic).

If you configure a rule to handle NetFlow discovery and log only connections data, the system also logs connections to and from IP addresses in the specified networks. Note that network discovery rules provide the only way to log NetFlow network connections.

You can also use network object or object groups to specify the networks to monitor.

Restricting the Monitored Network

Every discovery rule must include at least one network.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Click **Networks**, if it is not already open.

Step 4 (Optional) Add network objects to the Available Networks list as described in Creating Network Objects During Discovery Rule Configuration, on page 2649.

If you modify a network object used in the network discovery policy, the changes do not take effect for discovery until you deploy the configuration changes.

Step 5 Specify a network:

- Choose a network from the **Available Networks** list. If the network does not immediately appear on the list, click **Reload** ( ).
- Enter the IP address into the text box below the Available Networks label.

Step 6 Click **Add**.

Step 7 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Configuring Rules for NetFlow Data Discovery

The system can use data from NetFlow exporters to generate connection and discovery events, and to add host and application data to the network map.

If you choose a NetFlow exporter in a discovery rule, the rule is limited to discovery of NetFlow data for the specified networks. Choose the NetFlow device to monitor before you configure other aspects of rule behavior, as the available rule actions change when you choose a NetFlow device. You cannot configure port exclusions for monitoring NetFlow exporters.

Before you begin

- Add NetFlow-enabled devices to the network discovery policy; see Adding NetFlow Exporters to a Network Discovery Policy, on page 2658.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Choose **NetFlow Device**.

Step 4 From the **NetFlow Device** drop-down list, choose the IP address of the NetFlow exporter to be monitored.

Step 5 Specify the type of NetFlow data you want the system managed device to collect:

- Connection only — Choose `Log NetFlow Connections` from the **Action** drop-down list.
- Host, Application, and Connection — Choose `Discover` from the **Action** drop-down list. The system automatically checks the **Hosts** check box and enables collection of connection data. Optionally, you can check the **Application** check box to collect application data.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Creating Network Objects During Discovery Rule Configuration

You can add new network objects to the list of available networks that appears in a discovery rule by adding them to the list of reusable network objects and groups.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 In **Networks**, click **Add Rule**.

Step 3 Click **Add** (+) next to **Available Networks**.

Step 4 Create a network object as described in Creating Network Objects, on page 1403.

Step 5 Finish adding the network discovery rule as described in Configuring Network Discovery Rules, on page 2646.

Port Exclusions

Just as you can exclude hosts from monitoring, you can exclude specific ports from monitoring. For example:

- Load balancers can report multiple applications on the same port in a short period of time. You can configure your network discovery rules so that they exclude that port from monitoring, such as excluding port 80 on a load balancer that handles a web farm.
- Your organization may use a custom client that uses a specific range of ports. If the traffic from this client generates excessive and misleading events, you can exclude those ports from monitoring. Similarly, you may decide that you do not want to monitor DNS traffic. In that case, you could configure your rules so that your discovery policy does not monitor port 53.

When adding ports to exclude, you can decide whether to use a reusable port object from the Available Ports list, add ports directly to the source or destination exclusion lists, or create a new reusable port and then move it into the exclusion lists.

Note You cannot exclude ports in rules handling NetFlow data discovery.

Excluding Ports in Network Discovery Rules

You cannot exclude ports in rules handling NetFlow data discovery.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Click **Port Exclusions**.

Step 4 Optionally, add port objects to the Available Ports list as described in Creating Port Objects During Discovery Rule Configuration, on page 2650.

Step 5 Exclude specific source ports from monitoring, using either of the following methods:

- Choose a port or ports from the **Available Ports** list and click **Add to Source**.
- To exclude traffic from a specific source port without adding a port object, under the **Selected Source Ports** list, choose a **Protocol**, enter a **Port** number (a value from 1 to 65535), and click **Add**.

Step 6 Exclude specific destination ports from monitoring, using either of the following methods:

- Choose a port or ports from the **Available Ports** list and click **Add to Destination**.
- To exclude traffic from a specific destination port without adding a port object, under the **Selected Destination Ports** list, choose a **Protocol**, enter a **Port** number, and click **Add**.

Step 7 Click **Save** to save the changes you made.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Creating Port Objects During Discovery Rule Configuration

You can add new port objects to the list of available ports that appears in a discovery rule by adding them to the list of reusable port objects and groups that can be used anywhere in the system.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 In Networks, click **Add Rule**.

Step 3 Click **Port Exclusions**.

Step 4 To add a port to the Available Ports list, click **Add** (+).

Step 5 Enter **Name**.

Step 6 In the **Protocol** field, specify the protocol of the traffic you want to exclude.

Step 7 In the **Port** field, enter the ports you want to exclude from monitoring.

You can specify a single port, a range of ports using the dash (-), or a comma-separated list of ports and port ranges. Allowed port values are from 1 to 65535.

Step 8 Click **Save**.

Step 9 If the port does not immediately appear on the list, click **Refresh**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Zones in Network Discovery Rules

To improve performance, discovery rules can be configured so that the zones in the rule include the sensing interfaces on your managed devices that are physically connected to the networks-to-monitor in the rule.

Unfortunately, you may not always be kept informed of network configuration changes. A network administrator may modify a network configuration through routing or host changes without informing you, which may make it challenging to stay on top of proper network discovery policy configurations. If you do not know how the sensing interfaces on your managed devices are physically connected to your network, leave the zone configuration as the default. This default causes the system to deploy the discovery rule to all zones in your deployment. (If no zones are excluded, the system deploy the discovery policy to all zones.)

Configuring Zones in Network Discovery Rules

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Add Rule**.

Step 3 Click **Zones**.

Step 4 Choose a zone or zones from the **Available Zones** list.

Step 5 Click **Save** to save the changes you made.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

The Traffic-Based Detection Identity Source

Traffic-based detection is the only non-authoritative identity source supported by the system. When configured, managed devices detect LDAP, AIM, POP3, IMAP, Oracle, SIP (VoIP), FTP, HTTP, MDNS, and SMTP logins on the networks you specify. The data gained from traffic-based detection can be used only for user awareness. Unlike authoritative identity sources, you configure traffic-based detection in your network discovery policy as described in Configuring Traffic-Based User Detection, on page 2653.

Note the following limitations:

- Traffic-based detection interprets only Kerberos logins for LDAP connections as LDAP authentications. Managed devices cannot detect encrypted LDAP authentications using protocols such as SSL or TLS.
- Traffic-based detection detects AIM logins using the OSCAR protocol only. They cannot detect AIM logins using TOC2.
- Traffic-based detection cannot restrict SMTP logging. This is because users are not added to the database based on SMTP logins; although the system detects SMTP logins, the logins are not recorded unless there is already a user with a matching email address in the database.

Traffic-based detection also records failed login attempts. A failed login attempt does not add a new user to the list of users in the database. The user activity type for detected failed login activity detected by traffic-based detection is **Failed User Login**.

Note The system cannot distinguish between failed and successful HTTP logins. To see HTTP user information, you must enable **Capture Failed Login Attempts** in the traffic-based detection configuration.

Caution Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

Traffic-Based Detection Data

When a device detects a login using traffic-based detection, it sends the following information to the Firewall Management Center to be logged as user activity:

- The user name identified in the login.
- The time of the login.
- The IP address involved in the login, which can be the IP address of the user's host (for LDAP, POP3, IMAP, and AIM logins), the server (for HTTP, MDNS, FTP, SMTP and Oracle logins), or the session originator (for SIP logins).
- The user's email address (for POP3, IMAP, and SMTP logins).
- The name of the device that detected the login.

If the user was previously detected, the Firewall Management Center updates that user's login history. Note that the Firewall Management Center can use the email addresses in POP3 and IMAP logins to correlate with LDAP users. This means that, for example, if the Firewall Management Center detects a new IMAP login, and the email address in the IMAP login matches that for an existing LDAP user, the IMAP login does not create a new user; rather, it updates the LDAP user's history.

If the user was previously undetected, the Firewall Management Center adds the user to the users database. Unique AIM, SIP, and Oracle logins always create new user records, because there is no data in those login events that the Firewall Management Center can correlate with other login types.

The Firewall Management Center does **not** log user activity or user identities in the following cases:

- If you configured the network discovery policy to ignore that login type
- If a managed device detects an SMTP login, but the users database does not contain a previously detected LDAP, POP3, or IMAP user with a matching email address

The user data is added to the users table.

Traffic-Based Detection Strategies

You can restrict the protocols where user activity is discovered to reduce the total number of detected users so you can focus on users likely to provide the most complete user information. Limiting protocol detection helps minimize user name clutter and preserve storage space on your Firewall Management Center.

Consider the following when selecting traffic-based detection protocols:

- Obtaining user names through protocols such as AIM, POP3, and IMAP may introduce user names not relevant to your organization due to network access from contractors, visitors, and other guests.
- AIM, Oracle, and SIP logins may create extraneous user records. This occurs because these login types are not associated with any of the user metadata that the system obtains from an LDAP server, nor are they associated with any of the information contained in the other types of login that your managed devices detect. Therefore, the Firewall Management Center cannot correlate these users with other types of users.

Configuring Traffic-Based User Detection

When you enable traffic-based user detection in a network discovery rule, host discovery is automatically enabled. For more information about traffic-based detection, see The Traffic-Based Detection Identity Source, on page 2651.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Users**.

Step 3 Click **Edit** ( ).

Step 4 Check the check boxes for protocols where you want to detect logins or clear check boxes for protocols where you do not want to detect logins, and choose whether you want to **Capture Failed Login Attempts**.

Step 5 Click **Save**.

What to do next

Caution Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 254 for more information.

- Configure network discovery rules to discover users as described in Configuring Network Discovery Rules, on page 2646.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Configuring Advanced Network Discovery Options

The Advanced of the network discovery policy allows you to configure policy-wide settings for what events are detected, how long discovery data is retained and how often it is updated, what vulnerability mappings are used for impact correlation, and how operating system and server identity conflicts are resolved. In addition, you can add host input sources and NetFlow exporters to allow import of data from other sources.

Note Database event limits for discovery and user activity events are set in system configuration.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) or **Add** (+) next to the setting you want to modify:

- Data Storage Settings — Update the settings as described in Configuring Network Discovery Data Storage, on page 2660.
- Event Logging Settings — Update the settings as described in Configuring Network Discovery Event Logging, on page 2661.
- General Settings — Update the settings as described in Configuring Network Discovery General Settings, on page 2655.
- Identity Conflict Settings — Update the settings as described in Configuring Network Discovery Identity Conflict Resolution, on page 2656.
- Indications of Compromise Settings — Update the settings as described in Enabling Indications of Compromise Rules, on page 2658.
- NetFlow Exporters — Update the settings as described in Adding NetFlow Exporters to a Network Discovery Policy, on page 2658.
- OS and Server Identity Sources — Update the settings as described in Adding Network Discovery OS and Server Identity Sources, on page 2661.
- Vulnerabilities to use for Impact Assessment — Update the settings as described in Enabling Network Discovery Vulnerability Impact Assessment, on page 2657.

Step 4 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Network Discovery General Settings

The general settings control how often the system updates network maps and whether server banners are captured during discovery.

Capture Banners

Select this check box if you want the system to store header information from network traffic that advertises server vendors and versions (“banners”). This information can provide additional context to the information gathered. You can access server banners collected for hosts by accessing server details.

Update Interval

The interval at which the system updates information (such as when any of a host’s IP addresses was last seen, when an application was used, or the number of hits for an application). The default setting is 3600 seconds (1 hour).

Note that setting a lower interval for update timeouts provides more accurate information in the host display, but generates more network events.

Configuring Network Discovery General Settings

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **General Settings**.

Step 4 Update the settings as described in Network Discovery General Settings, on page 2655.

Step 5 Click **Save** to save the general settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Network Discovery Identity Conflict Settings

The system determines which operating system and applications are running on a host by matching fingerprints for operating systems and servers against patterns in traffic. To provide the most reliable operating system and server identity information, the system collates fingerprint information from several sources.

The system uses all passive data to derive operating system identities and assign a confidence value.

By default, unless there is an identity conflict, identity data added by a scanner or third-party application overrides identity data detected by the system. You can use the Identity Sources settings to rank scanner and third-party application fingerprint sources by priority. The system retains one identity for each source, but only data from the highest priority third-party application or scanner source is used as the current identity. Note, however, that user input data overrides scanner and third-party application data regardless of priority.

An identity conflict occurs when the system detects an identity that conflicts with an existing identity that came from either the active scanner or third-party application sources listed in the Identity Sources settings or from a system user. By default, identity conflicts are not automatically resolved and you must resolve them through the host profile or by rescanning the host or re-adding new identity data to override the passive identity. However, you can set your system to automatically resolve the conflict by keeping either the passive identity or the active identity.

Generate Identity Conflict Event

Specifies whether the system generates an event when an identity conflict occurs.

Automatically Resolve Conflicts

From the **Automatically Resolve Conflicts** drop-down list, choose one of the following:

- **Disabled** if you want to force manual conflict resolution of identity conflicts
- **Identity** if you want to the system to use the passive fingerprint when an identity conflict occurs
- **Keep Active** if you want the system to use the current identity from the highest priority active source when an identity conflict occurs

Configuring Network Discovery Identity Conflict Resolution

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Identity Conflict Settings**.

Step 4 Update the settings in the Edit Identity Conflict Settings pop-up window as described in Network Discovery Identity Conflict Settings, on page 2655.

Step 5 Click **Save** to save the identity conflict settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Network Discovery Vulnerability Impact Assessment Options

You can configure how the system performs impact correlation with intrusion events. Your choices are as follows:

- Check the **Use Network Discovery Vulnerability Mappings** check box if you want to use system-based vulnerability information to perform impact correlation.
- Check the **Use Third-Party Vulnerability Mappings** check box if you want to use third-party vulnerability references to perform impact correlation. For more information, see the *Firepower System Host Input API Guide*.

You can check either or both of the check boxes. If the system generates an intrusion event and the host involved in the event has servers or an operating system with vulnerabilities in the selected vulnerability mapping sets, the intrusion event is marked with the Vulnerable (level 1: red) impact icon. For any servers which do not have vendor or version information, note that you need to enable vulnerability mapping in the Firewall Management Center configuration.

If you clear both check boxes, intrusion events will **never** be marked with the Vulnerable (level 1: red) impact icon.

Mapping Third-Party Vulnerabilities, on page 2600

Enabling Network Discovery Vulnerability Impact Assessment

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Vulnerabilities to use for Impact Assessment**.

Step 4 Update the settings in the Edit Vulnerability Settings pop-up window as described in Network Discovery Vulnerability Impact Assessment Options, on page 2656.

Step 5 Click **Save** to save the vulnerability settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Indications of Compromise

The system uses IOC rules in the network discovery policy to identify a host as likely to be compromised by malicious means. When a host meets the conditions specified in these system-provided rules, the system tags it with an *indication of compromise* (IOC). The related rules are known as *IOC rules*. Each IOC rule corresponds to one type of IOC tag. The *IOC tags* specify the nature of the likely compromise.

The Firewall Management Center can tag the host and user involved when one of the following things occurs:

- The system correlates data gathered about your monitored network and its traffic, using intrusion, connection, Security Intelligence, and file or malware events, and determines that a potential IOC has occurred.
- The Firewall Management Center can import IOC data from your Secure Endpoint deployments via the AMP cloud. Because this data examines activity on a host itself—such as actions taken by or on individual programs—it can provide insights into possible threats that network-only data cannot. For your convenience, the Firewall Management Center automatically obtains any new IOC tags that Cisco develops from the AMP cloud.

To configure this feature, see Enabling Indications of Compromise Rules, on page 2658.

You can also write correlation rules against host IOC data and compliance allow lists that account for IOC-tagged hosts.

To investigate and work with tagged IOCs, see Cisco Secure Firewall Management Center Administration Guide.

Enabling Indications of Compromise Rules

For your system to detect and tag indications of compromise (IOC), you must first activate at least one IOC rule in your network discovery policy. Each IOC rule corresponds to one type of IOC tag, and all IOC rules are predefined by Cisco; you cannot create original rules. You can enable any or all rules, depending on the needs of your network and organization. For example, if hosts using software such as Microsoft Excel never appear on your monitored network, you may decide not to enable the IOC tags that pertain to Excel-based threats.

Tip To disable IOC rules for individual hosts or their associated users, see the *Discovery Events* chapter in the Cisco Secure Firewall Management Center Administration Guide.

Before you begin

Because IOC rules trigger based on data provided by other components of the system and by Secure Endpoint, those components must be correctly licensed and configured for IOC rules to set IOC tags. Enable the system features associated with the IOC rules you will enable, such as intrusion detection and prevention (IPS) and Advanced Malware Protection (AMP). If an IOC rule's associated feature is not enabled, no relevant data is collected and the rule cannot trigger.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Indications of Compromise Settings**.

Step 4 To toggle the entire IOC feature off or on, click the slider next to **Enable IOC**.

Step 5 To globally enable or disable individual IOC rules, click the slider in the rule's **Enabled** column.

Step 6 Click **Save** to save your IOC rule settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Adding NetFlow Exporters to a Network Discovery Policy

Use this procedure to add NetFlow exporters. Note that you cannot delete an exporter if it is currently in use in a disocvery rule.

Before you begin

- Review prerequisites: Requirements for Using NetFlow Data, on page 2584
- Configure NetFlow exporters: NetFlow Data, on page 2583

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Add** (+) next to **NetFlow Devices**.

Step 4 Enter the **IP Address** of the exporter.

Step 5 Click **Save**.

What to do next

- Configure a network discovery rule to monitor NetFlow traffic: Configuring Network Discovery Rules, on page 2646
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Network Discovery Data Storage Settings

Discovery data storage settings include the host limit and timeout settings.

When Host Limit Reached

The number of hosts a Secure Firewall Management Center can monitor, and therefore store in the network map, depends on its model. The **When Host Limit Reached** option controls what happens when you detect a new host after you reach the host limit. You can:

Drop hosts

The system drops the host that has remained inactive for the longest time, then adds the new host. This is the default setting.

Don't insert new hosts

The system does not track any newly discovered hosts. The system only tracks new hosts after the host count drops below the limit, such as after an administrator increases the domain's host limit or manually deletes hosts from the network map, or if the system identifies hosts as timed-out due to inactivity.

Table 143: Reaching the Host Limit with Multitenancy

Setting	Domain Host Limit Set?	Domain Host Limit Reached	Ancestor Domain Host Limit Reached
Drop hosts	yes	Drops oldest host in the constrained domain.	Drops the oldest host among all descendant leaf domains configured to drop hosts. If no host can be dropped, does not add the host.
	no	n/a	Drops the oldest host among all descendant leaf domains configured to drop hosts and that share the general pool.
Don't insert new hosts	yes or no	Does not add the host.	Does not add the host.

Host Timeout

The amount of time that passes, in minutes, before the system drops a host from the network map due to inactivity. The default setting is 10080 minutes (one week). Individual host IP and MAC addresses can time out individually, but a host does not disappear from the network map unless all its associated addresses time out.

To avoid premature timeout of hosts, make sure that the host timeout value is longer than the update interval in the network discovery policy general settings.

Server Timeout

The amount of time that passes, in minutes, before the system drops a server from the network map due to inactivity. The default setting is 10080 minutes (one week).

To avoid premature timeout of servers, make sure that the service timeout value is longer than the update interval in the network discovery policy general settings.

Client Application Timeout

The amount of time that passes, in minutes, before the system drops a client from the network map due to inactivity. The default setting is 10080 minutes (one week).

Make sure that the client timeout value is longer than the update interval in the network discovery policy general settings.

Related Topics

Host Limit, on page 2383

Configuring Network Discovery Data Storage

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Network Discovery Data Storage Settings**.

Step 4 Update the settings in the Data Storage Settings dialog as described in Network Discovery Data Storage Settings, on page 2659.

Step 5 Click **Save** to save the data storage settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Configuring Network Discovery Event Logging

The Event Logging Settings control whether discovery and host input events are logged. If you do not log an event, you cannot retrieve it in event views or use it to trigger correlation rules.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **Event Logging Settings**.

Step 4 Check or clear the check boxes next to the discovery and host input event types you want to log in the database , described in the *Discovery Events* chapter of the Cisco Secure Firewall Management Center Administration Guide.

Step 5 Click **Save** to save the event logging settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Adding Network Discovery OS and Server Identity Sources

In Advanced of the network discovery policy, you can add new active sources or change the priority or timeout settings for existing sources.

Adding a scanner to this page does not add the full integration capabilities that exist for the Nmap scanners, but does allow integration of imported third-party application or scan results.

If you import data from a third-party application or scanner, make sure that you map vulnerabilities from the source to the vulnerabilities detected in your network.

Procedure

Step 1 Choose **Policies** > **Network Discovery**.

Step 2 Click **Advanced**.

Step 3 Click **Edit** (✎) next to **OS and Server Identity Sources**.

Step 4 To add a new source, click **Add Source**.

Step 5 Enter a **Name**.

Step 6 Choose the input source **Type** from the drop-down list:

- Choose **Scanner** if you plan to import scan results using the AddScanResult function.
- Choose **Application** if you do not plan to import scan results.

Step 7 To indicate the duration of time that should elapse between the addition of an identity to the network map by this source and the deletion of that identity, choose **Hours**, **Days**, or **Weeks** from the **Timeout** drop-down list and enter the appropriate duration.

Step 8 Optionally:

- To promote a source and cause the operating system and application identities to be used in favor of sources below it in the list, choose the source and click the up arrow.
- To demote a source and cause the operating system and application identities to be used only if there are no identities provided by sources above it in the list, choose the source and click the down arrow.
- To delete a source, click **Delete** (🗑) next to the source.

Step 9 Click **Save** to save the identity source settings.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Mapping Third-Party Vulnerabilities, on page 2600

Troubleshooting Your Network Discovery Strategy

Before you make any changes to the system's default detection capabilities, you should analyze what hosts are not being identified correctly and why, so you can decide what solution to implement.

Are Your Managed Devices Correctly Placed?

If network devices such as load balancers, proxy servers, or NAT devices reside between the managed device and the unidentified or misidentified host, place a managed device closer to the misidentified host rather than using custom fingerprinting. Cisco does not recommend using custom fingerprinting in this scenario.

Do Unidentified Operating Systems Have a Unique TCP Stack?

If the system misidentifies a host, you should investigate why the host is misidentified to help you decide between creating and activating a custom fingerprint or substituting Nmap or host input data for discovery data.

Caution If you encounter misidentified hosts, contact your support representative before creating custom fingerprints.

If a host is running an operating system that is not detected by the system by default and does not share identifying TCP stack characteristics with existing detected operating systems, you should create a custom fingerprint.

For example, if you have a customized version of Linux with a unique TCP stack that the system cannot identify, you would benefit from creating a custom fingerprint, which allows the system to identify the host and continuing monitoring it, rather than using scan results or third-party data, which require you to actively update the data yourself on an ongoing basis.

Note that many open source Linux distributions use the same kernel, and as such, the system identifies them using the Linux kernel name. If you create a custom fingerprint for a Red Hat Linux system, you may see other operating systems (such as Debian Linux, Mandrake Linux, Knoppix, and so on) identified as Red Hat Linux, because the same fingerprint matches multiple Linux distributions.

You should not use a fingerprint in every situation. For example, a modification may have been made to a host's TCP stack so that it resembles or is identical to another operating system. For example, an Apple Mac OS X host is altered, making its fingerprint identical to a Linux 2.4 host, causing the system to identify it as Linux 2.4 instead of Mac OS X. If you create a custom fingerprint for the Mac OS X host, it may cause all legitimate Linux 2.4 hosts to be erroneously identified as Mac OS X hosts. In this case, if Nmap correctly identifies the host, you could schedule regular Nmap scans for that host.

If you import data from a third-party system using host input, you must map the vendor, product, and version strings that the third party uses to describe servers and application protocols to the Cisco definitions for those products. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

The system may reconcile data from multiple sources to determine the current identity for an operating system or application.

For Nmap data, you can schedule regular Nmap scans. For host input data, you can regularly run the Perl script for the import or the command line utility. However, note that active scan data and host input data may not be updated with the frequency of discovery data.

Can the System Identify All Applications?

If a host is correctly identified by the system but has unidentified applications, you can create a user-defined detector to provide the system with port and pattern matching information to help identify the application.

Have You Applied Patches that Fix Vulnerabilities?

If the system correctly identifies a host but does not reflect applied fixes, you can use the host input feature to import patch information. When you import patch information, you must map the fix name to a fix in the database.

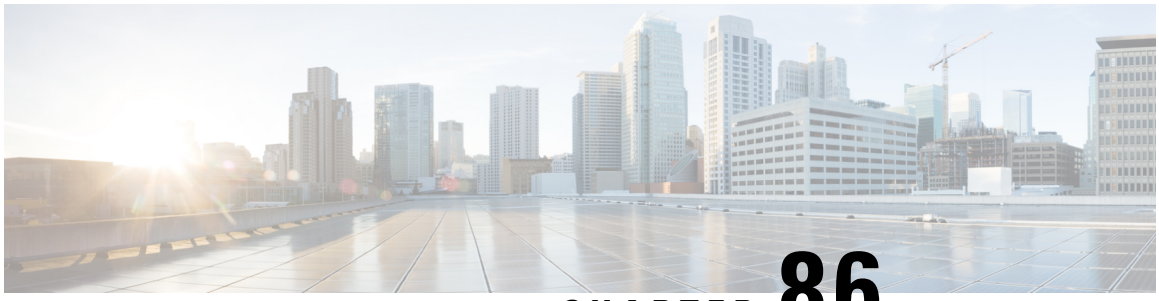
Do You Want to Track Third-Party Vulnerabilities?

If you have vulnerability information from a third-party system that you want to use for impact correlation, you can map the third-party vulnerability identifiers for servers and application protocols to vulnerability identifiers in the Cisco database and then import the vulnerabilities using the host input feature. For more information on using the host input feature, see the *Firepower System Host Input API Guide*. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

PART XIV

FlexConfig Policies

- FlexConfig Policies, on page 2667



CHAPTER 86

FlexConfig Policies

The following topics describe how to configure and deploy FlexConfig policies.

- FlexConfig Policy Overview, on page 2667
- Requirements and Prerequisites for FlexConfig Policies, on page 2687
- Guidelines and Limitations for FlexConfig, on page 2687
- Customizing Device Configuration with FlexConfig Policies, on page 2688
- Examples for FlexConfig, on page 2701
- Migrating FlexConfig Policies, on page 2708
- History for FlexConfig, on page 2710

FlexConfig Policy Overview

A FlexConfig policy is a container of an ordered list of FlexConfig objects. Each object includes a series of Apache Velocity scripting language commands, ASA software configuration commands, and variables that you define. The contents of each FlexConfig object is essentially a program that generates a sequence of ASA commands that will then be deployed to the assigned devices. This command sequence then configures the related feature on the Firewall Threat Defense device.

Firewall Threat Defense uses ASA configuration commands to implement some features, but not all features. There is no unique set of Firewall Threat Defense configuration commands. Instead, the point of FlexConfig is to allow you to configure features that are not yet directly supported through Firewall Management Center policies and settings.

Caution Cisco **strongly** recommends using FlexConfig policies only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not prohibited. Enabling features through FlexConfig policies may cause unintended results with other configured features.

You may contact the Cisco Technical Assistance Center for support concerning FlexConfig policies that you have configured. The Cisco Technical Assistance Center does not design or write custom configurations on any customer's behalf. Cisco expresses no guarantees for correct operation or interoperability with other Firepower System features. FlexConfig features may become deprecated at any time. For fully guaranteed feature support, you must wait for the Firewall Management Center support. When in doubt, do not use FlexConfig policies.

Recommended Usage for FlexConfig Policies

There are two main recommended uses for FlexConfig:

- You are converting from ASA to Firewall Threat Defense, and there are compatible features you are using (and need to continue using) that Firewall Management Center does not directly support. In this case, use the **show running-config** command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Experiment with the object's deployment settings (once/every time and append/prepend) to get the right setting. Verify by comparing **show running-config** output on the two devices.
- You are using Firewall Threat Defense but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

The system includes a set of predefined FlexConfig objects that represent tested configurations. If the feature you need is not represented by these objects, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control, which the ASA implements using separate features. Because many features are not configured using CLI commands, you will not see every policy represented within the output of **show running-config**.

Note At all times, keep in mind that there is not a one-to-one overlap between ASA and Firewall Threat Defense. Do not attempt to completely recreate an ASA configuration on a Firewall Threat Defense device. You must carefully test any feature that you configure using FlexConfig.

CLI Commands in FlexConfig Objects

The Firewall Threat Defense uses ASA configuration commands to configure some features. Although not all ASA features are compatible with the Firewall Threat Defense, there are some features that can work on the Firewall Threat Defense but that you cannot configure in the Firewall Management Center policies. You can use FlexConfig objects to specify the CLI required to configure these features.

If you decide to use FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig policies do not validate CLI command syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference:

- ASA CLI configuration guides explain how to configure a feature. Find the guides at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-installation-and-configuration-guides-list.html
- ASA command references provide additional information sorted by command name. Find the references at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-command-reference-list.html

The following topics explain more about configuration commands.

Determine the ASA Software Version and Current CLI Configuration

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the Firewall Threat Defense device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from a Firewall Threat Defense configuration. Many Firewall Threat Defense policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and Firewall Threat Defense configuration.

To view this information, make an SSH connection to the device's management interface and issue the following commands:

- **show version system** and look for the Cisco Adaptive Security Appliance Software Version number. (If you issue the command through the Secure Firewall Management Center CLI tool, omit the **system** keyword.)
- **show running-config** to view the current CLI configuration.
- **show running-config all** to include all the default commands in the current CLI configuration.

You can also issue these commands from within Firewall Management Center using the following procedure.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Step 2 Click the name of the device targeted by the FlexConfig policy.

You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

Step 3 Click **View System and Troubleshoot Details**.

Step 4 Click **Advanced Troubleshooting**.

Step 5 Click **Threat Defense CLI**.

Step 6 Choose the **Device**, then choose **show** as the command, and type **version** or one of the other commands as the parameter.

Step 7 Click **Execute**.

For version, search the output for the Cisco Adaptive Security Appliance Software Version number.

You can select the output and press Ctrl+C, then paste it into a text file for later analysis.

Prohibited CLI Commands

The purpose of FlexConfig is to configure features that are available on ASA devices that you cannot configure on Firewall Threat Defense devices using Firewall Management Center.

Thus, you are prevented from configuring ASA features that have equivalents in Firewall Management Center. The following table lists some of these prohibited command areas.

In addition, some **clear** commands are prohibited because they overlap with managed policies, and can delete part of the configuration for a managed policy.

The FlexConfig object editor prevents you from including prohibited commands in the object.

Prohibited CLI Command	Description
AAA	Configuration blocked.
AAA-Server	Configuration blocked.
Access-list	Advanced ACL, Extended ACL, and Standard ACL are blocked. Ethertype ACL is allowed. You can use standard and extended ACL objects defined in the object manager inside the template as variables.
ARP Inspection	Configuration blocked.
As-path Object	Configuration blocked.
Banner	Configuration blocked.
BGP	Configuration blocked.
Clock	Configuration blocked.
Community-list Object	Configuration blocked.
Copy	Configuration blocked.
Delete	Configuration blocked.
DHCP	Configuration blocked.
Enable Password	Configuration blocked.
Erase	Configuration blocked.
Fragment Setting	Blocked, except for **fragment reassembly**.
Fsck	Configuration blocked.
HTTP	Configuration blocked.
ICMP	Configuration blocked.
Interface	Only **nameif**, **mode**, **shutdown**, **ip address** and **mac-address** commands are blocked.
Multicast Routing	Configuration blocked.
NAT	Configuration blocked.
Network Object/Object-group	Network object creation in the FlexConfig object is blocked, but you can use network objects and groups defined in the object manager inside the template as variables.

Prohibited CLI Command	Description
NTP	Configuration blocked.
OSPF/OSPFv3	Configuration blocked.
pager	Configuration blocked.
Password Encryption	Configuration blocked.
Policy-list Object	Configuration blocked.
Prefix-list Object	Configuration blocked.
Reload	You cannot schedule reloads. The system does not use the **reload** command to restart the system, it uses the **reboot** command.
RIP	Configuration blocked.
Route-Map Object	Route-map object creation in the FlexConfig object is blocked, but you can use route map objects defined in the object manager inside the template as variables.
Service Object/Object-group	Service object creation in the FlexConfig object is blocked, but you can use port objects defined in the object manager inside the template as variables.
SNMP	Configuration blocked.
SSH	Configuration blocked.
Static Route	Configuration blocked.
Syslog	Configuration blocked.
Time Synchronization	Configuration blocked.
Timeout	Configuration blocked.
VPN	Configuration blocked.

Template Scripts

You can use scripting language to control processing within a FlexConfig object. Scripting language instructions are a subset of commands supported in the Apache Velocity 1.3.1 template engine, a Java-based scripting language that supports looping, if/else statements, and variables.

To learn how to use the scripting language, see the *Velocity Developer Guide* at http://velocity.apache.org/engine/devel/developer-guide.html.

FlexConfig Variables

You can use variables in a FlexConfig object in cases where part of a command or processing instruction depends on runtime information rather than static information. During deployment, the variables are replaced with strings obtained from other configurations for the device based on the type of variable:

- Policy object variables are replaced with strings obtained from objects defined in Firewall Management Center.
- System variables are replaced with information obtained from the device itself or from policies configured for it.
- Processing variables are loaded with the contents of policy object or system variables as scripting commands are processed. For example, in a loop, you iteratively load one value from a policy object or system variable into a processing variable, then use the processing variable to form a command string or perform some other action. These processing variables do not show up in the Variables list within a FlexConfig object. Also, you do not add them using the **Insert** menu in the FlexConfig object editor.
- Secret key variables are replaced with the single string defined for the variable within the FlexConfig object.

Variables start with the $ character, except for secret keys, which start with the @ character. For example, $ifname is a policy object variable in the following command, whereas @keyname is a secret key.

```
interface $ifname
key @keyname
```

Note The first time you insert a policy object or system variable, you must do so through the **Insert** menu in the FlexConfig object editor. This action adds the variable to the **Variables** list at the bottom of the FlexConfig object editor. But you must type in the variable string on subsequent uses, even when using system variables. If you are adding a processing variable, which does not have an object or system variable assignment, do not use the **Insert** menu. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Whether a variable is resolved as a single string, a list of strings, or a table of values depends on the type of policy object or system variable you assign to the variable. (Secret keys always resolve to a single string.) You must understand what will be returned in order to process the variables correctly.

The following topics explain the various types of variable and how to process them.

How to Process Variables

At runtime, a variable can resolve to a single string, a list of strings of the same type, a list of strings of different types, or a table of named values. In addition, variables that resolve to multiple values can be of determinate or indeterminate length. You must understand what will be returned in order to process the values correctly.

Following are the main possibilities.

Single Value Variables

If a variable always resolves to a single string, use the variable directly without modification in the FlexConfig script.

For example, the predefined text variable tcpMssBytes always resolves to a single value (which must be numeric). The **Sysopt_basic** FlexConfig then uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, tcpMssMinimum:

```
#if($tcpMssMinimum == "true")
  sysopt connection tcpmss minimum $tcpMssBytes
#else
  sysopt connection tcpmss $tcpMssBytes
#end
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $tcpMssBytes, but you would type in the variable directly on the #else line.

Secret key variables are a special type of single value variable. For secret keys, you always use the **Insert** menu to add the variable, even for second and subsequent uses. These variables do not show up in the Variables list within the FlexConfig object.

Note Policy object variables for network objects also equate to a single IP address specification, either a host address, network address, or address range. However, in this case, you must know what type of address to expect, because the ASA commands require specific address types. For example, if a command requires a host address, using a network object variable that points to an object that contains a network address will result in an error during deployment.

Multiple Value Variables, All Values Are the Same Type

Several policy object and system variables resolve to multiple values of the same type. For example, an object variable that points to a network object group resolves to a list of the IP addresses within the group. Similarly, the system variable $SYS_FW_INTERFACE_NAME_LIST resolves to a list of interface names.

You can also create text objects for multiple values of the same type. For example, the predefined text object enableInspectProtocolList can contain more than one protocol name.

Multiple value variables that resolve to a list of items of the same type are frequently of indeterminate length. For example, you cannot know beforehand how many interfaces on a device are named, as users can configure or unconfigure interfaces at any time.

Thus, you would typically use a loop to process multiple value variables of the same type. For example, the predefined FlexConfig **Default_Inspection_Protocol_Enable** uses a #foreach loop to go through the enableInspectProtocolList object and process each value.

```
policy-map global_policy
    class inspection_default
    #foreach ( $protocol in $enableInspectProtocolList)
    inspect $protocol
    #end
```

In this example, the script assigns each value in turn to the $protocol variable, which is then used in an ASA **inspect** command to enable the inspection engine for that protocol. In this case, you simply type in $protocol as a variable name. You do not use the **Insert** menu to add it, because you are not assigning an object or system value to the variable. However, you must use the **Insert** menu to add $enableInspectProtocolList.

The system loops through the code between #foreach and #end until there are no values remaining in $enableInspectProtocolList.

Multiple Value Variables, Values Are Different Types

You can create multiple value text objects, but have each value serve a different purpose. For example, the predefined **netflow_Destination** text object should have 3 values, in order, interface name, destination IP address, and UDP port number.

Objects defined in this way should have a determinate number of values. Otherwise, they would be hard to process.

Use the get method to process these objects. Type **.get(*n*)** at the end of the object name, replacing *n* with an index into the object. Start counting at 0, even though the text object lists its values starting at 1.

For example, the Netflow_Add_Destination object uses the following line to add the 3 values from netflow_Destination to the ASA **flow-export** command.

```
flow-export destination $netflow_Destination.get(0) $netflow_Destination.get(1)
$netflow_Destination.get(2)
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $netflow_Destination, and then add **.get(0)**. But you would type in the variable directly for the **$netflow_Destination.get(1)** and **$netflow_Destination.get(2)** specifications.

Multiple Value Variables that Resolve to a Table of Values

Some system variables return a table of values. These variables include MAP in their name, for example, $SYS_FTD_ROUTED_INTF_MAP_LIST. The routed interface map returns data that looks like the following (line returns added for clarity):

```
[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]
```

In the above example, information is returned for 4 interfaces. Each interface includes a table of named values. For example, intf_hardwarare_id is the name of the interface hardware name property, and returns strings such as GigabitEthernet0/0.

This type of variable is typically of indeterminate length, so you need to use looping to process the values. But you also need to add the property name to the variable name to indicate which value to retrieve.

For example, IS-IS configuration requires that you add the ASA **isis** command to an interface that has a logical name in interface configuration mode. However, you enter that mode using the interface's hardware name. Thus, you need to identify which interfaces have logical names, then configure just those interfaces using their hardware names. The ISIS_Interface_Configuration predefined FlexConfig does this using an if/then

structure nested in a loop. In the following code, you can see that the #foreach scripting command loads each interface map into the $intf variable, then the #if statement keys off the intf_logical_name value in the map ($intf.intf_logical_name), and if the value is in the list defined in the isisIntfList predefined text variable, enters the interface command using the intf_hardwarare_id value ($intf.intf_hardwarare_id). You would need to edit the isisIntfList variable to add the names of the interfaces on which to configure IS-IS.

```
#foreach ($intf in $SYS_FTD_ROUTED_INTF_MAP_LIST)
 #if ($isIsIntfList.contains($intf.intf_logical_name))
  interface $intf.intf_hardwarare_id
   isis
   #if ($isIsAddressFamily.contains("ipv6"))
   ipv6 router isis
   #end
 #end
#end
```

How to See What a Variable Will Return for a Device

An easy way to evaluate what a variable will return is to create a simple FlexConfig object that does nothing more than process an annotated list of variables. Then, you can assign it to a FlexConfig policy, assign the policy to a device, save the policy, then preview the configuration for that device. The preview will show the resolved values. You can select the preview text, press Ctrl+C, then paste the output into a text file for analysis.

Note Do not deploy this FlexConfig to the device, however, because it will not contain any valid configuration commands. You would get deployment errors. After obtaining the preview, delete the FlexConfig object from the FlexConfig policy and save the policy.

For example, you could construct the following FlexConfig object:

```
Following is a network object group variable for the
IPv4-Private-All-RFC1918 object:

$IPv4_Private_addresses

Following is the system variable SYS_FW_MANAGEMENT_IP:

$SYS_FW_MANAGEMENT_IP

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

$SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

$SYS_FTD_ROUTED_INTF_MAP_LIST

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

$SYS_FW_INTERFACE_NAME_LIST
```

The preview of this object might look like the following (line returns added for clarity):

```
###Flex-config Prepended CLI ###
```

```
###CLI generated from managed features ###

###Flex-config Appended CLI ###
Following is an network object group variable for the
IPv4-Private-All-RFC1918 object:

[10.0.0.0, 172.16.0.0, 192.168.0.0]

Following is the system variable SYS_FW_MANAGEMENT_IP:

192.168.0.171

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

[dns, ftp, h323 h225, h323 ras, rsh, rtsp, sqlnet, skinny, sunrpc,
xdmcp, sip, netbios, tftp, icmp, icmp error, ip-options]

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

[outside, inside, management]
```

FlexConfig Policy Object Variables

A policy object variable is associated with a specific policy object configured in the Object Manager. When you insert a policy object variable in a FlexConfig object, you give the variable a name and select the object associated with it.

Although you can give the variable the exact same name as the associated object, the variable itself is not the same thing as the associated object. You must use the **Insert** > **Insert Policy Object** > ***Object Type*** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the object. Simply typing in the name of the object preceded by a $ sign does not create a policy object variable.

You can create variables to point to the following types of object. Ensure that you create the right type of object for each variable. To create objects, go to the **Objects** > **Object Management** page.

- **Text Objects**—For text strings, which can include IP addresses, numbers, and other free-form text such as interface or zone names. Select **FlexConfig** > **Text Object** from the table of contents, then click **Add Text Object**. You can configure these objects to contain a single value or multiple values. These objects

are highly flexible and built specifically for use within FlexConfig objects. For detailed information, see Configure FlexConfig Text Objects, on page 2694.

- **Network**—For IP addresses. You can use network objects or groups. Select **Network** from the table of contents, then select **Add Network** > **Add Object** or **Add Group**. If you use a group object, the variable returns a list of each IP address specification within the group. Addresses can be host, network, or address ranges, depending on the object contents. See Network, on page 1401.
- **Security Zones**—For interfaces within a security zone or interface group. Select **Interface** from the table of contents, then select **Add** > **Security Zone** or **Interface Group**. A security zone variable returns a list of the interfaces within that zone or group for the device being configured. See Interface, on page 1398.
- **Standard ACL Object**—For standard access control lists. A standard ACL variable returns the name of the standard ACL object. Select **Access List** > **Standard** from the table of contents, then click **Add Standard Access List Object**. See Access List, on page 1369.
- **Extended ACL Object**—For extended access control lists. An extended ACL variable returns the name of the extended ACL object. Select **Access List** > **Extended** from the table of contents, then click **Add Extended Access List Object**. See Access List, on page 1369.
- **Route Map**—For route map objects. A route map variable returns the name of the route map object. Select **Route Map** from the table of contents, then click **Add Route Map**. See Route Map, on page 1426.

FlexConfig System Variables

System variables are replaced with information obtained from the device itself or from policies configured for it.

You must use the **Insert** > **Insert System Variable** > ***Variable Name*** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the system variable. Simply typing in the name of the system variable preceded by a $ sign does not create a system variable within the context of the FlexConfig object.

The following table explains the available system variables. Before using a variable, examine what is typically returned for the variable; see How to See What a Variable Will Return for a Device, on page 2675.

Name	Description
SYS_FW_OS_MODE	The operating system mode of the device. Possible values are ROUTED or TRANSPARENT.
SYS_FW_OS_MULTIPLICITY	Whether the device is running in single or multiple context mode. Possible values are SINGLE, MULTI, or NOT_APPLICABLE.
SYS_FW_MANAGEMENT_IP	The management IP address of the device
SYS_FW_HOST_NAME	The device hostname
SYS_FTD_INTF_POLICY_MAP	A map with interface name as key and policy-map as value. This variable returns nothing if there are no interface-based service policies defined on the device.
SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST	The list of protocols for which inspection is enabled.

Name	Description
SYS_FTD_ROUTED_INTF_MAP_LIST	A list of routed interface maps on the device. Each map includes a set of named values related to routed interface configuration.
SYS_FTD_SWITCHED_INTF_MAP_LIST	A list of switched interface maps on the device. Each map includes a set of named values related to switched interface configuration.
SYS_FTD_INLINE_INTF_MAP_LIST	A list of inline interface maps on the device. Each map includes a set of named values related to inline set interface configuration.
SYS_FTD_PASSIVE_INTF_MAP_LIST	A list of passive interface maps on the device. Each map includes a set of named values related to passive interface configuration.
SYS_FTD_INTF_BVI_MAP_LIST	A list of Bridge Virtual Interface maps on the device. Each map includes a set of named values related to BVI configuration.
SYS_FW_INTERFACE_HARDWARE_ID_LIST	A list of the hardware names for interfaces on the device, such as GigabitEthernet0/0.
SYS_FW_INTERFACE_NAME_LIST	A list of logical names for interfaces on the device, such as inside.
SYS_FW_INLINE_INTERFACE_NAME_LIST	A list of logical names for interfaces configured as passive or ERSPAN passive.
SYS_FW_NON_INLINE_INTERFACE_NAME_LIST	A list of logical names for interfaces that are not part of inline sets, such as all routed interfaces.

Predefined FlexConfig Objects

The predefined FlexConfig objects provide tested configurations for select features. Use these objects if you need to configure these features, which otherwise cannot be configured using the Firewall Management Center.

The following table lists the available objects. Make note of the associated text objects. You must edit these text objects to customize the behavior of the predefined FlexConfig object. The text objects make it possible for you to customize the configuration using the IP addresses and other attributes required by your network and device.

If you need to modify a predefined FlexConfig object, copy the object, make changes to the copy, and save it with a new name. You cannot directly edit a predefined FlexConfig object.

Although you might be able to configure other ASA-based features using FlexConfig, the configuration of those features has not been tested. If an ASA feature overlaps with something that you can configure in Firewall Management Center policies, do not attempt to configure it through FlexConfig.

For example, Snort inspection includes the HTTP protocol, so do not enable ASA-style HTTP inspection. (In fact, you cannot add **http** to the enableInspectProtocolList object. In this case, you are prevented from misconfiguring your device.) Instead, configure the access control policy to perform application or URL filtering, as needed, to implement your HTTP inspection requirements.

Table 144: Predefined FlexConfig Objects

FlexConfig Object Name	Description	Associated Text Objects
Default_Inspection_Protocol_Disable	Disables protocols in the global_policy default policy map.	disableInspectProtocolList
Default_Inspection_Protocol_Enable	Enables protocols in the global_policy default policy map.	enableInspectProtocolList
Inspect_IPv6_Configure	Configures IPv6 inspection in the global_policy policy map, logging and dropping traffic based on IPv6 header contents.	IPv6RoutingHeaderDropLogList, IPv6RoutingHeaderLogList, IPv6RoutingHeaderDropList.
Inspect_IPv6_UnConfigure	Clears and disables IPv6 inspection.	—
ISIS_Configure	Configures global parameters for IS-IS routing.	isIsNet, isIsAddressFamily, isISType
ISIS_Interface_Configuration	Interface level IS-IS configuration.	isIsAddressFamily, IsIsIntfList Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST
ISIS_Unconfigure	Clears the IS-IS router configuration on the device.	—
ISIS_Unconfigure_All	Clears the IS-IS router configuration from the device, including the router assignment from the device interface.	—
NGFW_TCP_NORMALIZATION	Modifies the default TCP normalization configuration.	—
Policy_Based_Routing	To use this example configuration, copy it, modify the interface name, and use the r-map-object text object to identify a route map object in the object manager.	—
Policy_Based_Routing_Clear	Clears Policy Based Routing configurations from the device.	—
Sysopt_AAA_radius	Ignores the authentication key in RADIUS accounting responses.	—
Sysopt_AAA_radius_negate	Negates the Sysopt_AAA_radius configuration.	—
Sysopt_basic	Configures sysopt wait time , maximum segment size for TCP packets, and detailed traffic statistics.	tcpMssMinimum, tcpMssBytes

FlexConfig Object Name	Description	Associated Text Objects
Sysopt_basic_negate	Clears sysopt_basic detailed traffic statistics, wait time, and TCP maximum segment size.	—
Sysopt_clear_all	Clears all sysopt configurations from the device.	—
Sysopt_noproxyarp	Configures noproxy-arp CLIs.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_noproxyarp_negate	Clears Sysopt_noproxyarp configurations.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_Preserve_Vpn_Flow	Configures syopt preserve VPN flow.	—
Sysopt_Preserve_Vpn_Flow_negate	Clears the Sysopt_Preserve_Vpn_Flow configuration.	—
Sysopt_Reclassify_Vpn	Configures sysopt reclassify vpn.	—
Sysopt_Reclassify_Vpn_Negate	Negates sysopt reclassify vpn.	—
Threat_Detection_Clear	Clear the threat detection TCP Intercept configuration.	—
Threat_Detection_Configure	Configure threat detection statistics for attacks intercepted by TCP Intercept.	threat_detection_statistics
Wccp_Configure	This template provides an example for configuring WCCP.	isServiceIdentifier, serviceIdentifier, wccpPassword
Wccp_Configure_Clear	Clears WCCP configurations.	—

Deprecated FlexConfig Objects

The following table lists objects that configure features you can now configure natively in the GUI. Discontinue using these objects at the earliest convenience.

Table 145: Deprecated Predefined FlexConfig Objects

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.3	DHCPv6_Prefix_Delegation_Configure	Configure one outside (Prefix Delegation client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation. To use this template, copy it and modify the variables. Associated text objects: pdoutside, pdinside Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	Interface IPv6 Settings.
7.3	DHCPv6_Prefix_Delegation_UnConfigure	Removes the DHCPv6 prefix delegation configuration.	Interface IPv6 Settings.
6.3	Default_DNS_Configure	Configure the Default DNS group, which defines the DNS servers that can be used when resolving fully-qualified domain names on the data interfaces. Associated text objects: defaultDNSNameServerList, defaultDNSParameters	Platform settings.
6.3	DNS_Configure	Configure DNS servers in a non-default DNS server group. Copy the object to change the name of the group.	**DNS Server Group** in the object manager.
6.3	DNS_UnConfigure	Removes the DNS server configuration performed by Default_DNS_Configure and DNS_Configure. Copy the object to change the DNS server group names if you altered DNS_Configure.	**DNS Server Group** in the object manager.
7.2	Eigrp_Configure	Configures EIGRP routing next-hop, auto-summary, router-id, eigrp-stub. Associated text objects: eigrpAS, eigrpNetworks, eigrpDisableAutoSummary, eigrpRouterId, eigrpStubReceiveOnly, eigrpStubRedistributed, eigrpStubConnected, eigrpStubStatic, eigrpStubSummary	For all EIGRP objects, see EIGRP, on page 1267. The system does allow you to deploy post-upgrade, but also warns you to redo your EIGRP configurations. To help you with this process, we provide a command-line migration tool.

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.2	Eigrp_Interface_Configure	Configures EIGRP interface authentication mode, authentication key, hello interval, hold time, split horizon. Associated text objects: eigrpIntfList, eigrpAS, eigrpAuthKey, eigrpAuthKeyId, eigrpHelloInterval, eigrpHoldTime, eigrpDisableSplitHorizon Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	
7.2	Eigrp_Unconfigure	Clears EIGRP configuration for an autonomous system from the device.	
7.2	Eigrp_Unconfigure_all	Clears all EIGRP configurations.	
7.4	Netflow_Add_Destination	Creates and configures a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Clear_Parameters	Restores Netflow export global default settings.	Platform settings.
7.4	Netflow_Delete_Destination	Deletes a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Set_Parameters	Sets global parameters for Netflow export. Associated text objects: netflow_Parameters	Platform settings.
6.3	TCP_Embryonic_Conn_Limit	Configures embryonic connection limits to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_limit	Service policy.

Deprecated Version	FlexConfig Object	Description	Now Configure In
6.3	TCP_Embryonic_Conn_Timeout	Configures embryonic connection timeouts to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_timeout	Service policy.
7.2	VxLAN_Clear_Nve	Removes the NVE 1 configured when VxLAN_Configure_Port_And_Nve is used from the device.	For all VxLAN objects, see Configure VXLAN Interfaces, on page 838. If you configured VXLAN interfaces with FlexConfig in a previous version, they continue to work. In fact, FlexConfig takes precedence in this case—if you redo your VXLAN configurations in the web interface, remove the FlexConfig settings.
7.2	VxLAN_Clear_Nve_Only	Clears the NVE configured on the interface when deployed.	
7.2	VxLAN_Configure_Port_And_Nve	Configures VLAN port and NVE 1. Associated text objects: vxlan_Port_And_Nve	
7.2	VxLAN_Make_Nve_Only	Sets an interface for NVE only. Associated text objects: vxlan_Nve_Only Also uses system variables SYS_FTD_ROUTED_MAP_LIST and SYS_FTD_SWITCHED_INTF_MAP_LIST	
7.2	VxLAN_Make_Vni	Creates a VNI interface. After deploying this you have to unregister and re-register the device to properly discover the VNI interface. Associated text objects: vxlan_Vni	

Predefined Text Objects

There are several predefined text objects. These objects are associated with variables used in the predefined FlexConfig objects. In most cases, you must edit these objects to add values if you use the associated FlexConfig object, or you will see errors during deployment. Although some of these objects contain default values, others are empty.

For information on editing text objects, see Configure FlexConfig Text Objects, on page 2694.

Name	Description	Associated FlexConfig Object
defaultDNSNameServerList (Deprecated.)	The DNS server IP address to configure in the Default DNS group. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
defaultDNSParameters (Deprecated.)	The parameters to control DNS behavior for the default DNS server group. The object contains separate entries, in order, for retries, timeout, expire-entry-timer, poll-timer, domain-name. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
disableInspectProtocolList	Disables protocols in the default policy map (global_policy).	Disable_Default_Inspection_Protocol
dnsNameServerList	The DNS server IP address to configure in a user-defined DNS group.	DNS_Configure
dnsParameters	The parameters to control DNS behavior for a non-default DNS server group. The object contains separate entries, in order, for retries, timeout, domain-name, name-server-interface.	DNS_Configure
enableInspectProtocolList	Enables protocols in the default policy map (global_policy). You are prevented from adding protocols whose inspection conflicts with Snort inspection.	Enable_Default_Inspection_Protocol
IPv6RoutingHeaderDropList	The list of IPv6 routing header types that you want to disallow. IPv6 inspection drops packets that contain these headers without logging the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderDropLogList	The list of IPv6 routing header types that you want to disallow and log. IPv6 inspection drops packets that contain these headers and sends a syslog message about the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderLogList	The list of IPv6 routing header types that you want to allow but log. IPv6 inspection allows packets that contain these headers, but sends a syslog message about the existence of the header.	Inspect_IPv6_Configure

Name	Description	Associated FlexConfig Object
isIsAddressFamily	The IPv4 or IPv6 address family.	ISIS_Configure ISIS_Interface_Configuration
IsIsIntfList	List of logical interface names.	ISIS_Interface_Configuration
isIsISType	IS Type (level-1, level-2-only or level-1-2).	ISIS_Configure
isIsNet	Network entity.	ISIS_Configure
isServiceIdentifier	When false, uses the standard **web-cache** service identifier.	Wccp_Configure
netflow_Destination	Defines a single NetFlow export destination's interface, destination, and UDP port number.	Netflow_Add_Destination
netflow_Event_Types	Defines the types of events to be exported for a destination as any subset of: **all**, **flow-create**, **flow-defined**, **flow-teardown**, **flow-update**.	Netflow_Add_Destination
netflow_Parameters	Provides the NetFlow export global settings: active refresh interval (number of minutes between flow update events), delay (flow create delay in seconds; default 0 = command will not appear), and template time-out rate in minutes.	Netflow_Set_Parameters
PrefixDelegationInside	Configures the inside interface for DHCPv6 prefix delegation. The object includes multiple entries, in order, interface name, IPv6 suffix with prefix length, and prefix pool name.	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
PrefixDelegationOutside	Configure the outside DHCPv6 prefix delegation client. The object includes multiple entries, in order, interface name and IPv6 prefix length	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
serviceIdentifier	Dynamic WCCP service identifier number.	Wccp_Configure
tcp_conn_limit (Deprecated.)	Parameters used for configuring the TCP embryonic connection limits. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit

Name	Description	Associated FlexConfig Object
tcp_conn_misc (Deprecated.)	Parameters used for configuring the TCP embryonic connection settings. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit, TCP_Embryonic_Conn_Timeout
tcp_conn_timeout (Deprecated.)	Parameters used for configuring the TCP embryonic connection timeouts. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Timeout
tcpMssBytes	Maximum segment size in bytes.	Sysopt_basic
tcpMssMinimum	Checks whether to set maximum segment size (MSS), which is set only if this flag is true.	Sysopt_basic
threat_detection_statistics	Parameters used for threat detection statistics for TCP Intercept.	Threat_Detection_Configure
vxlan_Nve_Only	Parameters for configuring NVE-only on interface: • logical name of interface • IPv4 address (optional for routed interface) • IPv4 netmask (optional for routed interface)	VxLAN_Make_Nve_Only
vxlan_Port_And_Nve	Parameters used for configuring ports and NVE for VXLAN: • vxlan port • source interface (logical name) • type (peer or mcast) • Peer IP Address or default-mcast-group	VxLAN_Configure_Port_And_Nve

Name	Description	Associated FlexConfig Object
vxlan_Vni	Parameters used for creating VNI: • Interface number (1-10000) • segment-id (1-16777215) • nameif (Logical Name of the interface) • type (routed or transparent) • IP address (used in case of routed mode device) or bridge-group number (used in case of transparent mode device) • netmask (If device is in routed mode) or unused	VxLAN_Make_Vni
wccpPassword	WCCP password.	Wccp_Configure

Requirements and Prerequisites for FlexConfig Policies

Guidelines and Limitations for FlexConfig

- If you make a mistake in the FlexConfig policy, the system will roll back all changes included in the deployment attempt that includes the failed FlexConfig. Because rollback due to a failed deployment includes clearing the configuration, this can be disruptive to your network. Consider timing deployments that include FlexConfig changes to non-business hours. Also, consider isolation the deployment so it includes just FlexConfig changes, and no other policy updates.
- When you use the VxLAN_Make_VNI object, you must deploy the same FlexConfig to all units in a cluster or high availability pair before you form the cluster or high availability pair. The Management Center requires the VXLAN interfaces to match on all devices before forming the cluster or high availability pair.

- If you configure any service that applies to connections, such as SIP inspection, go to the device CLI and enter the **clear conn** command to clear connections. When the connections are rebuilt, the new configuration is applied to the sessions.

Customizing Device Configuration with FlexConfig Policies

Use FlexConfig policies to customize the configuration of a Firewall Threat Defense device.

Before using FlexConfig, try to configure all the policies and settings you need using the other features in Firewall Management Center. FlexConfig is a method of last resort to configure ASA-based features that are compatible with Firewall Threat Defense but which are not otherwise configurable in Firewall Management Center.

Following is the end-to-end procedure for configuring and deploying a FlexConfig policy.

Procedure

Step 1 Determine the CLI command sequence that you want to configure.

If you have a functioning configuration on an ASA device, use **show running-config** to get the sequence of commands that you need. Make adjustments to items such as interface names and IP addresses as needed.

If this is for a new feature, it is best to try to implement it on an ASA device in a lab setting to verify that you have the correct command sequence.

For more information, see the following topics:

- Recommended Usage for FlexConfig Policies, on page 2668
- CLI Commands in FlexConfig Objects, on page 2668

Step 2 Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

Examine the predefined FlexConfig objects to determine if any will be able to generate the commands you need. Click **View** ( ) to see the object contents. If an existing object is close to what you want, start by making a copy of the object, and then edit the copy. See Predefined FlexConfig Objects, on page 2678.

Examining the objects will also give you an idea of the structure, command syntax, and expected sequencing for a FlexConfig object.

Note
If you find any objects that you will use, either directly or as copies, examine the Variables list at the bottom of the object. Make note of the variable names, except those in all capitals that start with SYS, which are system variables. These variables are text objects that you will probably need to edit and define overrides for, especially if the default value column shows the object has no value.

Step 3 If you need to create your own FlexConfig objects, determine what variables you will need and create the associated objects.

The CLI you need to deploy might contain IP addresses, interface names, port numbers, and other parameters that you might want to adjust over time. These are best isolated into variables, which point to objects that

contain the necessary values. You might also need variables for strings that are part of the configuration but which might change over time.

Also, determine if you need different values for each device to which you will assign the policy. For example, you might want to configure the feature on three devices, but you might need to specify a different interface name or IP address on a given command for each of these devices. If you need to customize the object for each device, ensure that you enable overrides when creating the object, and then define the override values per device.

See the following topics for an explanation of the various types of variables and how to configure the related objects when necessary.

- FlexConfig Variables, on page 2672
- FlexConfig Policy Object Variables, on page 2676
- FlexConfig System Variables, on page 2677
- Configure FlexConfig Text Objects, on page 2694

Step 4 If you are using the predefined FlexConfig objects, edit the text objects used as variables.

See Configure FlexConfig Text Objects, on page 2694.

Step 5 (If necessary.) Configure FlexConfig Objects, on page 2690.

You need to create objects only if the predefined objects cannot do the job.

Step 6 Configure the FlexConfig Policy, on page 2695.

Step 7 Set Target Devices for a FlexConfig Policy, on page 2696.

You can also assign the policy to devices when you create the policy. The policy must have at least one assigned device before you can preview it.

Step 8 Preview the FlexConfig Policy, on page 2697.

You must save changes before you can preview the policy.

Verify that the generated commands are the ones intended, and that all variables are resolving correctly.

Step 9 Choose **Deploy** > **Deployment** in the menu bar.

Step 10 Select the devices assigned to the policy, and click **Deploy**.

Wait for deployment to complete.

Step 11 Verify the Deployed Configuration, on page 2698.

Step 12 (If necessary.) Remove Features Configured Using FlexConfig, on page 2699.

Unlike other types of policy, simply unassigning a FlexConfig from a device might not remove the related configuration. If you want to remove a FlexConfig-generated configuration, you follow the cited procedure.

If you are removing a Feature because it is now directly supported by the product, see also Convert from FlexConfig to Managed Feature, on page 2701.

Configure FlexConfig Objects

Use FlexConfig objects to define a configuration to be deployed to a device. Each FlexConfig policy is composed of a list of FlexConfig objects, so the objects are essentially code modules composed of Apache Velocity scripting commands, ASA software configuration commands, and variables.

There are several predefined FlexConfig objects that you can use directly, or you can make copies if you need to edit them. You can also create your own objects from scratch. A FlexConfig object's content can range from a single simple command string to elaborate CLI command structures that use variables and scripting commands to deploy commands whose content can differ from device to device or deployment to deployment.

You can also create FlexConfig policy objects when defining FlexConfig policies.

Before you begin

Keep the following in mind:

- FlexConfig objects translate into commands that are then deployed to the device. These commands are already issued in global configuration mode. Therefore, do not include the **enable** and **configure terminal** commands as part of the FlexConfig object.
- Determine what types of variables you will need, and create any policy objects that you will require. You cannot create objects for variables while editing a FlexConfig object.
- Ensure that your commands do not conflict in any way with the VPN or access control configuration on the devices.
- If there is more than one set of commands for an interface, only the last set of commands is deployed. Therefore, we recommend you not use beginning and ending commands to configure interfaces. For an example of configuring interfaces, see the ISIS_Interface_Configuration predefined FlexConfig object.

Procedure

Step 1 Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

Step 2 Do one of the following:

- Click **Add FlexConfig Object** to create a new object.
- Click **Edit** ( ) to edit an existing object.
- Click **View** ( ) to see the contents of a predefined object.
- If you want to edit a predefined object, click **Clone** ( ) to create a new object with the same contents.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 In the object body area, enter the commands and instructions to produce the required configuration.

The object content is a sequence of scripting commands and configuration commands that generate a valid ASA software command sequence. The Firewall Threat Defense device uses ASA software commands to configure some features. For more information on scripting and configuration commands, see:

- Template Scripts, on page 2671

- CLI Commands in FlexConfig Objects, on page 2668

You can use variables to supply information that can be known only at runtime, or which can differ from device to device. You simply type in processing variables, but you must use the **Insert** menu to add variables that are associated with policy objects or system variables, or which are secret keys. For a complete discussion of variables, see FlexConfig Variables, on page 2672.

- To insert system variables, choose **Insert** > **Insert System Variable** > ***Variable Name***. For a detailed explanation of these variables, see FlexConfig System Variables, on page 2677.
- To insert policy object variables, choose **Insert** > **Insert Policy Object** > ***Object Type***, selecting the appropriate type of object. Then, give the variable a name (which can be the same name as the associated policy object), select the object to associate with the variable, and click **Save**. For a detailed explanation of these types, see FlexConfig Policy Object Variables, on page 2676. For more detail on the procedure, see Add a Policy Object Variable to a FlexConfig Object, on page 2692.
- To insert secret key variables, choose **Insert** > **Secret Key** and define the variable name and value. For more detail on the procedure, see Configure Secret Keys, on page 2693.

Note
You must use the **Insert** menu to create a new policy object or system variable. However, for subsequent uses of that variable, you must type it in, $ included. This is also true for system variables: the first time you use it, add it from the **Insert** menu. Then, type it out for subsequent uses. If you use the **Insert** menu more than once for a system variable, the system variable is added to the Variables list multiple times, and the FlexConfig will not validate, meaning you cannot save your changes. For processing variables (those not associated with a policy object or system variable), simply type in the variable. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Step 5 Choose the deployment frequency and type.

- **Deployment**—Whether to deploy the commands in the object **Once** or **Everytime**. The only way to choose the right option is to test the results of deployment.

  Start by selecting **Everytime**. Then, after you attach the object to a FlexConfig policy, deploy the configuration. After a successful deployment, come back to the FlexConfig policy and preview the configuration for one of the assigned devices as described in Preview the FlexConfig Policy, on page 2697. If the section labeled `###CLI generated from managed features ###` contains commands that clear or negate the commands in the object, and the `###Flex-config Appended CLI ###` section contains the commands to reconfigure the feature, you know that **Everytime** is the right option.

  Even if you do not see negate commands, make some minor change to the device configuration, then run another deployment. If the deployment completes successfully, you can check the deployment transcript (see Verify the Deployed Configuration, on page 2698). If you see that the commands were issued again (even when they were already configured) without error, then you can keep **Everytime**.

  Change to **Once** only if the system does not first negate the commands in the object before issuing them again, or if the deployment results in errors that are specific to the command. In some cases, the system does not allow you to issue a command that is already configured, but this is the exception.

  Some additional tips:

  - If the FlexConfig object points to system-managed objects such as network or ACL objects, choose **Everytime**. Otherwise, updates to the objects might not get deployed.
  - Use **Once** if the only thing you do in the object is to clear a configuration. Then, remove the object from the FlexConfig policy after the next deployment.

- **Type**—Select one of the following:
  - **Append**—(The default.) Commands in the object are put at the end of the configurations generated from the Firewall Management Center policies. You must use Append if you use policy object variables, which point to objects generated from managed objects. If commands generated for other policies overlap with those specified in the object, you should select this option so your commands are not overwritten. This is the safest option.
  - **Prepend**—Commands in the object are put at the beginning of the configurations generated from the Firewall Management Center policies. You would typically use prepend for commands that clear or negate a configuration.

Step 6 (Optional.) Click **Validate** ( ) above the object body to check the integrity of the script.

The object is always validated when you click **Save**. You cannot save an invalid object.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 259.

Add a Policy Object Variable to a FlexConfig Object

You can insert variables into a FlexConfig policy object that are associated with other types of policy object. When the FlexConfig is deployed to a device, these variables resolve to the names or content of the associated object.

Use the following procedure for the first use of a policy object variable in a FlexConfig object. If you need to refer to the object again, type in the variable (including the $ sign). To understand how to use these variables, see How to Process Variables, on page 2672.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig Objects, on page 2690.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Insert Policy Object** > ***Object Type***, selecting the appropriate type of object.

Step 2 Enter a name for the variable, and optionally, a description.

The name must be unique within the context of the FlexConfig object. It cannot include spaces. You are allowed to use the exact same name as the object associated with the variable.

Step 3 Select the object to associate with the variable and click **Add** to move it to the **Selected Object** list.

You can associate a variable with a single object only.

Note

For text objects, you can select any of the predefined objects as needed. However, many of these objects have no default values. You must update the objects to add the required values either directly or as overrides for the device to which you will deploy the FlexConfig object. Trying to deploy a FlexConfig without updating these objects typically results in deployment errors.

Step 4 Click **Save**.

The variable appears in the Variables list at the bottom of the FlexConfig object editor.

Configure Secret Keys

A secret key is any single-string variable whose content you want to mask, such as passwords. The system provides special treatment for these variables to help you prevent the dissemination of sensitive information.

Secret key variables do not show up in the Variables list in the FlexConfig object.

Use the following procedure to create, insert, and otherwise manage secret key variables in a FlexConfig object. Unlike other types of variables, you can use the **Insert** command every time you need to insert a given secret key variable. With respect to processing, these variables behave like single-value text object variables; see Single Value Variables, on page 2672.

Note Any data defined in a secret key variable is masked from users except when previewing a FlexConfig policy. In addition, if you export a FlexConfig policy, the content of any secret key variable is erased. When you import the policy, you will need to manually edit each secret key variable to enter the data.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig Objects, on page 2690.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Secret Key**.

Step 2 In the **Insert Secret Key** dialog box, do any of the following:

- To create a new key, click **Add Secret Key**, then fill in the following information and click **Add**.
  - **Secret Key Name**—The name of the variable. This name appears in the FlexConfig object prefixed with @.
  - **Password**, **Confirm Password**—The secret string, which is masked with asterisks as you type.
- To insert a secret key variable in the FlexConfig object, select the check box for the variable.
- To edit the value of a secret key variable, click **Edit** () for the variable. Make your changes and click **Add**.
- To delete a secret key variable, click **Delete** () for the variable.

Step 3 Click **Save**.

Configure FlexConfig Text Objects

Use text objects in FlexConfig objects as the target of policy object variables. You can use variables to supply information that can be known only at runtime, or which can differ from device to device. During deployment, variables that point to text objects are replaced by the content of the text object.

Text objects contain free-form strings, which can be keywords, interface names, numbers, IP addresses, and so forth. The content depends on how you will use the information within a FlexConfig script.

Before creating or editing a text object, determine exactly what content you will need. This includes how you intend to process the object, which will help you decide between creating a single string or multiple string object. Read the following topics:

- FlexConfig Variables, on page 2672
- How to Process Variables, on page 2672

Procedure

Step 1 Choose **Objects** > **Object Management** > **FlexConfig** > **Text Object**.

Step 2 Do one of the following:

- Click **Add Text Object** to create a new object.
- Click **Edit** (✎) to edit an existing object. You are allowed to edit the predefined text objects, which is required if you intended to use the predefined FlexConfig objects.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 (New objects only.) Choose a **Variable Type** from the drop-down list:

- **Single**—If the object should contain a single text string.
- **Multiple**—If the object should contain a list of text strings.

You cannot change the variable type after you save the object.

Step 5 If the variable type is **Multiple**, use the up and down arrows to specify a **Count**.

Rows are added or removed from the object as you change the number.

Step 6 Add content to the object.

You can either click in the text box next to a variable number and type in a value, or you can set up device overrides for each device that will be assigned a FlexConfig object that uses the text object. You can also do both, in which case the values configured in the base object act as default values in cases where an override does not exist for a given device.

When editing predefined objects, it is a good practice to use device overrides, so that the system defaults remain in place for other users who might need to use the object in different FlexConfig policies. The approach you take depends on the requirements of your organization.

Tip
Some predefined objects require multiple values where each value serves a specific purpose. Read the description text carefully to determine the expected values in the object. In some cases, the instructions specify that you must use overrides instead of changing the base values. In the case of enableInspectProtocolList, you are prevented from entering protocols whose inspection is incompatible with Snort inspection.

If you decide to use device overrides, do the following.

a) Check the check box of **Allow Overrides**.
b) Expand the Overrides area (if necessary) and click **Add**.

   If an override already exists for the device, click edit for the override to change it.

c) On **Targets** in the Add Object Override dialog box, select the device for which you are defining values and click **Add** to move it to the Selected Devices list.
d) Click **Override**, adjust the **Count** as needed, then click in the variable fields and type in the values for the device.
e) Click **Add**.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 259.

Configure the FlexConfig Policy

A FlexConfig policy contains two ordered lists of FlexConfig objects, one prepended list and one appended list. For an explanation of prepend/append, see Configure FlexConfig Objects, on page 2690.

FlexConfig policies are shared policies that you can assign to multiple devices.

Procedure

Step 1 Choose **Devices** > **FlexConfig**.

Step 2 Do one of the following:

- Click **New Policy** to create a new FlexConfig Policy. You are prompted to enter a name. Optionally, select devices in the Available Devices list and click **Add to Policy** to assign devices. Click **Save**.
- Click **Edit** ( ) to edit an existing Policy. You can change the name or description by clicking them in edit mode.
- Click **Copy** ( ) to create a new policy with the same contents. You are prompted for a name. Device assignments are not retained for the copy.
- Click delete to remove a policy you no longer need.

Step 3 Select the FlexConfig objects required for the policy from the **Available FlexConfig** list and click > to add them to the policy.

Objects are automatically added to the prepended or appended list based on the deployment type specified in the FlexConfig object.

To remove a selected object, click **Delete** ( ) next to an object.

Step 4 For each selected object, click **View** ( ) next to the object to identify the variables used in the object.

Except for system variables, which start with SYS, you need to ensure that the objects associated with the variables are not empty. A blank or brackets with nothing between them, [ ], indicate an empty object. You will need to edit these objects before deploying the policy.

Note
If you use object overrides, those values will not show up in this view. Thus, an empty default value does not necessarily mean that you have not updated the object with the required values. Previewing the configuration will show whether the variables resolve correctly for a given device. See Preview the FlexConfig Policy, on page 2697.

Step 5 Click **Save**.

What to do next

- Set target devices for the policy; see Set Target Devices for a FlexConfig Policy, on page 2696.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Set Target Devices for a FlexConfig Policy

When you create a FlexConfig policy, you can select the devices that use the policy. You can subsequently change device assignments for the policy as described below.

Note Normally, when you unassign a policy from a device, the system automatically removes the associated configuration upon the next deployment. However, because FlexConfig objects are scripts for deploying customized commands, simply unassigning a FlexConfig policy from a device does not remove the commands that were configuring by the FlexConfig objects. If your intention is to remove FlexConfig-generated commands from a device's configuration, see Remove Features Configured Using FlexConfig, on page 2699.

Procedure

Step 1 Choose **Devices** > **FlexConfig** and edit a FlexConfig policy.

Step 2 Click **Policy Assignments**.

Step 3 On **Targeted Devices**, build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**. You can assign the policy to devices, high availability pairs, and clustered devices.
- Delete—Click **Delete** ( ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.

Step 4 Click **OK** to save your selection.

Step 5 Click **Save** to save the FlexConfig policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Preview the FlexConfig Policy

Preview a FlexConfig policy to see how the FlexConfig objects get translated into CLI commands. The preview shows the commands that will be generated for a selected device from the scripts and variables used in the FlexConfig objects. The variables are resolved based on the configuration for the device, so you get a clear idea of what will be deployed.

Use the preview to look for potential problems in the FlexConfig objects. Correct the objects until the preview shows the expected results.

You must preview the configuration separately for each device, because the variables can resolve differently based on the device configuration.

Procedure

Step 1 Choose **Devices** > **FlexConfig** and edit a FlexConfig policy.

Step 2 If there are any pending changes, click **Save**.

The preview shows results only for those FlexConfig objects that were in the most recently saved version of the policy. You must save the policy to see a preview of newly-added objects.

Step 3 Click **Preview Config**.

Step 4 Choose a device from the **Select Device** drop-down list.

The system retrieves information from the device and configured policies, and determines what CLI commands will be generated on the next deployment to the device. You can select the output and use Ctrl+C to copy it to the clipboard, where you can paste it into a text file for further analysis.

The preview includes the following sections:

- Flex-config Prepended CLI—These are the commands generated by FlexConfigs that are prepended to the configuration.
- CLI generated from managed features—These are commands generated for policies configured in the Firewall Management Center. Commands are generated for new or changed policies since the last successful deployment to the device. These commands do not represent all commands needed to implement the assigned policies. No commands in this section are generated from FlexConfig objects.

- Flex-config Appended CLI—These are the commands generated by FlexConfigs that are appended to the configuration.

Step 5 Click **Close** to close the preview dialog.

Verify the Deployed Configuration

After you deploy a FlexConfig policy to a device, verify that the deployment was successful and that the resulting configuration is what you expected. Also, verify that the device is performing as expected.

Procedure

Step 1 To verify that deployment was successful:

a) Click **Notifications** in the menu bar, which is unnamed between **Deploy** and **System**.

The icon looks like one of the following, and it might include a number if there are errors:

- **Indicates No Warnings** — Indicates no warnings or errors are present on the system.
- Indicates **One or More Warnings** — Indicates one or more warnings and no errors are present on the system.
- **Indicates One or More Errors** — Indicates one or more errors and any number of warnings are present on the system.

b) On **Deployments**, verify that the deployment was successful.

c) To see more detailed information, especially for failed deployments, click **Show History**.

d) Select the deployment job in the list of jobs in the left column.

Jobs are listed in reverse chronological order, with the most recent job at the top of the list.

e) Click download in the **Transcript** column for the device in the right column.

The deployment transcript includes commands sent to the device, and any responses returned from the device. These response can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands that you sent through FlexConfig. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

Note
There is no distinction made in the transcript between commands sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. Firewall Threat Defense does not use the security level for anything. Messages relevant to FlexConfig are in the CLI Apply section of the transcript.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
```

```
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

Step 2 Verify that the deployed configuration includes the expected commands.

You can do this by making an SSH connection to the device's management IP address. Use the **show running-config** command to view the configuration.

Alternatively, use the CLI tool within Secure Firewall Management Center.

a) Choose **System** (⚙) > **Health** > **Monitor** and click the name of the device.

You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

b) Click **Advanced Troubleshooting**.
c) Click **Threat Defense CLI**.
d) Select **show** as the command, and type **running-config** as the parameter.
e) Click **Execute**.

The running configuration appears in the text box. You can select the configuration and press Ctrl+C, then paste it into a text file for later analysis.

Step 3 Verify that the device is performing as expected.

Use the **show** commands related to the feature to see detailed information and statistics. For example, if you enabled additional protocol inspections, the **show service-policy** command provides this information. The exact commands to use are feature-dependent and should be mentioned in the ASA configuration guide and command reference you used to learn how to configure the feature.

If commands that show statistics indicate that numbers are not changing (for example, hit counts, connection counts, and so forth), the configuration might be valid but not meaningful. If you know that traffic is going through the device that should show up in statistics, look for what is missing in your configuration. For example, NAT or access rules might be dropping or changing traffic before a feature can act on it.

You can use the **show** commands from an SSH session or through the Firewall Management Center CLI tool.

However, if the **show** command that you need to use is not available directly within the Firewall Threat Defense CLI, you will need make an SSH connection to the device to use the commands. From the CLI, enter the following command sequence to enter Privileged EXEC mode within the diagnostic CLI. From there, you should be able to enter these otherwise unsupported **show** commands.

```
> system support diagnostic-cli
Attaching to Diagnostic CLI ... Press 'Ctrl+a then d' to detach.
Type help or '?' for a list of available commands.
firepower> enable
Password: <press enter, do not enter a password>
firepower#
```

Remove Features Configured Using FlexConfig

If you decide you need to remove a set of configuration commands you configured using FlexConfig, you might need to manually remove that configuration. Unassigning the FlexConfig policy from a device might not remove all of the configuration.

To manually remove the configuration, you create new FlexConfig objects to clear or negate the configuration commands.

Before you begin

To determine if you need to manually remove some or all of the configuration generated by an object:

1. Examine the configuration preview, as described in Preview the FlexConfig Policy, on page 2697. If the `###CLI generated from managed features ###` section contains the clear or negate commands to remove all of the commands in the FlexConfig object, then you can simply remove the object from the FlexConfig policy, save, and redeploy.
2. Remove the object from the FlexConfig policy, save the change, then preview the configuration again. If the `###CLI generated from managed features ###` section still does not include the required clear or negate commands, you must follow this procedure to manually remove the configuration.

Procedure

Step 1 Choose **Objects** > **Object Management** and create the FlexConfig Objects to clear or negate the configuration commands.

If a feature has a **clear** command that can remove all configuration settings, then use that command. For example, the predefined ISIS_Unconfigure_All object contains a single command that removes all ISIS-related configuration commands:

```
clear configure router isis
```

If there is not a **clear** command for the feature, you need to use the **no** form of each command you want to remove. For example, the predefined Sysopt_basic_negate object removes the commands configured through the predefined Sysopt_basic object.

```
no sysopt traffic detailed-statistics
```

```
no sysopt connection timewait
```

You would typically configure a FlexConfig object that removes configurations as a prepended, deploy once object.

Step 2 Choose **Devices** > **FlexConfig** and create a new FlexConfig policy or edit the existing policy.

If you want to preserve the FlexConfig policy that deploys the configuration commands, create a new policy specifically for negating the commands, and assign the devices to the policy. Then, add the new FlexConfig objects to the policy.

If you want to completely remove the FlexConfig configuration objects from all devices, you can simply delete those commands from the existing FlexConfig policy and replace them with the objects that negate the configuration.

Step 3 Click **Save** to save the FlexConfig policy.

Step 4 Click **Preview Config** and verify that the clear and negation commands are generating correctly.

Step 5 Choose **Deploy** > **Deployment** in the menu bar, select the device, and click **Deploy**.

Wait for deployment to complete.

Step 6 Verify that the commands were removed.

View the running configuration on the device to confirm that the commands are removed. For more detailed information, see Verify the Deployed Configuration, on page 2698.

Step 7 While editing the FlexConfig policy, click **Policy Assignments** and remove the device. Optionally, remove the FlexConfig Objects from the policy.

Assuming that the FlexConfig policy simply removes the unwanted configuration commands, there is no need to keep the policy assigned to the device after the removal is complete.

However, if the FlexConfig policy retains options that you still want configured on the device, remove the negation objects from the policy. They are no longer needed.

Convert from FlexConfig to Managed Feature

Each software release adds managed features to the product, that is, features that you configure directly through policies that are controlled outside of FlexConfig. This can deprecate FlexConfig commands that you are currently using; your configurations are not automatically converted. After the upgrade, you cannot assign or create FlexConfig objects using the newly deprecated commands. After upgrading software, examine your FlexConfig policies and objects.

When a feature you configured using FlexConfig starts to be supported as a managed feature, you must convert from using FlexConfig to using the managed feature. In most cases, your existing FlexConfig configurations continue to work post-upgrade and you can still deploy. However, in some cases, using deprecated commands can cause deployment issues. Configuring a feature in both the GUI and FlexConfig is not supported.

Note Use the migration tool instead of this procedure if the tool supports the feature configuration you are migrating.

Procedure

Step 1 Remove the FlexConfig, as explained in Remove Features Configured Using FlexConfig, on page 2699.

Step 2 Configure the settings in the newly supported managed feature.

The release notes have a list of new features for the release.

Examples for FlexConfig

Following are some examples of using FlexConfig.

How to Configure Precision Time Protocol (ISA 3000)

The Precision Time Protocol (PTP) is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. These device clocks are generally of varying precision and stability. The protocol is designed specifically for industrial, networked measurement and control systems, and is optimal for use in distributed systems because it requires minimal bandwidth and little processing overhead.

A PTP system is a distributed, networked system consisting of a combination of PTP and non-PTP devices. PTP devices include ordinary clocks, boundary clocks and transparent clocks. Non-PTP devices include network switches, routers and other infrastructure devices.

You can configure the Firewall Threat Defense device to be a transparent clock. The Firewall Threat Defense device does not synchronize its clock with the PTP clocks. The Firewall Threat Defense device will use the PTP default profile, as defined on the PTP clocks.

When you configure the PTP devices, you define a domain number for the devices that are meant to function together. Thus, you can configure multiple PTP domains, and then configure each non-PTP device to use the PTP clocks for one specific domain.

Before you begin

Determine the domain number configured on the PTP clocks that the device should use. This example assumes the PTP domain number is 10. Also, determine the interfaces through which the system can reach the PTP clocks in the domain.

Following are guidelines for configuring PTP:

- This feature is only available on the Cisco ISA 3000 appliance.
- Cisco PTP supports multicast PTP messages only.
- PTP is available only for IPv4 networks, not for IPv6 networks.
- PTP configuration is supported on physical Ethernet data interfaces, whether stand-alone or bridge group members. It is not supported on the management interface, subinterfaces, EtherChannels, Bridge Virtual Interfaces (BVI), or any other virtual interfaces.
- PTP flows on VLAN subinterfaces are supported, assuming the appropriate PTP configuration is present on the parent interface.
- You must ensure that PTP packets are allowed to flow through the device. PTP traffic is identified by UDP destination ports 319 and 320, and destination IP address 224.0.1.129, so any access control rule that allows this traffic should work.
- In Routed firewall mode, you must enable Multicast routing for PTP multicast groups. In addition, if an interface on which you enable PTP is **not** in a bridge group, you must configure the interface to join the IGMP multicast group 224.0.1.129. If the physical interface is a bridge group member, you do not configure it to join the IGMP multicast group.

Procedure

Step 1 (Routed mode only.) Enable Multicast routing, and configure the IGMP group for the interfaces.

In Routed mode, you must enable Multicast routing. In addition, for stand-alone physical interfaces, that is, those that are not bridge group members, you must also configure the interface to join the 224.0.1.129 IGMP group. You cannot configure bridge group members to join an IGMP group, but PTP configuration on bridge group members will work without the IGMP join.

Perform this procedure for each device on which you will configure PTP.

Note
Write down the hardware names of each PTP-clock-facing interface on each device, for example, GigabitEthernet1/1.

a) Choose **Devices** > **Device Management**, and edit the device.
b) Click **Routing**.
c) Choose **Multicast Routing** > **IGMP**.
d) Check the **Enable Multicast Routing** check box.
e) Click **Join Group**.
f) Click **Add**, and in the **Add IGMP Join Group Parameters** dialog box, configure the following options and click **OK**.

- **Interface**—Select the PTP-clock-facing stand-alone interface.
- **Join Group**—Click **+** to add a new network object. Create a Host object with the address 224.0.1.129. When configuring additional interfaces, simply select this object. (See Creating Network Objects, on page 1403.)

Repeat this step for each PTP-clock-facing stand-alone interface on the device.

g) Click **Save** on the Routing page.

Step 2 Create the FlexConfig object to enable PTP globally and on the interface.

The following procedure assumes that the PTP-clock-facing interface is the same on every device you are configuring. If you have used different interfaces on different devices, you need to create separate objects for each distinct combination. For example, if you use GigabitEthernet1/1 on devices A and B, GigabitEthernet1/2 on devices C and D, and both GigabitEthernet1/1 and 1/2 on devices E and F, you need 3 separate FlexConfig objects, and subsequently, 3 separate FlexConfig policies (explained in the next step).

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.
b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Enable_PTP.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features. This ensures that any other changes you make to interface configuration are configured before these commands.
- **Object body**—In the object body, type the commands needed to configure PTP globally and on each PTP-clock-facing interface. For example, the commands needed for the global configuration for PTP domain 10 and the interface configuration on GigabitEthernet1/1 are:

```
ptp mode e2etransparent
ptp domain 10
```

```
interface gigabitethernet1/1
 ptp enable
```

The object body should look similar to the following:

Step 3 Create the FlexConfig policy and assign it to the devices.

If you created multiple FlexConfig objects for different combinations of PTP-clock-facing interfaces, you need to create separate FlexConfig policies for each object, and assign those policies to the correct devices based on the interfaces you need to configure. Repeat the following procedure for each group of devices.

a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the PTP FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the PTP FlexConfig object look correct. These will be shown at the end of the

preview. Note that you will also see commands generated from other changes you have made to managed features. For the PTP commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
 ptp enable
```

Step 4 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the Deployed Configuration, on page 2698.

Step 5 Verify the PTP configuration on each device.

From an SSH or Console session into each device, verify the PTP settings:

```
> show ptp clock
 PTP CLOCK INFO
  PTP Device Type: End to End Transparent Clock
  Operation mode: One Step
  Clock Identity: 34:62:88:FF:FE:1:73:81
  Clock Domain: 10
  Number of PTP ports: 4
> show ptp port
 PTP PORT DATASET: GigabitEthernet1/1
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 1
  PTP version: 2
  Port state: Enabled

 PTP PORT DATASET: GigabitEthernet1/2
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 2
  PTP version: 2
  Port state: Disabled

 PTP PORT DATASET: GigabitEthernet1/3
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 3
  PTP version: 2
  Port state: Disabled

 PTP PORT DATASET: GigabitEthernet1/4
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 4
  PTP version: 2
  Port state: Disabled
```

How to Configure Automatic Hardware Bypass for Power Failure (ISA 3000)

You can enable hardware bypass so that traffic continues to flow between an interface pair during a power outage. Supported interface pairs are copper interfaces GigabitEthernet 1/1 and 1/2; and GigabitEthernet 1/3 and 1/4. If you have a fiber Ethernet model, only the copper Ethernet pair (GigabitEthernet 1/1 and 1/2) supports hardware bypass.

When hardware bypass is active, traffic passes between these interface pairs at layer 1. The Firewall Threat Defense CLI will see the interfaces as being down. No firewall functions are in place, so make sure you understand the risks of allowing traffic to pass through the device.

In CLI Console or an SSH session, use the **show hardware-bypass** command to monitor the operational status.

Before you begin

For hardware bypass to work:

- You must place the interface pairs in the same bridge group.
- You must attach the interfaces to access ports on the switch. Do not attach them to trunk ports.

We recommend that you disable TCP sequence number randomization globally using the Threat Defense Service Policy attached to the access control policy assigned to the device. By default, the ISA 3000 rewrites the initial sequence number (ISN) of TCP connections passing through it to a random number. When hardware bypass is activated, the ISA 3000 is no longer in the data path and does not translate the sequence numbers. The receiving client receives an unexpected sequence number and drops the connection, so the TCP session needs to be re-established. Even with TCP sequence number randomization disabled, some TCP connections will have to be re-established because of the link that is temporarily down during the switchover.

Procedure

Step 1 Create the FlexConfig object to enable automatic bypass.

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Enable_HW-Bypass.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to enable automatic hardware bypass. For example, the commands needed for both possible interface pairs:

```
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

The object body should look similar to the following:

Step 2 Create the FlexConfig policy and assign it to the devices.

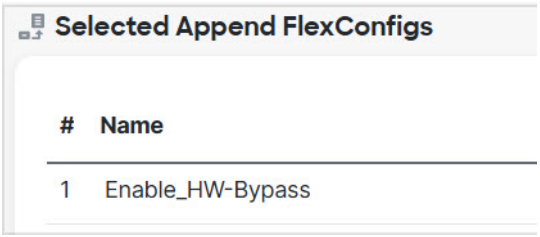
a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the hardware bypass FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.



d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the hardware bypass FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the hardware bypass commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the Deployed Configuration, on page 2698.

What to do next

If you want to manually invoke hardware bypass or manually turn it off, you need to create two FlexConfig objects:

- One that manually starts bypass, which would contain one or both of the following commands, depending on whether you want to invoke bypass for both pairs:

```
hardware-bypass manual GigabitEthernet 1/1-1/2
hardware-bypass manual GigabitEthernet 1/3-1/4
```

- One that manually turns off bypass, which would contain one or both of the following commands:

```
no hardware-bypass manual GigabitEthernet 1/1-1/2
no hardware-bypass manual GigabitEthernet 1/3-1/4
```

You would then need to add one or the other object to the FlexConfig policy, and deploy changes, to either turn bypass on or off. You would also need to immediately remove the object from the FlexConfig policy after deployment. If you manually invoke bypass, you would then need to repeat the process to turn it off again. Thus, using this manual method requires frequent and careful editing of the FlexConfig policy and additional deployments.

Migrating FlexConfig Policies

Attention This section on migrating FlexConfig policies is applicable only for migrating ECMP, VXLAN, and EIGRP policies.

The ECMP, VXLAN, and EIGRP policies were configured using the FlexConfig objects and policies in earlier versions of the Firewall Management Center. You can now directly configure these policies in the management center UI. When you are upgrading the management center from earlier versions, the FlexConfig configuration is retained. However, to manage the policies from the UI, you must redo the configuration in the corresponding **Device (Edit)** > **Routing** page and remove the configuration from FlexConfig. To automate creation of the policies in the UI, Firewall Management Center provides an option to migrate the policies from FlexConfig to the UI. However, it does not remove the migrated policies from the FlexConfig. For post-migration procedure, refer to Step 7, on page 2709.

Before you begin

- Ensure that the deployed FlexConfig policy is up-to-date and not out-of-date. The migration option will be available only if the policy is up-to-date on at least 1 device. Migration does not take place for those devices that have out-of-date policies.
- If the policy is configured in both FlexConfig and the management center:

- Migration will not be initiated if the policy is already configured at **Device (Edit)** > **Routing**.
- During deployment, the management center displays an error message. Example EIGRP migration error message—*EIGRP is configured through FlexConfig object and also under Device Listing ->Routing EIGRP for the device. Maintain the EIGRP configuration in either Routing EIGRP or FlexConfig.*

- If the network objects used in the policy exist in the management center, during migration, they are reused. During migration, when a network object that is matching the IP configuration is not available, a new network object is created as *bb* appended with a timestamp and integer, like ***bb_<timestamp>_<integer>***. For more than one such network object, the integer variable in the name would be incremented by one.

Procedure

Step 1 Choose **Devices** > **FlexConfig**, click **Edit** (✎) against the FlexConfig policy that you want to migrate.

Step 2 Click **Migrate Config**.

Note
Once migration starts, both **Migrate Config** and FlexConfig **Edit** options are not available.

The **Migrate Config** option is not available, when:

- There are no applicable FlexConfig CLIs to be migrated.
- The FlexConfig policy is not associated with any FlexConfig objects.
- There are no devices that are associated with the FlexConfig policy.

Step 3 In the **Migrate Flex Configuration** dialog box, select the device to which you wish to migrate the configuration, and then click **Ok**.

The migration progress is displayed as task notification. When the migration is complete, click the *View Details* link and download the migration report (PDF format).

Step 4 To view the policy changes, choose **System** (⚙) > **Monitoring** > **Audit** and click on the *Flex Config Migration* message.

Step 5 To view the FlexConfig migration report, choose **System** (⚙) > **Monitoring** > **Audit** and click on the *Flex Config Migration* message. To view the complete migration report, click the **Report** icon.

Step 6 Verify the migrated configuration settings in the corresponding **Device (Edit)** > **Routing**. page.

Step 7 To remove the specific policy config from FlexConfig for the device, in the management center, do the following:

a) Identify the migrated FlexConfig policy for the device.
b) Use the copy option and create duplicate of the FlexConfig policy.
c) Remove the corresponding CLI objects from the duplicated FlexConfig policy.
d) Associate the device to the duplicated FlexConfig policy.

Step 8 Save and deploy the configuration.

History for FlexConfig

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Quick recovery after data plane failure for the Firepower 1000/2100 and Firepower 4100/9300.	7.4.1	7.4.1	If the data plane process crashes, the system now reloads only the data plane process instead of rebooting the device. Along with the data plane process reload, Snort and a few other processes also get reloaded. However, if the data plane process crashes during bootup, the device follows the normal reload/reboot sequence, which helps avoid a reload process loop from occurring. This feature is enabled by default for both new and upgraded devices. New/modified CLI commands: **data-plane quick-reload**, **no data-plane quick-reload**, **show data-plane quick-reload status** Supported platforms: Firepower 1000/2100, Firepower 4100/9300 Platform restrictions: Not supported in multi-instance mode. See: Cisco Secure Firewall Threat Defense Command Reference and Cisco Secure Firewall ASA Series Command Reference.
Migration tool support.	7.3.0	Any	Support to migrate Flex configured ECMP, VXLAN, and EIGRP policies to management center was introduced. New/modified screens: **Devices** > **FlexConfig** > **Migrate FlexConfig**
Removal of BFD configuration in FlexConfig.	7.3.0	Any	Support to configure BFD policies directly in the management center user interface was introduced. Hence, FlexConfig support to configure BFD policies was removed.
Removal of priority-queue.	7.2.5	7.2.5	Support to configure priority-queue in threat defense was removed.
Removal of EIGRP configuration in FlexConfig.	7.2.0	Any	Support to configure EIGRP directly in the management center user interface was introduced. Hence, FlexConfig support to configure EIGRP policies was removed.
Removal of PBR configuration.	7.1.0	7.1.0	Support to configure the PBR directly in the FMC user interface was introduced. Hence, FlexConfig support to configure PBR for FTD 7.1 and higher was removed. New/modified commands: **policy-route route-map***routemap-object-name*.
Removal of ECMP zone creation support in FlexConfig.	7.1.0	Any	Support to configure the ECMP zones directly in the FMC user interface was introduced. Hence, FlexConfig support to configure ECMP zones was removed.

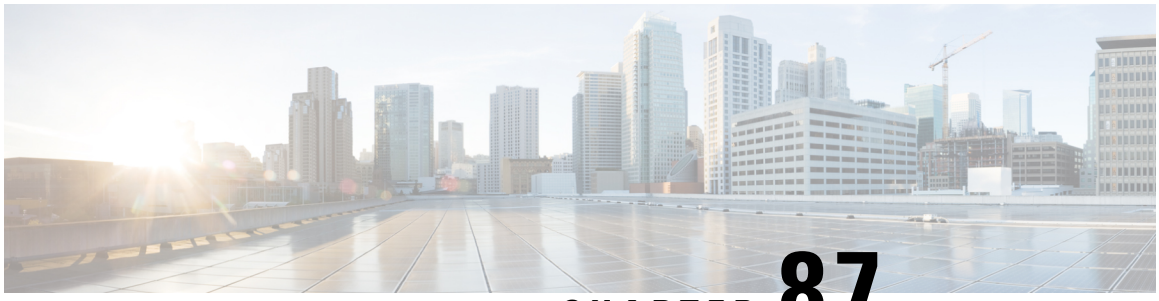
Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Precision Time Protocol (PTP) configuration for ISA 3000 devices.	6.5.0	Any	You can use FlexConfig to configure the Precision Time Protocol (PTP) on ISA 3000 devices. PTP is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. The protocol is designed specifically for industrial, networked measurement and control systems. We now allow you to include the **ptp** (interface mode) command, and the global commands **ptp mode e2etransparent** and **ptp domain**, in FlexConfig objects. New/modified commands: **show ptp**.
Deprecated FlexConfig objects.	6.3.0	Any	Several features that in previous releases you configured using FlexConfig are now directly supported in FMC. You need to remove these FlexConfig objects if you are using them, and convert your configuration to use the new objects. Following are the deprecated FlexConfig objects and text objects. • **Default_DNS_Configure**, including the defaultDNSNameServerList and defaultDNSParameters text objects. Now, please configure DNS for the data interfaces using the Platform Settings policy. • **TCP_Embryonic_Conn_Limit**, and the tcp_conn_misc and tcp_conn_limit text objects. Configure these features in the FTD Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device. • **TCP_Embryonic_Conn_Timeout**, and the tcp_conn_misc and tcp_conn_timeout text objects. Configure these features in the FTD Service Policy.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
FlexConfig updates.	6.2.1	Any	As per the Government Certification requirements, all sensitive information like password, shared keys in system-provided or user-defined FlexConfig object should be masked using secret key variables. After you update the FMC to Version 6.2.1+, all sensitive information in FlexConfig Objects are converted to secret key variable format. In addition, the following new FlexConfig templates are added: • **Default_DNS_Configure** template allows you to the default DNS group, which is used to resolve hostnames for commands or features that resolve names through the data interfaces. • **TCP Embryonic connection limit and timeout configuration** template allows you to configure embryonic connection limits/timeout CLIs to protect from SYN Flood DoSAttack. • **Turn on threat detection configure and clear** templates allow you to configure threat detection statistics for attacks intercepted by TCP Intercept. • **IPV6 router header inspection** template allows you to configure of IPV6 inspection header for selectively allow/block certain headers with different types (e.g. allowing RH Type 2,mobile). • **DHCPv6 prefix delegation** template allows you to configure one outside (PD client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation.
FlexConfig.	6.2.0	Any	The FlexConfig feature allows you use the FMC to deploy ASA CLI template-based functionality to FTD devices. This feature allows you to enable some of the most valuable ASA functions that are not currently available on FTD devices. This functionality is structured as templates and objects that work together in a policy. The default templates are officially supported by Cisco TAC. New/modified screens: • **Devices** > **FlexConfig** • **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Objects** • **Objects** > **Object Management** > **FlexConfig** > **Text Object**

PART XV

Advanced Network Analysis in Snort 3

- Advanced Access Control Settings for Network Analysis and Intrusion Policies, on page 2715
- Transport and Network Layer Preprocessors, on page 2723
- Adaptive Profiles, on page 2727



CHAPTER 87

Advanced Access Control Settings for Network Analysis and Intrusion Policies

The following topics describe how to configure advanced settings for network analysis and intrusion policies:

- About Advanced Access Control Settings for Network Analysis and Intrusion Policies, on page 2715
- Requirements and Prerequisites for Advanced Access Control Settings for Network Analysis and Intrusion Policies, on page 2715
- Inspection of Packets That Pass Before Traffic Is Identified, on page 2716
- Advanced Settings for Network Analysis Policies, on page 2717

About Advanced Access Control Settings for Network Analysis and Intrusion Policies

Many of the advanced settings in an access control policy govern intrusion detection and prevention configurations that require specific expertise to configure. Advanced settings typically require little or no modification and are not common to every deployment.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Requirements and Prerequisites for Advanced Access Control Settings for Network Analysis and Intrusion Policies

Inspection of Packets That Pass Before Traffic Is Identified

For some features, including URL filtering, application detection, rate limiting, and Intelligent Application Bypass, a few packets must pass in order for the connection to be established, and to enable the system to identify the traffic and determine which access control rule (if any) will handle that traffic.

You must explicitly configure your access control policy to inspect these packets, prevent them from reaching their destination, and generate any events.

As soon as the system identifies the access control rule or default action that should handle the connection, the remaining packets in the connection are handled and inspected accordingly.

Best Practices for Handling Packets That Pass Before Traffic Identification

- The default action specified for an access control policy is NOT applied to these packets.
- Instead, use the following guidelines to choose a value for the **Intrusion Policy used before Access Control rule is determined** setting in the Advanced settings of the access control policy.
  - You can choose a system-created or custom intrusion policy. For example, you can choose **Balanced Security and Connectivity**.
  - For performance reasons, unless you have good reason to do otherwise, this setting should match the default action set for your access control policy.
  - If your system does not perform intrusion inspection (for example, in a discovery-only deployment), select **No Rules Active**. The system will not inspect these initial packets, and they will be allowed to pass.
  - By default, this setting uses the default variable set. Ensure that this is suitable for your purposes. For information, see Variable Set, on page 1446.
  - The network analysis policy associated with the first matching network analysis rule preprocesses traffic for the policy you select. If there are no network analysis rules, or none match, the default network analysis policy is used.

Specify a Policy to Handle Packets That Pass Before Traffic Identification

Note This setting is sometimes referred to as the *default intrusion policy*. (This is distinct from the default action for an access control policy.)

Before you begin

Review best practices for these settings. See Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2716.

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** () next to the **Network Analysis** and **Intrusion Policies** section.

If **View** () appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Select an intrusion policy from the **Intrusion Policy used before Access Control rule is determined** drop-down list.

If you choose a user-created policy, you can click **Edit** () to edit the policy in a new window. You cannot edit system-provided policies.

Step 3 Optionally, select a different variable set from the **Intrusion Policy Variable Set** drop-down list. You can also select **Edit** () next to the variable set to create and edit variable sets. If you do not change the variable set, the system uses a default set.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Related Topics

Variable Set, on page 1446

Advanced Settings for Network Analysis Policies

Network analysis policies govern how traffic is decoded and preprocessed so that it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt. This traffic preprocessing occurs after Security Intelligence matching and traffic decryption, but before intrusion policies inspect packets in detail. By default, the system-provided Balanced Security and Connectivity network analysis policy is the default network analysis policy.

Tip The system-provided Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules.

A simple way to tune preprocessing is to create and use a custom network analysis policy as the default. For advanced users with complex deployments, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs.

To accomplish this, you add custom *network analysis rules* to your access control policy. A network analysis rule is simply a set of configurations and conditions that specifies how you preprocess traffic that matches those qualifications. You create and edit network analysis rules in the advanced options in an existing access control policy. Each rule belongs to only one policy.

Each rule has:

- a set of rule conditions that identifies the specific traffic you want to preprocess
- an associated network analysis policy that you want to use to preprocess traffic that meets all the rules' conditions

When it is time for the system to preprocess traffic, it matches packets to network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rules is preprocessed by the default network analysis policy.

Setting the Default Network Analysis Policy

You can choose a system- or user-created policy.

Note If you disable a preprocessor but the system needs to evaluate preprocessed packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although it remains disabled in the network analysis policy web interface. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful that you allow the network analysis and intrusion policies examining a single packet to complement each other.

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** ( ) next to the Network Analysis and Intrusion Policies section.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 From the **Default Network Analysis Policy** drop-down list, select a default network analysis policy.

If you choose a user-created policy, you can click **Edit** (✎) to edit the policy in a new window. You cannot edit system-provided policies.

Step 3 Click **OK**.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Related Topics

Limitations of Custom Policies

Network Analysis Rules

Within your access control policy's advanced settings, you can use network analysis rules to tailor preprocessing configurations to network traffic.

Network analysis rules are numbered, starting at 1. When it is time for the system to preprocess traffic, it matches packets to network analysis rules in top-down order by ascending rule number, and preprocesses traffic according to the first rule where all the rule's conditions match.

You can add zone, network, and VLAN tag conditions to a rule. If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a network condition but no zone condition evaluates traffic based on its source or destination IP address, regardless of its ingress or egress interface. Traffic that does not match any network analysis rules is preprocessed by the default network analysis policy.

Network Analysis Policy Rule Conditions

Rule conditions enable you to fine-tune your network analysis policy to target the users and networks you want to control. See one of the following sections for more information.

Related Topics

Security Zone Rule Conditions, on page 1905
Network Rule Conditions, on page 939
VLAN Tags Rule Conditions, on page 1787

Security Zone Rule Conditions

Security zones segment your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices.

Security zones control or decrypt traffic by its source and destination security zones. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

Just as all interfaces in a zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Security Zone Conditions and Multitenancy

In a multidomain deployment, a zone created in an ancestor domain can contain interfaces that reside on devices in different domains. When you configure a zone condition in an descendant domain, your configurations apply to only the interfaces you can see.

Network Rule Conditions

Networks control or decrypt traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

VLAN Tags Rule Conditions

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

Configuring Network Analysis Rules

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to the Network Analysis and Intrusion Policies section.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Tip
Click **Network Analysis Policy List** to view and edit existing custom network analysis policies.

Step 2 Next to **Network Analysis Rules**, click the statement that indicates how many custom rules you have.

Step 3 Click **Add Rule**.

Step 4 Configure the rule's conditions by clicking the conditions you want to add.

Step 5 Click **Network Analysis** and choose the **Network Analysis Policy** you want to use to preprocess the traffic matching this rule.

Click **Edit** (✎) to edit a custom policy in a new window. You cannot edit system-provided policies.

Step 6 Click **Add**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.

Managing Network Analysis Rules

A network analysis rule is simply a set of configurations and conditions that specifies how you preprocess traffic that matches those qualifications. You create and edit network analysis rules in the advanced options in an existing access control policy. Each rule belongs to only one policy.

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to the Intrusion and Network Analysis Policies section.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Next to **Network Analysis Rules**, click the statement that indicates how many custom rules you have.

Step 3 Edit your custom rules. You have the following options:

- To edit a rule's conditions, or change the network analysis policy invoked by the rule, click **Edit** ( ) next to the rule.
- To change a rule's order of evaluation, click and drag the rule to the correct location. To select multiple rules, use the Shift and Ctrl keys.
- To delete a rule, click **Delete** ( ) next to the rule.

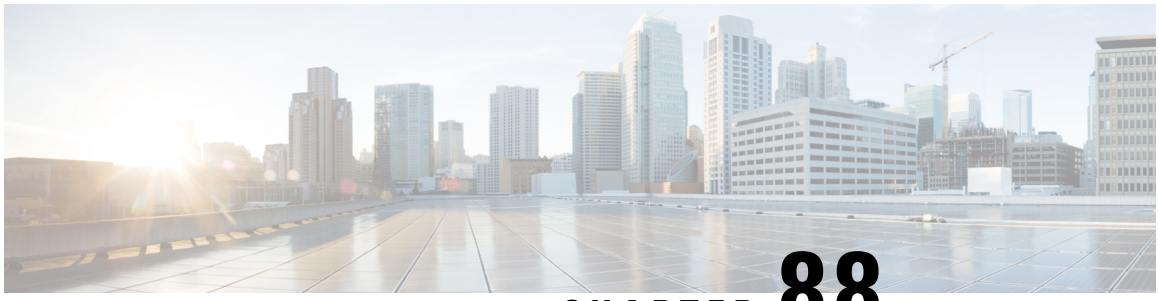
Tip
Right-clicking a rule displays a context menu that allows you to cut, copy, paste, edit, delete, and add new network analysis rules.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 259.



CHAPTER 88

Transport and Network Layer Preprocessors

The following topics explain transport and network layer preprocessors and how to configure them:

- Introduction to Transport and Network Layer Preprocessors, on page 2723
- License Requirements for Transport and Network Layer Preprocessors, on page 2723
- Requirements and Prerequisites for Transport and Network Layer Preprocessors, on page 2724
- Advanced Transport/Network Preprocessor Settings, on page 2724

Introduction to Transport and Network Layer Preprocessors

Transport and network layer preprocessors detect attacks that exploit IP fragmentation, checksum validation, and TCP and UDP session preprocessing. Before packets are sent to preprocessors, the packet decoder converts packet headers and payloads into a format that can be easily used by the preprocessors and the intrusion rules engine and detects various anomalous behaviors in packet headers. After packet decoding and before sending packets to other preprocessors, the inline normalization preprocessor normalizes traffic for inline deployments.

When an intrusion rule or rule argument requires a disabled preprocessor, the system automatically uses it with its current configuration even though it remains disabled in the network analysis policy's web interface.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

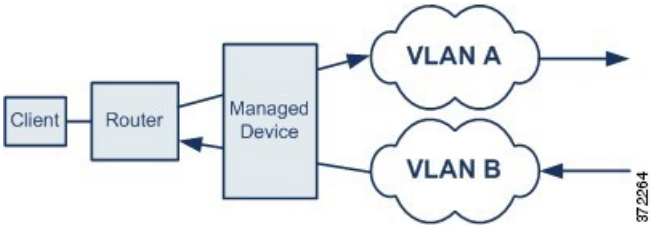
Advanced Transport/Network Preprocessor Settings

Advanced transport and network preprocessor settings apply globally to all networks, zones, and VLANs where you deploy your access control policy. You configure these advanced settings in an access control policy rather than in a network analysis policy.

Ignored VLAN Headers

Different VLAN tags in traffic traveling in different directions for the same connection can affect traffic reassembly and rule processing. For example, in the following graphic traffic for the same connection could be transmitted over VLAN A and received over VLAN B.



You can configure the system to ignore the VLAN header so packets can be correctly processed for your deployment.

Active Responses in Intrusion Drop Rules

A drop rule is an intrusion or preprocessor rule whose rule state is set to Drop and Generate Events. In an inline deployment, the system responds to TCP or UDP drop rules by dropping the triggering packet and blocking the session where the packet originated.

Tip Because UDP data streams are not typically thought of in terms of *sessions*, the stream preprocessor uses the source and destination IP address fields in the encapsulating IP datagram header and the port fields in the UDP header to determine the direction of flow and identify a UDP session.

You can configure the system to initiate one or more *active responses* to more precisely and specifically close a TCP connection or UDP session when an offending packet triggers a TCP or UDP drop rule. You can use active responses in inline, including routed and transparent, deployments. Active responses are not suited or supported for passive deployments.

To configure active responses:

- Create or modify a TCP or UDP (**resp** keyword only) intrusion rule.
- Add the **react** or **resp** keyword to the intrusion rule; see xActive Response Keywords.
- Optionally, for a TCP connection, specify the maximum number of additional active responses to send and the number of seconds to wait between active responses; see **Maximum Active Responses** and **Minimum Response Seconds** in Advanced Transport/Network Preprocessor Options, on page 2725.

Active responses close the session when matching traffic triggers a drop rule, as follows:

- **TCP**—drops the triggering packet and inserts a TCP Reset (RST) packet in both the client and server traffic.
- **UDP**—sends an ICMP unreachable packet to each end of the session.

Advanced Transport/Network Preprocessor Options

Ignore the VLAN header when tracking connections

Specifies whether to ignore or include VLAN headers when identifying traffic, as follows:

- When this option is selected, the system ignores VLAN headers. Use this setting for deployed devices that might detect different VLAN tags for the same connection in traffic traveling in different directions
- When this option is disabled, the system includes VLAN headers. Use this setting for deployed devices that will not detect different VLAN tags for the same connection traffic traveling in different directions.

Maximum Active Responses

Specifies a maximum number of active responses per TCP connection. When additional traffic occurs on a connection where an active response has been initiated, and the traffic occurs more than **Minimum Response Seconds** after a previous active response, the system sends another active response unless the specified maximum has been reached. A setting of 0 disables additional active responses triggered by **resp** or **react** rules. See Active Responses in Intrusion Drop Rules, on page 2724 and Active Response Keywords.

Note that a triggered **resp** or **react** rule initiates an active response regardless of the configuration of this option.

Minimum Response Seconds

Until **Maximum Active Responses** occur, specifies the number of seconds to wait before any additional traffic on a connection where the system has initiated an active response results in a subsequent active response.

Troubleshooting Options: Session Termination Logging Threshold

Caution Do not modify Session Termination Logging Threshold unless instructed to do so by Support.

Support might ask you during a troubleshooting call to configure your system to log a message when an individual connection exceeds the specified threshold. Changing the setting for this option will affect performance and should be done only with Support guidance.

This option specifies for the number of bytes that result in a logged message when the session terminates and the specified number was exceeded.

Note The upper limit of 1GB is also restricted by the amount of memory on the managed device allocated for stream processing.

Related Topics

Active Response Keywords

Configuring Advanced Transport/Network Preprocessor Settings

You must be an Admin, Access Admin, or Network Admin to perform this task.

Procedure

Step 1 In the access control policy editor, click **Edit** (✎) on the policy you want to modify.

Step 2 Click **More** > **Advanced Settings**, and then click **Edit** (✎) next to the **Transport/Network Preprocessor Settings** section.

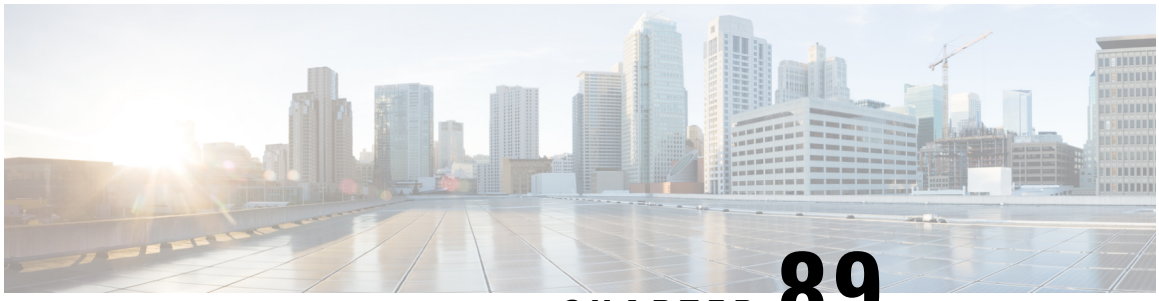
Step 3 Except for the troubleshooting option **Session Termination Logging Threshold**, modify the options described in Advanced Transport/Network Preprocessor Options, on page 2725.

Caution
Do not modify **Session Termination Logging Threshold** unless instructed to do so by Support.

Step 4 Click **OK**.

What to do next

- Optionally, further configure the policy as described in Editing an Access Control Policy, on page 1749.
- Deploy configuration changes; see Deploy Configuration Changes, on page 259.



CHAPTER 89

Adaptive Profiles

The following topics describe how to configure adaptive profiles:

- About Adaptive Profiles, on page 2727
- License Requirements for Adaptive Profiles, on page 2728
- Requirements and Prerequisites for Adaptive Profiles, on page 2728
- Adaptive Profile Updates, on page 2728
- Adaptive Profile Updates and Cisco Recommended Rules, on page 2729
- Adaptive Profile Options, on page 2729
- Configuring Adaptive Profiles, on page 2730

About Adaptive Profiles

Adaptive profiles must be enabled in order to:

- Perform application and file control, including malware protection (AMP), and to allow intrusion rules to use service metadata.

Caution Adaptive profiling **must** be enabled (its default state) as described in Configuring Adaptive Profiles, on page 2730 for access control rules to perform application and file control, including malware protection (AMP), and for intrusion rules to use service metadata.

- For passive deployments, enable adaptive profile updates to defragment and reassemble IP traffic according to the destination hosts' operating systems.

Note For inline deployments Cisco recommends that, instead of enabling adaptive profile updates, you configure the inline normalization preprocessor with the **Normalize TCP Payload** option enabled.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Firewall Management Center guide that matches your Firewall Threat Defense version.

Adaptive Profile Updates

Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates, the system can adapt processing behavior using host information either detected by network discovery or imported from a third party.

Profile updates, like the target-based profiles you can configure manually in a network analysis policy, help to defragment IP packets and reassemble streams in the same way as the operating system on the target host. The intrusion rules engine then analyzes the data in the same format as that used by the destination host.

Manually configured target-based profiles apply either the default operating system profile you select, or profiles you bind to specific hosts. Profile updates, however, switch to the appropriate operating system profile based on the operating system in the host profile for the target host.

Consider a scenario where you configure profile updates for the 10.6.0.0/16 subnet and set the default IP Defragmentation target-based policy to Linux. The Firewall Management Center where you configure the settings has a network map that includes the 10.6.0.0/16 subnet.

- When the system detects traffic from Host A, which is not in the 10.6.0.0/16 subnet, it uses the Linux target-based policy to reassemble IP fragments.
- When the system detects traffic from Host B, which is in the 10.6.0.0/16 subnet, it retrieves Host B's operating system data from the network map. The system uses a profile based on that operating system to defragment the traffic destined for Host B.

Adaptive Profile Updates and Cisco Recommended Rules

The adaptive profile updates feature is an advanced setting in an access control policy that applies globally to all intrusion policies invoked by that access control policy. The Cisco recommended rules feature applies to the individual intrusion policy where you configure it.

Like Cisco recommended rules, profile updates compare metadata in a rule to host information to determine whether a rule should apply for a particular host. However, while Cisco recommended rules provide recommendations for enabling or disabling rules using that information, profile updates use the information to apply specific rules to specific traffic.

Cisco recommended rules require your interaction to implement suggested changes to rule states. Profile updates, on the other hand, do not modify intrusion policies. Treatment of rules based on profile updates happens on a packet-by-packet basis.

Additionally, Cisco recommended rules can result in enabling disabled rules. Profile updates, in contrast, only affect the application of rules that are already enabled in intrusion policies. Profile updates never change the rule state.

You can use profile updates and Cisco recommended rules in combination. Profile updates use the rule state for a rule when your intrusion policy is deployed to determine whether to include it as a candidate for applying, and your choices to accept or decline recommendations are reflected in that rule state. You can use both features to ensure that you have enabled or disabled the most appropriate rules for each network you monitor, and then to apply enabled rules most efficiently for specific traffic.

Related Topics

About Cisco Recommended Rules

Adaptive Profile Options

Enable

Enabling this option is required for:

- access control rules to perform application and file control, including malware protection (AMP)
- intrusion rules to use service metadata

This option is enabled by default.

Note To enable Adaptive Profiles in Snort 3, both **Enable** and **Enable Profile Updates** options must be selected.

Enable Profile Updates

In passive deployments, enable profile updates to defragment and reassemble IP traffic according to a profile of the operating system used by the hosts in your network map

For Snort 3, this must be enabled if Adaptive Profiles is enabled.

Adaptive Profiles - Attribute Update Interval

When profile updates are enabled, you can control how frequently in minutes network map data is synced from the Firewall Management Center to its managed devices. The system uses the data to determine what profiles should be used when processing traffic. Increasing the value for this option can improve performance in a large network.

Adaptive Profiles - Networks

Optionally, when profile updates are enabled, you can improve performance by constraining profile updates to a comma-separated list of IP addresses, address blocks, and network variables. If you use a network variable, the system uses the variable's value in the variable set linked to the default intrusion policy for your access control policy. For example, you could enter: **`192.168.1.101, 192.168.4.0/24, $HOME_NET`**. IPv4 and IPv6 are supported.

The default value (**`0.0.0.0/0`**) applies adaptive profile updates to all networks.

Related Topics

Inspection of Packets That Pass Before Traffic Is Identified, on page 2716
Variable Set, on page 1446

Configuring Adaptive Profiles

In a passive deployment, Cisco recommends that you configure adaptive profile updates. In an inline deployment, configure the inline normalization preprocessor with the **Normalize TCP Payload** option enabled.

Caution Adaptive profiling **must** be enabled (its default state) as described in this procedure for access control rules to perform application or file control, including AMP, and for intrusion rules to use service metadata.

Before you begin

The access control policy must have a network discovery policy that is enabled to do host/service discovery, or host data must be imported from a third-party source.

Procedure

Step 1 In the access control policy editor, click **Edit** (✎) on the policy you want to modify.

Step 2 Click **More** > **Advanced Settings**, and then click **Edit** (✎) next to the **Detection Enhancement Settings** section.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Set adaptive profile options as described in Adaptive Profile Options, on page 2729.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

What to do next

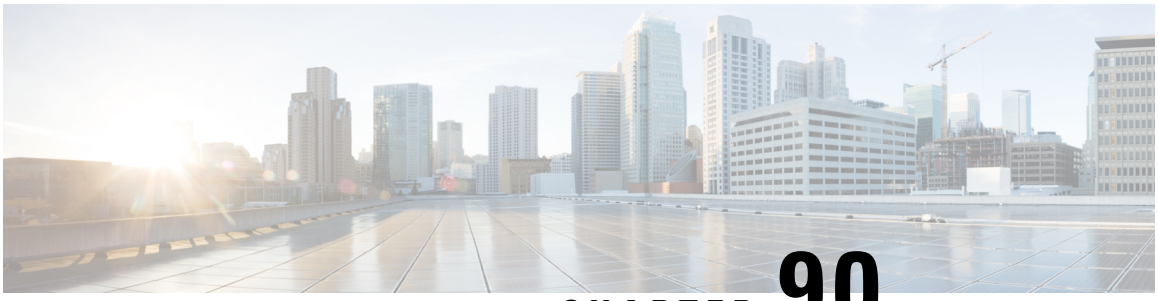
Threat Intelligence Director

- Secure Firewall Threat Intelligence Director, on page 2735



CHAPTER 90

Secure Firewall Threat Intelligence Director

The topics in this chapter describe how to configure and use Threat Intelligence Director.

- Secure Firewall Threat Intelligence Director Overview, on page 2735
- Requirements and Prerequisites for Threat Intelligence Director, on page 2738
- How To Set Up Threat Intelligence Director, on page 2740
- Analyze Threat Intelligence Director Incident and Observation Data, on page 2749
- View and Change Threat Intelligence Director Configurations, on page 2761
- Troubleshoot Threat Intelligence Director, on page 2776
- History for Threat Intelligence Director, on page 2778

Secure Firewall Threat Intelligence Director Overview

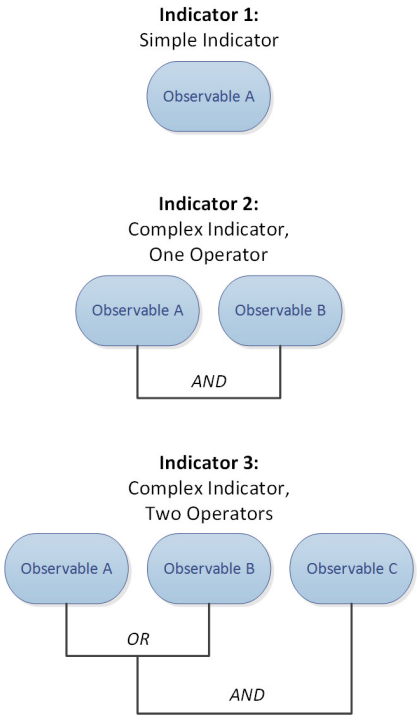
The Secure Firewall Threat Intelligence Director operationalizes threat intelligence data, helping you aggregate intelligence data, configure defensive actions, and analyze threats in your environment. This feature is intended to supplement other Firepower functionality, offering an additional line of defense against threats.

When configured on your hosting platform, Threat Intelligence Director ingests data from threat intelligence *sources* and publishes the data to all configured managed devices (*elements*.) For more information about the hosting platforms and elements supported in this release, see Platform, Element, and License Requirements, on page 2738.

Sources contain *indicators*, which contain *observables*. An indicator conveys all of the characteristics associated with a threat, and individual observables represent individual characteristics (e.g. a SHA-256 value) associated with the threat. *Simple indicators* contain a single observable, and *complex indicators* contain two or more observables.

Observables and the AND/OR operators between them form an indicator's *pattern*, as illustrated in the following examples.

Figure 450: Example: Indicator Patterns



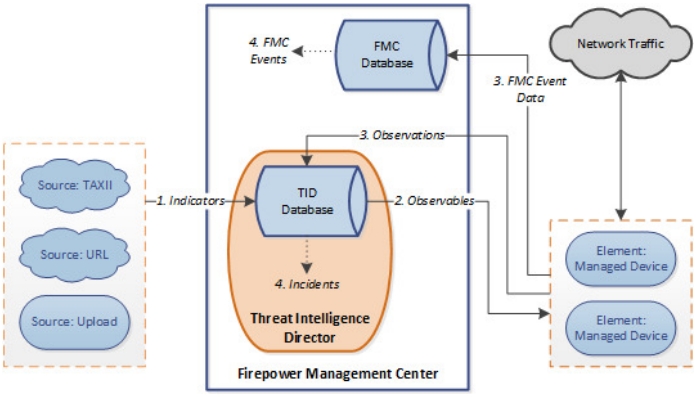
After the observables are published to the elements, the elements monitor traffic and report *observations* to the Firewall Management Center when the system identifies observables in traffic.

The Firewall Management Center collects observations from all elements, evaluates the observations against Threat Intelligence Director indicators, and generates or updates *incidents* associated with the observable's parent indicator(s).

An incident is *fully realized* when an indicator's pattern is fulfilled. An incident is *partially realized* if traffic matches one or more observables in the indicator but not the entire pattern. For more information, see Observation and Incident Generation, on page 2749.

The following diagram shows data flow in a sample system configuration.

Figure 451: Firewall Management Center Data Flow



When a Threat Intelligence Director incident is fully or partially realized, the system takes the configured *action* (monitor, block, partially block, or no action). For details, see Factors That Affect the Action Taken, on page 2757.

Threat Intelligence Director and Security Intelligence

As part of your access control policy, Security Intelligence uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domains. Security Intelligence uniquely provides access to industry-leading threat intelligence from Talos Intelligence Group. For more information on Security Intelligence, see About Security Intelligence, on page 1885.

Threat Intelligence Director enhances the system's ability to block connections based on security intelligence from third-party sources as follows:

- **Threat Intelligence Director supports additional traffic filtering criteria**—Security Intelligence allows you to filter traffic based on IP address, URL, and (if DNS policy is enabled) domain name. Threat Intelligence Director also supports filtering by these criteria and adds support for filtering on SHA-256 hash values.
- **Threat Intelligence Director supports additional intelligence ingestion methods**—With both Security Intelligence and Threat Intelligence Director, you can import threat intelligence into the system by either manually uploading flat files or configuring the system to retrieve flat files from a third-party host. Threat Intelligence Director provides increased flexibility in managing those flat files. In addition, Threat Intelligence Director can retrieve and ingest intelligence provided in Structured Threat Information eXpression (STIX™) format.
- **Threat Intelligence Director provides granular control of filtering actions**—With Security Intelligence, you can specify filtering criteria by network, URL, or DNS object. Security Intelligence objects, especially list and feeds, can contain multiple IP addresses, URLs, or DNS domain names, but you can only block or not block based on entire objects, not based on individual components of an object. With Threat Intelligence Director, you can configure filtering actions for individual criteria (that is, simple indicators or individual observables).
- **Threat Intelligence Director configuration changes do not require redeployment**—After you modify Security Intelligence settings in the access control policy, you must redeploy the changed configuration to managed devices. With Threat Intelligence Director, after initial deployment of the access control policy to the managed devices, you can configure sources, indicators, and observables without redeploying, and the system automatically publishes new Threat Intelligence Director data to the elements.

For information about what the system does when either Security Intelligence or Threat Intelligence Director could handle a particular incident, see Threat Intelligence Director-Firewall Management Center Action Prioritization, on page 2757.

Performance Impact of Threat Intelligence Director

Secure Firewall Management Center

In some cases, you may notice the following:

- The system may experience minor performance issues while ingesting particularly large STIX sources, and ingestion may take longer than expected to finish.

- The system may take up to 15 minutes to publish new or modified Threat Intelligence Director data down to elements.

Managed Device

There is no exceptional performance impact. Threat Intelligence Director impacts performance identically to the Secure Firewall Management Center Security Intelligence feature.

Requirements and Prerequisites for Threat Intelligence Director

Model Support

Any

User Roles

Admin

Threat Intelligence Director User

Additional Requirements

The following topics explain additional requirements for using Threat Intelligence Director.

Platform, Element, and License Requirements

Hosting Platforms

You can host Threat Intelligence Director on physical and virtual Secure Firewall Management Centers:

- running Version 6.2.2 or later.
- configured with a minimum of 15 GB of memory.
- configured with REST API access enabled. See *Enabling REST API Access* in the Cisco Secure Firewall Management Center Administration Guide.

Elements

You can use any Secure Firewall Management Center-managed device as a Threat Intelligence Director element if the device is running Version 6.2.2 or later.

Licensing

To configure the file policies for SHA-256 observable publishing, you need the following licensed devices:

- For smart licensed devices:

- IPS License - For IPv4, IPv6, URL, and DNS detection and observables
- Malware Defense License - For SHA-256 detection and observables

For more information, see Configure Policies to Support Threat Intelligence Director, on page 2741 and the *Licenses* chapter in the Cisco Secure Firewall Management Center Administration Guide.

Source Requirements

Source Type Requirements:

STIX

Files must be STIX Version 1.0, 1.1, 1.1.1, or 1.2 and adhere to the guidelines in the STIX documentation: http://stixproject.github.io/documentation/suggested-practices/.

STIX files can include complex indicators.

The maximum size for a STIX file is 40MB when configured via URL download or file upload. If you have STIX files larger than this, we recommend using a TAXII server.

Flat File

Files must be ASCII text files with one observable value per line.

Flat files include only simple indicators (one observable per indicator.)

Flat files can be up to 500 MB.

Threat Intelligence Director does **not** support:

- Delimiter characters separating observable values (e.g. `observable,` is invalid).
- Enclosing characters around observable values (e.g. `"observable"` is invalid).

Each file should contain only one type of content:

- `SHA-256`—SHA-256 hash values.
- `Domain`—domain names as defined in RFC 1035.
- `URL`—URLs as defined in RFC 1738.

Note Threat Intelligence Director normalizes any URLs that contain port, protocol, or authentication information, and uses the normalized version when detecting indicators. For example, Threat Intelligence Director normalizes any of the following URLs:

```
http://example.com/index.htm
http://example.com:8080/index.htm
example.com:8080/index.htm
example.com/index.htm
```

as:

```
example.com/index.htm
```

Or, for example, Threat Intelligence Director normalizes the following URL:

```
http://abc@example.com:8080/index.htm
```

as

```
abc@example.com/index.htm/
```

- `IPv4`—IPv4 addresses as defined in RFC 791.

  Threat Intelligence Director does not accept CIDR blocks.

- `IPv6`—IPv6 addresses as defined in RFC 4291.

  Threat Intelligence Director does not accept prefix lengths.

Source Content Limitations

The system ingests, and matches on, only the first 1000 characters of a URL observable.

How To Set Up Threat Intelligence Director

Note If you encounter an issue during Threat Intelligence Director configuration or operation, see Troubleshoot Threat Intelligence Director, on page 2776.

Procedure

Step 1 Ensure that your installation meets the requirements for running Threat Intelligence Director.

See Platform, Element, and License Requirements, on page 2738

Step 2 For each managed device, configure the policies required to support Threat Intelligence Director and deploy those policies to the devices.

See Configure Policies to Support Threat Intelligence Director, on page 2741.

You can configure elements before or after you ingest intelligence data sources.

Step 3 Configure the intelligence sources that you want Threat Intelligence Director to ingest.

See Source Requirements, on page 2739 and the topics under Options for Ingesting Data Sources, on page 2742.

Step 4 Publish data to the elements if you have not yet done so. See Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

What to do next

- Include Threat Intelligence Director in your regularly scheduled backups. See About Backing Up and Restoring Threat Intelligence Director Data, on page 2748.

  If your Secure Firewall Management Center deployment is a high availability configuration, see also *Firewall Management Center High Availability Disaster Recovery* in the Cisco Secure Firewall Management Center Administration Guide.
- (Optional) Grant administrative access to Threat Intelligence Director functionality as desired. See User Roles with Threat Intelligence Director Access, on page 2748 and the *Users* chapter in the Cisco Secure Firewall Management Center Administration Guide.
- As needed during operation, fine-tune your configuration. For example, add observables that produce false-positive incidents to the Do Not Block list. See View and Change Threat Intelligence Director Configurations, on page 2761.

Configure Policies to Support Threat Intelligence Director

You must configure access control policies to publish Threat Intelligence Director data from the Firewall Management Center to your managed devices (elements). In addition, we recommend that you configure your access control policies to maximize observation and Firewall Management Center event generation.

For each managed device that you want to support Threat Intelligence Director, perform the steps below to configure the associated access control policy.

Elements that are configured to use Threat Intelligence Director after data has been published will automatically receive all currently-published observables.

Procedure

Step 1 Verify that the **Enable Threat Intelligence Director** check box is checked in **General Settings** of the access control policy. To navigate to **General Settings**, choose **Policies** > **Access Control heading** > **Access Control**, and click **Edit** > **More** > **Advanced Settings**. This option is enabled by default.

For more information, see Access Control Policy Advanced Settings, on page 1756.

Step 2 Add rules that allow (rather than trust) connections to the access control policy if they are not already present. Threat Intelligence Director requires that the access control policy specify at least one rule.

Because Threat Intelligence Director depends on inspection, ensure that you allow traffic, rather than trust it, because the purpose of trusting traffic is to bypass inspection. For more information, see Creating a Basic Access Control Policy, on page 1748.

Step 3 If you choose **Intrusion Prevention** as the default action for the access control policy and you want to decrypt traffic for TID detection, associate an SSL policy with the access control policy; see Associating Other Policies with Access Control, on page 1762.

Step 4 If you want `SHA-256` observables to generate observations and Secure Firewall Management Center events:

a) Create a file policy containing one or more **Malware Cloud Lookup** or **Block Malware** file rules.

For more information, see Configure File Policies, on page 2216.

b) Associate this file policy with one or more rules in the access control policy.

Step 5 If you want `IPv4`, `IPv6`, `URL`, or `Domain Name` observations to generate connection and security intelligence events, enable connection and security intelligence logging in the access control policy:

a) In access control rules where you invoked a file policy, enable **Log at End of Connection** and **File Events: Log Files**, if not already enabled.

For more information, see *Logging Connections with Access Control Rules* in the Cisco Secure Firewall Management Center Administration Guide.

b) Verify that default logging (**DNS Policy**, **Networks**, and **URLs**) is enabled in your Security Intelligence settings.

For more information, see *Logging Connections with Security Intelligence* in the Cisco Secure Firewall Management Center Administration Guide.

Step 6 Deploy configuration changes; see Deploy Configuration Changes, on page 259.

What to do next

Complete remaining items in How To Set Up Threat Intelligence Director, on page 2740

Options for Ingesting Data Sources

Choose a configuration option based on the data type and delivery mechanism you want to use.

For more information about these data types, see Source Requirements, on page 2739.

Table 146: Options for Ingesting Data Sources

Data Type	Ingestion Options
STIX	• Ingest STIX feeds from a TAXII server: See Fetch TAXII Feeds to Use as Sources, on page 2743 • Download STIX data from a URL: See Fetch Sources from a URL, on page 2744 • Upload a STIX file: See Upload a Local File to Use as a Source, on page 2745

Data Type	Ingestion Options
Flat file	• Download data from a URL: See Fetch Sources from a URL, on page 2744 • Upload a flat file: See Upload a Local File to Use as a Source, on page 2745

Fetch TAXII Feeds to Use as Sources

If you encounter an issue during TID configuration or operation, see Troubleshoot Threat Intelligence Director, on page 2776

Procedure

Step 1 Make sure your source meets the requirements in Source Requirements, on page 2739

Step 2 Choose **Integration** > **Intelligence** > **Sources**.

Step 3 Click **Add** (+).

Step 4 Choose `TAXII` as the **Delivery** method for the source.

Step 5 Enter information.

- If the host server requires an encrypted connection, configure the **SSL Settings** as described in Configure TLS/SSL Settings for a Threat Intelligence Director Source, on page 2747.
- You cannot change the **Action** selection for TAXII sources.

  `Block` is not an **Action** option for TAXII sources, as STIX data can contain complex indicators, which the system cannot block. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

  However, after ingestion, you can block individual observables and simple indicators obtained from the source. For more information, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772.
- It may take some time for the list of feeds to load.
- The **Update Every** interval specifies the frequency that Threat Intelligence Director retrieves updates from the TAXII source.

  Set an update frequency that makes sense for how often the data source is updated. For example, if the source is updated 3 times per day, set your update interval to 1440/3 or 480 minutes to regularly capture the latest data.
- After the number of days you specify for **TTL**, Threat Intelligence Director deletes:
  - all of the source's indicators that are not included in subsequent source updates.
  - all observables not referenced by a surviving indicator.

Note

If the source contains no updates for the number of days specified for TTL and the source checksum remains unchanged, downloads are treated as feeds with no updates. For observables to receive a new TTL value, the source must contain a few updates.

Step 6 If you want to immediately begin publishing to elements, confirm that the **PUBLISH Slider** ( ) is enabled.

When this option is enabled, the system automatically publishes the initial source data and any subsequent changes.

For details, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

Step 7 Click **Save**.

What to do next

- TAXII feeds can contain a lot of data, it may take some time for the system to ingest all of the data. To view ingestion status, refresh the Sources page.
- If you see an error for this source, hover over status for details.
- If you are doing initial Threat Intelligence Director configuration, return to How To Set Up Threat Intelligence Director, on page 2740.

Fetch Sources from a URL

Configure a URL source if you want Threat Intelligence Director to fetch files from a host.

If you encounter an issue during TID configuration or operation, see Troubleshoot Threat Intelligence Director, on page 2776

Procedure

Step 1 Make sure your source meets the requirements in Source Requirements, on page 2739

Step 2 Choose **Integration** > **Intelligence** > **Sources**.

Step 3 Click **Add** ( ).

Step 4 Choose `URL` as the **Delivery** method for the source.

Step 5 Complete the form.

- If you are ingesting a flat file, choose a **Type** that describes the data contained within the source.
- If the host server requires an encrypted connection, configure the **SSL Settings** as described in Configure TLS/SSL Settings for a Threat Intelligence Director Source, on page 2747.
- For Name: To simplify sorting and handling of incidents based on Threat Intelligence Director indicators, use a consistent naming scheme across sources. For example, <source>-<type>.

  Including the source name simplifies returning to the source for further information or feedback.

Be sure to enter the name consistently. For example, for a source with IPv4 addresses, you might always use IPV4 (not IPv4 or ipv4 or IP_v4 or IP_V4 or ip-v4 or IP-v4, IP-V4, etc.)

- If you are ingesting a STIX file, `Block` is not an **Action** option, as STIX data can contain complex indicators, which the system cannot block. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

  However, after ingestion, you can block individual observables and simple indicators obtained from the source. For more information, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772.

- Set an update frequency that makes sense for how often the data source is updated. For example, if the source is updated 3 times per day, set your update interval to 1440/3 or 480 minutes to regularly capture the latest data.

- After the number of days you specify for the **TTL** interval, Threat Intelligence Director deletes:

  - all of the source's indicators that are not included in subsequent source updates.
  - all observables not referenced by a surviving indicator.

Note
If the source contains no updates for the number of days specified for TTL and the source checksum remains unchanged, downloads are treated as feeds with no updates. For observables to receive a new TTL value, the source must contain a few updates.

Step 6 If you want to immediately begin publishing to elements, confirm that the **Publish Slider** ( ) is enabled.

When this option is enabled, the system automatically publishes the initial source data and any subsequent changes.

For details, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

Step 7 Click **Save**.

What to do next

- To view ingestion status, refresh the Sources page. If you see an error, hover over status for details.
- If you are doing initial Threat Intelligence Director configuration, return to How To Set Up Threat Intelligence Director, on page 2740.

Upload a Local File to Use as a Source

Use this procedure for a one-time manual upload of a local file.

When ingesting a STIX file, Threat Intelligence Director creates a simple or complex indicator from the contents of the STIX file.

When ingesting a flat file, Threat Intelligence Director creates a simple indicator for each observable value in the file.

If you encounter an issue during Threat Intelligence Director configuration or operation, see Troubleshoot Threat Intelligence Director, on page 2776

Procedure

Step 1 Make sure your file meets the requirements in Source Requirements, on page 2739

Step 2 Choose **Integration** > **Intelligence** > **Sources**.

Step 3 Click **Add** (+).

Step 4 Choose `Upload` as the **Delivery** method for the source.

Step 5 Complete the form.

- If you are uploading a flat file, choose a **Type** that describes the data contained within the source.
- For Name: To simplify sorting and handling of incidents based on Threat Intelligence Director indicators, use a consistent naming scheme across sources. For example, <source>-<type>.

  Including the source name simplifies returning to the source for further information or feedback.

  Be sure to enter the name consistently. For example, for a source with IPv4 addresses, you might always use IPV4 (not IPv4 or ipv4 or IP_v4 or IP_V4 or ip-v4 or IP-v4, IP-V4, etc.)
- If you are uploading a STIX file, `Block` is not an **Action** option, because STIX data can contain complex indicators. Devices (elements) store and take action based on single observables; they cannot take action based on multiple observables.

  However, you can block a simple indicator at the indicator or observable level. For more information, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772.
- After the number of days you specify for the **TTL** interval, Threat Intelligence Director deletes:
  - all of the source's indicators that are not included in a subsequent upload.
  - all observables not referenced by a surviving indicator.

  Note
  If the source contains no updates for the number of days specified for TTL and the source checksum remains unchanged, downloads are treated as feeds with no updates. For observables to receive a new TTL value, the source must contain a few updates.

Step 6 If you want to immediately begin publishing to elements, confirm that the **Publish Slider** (toggle) is enabled.

If you do not publish the source at ingestion, you cannot publish all source indicators at once later; instead, you must publish each observable individually. See Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

Step 7 Click **Save**.

What to do next

- To view ingestion status, refresh the Sources page. If you see an error, hover over status for details.
- If you are doing initial Threat Intelligence Director configuration, return to How To Set Up Threat Intelligence Director, on page 2740.

Handling of Duplicate Indicators

If a single indicator is included in multiple sources:

Each instance of the indicator generates an incident, so one encounter with a particular threat may generate multiple incidents.

To avoid future duplicate incidents, pause publishing of all but one of the duplicated indicators. See Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

Configure TLS/SSL Settings for a Threat Intelligence Director Source

Configure **SSL Settings** if the host server requires an encrypted connection.

Before you begin

- Begin configuring a `TAXII` or `URL` source, as described in Fetch TAXII Feeds to Use as Sources, on page 2743 or Fetch Sources from a URL, on page 2744.

Procedure

Step 1 In the **Edit Source** dialog box, expand the **SSL Settings** section.

Step 2 If your server certificate is self-signed:

a) Enable **Self-Signed Certificate**.

b) Choose a **SSL Hostname Verification** method.

- `Strict`—Threat Intelligence Director requires the source **URL** to match the hostname provided in the server certificate.

  If the hostname includes a wildcard, TID cannot match more than one subdomain.

- `Browser Compatible`—Threat Intelligence Director requires the source **URL** to match the hostname provided in the server certificate.

  If the hostname includes a wildcard, TID matches all subdomains.

- `Allow All`—Threat Intelligence Director does not require the source **URL** to match the hostname provided in the server certificate.

For example, if `subdomain1.subdomain2.cisco.com` is your source **URL** and `*.cisco.com` is the hostname provided in the server certificate:

- `Strict` hostname verification fails.
- `Browser Compatible` hostname verification succeeds.
- `Allow All` hostname verification ignores the hostname values completely.

c) For **Server Certificate**:

- If you have access to the PEM-encoded self-signed server certificate, open the certificate in a text editor and copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Enter this entire string into the field.

- If you do not have access to the self-signed server certificate, leave the field blank. After you save the source, Threat Intelligence Director retrieves the certificate from the server.

Step 3 If your server requires a user certificate:

a) Enter a **User Certificate**:

Open the PEM-encoded certificate in a text editor and copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Enter this entire string into the field.

b) Enter a **User Private Key**:

Open the private key file in a text editor and copy the entire block of text, including the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines. Enter this entire string into the field.

What to do next

- Take note of the certificate's expiration date. You may want to set a calendar reminder to enter a new server certificate after the current certificate expires.
- Continue configuring the source:
  - Fetch TAXII Feeds to Use as Sources, on page 2743
  - Fetch Sources from a URL, on page 2744

User Roles with Threat Intelligence Director Access

You can use Firewall Management Center user accounts to access the Threat Intelligence Director menus and pages:

- Accounts with the **Admin** or **Threat Intelligence Director User** user role.
- Accounts with a custom user role containing the **Intelligence** permission.

In addition, you can use Firewall Management Center user accounts with the **Admin**, **Access Admin**, or **Network Admin** user role to enable or disable Threat Intelligence Director in your access control policies.

For more information about user accounts, see the *Users for the Firewall Management Center* chapter in the Cisco Secure Firewall Management Center Administration Guide.

About Backing Up and Restoring Threat Intelligence Director Data

You can use the Firewall Management Center to back up and restore all of the data needed for Threat Intelligence Director: Element data, security intelligence events, connection events, Threat Intelligence Director configurations, and Threat Intelligence Director data. For more information, see the *Backup/Restore* chapter in the Cisco Secure Firewall Management Center Administration Guide.

Note If you host Threat Intelligence Director on the active Firewall Management Center in a high availability configuration, the system does not synchronize Threat Intelligence Director configurations and Threat Intelligence Director data to the standby Firewall Management Center. We recommend performing regular backups of Threat Intelligence Director data on your active Firewall Management Center so that you can restore the data after failover.

Before you attempt to restore the Threat Intelligence Director data on the active Firewall Management Center, pause synchronization on the active peer. For more information, see *Pausing Communication Between Paired Firepower Management Centers* in the Cisco Secure Firewall Management Center Administration Guide.

Table 147: Threat Intelligence Director-Related Backup and Restore File Contents

Threat Intelligence Director-Related File Contents	Backup Selection	Restore Selection
Element data	**Back Up Configuration**	**Restore Configuration Data**
Secure Firewall Management Center event data	**Back Up Events**	**Restore Event Data**
Threat Intelligence Director configurations and Threat Intelligence Director data	**Back Up Threat Intelligence Director**	**Restore Threat Intelligence Director Data**

Analyze Threat Intelligence Director Incident and Observation Data

To analyze incident and observation data generated by Threat Intelligence Director elements, use the Incidents table and Incident Details page.

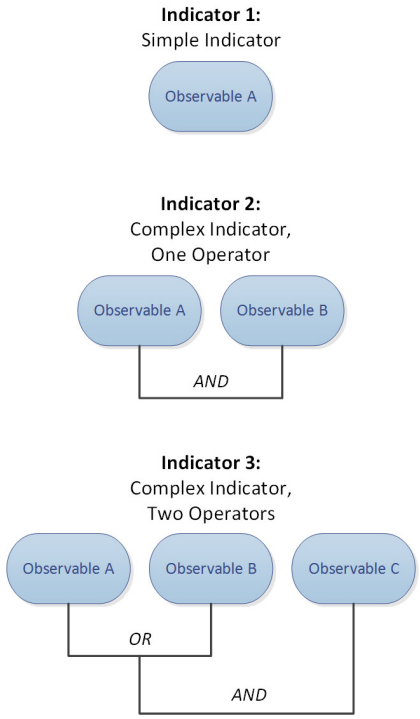
Observation and Incident Generation

Threat Intelligence Director generates an incident when the first observable for an indicator is seen in traffic. Simple indicators are fully realized after a single observation. Complex indicators are partially realized until one or more additional observations fulfill their pattern. Complex indicators need not necessarily be fulfilled during a single transaction; each observable can be fulfilled separately over time, by different transactions.

Note When evaluating an indicator's pattern, Threat Intelligence Director ignores unsupported and invalid objects and observables on the Do Not Block list.

After an incident is fully realized, subsequent observations trigger new incidents.

Figure 452: Example: Indicator Patterns



If Threat Intelligence Director ingested the observables from the example above and the observables were seen in order, incident generation would proceed as follows:

1. When the system identifies Observable A in traffic, Threat Intelligence Director:
   - Generates a fully-realized incident for Indicator 1.
   - Generates partially-realized incidents for Indicator 2 and Indicator 3.
2. When the system identifies Observable B in traffic, Threat Intelligence Director:
   - Updates the incident to fully-realized for Indicator 2, since the pattern was fulfilled.
   - Updates the incident to partially-realized for Indicator 3.
3. When the system identifies Observable C in traffic, Threat Intelligence Director:
   - Updates the incident to fully-realized for Indicator 3, since the pattern was fulfilled.
4. When the system identifies Observable A for a second time, Threat Intelligence Director:
   - Generates a new fully-realized incident for Indicator 1.
   - Generates new partially-realized incidents for Indicator 2 and Indicator 3.

If a particular indicator exists in multiple sources, you may see duplicate incidents. For more information, see Troubleshoot Threat Intelligence Director, on page 2776.

Note that incidents are generated only by actual traffic. If there is an observable for URL B, and a user visits URL A which displays a link to URL B, no incident occurs unless the user clicks the URL B link.

View and Manage Incidents

The Incidents page displays summary information for up to 1.1 million of the most recent Threat Intelligence Director incidents; see Incident Summary Information, on page 2752.

Before you begin

- Configure the feature as described in How To Set Up Threat Intelligence Director, on page 2740.
- Understand observation and incident generation, as described in Observation and Incident Generation, on page 2749.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Incidents**.

Step 2 View your incidents:

- Click **Filter** ( ) to add one or more filters. The default filter is 6 hours. For more information, see Filter Threat Intelligence Director Data in Table Views, on page 2769.
- To view the date and time an incident was last updated by Threat Intelligence Director, hover the cursor over the value in the **Last Updated** column.
- To view more information about the indicator associated with the incident, click the text in the **Indicator Name** column; see View and Manage Indicators, on page 2765.

Step 3 View additional details by clicking a value in the **Incident ID** column.

For an explanation of the details you see, see Incident Details, on page 2752.

- To view indicator details, click an indicator value (for example, an IP address or SHA-256 value) under the **Indicator** heading in the lower section of the window.
- To view observation details, click the arrow to the left of an observation immediately under the **Observations** heading.
- To view this incident on the Security Intelligence Events page, click the **Events** link in the observation details section.

Step 4 (Optional) Enter descriptive information on the incident details page:

Tip: To maximize consistency and usefulness of the options below, plan ahead and document your naming conventions, category choices, and confidence level criteria.

- Enter any value you like in the following fields: **Name**, **Description**, and **Category**.
- Click a rating level for **Confidence**.
- Indicate the status of your investigation into the incident by choosing a value from the drop-down list in the **Status** field.

Incident Summary Information

The Incidents page displays summary information for all Threat Intelligence Director incidents.

Table 148: Incident Summary Information

Field	Description
Last Updated	The number of days since either the system or a user last updated the incident. To view the date and time of the update, hover the cursor over the value in this column.
Incident ID	The unique identifier for the incident. This ID has the following format: `<type>-<date>-<number>` • `<type>`—The type of indicator or observable involved in the incident. For simple indicators, this value indicates the observable type: `IP` (IPv4 or IPv6), `URL` (URL), `DOM` (domain), or `SHA` (SHA-256). For complex indicators, this value is `COM`. • `<date>`—The date (*yyyymmdd*) on which the incident was created. • `<number>`—The daily incident number, that is, a number specifying where the incident occurs in the daily sequence of incidents. Note that this sequence starts at 0. For example, `DOM-20170828-10` is the 11th incident created on that day. Next to the identifier, the system displays an icon that indicates whether the incident is **Partially Realized** or **Fully Realized**. For more information, see Observation and Incident Generation, on page 2749.
Indicator Name	The name of the indicator involved in the incident. To view additional information about the indicator, click the value in this column; see View and Manage Indicators, on page 2765.
Type	The type of indicator involved in the incident. • Indicators that contain a single observable display the data type (`URL`, `SHA-256`, etc.) • Indicators that contain two or more observables display as `Complex`.
Action Taken	The action taken by the system in relation to the incident. For more information, see Incident Details, on page 2752.
Status	The status of your investigation into the incident. For more information, see Incident Details, on page 2752.
Delete ( )	Clicking this icon permanently deletes the incident.

Incident Details

The Incident Details window displays information about a single Threat Intelligence Director incident. This window is divided into two sections:

- Incident Details: Basic Information, on page 2753
- Incident Details: Indicator and Observations, on page 2754

Incident Details: Basic Information

The upper section of the Incident Details window provides the information described below.

Table 149: Basic Incident Information Fields

Field	Description
Partially-Realized *IncidentID* or **Fully-Realized** *IncidentID*	An icon indicating the incident's status (partially-realized or fully-realized), as well as the unique identifier for the incident. **Note** When determining an incident's status, Threat Intelligence Director ignores unsupported and invalid observables and observables on the Do Not Block list.
Opened	The date and time the incident was last updated.
Name	A custom, optional incident name that you enter manually. Tip: If there is information from the source in the Description field (in the bottom part of the window), use information from that field to name the incident.
Description	A custom, optional incident description that you enter manually. Tip: If there is information from the source in the Description field (in the bottom part of the window), use information from that field to describe the incident.
Observations	The number of observations within the incident.
Confidence	An optional rating that you can manually select to indicate the relative importance of the incident.
Action Taken	The action taken by the system: `Monitored`, `Blocked`, or `Partially Blocked`. `Partially Blocked` indicates that the incident contained both `Monitored` and `Blocked` observations. **Note** The **Action Taken** indicates the action taken by the system, not necessarily the action selected in Threat Intelligence Director. For more information, see Threat Intelligence Director-Firewall Management Center Action Prioritization, on page 2757.
Category	A custom, optional tag or keyword that you manually add to the incident.
Status	A value indicating the current stage of your analysis of the incident. All incidents are `New` until you change the **Status** for the first time. This field is optional. Depending on the needs of your organization, consider using the status values as follows: • `New`—The incident requires investigation, but you have not started investigating. • `Open`—You are currently investigating the incident. • `Closed`—You investigated the incident and took action. • `Rejected`—You investigated the incident and determined there was no action to take.
Delete ( )	Clicking this icon permanently deletes this incident.

Incident Details: Indicator and Observations

The lower section of the Incident Details window provides an in-depth view of the indicator and observation information. This information is organized as **Indicator** fields, the indicator pattern, and **Observations** fields.

Indicator Section

When you first view indicator details, this section displays only the indicator name.

Click the indicator name to view the indicator on the Indicators page.

Click the down arrow next to the indicator name to view more indicator details without leaving the incident. Detail fields include:

Table 150: Indicator Fields

Field	Description
Description	The indicator description provided by the source.
Source	The source that contained the indicator. Click this link to access full source details.
Expires	The date and time the incident will expire, based on the source's **TTL** value.
Action	The action associated with the indicator. For more information, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772.
Publish	The publish setting for the indicator. For more information, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.
Download STIX	If the source type is `STIX`, click this button to download the STIX file.

Indicator Pattern

The indicator pattern is a graphical representation of the observables and operators that comprise the indicator. Operators link the observables within the indicator. AND relationships are indicated with the **AND** operator. OR relationships are indicated with the **OR** operator or by a close grouping of several observables.

If an observable in the pattern has already been seen, the observable box is white. If an observable has not already been seen, the observable box is grey.

In the indicator pattern:

- Click the **Add to Do-Not-Block List** button to add the observable to the Do Not Block list. This icon is present in both white and grey observable boxes. For more information, see About Adding Threat Intelligence Director Observables to the Do Not Block List, on page 2775.
- If you hover the cursor over a white observable box, the system highlights the related observation in the **Observations** section.
- If you click a white observable box, the system highlights the related observation in the **Observations** section, scrolls that observation into view (if multiple observations are present), and expands that observation's detailed display.

- If you hover the cursor over or click a grey observable box in the indicator pattern, there is no change in the **Observations** section. Because the observable is unseen, there are no observation details to display yet.

Observations Section

By default, the **Observations** section displays summary information, which includes:

- The type of observable that triggered the observation (for example, `Domain`)
- The data that comprises the observable
- Whether the observation is the first observation or a subsequent observation (for example, `1st` or `3rd`)

Note If a single observable has been seen three or more times, Threat Intelligence Director displays the first and last observation details. The details for intermediary observations are not available.

- The date and time of the observation
- The action configured for the observable

If you hover the cursor over an observation in the **Observations** section, the system highlights the related observable in the indicator pattern.

If you click an observation in the **Observations** section, the system highlights the related observable(s) in the indicator pattern and scrolls the first related observable into view (if multiple observables are present). Clicking an observation also expands the details of the observation in the **Observations** section.

Observation details include the following fields:

Table 151: Observation Detail Fields

Field	Description
SOURCE	The source IP address and port for the traffic that triggered the observation.
DESTINATION	The destination IP address and port for the traffic that triggered the observation.
ADDITIONAL INFORMATION	DNS and authentication information related to the traffic that triggered the observation.
Events	This clickable link displays if the observation generated connection, security intelligence, file, or malware events. Click the link to view the events in the Secure Firewall Management Center event table; see Cisco Secure Firewall Management Center Administration Guide.

View Events for a Threat Intelligence Director Observation

For more information about the Secure Firewall Management Center events that Threat Intelligence Director observations generate, see Threat Intelligence Director Observations in Secure Firewall Management Center Events, on page 2756.

The system action logged for Threat Intelligence Director-related events can vary, depending on the interaction of Threat Intelligence Director and other Secure Firewall Management Center features. For more information about action prioritization, see Threat Intelligence Director-Firewall Management Center Action Prioritization, on page 2757.

Before you begin

- Configure the feature as described in How To Set Up Threat Intelligence Director, on page 2740.
- Confirm that you enabled event logging required for Threat Intelligence Director in your access control policy, as described in Configure Policies to Support Threat Intelligence Director, on page 2741.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Incidents**.

Step 2 Click the **Incident ID** value for the incident.

Step 3 Click the observation in the **Indicator** section to display the observation box.

Step 4 Expand the observation box by clicking the arrow in the upper-left corner of the box.

Step 5 Click the **Events** link in the observation information. For more information on the Security Intelligence display, see the *Connection and Security Intelligence Events* chapter in the Cisco Secure Firewall Management Center Administration Guide.

Threat Intelligence Director Observations in Secure Firewall Management Center Events

If you fully configure your access control policy, Threat Intelligence Director observations generate the following Secure Firewall Management Center events:

Table 152: Secure Firewall Management Center Events Generated by Observations

Observation Content	Connection Events Table	Security Intelligence Events Table	File Events Table	Malware Events Table
SHA-256	Yes	No	Yes	Yes, if disposition is Malware or Custom Detection.

Observation Content	Connection Events Table	Security Intelligence Events Table	File Events Table	Malware Events Table
Domain Name, **URL**, or **IPv4/IPv6**	Yes Threat Intelligence Director-related connection events are identified with a Threat Intelligence Director-related **Security Intelligence Category** value.	Yes Threat Intelligence Director-related security intelligence events are identified with a Threat Intelligence Director-related **Security Intelligence Category** value.	No	No

Factors That Affect the Action Taken

Many factors determine when the system takes action and what action the system takes when it detects traffic that matches a Threat Intelligence Director observable.

- Features like Security Intelligence take action before Threat Intelligence Director does. For details, see Threat Intelligence Director-Firewall Management Center Action Prioritization, on page 2757.
- Generally, the action configured for an observable (which may differ from the action configured for its parent indicator or source) is the action that will be taken.
- Because STIX sources can contain complex indicators, the Action setting for the source can be set only to Monitor. However, individual simple indicators or observables contained in a STIX feed or file can be set to Block.
- Action settings for indicators and observables can be inherited or individually configured to override inheritance. See Inheritance in Threat Intelligence Director Configurations, on page 2770 and Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772.
- Traffic that might otherwise be actionable might be on a Do Not Block list. For details, see Add Threat Intelligence Director Observables to a Do Not Block List, on page 2776.
- The configured action is taken for both partially- and fully-realized incidents.
- An incident based on a complex indicator can be partially blocked. This can occur if the indicator includes both monitored and blocked observations.
- Pausing publishing affects actions the system takes. See About Pausing Publishing, on page 2772 and Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.
- Pausing the Threat Intelligence Director feature prevents all actions. After you resume the feature, actionable data may be different from before. For details, see Pause Threat Intelligence Director and Purge Threat Intelligence Director Data from Elements, on page 2773.

Threat Intelligence Director-Firewall Management Center Action Prioritization

If Threat Intelligence Director observable actions conflict with Firewall Management Center policy actions, the system prioritizes actions as follows:

- Security Intelligence Do Not Block
- TID Block
- Security Intelligence Block
- TID Monitor
- Security Intelligence Monitor

Specifically:

Table 153: Threat Intelligence Director URL Observable Action vs. Security Intelligence Action

Setting: Security Intelligence Action	Setting: Threat Intelligence Director Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
`Do Not Block`	`Monitor` or `Block`	No TID incident	No Security Intelligence event		
`Block`	`Monitor`	`Blocked`	`Block`	as determined by system analysis; see Security Intelligence Categories, on page 1891	`URL Block`
	`Block`	`Blocked`	`Block`	`TID URL Block`	`URL Block`
`Monitor`	`Monitor`	`Monitored`	Determined by access control rules processed after Security Intelligence and TID.	`TID URL Monitor`	`URL Monitor`
	`Block`	`Blocked`	`Block`	`TID URL Block`	`URL Block`

Table 154: Threat Intelligence Director IPv4/IPv6 Observable Action vs. Security Intelligence Action

Setting: Security Intelligence Action	Setting: Threat Intelligence Director Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
`Do Not Block`	`Monitor` or `Block`	No TID incident	No Security Intelligence event		

Setting: Security Intelligence Action	Setting: Threat Intelligence Director Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
Block	Monitor	No TID incident	Block	as determined by system analysis; see Security Intelligence Categories, on page 1891	IP Block
	Block	Blocked	Block	TID IPv4 Block TID IPv6 Block	IP Block
Monitor	Monitor	Monitored	Determined by access control rules processed after Security Intelligence and TID.	TID IPv4 Monitor TID IPv6 Monitor	IP Monitor
	Block	Blocked	Block	TID IPv4 Block TID IPv6 Block	IP Block

Table 155: Threat Intelligence Director Domain Name Observable Action vs. DNS Policy Action

Setting: DNS Policy Action	Setting: Threat Intelligence Director Domain Name Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
Do Not Block	Monitor or Block	No TID incident	No Security Intelligence event		
Drop, Domain Not Found Sinkhole—Log Sinkhole—Block and Log	Monitor	Blocked	Block	as determined by system analysis; see Security Intelligence Categories, on page 1891	DNS Block
	Block	Blocked	Block	TID Domain Name Block	DNS Block

Setting: DNS Policy Action	Setting: Threat Intelligence Director Domain Name Observable Action	Threat Intelligence Director Incidents Field: Action Taken	Security Intelligence Events Fields:		
			Action	Security Intelligence Category	Reason
Monitor	Monitor	Monitored	Determined by access control rules processed after Security Intelligence and TID.	TID Domain Name Monitor	DNS Monitor
	Block	Blocked	Block	TID Domain Name Block	DNS Block

Table 156: TID SHA-256 Observable Action vs. Malware Cloud Lookup File Policy

File Disposition	Threat Intelligence Director SHA-256 Observable Action	Action Taken in Threat Intelligence Director Incidents	Action in File Events	Action in Malware Events
Clean	Monitor or Block	Monitored	Malware Cloud Lookup	n/a
Malware	Monitor or Block	Monitored	Malware Cloud Lookup	n/a
Custom	Monitor or Block	Monitored	• Malware Cloud Lookup, if SHA-256 is not in a custom detection list. • Custom Detection, if SHA-256 is in a custom detection list.	• Malware Cloud Lookup, if SHA-256 is not in a custom detection list. • Custom Detection, if SHA-256 is in a custom detection list.
Unknown	Monitor or Block	Monitored	Malware Cloud Lookup	n/a

Note Threat Intelligence Director matching occurs before the system sends a file for dynamic analysis.

Table 157: TID SHA-256 Observable Action vs. Block Malware File Policy

File Disposition	Threat Intelligence Director SHA-256 Observable Action	Action Taken in Threat Intelligence Director Incidents	Action in File Events	Action in Malware Events
Clean or Unknown	Monitor	Monitored	Malware Cloud Lookup	n/a
	Block	Blocked	• TID Block, if SHA-256 is not in a custom detection list. Modified file disposition is Custom. • Custom Detection Block, if SHA-256 is in a custom detection list.	TID Block Modified file disposition is Custom.
Malware or Custom	Monitor	Blocked	Block Malware	Block Malware
	Block	Blocked	• TID Block, if SHA-256 is not in a custom detection list. Modified file disposition is Custom. • Custom Detection Block, if SHA-256 is in a custom detection list.	TID Block Modified file disposition is Custom.

View and Change Threat Intelligence Director Configurations

Use the following information to review and fine-tune your configuration as needed.

View Threat Intelligence Director Status of Elements (Managed Devices)

All devices that are registered to the Firewall Management Center as managed devices appear automatically on the Elements page. All properly-configured elements (as specified in Configure Policies to Support Threat

Intelligence Director, on page 2741) will receive all currently-published observables, including those ingested before the element was added.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Elements**.

Step 2 To see whether the element is connected and Threat Intelligence Director is enabled, hover over the icon beside the element name.

Note
After deploying, it may take up to 5 minutes for information on this page to update, including the applied access control policy and whether TID is enabled.

View and Manage Sources

The Sources page displays summary information about all configured sources; see Source Summary Information, on page 2763.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**.

Step 2 View your sources:

- To filter the sources displayed on the page, click **Filter** ( ). For more information, see Filter Threat Intelligence Director Data in Table Views, on page 2769.
- To view detailed ingestion status, hover the cursor over the text in the **Status** column. For more information, see Source Status Details, on page 2764.

Step 3 Manage your sources:

- To edit the **Action** setting, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772. If an action is fixed, it is the only supported action for the source **Type**.
- To edit the **Publish** setting, click **Slider** ( ). For more information, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.
- To pause or resume Threat Intelligence Director updating the source, click **Pause Updates** or **Resume Updates**. If you pause updates, updating is paused but existing indicators and observables remain in TID.

- To delete the source, click **Delete** ( ). Delete is greyed out if the source is still processing. Deleting a source deletes all indicators associated with that source. Associated observables may also be deleted; they are retained if they are associated with indicators remaining in the system.

Source Summary Information

The Sources page displays summary information for all configured sources. The table below provides brief descriptions of the fields in the summary display. For detailed information on these fields, see descriptions in the relevant configuration topic for the source: See Options for Ingesting Data Sources, on page 2742.

Table 158: Sources Summary Information

Field	Description
Name	The source name.
Type	The data format of the source (`STIX` or `Flat File`).
Delivery	The method Threat Intelligence Director uses to retrieve the source.
Action	The action (`Block` or `Monitor`) that the system is configured to perform on traffic matching the data contained within this source. For more information about Threat Intelligence Director actions, including availability, inheritance, and overriding inheritance, see Factors That Affect the Action Taken, on page 2757.
Publish	`On` or `Off` toggle specifying whether Threat Intelligence Director publishes data from the source to registered elements (managed devices configured to support Threat Intelligence Director). Indicators can inherit **Publish** settings from a parent source, and observables can inherit **Publish** settings from a parent indicator. For more information, see Inheritance in Threat Intelligence Director Configurations, on page 2770.
Last Updated	The date and time Threat Intelligence Director last updated the source.

Field	Description
Status	The current status of the source: • **New**—The source is newly created. • **Scheduled**—The initial download or subsequent update is scheduled, but not yet in progress. • **Downloading**—Threat Intelligence Director is performing the initial download or update refresh. • **Parsing** or **Processing**—Threat Intelligence Director is ingesting the source. • **Completed**—Threat Intelligence Director finished ingesting the source. • **Completed with Errors**—Threat Intelligence Director finished ingesting the source, but some observables are unsupported or invalid. • **Error**—Threat Intelligence Director experienced a problem. If the source is a TAXII or URL source with an **Update Frequency** specified, and updates are not paused, Threat Intelligence Director retries on the next scheduled update. Refresh the page to update the status.
Edit ( )	Clicking this icon allows you to edit settings for the source.
Delete ( )	Clicking this icon permanently deletes the source.

Source Status Details

When you hover over a source's **Status** value in the Sources summary page, Threat Intelligence Director provides the additional details described below.

Data	Description
Status Message	Briefly describes the current status of the source.
Last Updated	Specifies the date and time Threat Intelligence Director last updated the source.
Next Update	For TAXII and URL sources, this value specifies when Threat Intelligence Director will update the source next.

Data	Description
Indicators	Specifies indicator counts: • **Consumed**—The number of indicators Threat Intelligence Director processed during the most recent source update. This number represents all indicators contained in the update, regardless of whether they were ingested or discarded. • **Discarded**—The number of malformed indicators that the system did not add to Threat Intelligence Director during the most recent update. **Note** For `TAXII` sources, Threat Intelligence Director provides separate **Last Update** and **Total** indicator counts, because TAXII updates add incremental data, rather than replacing existing data. For indicators from other source types, Threat Intelligence Director provides only the **Last Update** count, because updates from those sources replace the existing data set entirely. If all of an indicator's observables are **Invalid**, Threat Intelligence Director discards the indicator.
Observables	Specifies observable counts: • **Consumed**—The number of observables Threat Intelligence Director processed during the most recent source update. This number represents all observables contained in the update, regardless of whether they were ingested or discarded. • **Unsupported**—The number of unsupported observables that the system did not add to Threat Intelligence Director during the most recent update. For more information about supported observable types, see information about content types in Source Requirements, on page 2739. • **Invalid**—The number of invalid observables that the system did not add to Threat Intelligence Director during the most recent update. An observable is invalid if it is improperly constructed. For example, `10.10.10.10.123` is not a valid IPv4 address. **Note** For `TAXII` sources, Threat Intelligence Director provides separate **Last Update** and **Total** observable counts, because TAXII updates add incremental data, rather than replacing existing data. For observables from other source types, Threat Intelligence Director provides only the **Last Update** count, because updates from those sources replace the existing data set entirely.

View and Manage Indicators

Indicators are generated automatically from ingested sources. For more information about information on this page, see Indicator Summary Information, on page 2766.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**.

Step 2 Click **Indicators**.

Step 3 View your current indicators:

- To filter the indicators displayed on the page, click **Filter** (). For more information, see Filter Threat Intelligence Director Data in Table Views, on page 2769.
- To view additional details about an indicator (including associated observables), click the indicator name. For more information, see Indicator Details, on page 2767.
- In the **Incidents** column, click the number to view information about incidents associated with an indicator, or hover the cursor over Incidents to view whether the incidents are fully- or partially-realized.
- To determine whether Threat Intelligence Director finished ingesting an indicator from the source, view the **Status** column.

Step 4 Manage your current indicators:

- To edit the **Action**, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772. If an action is fixed, it is the only supported action for the source **Type**.
- To edit the **Publish** setting, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.
- To add one or more of an indicator's observables to the Do Not Block list, click the indicator name to access the Indicator Details page. For more information, see About Adding Threat Intelligence Director Observables to the Do Not Block List, on page 2775.

Indicator Summary Information

The Indicators page displays summary information for all indicators associated with configured sources.

Table 159: Indicators Summary Information

Field	Description
Type	• Indicators that have a single observable list the data type of that observable (URL, SHA-256, etc.) • Indicators that have two or more observables are listed as `Complex`. Hover over the type to see the specific observable.
Name	The indicator name.
Source	The source that contained the indicator (the parent source).
Incidents	Information about any incidents associated with the indicator: • an icon specifying whether the incident is **Partially** or **Fully** realized • the number of incidents associated with the indicator

Field	Description
Action	The action associated with the indicator. For more information, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772. Indicators can inherit **Action** settings from a parent source, and observables can inherit **Action** settings from a parent indicator. For more information, see Inheritance in Threat Intelligence Director Configurations, on page 2770.
Publish	The publish setting for the indicator. For more information, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774. Indicators can inherit **Publish** settings from a parent source, and observables can inherit **Publish** settings from a parent indicator. For more information, see Inheritance in Threat Intelligence Director Configurations, on page 2770.
Last Updated	The date and time Threat Intelligence Director last updated the indicator.
Status	The current status of the indicator: • **Pending**—Threat Intelligence Director is ingesting the indicator's observables. • **Completed**—Threat Intelligence Director successfully ingested all of the indicator's observables. • **Completed With Errors**—Threat Intelligence Director finished ingesting the indicator, but some observables are unsupported or invalid.

Indicator Details

The Indicator Details page displays indicator and observable data for an incident.

Table 160: Indicator Details Information

Field	Description
Name	The indicator name.
Description	The indicator description provided by the source.
Source	The source that contained the indicator.
Expires	The date and time the indicator will expire, based on the source's **TTL** value.
Action	The action associated with the indicator. For more information, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772. Indicators can inherit the **Action** setting from a parent source, and observables can inherit the **Action** setting from a parent indicator. For more information, see Inheritance in Threat Intelligence Director Configurations, on page 2770.

Field	Description
Publish	The publish setting for the indicator. For more information, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774. Indicators can inherit the **Publish** setting from a parent source, and observables can inherit the **Publish** setting from a parent indicator. For more information, see Inheritance in Threat Intelligence Director Configurations, on page 2770.
Indicator Pattern	The observables and operators that form the indicator's pattern. Operators link the observables within the indicator. AND relationships are indicated with the **AND** operator. OR relationships are indicated with the **OR** operator or by a close grouping of several observables. Optionally, click the **Add to Do-Not-Block List** button to add an observable to the Do Not Block list. For more information, see About Adding Threat Intelligence Director Observables to the Do Not Block List, on page 2775.

View and Manage Observables

The Observables page displays all successfully ingested observables; see Observable Summary Information, on page 2769.

Before you begin

- Configure one or more sources as described in Fetch TAXII Feeds to Use as Sources, on page 2743, Fetch Sources from a URL, on page 2744, or Upload a Local File to Use as a Source, on page 2745.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**.

Step 2 Click **Observables**.

Step 3 View your current observables:

- To filter the observables displayed on the page, click **Filter** (). For more information, see Filter Threat Intelligence Director Data in Table Views, on page 2769.
- If the information in the **Value** column is cut off, hover over the value.
- To view indicators that contain the observable, click the number in the **Indicators** column. The Incidents page opens with the observable value as the filter. For more information, see View and Manage Indicators, on page 2765.

Step 4 Manage your current observables:

- To edit the **Action**, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772.
- To edit an observable's **Publish** setting, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

- To change an observable's expiration date, modify the **TTL** for the parent source. For more information, see View and Manage Sources, on page 2762.
- To add an observable to the Do Not Block list, click the **Add to Do-Not-Block List** button. For more information, see About Adding Threat Intelligence Director Observables to the Do Not Block List, on page 2775.

Observable Summary Information

The Observables page displays summary information for all ingested observables.

Table 161: Observables Summary Information

Field	Description
Type	The type of observable data: `SHA-256`, `Domain`, `URL`, `IPv4`, or `IPv6`.
Value	The data that comprises the observable.
Indicators	The number of parent indicators containing the observable.
Action	The action configured for the observable. For more information, see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772. Indicators can inherit **Action** settings from a parent source, and observables can inherit **Action** settings from a parent indicator. For more information, see Inheritance in Threat Intelligence Director Configurations, on page 2770.
Publish	The publish setting for the observable; see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774. Indicators can inherit **Publish** settings from a parent source, and observables can inherit **Publish** settings from a parent indicator. For more information, see Inheritance in Threat Intelligence Director Configurations, on page 2770.
Updated At	The date and time Threat Intelligence Director last updated the observable.
Expires	The date that the observable will be automatically purged from Threat Intelligence Director based on **TTL** for the parent indicator.
Add to Do-Not-Block List button	Clicking this button adds the observable to the Do Not Block list; see About Adding Threat Intelligence Director Observables to the Do Not Block List, on page 2775.

Filter Threat Intelligence Director Data in Table Views

Procedure

Step 1 Choose one of the following Threat Intelligence Director table views:

- **Integration** > **Intelligence** > **Incidents**
- **Integration** > **Intelligence** > **Sources**
- **Integration** > **Intelligence** > **Sources**, and click **Indicators**
- **Integration** > **Intelligence** > **Sources**, and click **Observables**

Step 2 Click **Filter** ( ) and choose a filter attribute.

Step 3 Choose or enter a value for that filter attribute.

Filters are case-sensitive.

Step 4 (Optional) To filter by multiple attributes, click **Filter** ( ) and repeat Step 2 and Step 3.

Step 5 To cancel the changes you have made since you last applied the filter, click **Cancel**.

Step 6 Click **Apply** to refresh the table with the filter applied.

Step 7 To remove a filter attribute individually, click **Remove** ( ) next to the filter attribute and click **Apply** to refresh the table.

Inheritance in Threat Intelligence Director Configurations

When Threat Intelligence Director ingests intelligence data from a source, it creates indicators and observables as child objects of that source. On creation, these child objects inherit **Action** and **Publish** settings from the parent configuration.

An indicator inherits these settings from the parent source. An indicator can only have one parent source.

An observable inherits these settings from the parent indicator(s). An observable can have multiple parent indicators.

For more information, see:

- Inheritance of TID Settings from Multiple Parents, on page 2770
- About Overriding Inherited TID Settings, on page 2771

Inheritance of TID Settings from Multiple Parents

If an observable has multiple parent indicators, the system compares the inherited settings from all the parents and assigns the most secure option to the observable. Thus:

- **Action**: `Block` is more secure than `Monitor`
- **Publish**: `On` is more secure than `Off`

For example, SourceA might contribute IndicatorA and related ObservableA:

Setting	SourceA	IndicatorA	ObservableA
Action	`Block`	`Block`	`Block`
Publish	`Off`	`Off`	`Off`

If SourceB later contributes IndicatorB, which also includes ObservableA, the system modifies ObservableA as follows:

Setting	SourceB	IndicatorB	ObservableA
Action	`Monitor`	`Monitor`	`Block` (inherited from IndicatorA)
Publish	`On`	`On`	`On` (inherited from IndicatorB)

In this example, ObservableA has two parents: one parent for its **Action** setting and one parent for its **Publish** setting. If you manually edit the settings for the observable and then revert the settings, the system sets the **Action** setting to the IndicatorA value and the **Publish** setting to the IndicatorB value.

About Overriding Inherited TID Settings

To override an inherited setting, change the setting at the child level; see Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level, on page 2772 and Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774. After you override an inherited setting, the child object retains that setting despite changes to the parent object(s).

For example, you might start with the following original settings, with no overrides set:

Setting	SourceA	IndicatorA	ObservableA1	ObservableA2
Publish	`Off`	`Off`	`Off`	`Off`

If you override the setting for IndicatorA, the settings would be the following:

Setting	SourceA	IndicatorA	ObservableA1	ObservableA2
Publish	`Off`	`On`	`On`	`On`

In this case, any changes to the **Publish** setting for SourceA no longer cascade automatically to IndicatorA. However, inheritance from IndicatorA to ObservableA1 and ObservableA2 continues, because the observable settings are not currently set to override values.

If you later override the setting for ObservableA1:

Setting	SourceA	IndicatorA	ObservableA1	ObservableA2
Publish	`Off`	`On`	`Off`	`On`

Any changes to the **Publish** setting for IndicatorA no longer cascade automatically to ObservableA1. However, those changes continue to cascade to ObservableA2, because it is not set to an override value.

At the observable level, you can revert from an override setting to the inherited setting, and the system resumes cascading setting changes automatically from the parent indicator to that observable.

Edit Threat Intelligence Director Actions at the Source, Indicator, or Observable Level

Note:

- Editing the action for a parent sets the action for all children. If you edit the action at the source level, you set the action for all its indicators. If you edit the action at the indicator level, you set the action for all of its observables.
- Editing the action for a child interrupts inheritance. If you edit the action at the indicator level, and subsequently edit it at the source level, the indicator's action is retained until you edit the action for the individual indicator. If you edit the action at the observable level, and subsequently edit it at the indicator level, the observable's action is retained until you edit the action for the individual observable. At the observable level, you can revert automatically to the parent indicator's action. For more information about inheritance, see Inheritance in Threat Intelligence Director Configurations, on page 2770.

You may also want to review other Factors That Affect the Action Taken, on page 2757.

Procedure

Step 1 Choose any of the following:

- **Integration** > **Intelligence** > **Sources**

  Note
  Threat Intelligence Director does not support blocking TAXII sources at the source level. If the TAXII source contains a simple indicator, you can block at the indicator or observable level.

- **Integration** > **Intelligence** > **Sources**, and click **Indicators**

  Note
  Threat Intelligence Director does not support blocking complex indicators. Instead, block individual observables within the complex indicator.

- **Integration** > **Intelligence** > **Sources**, and click **Observables**

Step 2 Use the **Action** dropdown to choose **Monitor** ( ) or **Block** ( ).

Step 3 (Observables only) If you want to resume inheriting the action setting from the parent indicator, click **Revert** next to the **Action** setting for the observable.

About Pausing Publishing

- If you pause publishing at the feature level, the system purges all Threat Intelligence Director observables stored on your elements. This means that Threat Intelligence Director cannot detect, monitor or block threats. Other security features on your system are not affected.
- If you pause publishing at the source, indicator, or observable level, the system removes the paused Threat Intelligence Director observables from your elements, preventing them from matching traffic.

- Pausing publication for a parent pauses all children. If you pause publishing at the source level, you pause publishing for all its indicators. If you pause publishing at the indicator level, you pause publishing for all of its observables.
- Pausing publication for a child interrupts inheritance. If you pause publishing at the indicator level, and subsequently publish at the source level, publishing for the indicator remains paused until you change the individual setting for the indicator. If you pause publishing at the observable level, and subsequently publish at the indicator level, publishing for the observable remains paused until you change the individual setting for the observable. At the observable level, you can revert automatically to the parent indicator's publishing status. For more information about inheritance, see Inheritance in Threat Intelligence Director Configurations, on page 2770.
- Publishing for Uploaded sources can only be paused at the indicator level.
- For a comparison of pausing publishing for an observable vs adding the observable to the Do Not Block list, see About Adding Threat Intelligence Director Observables to the Do Not Block List, on page 2775.
- If you have specified a publish/pause setting for an individual observable or indicator, source updates do not change that setting if the update contains the same observable or indicator.
- Publishing can be disabled on the object management pages. See Modify the Observable Publication Frequency, on page 2775.
- The option on the Sources page to pause updates is not related to publishing data to elements; it applies to updating sources on the Firewall Management Center from feeds.

Pause Threat Intelligence Director and Purge Threat Intelligence Director Data from Elements

Caution This setting pauses publishing to all elements, purges all Threat Intelligence Director observables stored on your elements, and stops inspecting traffic using the Threat Intelligence Director feature.

To disable observables at a more granular level, see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

Data on the management center (existing incidents and configured sources, indicators, and observables, and ingestion of sources) is not affected by this setting.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Settings**.

Step 2 Click **Pause**.

What to do next

When you are ready to resume synchronizing Threat Intelligence Director data on your elements and generating observations, manually **Resume** publishing from this page. Existing observables on the management center are published to all elements.

Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level

If publishing is enabled at the Source level, the system automatically publishes the initial source data and any subsequent changes including:

- changes from periodic source refreshes
- changes resulting from system action (for example, **TTL** expiration)
- any user-initiated changes (for example, a change in the **Action** setting for an indicator or observable)

Note To purge all Threat Intelligence Director observables at once from your devices (elements), see Pause Threat Intelligence Director and Purge Threat Intelligence Director Data from Elements, on page 2773.

Before you begin

Before pausing publishing, understand the ramifications described in About Pausing Publishing, on page 2772.

Procedure

Step 1 Choose any of the following:

- **Integration** > **Intelligence** > **Sources**
- **Integration** > **Intelligence** > **Sources**, and click **Indicators**
- **Integration** > **Intelligence** > **Sources**, and click **Observables**

Step 2 Locate the **Publish Slider** ( ) and use it to toggle publishing to elements.

Step 3 (Observables only) If you want to resume inheriting the publication setting from the parent indicator, click **Revert** next to the **Publish** setting for the observable.

What to do next

- Wait at least 10 minutes for elements to receive changes. Changes involving large sources will take longer.
- (Optional) Change the publication frequency for TID data at the observable level; see Modify the Observable Publication Frequency, on page 2775.

Modify the Observable Publication Frequency

By default, the system publishes observables to TID elements every 5 minutes. Use this procedure to set this interval to a different value.

Before you begin

- Enable publication of TID data at the observable level; see Pause or Publish Threat Intelligence Director Data at the Source, Indicator, or Observable Level, on page 2774.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** > **Network Lists and Feeds**.

Step 2 Click **Edit** (✎) next to the **Cisco-TID-Feed**.

Step 3 Choose a value from the **Update Frequency** drop-down list:

- Choose **Disable** to stop publication of observable data to elements.
- Choose any other value to set the interval for observable publication.

Step 4 Click **Save**.

About Adding Threat Intelligence Director Observables to the Do Not Block List

If you want to exempt an observable in a simple indicator from the specified **Action** (let the traffic pass without monitoring or blocking), you can add the observable to a Do Not Block list.

In a complex indicator, Threat Intelligence Director ignores observables on the Do Not Block list when evaluating traffic, but other observables in that indicator are still evaluated. For example, if an indicator includes Observable 1 and Observable 2 linked by the AND operator, and you add Observable 1 to a Do Not Block list, Threat Intelligence Director generates a fully realized incident when Observable 2 is seen.

By comparison, in the same complex indicator, if you disable publishing of Observable 1 instead of adding it to the Do Not Block list, Threat Intelligence Director generates a partially-realized incident when Observable 2 is seen.

Note If you add an observable to the Do Not Block list, this always takes precedence over the **Action** setting, whether the setting in the observable is an inherited or override value.

Source updates do not affect the Do Not Block list setting for individual observables if the update contains the same observable.

Add Threat Intelligence Director Observables to a Do Not Block List

For detailed information about using Do Not Block lists, see About Adding Threat Intelligence Director Observables to the Do Not Block List, on page 2775.

Tip An "Add to Do Not Block List" button ( ) can appear in several places in the web interface. You can add an observable to a Do Not Block list in any of those locations by clicking this button.

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**, and click **Observables**.

Step 2 Navigate to the observable that you want to allow.

Step 3 Click (**Add to Do-Not-Block List**) for that observable.

What to do next

(Optional) If you need to remove an observable from the Do Not Block list, click the button again.

View a STIX Source File

Procedure

Step 1 Choose **Integration** > **Intelligence** > **Sources**, and click **Indicators**.

Step 2 Click the indicator name.

Step 3 Click **Download STIX**.

Step 4 Open the file in a text editor.

Troubleshoot Threat Intelligence Director

The sections below describe possible solutions and mitigations for common Threat Intelligence Director issues.

Fetching or uploading flat file sources generates an error

If the system fails to fetch or upload a flat file source, check that the data in the flat file matches the **Type** column on the **Integration** > **Intelligence** > **Sources** page.

TAXII or URL source update generates an error

If a TAXII or URL source update generates a source status error, check that your Server Certificate is not expired. If the certificate has expired, enter a new **Server Certificate** or delete the existing **Server Certificate** so Threat Intelligence Director can retrieve a new certificate. For more information, see Configure TLS/SSL Settings for a Threat Intelligence Director Source, on page 2747.

"Block" action is not available for an indicator or source, only "Monitor"

You can change the action for individual observables in the indicator or source.

Threat Intelligence Director table views return "No results"

Table views include the **Sources**, **Indicators**, **Observables**, and **Incidents** pages.

If you do not see data in one of the Threat Intelligence Director table views:

- Check your table filter and consider expanding the time window for the **Last Updated** filter attribute; see Filter Threat Intelligence Director Data in Table Views, on page 2769.
- Verify that you correctly configured your sources; see Options for Ingesting Data Sources, on page 2742.
- Verify that you configured your access control policy and related policies to support Threat Intelligence Director; see Configure Policies to Support Threat Intelligence Director, on page 2741. For example, if your SHA-256 observables are not generating observations, verify that your deployed access control policy contains one or more access control rules that invoke a **Malware Cloud Lookup** or **Block Malware** file policy.
- Verify that you deployed the Threat Intelligence Director-supporting access control policy and related policies to your elements; see Deploy Configuration Changes, on page 259.
- Verify that you did not pause Threat Intelligence Director data publication at the feature level; see Pause Threat Intelligence Director and Purge Threat Intelligence Director Data from Elements, on page 2773.

System is experiencing slowness or decreased performance

For more information about performance impact, see Performance Impact of Threat Intelligence Director, on page 2737.

Secure Firewall Management Center table views do not show Threat Intelligence Director data

If you are publishing observables to your elements but no Threat Intelligence Director data appears in the connection, security intelligence, file, or malware events tables, check the access control and file policies deployed to your elements. For more information, see Configure Policies to Support Threat Intelligence Director, on page 2741.

One or more elements are overwhelmed by Threat Intelligence Director data

If Threat Intelligence Director data is overwhelming one or more of your devices, consider pausing Threat Intelligence Director publishing and purging the data stored on your elements. For more information, see Pause Threat Intelligence Director and Purge Threat Intelligence Director Data from Elements, on page 2773.

System is performing a Malware Cloud Lookup instead of a TID block

This is by design. For more information, see Threat Intelligence Director-Firewall Management Center Action Prioritization, on page 2757.

System is performing a Security Intelligence or DNS Policy action instead of a TID action

This is by design. For more information, see Threat Intelligence Director-Firewall Management Center Action Prioritization, on page 2757.

TID is disabled

- Add memory to your appliance. Threat Intelligence Director can only be used on appliances with at least 15GB of memory.
- Enable REST API access for the Secure Firewall Management Center. For more information, see *Enabling REST API Access* in the Cisco Secure Firewall Management Center Administration Guide.

The system does not generate the Threat Intelligence Director incident or take the Threat Intelligence Director action that you expected

- Verify that all of your managed devices are properly enabled and configured for Threat Intelligence Director. See View Threat Intelligence Director Status of Elements (Managed Devices), on page 2761 and Configure Policies to Support Threat Intelligence Director, on page 2741.
- It takes at least 5-10 minutes for changes to be published to elements, and significantly longer if publishing a large data feed.
- Check the action setting for the observable. See View and Manage Observables, on page 2768.
- For a list of the other factors that influence the Threat Intelligence Director action that the system takes, see Factors That Affect the Action Taken, on page 2757.
- Elements (managed devices) may not have the threat data you think they have. See About Pausing Publishing, on page 2772.

One encounter with a particular threat generates multiple incidents

This can occur if a single indicator is included in multiple sources.

For details, see Handling of Duplicate Indicators, on page 2747.

History for Threat Intelligence Director

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Handling of an indicator that is included in multiple STIX feeds	7.1	Any	If STIX feeds contain identical indicators, an indicator is created for each feed, which may lead to multiple incidents being generated for the same indicator. Previously, only the feed that was downloaded last took effect.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details

Change in action prioritization	6.5	Any	These changes apply if more than one Firepower feature could apply to a particular observable.
			TID blocking/monitoring observable actions now have priority over blocking/monitoring by Security Intelligence.
			Important
			The system still effectively handles traffic as before. Traffic that was previously blocked is still blocked, and monitored traffic is still monitored. This simply changes the component reported in the event as responsible for the action. You may also see more TID incidents generated.
			• If you configure the Block TID observable action, even if the traffic also matches a Security Intelligence Block action:
			  • The Security Intelligence category in the connection event is a variant of TID Block.
			  • The system generates a TID incident with an action taken of Blocked.
			• If you configure the Monitor TID observable action, even if the traffic also matches a Security Intelligence Monitor rule:
			  • The Security Intelligence category in the connection event is a variant of TID Monitor
			  • The system generates a TID incident with an action taken of Monitored.
			Previously, in each of these cases, the system reported the category by analysis and did not generate a TID incident.

Secure Firewall Threat Intelligence Director	6.2.2	Any	Feature introduced: Lets you use threat intelligence from external sources to identify and process threats. New screens: A new top-level **Intelligence** menu with multiple tabs. Supported platforms: Secure Firewall Management Center
