Recent enhancements to the IP Security (IPsec) VPN implementation simplify firewall policy configuration for VPN connectivity. IPSec Virtual Tunnel Interface (VTI) and GRE+IPSec allow the confinement of VPN site-to-site and client connections to a specific security zone by placing the tunnel interfaces in that security zone. Connections can be isolated in a VPN DMZ if connectivity must be limited by a specific policy. Or, if VPN connectivity is implicitly trusted, VPN connections can be placed in the same security zone as the trusted inside network.

To configure the router to use zone-based firewall rules with dynamic VPNs (those which dynamically create Tunnel/Loopback/Virtual interfaces):

- Define a zone specifically for the VPN interfaces.
- Enter this zone in the **VPN Zone** field on the VPN tab of the Zone Based Firewall Page, page 20-48.
- Create zone-based firewall rules to allow the VPN traffic, as appropriate.
If non-VTI IPSec is employed, you must exercise caution when you configure a zone-based firewall policy for VPN. The zone policy must specifically allow access to protected hosts by remote VPN hosts or clients if they are in a different zone than the ingress interface for encrypted VPN traffic. This access policy must be configured by including an access control list (ACL) enumerating the source IP addresses of the VPN clients, and the destination IP addresses of all protected hosts the VPN clients are allowed to reach. If the access policy is not properly configured, the policy could expose vulnerable hosts to hostile traffic.

Refer to this white paper on cisco.com “Using VPN with Zone-Based Policy Firewall” for further discussion of these topics.

Zones and VRF-aware Firewalls

Cisco IOS firewalls are VRF-aware (Virtual Routing and Forwarding), providing management of IP address overlap across different VRFs, separate thresholds and timeouts for VRFs, and so forth. For application of zone-based firewall rules, all interfaces in a zone must belong to the same VRF.

When multiple VRFs are configured on a router and one interface provides common services to all the VRFs (for example, Internet service), you should place that interface in a separate zone. You can then define policies between the common zone and other zones. (There can be one or more zones per VRF.) You can configure rules between two zones that contain different VRFs, as shown in the following illustration.

In this illustration:
- The interface providing common services is a member of the zone “common.”
- All of VRF A is in a single zone, “vrf_A.”
- VRF B, which has multiple interfaces, is partitioned into two zones “vrf_B_1” and “vrf_B_2.”
- Zone Z1 does not have VRF interfaces.
Based on this configuration:

- You can specify policies between each of these zones and the common zone. Additionally, you can specify policies between each of the zones vrf_A, vrf_B_n and Z1 if VRF route export is configured and the traffic patterns make sense.
- You can configure a policy between zones vrf_A and vrf_B_1, but be sure that traffic can flow between them.
- You do not need to specify the global thresholds and timers on a per-VRF basis. Instead, parameters are supplied to the Inspect action through a parameter map.

Understanding the Relationship Between Permit/Deny and Action in Zone-based Firewall Rules

When you create a zone-based firewall rule, you must specify two execution-related settings: Permit/Deny and an Action (Drop, Pass, Inspect, or Content Filter). To obtain the results you want, you must clearly understand the relationship between these two parameters:

- **Permit/Deny**—The Permit/Deny setting appears to correspond to Permit/Deny in an access control list (ACL) entry. However, in zone-based firewall rules, unlike in standard access rules, these keywords do not permit or deny traffic. Instead, they specify whether you want to apply an Action to the traffic flow defined by the Source, Destination, and Services fields, and they affect processing of related class maps.
  - **Permit** — Applies the specified Action to traffic that matches the Source, Destination, and Services fields. (If protocols are listed in the Protocols table, the Action is further limited to those protocols.)
    - **Tip:** Essentially all of your zone-based rules should be Permit rules. This is the easiest configuration to understand—it means you are identifying the traffic to which you want the chosen Action applied.
  - **Deny** — Exempts the traffic defined by the Source, Destination, and Services fields. (If protocols are listed in the Protocols table, the exemption is further limited to those protocols.) In other words, treat the traffic as not matching the rule. Instead, evaluate subsequent class maps (which are not the same as zone rules) for the zone pair and look for a subsequent map that matches the traffic. If no subsequent map matches the traffic, apply the default rule to the traffic (see Changing the Default Drop Behavior, page 20-46).

It is important to understand that there is not a one-to-one relationship between zone rules and class maps. Therefore, you cannot determine just by looking at the rules table how the rules will be converted to class maps. You must preview the configuration to see which subsequent rules might be applied to traffic that matches your Deny rule. (To preview the configuration, save your changes and select Tools > Preview Configuration. For more information, see Previewing Configurations, page 8-42.)

In general, you might use a Deny rule to exempt a specific IP address within a subnet from a Permit rule you want to apply to the subnet in general; for example, exempting 10.100.10.1 from a rule applying to 10.100.10.0/24. However, it is much easier to create a Permit rule for the specific IP address and apply a desired Action, and ensure that the rule is listed above the general rule in the zone-based rules table.

If you decide to use Deny rules, be sure to also read Troubleshooting Zone-based Rules and Configurations, page 20-51.
**Action**—The Action parameters define what happens to traffic that matches a Permit rule. These parameters are ignored for Deny rules, except to determine to which class map the rule is added.

When you create a Permit rule, traffic that matches the Source, Destination, Services, and Protocol fields is processed according to the Action you choose: drop the traffic (and optionally log it), pass the traffic (and optionally log it), inspect the traffic, or apply content filtering (for Web traffic only).

When you inspect traffic for some protocols, or perform content filtering, you have the option of specifying a policy map to use for deep inspection. The deep inspection policy map also specifies actions based on the deeper characteristics of the traffic. This additional inspection applies to packets that meet the requirements of the class map to which the assigned policy map refers. Packets that do not match the deep inspection class map are allowed. Thus, deep inspection might reset TCP connections if the policy map specifies that action.

The following table illustrates the relationship between Permit/Deny and the chosen Action in a zone-based firewall rule. The table uses the TCP service as an example, but the general explanation applies to the IP service as well. The result applies only to the From and To zones specified in the rule.

### Table 20-1 Relationship Between Permit/Deny and Action in Zone-based Rules

</tbody>
</table>
Understanding the Relationship Between Permit/Deny and Action in Zone-based Firewall Rules

Permit TCP Inspect HTTP Allow and inspect HTTP traffic. If you specify a policy map for deep inspection, the action from the policy map is applied to any packets that match deep inspection parameters (for example, reset the connection for protocol violations).

Deny TCP Inspect HTTP Skip the rule for HTTP traffic and evaluate the next class map. Either a subsequent class map with a Permit rule is applied, or the class default rule is applied. The Inspect action is ignored.

Tip If subsequent rules, or the class default, pass the traffic without inspection, you need to create a Permit/Pass rule in the other direction (or an access rule) to allow return traffic for the HTTP connection. If your intention is to prohibit HTTP connections, create a Permit/Drop rule instead of a Deny/Inspect rule.

Permit TCP Content Filter HTTP Allow and inspect HTTP traffic, and apply URL filtering maps to selectively permit or deny Web connections based on the Web sites requested.

If you specify a policy map for deep inspection, the action from the policy map is applied to any packets that match deep inspection parameters (for example, reset the connection for protocol violations).

Thus, traffic can be dropped either because the Web site is blacklisted, or because the HTTP packets violate your deep inspection rules.

Chapter 20    Managing Zone-based Firewall Rules

Understanding the Relationship Between Services and Protocols in Zone-based Firewall Rules

When you create a zone-based firewall rule, there are two seemingly similar parameters which help identify the characteristics of the target traffic: Services and Protocols. The entries in these fields can provide very similar information, but it is used differently when constructing zone-based firewall policies in the device configuration. This section describes the recommended uses of these fields.

- **Services** – The Services field is used to define traffic protocol(s) in an access control list (ACL) entry. Along with the Sources and Destinations specified, this ACL entry is used by a class map to define the traffic to which you want to apply a policy. However, unlike in standard access rules, the Services information is not the primary means of identifying the traffic protocol. It is required only because ACLs must have a service designation for each entry.

In general, you can leave the default entry (IP) in the Services field for all of your zone-based firewall rules, using the Protocol table to identify specific protocols that you want to Drop, Pass, or Inspect.

If you do elect to specify a Service other than IP, ensure that your selection does not conflict with any protocols listed in the Protocol table. For example, do not specify UDP in the Services field, and then list a TCP-based protocol in the table. In general, for a given rule, if you specify a specific service in the Services field, do not enter any protocols in the Protocol table.

- **Protocol** – The Protocol table, in the Action area of the Add and Edit Zone Based Rule dialog boxes, is used to select one or more protocols, add custom port application mappings (if you specify non-default ports), and apply deep inspection policy maps. You can specify very specific protocols, such as DNS, general protocols such as TCP and UDP, and even custom protocols that identify ports you use for special applications.

As a general rule, leave Services set to IP and use the Protocol table to identify the protocols (which are also services) for all of your zone-based rules for the Drop, Pass, and Inspect actions. (The Content Filter action automatically uses the HTTP protocol, which you can configure but not change.) Following this approach will create a configuration that is as “clean” and easy to interpret (and troubleshoot) as possible.

For more detailed information on how these fields are used when generating device configurations, see Troubleshooting Zone-based Rules and Configurations, page 20-51.
General Recommendations for Zone-based Firewall Rules

Zone-based firewall rules allow a wide variety of configurations. You can quickly generate a set of rules that will be very complex and difficult to analyze, because you can use the zone-based rules in place of the standard access rules, inspection rules, and Web filter rules.

When defining zone-based rules, strive to keep them as simple and straightforward as possible. Consider the following recommendations for helping to maintain simplicity in your zone-based firewall policy:

- Only use Permit rules. The chosen Action determines what happens to matched traffic, and Deny rules are difficult to analyze. For more information, see Understanding the Relationship Between Permit/Deny and Action in Zone-based Firewall Rules, page 20-7.

- The Drop and Pass rules are equivalent to standard interface access rules, but are applied to the specified zone pair. You can use either the Services field or the Protocol table to identify the type of traffic, but we recommend using the Protocol table exclusively. To drop traffic, specify Permit with the Action Drop.

- You do not need to first pass traffic before inspecting it. For example, if you want to allow HTTP traffic between zones, you need only a single Permit/Inspect rule; you do not need to first create a Permit/Pass rule. If you do use Pass rules, note that you must also create a Pass rule in the return direction if you want to allow returning traffic. In practice, you generally can avoid creating Pass rules, using only Inspect rules.

- You can use Permit/Pass and Permit/Drop rules to perform the same functions as standard access rules. Thus, you can eliminate your access rules policy and use only zone-based firewall rules.

   However, because there are several tools available for analyzing interface access rules, and Security Manager allows you to use the same interface rules in zone-based rules and access rules, you might find it more convenient to create your Pass/Drop policies (which are Permit/Deny in standard access rules) in the access rules table instead of the zone rules table. Use the zone rules table primarily for zone-based Inspection and Content Filter rules.

- Use sections to organize the rules for each zone pair. Sections make it easy for you to see all of the rules for a pair, which can be critical if your rules have sequential dependencies. For more information on working with sections, see Using Sections to Organize Rules Tables, page 12-19.

Developing and Applying Zone-based Firewall Rules

The following is a general overview of how to develop and apply zone-based firewall rules to your network.

- Consider your network, and its sub-networks, in terms of security zones—think about the security requirements of the various zones. As a general guideline, group router interfaces that are similar when viewed from a security perspective.

- Determine the types of traffic to be examined as it travels from one zone to another, decide how each type is to be examined and handled.

- Define zone-based firewall rules that implement these decisions. This process may include some or all of the following procedures, which you can perform prior to defining the rules themselves, or which you can perform as necessary during rule definition:
  - Define the zones by creating named Interface Role objects, assigning the appropriate interfaces and interface patterns to them.
  - Define/edit Port Application Mapping (PAM) settings for specific Layer 4 protocols and ports, and optionally specific networks and hosts.
Adding Zone-Based Firewall Rules

This procedure explains how to configure a zone-based firewall rule in Security Manager.

Related Topics
- Understanding the Zone-based Firewall Rules, page 20-3
- Configuring Settings for Zone-based Firewall Rules, page 20-47
- Understanding Map Objects, page 6-67
- Enabling and Disabling Rules, page 12-19
- Adding and Removing Rules, page 12-9
- Moving Rules and the Importance of Rule Order, page 12-18

Step 1  Access the Zone-based Firewall Rules Page, page 20-55 as follows:
- (Device view) Select an IOS router and then select Firewall > Zone Based Firewall Rules from the Policy selector.
- (Policy view) Select Firewall > Zone Based Firewall Rules from the Policy Type selector. Select an existing policy or create a new one.

Step 2  Click the Add Row button below the rules table, or right-click anywhere inside the table, and choose Add Row to open the Add Zone Based Firewall Rule dialog box.
Refer to Adding and Editing Zone-based Firewall Rules, page 20-58 for a complete description of this dialog box.

Step 3  Define the base Traffic flow for this rule.

Note  Together, the Permit/Deny, Sources, Destinations, and Services options can be thought of as defining a simple access rule that can be enhanced by the application of in-depth Action-related policies, and restricted to a specific direction between a specific pair of zones.

a.  Choose whether to Permit or Deny further processing of traffic that matches this rule. See Understanding the Relationship Between Permit/Deny and Action in Zone-based Firewall Rules, page 20-7 for more information.
b. Optionally, provide Source and Destination hosts/networks.

By default, the traffic definition encompasses packets from “any” source, to “any” destination. You can use these fields to refine this base traffic definition by providing one or more source and destination hosts/networks. (Refer Understanding Network/Host Objects (IPv4 and IPv6), page 6-69 to for more information.)

c. Specify one or more Services (protocols) that indicate the type of traffic; for example, IP, TCP, etc.

You can provide more than one Service; however, IP generally stands alone. (See Understanding and Specifying Services and Service and Port List Objects, page 6-79.)

d. Provide the From Zone; that is, the only zone from which matched traffic can originate.

e. Provide the To Zone; that is, the only zone to which matched traffic can flow.

Refer to Understanding Interface Role Objects, page 6-62 for more information about zone/interface objects.

Note: Together, the From Zone and the To Zone constitute what is sometimes referred to as a “zone-pair.”

f. Click the Advanced button to add a time range, or to apply a packet-fragment or an established-connection restriction to this zone-based firewall rule.

See Zone-based Firewall Rule: Advanced Options Dialog Box, page 20-61 for more information about these options.

Step 4 Specify the actions to be applied to traffic matching this definition by choosing a base Action, and supplying additional parameters as necessary.

a. Choose a base Action:

- **Drop** – Matching traffic is silently dropped; no notification of the drop is sent to the originating host.

- **Drop and Log** – Matching traffic is dropped and a syslog message generated; no notification of the drop is sent to the originating host.

- **Pass** – Traffic is forwarded. This action is unidirectional; Pass allows traffic in only the specified direction.

- **Pass and Log** – Traffic is forwarded and a syslog message generated.

Note: The Pass actions do not track the state of connections or sessions within the traffic. Pass only allows the traffic in one direction. A corresponding rule must be defined to allow return traffic. The Pass actions are useful for protocols such as IPSec ESP, IPSec AH, ISAKMP, and other inherently secure protocols with predictable behavior. However, most application traffic is better handled in the zone-based firewall rules with the Inspect action.

- **Inspect** – This option offers state-based traffic control—the device maintains connection or session information for TCP and UDP traffic, meaning return traffic in reply to connection requests is permitted.

Choose this option to apply packet inspection based on your selected Layer 4 (TCP, UDP) and Layer 7 (HTTP, IMAP, instant messaging, and peer-to-peer) protocols. You also can edit the Port Application Mapping (PAM) settings for the selected protocols, and you can set up deep packet inspection (DPI) and provide additional protocol-related information for the Layer 7 protocols.
Adding Zone-Based Firewall Rules

- **Content Filter** – Lets you configure HTTP content inspection (URL filtering) based on a WebFilter parameter map, or a WebFilter policy map. This action is generally equivalent to a Web Filter rule; however, zone-based firewall rules support additional advanced options, such as HTTP deep packet inspection (DPI).

  The router intercepts HTTP requests, performs protocol-related inspection, and optionally contacts a third-party server to determine whether the requests should be allowed or blocked. You can provide a WebFilter parameter map, which defines filtering based on local URL lists, as well as information from an external SmartFilter (previously N2H2) or Websense server. Alternately, you can provide a WebFilter policy map that accesses Local, N2H2, Websense, or Trend Micro filtering data.

b. For any Action except Content Filter, you can select and edit the specific traffic Protocol(s) to be considered:

  Click Select next to the Protocol table to open the Protocol Selector Dialog Box, page 20-62. Select one or more protocols and click >> to move them to the Selected Protocol list. You can edit the Port Application Mapping (PAM) settings for the selected protocols; see Configure Protocol Dialog Box, page 20-63 for more information.

  The Instant Messaging and Stun-ice protocols also allow selection of Protocol Info parameter maps. Further, when Inspect is the chosen Action, some protocols allow selection of deep-inspection policy maps.

  **Note**

  It is not necessary to specify protocols for the Drop, Drop and Log, Pass, and Pass and Log actions. You can leave the Protocol table empty and pass or drop traffic based on the Sources, Destinations, and Services parameters.

c. When the chosen Action is Content Filter, configure the URL filtering:

  1. Click Configure next to the Protocol field to customize the HTTP PAM settings, and to apply an HTTP deep-inspection policy map. See the Configure Protocol Dialog Box, page 20-63 for more information.

  2. Select either WebFilter Parameter Map, or WebFilter Policy Map, and enter or Select the name of the appropriate WebFilter map. See Configuring Content Filtering Maps for Zone-based Firewall Policies, page 20-34 for more information.

d. When the chosen Action is Inspect or Content Filter, you can enter or Select the name of an Inspect Parameter map to apply a customized set of connection, timeout, and other settings. See Configuring Inspect Parameter Maps, page 20-28 for more information.

**Step 5** (Optional) Enter a description to help you identify the rule.

**Step 6** (Optional) Under Category, select a category to help you identify this rule in the rules table. See Using Category Objects, page 6-11.

**Step 7** Click OK to close the Add Zone Based Firewall Rule dialog box and return to the Zone Based Firewall Rules table.

The new rule is listed in the table.
Configuring Inspection Maps for Zone-based Firewall Policies

When you configure zone-based firewall policies for a router, you can define rules to inspect traffic by choosing Inspect as the Action for the rule. You can then select the specific protocols to inspect.

For some protocols, you can select policy maps to perform deep inspection on packets that match your criteria. You can configure these maps from the policy object selector dialog box while defining the rule, or at any time in the Policy Object Manager window (select Manage > Policy Objects). In addition to policy maps, there are some parameter maps you can configure for inspection.

- For protocols that allow deep inspection, you can select a related policy map, which in turn incorporates class maps that define match conditions for the targeted traffic. To create these policy maps in the Policy Object Manager, select one of the available map types (which are listed in the following table) from the Maps > Policy Maps > Inspect folder, and review the detailed usage information in Configuring Policy Maps for Zone-Based Firewall Policies, page 20-32.

  For information on creating class maps for use in your deep-inspection policy maps, see the references to the match criterion dialog boxes in the following table, as well as the topic Configuring Class Maps for Zone-Based Firewall Policies, page 20-16. These class map are found in the Maps > Class Maps > Inspect folder in the Policy Object Manager.

- When Inspect (or Content Filter) is the chosen Action, you can also apply an Inspect Parameters map in the Adding and Editing Zone-based Firewall Rules. Zone-based firewall inspection includes several general settings, all of which have default values that are appropriate for most networks. If you want to adjust any of these settings, you must create an Inspect Parameters map. In the Policy Object Manager, select Maps > Parameter Maps > Inspect > Inspect Parameters and review the detailed usage information in Configuring Inspect Parameter Maps, page 20-28.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Minimum IOS Software Version</th>
<th>Policy Map</th>
<th>Class Map</th>
<th>Parameter Map</th>
<th>Description and Match Criteria Reference</th>
</tr>
</thead>
</table>
Use the Add and Edit Class Map dialog boxes to define class maps to be used in policy maps of the same type. The name of the dialog box indicates the type of map you are creating.

A class map defines application traffic based on criteria specific to the application. You then select the class map in the corresponding policy map and configure the action to take for the selected traffic. Thus, each class map must contain traffic that you want to handle in the same way (for example, to allow it or to drop it).
When configuring zone-based firewall rules for devices running Cisco IOS Software, you can create class maps for the following purposes:

- For 12.4(6)T and higher, you can create classes for the inspection of the following types of traffic: H.323, HTTP, IMAP, POP3, SIP, SMTP, and SunRPC. You can create classes for web filtering using the following class types: Local, N2H2 (SmartFilter), and WebSense. See the following topics for information on the match criteria:
  - H.323 (IOS) Class Maps Add or Edit Match Criterion Dialog Boxes, page 20-20
  - HTTP (IOS) Class Add or Edit Match Criterion Dialog Boxes, page 20-20
  - IMAP and POP3 Class Maps Add or Edit Match Criterion Dialog Boxes, page 20-22
  - SIP (IOS) Class Add or Edit Match Criterion Dialog Boxes, page 20-23
  - SMTP Class Maps Add or Edit Match Criterion Dialog Boxes, page 20-24
  - Sun RPC Class Maps Add or Edit Match Criterion Dialog Boxes, page 20-27
  - Local Web Filter Class Add or Edit Match Criterion Dialog Boxes, page 20-27
  - N2H2 and Websense Class Add or Edit Match Criterion Dialog Boxes, page 20-28

- For 12.4(9)T and higher, you can create classes for the inspection of the following types of traffic: AOL, eDonkey, FastTrack, Gnutella, ICQ, Kazaa2, MSN Messenger, Windows Messenger, and Yahoo Messenger. See the following topics for information on the match criteria:
  - Zone-based Firewall IM Application Class Maps: Add or Edit Match Condition Dialog Boxes, page 20-19
  - Zone-based Firewall P2P Application Class Maps: Add or Edit Match Condition Dialog Boxes, page 20-19

- For 12.4(20)T and higher, you can create classes for web filtering using the Trend policy object. Match criteria for Trend Content Filter class maps is described in the table below.

### Navigation Path
Select Manage > Policy Objects, then select any zone-based class map object in the folders in the Maps > Class Maps folder in the table of contents. Right-click inside the work area, then select New Object, or right-click a row, then select Edit Object.

Chapter 20  Managing Zone-based Firewall Rules

Configuring Inspection Maps for Zone-based Firewall Policies

The Match table lists the criteria included in the class map. Each row indicates whether the inspection is looking for traffic that matches or does not match each criterion and the criterion and value that is inspected.

The name of the table indicates whether every one of the criteria must be met for the traffic to match the class (Match All), or whether matching any of the listed criteria is sufficient (Match Any). For the HTTP (IOS) and SMTP classes, you can choose whether to match all or any. When using a Match All table, if you add more than one criteria, ensure that you are not defining a set of characteristics that no traffic can match.

Tip  Match All works for devices running Cisco IOS Software version 12.4(20)T or higher only.

- To add a criterion, click the Add button and fill in the Match Criterion dialog box. For more information, see the topics referenced above.
- To edit a criterion, select it and click the Edit button.
- To delete a criterion, select it and click the Delete button.

The match criteria for Trend Content Filter class maps differs from that of all other class maps. Instead of adding items to a table, you simply select the items you want from a list. Select the Enable checkbox for any of the Trend-Micro classifications on the following tabs. Traffic matches the class if it matches any of your selections.

- Productivity Categories—Matches the traffic to the category to which the URL belongs. For example, you can target traffic associated with gambling or pornography.
- Security Ratings—Matches the traffic to the security rating assigned to it by Trend-Micro. For example, you can target adware, which is traffic associated with advertising.

See the Trend-Micro documentation for specific information on these categories or security classifications.

The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects, page 6-11.

Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden, page 6-16 and Understanding Policy Object Overrides for Individual Devices, page 6-16.

If you allow device overrides, you can click the Edit button to create, edit, and view the overrides. The Overrides field indicates the number of devices that have overrides for this object.

Zone-based Firewall IM Application Class Maps: Add or Edit Match Condition Dialog Boxes

Use the Add or Edit Match Criterion dialog boxes for the various instant messenger (IM) application classes used with zone-based firewall policies to define a match criterion and value for the class map. You can define a match for the following types of traffic:

- Any—Any type of traffic from the application except text chat traffic.
- Text-chat—Text chat traffic.

Navigation Path
From the Add or Edit Class Maps dialog boxes for AOL, ICQ, MSN Messenger, Windows Messenger, or Yahoo Messenger classes, right-click inside the table and select Add Row or right-click a row and select Edit Row. See Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

Zone-based Firewall P2P Application Class Maps: Add or Edit Match Condition Dialog Boxes

Use the Add or Edit Match Criterion dialog boxes for the various peer-to-peer (P2P) application classes used with zone-based firewall policies to define a match criterion and value for the class map.

Navigation Path
From the Add or Edit Class Maps dialog boxes for eDonkey, FastTrack, Gnutella, or Kazaa2 classes, right-click inside the table and select Add Row, or right-click a row and select Edit Row. See Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

H.323 (IOS) Class Maps Add or Edit Match Criterion Dialog Boxes

Use the Add or Edit Match Criterion dialog boxes for the H.323 (IOS) class used with zone-based firewall policies to define a match criterion and value for the class map. You can match traffic based on the H.323 protocol message type. Select the message that you want to match.

**Navigation Path**

From the Add or Edit Class Maps dialog boxes for the H.323 (IOS) class, right-click inside the table and select **Add Row** or right-click a row and select **Edit Row**. See Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

HTTP (IOS) Class Add or Edit Match Criterion Dialog Boxes

Use the Add or Edit Match Criterion dialog boxes for the HTTP (IOS) class used with zone-based firewall policies to define a match criterion and value for the class map.

The fields on this dialog box change based on the criterion you select. You can use the following criteria:

- Request/Response Body Length, Request Body Length, Response Body Length—Specifies that the body length of the request, response, or both, is less than or greater than the specified number. This allows you to set a minimum or maximum message length.
- Request/Response Body, Request Body, Response Body—Applies a regular expression to match the body of the request, response, or both.
- Request/Response Header, Request Header, Response Header—You can match a regular expression against the header, test for repeated fields, check the content type, or check the total length or number of records in the header.
- Request/Response Protocol Violation—Matches non-compliant HTTP traffic.
- Request Argument, Request URI—Matches the length or content (with a regular expression) of the argument (parameters) or uniform resource identifier (URI) in a request message.
- Request Port Misuse—Matches the misuse of ports by certain types of applications.
- Response Body Java Applet—Matches Java applets in an HTTP connection.
- Response Header Status Line—Applies a regular expression to match the content of the status line in the header.

File Name The name of the file associated with the traffic. You can use regular expressions to specify a name pattern. For information on the metacharacters you can use to build regular expressions, see Metacharacters Used to Build Regular Expressions, page 16-80.

**Tip** eDonkey does not require a file name.
Navigation Path
From the Add or Edit Class Maps dialog boxes for the HTTP (IOS) class, right-click inside the table and select **Add Row** or right-click a row and select **Edit Row**. See Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

Related Topics

<tr>
<td>Criterion</td>
<td>Specifies which criterion of HTTP traffic to match. The criteria are described above.</td>
</tr>
<tr>
<td>Type</td>
<td>Specifies that the map includes traffic that matches the criterion.</td>
</tr>
</tbody>
</table>

**Variable Fields**
The following fields vary based on what you select in the Criterion field. This list is a super-set of the fields you might see.

| Less Than Length | The minimum length in bytes of the evaluated field. The criterion matches if the length is less than the specified number. |
| Greater Than Length | The maximum length in bytes of the evaluated field. The criterion matches if the length is greater than the specified number. |
| Header Option   | The type of header record. If you do not select a record type, the count or expression is applied to all records in the header. If you select a record type, those selections are applied only to the records of the selected type. If you select content type or transfer encoding, you can make additional selections related to those types. |
| Request Method  | The request method you want to match. |
| Value (Content Type) | If you select content-type in the Header Option field, you can select these types:  
  - Mismatch—Verifies the content-type of the response message against the accept field value of the request message.  
  - Unknown—The content type is not known. Select Unknown when you want to evaluate the item against all known MIME types.  
  - Violation—The content-type definition and the content type of the actual body do not match. |

IMAP and POP3 Class Maps Add or Edit Match Criterion Dialog Boxes

Use the Add or Edit MatchCriterion dialog boxes for the InternetMessage Access Protocol (IMAP) and Post Office Protocol 3 (POP3) classes used with zone-based firewall policies to define a match criterion and value for the class map.

You can select the following criteria to identify matching traffic:

• Invalid Command—Matches commands that are not valid on a POP3 server or IMAP connection.
• Login Clear Text—Matches non-secure logins, where the password is being provided in clear text.

Navigation Path
From the Add or Edit Class Maps dialog boxes for the IMAP or POP3 classes, right-click inside the table and select Add Row or right-click a row and select Edit Row. See Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

<tr>
<td>Criterion</td>
<td>Specifies which criterion of traffic to match. You can select from the following:</td>
</tr>
<tr>
<td></td>
<td>- Protocol Violation—Matches traffic that violates the protocol.</td>
</tr>
<tr>
<td></td>
<td>- Request/Response Header Options—Matches a regular expression against the selected request or response header field.</td>
</tr>
<tr>
<td></td>
<td>- Request Options—Matches the request method or matches a regular expression against the selected request header field.</td>
</tr>
<tr>
<td></td>
<td>- Response Options—Matches a regular expression against the selected response header field or status message.</td>
</tr>
<tr>
<td>Type</td>
<td>Specifies that the map includes traffic that matches the criterion.</td>
</tr>
</tbody>
</table>

**Variable Fields**

The following fields vary based on what you select in the Criterion field. This list is a super-set of the fields you might see.

| Header   | The type of header in the request or response message. The regular expression is matched against the content of headers of the selected type. |
Tip Only the Data Length criterion is available for routers running Cisco IOS Software lower than 12.4(20)T.

The fields on this dialog box change based on the criterion you select. You can use the following criteria:

- **Data Length**—Specifies that the data length of the traffic is greater than the specified number. You can match the data length of the traffic to determine if the data transferred in an SMTP connection exceeds the specified length in bytes. By default, inspection keeps data length below 20.
- **Body Regular Expression**—Applies a regular expression to match the content types and content encoding types for text and HTML in the body of an e-mail message. Only text or HTML that uses 7-bit or 8-bit encoding is checked. The regular expression cannot be scanned in messages that use another encoding type (such as base64 or zip files).
• Command Line Length—Specifies that the length of the ESMTP command line not be greater than the specified number. Use this to thwart Denial of Service (DoS) attacks.

• Command Verb—Limits inspection to the selected SMTP or ESMTP command. If you configure inspection for SMTP, all commands are inspected unless you limit them.

• Header Length—Specifies that the length of the SMTP header is greater than the specified number. Use this to thwart DoS attacks by limiting the possible size of the header.

• Header Regular Expression—Applies a regular expression to match the content of the header of an e-mail message. For example, you can use this to test for particular patterns in the subject, from, or to fields.

• Mime Content-Type Regular Expression—Applies a regular expression to match the Multipurpose Internet Message Exchange (MIME) content type of an e-mail attachment. Use this to prevent the transmission of undesired types of attachments.

• Mime Encoding—Specifies the MIME encoding type for e-mail attachments that you want to inspect. You can use this to identify unknown or non-standard encodings to restrict their transmission.

• Recipient Address—Applies a regular expression to match the recipient of an e-mail message in the SMTP RCPT command. Use this to search for a non-existent recipient, which might help you identify the source of spam.

• Recipient Count—Specifies that the number of recipients for an e-mail message cannot be greater than the specified number. Use this to prevent spammers from sending e-mails to a large number of users.

• Recipient Invalid Count—Specifies that the number of invalid recipients for an e-mail message cannot be greater than the specified number. Use this prevent spammers from sending e-mails to a large number common names, where they are fishing for real addresses. SMTP typically replies with a “no such address” message when an address is invalid; by putting a limit on the number of invalid addresses, you can prevent these replies to spammers.

• Reply EHLO—Specifies the service extension parameter in an EHLO server reply. Use this to prevent a client from using a particular service extension.

• Sender Address—Applies a regular expression to match the sender of an e-mail message. Use this to block specific senders, such as known spammers, from sending e-mail messages through the device.

Navigation Path
From the Add or Edit Class Maps dialog boxes for SMTP classes, right-click inside the table and select Add Row or right-click a row and select Edit Row. See Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

Field Reference

| Table 20-8 Local Web Filter Class Add or Edit Match Criterion Dialog Boxes |
|---------------------------|--------------------------|
| Element                  | Description              |
| Criterion                | Specifies which criterion of traffic to match. You can select from the following: |
|                          | • Server Domain—Matches traffic based on the name of the server. The URLF Glob parameter map you select should specify server domain names such as *.cisco.com or www.cisco.com. |
|                          | • URL Keyword—Matches traffic based on keywords in the URLs. A keyword is any complete string that occurs between / characters in a URL. For example, in the URL segment www.cisco.com/en/US, en and US are examples of keywords. |
| Type                     | Specifies that the map includes traffic that matches the criterion. |
Configuring Inspection Maps for Zone-based Firewall Policies

N2H2 and Websense Class Add or Edit Match Criterion Dialog Boxes

Use the Add or Edit Match Criterion dialog boxes for the N2H2 (SmartFilter) and Websense web filter classes to define a match criterion and value for the class map. The only match criterion available is to match any response from the SmartFilter or Websense server.

Navigation Path
From the Add or Edit Class Maps dialog boxes for the N2H2 or Websense web filter class, right-click inside the table and select Add Row or right-click a row and select Edit Row. See Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

Configuring Inspect Parameter Maps

Use the Add and Edit Inspect Parameter Map dialog boxes to define a parameter map for inspection for zone-based firewall policies on routers. If you configure the action of a zone-based firewall policy rule as Inspect or Content Filter, you can select an inspect parameter map to define connection, timeout, and other settings for the inspection action. If you do not select an inspect parameter map for a zone-based firewall rule, the system uses default values for these settings.

Navigation Path
Select Manage > Policy Objects, then select Maps > Parameter Maps > Inspect > Inspect Parameters in the table of contents. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

</tbody>
</table>
Table 20-9  Add or Edit Inspect Parameter Map Dialog Boxes (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| TCP Max Incomplete Hosts       | The maximum incomplete hosts is the number of half-open TCP sessions with the same host destination address that can simultaneously exist before the software starts deleting half-open sessions to that host. An unusually high number of half-open sessions with the same destination host address could indicate that a DoS attack is being launched against the host. When the threshold is exceeded, half-open sessions are dropped based on the maximum incomplete block time:  
  - If the block time is 0, the software deletes the oldest existing half-open session for the host for every new connection request to the host. This ensures that the number of half-open sessions to a given host never exceeds the threshold.  
  - If the block time is greater than 0, the software deletes all existing half-open sessions for the host and then blocks all new connection requests to the host. The software continues to block all new connection requests until the block time expires.  
  The software sends syslog messages whenever the specified threshold is exceeded and when blocking of connection initiations to a host starts or ends. |
| TCP Max Incomplete Block Time   |                                                                                                 |
| UDP Idle Timeout                | How long to maintain a UDP session while there is no activity in the session, in seconds.        |
| Enable Alert                    | Whether to generate stateful packet inspection alert messages on the console.                    |
| Enable Audit Trail              | Whether audit trail messages are logged to the syslog server or router.                          |
| Category                        | The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects, page 6-11. |
| Allow Value Override per Device | Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden, page 6-16 and Understanding Policy Object Overrides for Individual Devices, page 6-16. If you allow device overrides, you can click the Edit button to create, edit, and view the overrides. The Overrides field indicates the number of devices that have overrides for this object. |
Configuring Protocol Info Parameter Maps

Use the Add and Edit Protocol Info Parameter Map dialog boxes to define a parameter map for the inspection of Instant Messaging (IM) applications or the Stun-ice protocol for zone-based firewall policies on routers. If you configure the action of a zone-based firewall policy rule as Inspect, you must select a protocol info parameter map when you configure any of these applications: AOL, ICQ, MSN Messenger, Windows Messenger, Yahoo Messenger, Stun-ice. The protocol info parameter map defines the DNS servers that interact with these applications, which helps the instant messenger application engine to recognize the instant messenger traffic and to enforce the configured policy for that instant messenger application.

Navigation Path
Select Manage > Policy Objects, then select Maps > Parameter Maps > Inspect > Protocol Info Parameters in the table of contents. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

Add or Edit DNS Server for Protocol Info Parameters Dialog Box

Use the Add or Edit DNS Server dialog box to identify DNS servers for which traffic will be permitted (and inspected) or denied. These servers are defined in a Protocol Info parameter map for use with the inspection of protocols that require them in a zone-based firewall policy.

You can identify a server using any of these types:

- **Server Name**—The name of the DNS server. You can use an asterisk (*) as a wildcard character to match one or more characters. For example, if you want to identify all DNS servers on the cisco.com domain, you can specify *.cisco.com.
- **IP Address**—The IP address of a single DNS server.
- **IP Address Range**—A range of IP addresses identifying any DNS server within the start and end addresses.

**Navigation Path**

From the Add or Edit Protocol Info Parameter Map dialog boxes, click the **Add** button beneath the server table, or select a server and click the **Edit** button. See Configuring Protocol Info Parameter Maps, page 20-31.

Configuring Policy Maps for Zone-Based Firewall Policies

Use the Add and Edit Policy Map dialog boxes for zone-based firewall policies to define the match criterion and values for an inspection map used in a zone-based firewall policy for a Cisco IOS router. You can create policy inspection maps for H.323 (IOS), HTTP (Zone based IOS), IM (Zone based IOS), IMAP, P2P, POP3, SIP (IOS), SMTP, and Sun RPC inspection, and the name of the dialog box indicates the type of map you are creating.

When defining the inspection map, you select class maps of the same type and define the action to take for matching traffic. You can configure the required class maps before creating the policy maps or while you are creating them.

**Navigation Path**

Select Manage > Policy Objects, then any of the following items in the Maps > Policy Maps > Inspect folder in the table of contents: H.323 (IOS), HTTP (Zone based IOS), IM (Zone based IOS), IMAP, P2P, POP3, SIP (IOS), SMTP, and Sun RPC. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

### Add or Edit Match Condition and Action Dialog Boxes for Zone-Based Firewall and Web Filter Policies

Use the Add or Edit Match Condition and Action dialog boxes for zone-based firewall and web filter policies to select the class maps for inspection and to define the action to take for traffic that matches the class. This dialog box is used for the following types of policy maps: H.323 (IOS), HTTP (Zone based IOS), IM (Zone based IOS), IMAP, P2P, POP3, SIP (IOS), SMTP, Sun RPC, Web Filter.

The fields on this dialog box differ slightly depending on the type of policy map you are defining.

### Navigation Path

From the Add or Edit Policy Maps dialog boxes for Zone-Based Firewall Policies, right-click inside the match table and select **Add Row** or right-click a row and select **Edit Row**. See Configuring Policy Maps for Zone-Based Firewall Policies, page 20-32.

Configuring Content Filtering Maps for Zone-based Firewall Policies

When you configure zone-based firewall policies for a router, you can define rules to filter Web content by choosing Content Filter as the Action for the rule.

To filter Web content, you must configure certain map objects, which you can do from the policy object selector dialog box while defining the rule, or at any time in the Policy Object Manager window (select Manage > Policy Objects).

The type of maps required depends on the technique you are using to filter content, and on the Cisco IOS software version you are using. You can filter content based on URL lists defined locally on the device, or you can use external filtering servers such as SmartFilter (N2H2), Websense, or Trend Micro.

Tip

If you use an external server, you must have set up and configured the server appropriately based on the documentation for the type of server you select. If you use Trend Micro servers, you must specify the server details, and register the product and download certificates, on the Content Filtering tab of the Zone Based Firewall page (select Firewall > Settings > Zone Based Firewall). See Zone Based Firewall Page, page 20-48.

The following are requirements for the map objects used with zone-based content filtering:

- For devices running releases below 12.4(20)T, you must create a URL Filter parameter map. In the Policy Object Manager, select Maps > Parameter Maps > Web Filter > URL Filter, and review the detailed usage information in Configuring URL Filter Parameter Maps, page 20-41.
  - To perform local filtering on the router using lists of allowed (whitelisted) and denied (blacklisted) hosts, create the lists on the Local Filtering tab. Any Web access request is first compared to these lists before the request is sent on to an external filtering server (if you have
configured one). These lists contain either complete domain names (such as www.cisco.com), or partial names (such as cisco.com), but they do not include paths or page names, and you cannot use wildcards.

- To use a SmartFilter (N2H2) or Websense server, configure the type of server you are using and its address information on the External Filter tab. You can also configure other settings that control communication with the server. You cannot configure a Trend Micro server using the URL Filter parameter map.

- For devices running release 12.4(20)T and higher, the preferred approach is to use a Web Filter policy map. Although Web Filter policy maps are more complex, they provide added flexibility, and they let you access Trend Micro filtering servers. In the Policy Object Manager, select Maps > Policy Maps > Web Filter > Web Filter, and review the detailed usage information in Configuring Web Filter Maps, page 20-45.

A Web Filter policy map incorporates other types of maps. To create the policy map, you will need one or more of these other types of maps:

- Parameter maps – On the Parameters tab of the Add and Edit Web Filter Map dialog boxes, you can select parameter maps for the various types of Web filtering if you do not want to use the default settings. If you are using SmartFilter (N2H2) or Websense, you need to select a parameter map because the map identifies those servers. For Local and Trend Micro filtering, parameter maps configure some general settings, the most interesting of which is whether to display a message or Web page when a URL is blocked. In the Policy Object Manager, you can find parameter maps for Local, N2H2, Trend, and Websense in the Maps > Parameter Maps > Web Filter folder. For detailed usage information, see Configuring Local Web Filter Parameter Maps, page 20-36, Configuring N2H2 or WebSense Parameter Maps, page 20-37, or Configuring Trend Parameter Maps, page 20-39.

Note You configure Trend Micro server information on the Content Filtering tab of the Zone Based Firewall page (select Firewall > Settings > Zone Based Firewall). See Zone Based Firewall Page, page 20-48.

- Class maps for match conditions – These classmaps define the type of traffic you want to target and specify the action to be taken. You select a type of filtering (Local, SmartFilter/N2H2, Websense, or Trend Micro), specify the class map that identifies the targeted traffic, and choose an action (such as Allow, Reset, etc.) to be taken for that traffic. In the Policy Object Manager, you can find class maps for Local, N2H2, Trend, and Websense in the Maps > Class Maps > Web Filter folder.

These class-map configurations depend on the type of filtering:

Local Filtering – The Local WebFilter class map is a list of one or more URLF Glob parameter maps that specify either domain names or URL keywords that you want to target. A URL keyword is any text string delineated by forward-slash (/) characters in a URL. These class maps help you define allowed (whitelisted) and denied (blacklisted) URL lists for a WebFilter policy—create separate maps for each list. For detailed usage information, see Configuring Class Maps for Zone-Based Firewall Policies, page 20-16, Local Web Filter Class Add or Edit Match Criterion Dialog Boxes, page 20-27, and Configuring URLF Glob Parameter Maps, page 20-43.

SmartFilter (N2H2) or Websense Filtering—The class maps for N2H2 and Websense define any server response as the matching criterion. For detailed usage information, see Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.
Trend Micro Filtering – The Trend class map lets you select various Productivity Categories and Security Ratings, as defined by Trend Micro, that you want to target. For detailed usage information, see Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

Besides the maps used to define content filtering, you can also configure the following maps for content filter rules:

- Inspect Parameters maps – Zone-based firewall inspection includes several general settings, all of which have default values that are appropriate for most networks. If you want to adjust any of these settings, you can create an Inspect Parameters map. In the Policy Object Manager, select Maps > Parameter Maps > Inspect > Inspect Parameters, and review the detailed usage information in Configuring Inspect Parameter Maps, page 20-28.

- HTTP policy map – If you want to use deep inspection on the individual HTTP packets in addition to Web filtering, you can configure an HTTP policy map by clicking Configure next to the Protocol field in the Action section of the Adding and Editing Zone-based Firewall Rules, page 20-58. The HTTP policy map incorporates HTTP class maps that define the type of traffic you want to match and then defines the action to take. For example, you can target traffic that includes Java applets. In the Policy Object Manager, select Maps > Policy Maps > Inspect > HTTP (Zone Based IOS), and review the detailed usage information in Configuring Policy Maps for Zone-Based Firewall Policies, page 20-32, HTTP (IOS) Class Add or Edit Match Criterion Dialog Boxes, page 20-20, and Configuring Class Maps for Zone-Based Firewall Policies, page 20-16.

Configuring Local Web Filter Parameter Maps

Use the Add and Edit Local Parameter Map dialog boxes to define a parameter map for local web filtering for zone-based firewall policies on routers. If you configure the action of a zone-based firewall policy rule as Content Filter, you can select a Web Filter policy map that incorporates a Local web filter parameter map (when you select Local for the parameter type on the Parameter tab). For more information about Web Filter policy maps, see Configuring Web Filter Maps, page 20-45.

Navigation Path
Select Manage > Policy Objects, then select Maps > Parameter Maps > Web Filter > Local in the table of contents. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

Configuring N2H2 or WebSense Parameter Maps

Use the Add and Edit N2H2 or Websense Parameter Map dialog boxes to define a parameter map for Smartfilter (N2H2) or Websense web filtering for zone-based firewall policies on routers. If you configure the action of a zone-based firewall policy rule as Content Filter, you can select a Web Filter policy map that incorporates an N2H2 or Websense web filter parameter map (when you select N2H2 or Websense for the parameter type on the Parameter tab). For more information about Web Filter policy maps, see Configuring Web Filter Maps, page 20-45.

Navigation Path

Select Manage > Policy Objects, then select N2H2 or WebSense from the Maps > Parameter Maps > Web Filter folder in the table of contents. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

Configuring URL Filter Parameter Maps

Use the Add and Edit URL Filter Parameter Map dialog boxes to define the parameters and match criterion and values for an inspection map used in a zone-based firewall policy for a router.

If you configure the action of a zone-based firewall policy rule as Content Filter, you can select a URL Filter parameter map to define web filtering parameters and match criteria. However, if the router is running Cisco IOS Software release 12.4(20)T or higher, the recommended approach is to configure a Web Filter policy map along with parameter and class maps for the appropriate server type (local, N2H2, Trend, or Websense). For more information, see Configuring Web Filter Maps, page 20-45.

Navigation Path
Select Manage > Policy Objects, then select Maps > Parameter Maps > Web Filter > URL Filter in the table of contents. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

Add or Edit URL Domain Name Dialog Box for URL Filter Parameters

Use the Add URL Domain Name dialog box to add website domain names to the whitelisted (allowed) or blacklisted (not allowed) lists.

Domain names can be complete (including the host name, such as www.cisco.com), or partial (such as cisco.com). For partial names, all website hosts on that domain are either permitted or denied. You can also enter host IP addresses.

Navigation Path

From the Add or Edit URL Filter Parameter Map dialog boxes, click the Add button beneath the whitelist or blacklist tables, or select a name and click the Edit button. See Configuring URL Filter Parameter Maps, page 20-41.

Configuring URLF Glob Parameter Maps

Use the Add and Edit URLF Glob Parameter Map dialog boxes to define a parameter map for the inspection of URLs in a Local web filter class map.

A single URLF Glob should contain only segments of URLs that you want to block or allow. Your goal is to create class maps of whitelisted (allowed) or blacklisted (blocked) URLs. You can then define Local web filter policy maps to allow or block the identified URLs.

A single URLF Glob must also be limited to one of these types of URL segments:

- Strings that appear in the server name of a URL, which includes the name of the server and the domain name of the network. For example, www.cisco.com.
- Strings that appear in URL keywords, which are the strings that appear between / characters in a URL, or which are the file names. For example, in the URL segment www.cisco.com/en/US/, both en and US are keywords. The file name in a URL, such as index.html, is also considered a keyword.

You cannot use the characters /, {, }, and ? in a URLF glob.

To match a server name or URL keyword, the string in the URL must match exactly the string included in the URLF glob unless you use wildcard metacharacters to specify a variable string pattern. You can use the following metacharacters for pattern matching for either server names or URL keywords:

- * (Asterisk). Matches any sequence of zero or more characters. For example, *.edu matches all servers in the education domain, and you could use hack* to block www.example.com/hacksite/123.html.
- [abc] (Character class). Matches any character in the brackets. The character matching is case sensitive. For example, [abc] matches a, b, or c, but not A, B, or C. Thus, you could use www.[ey]xample.com to block both www.example.com and www.yexample.com.
[a-c] (Character range class). Matches any character in the range. The character matching is case sensitive. [a-z] matches any lowercase letter. You can mix characters and ranges; for example, [abcq-z] matches a, b, c, q, r, s, t, u, v, w, x, y, z, and so does [a-cq-z]. The dash (-) character is literal only if it is the last or the first character within the brackets, [abc-] or [-abc].

[0-9] (Numerical range class). Matches any number in the brackets. For example [0-9] matches 0, 1, 2, 3, 4, 5, 6, 7, 8, or 9. Thus, you can use www.example[0-9][0-9].com to block www.example01.com, www.example33.com, and www.example99.com (and so forth).

Navigation Path
Select Manage > Policy Objects, then select Maps > Parameter Maps > Web Filter > URLF Glob Parameters in the table of contents. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

Configuring Web Filter Maps

Use the Add and Edit Web Filter Map dialog boxes to define the parameters and match criterion and values for an inspection map used in a zone-based firewall policy for a router.

If you configure the action of a zone-based firewall policy rule as Content Filter, you can select a Web Filter policy map to define web filtering parameters and match criteria. You can select Web Filter policy maps only for routers running Cisco IOS Software release 12.4(20)T and higher. If you are configuring zone-based firewalls for routers running Cisco IOS Software release 12.4(6)T up to 12.4(20)T, you must configure a URL Filter parameter map instead of a Web Filter policy map. For more information, see Configuring URL Filter Parameter Maps, page 20-41.

You can configure a mix of local and server-based web filtering. To do this, you should select a parameter map appropriate for the type of server you are using, and for the match criteria, an appropriate mix of local and server class maps. Do not mix class and parameter maps for different types of servers.

Navigation Path
Select Manage > Policy Objects, then select Maps > Policy Maps > Web Filter > Web Filter from the Object Type selector. Right-click inside the table and select New Object or right-click a row and select Edit Object.

Match Condition and Action Tab

The Match All table lists class maps included in the policy map, and the action to take for traffic that matches the class. For traffic to match this class, all criteria defined in the selected class maps must be met.

- To add a criterion, click the Add button and fill in the Match Condition and Action dialog box (see Add or Edit Match Condition and Action Dialog Boxes for Zone-Based Firewall and Web Filter Policies, page 20-33).
- To edit a criterion, select it and click the Edit button.
- To delete a criterion, select it and click the Delete button.
Changing the Default Drop Behavior

By default, all traffic between zones is dropped unless explicitly allowed. However, you can change this default behavior, as described in this section.

Security Manager converts the parameters—including class, parameter, and policy maps—that you supply for zone-based firewall rules into a series of IOS commands that the router will recognize. These are the so-called “CLI” (command line interface) configuration commands, which you can preview in separate window by choosing Tools > Preview Configuration. See Previewing Configurations, page 8-42 for more information. In addition, the section, Troubleshooting Zone-based Rules and Configurations, page 20-51, discusses an example of zone-based firewall CLI commands.

For the purposes of this discussion, the most interesting of these commands is policy-map, which is used to apply your zone policy for each pair of zones. That is, for any given zone-pair, all rules defining traffic (classes) and actions are applied within one policy-map. Further, Security Manager appends the current class-default class to the end of each policy-map’s class list to capture any packets not processed by a zone rule.

The default class-default is drop—appending this class to each policy-map is how the implicit dropping of traffic between zones is accomplished. However, as mentioned, you can change this default behavior for any zone-pair. For example, you might elect to pass all unmatched traffic, or you might change the default to drop and log so you can determine what traffic is not being matched by your existing rules.

Note

The only options for the default behavior are Drop, Drop and Log, Pass, and Pass and Log.

If you want the default policy to continue to drop packets, you do not have to do anything in Security Manager. This rule is generated automatically. If you do want to change the default behavior for a zone-pair, you must provide a Permit any any IP rule (that is, Match: Permit; Sources: any; Destinations: any; Services: IP in the Adding and Editing Zone-based Firewall Rules, page 20-58), with Drop and Log, Pass, or Pass and Log as the chosen Action. You must also ensure that this rule appears last in the list of rules for a zone pair. Security Manager interprets this as the intended class-default rule.

If your zone-based rules table includes a large number of rules, it might be difficult to ensure that this rule comes after all other rules for a zone pair. Here are a couple of techniques you can use to alleviate this:

- Use sections to organize the table, with one section per zone-pair. This will make it easier for you to order the rules for a zone-pair, as well as ensuring that the class-default rule comes last. For more information on working with sections, see Using Sections to Organize Rules Tables, page 12-19.
• Create a shared zone-based rules policy that includes the class-default rule in the Default scope, and inherit this rule in the device’s local zone-based rule policy. For more information on inheritance and creating shared policies, see Inheriting or Uninheriting Rules, page 5-43 and Creating a New Shared Policy, page 5-51.

Configuring Settings for Zone-based Firewall Rules

Use the Zone Based Firewall settings page to: identify unreferenced zones; specify a zone for VPN interfaces; enable or disable WAAS support; maintain Trend Micro server and certificate information; and specify global Log settings on supported ASR devices.

Related Topics
• Zone Based Firewall Page, page 20-48
• Understanding the Zone-based Firewall Rules, page 20-3

Step 1
Access the Zone Based Firewall Page, page 20-48 as follows:
• (Device view) Select an IOS device and then select Firewall > Settings > Zone Based Firewall from the Policy selector.
• (Policy view) Select Firewall > Settings > Zone Based Firewall from the Policy Type selector. Select an existing policy or create a new one.

Step 2
(Optional) On the Zones tab: add, edit and delete unreferenced zones.
The Zones tab lists all unreferenced zones defined on the device; that is, zones without any associated interfaces, rules or policies. Unreferenced zones are usually found and listed during device discovery, but you also can create named, “empty” zones here.

Step 3
(Optional) On the VPN tab, supply the name of the zone specifically set up for VPN traffic.
This zone ensures that dynamic VPN traffic can be processed by the zone-based firewall rules on this router. See Using VPNs with Zone-based Firewall Policies, page 20-5 for more information.

Step 4
(Optional) On the WAAS tab, select Enable WAAS to enable Wide Area Application Services interoperability.
If this option is not enabled, packets being optimized by a WAAS device may be dropped because WAAS increases the TCP packet sequence number during the TCP handshake. This behavior may be viewed as a possible attack by the IOS device.

Step 5
(Optional) On the Content Filter Settings tab, provide server settings for Trend Micro-based content filtering.
To use Trend Micro-based content filtering, you must configure contact information for the Trend Micro server on this tab of the Zone Based Firewall page. This tab also provides links to Trend Micro registration and certificate download. You must have an active subscription with Trend Micro to utilize this form of content filtering, and you must download and install a valid subscription certificate on this IOS device.
For more information, see Zone Based Firewall Page - Content Filter Tab, page 20-50.

Step 6
(Optional) On the Global Parameters (ASR) tab, you can configure global, logging-related settings specific to ASR devices:
• Log Dropped Packets – Select this option to log all packets dropped by the device; syslog logging must be enabled to view the information.
• Log Flow export timeout rate – NetFlow logs are created after a flow either expires or is timed out, and it is important to put a time limit on how long a flow can be active before expiring. This value is maximum number of minutes a flow can remain active before it is expired. The value can be any integer from 1 to 3600; the default is 30.

• Log Flow export destination IP – The IP address or host name of the NetFlow collector to which flow data is to be sent.

• Log Flow export destination port – The UDP port monitored by the NetFlow collector for flow data.

### Zone Based Firewall Page

Use the Zone Based Firewall page to configure and identify unreferenced zones, specify a VPN zone, enable or disable WAAS support, maintain Trend Micro server and certificate information, and specify global Log settings on supported ASR devices.

The following tabs are described in the table on this page:

- Zones
- VPN
- WAAS
- Global Parameters (ASR)

The Content Filtering tab is detailed in Zone Based Firewall Page - Content Filter Tab, page 20-50.

### Navigation Path

To access the Zone Based Firewall page, do one of the following:

- (Device view) Select a device, then select **Firewall > Settings > Zone Based Firewall** from the Policy selector.
- (Policy view) Select **Firewall > Settings > Zone Based Firewall** from the Policy Type selector. Create a new policy or select an existing one.
- (Map view) Right-click a device and choose **Edit Firewall Settings > Zone Based Firewall**.

Chapter 20 Managing Zone-based Firewall Rules

Troubleshooting Zone-based Rules and Configurations

Zone Dialog Box

Use the Add and Edit Zone dialog boxes to add and edit unreferenced zones—zones without any associated interfaces, rules or policies.

Navigation Path

To access the Add and Edit Zone dialog boxes, do one of the following:

- (Device view) Select a device, then select Firewall > Settings > Zone Based Firewall from the Device selector. Right-click inside the Zones table, then select Add Row, or right-click a line item, then select Edit Row.
- (Policy view) Select Firewall > Settings > Zone Based Firewall from the Policy selector. Right-click inside the table, then select Add Row, or right-click a line item, then select Edit Row.
- (Map view) Right-click a device and select Edit Firewall Policies > Settings > Zone Based Firewall Rules.

Enter a zone name in the Zone field, or click Select to choose one from the Interfaces Selector dialog box.

Troubleshooting Zone-based Rules and Configurations

Zone-based firewall rules are powerful, but also complex. Using zone rules, you can replace access rules, inspection rules, and Web filter rules with a single type of firewall rule. Because zone-based firewall rules can perform so many possible actions, the configuration generated from them uses many different types of configuration commands, including structures for access control lists (ACLs), class maps, and policy maps. There is no one-to-one correspondence between a zone-based firewall rule and a line in the configuration (unlike access rules, for example).

To illustrate this complexity, this topic describes the relationship between zone-based firewall rules and the configuration generated from them. You do not need to know any of the information in this topic to create and deploy zone-based firewall rules. However, if you are familiar with the CLI (command line interface), or if you find that your rules are generating undesired results, this information can help you understand and troubleshoot zone-based firewall rules.

Consider the set of rules shown in the following illustration. These rules form a policy for a single zone pair, affecting traffic moving from the Inside zone to the Outside zone. This is traffic from your internal network going to the Internet. The rules define the following actions:

- Drop all traffic from the 10.100.10.0/24 and 10.100.11.0/24 networks.
- Drop all FTP and FTPS traffic from the 10.100.12.0/24 network.
- Drop all peer-to-peer traffic from any network.
- Inspect (and allow) all FTP/FTPS traffic (except for that from 10.100.12.0/24, which is already dropped).
- Inspect all HTTP traffic using an additional deep-inspection policy map.
- And finally, perform generic inspection of all remaining TCP/UDP traffic.

When you deploy these rules, Security Manager generates the following configuration. The bold letters are added for reference in the explanation that follows the configuration.

A.

```bash
class-map type inspect http match-any HTTPcmap
match req-resp protocol-violation
match request port-misuse any
!
```

B.

        permit ip 10.100.11.0 0.0.0.255 any

L.
    ip access-list extended CSM_ZBF_CMAP_ACL_2
        permit ip 10.100.12.0 0.0.0.255 any

The following list explains how the rules in Security Manager are converted to device-configuration commands, to aid your understanding of the relationship between the two. The list numbering corresponds to the rule numbers from the rules table in Security Manager (see the previous illustration):

1. This rule drops all traffic from the 10.100.10.0/24 network. The Permit, Source, Destination, and Service fields are used to create the first access control entry (ACE) in the ACL named CSM_ZBF_CMAP_ACL_1 defined in (K). This ACL is referenced from the class map CSM_ZBF_CLASS_MAP_1 defined in (C), which then defines the first drop rule in the policy map CSM_ZBF_POLICY_MAP_1, defined in (I).
   
   The policy map (I) is used to define the zone service policy in (J). Because this policy map is how all of the rules are assigned to the zone pair, (J) is not mentioned again.

2. This rule drops all traffic from the 10.100.11.0/24 network. This rule is combined with rule 1 by adding an ACE to the ACL defined in (K). The rest of the configuration is identical to rule 1. Thus, rules 1 and 2 essentially become a single rule in the device configuration.

3. This rule drops all FTP/FTPS traffic from the 10.100.10.12/24 network. The Permit, Source, Destination, and Service fields are used to create the ACL named CSM_ZBF_CMAP_ACL_2 defined in (L). The Protocol table generates the class map CSM_ZBF_CMAP_PLMAP_1 defined in (D), which specifies the FTP and FTPS protocols. The ACL and FTP/FTPS class map are then used in a new class map, CSM_ZBF_CLASS_MAP_2 defined in (E), which completes the characterization of the traffic based on the combination of source and protocol. Finally, (E) is referenced in the policy map (I) as the second rule.

4. This rule drops peer-to-peer traffic from any source that uses any of these protocols: BitTorrent, eDonkey, FastTrack, ICQ, or Kazaa2. This rule prevents any of your internal servers from being used as a file-sharing source for these services. Because the rule applies to all sources and destinations
for the default IP service, no ACL is required. Instead, the configuration starts with the class map CSM_ZBF_CLASS_MAP_3 defined in (F). This class map is referenced by the third drop rule in the policy map (I).

5. This rule inspects FTP/FTPS traffic from any source to any destination, which means these services are allowed. Note that rule 3, because it comes above rule 5, already drops FTP/FTPS traffic from the 10.100.12.0/24 network, so the combination of these rules means that FTP/FTPS traffic is inspected for all sources except 10.100.12.0/24. Because the Protocol table specifies the same protocols as it does for rule 3, no new class map is needed. Instead, the policy map (I) simply refers to the class map (D) as the fourth class type, but this time with the Inspect action.

6. This rule inspects HTTP traffic and applies a deep-inspection policy map named HTTPpmap. The HTTPpmap policy map (B) defines the action to take when traffic matches the criteria defined in the class map HTTPcmap (A). These maps specify that any HTTP connection that violates the HTTP protocol, or that misuses ports, should be reset (dropped) and a syslog entry generated. (Protocol violation and port misuse can characterize Denial of Service attacks.) The combination of (A) and (B) define the deep-inspection rules for this policy.

An additional class map, CSM_ZBF_CLASS_MAP_4, is needed to specify the HTTP protocol (G). Then, the fifth class type rule in the policy map (I) refers to class map (G) for inspection, and the service-policy command refers to the policy map (B) for deep inspection.

7. This rule provides generic inspection on TCP/UDP traffic, allowing and inspecting the remaining TCP/UDP traffic from the internal network to the Internet and back. The class map CSM_ZBF_CLASS_MAP_5 defined in (H) is generated from the Protocols table. This class map then becomes the next-to-last rule in the policy map (I).

8. Finally, there is an automatic rule, which appears as the final class-default rule in the policy map (I). This rule drops any traffic that does not match one of the class maps referenced in the policy map (I). For example, ICMP traffic from the internal network to the Internet will not be allowed. For information on configuring a different class-default rule, see Changing the Default Drop Behavior, page 20-46.

**Zone-based Firewall Rules Page**

Zone-based firewall rules provide unidirectional application of firewall policies between groups of interfaces known as “zones.” That is, interfaces are assigned to zones, and specific inspection policies are applied to traffic moving between zones in one direction or the other.

A zone defines a boundary where traffic is subjected to specific restrictions as it crosses into another region of your network. The default zone-based firewall policy between zones is **deny all**. Thus, if no policy is explicitly configured, all traffic between zones is blocked.

---

**Note**

Zone-based firewall policies can be configured only on Cisco IOS and ASR devices.

The Zone Based Firewall Rules page displays a list of currently configured zone-based firewall rules, and lets you add, edit and delete rules.

---

**Tip**

Disabled rules are shown with hash marks covering the table row. When you deploy the configuration, disabled rules are removed from the device. For more information, see Enabling and Disabling Rules, page 12-19.
Navigation Path
To access the Zone Based Firewall Rules page, do one of the following:

- (Device view) Select a device, then select Firewall > Zone Based Firewall Rules from the Policy selector.
- (Policy view) Select Firewall > Zone Based Firewall Rules from the Policy Type selector. Create a new policy or select an existing one.
- (Map view) Right-click a device and select Edit Firewall Policies > Zone Based Firewall Rules.

If you type in a service, you are prompted as you type with valid values. You also can click Select to select services from a list. For complete information on how to specify services, see Understanding and Specifying Services and Service and Port List Objects, page 6-79.</td>
</tr>
<tr>
<td>From Zone</td>
<td>Basic zone-based firewall rules are unidirectional; that is, they define a traffic flow that moves in only one direction between two zones. Enter or Select the zone from which traffic flows can originate for this rule, and enter or Select the zone to which traffic can flow.</td>
</tr>
<tr>
<td>To Zone</td>
<td></td>
</tr>
<tr>
<td>Advanced button</td>
<td>Opens the Advanced Options dialog box where you can select time-range options. See Zone-based Firewall Rule: Advanced Options Dialog Box, page 20-61.</td>
</tr>
<tr>
<td>Action</td>
<td>The action applied to traffic that matches this rule. Choose the desired Action:</td>
</tr>
</tbody>
</table>
| Action: Drop, Drop and Log, Pass, Pass and Log | • Drop – Silently drops all packets for the specified Services. The default action for all traffic.  
• Drop and Log – Matched traffic is logged and dropped.  
• Pass – The router forwards matched packets from the From Zone to the To Zone. Return traffic is not recognized, so you have to specify additional rules for return traffic. This option is useful only for protocols such as IPsec-encrypted traffic.  
• Pass and Log – Traffic is logged and forwarded. |

For any of these Actions, you can select one or more protocols to be matched by clicking the Select button next to the Protocol table to open the Protocol Selector Dialog Box, page 20-62. However, this is not necessary; you can leave the Protocol table empty and pass drop traffic based on the Sources, Destinations, and Services parameters; in effect, these are standard access rules. The Protocol Selector dialog box also provides access to the Configure Protocol Dialog Box, page 20-63, where you can edit the Port Application Mapping (PAM) parameters for the selected protocol. 

Note  The Log options generate system-log messages; you must ensure that syslog logging is configured to capture these messages.
Inspect provides state-based traffic control—the device maintains connection or session information for TCP and UDP traffic, meaning return traffic in reply to connection requests is permitted.

Choose this option to apply packet inspection based on your selected Layer 4 (TCP, UDP) and Layer 7 (HTTP, IMAP, instant messaging, and peer-to-peer) protocols. You also can edit PAM settings for the selected protocols, and you can set up deep packet inspection (DPI) and provide additional protocol-related information for the Layer 7 protocols. See Configuring Inspection Maps for Zone-based Firewall Policies, page 20-15 for more information.

1. You can select one or more protocols for inspection by clicking the Select button next to the Protocol table to open the Protocol Selector Dialog Box, page 20-62.

2. The Protocol Selector dialog box also provides access to the Configure Protocol Dialog Box, page 20-63, where you can create custom protocols, and edit the PAM and DPI parameters for the selected protocol.

3. Inspect Parameters – You can apply a customized set of connection, timeout, and other settings by entering the name of an Inspect Parameter map in this field, or you can click Select to select one from a list. You also can create new Inspect Parameter maps from the selection-list dialog box; see Configuring Inspect Parameter Maps, page 20-28 for more information.

If you do not specify an Inspect Parameters map, the default settings are used.
Use the Zone-Based Firewall Rule Advanced Options dialog box to apply specific time-range information to a zone-based firewall rule.

**Navigation Path**

In the Traffic section of the Add or Edit Zone based Firewall Rule dialog box, click the **Advanced** button.

**Related Topics**

Field Reference

Table 20-24  Advanced Options Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time Range</td>
<td>This feature lets you define time periods during which this zone-based firewall rule is active. If you do not specify a time range, the rule is immediately and always active. Enter the name of a time-range object, or click Select to choose one from a list in the Time Ranges Selector dialog box. You can create and edit time-range objects from this dialog box. For more information, see Configuring Time Range Objects, page 6-60.</td>
</tr>
</tbody>
</table>

Options

This feature lets you apply an initial-packet-fragment or an established-connection restriction to this zone-based firewall rule. Choose one of the following options:

- **None**—No packet-fragment or established-connection restrictions are applied.
- **Fragment** — If chosen, the rule is applied to non-initial packet fragments; the fragment is either permitted or denied accordingly. The white paper, “Access Control Lists and IP Fragments,” provides additional information that is also relevant to zone-based firewall rules.
- **Established** — For the TCP protocol only; requires an established connection. A match occurs if the TCP datagram has the ACK or RST control bits set. The non-matching case is that of the initial TCP datagram to form a connection.

Protocol Selector Dialog Box

Use the Protocol Selector dialog box to specify one or more communication protocols as part of the definition of traffic for a zone-based firewall rule.

The Protocol Selector dialog box also provides access to the Configure Protocol dialog box, which you can use to create custom protocols and edit Port Application Mapping (PAM) parameters for existing protocols. The Configure Protocol dialog box is also where you select Deep Inspection policy maps, and Protocol Info parameter maps for certain protocols. See Configure Protocol Dialog Box, page 20-63 for more information.

Navigation Path

The Protocol Selector dialog box can be accessed from the Add and Edit Zone-based Firewall Rule dialog boxes (described in Adding and Editing Zone-based Firewall Rules, page 20-58). In either dialog box, choose any Action except Content Filter and then click the Select button next to the Protocol table.

You can also open the Protocol Selector dialog box by right-clicking the Inspected Protocol column for any entry in the Zone Based Firewall Rules table, and then choosing Edit Protocols.

Related Topics

- Selecting Objects for Policies, page 6-2
- Configure Protocol Dialog Box, page 20-63
Configure Protocol Dialog Box

Packet inspection can be configured in zone-based firewall rules by the selection of specific protocol objects, which define Port Application Mapping (PAM) parameters (Layer 4 protocols and ports, and optionally specific networks and hosts). A Layer 7 (HTTP, IMAP, Instant Messaging, and peer-to-peer) protocol can also include a deep-packet inspection policy specific to that protocol. Refer to Adding and Editing Zone-based Firewall Rules, page 20-58 for information about selecting protocols during zone-based firewall rule definition.

The Configure Protocol dialog box is used to edit existing protocol definitions, and to create custom definitions, for use with zone-based firewall rules. For example, if a protocol does not use its default ports for some or all networks, you can configure different port mappings.

Navigation Path

The Configure Protocol dialog box is accessed from the Protocol Selector Dialog Box, page 20-62, as follows:

- Click the Create (+) button below the Selected Protocols list to create a new protocol.
- Select a protocol in the Selected Protocols list, and click the Edit (pencil) button to edit that protocol.

</tbody>
</table>
Managing Transparent Firewall Rules

Transparent firewall rules are access control rules for non-IP layer 2 traffic. You can use these rules to permit or drop traffic based on the Ethertype value in the layer-2 packet.

This chapter contains the following topics:

- Configuring Transparent Firewall Rules, page 21-1
- Transparent Rules Page, page 21-3

Configuring Transparent Firewall Rules

Transparent firewall rules are access control rules for non-IP layer 2 traffic. You can use these rules to permit or drop traffic based on the Ethertype value in the layer-2 packet. These rules create Ethertype access control lists on the device. With transparent rules, you can control the flow of non-IP traffic across the device. (To control IP traffic, use access rules; see Understanding Access Rules, page 15-2.)

Transparent firewalls are devices that you place within a single subnet to control traffic flow across a bridge. They allow you to insert a firewall on a subnet without renumbering your networks.

You can configure transparent rules only on the following types of interfaces:

- **IOS 12.3(7)T or higher devices**—On layer-3 interfaces that are part of a bridge group:
  - Configure the interfaces you want to bridge as layer 3 in the Interfaces > Interfaces policy.
  - Configure a bridge group with two or more layer 3 interfaces in the Platform > Device Admin > Bridging policy (see Bridging on Cisco IOS Routers, page 59-18 and Defining Bridge Groups, page 59-19).
  - Create a bridge group virtual interface (BVI) using the same number as the bridge group (see Bridge-Group Virtual Interfaces, page 59-18). For example, if you create bridge group 12, create BVI12.

- **ASA, PIX 7.0+, FWSM devices**—On any interface when the device is running in transparent mode. If you are using multiple contexts, configure the rules on the individual security contexts.

There are several other bridging policies that you can configure in the Platform > Bridging policy group including: ARP table and ARP inspection, MAC table and the ability to disable MAC learning, and the ability to configure a management IP address so that you can remotely manage the device. For more detail about transparent firewalls, see Chapter 45, “Configuring Bridging Policies on Firewall Devices” and Interfaces in Routed and Transparent Modes, page 44-4.
On ASA, PIX, and FWSM in transparent mode, you must configure access rules to allow any IP traffic to pass through the device. Transparent rules control layer 2 non-IP traffic only.

Also, see NAT in Transparent Mode, page 22-16 for information about using network address translation on security devices.

You can also configure other types of firewall rules on these interfaces. The other types of rules apply to layer-3 and higher traffic.

If you configure any transparent rule, an implicit deny all rule is added at the end of the rule list for each interface. You must ensure that you permit all desired traffic. You might want to include a permit any (for ASA/PIX/FWSM devices) or permit 0x0000 0xFFFF (for IOS devices) rule as the final rule in the table if your desire is simply to deny specific types of traffic, rather than permitting only specific types of traffic.

### Related Topics
- Adding and Removing Rules, page 12-9
- Editing Rules, page 12-9
- Enabling and Disabling Rules, page 12-19

### Step 1
Do one of the following to open the Transparent Rules Page, page 21-3:
- (Device view) Select **Firewall > Transparent Rules** from the Policy selector for a supported device type.
- (Policy view) Select **Firewall > Transparent Rules** from the Policy Type selector. Select an existing policy or create a new one.

### Step 2
Select the row after which you want to create the rule and click the **Add Row** button or right-click and select **Add Row**. This opens the Add and Edit Transparent Firewall Rule Dialog Boxes, page 21-5.

### Tip
If you do not select a row, the new rule is added at the end of the local scope. You can also select an existing row and edit either the entire row or specific cells. For more information, see Editing Rules, page 12-9.

### Step 3
Configure the rule. Following are the highlights of what you typically need to decide. For specific information on configuring the fields, see Add and Edit Transparent Firewall Rule Dialog Boxes, page 21-5.

- **Permit or Deny**—Whether you are allowing traffic that matches the rule or dropping it.
- **Interfaces**—The interface or interface role for which you are configuring the rule.
- **The direction of traffic** to which this rule should apply (in or out). The default is in.
- **EtherType**—The hexadecimal code or keyword (for ASA/PIX/FWSM only) that identifies the traffic. For a list of codes, see RFC 1700 at http://www.ietf.org/rfc/rfc1700.txt and search for “Ether Type.” For ASA/PIX/FWSM, you can select a keyword to identify some EtherTypes. For ASA/PIX/FWSM, the code must be 0x0600 at minimum.
Transparent Rules Page

Use the Transparent Rules page to control access for non-IP layer-2 traffic. (To control IP traffic access, use access rules; see Understanding Access Rules, page 15-2.)

Transparent rules are limited to transparent firewalls, which are ASA, PIX 7.0+, and FWSM devices running in transparent mode, or layer-3 interfaces that are part of a bridge group on IOS 12.3(7)T+ devices. When deployed, transparent rules become Ethertype access control lists.

Configure the same rules on all bridged interfaces to allow traffic to pass both ways through the device.

For more detailed information about configuring transparent firewalls and the device requirements for deploying these rules, see Configuring Transparent Firewall Rules, page 21-1.

Tip

Disabled rules are shown with hash marks covering the table row. When you deploy the configuration, disabled rules are removed from the device. For more information, see Enabling and Disabling Rules, page 12-19.

Navigation Path

To access Transparent Rules, do one of the following:

- (Device view) Select Firewall > Transparent Rules from the Policy selector for a supported device type.
- (Policy view) Select Firewall > Transparent Rules from the Policy Type selector. Select an existing policy or create a new one.
- (Map view) Right-click a device and select Edit Firewall Policies > Transparent Rules.

</table>
Use the Edit Transparent EtherType dialog box to edit the EtherType in a transparent firewall rule. Enter the hexadecimal code that identifies the traffic. For ASA/PIX/FWSM devices, you can also select the keyword for some types of traffic. For a list of codes, see RFC 1700 at http://www.ietf.org/rfc/rfc1700.txt and search for “Ether Type.”

For ASA/PIX/FWSM devices, you can also select these keywords:
- bpdu—Spanning Tree Bridge Protocol Data Units
- ipx—Internet Packet Exchange
- mpls-unicast—Multi-Protocol Label Switching, unicast.
- mpls-multicast—MPLS multicast.
- any—Any packet regardless of EtherType.

A mask of 0xFFFF indicates the EtherType is literal. Any other mask indicates the corresponding bits in the EtherType to ignore. You must convert the hexadecimal number to binary to fully interpret the mask (binary 1 means interpret the corresponding EtherType value literally, 0 means allow any value at that position).

For more information, see Configuring Transparent Firewall Rules, page 21-1.

Navigation Path
Right-click the EtherType cell in a transparent rule (on the Transparent Rules Page, page 21-3) and select Edit EtherType. You can edit the EtherType for one row at a time.
Edit Transparent Mask Dialog Box

Use the Edit Transparent Mask dialog box to edit the mask in a transparent firewall rule for an IOS device. The mask is a 16-bit hexadecimal number that determines how the EtherType code is interpreted.

A mask of 0xFFFF indicates the EtherType is literal. Any other mask indicates the corresponding bits in the EtherType to ignore. You must convert the hexadecimal number to binary to fully interpret the mask (binary 1 means interpret the corresponding EtherType value literally, 0 means allow any value at that position).

For more information, see Configuring Transparent Firewall Rules, page 21-1.

Navigation Path

Right-click the Mask cell in a transparent rule (on the Transparent Rules Page, page 21-3) and select Edit Mask. You can edit the mask for one row at a time.
Configuring Network Address Translation

These topics provide conceptual information about network address translation (NAT) in general, and about translation types and various implementations:

Understanding Network Address Translation

Address translation substitutes the real address in a packet with a mapped address that is routable on the destination network. As part of the process, the device also records the substitution in a translation database; these records are known as “xlate” entries. The appropriate xlate entry must exist to allow address translation on return packets—the substitution of the original real address for the mapped address; this procedure is sometimes referred to as “untranslation.” Thus, network address translation (NAT) actually consists of two steps: the translation of a real address into a mapped address, and the reverse translation for returning traffic.

One of the main functions of NAT is to enable private IP networks to connect to the Internet. Network address translation replaces a private IP address with a public IP address, translating the private addresses in the internal network into legal, routable addresses that can be used on the public Internet. In this way, NAT conserves public addresses; for example, NAT rules can be configured to utilize only one public address for the entire network in communications with the outside world.

Other functions of NAT include:

- **Security** – Keeping internal IP addresses hidden discourages direct attacks.
- **IP routing solutions** – Overlapping IP addresses are not a problem.
- **Flexibility** – You can change internal IP addressing schemes without affecting the public addresses available externally. For example, for a server accessible to the Internet, you can maintain a fixed IP address for Internet use, but internally, you can change the server address.

Cisco devices support both NAT, which provides a globally unique address for each outbound host session, and Port Address Translation (PAT), which provides the same single address combined with a unique port number, for up to 64,000 simultaneous outbound or inbound host sessions. The global addresses used for NAT come from a pool of addresses specifically designated for address translation. The unique global address that is used for PAT can be either one global address, or the IP address of a given interface.

The device translates an address when an existing NAT rule matches the specific traffic. If no NAT rule matches, processing for the packet continues. The exception is when you enable NAT control. NAT control requires that packets traversing from a higher security interface (inside) to a lower security interface (outside) match a NAT rule, or processing for the packet stops.

Cisco devices can perform NAT or PAT on both inbound and outbound connections. This ability to translate inbound addresses is called “Outside NAT” because addresses on the outside, or less secure, interface are translated to a usable inside IP address. Just as when you translate outbound traffic, you may choose dynamic NAT, static NAT, dynamic PAT, or static PAT. If necessary, you can use outside NAT together with inside NAT to translate the both source and destination IP addresses of a packet.

Note

In this document, all types of translation are generally referred to as NAT; see Types of Address Translation, page 22-3 for descriptions of the various types. When describing NAT, the terms inside and outside represent the security relationship between any two interfaces. The higher security level is inside and the lower security level is outside.

The release of ASA version 8.3 provides a simplified, interface-independent approach to configuring network address translation, as compared to earlier ASA versions and other devices. See About “Simplified” NAT on ASA 8.3+ Devices, page 22-3 for more information.

Types of Address Translation

The following table briefly describes the various types of address translation.

<table>
<thead>
<tr>
<th>Table 22-1</th>
<th>Types of Address Translation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static NAT</td>
<td>Fixed translation of real source addresses to specific mapped addresses—each source address is always translated to the same mapped address, regardless of IP protocol and port number.</td>
</tr>
<tr>
<td>Static PAT</td>
<td>Fixed translation of real source addresses with specific TCP or UDP port numbers, to specific mapped addresses and ports. That is, each source address/port is always translated to the same mapped address/port.</td>
</tr>
<tr>
<td>Policy Static NAT</td>
<td>Fixed translation of real source addresses to specific mapped addresses. Destination networks/hosts are also specified, and the service is always IP.</td>
</tr>
<tr>
<td>Policy Static PAT</td>
<td>Fixed translation of real source addresses with specific TCP or UDP port numbers, to specific mapped addresses and ports. Destination networks/hosts and services are also specified.</td>
</tr>
<tr>
<td>Dynamic NAT</td>
<td>Dynamic translation of real source addresses to mapped addresses obtained from a pool of shared addresses. Each source address can be mapped to any available address in the pool.</td>
</tr>
<tr>
<td>Dynamic PAT</td>
<td>Translation of real source addresses to a single mapped address; singularity is provided by dynamic translation of related port numbers. That is, each real address/port combination is translated to the same mapped address, but assigned a unique port. This is sometimes referred to as “overloading.”</td>
</tr>
<tr>
<td>Policy Dynamic NAT</td>
<td>Dynamic translation of specific source-address/destination-address/service combinations on a given interface, using a pool of shared addresses. Translation direction—outbound or inbound—is also specified.</td>
</tr>
<tr>
<td>Identity NAT</td>
<td>The specified address is translated to itself—that is, it is effectively not translated; applies to outbound connections only. Identity NAT is a particular type of Static NAT.</td>
</tr>
<tr>
<td>NAT Exempt</td>
<td>Translation is bypassed for specified source/destination address combinations; connections can be initiated in both the outbound and inbound directions.</td>
</tr>
</tbody>
</table>

Note

While certain of these types do not apply to ASA 8.3 and later devices, the ASA 8.3+ devices do provide a Dynamic NAT and PAT option, which is Dynamic NAT with a Dynamic PAT back-up feature.

About “Simplified” NAT on ASA 8.3+ Devices

The release of ASA version 8.3 provides a simplified approach to configuring network address translation (NAT), as compared to earlier ASA versions and other devices. Configuration of NAT was simplified by replacing the earlier flow-based scheme with an “original packet” to “translated packet” approach.

All NAT rules on the device—static NAT, dynamic PAT, and dynamic NAT—are presented in a single table, and essentially the same dialog box is used to configure all NAT rules. The NAT rules are interface independent (that is, interfaces are optional), meaning the rules are independent of security levels also.
NAT rules are no longer dependent on security levels. A global address space consisting of all interfaces is available, and is specified using the keyword “any.” All Interface fields default to any, so unless a specific interface is provided, the rule is applicable to all interfaces.

Network Object NAT
You also can define NAT properties on Host, Address Range, and Network objects, such that corresponding NAT rules are applied automatically to the designated security device. Using these objects means you need enter the necessary IP addresses, services, ports, and optional interfaces only once. These automatically generated, object-based rules are referred to as “Network Object NAT” rules. Note that these rules cannot be edited from the rules table; you must edit the appropriate objects in the Policy Object Manager.

The NAT Table
As mentioned, all NAT rules on a device are presented in a single table, which is divided into three sections: a “manual” section, the Network Object NAT rules section, and another manual-rules section. You can add, edit and order rules in both manual sections; the Network Object NAT rules are added and ordered automatically, and as mentioned, to edit these rules you must edit the related objects.

The NAT rules in the table are applied on a top-down, first-match basis. That is, a packet is translated only when it matches a NAT rule, and as soon as a match is made, regardless of its location or section, NAT rule processing stops.

You can use this table to organize and manage the manual rules—you can insert rules in any order, and you can re-order them. The two sections of manual rules are provided to let you order manual rules both before and after the automatic object rules.

Network Object NAT rules are automatically ordered such that static rules appear before dynamic rules. These two types are each further ordered as follows:

- Fewest number of IP addresses – Rules for objects with one IP address are listed before those for objects with two addresses, which are before those with three addresses, and so on.
- IP address numbers – For objects having the same number of IP addresses, the rules are arranged such that the IP addresses themselves are in numerical order, from lower to higher. For example, 10.1.1.1 rules are listed before 11.1.1.1 rules.
- Object names – If the IP address is the same, the rules are ordered by alphabetizing the object names.

And remember, translation is based on the first matching rule.

Destination Translation
With manual static rules, in addition to source address translation, you also can configure destination address translation. Source and destination translation are defined at the same time, in the same dialog box. Again, while source translation can be static or dynamic, destination translation is always static, and is only available with manual rules.

Bi-directional or Twice NAT
When creating a manual static rule, you can select the “Bi-directional” option, which will produce an entry in the rules table that actually represents two static NAT rules, encompassing both translation directions. That is, a static rule is created for the specified source/translated address pairing, along with a mirror rule for the translated address/source pairing.

For example, if Bi-directional is chosen when you create a static rule with Host1 in the Source field and Host2 in the Translated field, two lines are added to the rules table: one with Host1 being translated to Host2, and one with Host2 being translated to Host1.

This is sometimes referred to as “Twice NAT” because only one look-up is required to fetch and process what is in effect two rules.
Many-to-one Addressing

Generally, static NAT rules are configured with one-to-one address mapping. However, you can now define static NAT rules in which many IP addresses map to a few or one IP address. Functionally, many-to-few is the same as many-to-one, but because the configuration is more complicated, we recommend creating a many-to-one rule for each address as needed.

Many-to-one addressing might be useful, for example, in a situation where a range of public IP addresses is used to reach a load balancer which redirects requests to an internal network.

NAT Policies on Cisco IOS Routers

You can configure NAT policies on a Cisco IOS router from the following tabs on the NAT policy page:

- NAT Page: Static Rules, page 22-6
- NAT Page: Dynamic Rules, page 22-10
- NAT Page: Timeouts, page 22-13

Network Address Translation (NAT) converts private, internal LAN addresses into globally routable IP addresses. NAT enables a small number of public IP addresses to provide global connectivity for a large number of hosts.

For more information, see Understanding Network Address Translation, page 22-2.

Navigation Path

- (Device view) Select NAT from the Policy selector.
- (Policy view) Select NAT (Router) from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

NAT Page: Interface Specification

Before creating NAT rules, you must define the “direction” of the traffic to be translated by specifying the Inside and Outside interfaces. Inside interfaces typically connect to a LAN that the router serves. Outside interfaces typically connect to your organization’s WAN or to the Internet. You must designate at least one Inside interface and one Outside interface to enable the router to perform network address translation.

The Inside and Outside designations are used when interpreting translation rules: addresses connected to the Inside interface are translated to addresses on the Outside interface. After these interfaces are defined, they are used in all static and dynamic NAT translation rules.

Use the Interface Specification tab of the NAT policy page to specify the Inside and Outside interfaces.
Navigation Path

- (Device view) Select NAT from the Policy selector, then click the Interface Specification tab.
- (Policy view) Select NAT (Router) > Translation Rules from the Policy Type selector. Select an existing policy or create a new one, and then click the Interface Specification tab.

Defining the Inside and Outside Interfaces

In the NAT Inside Interfaces and NAT Outside Interfaces fields, enter or select the names of the interfaces or interface roles for the Inside and Outside interfaces, respectively. Separate multiple names or roles with commas (for example, Ethernet1/1, Ethernet1/2). Note that you cannot enter the same name in both fields.

NAT Page: Static Rules

You define a static NAT rule by specifying a local address that must be translated, as well as the global address to which it is translated. This is a static or fixed mapping—the local address is always translated to the same global address.

You can define static NAT rules that translate the addresses of single hosts, as well as static rules that translate multiple addresses in a subnet. When multiple local addresses must use the same global address, you must define the necessary port redirection information, which defines a different port for each local address using the global address.

Note

We strongly recommend that you do not perform NAT on traffic that will be transmitted over a VPN. Translating addresses on this traffic causes it to be sent out unencrypted instead of encrypted over the VPN.

The procedure for creating a static rule depends on whether the address being translated represents a port, a single host, or an entire subnet:

- You define a static NAT rule for a single host by entering the original address to translate and the global address to which it is translated. The global address may be taken from an interface on the device.
- You define a static NAT rule for a subnet by entering one of the addresses in the subnet (including the subnet mask) as the original address, and one of the global addresses that you want to use as the translated address. The router configures the remaining addresses based on the subnet mask you provide.
- You define a static NAT rule for a port by entering the original IP address and the global address to which it should be translated. The global address may be taken from an interface on the device. In addition, you must select the protocol used by the port, as well as the local and global port numbers.
The Add Static NAT Rule and Edit Static NAT Rule dialog boxes are used to add and edit these rules. Refer to NAT Static Rule Dialog Boxes, page 22-7 for descriptions of the fields displayed in the table on this page.

**Before You Begin**
- Define the inside and outside interfaces used for NAT. See NAT Page: Interface Specification, page 22-5.

**Navigation Path**
- (Device view) Select NAT from the Policy selector, then click the Static Rules tab.
- (Policy view) Select NAT (Router) > Translation Rules from the Policy Type selector. Select an existing policy or create a new one, and then click the Static Rules tab.

<tbody>
<tr>
<td>Static Rule Type</td>
<td>The type of local address to be translated by this static rule:</td>
</tr>
<tr>
<td></td>
<td>• Static Host – A single host requiring static address translation.</td>
</tr>
<tr>
<td></td>
<td>• Static Network – A subnet requiring static address translation.</td>
</tr>
<tr>
<td></td>
<td>• Static Port – A single port requiring static address translation. If you select this option, you must define the Port Redirection parameters.</td>
</tr>
<tr>
<td>Original Address</td>
<td>An IP address, or the name of a network/host object representing the address(es) to be translated. You can enter or Select the object name.</td>
</tr>
<tr>
<td></td>
<td>Network/host objects are logical collections of IP addresses that represent networks, hosts, or both. See Understanding Network/Host Objects (IPv4 and IPv6), page 6-69 for more information.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Do not enter a local address belonging to this router, as it could cause Security Manager management traffic to be translated. Translating this traffic will cause a loss of communication between the router and Security Manager.</td>
</tr>
<tr>
<td>Translated Address</td>
<td>Use the options in this section of the dialog box to specify the address(es) to which the Original Address(es) are translated:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Specify IP</strong> – Select this option to specify an IP address, or the name of a network/host object that provides the translated address(es). Add an IP address, or the name of a network/host object, in the Translated IP/Network field. You can enter or Select the object name.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Use Interface IP</strong> – Select this option to specify that the IP address assigned to a particular interface be used as the translated address. Enter or Select the name of the desired Interface. (This is typically the interface from which translated packets leave the router.)</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This option is not available when Static Network is the chosen rule type. Only one static rule may be defined per interface.</td>
</tr>
</tbody>
</table>
### Port Redirection

These parameters specify port information for the address translations. Port address translation lets you to use the same public IP address for multiple devices as long as the port specified for each device is different.

**Note**  These parameters are available only when Static Port is the chosen rule type.

**Redirect Port** – When Static Port is chosen as the rule type, this box is automatically checked; it cannot be changed. Enter the appropriate information in the following fields:

- **Protocol** – The communications protocol used for these ports: TCP or UDP.
- **Local Port** – The port number on the source network. Valid values range from 1 to 65535.
- **Global Port** – The port number on the destination network that the router is to use for this translation. Valid values range from 1 to 65535.

### Advanced

This section contains optional, advanced translation options.

**Note**  The Advanced options are available only when the Specify IP option is the selected method for defining the translated address(es).

- **No Alias** – When selected, disables automatic aliasing for the global IP address translation.
  
  If the NAT pool used as an inside global pool consists of addresses on an attached subnet, an alias is generated for that address so that the router can answer Address Resolution Protocol (ARP) requests for those addresses. When deselected, global address aliases are permitted.

- **No Payload** – When selected, prohibits an embedded address or port in the payload from being translated.
  
  The payload option performs NAT between devices on overlapping networks that share the same IP address. When an outside device sends a DNS query to reach an inside device, the local address inside the payload of the DNS reply is translated to a global address according to the relevant NAT rule.

  You can disable this feature by selecting the No Payload option. Otherwise, embedded addresses and ports in the payload may be translated. See Disabling the Payload Option for Overlapping Networks, page 22-10 for more information.

- **Create Extended Translation Entry** – When checked, extended translation entries (addresses and ports) are created in the translation table. This lets you associate multiple global addresses with a single local address. This is the default.

  When this option is deselected, simple translation entries are created, allowing association of a single global address with the local address.

**Note**  This option is not available when Static Port is the chosen rule type.

---

Enter the appropriate information in the following fields:  
  - **Protocol** – The communications protocol used for these ports: TCP or UDP.  
  - **Local Port** – The port number on the source network. Valid values range from 1 to 65535.  
  - **Global Port** – The port number on the destination network that the router is to use for this translation. Valid values range from 1 to 65535.  

| Advanced       | This section contains optional, advanced translation options.  
  
  The Advanced options are available only when the Specify IP option is the selected method for defining the translated address(es).  

- **No Alias** – When selected, disables automatic aliasing for the global IP address translation.  
  
  If the NAT pool used as an inside global pool consists of addresses on an attached subnet, an alias is generated for that address so that the router can answer Address Resolution Protocol (ARP) requests for those addresses. When deselected, global address aliases are permitted.  

- **No Payload** – When selected, prohibits an embedded address or port in the payload from being translated.  
  
  The payload option performs NAT between devices on overlapping networks that share the same IP address. When an outside device sends a DNS query to reach an inside device, the local address inside the payload of the DNS reply is translated to a global address according to the relevant NAT rule.  

  You can disable this feature by selecting the No Payload option. Otherwise, embedded addresses and ports in the payload may be translated. See Disabling the Payload Option for Overlapping Networks, page 22-10 for more information.  

- **Create Extended Translation Entry** – When checked, extended translation entries (addresses and ports) are created in the translation table. This lets you associate multiple global addresses with a single local address. This is the default.  

  When this option is deselected, simple translation entries are created, allowing association of a single global address with the local address.  

**Note**  This option is not available when Static Port is the chosen rule type.
Disabling the Payload Option for Overlapping Networks

Overlapping networks result when you assign an IP address to a device on your network that is already legally owned and assigned to a different device on the Internet or outside network. Overlapping networks can also result after the merger of two companies using RFC 1918 IP addresses in their networks. These two networks need to communicate, preferably without your having to re-address all their devices.

This communication is achieved as follows. The outside device cannot use the IP address of the inside device because it is the same as the address assigned to itself (the outside device). Instead, the outside device sends a Domain Name System (DNS) query for the inside device’s domain name. The source of this query is the IP address of the outside device, which is translated to an address from a designated address pool. The DNS server located on the inside network replies with the IP address associated with the inside device’s domain name in the data portion of the packet. The destination address of the reply packet is translated back to the outside device’s address, and the address in the data portion of the reply packet is translated to an address from a different address pool. In this way, the outside device learns that the IP address for the inside device is one of the addresses from that second address pool, and it uses this address when it communicates with the inside device. The router running NAT takes care of the translations at this point.

To disable the translation of the address inside the payload, check the **No Payload** option when you create a static NAT rule based on a global IP translation.

### NAT Page: Dynamic Rules

Use the NAT Dynamic Rules tab of the router’s NAT page to manage dynamic address translation rules. A dynamic address translation rule dynamically maps hosts to addresses, using either the IP address of a specific interface (with dynamic port translation), or the addresses included in an address pool that are globally unique in the destination network.

**Defining Dynamic NAT Rules**

You define a dynamic NAT rule by first selecting an access control list (ACL) whose rules specify the traffic requiring translation.

Then, you must either select an interface with an IP address to which the addresses should be translated, or define a pool of addresses to be used. You define the pool by specifying a range of addresses and giving the range a unique name; you can specify multiple ranges. The router uses the available addresses in the pool (those not used for static translations, or for its own WAN IP address) for connections to the Internet or another outside network. When an address is no longer in use, it is returned to the address pool to be dynamically assigned later to another device.

If the addressing requirements of your network exceed the available addresses in your dynamic NAT pool, you can use the Port Address Translation (PAT) feature (also called Overloading) to associate many private addresses with one or a small group of public IP address, using port addressing to make each translation unique. With PAT enabled, the router chooses a unique port number for the IP address of each outbound translation slot. This feature is useful if you cannot allocate enough unique IP addresses for your outbound connections. Note that Port Address Translation does not occur until the address pool is depleted.

By default, Security Manager does not perform NAT on traffic that is meant to be transmitted over a VPN. Otherwise, any traffic appearing in both the NAT ACL and the crypto ACL defined on an interface would be sent out unencrypted because NAT is always performed before encryption. However, you can change this default setting.
You can perform PAT on split-tunneled traffic on the spokes of your VPN topology directly from the Global VPN Settings page. There is no need to create a dynamic NAT rule for each spoke. Any NAT rules that you define on an individual device override the VPN setting. For more information, see Configuring VPN Global NAT Settings, page 24-35.

The Add Dynamic NAT Rule and Edit Static NAT Rule dialog boxes are used to add and edit these rules. Refer to NAT Dynamic Rule Dialog Box, page 22-11 for descriptions of the fields displayed in the table on this page.

Before You Begin
- Define the inside and outside interfaces used for NAT. See NAT Page: Interface Specification, page 22-5.

Navigation Path
- (Device view) Select NAT from the Policy selector, then click the Dynamic Rules tab.
- (Policy view) Select NAT (Router) > Translation Rules from the Policy Type selector. Select an existing policy or create a new one, and then click the Dynamic Rules tab.

**Table 22-3  NAT Dynamic Rule Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traffic Flow</td>
<td>In the <strong>Access List</strong> field, enter or Select the name of the access control list (ACL) object whose entries define the addresses requiring dynamic translation. Note: Make sure that the specified ACL does not permit the translation of Security Manager management traffic over any device address on this router. Translating this traffic will cause a loss of communication between the router and Security Manager.</td>
</tr>
<tr>
<td>Translated Address</td>
<td>Use the options in this section of the dialog box to specify the method and address(es) used for dynamic translation:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Use Interface IP</strong> – Select this option to specify that the globally registered IP address assigned to a particular interface be used as the translated address; port addressing ensures each translation is unique. (The Enable Port Translation (Overload) option is checked automatically when you select Use Interface IP.) Enter or Select the name of the desired Interface. This is typically the interface from which translated packets leave the router, meaning the interface or interface role must represent an outside interface on the router (see <strong>NAT Page: Interface Specification, page 22-5</strong>).</td>
</tr>
<tr>
<td></td>
<td>• <strong>Address Pool</strong> – Select this option to base address translation on the addresses you specify in the <strong>Network Ranges</strong> pool. Enter one or more address ranges, including the prefix, using the format min1-max1/prefix (in CIDR notation), where “prefix” represents a valid netmask. For example, 172.16.0.0–172.31.0.223/12. You can add as many address ranges to the address pool as required, but all ranges must share the same prefix. Separate multiple entries with commas.</td>
</tr>
</tbody>
</table>
NAT Page: Timeouts

Use the NAT Timeouts tab of the router’s NAT page to manage the timeout values for port address (overload) translations. These timeouts cause a dynamic translation to expire after a specified period of inactivity. In addition, you can use options on this page to place a limit on the number of entries allowed in the dynamic NAT table, and to modify the default timeout on all dynamic translations that do not include PAT processing.

About Dynamic NAT Timeouts

Dynamic NAT translations have a timeout period for non-use, after which they expire and are purged from the translation table. If you enable the Overload feature for performing PAT, you can specify a variety of values that provide finer control over these timeouts, because each translation entry contains additional contextual information about the traffic using it.

For example, non-DNS translations time out by default after five minutes, but DNS translations time out after 1 minute. Further, TCP translations time out after 24 hours, unless an RST or FIN is seen on the stream, in which case they time out after one minute. You can change any of these timeout values.

<tr>
<td></td>
<td>section, this box is checked automatically; it cannot be changed.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Do Not Translate VPN Traffic (Site-to-Site VPN only)</strong> – Deselect this</td>
</tr>
<tr>
<td></td>
<td>option to allow address translation on traffic intended for a site-to-site</td>
</tr>
<tr>
<td></td>
<td>VPN. When selected, address translation is not performed on VPN traffic.</td>
</tr>
<tr>
<td></td>
<td>When deselected, the router performs address translation on VPN traffic in</td>
</tr>
<tr>
<td></td>
<td>cases of overlapping addresses between the NAT ACL and the crypto ACL.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> We strongly recommend that you not deselect this option, or any</td>
</tr>
<tr>
<td></td>
<td>traffic defined in both the NAT ACL and the crypto ACL will be sent</td>
</tr>
<tr>
<td></td>
<td>unencrypted. When you perform NAT into IPsec, we also recommend that you</td>
</tr>
<tr>
<td></td>
<td>leave this option selected; it does not interfere with the translation of</td>
</tr>
<tr>
<td></td>
<td>addresses arriving from overlapping networks. This setting applies only in</td>
</tr>
<tr>
<td></td>
<td>situations where the NAT ACL overlaps the crypto ACL used by the site-to-site</td>
</tr>
<tr>
<td></td>
<td>VPN. Because the interface performs NAT first, any traffic arriving from an</td>
</tr>
<tr>
<td></td>
<td>address within this overlap would get translated, causing the traffic to be</td>
</tr>
<tr>
<td></td>
<td>sent unencrypted. Leaving this box checked prevents that from happening.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This option does not apply to remote access VPNs.</td>
</tr>
</tbody>
</table>

Note: This option does not apply to remote access VPNs.
Note
If you disable the Port Translation (Overload) feature for all dynamic rules, you need not enter any PAT-related timeout values. However, you can still modify the default timeout value for non-PAT dynamic translations. (By default, all dynamic translations expire after 24 hours.) For more information about the Overload feature, see NAT Dynamic Rule Dialog Box, page 22-11.

Navigation Path
- (Device view) Select NAT from the Policy selector, then click the Timeouts tab.
- (Policy view) Select NAT (Router) > Translation Rules from the Policy Type selector. Select an existing policy or create a new one, and then click the Timeouts tab.

### NAT Policies on Security Devices

The following topics describe configuring network address translation (NAT) options on managed security appliances: PIX firewalls, Firewall Service Modules (FWSMs) on Catalyst switches, pre-version-8.3 Adaptive Security Appliances (ASAs), and ASA 8.3+ devices. The topics are arranged as follows:

- **NAT in Transparent Mode**, page 22-16
- **Translation Options Page**, page 22-16
- **PIX, FWSM, and pre-8.3 ASA**
  - Configuring NAT on PIX, FWSM, and pre-8.3 ASA Devices, page 22-18
  - Address Pools, page 22-18
  - Translation Rules: PIX, FWSM, and pre-8.3 ASA, page 22-19
- **ASA 8.3+**
  - Configuring NAT on ASA 8.3+ Devices, page 22-33
  - Translation Rules: ASA 8.3+, page 22-33
NAT in Transparent Mode

Using NAT on a security appliance operating in transparent mode eliminates the need for upstream or downstream routers to perform NAT for their networks. NAT in transparent mode has the following requirements and limitations:

- When the mapped addresses are not on the same network as the transparent firewall, you need to add a static route for the mapped addresses on the upstream router that points to the downstream router (through the security appliance).

- If the real destination address is not directly connected to the security appliance, you also need to add a static route on the security appliance for the real destination address that points to the downstream router. Without NAT, traffic from the upstream router to the downstream router does not need any routes on the security appliance because it uses the MAC address table. Using NAT, however, causes the security appliance to use a route look-up instead of a MAC address look-up, so it needs a static route to the downstream router.

- Because the transparent firewall does not have any interface IP addresses, you cannot use interface PAT.

- ARP inspection is not supported. Moreover, if for some reason a host on one side of the security appliance sends an ARP request to a host on the other side of the security appliance, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.

Translation Options Page

Use the Translation Options page to set options that affect network address translation for the selected security appliance. These settings apply to all interfaces on the device.

Navigation Path

- (Device view) Select NAT > Translation Options from the Device Policy selector.
- (Policy view) Select NAT (PIX/ASA/FWSM) > Translation Options from the Policy Type selector. Select an existing policy from the Shared Policy selector, or right-click Translation Options to create a new policy.

### Field Reference

#### Table 22-5 Translation Options Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Enable traffic through the firewall without address translation | When selected, lets traffic pass through the security appliance without address translation. If this option is not selected, any traffic that does not match a translation rule will be dropped.  
**Note** This option is available only on PIX 7.x, FWSM 3.x, and ASA devices. |
| Enable xlate bypass                          | When selected, establishment of NAT sessions for untranslated traffic is disabled (this feature is called “xlate bypass”).  
**Note** This option is available only on FWSM 3.2 and higher.  
By default, the FWSM creates NAT sessions for all connections even if NAT is not used. For example, a session is created for each untranslated connection even if NAT control is not enabled, if NAT exemption or identity NAT is used, or if you use same-security interfaces and do not configure NAT. Because there is a maximum number of NAT sessions (266,144 concurrent), these kinds of NAT sessions might cause you to run into the limit. To avoid reaching the limit, enable xlate bypass.  
If you disable NAT control and have untranslated traffic or use NAT exemption, or if you enable NAT control and use NAT exemption, then with xlate bypass, the FWSM does not create a session for those types of untranslated traffic. However, NAT sessions are still created in the following instances:  
- You configure identity NAT (with or without NAT control)—identity NAT is considered to be a translation.  
- You use same-security interfaces with NAT control. Traffic between same-security interfaces create NAT sessions even when you do not configure NAT for the traffic. To avoid NAT sessions in this case, disable NAT control, or use NAT exemption as well as xlate bypass. |
| Do not translate VPN traffic                 | When selected, VPN traffic passes through the security appliance without address translation.                                                                                                                                                                                                                                             |
| Clear translates for existing connections    | When selected, the translation slots assigned to dynamic translations and any associated connections are cleared following each session.  
Each session connecting through the security appliance, and undergoing some form of NAT or PAT, is assigned a translation slot known as an “xlate.” These translation slots can persist after the session is complete, which can lead to a depletion of translation slots, unexpected traffic behavior, or both. |
Configuring NAT on PIX, FWSM, and pre-8.3 ASA Devices

The following sections describe configuring network address translation on PIX and FWSM devices, and on pre-8.3-version ASAs. (See Configuring NAT on ASA 8.3+ Devices, page 22-33 for information about configuring NAT on ASA 8.3+ devices.)

- Address Pools, page 22-18
- Translation Rules: PIX, FWSM, and pre-8.3 ASA, page 22-19
  - Translation Exemptions (NAT 0 ACL), page 22-20
  - Dynamic Rules Tab, page 22-22
  - Policy Dynamic Rules Tab, page 22-24
  - Static Rules Tab, page 22-26
  - General Tab, page 22-31

Address Pools

Use the Address Pools page to view and manage the global address pools used in dynamic NAT rules. The Address Pool dialog box is used to add and edit these address pools. Refer to Address Pool Dialog Box, page 22-18 for descriptions of the fields displayed in the Global Address Pools table on this page.

Navigation Path

- (Device view) Select NAT > Address Pools from the Device Policy selector.
- (Policy view) Select NAT (PIX/ASA/FWSM) > Address Pools from the Policy Type selector. Select an existing policy from the Shared Policy selector, or right-click Address Pools to create a new policy.

Related Topics

- Configuring NAT on PIX, FWSM, and pre-8.3 ASA Devices, page 22-18

Address Pool Dialog Box

Use the Address Pool dialog box to add or edit a global address pool for use in dynamic NAT rules.

Navigation Path

You open the Address Pool dialog box by clicking the Add Row or Edit Row buttons on the Address Pools, page 22-18.

Related Topics

- Configuring NAT on PIX, FWSM, and pre-8.3 ASA Devices, page 22-18
**Field Reference**

**Table 22-6 Address Pools Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Name</td>
<td>Enter or Select the name of the device interface on which the mapped IP addresses will be used.</td>
</tr>
<tr>
<td>Pool ID</td>
<td>Enter a unique identification number for this address pool, an integer between 1 and 2147483647. When configurring a dynamic NAT rule, you select a Pool ID to specify the pool of addresses to be used for translation.</td>
</tr>
</tbody>
</table>
| IP address ranges| Enter or Select the addresses to be assigned to this address pool. You can specify these addresses as follows:  
  - Address range for dynamic NAT (e.g., 192.168.1.1-192.168.1.15)  
  - Subnetwork (e.g., 192.168.1.0/24)  
  - List of addresses separated by commas (e.g., 192.168.1.1, 192.168.1.2, 192.168.1.3)  
  - Single address to use for PAT (e.g., 192.168.1.1)  
  - Combinations of the above (e.g., 192.168.1.1-192.168.1.15, 192.168.1.25)  
  - Names of hosts on the connected network; these will be resolved to IP addresses. |
| Description      | Enter a description for the address pool.                                   |
| Enable Interface PAT | When checked, port address translation is enabled on the specified interface. |

**Translation Rules: PIX, FWSM, and pre-8.3 ASA**

Use the Translation Rules page to define network address translation (NAT) rules on the selected device. The Translation Rules page consists of the following tabs:

- **Translation Exemptions (NAT 0 ACL), page 22-20** – Use this tab to configure rules specifying traffic that is exempt from address translation.

  **Note** Translation exemptions are only supported by PIX, ASA and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules.

- **Dynamic Rules Tab, page 22-22** – Use this tab to configure dynamic NAT and PAT rules.

  **Note** Dynamic translation rules are only supported by PIX, ASA and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules.
- **Policy Dynamic Rules Tab, page 22-24** – Use this tab to configure dynamic translation rules based on source and destination addresses and services.
  
  **Note**  
  Policy dynamic rules are only supported by PIX, ASA and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules.

- **Static Rules Tab, page 22-26** – Use this tab to configure static translation rules for a security appliance or shared policy.

- **General Tab, page 22-31** – Use this tab to view all current translation rules, listed in the order that they will be evaluated on the device.
  
  **Note**  
  The General tab is visible only for PIX, ASA and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules and do not need to display summary information.

**Navigation Path**
To access the Translation Rules page, do one of the following:

- (Device view) Select **NAT > Translation Rules** from the Device Policy selector.
- (Policy view) Select **NAT (PIX/ASA/FWSM) > Translation Rules** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or right-click **Translation Rules** to create a new policy.

**Translation Exemptions (NAT 0 ACL)**

Use the Translation Exemptions (NAT 0 ACL) tab of the Translation Rules page to view and specify rules that exempt traffic from address translation. Rules are evaluated sequentially in the order listed. The row number indicates the rule’s position in the ordering of the list. You can use the Up Row and Down Row buttons to change the position of the selected rule.

The Add/Edit Translation Exemption (NAT-0 ACL) Rule dialog box is used to add and edit these rules. Refer to **Add/Edit Translation Exemption (NAT-0 ACL) Rule Dialog Box, page 22-21** for descriptions of the fields displayed in the table on this page.

**Note**  
Translation exemptions are only supported by PIX, ASA and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules.

**Navigation Path**
You can access the Translation Exemptions (NAT 0 ACL) tab from the **Translation Rules: PIX, FWSM, and pre-8.3 ASA, page 22-19** page.

**Related Topics**

Field Reference

| Table 22-7 Add/Edit Translation Exemption (NAT-0 ACL) Rule Dialog Box |
|-----------------------------|------------------|
| **Element**                | **Description**  |
| Enable Rule                | If checked, the rule is enabled. Deselect this option to disable the rule without deleting it. |
| Action                     | Select the action for this rule: |
|                            | • exempt – The rule identifies traffic that is exempt from NAT. |
|                            | • do not exempt – The rule identifies traffic that is not exempt from NAT. |
| Original: Interface        | Enter the name of (or Select) the device interface to which the rule applies. |
| Original: Sources          | Enter IP addresses for (or Select) the source hosts and network objects to which the rule applies. Multiple entries must be separated by commas. Note that this parameter is displayed in the Translation Exemptions (NAT 0 ACL) table under the column heading “Original Address.” |
| Translated: Direction      | The rule can be applied to Inbound or Outbound traffic, as specified with this option. |
| Traffic flow: Destinations | Enter IP addresses for (or Select) the destination hosts and network objects to which the rule applies. Multiple entries must be separated by commas. |
| Category                   | To assign the rule to a category, choose the category from this list. Categories can help identify rules and objects using labels and color-coding. See Using Category Objects, page 6-11 for more information. |
| Note                       | No commands are generated for the Category attribute. |
Chapter 22  Configuring Network Address Translation

NAT Policies on Security Devices

Dynamic Rules Tab

Use the Dynamic Rules tab of the Translation Rules page to view and configure dynamic NAT and PAT rules. Rules are evaluated sequentially in the order listed. The row number indicates the rule’s position in the ordering of the list. You can use the Up Row and Down Row buttons to change the position of the selected rule.

With dynamic NAT, internal IP addresses are dynamically translated using IP addresses from a pool of global addresses. With dynamic PAT, internal IP addresses are translated to a single mapped address by using dynamically assigned port numbers with the mapped address. Dynamic translations are often used to map local RFC 1918 IP addresses to addresses that are Internet-routable.

The Add/Edit Dynamic Translation Rule dialog box is used to add and edit these rules. Refer to Add/Edit Dynamic Translation Rule Dialog Box, page 22-23 for descriptions of the fields displayed in the table on this page.

Note

Dynamic translation rules are only supported by PIX, ASA and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules.

Navigation Path

You can access the Dynamic Rules tab from the Translation Rules page. For more information about the Translation Rules page, see Translation Rules: PIX, FWSM, and pre-8.3 ASA, page 22-19.

Note

By default, only standard Dynamic Rule elements are displayed in this table. Additional columns for elements defined in the Advanced NAT Options dialog box can be displayed by right-clicking any column heading. (All columns are displayed by default on the General Tab, page 22-31.)

Policy Dynamic Rules Tab

Use the Policy Dynamic Rules tab of the Translation Rules page to view and configure dynamic translation rules based on source and destination addresses and services. Rules are evaluated sequentially in the order listed. The row number indicates the rule’s position in the ordering of the list. You can use the Up Row and Down Row buttons to change the position of the selected rule.

The Add/Edit Policy Dynamic Rule dialog box is used to add and edit these rules. Refer to Add/Edit Policy Dynamic Rules Dialog Box, page 22-25 for a description of the fields displayed in the table on this page.

Note
Policy dynamic rules are only supported by PIX, ASA and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules.

Navigation Path

You can access the Policy Dynamic Rules tab from the Translation Rules page. See Translation Rules: PIX, FWSM, and pre-8.3 ASA, page 22-19 for more information.

Note
By default, only standard Policy Dynamic Rule elements are displayed in this table. Additional columns for elements defined in the Advanced NAT Options dialog box can be displayed by right-clicking any column heading. (All columns are displayed by default on the General Tab, page 22-31.)

</table>
Static Rules Tab

Use the Static Rules tab of the Translation Rules page to view and configure static translation rules for a security appliance or shared policy. Rules are evaluated sequentially in the order listed. The row number indicates the rule’s position in the ordering of the list. You can use the Up Row and Down Row buttons to change the position of the selected rule.

With static translation, internal IP addresses are permanently mapped to a global IP address. These rules map a host address on a lower security-level interface to a global address on a higher security-level interface. For example, a static rule would be used for mapping the local address of a web server on a perimeter network to a global address that hosts on the outside interface would use to access the web server.

---

Caution

The order of Static NAT rules on a security device is important, and Security Manager preserves this ordering during deployment. However, security appliances do not support in-line editing of Static NAT rules. This means that if you move, edit, or insert a rule anywhere above the end of the list, Security Manager will remove from the device all Static NAT rules that follow the new or modified rule, and then re-send the updated list from that point. Depending on the length of the list, this can require substantial overhead, and may result in traffic interruption. Whenever possible, add any new Static NAT rules to the end of the list.

---

The Add/Edit Static Rule dialog box is used to add and edit these rules. Refer to Add/Edit Static Rule Dialog Box, page 22-27 for descriptions of the fields displayed in the table on this page.

The "Nailed" Column in the Static Rules Table

In addition to the columns representing parameters specified in the Add/Edit Static Rule Dialog Box, page 22-27, the Static Rules table displays a column labeled “Nailed.” This value is a product of device discovery; it cannot be changed in Security Manager.

The entry in the “Nailed” Column indicates whether TCP state tracking and sequence checking is skipped for the connection: true or false.

---

Navigation Path

You can access the Static Rules tab from the Translation Rules page. See Translation Rules: PIX, FWSM, and pre-8.3 ASA, page 22-19 for more information.

---

Note

By default, only standard Static Rules elements are displayed in this table. Additional columns for elements defined in the Advanced NAT Options dialog box can be displayed by right-clicking any column heading. (All columns are displayed by default on the General Tab, page 22-31.)

Chapter 22      Configuring Network Address Translation

NAT Policies on Security Devices

Edit Translated Address Dialog Box

Use the Edit Translated Address dialog box to change just the translated address assigned to a static translation rule. The translated address is the address to which the original address is changed. The interface’s IP address can be used, or you can enter a specific IP address. See Static Rules Tab, page 22-26 for more information about static rules and translated addresses.

For detailed information on editing firewall rules cells, see Editing Rules, page 12-9.
**Navigation Path**

Right-click the Translated Address cell in the Static Rules table (on the NAT > Translation Rules page) and choose **Edit Translated Address**.

**Advanced NAT Options Dialog Box**

Use the Advanced NAT Options dialog box to configure the advanced connection settings—DNS Rewrite, Maximum TCP and Maximum UDP Connections, Embryonic Limit, Timeout (PIX 6.x), and Randomize Sequence Number—for NAT and Policy NAT. You can also configure these options for Translation Exemption (NAT 0 ACL) rules on an FWSM.

**Navigation Path**

You can access the Advanced NAT Options dialog box by clicking the **Advanced** button when adding or editing a translation rule. See the following topics for more information:

- Add/Edit Translation Exemption (NAT-0 ACL) Rule Dialog Box, page 22-21
- Add/Edit Dynamic Translation Rule Dialog Box, page 22-23
- Add/Edit Policy Dynamic Rules Dialog Box, page 22-25

**Field Reference**

**Table 22-12 Advanced NAT Options Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Translate the DNS replies that match the translation rule</td>
<td>If checked, the security appliance rewrites DNS replies so an outside client can resolve the name of an inside host using an inside DNS server, and vice versa. For instance, if your NAT rule includes the real address of a host with an entry in a DNS server, and the DNS server is on a different interface from a client, then the client and the DNS server need different addresses for the host: one needs the mapped address and one needs the real address. This option rewrites the address in the DNS reply to the client. As an example, assume an inside web server, <a href="http://www.example.com">www.example.com</a>, has the IP address 192.168.1.1, which is translated to 10.1.1.1 on the outside interface of the appliance. An outside client sends a DNS request to an inside DNS server, which will resolve <a href="http://www.example.com">www.example.com</a> to 192.168.1.1. When the reply comes to the security appliance with DNS Rewrite enabled, the security appliance will translate the IP address in the payload to 10.1.1.1, so that the outside client will get the correct IP address. Note that the mapped host needs to be on the same interface as either the client or the DNS server. Typically, hosts that need to allow access from other interfaces use a static translation, so this option is more likely to be used with a static rule.</td>
</tr>
</tbody>
</table>
Chapter 22  Configuring Network Address Translation

NAT Policies on Security Devices

Max TCP Connections per Rule

Enter the maximum number of TCP connections allowed; valid values are 0 through 65,535. If this value is set to zero, the number of connections is unlimited.

Max UDP Connections per Rule

Enter the maximum number of UDP connections allowed; valid values are 0 through 65,535. If this value is set to zero, the number of connections is unlimited.

Max Embryonic Connections

Enter the number of embryonic connections allowed to form before the security appliance begins to deny these connections. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. Set this limit to prevent attack by a flood of embryonic connections. Valid values are 0 through 65,535. If this value is set to zero, the number of connections is unlimited.

Any positive value enables the TCP Intercept feature. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP Intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help to minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server.

Timeout

For PIX 6.x devices, enter a timeout value for this translation rule, in the format hh:mm:ss. This value overrides the default translation timeout specified in Platform > Security > Timeouts, unless this value is 00:00:00, in which case translations matching this rule use the default translation timeout (specified in Platform > Security > Timeouts).

Randomize Sequence Number

If checked, the security appliance randomizes the sequence numbers of TCP packets. Each TCP connection has two Initial Sequence Numbers (ISNs): one generated by the client and one generated by the server. The security appliance randomizes the ISN of the TCP SYN in both the inbound and outbound directions. Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session.

Disable this feature only if:

- Another in-line security appliance is also randomizing initial sequence numbers and data is being scrambled.
- You are using eBGP multi-hop through the security appliance, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- You are using a WAAS device which requires that the security appliance not randomize the sequence numbers of connections.

Disabling this option opens a security hole in the security appliance.

</tbody>
</table>
General Tab

Use the General tab of the Translation Rules page to view a summary of all translation rules defined for the current device or shared policy. The translation rules are listed in the order that they will be evaluated on the device.

Note
The General tab is only visible for PIX, ASA, and FWSM devices in router mode, and FWSM 3.2 devices in transparent mode. Other devices in transparent mode support only static translation rules and do not need to display summary information.

Navigation Path
You can access the General tab from the Translation Rules page. See Translation Rules: PIX, FWSM, and pre-8.3 ASA, page 22-19 for more information.

</tr>
</tbody>
</table>
Configuring NAT on ASA 8.3+ Devices

The following section describes configuring network address translation on version 8.3 or later ASA devices:

- Translation Rules: ASA 8.3+, page 22-33
  - Add and Edit NAT Rule Dialog Boxes, page 22-35
  - Add or Edit Network/Host Dialog Box: NAT Tab, page 22-42

See Configuring NAT on PIX, FWSM, and pre-8.3 ASA Devices, page 22-18 for information about configuring NAT on other security appliances. Refer to About “Simplified” NAT on ASA 8.3+ Devices, page 22-3 for general information about NAT rules, and the changes to NAT configuration implemented on the ASA 8.3.

Translation Rules: ASA 8.3+

Use the Translation Rules page to manage network address translation (NAT) rules on the selected ASA 8.3+ device. See NAT Policies on Security Devices, page 22-15 for information about configuring Translation Rules on other security devices.

Two types of NAT rules are displayed in this table: “manual” rules added by you and any other users, and “automatic” rules generated and applied by Security Manager when an object with NAT properties is assigned to the device. These are referred to as “NAT rules” and “Network Object NAT rules,” respectively.

Some Features of the Translation Rules Table

This Translation Rules table is a standard Security Manager rules table, as described in Using Rules Tables, page 12-7. For example, you can move, show and hide columns; you can re-order the manual rules; and you can right-click certain table cells to edit that parameter. In addition, the following features are specific to this Translation Rules table:

- All rules are assigned to one of three pre-defined sections in the table:
  - NAT Rules Before – These are rules you or another user have “manually” defined on the device. You can specify that a rule be added to this section by clicking the section heading before adding the rule, although if you do not specify a section, the new rule will be added to this section by default.
  - Network Object NAT Rules – These are rules generated and ordered automatically by Security Manager when network objects that include NAT properties are assigned to the device. See Add or Edit Network/Host Dialog Box: NAT Tab, page 22-42 for information about assigning NAT properties to objects. See the section “The NAT Table” in About “Simplified” NAT on ASA 8.3+ Devices, page 22-3 for information about how these rules are ordered.
  - NAT Rules After – These also are rules you or another user have manually defined on the device. You can specify that a rule is added to this section by clicking the section heading before adding the rule.

The NAT rules listed in this table are processed on a first-match basis; therefore, order is important. Providing a manual section both before and after the automatic rules lets you ensure all your rules are in the appropriate order, since you can re-order rules only within their section. The rules in each section take precedence over the rules in the section below it. For example, the rules in the top, “Before” section take precedence over the rules in the Network Object NAT section, and so on.
Chapter 22      Configuring Network Address Translation

- The type of each rule—Static, Dynamic PAT, or Dynamic NAT and PAT— is indicated visually in the table by presenting (S), (DP), or (DNP) in blue following the Source parameter in the “Translated” column.

- A Bi-directional rule is a static rule that actually consists of two paired rules, one each for outgoing and incoming translation of the specified source and destination values. Each Bi-directional rule entry in the rules table is presented as two lines.

For example, if Bi-directional is chosen when you create a static rule with Host1 in the Source field and Host2 in the Translated field, two lines are added to the rules table: one with Host1 being translated to Host2, and one with Host2 being translated to Host1.

Related Topics
- NAT Policies on Security Devices, page 22-15
- About “Simplified” NAT on ASA 8.3+ Devices, page 22-3
- Standard rules table topics:
  - Using Rules Tables, page 12-7
  - Filtering Tables, page 1-44
  - Table Columns and Column Heading Features, page 1-44

Navigation Path
- (Device view) Select NAT > Translation Rules from the Device Policy selector.
- (Policy view) Select NAT (PIX/ASA/FWSM) > Translation Rules from the Policy Type selector.
  Select an existing policy from the Shared Policy selector, or right-click Translation Rules to create a new policy.

The Translation Rules page is displayed. Note that in Policy View, the Network Object NAT Rules section is not displayed because those rules are device-specific.

Adding, Editing and Deleting Rules
To add a NAT rule:
1. Select the heading of the section to which the rule is to be added. If you do not select a heading, the rule will be added to NAT Rules Before by default.
2. Open the Add NAT Rule dialog box: either click the Add Row button at the bottom of the table, or right-click anywhere in the table (except on an existing rule entry) and choose Add Row from the pop-up menu.
3. Define the rule and then click OK to close the dialog box, adding the rule to the table.

To edit a NAT rule:
1. Open the Edit NAT Rule dialog box for the desired rule: either select the rule in the NAT rules table and then click the Edit Row button at the bottom of the table, or simply right-click the desired rule entry and choose Edit Row from the pop-up menu.
2. Edit the rule and then click OK to close the dialog box.

See Add and Edit NAT Rule Dialog Boxes, page 22-35 for a complete description of the Add NAT Rule dialog box.

To delete a NAT rule, select the rule in the table and click the Delete Row button at the bottom of the table, or simply right-click the desired rule entry and choose Delete Row from the pop-up menu.
To remove a Network Object NAT rule from this table, you must deselect the Add Automatic Address Translation NAT Rule option, or change the device to which the rule is assigned, in the related Edit Network Host dialog box. See Add or Edit Network/Host Dialog Box: NAT Tab, page 22-42 for additional information.

Enabling and Disabling Rules

You can disable one or more consecutive rules without removing them from the table, as follows:

1. Select the rule(s) to be disabled. If selecting a contiguous block of rules, click the first and then Shift-click the last rule of the block.

2. Right-click a selected rule, and choose Disable from the pop-up menu.

Disabled rules are indicated by hatching (a series of slanted lines) over the entire rule entry in the table.

To re-enable one or one or more consecutive disabled rules, repeat this process, choosing Enable from the pop-up menu.

Add and Edit NAT Rule Dialog Boxes

Use the Add NAT Rule dialog box to add a NAT rule to the selected ASA 8.3+ device; this dialog box is not available on earlier-version ASAs, nor on PIX or FWSM devices. Refer to Configuring NAT on PIX, FWSM, and pre-8.3 ASA Devices, page 22-18 for information about adding and editing NAT rules on those devices.

Note

Except for their titles, the Add NAT Rule and Edit NAT Rule dialog boxes are identical, and the following descriptions apply to both.

Navigation Path

To add a rule, select the section to which you want the rule added (NAT Rules Before or NAT Rules After), and then click the Add Row button below the rules table, or right-click anywhere inside the table and choose Add Row to open the Add NAT Rule dialog box. Note that if you do not select a section, the new rule is added to the NAT Rules Before section.

To edit a rule, select the rule and click the Edit Row button, or simply right-click the rule and choose the Edit Row command, to open the Edit NAT Rule dialog box for that rule.

</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>The type of translation rule you are creating:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Static</strong> – Provides static assignment of real addresses to mapped addresses.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Dynamic PAT (Hide)</strong> – Provides dynamic assignment of multiple local addresses to a single global IP address and a unique port number, in effect “hiding” the local addresses behind the one global address.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Dynamic NAT and PAT</strong> – Provides dynamic assignment of real addresses to mapped addresses, and real ports to mapped ports.</td>
</tr>
<tr>
<td></td>
<td>Selecting this option adds the PAT Pool Address Translation options to the dialog box. On devices operating in routed mode, this option also provides the fallthrough option described below.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  This selection applies only to the specified source translation; destination translation is always static.</td>
</tr>
<tr>
<td><strong>Original Source</strong></td>
<td>The source address the NAT rule will translate. If this is a range or network, all addresses in the range or network are translated.</td>
</tr>
<tr>
<td><strong>Address Interface</strong></td>
<td>Whether the translation is based on an address or an interface on the device. Select either:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Address</strong> – Translate the original address using the networks/hosts (or networks/hosts objects) specified in the Translated Source field.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Interface</strong> – Translate the original address based on the interface specified in the Translated Source field.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  These options are not available when Dynamic NAT and PAT is the selected Type, nor are they available on devices operating in transparent mode.</td>
</tr>
<tr>
<td><strong>Translated Source</strong></td>
<td>If Address is selected above, this entry represents the pool of translation addresses: enter or Select the desired Networks/Hosts; defaults to the Original Source (which will produce an Identity NAT rule).</td>
</tr>
<tr>
<td></td>
<td>If Interface is selected above, enter or Select the desired interface. The Interface Selector list contains all interfaces currently defined on the device. For port address translation based on this interface, be sure to configure the options in the Service Translation section (in the Advanced panel of this dialog box).</td>
</tr>
<tr>
<td></td>
<td>If you leave the Interface field blank, the Address/Interface selection reverts to Address and the Original Source is inserted into the Address field. This produces an Identity NAT rule, meaning the specified address(es) are translated to themselves (effectively not translated); Identity NAT applies to outbound connections only.</td>
</tr>
</tbody>
</table>
This option is available when Dynamic NAT and PAT is the selected Type. The related parameters let you specify a “pool” of IP addresses to be used for specifically for port address translation, as well as change the algorithm used for PAT mapping. Refer to PAT Pools and Round Robin Allocation, page 22-41 for additional information about these features.

Check the PAT Pool Address Translation box to enable the following options:

- **Address or Interface** – Select Address to indicate that the PAT Pool Address field contains networks/hosts (or networks/hosts objects) for use as the PAT pool. Select Interface to provide a Fallthrough Interface.

- **PAT Pool Address** – Enter or Select the desired Networks/Hosts or desired Interface according to your Address or Interface selection above.

- **Use Round Robin Allocation for PAT Pool** – Check this box to map addresses/ports using a “round-robin” approach. See PAT Pools and Round Robin Allocation, page 22-41 for more information about this option.

- **Extended PAT Table** (Available for ASA 8.4(3) and later, not including 8.5(1) or 8.6(1)) - Check this box to enable extended PAT. Extended PAT uses 65535 ports per service, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. This option is available for ASA 8.4(3) and later, not including 8.5(1) or 8.6(1).

- **Flat Port Range** (Available for ASA 8.4(3) and later, not including 8.5(1) or 8.6(1)) - Check this box to enable use of the entire 1024 to 65535 port range when allocating ports. When choosing the mapped port number for a translation, the ASA uses the real source port number if it is available. However, without this option, if the real port is not available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also select **Include Reserve Ports**.

- **Include Reserve Ports** (Available for ASA 8.4(3) and later, not including 8.5(1) or 8.6(1)) - Check this box to include the reserve ports, 1-1023, in the PAT range.

Click the Advanced header to expand the dialog box and display the following Advanced options. Click the header again to hide the Advanced panel.

</tr>
<tr>
<td></td>
<td>These service objects represent a service protocol (TCP or UDP), and one or more ports. The mapping of original ports to translated port is circular. That is, the first original value is mapped to the first translated value, and the second original value is mapped to the second translated value, and so on until all original values are translated. If the pool of translated port is exhausted before that point, mapping continues using the first translated value again. See Understanding and Specifying Services and Service and Port List Objects, page 6-79 for information about configuring service objects.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Service Translation and the following Translate DNS replies that match this rule option cannot be used together.</td>
</tr>
</tbody>
</table>
Interface Translation

Use the options in this section of the Advanced panel to configure interface translation options:

- **Translate DNS replies that match this rule** – When checked, addresses embedded in DNS replies that match this rule are rewritten.
  
  For DNS replies traversing from a mapped interface to a real interface, the Address (or “A”) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the A record is rewritten from the real value to the mapped value. Note that DNS inspection must be enabled to support this functionality.

- **Source Interface** – The name of the interface on which a packet may originate; this is the “real” interface. Defaults to “any,” which represents all interfaces. Enter or Select the desired interface.

- **Destination Interface** – The name of the interface on which a packet may terminate; this is the “mapped” interface. Defaults to “any,” which represents all interfaces. Enter or Select the desired interface.

- **Fallthrough to Interface PAT** (Destination Interface) – When checked, dynamic PAT back-up is enabled. When the pool of dynamic NAT addresses is depleted, port address translation is performed, using the address pool specified in the Use Address field. This option is available only when Dynamic NAT and PAT is the chosen Type on devices operating in routed mode.
Chapter 22  Configuring Network Address Translation

Others Use the options in this section of the Advanced panel to configure other NAT rule options.

Note These options are available only when Static is the chosen rule Type.

- **Direction** – This feature lets you configure a static NAT rule in a single direction only; or dual rules, one each for both directions (forward and reverse). Choose either:

  - **Uni-directional** – A single static NAT is created, as specified by the other options in this dialog box. Dynamic rules are uni-directional by default.

  - **Bidirectional** – Two linked static NAT rules are created, encompassing both directions of the translation, as specified by the other options in this dialog box. Note that each bi-directional rule entry in the rules table consists of two lines.

- **Do not proxy ARP on Destination Interface** – Check this box to disable proxy ARP on the specified Destination Interface.

  Note This option is available on ASA 8.4.2+ devices, only when Bidirectional is the chosen Direction.

  By default, all NAT rules include proxy ARP on the egress interface. A NAT Exempt rule is used to bypass NAT for both ingress and egress traffic, relying on route look-up to locate the egress interface. Thus, Proxy ARP should be disabled for NAT Exempt rules. (The NAT Exempt rules always take priority and appear above all other NAT rules in the Translation Rules table.)

  Note You also can disable Proxy ARP on individual interfaces, as described in Configuring No Proxy ARP, page 53-1.

- **Perform route lookup for Destination Interface** – If this option is selected, the egress interface is determined using route look-up instead of using the specified Destination Interface. Be sure this box is checked for a NAT Exempt rule.

  Note This option is available on ASA 8.4.2+ devices, only when Bidirectional is the chosen Direction. The option is not available on devices operating in transparent mode.

Chapter 22      Configuring Network Address Translation

NAT Policies on Security Devices

PAT Pools and Round Robin Allocation

Adaptive Security Appliances, version 8.4.2 and later, include two features that let you alter how port address translation (PAT) occurs: you can explicitly define a pool of IP addresses specifically for PAT, and you can select a “round robin” algorithm for port allocation during PAT.

These features simplify configuration of large numbers of PAT addresses, and help prevent a large number of connections from a single PAT address, which can appear to be part of a DoS attack.

Explicit PAT Pool Definition

Prior to version 8.4.2, when you defined a Dynamic NAT and PAT rule, you provided a “pool” of IP addresses (in the Translated Source field of the Add/Edit NAT Rule dialog boxes) to be used for translation. This pool could consist of individual IP addresses, ranges of addresses, Networks/Hosts objects, or Network/Host group objects, and combinations thereof.

Ranges and objects with more than one IP address were considered to be in the “NAT Pool,” while individual IP addresses and group objects consisting of one or more individual addresses were considered to be part of the “PAT Pool.”

Address translation on the device would work its way through the NAT Pool until all available addresses were exhausted. Port address translation would then begin using the PAT Pool—assigning ports on the first IP address in the PAT Pool until all ports (approximately 64,000) are assigned, then assigning ports on the next address in the pool, and so on. When all ports are fully subscribed on all IP addresses in the PAT Pool, no further translation could occur.

On version 8.4.2 and later ASA devices, you can explicitly define a separate PAT Pool for a Dynamic NAT and PAT rule. If you do so, the first collection of addresses (defined in the Translated Source field) is considered the NAT Pool, while the PAT Pool addresses are specified in the PAT Pool Address Translation field.

If you do not explicitly specify a PAT Pool, address translation takes place as described for pre-8.4.2 devices.

Refer to Add and Edit NAT Rule Dialog Boxes, page 22-35 for more information about the defining translation rules.

Round Robin Port Assignment

On version 8.4.2 and later ASA devices, you also can specify an alternate method of port assignment during PAT processing. As mentioned earlier, PAT port numbers are assigned to a single IP address in succession until the final port number is assigned, and then the process begins again with the next available IP address in the pool.

However, a new parameter on 8.4.2 and later devices—Use Round Robin Allocation for PAT Pool—lets you specify “round robin” cycling through available IP addresses and port numbers. This method assigns an address/port combination using each successive address in the pool; it then uses the first address again with a different port, proceeds to the second address again, and so on.

Further, the round-robin algorithm incorporates two additional principles it will attempt to adhere to when assigning address/port combinations during PAT processing:

- If a specific source-to-destination mapping already exists, the algorithm attempts to use the existing translation for the new connection. If this is not possible (for example, when all ports for that IP address have been exhausted), the algorithm proceeds with standard round-robin cycling.
• If possible, the original source port number is used as the mapped port number. That is, if the port number of the address/port combination to be translated is 4904, for example, and 4904 is available with the next IP address in the PAT Pool, the translated address will be PAT_address/4904. Note if this is not possible (that ports not available with the next PAT address), the algorithm proceeds with standard round-robin cycling.

Note
If you do not explicitly specify Round Robin Allocation, port-allocation cycling occurs as described for pre-8.4.2 devices.

Add or Edit Network/Host Dialog Box: NAT Tab

Use the NAT tab in any of the dialog boxes used to add or edit host, network, or address range objects to create or update object NAT rules. This NAT configuration is used only for ASA 8.3+ devices; if you use the object on any other type of device, the NAT configuration is ignored.

The NAT configuration is created as a device override and is not kept in the global object. Therefore, you must select the Allow Value Override per Device option if you configure these NAT options. (This option is selected automatically when you close the dialog box.)

This topic describes the fields on the NAT tab. For information about the fields on the General tab, see Add or Edit Network/Host Dialog Box (IPv4 or IPv6), page 6-73.

Navigation Path
Select the NAT tab on the Add or Edit Network/Host Dialog Box (IPv4 or IPv6) when creating or editing a host, network, or address range object.

PART 3

VPN Configuration
Managing Site-to-Site VPNs: The Basics

A virtual private network (VPN) consists of multiple remote peers transmitting private data securely to one another over an unsecured network, such as the Internet. Site-to-site VPNs use tunnels to encapsulate data packets within normal IP packets for forwarding over IP-based networks, using encryption to ensure privacy and authentication to ensure integrity of data.

In Cisco Security Manager, site-to-site VPNs are implemented based on IPsec policies that are assigned to VPN topologies. An IPsec policy is a set of parameters that define the characteristics of the site-to-site VPN, such as the security protocols and algorithms that will be used to secure traffic in an IPsec tunnel. Security Manager translates IPsec policies into CLI commands that can be deployed to the devices in the VPN topology. Several policy types might be required to define a full configuration image that can be assigned to a VPN topology, depending on the IPsec technology type.

The Site-to-Site VPN Manager defines and configures site-to-site VPN topologies and policies on Cisco IOS security routers, PIX Firewalls, Catalyst VPN Service Modules, and Adaptive Security Appliance (ASA) firewall devices.

Tip

In ASA documentation, site-to-site VPNs are called LAN-to-LAN VPNs. These phrases are equivalent, and we use “site-to-site VPN” in this documentation.

You can access the Site-to-Site VPN Manager by selecting Manage > Site-To-Site VPNs or clicking the Site-To-Site VPN Manager button on the toolbar.

You can also configure shared policies in Policy view and view and configure topologies in Device view. In Policy View, you can assign IPsec policies to VPN topologies.

This chapter contains the following topics:

- Understanding VPN Topologies, page 23-2
- Understanding IPsec Technologies and Policies, page 23-5

- Deleting a VPN Topology, page 23-66
Understanding VPN Topologies

A VPN topology specifies the peers and the networks that are part of the VPN and how they connect to one another. After you create a VPN topology, the policies that can be applied to your VPN topology become available for configuration, depending on the assigned IPsec technology.

Security Manager supports three main types of topologies—hub and spoke, point to point, and full mesh, with which you can create a site-to-site VPN. Not all policies can be applied to all VPN topologies. The policies that can be applied depend on the IPsec technology that is assigned to the VPN topology. In addition, the IPsec technology that is assigned to a VPN depends on the topology type. For example, the DMVPN and Easy VPN technologies can only be applied in a hub-and-spoke topology.

For more information, see Understanding IPsec Technologies and Policies, page 23-5.

The following topics describe:
- Hub-and-Spoke VPN Topologies, page 23-2
- Point-to-Point VPN Topologies, page 23-3
- Full Mesh VPN Topologies, page 23-4
- Implicitly Supported Topologies, page 23-5

Hub-and-Spoke VPN Topologies

In a hub-and-spoke VPN topology, multiple remote devices (spokes) communicate securely with a central device (hub). A separate, secured tunnel extends between the hub and each individual spoke.

The following illustration shows a typical hub-and-spoke VPN topology.

*Figure 23-1  Hub-and-Spoke VPN Topology*

This topology usually represents an intranet VPN that connects an enterprise’s main office with branch offices using persistent connections to a third-party network or the Internet. VPNs in a hub-and-spoke topology provide all employees with full access to the enterprise network, regardless of the size, number, or location of its remote operations.
A hub is generally located at an enterprise’s main office. Spoke devices are generally located at an enterprise’s branch offices. In a hub-and-spoke topology, most traffic is initiated by hosts at the spoke site, but some traffic might be initiated from the central site to the spokes.

If the hub in a hub-and-spoke configuration becomes unavailable for any reason, IPsec failover transfers tunnel connections seamlessly to a failover (backup) hub, which is used by all spokes. You can configure multiple failover hubs for a single primary hub.

In a hub-and-spoke VPN topology, all IPsec technology types can be assigned except GET VPN.

Related Topics

- Understanding IPsec Technologies and Policies, page 23-5
- Implicitly Supported Topologies, page 23-5
- Creating or Editing VPN Topologies, page 23-28
- Chapter 24, “Configuring IKE and IPsec Policies”

Point-to-Point VPN Topologies

In a point-to-point VPN topology, two devices communicate directly with each other, without the option of IPsec failover as in a hub-and-spoke configuration. To establish a point-to-point VPN topology, you specify two endpoints as peer devices. Because either of the two devices can initiate the connection, the assigned IPsec technology type can be only regular IPsec or IPsec/GRE.

In Security Manager, you can configure a special type of regular IPsec point-to-point VPN called an Extranet. An Extranet VPN is a connection between a device in your managed network and an unmanaged device, such as a router in your service provider’s network, a non-Cisco device, or simply a device in your network that is being managed by a different group (that is, one that does not appear in the Security Manager inventory).

The following illustration shows a typical point-to-point VPN topology.

Figure 23-2    Point-to-Point VPN Topology

- Chapter 24, “Configuring IKE and IPsec Policies”
Full Mesh VPN Topologies

A full mesh topology works well in a complicated network where all peers need to communicate with each other. In this topology type, every device in the network communicates with every other device through a unique IPsec tunnel. All devices have direct peer relationships with one another, preventing a bottleneck at the VPN gateway device, and saving the overhead of encryption and decryption on the device.

You can assign only Regular IPsec, IPsec/GRE, and GET VPN technologies to a full mesh VPN topology.

The following illustration shows a typical full mesh VPN topology.

Figure 23-3 Full Mesh VPN Topology

A full mesh network is reliable and offers redundancy. When the assigned technology is GRE and one device (or node) can no longer operate, all the rest can still communicate with one another, directly or through one or more intermediate nodes. With regular IPsec, if one device can no longer operate, a crypto access control list (ACL) that specifies the protected networks, is created per two peers.

GET VPN is based on the group trust model. In this model, group members register with a key server. The key server uses the Group Domain of Interpretation (GDOI) protocol for distributing the security policy and keys for encrypting traffic between the group members. Because you can configure a primary key server and secondary key servers that synchronize their policies with the primary one, if the primary key server becomes unavailable, a secondary key server can take over.

Note

When the number of nodes in a full mesh topology increases, scalability may become an issue—the limiting factor being the number of tunnels that the devices can support at a reasonable CPU utilization.
Implicitly Supported Topologies

In addition to the three main VPN topologies, other more complex topologies can be created as combinations of these topologies. They include:

- Partial mesh—A network in which some devices are organized in a full mesh topology, and other devices form either a hub-and-spoke or a point-to-point connection to some of the fully meshed devices. A partial mesh does not provide the level of redundancy of a full mesh topology, but it is less expensive to implement. Partial mesh topologies are generally used in peripheral networks that connect to a fully meshed backbone.

- Tiered hub-and-spoke—A network of hub-and-spoke topologies in which a device can behave as a hub in one or more topologies and a spoke in other topologies. Traffic is permitted from spoke groups to their most immediate hub.

- Joined hub-and-spoke—A combination of two topologies (hub-and-spoke, point-to-point, or full mesh) that connect to form a point-to-point tunnel. For example, a joined hub-and-spoke topology could comprise two hub-and-spoke topologies, with the hubs acting as peer devices in a point-to-point topology.

Understanding IPsec Technologies and Policies

Security Manager provides seven types of IPsec technologies that you can configure on the devices in your site-to-site VPN topology—Regular IPsec, IPsec/GRE, GRE Dynamic IP, standard and large scale DMVPN, Easy VPN, and GET VPN. The assigned technology determines which policies you can configure for the VPN.

You assign an IPsec technology to a VPN topology during its creation. After an IPsec technology is assigned to a VPN topology, you cannot change the technology, other than by deleting the VPN topology and creating a new one. See Defining the Name and IPsec Technology of a VPN Topology, page 23-30.

The following topics explain some basic concepts about IPsec technologies and site-to-site VPN policies:

- Understanding Mandatory and Optional Policies for Site-to-Site VPNs, page 23-6
- Overview of Site-to-Site VPN Policies, page 23-8
- Understanding Devices Supported by Each IPsec Technology, page 23-9
Understanding Mandatory and Optional Policies for Site-to-Site VPNs

Some site-to-site VPN policies are mandatory, which means that you must configure them to create a VPN topology or to save your changes when editing them. Most mandatory policies have predefined defaults, which you can use to complete the definition of a VPN topology, but you typically must edit the policies to ensure their settings work for your network.

Optional policies, which you need to configure only if you desire the services defined by the policy, do not come with predefined defaults.

You can configure your own mandatory policy defaults by creating shared policies that specify the desired settings, and then by selecting these shared policies when creating a VPN. You can even make the shared policies the defaults for the Create VPN wizard. However, these default policies do not apply when you create Extranet VPNs; with Extranet VPNs, you must always configure the settings for mandatory policies as part of the normal wizard flow. In addition, you cannot create a default policy for IKEv2 Authentication. For more information, see Understanding and Configuring VPN Default Policies, page 23-12.

Some mandatory policies are mandatory only under certain conditions. For example, an IKEv1 preshared key policy is mandatory only if the default (mandatory) IKEv1 proposal uses preshared key authentication. If the selected IKE authentication method is Certificate (RSA Signature), an IKEv1 Public Key Infrastructure policy is mandatory (see Deciding Which Authentication Method to Use, page 24-8). If you allow IKEv2 negotiations in the topology, an IKEv2 Authentication policy is mandatory.

The following table lists the mandatory and optional policies for each predefined technology that you can assign to the devices in your site-to-site VPN topology.

Overview of Site-to-Site VPN Policies

You can access site-to-site VPN policies by selecting Manage > Site-To-Site VPNs, or by clicking the Site-To-Site VPN Manager button on the toolbar, and then selecting the required policy in the Policies selector of the Site-to-Site VPN window. You can also access site-to-site VPN policies from Device view or Policy view. For more information, see Accessing Site-to-Site VPN Topologies and Policies, page 23-17.

The following is a summary of all of the site-to-site VPN policies, some of which you cannot create as shared policies. Note that some of these policies are documented in the sections that explain remote access VPNs, because the policies are used for both remote access and site-to-site VPNs. However, you must configure these policies separately for each type of VPN.

- GRE Modes. See Understanding the GRE Modes Page, page 25-1.
- IKEv2 Authentication. See Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59.
- IPsec Proposal. See Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20
Understanding Devices Supported by Each IPsec Technology

Each IPsec technology supports different devices as members of their topology. The following table describes the basic device support. These requirements are enforced when you select devices for a VPN; in some cases, the device lists are filtered to show only supported devices. In other cases, a device might be supported in one role (for example, as a spoke), but not supported in another role; in these cases, you can select the wrong device type, but you are prevented from saving the change (a message will explain the specific problem).

Some device models have NO-VPN versions, which do not support VPN configuration. Thus, although the 3845 model might be supported for a type of VPN, the 3845 NOVPN model is not supported. In addition, the Cisco Catalyst 6500 series ASA Services Module (running software release 8.5(x)) does not support any type of VPN.

<table>
<thead>

<tbody>
<tr>
<td>Dynamic Multipoint VPN (DMVPN), Large Scale DMVPN. See Dynamic Multipoint VPNs (DMVPN), page 25-9 and Configuring Large Scale DMVPNs, page 25-16.</td>
<td>DMVPN configuration is supported on Cisco IOS 12.3T devices and later, and on ASRs running Cisco IOS XE Software 2.x or later (known as 12.2(33)XNA+ in Security Manager). Large Scale DMVPN configuration also supports Catalyst 6500/7600 devices as IPsec Terminators. To use DMVPN phase 3 connections between spokes, devices must run IOS Software release 12.4(6)T or higher; ASRs must run IOS XE Software release 2.4 (called 12.2(33)XND) or higher.</td>
</tr>
<tr>
<td>Easy VPN. See Chapter 26, “Easy VPN”.</td>
<td>The Easy VPN Server can be a Cisco IOS security router (including ASRs), a Catalyst 6500/7600 (with supported VPN service modules or port adapters), a PIX Firewall, or an ASA 5500 series device. The Easy VPN client is supported on PIX 501, 506, 506E Firewalls running PIX 6.3, Cisco 800-3900 Series routers, and ASA 5505 devices running OS version 7.2 or later.</td>
</tr>
</tbody>
</table>
| GET VPN. See Chapter 27, “Group Encrypted Transport (GET) VPNs”. | Key servers can be configured on:  
- Cisco 1800, 2800, 3800 Series ISR, Cisco 7200 Series Routers, and Cisco 7301 Routers running Cisco IOS Software release 12.4(15)T or later.  
- Cisco 1900, 2900, 3900 Series ISR running release 15.0 or later. Group members can be configured on Cisco 1800, 1900, 2800, 2900, 3800, 3900 Series ISR, Cisco 7200 Series Routers, and Cisco 7301 Routers with the same minimum software releases. The Cisco 871 ISR can also be used as a group member if GET VPN is deployed with very few (1-3) IPSec SAs. In addition, you can configure Cisco ASR Routers using Cisco IOS XE Software Release 2.3 (12.2(33)XNC) and above as group members. |

Including Unmanaged or Non-Cisco Devices in a VPN

Your VPN might include devices that you cannot, or should not, manage in Security Manager. These include:

- Cisco devices that Security Manager supports, but for which your organization is not responsible. For example, you might have a VPN that includes spokes in networks managed by other organizations within your company, or a connection to a service provider or partner network.

- Non-Cisco devices. You cannot use Security Manager to create and deploy configurations to non-Cisco devices.

You have two options for handling these kinds of devices:

- If the connection is a regular IPsec point-to-point connection, you can configure the connection as an Extranet VPN as described in Creating or Editing Extranet VPNs, page 23-62.

- For other types of connections, you can include these devices in the Security Manager inventory as “unmanaged” devices. These devices can serve as endpoints in a VPN topology, but Security Manager does not discover any configurations from the device, nor does it deploy configurations to them.

When the Extranet VPN option will not work, you must do the following before you can add an unmanaged device to a VPN topology:

- Manually add the device as an unmanaged device to the device inventory using the procedure described in Adding Devices by Manual Definition, page 3-23. Ensure that you make the following selections:
  - Select a Cisco device type that is comparable to the device you are adding in terms of VPN-supported technologies. The device type controls the types of VPN topologies to which you can add the device. For example, for GRE/DMVPN, you might select an integrated services router such as an 1800 or 2800 series, whereas in Easy VPN you could also select an ASA or PIX device if appropriate.
  - Deselect the Manage in Cisco Security Manager option. This is very important, because the default is to make all new devices managed devices. If you forget to do this while adding the device, you can deselect the option later on the General tab in the device properties (right-click the device and select Device Properties).

- Using the interface policy for the device, define the external VPN interface to which managed devices will point. Because the device is unmanaged, your definitions in this policy are never configured on the device; the policy simply represents what you have configured on the device outside of Security Manager.

Understanding and Configuring VPN Default Policies

For most VPN policies that are mandatory, Security Manager includes “factory default” settings for the policies. These defaults are generic, and might not be appropriate for your network, but they do allow you to complete the creation of a VPN without having to stop and start over when you do not have the needed shared policy configured. Therefore, you can, and should, create your own default VPN policies for mandatory policies. You can also create defaults for certain optional policies.

Before configuring new defaults, consider the types of VPNs you are likely to configure, then review the types of policies for which you can create defaults. Select Tools > Security Manager Administration, then select VPN Policy Defaults from the table of contents. Select the tabs for the desired IPsec technologies to see which policies are available. If a policy is assigned Factory Default, or if this option is available from the drop-down list, the policy is mandatory; other policies are optional. You can also create default policies for remote access VPNs, and for site-to-site endpoint configurations. Click the View Content button next to a selected policy to see the policy definition.

The following procedure explains how to create and use VPN policy defaults.

**Tips**

- When you configure VPN default policies, you are selecting shared policies. Although you can configure only one default per policy per IPsec technology, users can select different shared policies when configuring VPNs. Thus, you might want to configure more than one shared policy that users can select, and configure the most commonly-used policy as the default policy. For more information about how users can select different policies when configuring a VPN, see Assigning Initial Policies (Defaults) to a New VPN Topology, page 23-58.

- Although the IKEv2 Authentication policy is a mandatory policy for topologies that allow IKEv2 negotiations, there are no IKEv2 Authentication factory default settings, and you cannot create IKEv2 Authentication shared policies. Therefore, whenever you allow IKEv2 in a topology, you must manually configure the IKEv2 Authentication policy before the topology is valid.

- The Public Key Infrastructure policy is required for IKEv1 if you configure the IKE Proposal policy to use certificate authentication. However, there are no factory default settings for this policy, so if you intend to use certificate authentication for IKEv1, consider creating default Public Key Infrastructure policies.

- Keep in mind that any change to a shared policy affects all VPNs that are using the policy. This can make it easy to implement across-the-board changes that are required for every VPN. However, after creating the VPN, the user can switch from a shared policy to a local policy, so that any changes to the configuration must be done specifically for the VPN topology. For more information about shared policies, see Managing Shared Policies in Policy View, page 5-47.

- These default policies do not apply when you create Extranet VPNs. With Extranet VPNs, you must always configure the settings for mandatory policies as part of the normal wizard flow.

**Step 1** Create the default policies. All default policies are shared policies.

a. In Policy view (select View > Policy View), select the policy for which you want to configure defaults. The policies are in the Site-to-Site VPN or Remote Access VPN folders.

b. Click the Create a Policy (+) button at the bottom of the shared policy selector, enter a name for the policy, and click OK.

c. Configure the desired settings. Click the Help (?) button in the toolbar to get reference information about the settings available in the selected policy.

d. Repeat the process until you have created at least one shared policy for each policy for which you want to define a default policy.
Step 2 If desired, create defaults for the VPN endpoints. These defaults are interface role objects, which identify the interface names used for VPN connections (for example, GigabitEthernet0/1). Create separate roles for internal and external VPN interfaces.

a. Select Manage > Policy Objects to open the Policy Object Manager Window, page 6-4.

b. Select Interface Roles from the table of contents.

c. Click the New Object (+) button, enter the interface name patterns that identify the most commonly used interfaces for VPN internal or external interfaces in your network, and click OK.

For more information about interface roles and the wildcards you can use to configure them, see Understanding Interface Role Objects, page 6-62 and Creating Interface Role Objects, page 6-63.

Step 3 Submit the policies and policy objects to the database. You will have to resolve any validation errors.

- In non-Workflow mode, select File > Submit.
- In Workflow mode without an activity approver, select Activities > Approve Activity.
- In Workflow mode with an activity approver, select Activities > Submit Activity. You will have to wait for the activity to be approved before you can select the policies and objects as defaults.

Step 4 Select your newly-configured policies and policy objects as VPN policy defaults.

a. Select Tools > Security Manager Administration, and then select VPN Policy Defaults from the table of contents (see VPN Policy Defaults Page, page 11-47).

b. Select the desired tabs, then select the policies you configured from the drop-down lists for each of the mandatory or optional policies for which you configured defaults.

On the S2S Endpoints tab, select the appropriate interface role objects.

c. Click Save to save your defaults.

The next time a user runs the Create VPN wizard, the defaults you selected will be used as the wizard’s defaults. Users can select any other shared policy or interface role to override the default.

Using Device Overrides to Customize VPN Policies

Many VPN policies use Security Manager policy objects in their configuration. Policy objects are containers that allow you to create reusable configurations.

Because a VPN policy applies to every device in a VPN topology, you might need to make modifications to a policy object used in a policy for certain devices within the VPN topology. There might even be situations where you need to make modifications for all devices within a topology. You accomplish these modifications with device-level overrides on the policy objects.

For example, when defining a PKI policy, you need to select a PKI enrollment object. If the hub of your VPN uses a different CA server than the spokes, you must use device-level overrides to specify the CA server used by the hub. Although the PKI policy references a single PKI enrollment object, the actual CA server represented by this object differs for the hub, based on the device-level override you define.

To enable a policy object to be overridden, you must select the Allow Override per Device option in the policy object definition. You can then create device-level overrides. For more information about overriding a VPN policy object at the device level, see the following topics:

- Understanding Policy Object Overrides for Individual Devices, page 6-16
- Allowing a Policy Object to Be Overridden, page 6-16
- Creating or Editing Object Overrides for a Single Device, page 6-17
- Creating or Editing Object Overrides for Multiple Devices At A Time, page 6-17
Understanding VRF-Aware IPsec

One obstacle to successfully deploying peer-to-peer VPNs is the separation of routing tables, and the use of overlapping addresses, which usually results from using private IP addresses in customer networks. The VRF-Aware IPsec feature, which introduces IPsec tunnel mapping to Multiprotocol Label Switching (MPLS) VPNs, solves this problem.

The VRF-Aware IPsec feature enables you to map IPsec tunnels to Virtual Routing Forwarding (VRF) instances, using a single public-facing address. A VRF instance defines the VPN membership of a customer site attached to the Provider Edge (PE) router. A VRF comprises an IP routing table, a derived Cisco Express Forwarding (CEF) table, a set of interfaces that use the forwarding table, and a set of rules and routing protocol parameters that control the information that is included in the routing table. A set of routing and CEF tables is maintained for each VPN customer across the MPLS/VPN network.

Since each VPN has its own routing and forwarding table in the router, any customer or site that belongs to a VPN is provided access only to the set of routes contained within that table. Any PE router maintains a number of routing tables and a global routing table per VPN, which can be used to reach other routers in the provider network. Effectively, a number of virtual routers are created in a single physical router. Across the MPLS core to the other PE routers, this routing separation is maintained by adding unique VPN identifiers, such as the route distinguisher (RD).

Note

VRF-Aware IPsec can also be configured on devices in a remote access VPN. For more information, see Configuring Dynamic VTI/VRF Aware IPsec in Remote Access VPNs (IOS Devices), page 31-7.

In Security Manager, you can configure VRF-Aware IPsec in your hub-and spoke VPN topology, with either a single device providing all functionality (“one-box” solution) or with multiple devices, each providing a part of the functionality (“two-box” solution). The solution of one device providing all the functionality can affect performance by overloading the system, whereas separating the functionality in a two-box solution provides better scaling for each function.

The following topics describe:

- VRF-Aware IPsec One-Box Solution, page 23-14
- VRF-Aware IPsec Two-Box Solution, page 23-15
- Enabling and Disabling VRF on Catalyst Switches and 7600 Devices, page 23-17

For information on configuring VRF-aware IPsec, see Configuring VRF Aware IPsec Settings, page 23-46.

VRF-Aware IPsec One-Box Solution

In the one-box solution, IPsec tunnels terminate on a Cisco IOS router, which serves as the Provider Edge (PE) device. The PE device maps these tunnels to the appropriate MPLS/VPN network and serves as the IPsec Aggregator, by performing IPsec encryption and decryption from the Customer Edge (CE) devices.

Note

The configuration of routing between the PE device and the MPLS cloud is done by Cisco IP Solution Center. See the Cisco IP Solution Center MPLS VPN User Guide.
The following illustration shows the topology of a one-box solution.

**Figure 23-4 VRF-Aware IPsec One-Box Solution**

Related Topics
- Understanding VRF-Aware IPsec, page 23-14
- Configuring VRF Aware IPsec Settings, page 23-46
- Defining the Endpoints and Protected Networks, page 23-33

**VRF-Aware IPsec Two-Box Solution**

In the two-box solution, the PE device does just the MPLS mapping, while a separate IPsec Aggregator device does the IPsec encryption and decryption from the CEs.

>Note

Security Manager fully manages the IPsec Aggregator, including routing to the PE device. The PE device is fully managed by Cisco IP Solution Center. This includes routing between the PE device and the MPLS cloud, and routing from the PE to the IPsec Aggregator. For more information, see the *Cisco IP Solution Center MPLS VPN User Guide*. 
Understanding IPsec Technologies and Policies

Chapter 23  Managing Site-to-Site VPNs: The Basics

The following illustration shows the topology of a two-box solution.

Figure 23-5  VRF-Aware IPsec Two-Box Solution

Using the two-box solution, you configure VRF-Aware IPsec on devices in your VPN topology, as follows:

1. Configure the connection between the IPsec Aggregator and the PE device.

   Create a hub-and-spoke VPN topology and assign an IPsec technology to it. In this topology, the hub is the IPsec Aggregator, and the spokes may be Cisco IOS routers, PIX Firewalls, Catalyst VPN service modules, or Adaptive Security Appliance (ASA) devices. The IPsec Aggregator may be a security router or a Catalyst VPN service module. You then define the VRF parameters (VRF name and unique routing identifier) on the hub.

   **Note**  VRF-Aware IPsec supports the configuration of IPsec, GRE, or Easy VPN technologies on Cisco IOS routers and Catalyst VPN service modules. DMVPN is also supported, but only on Cisco IOS routers.

2. Specify the VRF forwarding interface (or VLAN for a Catalyst VPN service module) between the IPsec Aggregator and the PE device.

3. Define the routing protocol and autonomous system (AS) number to be used between the IPsec Aggregator and the PE. Available routing protocols include BGP, EIGRP, OSPF, RIPv2, and Static Route.

   If the routing protocol defined between the IPsec Aggregator and the PE differs from the routing protocol used for the secured IGP, routing is redistributed to the secured IGP, using this routing protocol and AS number. Routing is also redistributed from the secured IGP to the PE.

   **Note**  Redistributing the routing is only relevant when IPsec/GRE or DMVPN is the selected technology.
Enabling and Disabling VRF on Catalyst Switches and 7600 Devices

Deployment fails when you change the virtual routing and forwarding (VRF) mode on the Catalyst switches and 7600 hub of an existing site-to-site VPN. For example, if you initially configured VRF in the Create VPN wizard and deployed, but later return to the Peers policy and deselect the Enable VRF Settings check box, deployment fails. (This setting is found in the VRF Aware IPSec tab of the Edit Endpoints dialog box; see Configuring VRF Aware IPsec Settings, page 23-46.) Deployment likewise fails if you try to enable VRF on a VPN that was not initially configured with it.

You cannot change the VRF mode on a Catalyst 6500/7600 during VPN operation. This restriction applies only to Catalyst 6500/7600 hubs, not to any other device type.

This restriction does not apply to changes made to the VRF settings themselves. For example, if VRF is configured on the VPN topology, you can return to the Peers policy and change the VRF name or route distinguisher.

If you need to change the VRF mode of a VPN, and you are using Catalyst 6500/7600 devices as hubs, use the following procedure.

**Related topics**
- Understanding VRF-Aware IPsec, page 23-14
- VRF-Aware IPsec One-Box Solution, page 23-14
- VRF-Aware IPsec Two-Box Solution, page 23-15

---

**Step 1**
Delete the VPN topology from Security Manager.

**Step 2**
Deploy your changes.

**Step 3**
Reload (restart) the Catalyst 6500/7600 device.

**Step 4**
Right-click the device in Security Manager and select Discover Policies on Device. Perform a complete policy rediscovery.

**Step 5**
Open the Create VPN wizard and redefine the VPN topology. At this point, you can select a different VRF mode. See Configuring VRF Aware IPsec Settings, page 23-46 and Creating or Editing VPN Topologies, page 23-28.

---

### Accessing Site-to-Site VPN Topologies and Policies

You can use the following methods to access and configure site-to-site VPN topologies and policies:

- **Site-to-Site VPN Manager**—This is the main tool for configuring VPN topologies. You can view a list of all site-to-site VPNs configured in Security Manager and edit their configurations and policies, including device membership. For information on using this tool, see Site-to-Site VPN Manager Window, page 23-18.
• **Site-to-Site VPN policy in Device view**—When you select a device in device view, you can select the Site-to-Site VPN policy in the Policies selector to see a list of all site-to-site VPNs in which the device participates and edit those topologies. You can also create new VPNs, or select a VPN and open the Site-to-Site VPN Manager to edit the policies for the selected VPN. This device view policy is essentially a short-cut into the Site-to-Site VPN Manager. For more information about using this policy, see Configuring VPN Topologies in Device View, page 23-19.

• **Site-to-Site VPN folder in Policy view**—Policy view is used to create shared policies. Many of the site-to-site VPN policies are shareable. Thus, you can configure shared policies that you can assign to more than one VPN topology while configuring the topology in the Site-to-Site VPN Manager. You can configure shared policies as defaults for the Create VPN wizard, as described in Understanding and Configuring VPN Default Policies, page 23-12.

You can also create shared policies from the Site-to-Site VPN Manager window in much the same way you can create them from local policies in Device view, although all sharing commands in the Site-to-Site VPN Manager window are available only on the right-click context menu (when right-clicking a shareable policy).

For more information on creating shared policies in Policy view, see Managing Shared Policies in Policy View, page 5-47.

### Site-to-Site VPN Manager Window

The Site-to-Site VPN Manager lists all site-to-site VPNs configured in Security Manager. The VPNs selector, in the upper left pane of the window, lists all existing VPN topologies (see Understanding VPN Topologies, page 23-2). An icon indicates the type of VPN (hub and spoke, point to point, or full mesh). To view or edit a topology, select it, and its policies are loaded into the policy selector in the lower left pane. Select a policy to see its definition in the right pane.

To open the Site-to-Site VPN Manager, click the **Site-To-Site VPN Manager** button on the toolbar or select **Manage > Site-To-Site VPNs**.

Use the Site-to-Site VPN Manager window to:

• Create, edit, and delete VPN topologies.
  
  - To create a VPN topology, click the **Create VPN Topology** (+) button above the VPN selector and select the type of topology you want to create from the options that are displayed. This action opens the Create VPN Wizard or the Create Extranet VPN wizard. For more information, see Creating or Editing VPN Topologies, page 23-28 or Creating or Editing Extranet VPNs, page 23-62.
  
  - To edit a VPN topology, select it and click the **Edit VPN Topology** (pencil) button, or right-click it and select **Edit**. This opens the Edit VPN or Edit Extranet VPN dialog box, which contains the most of the same pages as the Create VPN wizard in a tabbed layout.
  
  - To delete a VPN topology, select it and click the **Delete VPN Topology** (trash can) icon, or right-click it and select **Delete**. You are asked to confirm the deletion. See Deleting a VPN Topology, page 23-66.

• View detailed information about each VPN topology; select the topology, then select the VPN Summary policy. See Viewing a Summary of a VPN Topology’s Configuration, page 23-59.

• View and configure the endpoints defined for a VPN topology. You can see endpoints on the Endpoints tab or when editing a VPN topology, or by selecting the Peers policy. For GET VPN topologies, there is no Peers policy; instead, use the **Key Servers** and **Group Members** policies to view and configure endpoints. For Extranet VPNs, the endpoints are on the Device Selection tab when editing the VPN, or also in the Peers policy.
• View and edit the policies assigned to a VPN topology, assign shared policies, or create shared policies from existing policies. For information on individual policies, see Overview of Site-to-Site VPN Policies, page 23-8.

The options and methods for configuring shared policies from the Site-to-Site VPN Manager are the same as those from Device view, as explained in the sections under Working with Shared Policies in Device View or the Site-to-Site VPN Manager, page 5-34 and Using the Policy Banner, page 5-35. You can share, assign, unassign, edit assignments, and rename policies, but no VPN policies allow inheritance. To perform these tasks, select the VPN topology, then right-click the desired policy and select the desired command.

You can also use Policy view to configure shared VPN policies.

Configuring VPN Topologies in Device View

Use the Site-to-Site VPN Device view policy to view and edit the site-to-site VPN topologies to which a device belongs, if any. You can edit the VPN policies and change whether the device participates in the topology. You can also create new VPN topologies.

This policy is essentially an access point for the Site-to-Site VPN Manager (see Site-to-Site VPN Manager Window, page 23-18).

To open this policy, in Device view, select the desired device and then select Site-to-Site VPN from the Policy selector.

The VPN topologies table lists all of the site-to-site VPNs to which this device belongs. Information includes the type of VPN, its name, IPSec technology, and description.

• To add a VPN, click the Create VPN Topology button, or right-click in the table and select Create VPN Topology and select the type of topology you want to create from the options that are displayed. This action opens the Create VPN Wizard or the Create Extranet VPN wizard. For more information, see Creating or Editing VPN Topologies, page 23-28 or Creating or Editing Extranet VPNs, page 23-62.

• To edit a VPN, select it and click the Edit VPN Topology button, right-click the VPN and select Edit VPN Topology, or simply double-click the entry. This opens the Edit VPN or Edit Extranet VPN dialog box, which is a tabbed version of the Create VPN wizard (see Creating or Editing VPN Topologies, page 23-28 or Creating or Editing Extranet VPNs, page 23-62).

• To edit the policies for a VPN, select it and click the Edit VPN Policies button. The Site-to-Site VPN Window opens displaying information about the VPN topology; select the desired policy from the Policies selector to edit it.

• To delete a VPN, select it and click the Delete VPN Topology button, or right-click the VPN and select Delete VPN Topology. You are asked to confirm the deletion. For more information, see Deleting a VPN Topology, page 23-66.

Site-To-Site VPN Discovery

You can discover the VPN topologies that are already deployed in your network so that you can use Security Manager to manage them. Your VPN configurations are brought into Security Manager and displayed as site-to-site VPN policies.

Except for Extranet VPNs, you can also rediscover the configurations of existing VPN topologies that are already managed with Security Manager. For information about Site-to-Site VPN rediscovery, see Rediscovering Site-to-Site VPNs, page 23-26.
You can also discover configurations on devices in remote access VPNs that are already deployed in your network. See Discovering Remote Access VPN Policies, page 28-12.

These topics provide information about Site-to-Site VPN discovery:
- Supported and Unsupported Technologies and Topologies for VPN Discovery, page 23-20
- Prerequisites for VPN Discovery, page 23-21
- VPN Discovery Rules, page 23-21
- Discovering Site-to-Site VPNs, page 23-24
- Defining or Repairing Discovered VPNs with Multiple Spoke Definitions, page 23-25
- Rediscovering Site-to-Site VPNs, page 23-26

**Supported and Unsupported Technologies and Topologies for VPN Discovery**

This topic lists the technologies and topologies that Security Manager can discover, as well as the VPN features that are provisioned by Security Manager but cannot be discovered.

**Supported Technologies for VPN Discovery**
- IPsec, including LAN-to-LAN configurations on ASA devices.
- IPsec + GRE
- IPsec + GRE dynamic IP
- DMVPN
- Easy VPN
- GET VPN

**Supported Topologies for VPN Discovery**
- Point to point
- Hub and spoke
- Full mesh
- Extranet VPN (point-to-point to an unmanaged device)

**VPN Features Provisioned by Security Manager but Unsupported for VPN Discovery**
- Large Scale DMVPN with IPsec Terminator (high-concentration hub)
- VRF-Aware IPsec
- Dial backup
- IPsec and ISAKMP profiles for Easy VPN
- Easy VPN with High Availability

If you define and deploy policies of these types using Security Manager, your policies overwrite the device configurations that were not discovered. Therefore, if you want Security Manager to manage existing configurations, you should define policies that match the existing configurations as closely as possible. (Use **Tools > Preview Configuration** to examine the results before deploying.) The VPN
provisioning mechanism leverages the content of the existing configuration as much as possible (assuming the content matches the policies configured in Security Manager), but does not retain the naming conventions used in the CLI commands.

Related Topics

- Prerequisites for VPN Discovery, page 23-21
- VPN Discovery Rules, page 23-21
- Discovering Site-to-Site VPNs, page 23-24

Prerequisites for VPN Discovery

For successful VPN discovery, the following prerequisites must be met:

- Except for Extranet VPNs, all devices participating in the VPN must be added to the Security Manager inventory.
- You must provide Security Manager with some basic information about the VPN. The VPN discovery wizard prompts you for the following information:
  - VPN topology (hub and spoke, point to point, full mesh, Extranet).
  - VPN technology (Regular IPsec, IPsec/GRE, GRE dynamic IP, DMVPN, Easy VPN, GET VPN).
  - Devices in the VPN and their roles (hub/spoke). For Extranet VPNs, you specify the managed device only.
  - Source of the VPN configuration. The VPN can be discovered directly from the live network or from Security Manager’s Configuration Archive.
- Each device in the VPN must have a crypto map associated with a physical interface. This rule does not apply to the remote (unmanaged) devices in an Extranet VPN.
- If you use OSPF as your routing protocol in a VPN topology, all devices in the VPN must use the same OSPF process number.
- Each PIX 6.3 or ASA 5505 client device in an Easy VPN topology must have a vpnclient configuration.

Related Topics

- Supported and Unsupported Technologies and Topologies for VPN Discovery, page 23-20

VPN Discovery Rules

The following table describes the rules by which Security Manager translates and discovers your VPN configurations, and how it handles instances where your configuration on the device does not match what is supported by Security Manager.
Because Extranet VPN discovery involves the analysis of a single device (the managed device), most of these rules do not apply to Extranet VPN discovery. Any rule that involves consistency of values among devices in the VPN is not applicable.

### Table 23-3 VPN Discovery Rules

<table>
<thead>
<tr>
<th>If this condition exists:</th>
<th>The VPN discovery is handled as follows:</th>
</tr>
</thead>
</table>
| Security Manager cannot contact a device in the VPN for live device discovery. | - If the device is the only hub or spoke in the VPN, discovery fails.  
- If there are other hubs or spokes in the VPN, discovery proceeds but the unavailable device is not discovered.  
- Except for Extranet VPNs, if the device is a peer in a point-to-point topology, discovery fails. For Extranet VPNs, only the managed device is contacted, and discovery fails if it cannot be contacted.  
- If the device is a peer in a full mesh topology and there are only two devices, including the unavailable one, in the topology, discovery fails. If there are more than two devices, discovery proceeds but the unavailable device is not discovered. |
| The VPN is a LAN-to-LAN VPN on an ASA. | The ASA documentation uses “LAN-to-LAN” as a synonym for “site-to-site.” In a LAN-to-LAN VPN configuration, the ASA uses tunnel groups, which when used in a remote access VPN configuration, Security Manager discovers as connection profiles.  
When discovering site-to-site VPNs on an ASA that uses LAN-to-LAN (L2L) tunnel groups, Security Manager creates a site-to-site VPN topology, and the L2L tunnel groups are not presented to you as connection profiles. Instead, you edit the properties of the VPN topology, and during deployment, Security Manager will translate the configuration into the appropriate L2L tunnel group commands. |
There are inconsistencies in the policies or values in the VPN configurations across the devices in the VPN.

- If the values on the hub and the spokes differ, preference is given to the values on the hub.
- If a simple selection of one policy or value from several eligible policies or values is required and does not put functionality at risk, Security Manager selects a single policy/value that is common to all devices. For example, a VPN can have a single IKE policy only, whereas there can be more than one IKE policy on the devices.
- If selecting one value puts the functionality at risk, no value is discovered for the policy and a validation message is received upon deployment.
- If numeric values differ, a message is generated during discovery, and the lower value is discovered. For example, the lowest SA lifetime value in an IPsec policy.
- If none of the above options are possible, VPN discovery fails.

Preshared key configuration—there is a different key per set of peers.

The preshared key policy is not discovered; you will have to configure it after discovery is completed. Security Manager discovers preshared key policies only when the preshared key has the same value on all devices.

There is more than one eligible crypto map on the device.

The crypto map that is associated with all or the majority of the devices selected for VPN discovery is used.

A spoke does not have a crypto map associated with the hub.

VPN discovery proceeds but the spoke is not discovered and an error message is generated.

A device does not have the selected transform set value.

VPN discovery proceeds but the device might removed from the VPN topology.

A device does not have the selected IKE proposal.

VPN discovery proceeds but the device might removed from the VPN topology.

A device supports DVTI, but does not have DVTI or a crypto map configured.

VPN discovery fails.

A server supports DVTI, but does not have an IP address configured in the DVTI configuration.

VPN discovery proceeds but with a warning.

A client does not support DVTI.

If the hub is configured with DVTI, discovery proceeds without any warning or Error.

A Hub and Spoke topology where the spokes are not using the same VPNSPA/VSPA slot on the hub (Catalyst 6500/7600).

VPN discovery fails.

The same set of key servers and group members are participating in more than one GET VPN.

Security Manager discovers only one of the topologies.

Table 23-3  VPN Discovery Rules (Continued)
Discovering Site-to-Site VPNs

This procedure describes how to discover a Site-to-Site VPN that is already working in your network but that has not yet been defined in Security Manager.

**Related Topics**

- Discovering Site-to-Site VPNs, page 23-24
- Discovering Policies, page 5-12
- Supported and Unsupported Technologies and Topologies for VPN Discovery, page 23-20
- Prerequisites for VPN Discovery, page 23-21
- Discovering Site-to-Site VPNs, page 23-24
- Rediscovering Site-to-Site VPNs, page 23-26

---

**Step 1**

In Device view, select **Policy > Discover VPN Policies** to open the Discover VPN Policies Wizard—Name and Technology page.

**Step 2**

Specify the following information:

- **VPN Name**—The name of the VPN being discovered.
  
  You cannot specify the name when discovering Extranet VPNs. Instead, Security Manager discovers all Extranets defined on the device, and for each Extranet, the VPN name is a hyphenation of the local and remote IP addresses. For example, if the local address is 10.100.10.1 and the remote address is 10.100.11.1, the Extranet VPN is named `10.100.10.1-10.100.11.1`.

- **Description**—An optional description of the VPN. You cannot add a description to Extranet VPN discovery.

- **Topology**—The type of VPN that you are discovering—Hub and Spoke, Point to Point, Full Mesh, or Extranet.

---

**Table 23-3** VPN Discovery Rules (Continued)

<table>
<thead>
<tr>
<th>If this condition exists:</th>
<th>The VPN discovery is handled as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td>A User Group policy is configured with backup servers using hostnames instead of an IP addresses.</td>
<td>VPN policy discovery fails with the following error: Policy Discovery Failed: com.cisco.nm.vms.discovery.DiscoveryException: Internal Error In order for discovery to be successful, you need to reconfigure the user group policy on the device with backup servers using IP address, not hostnames.</td>
</tr>
</tbody>
</table>

A User Group policy is configured with backup servers using hostnames instead of an IP addresses.

In order for discovery to be successful, you need to reconfigure the user group policy on the device with backup servers using IP address, not hostnames.
• **IPsec Technology**—The IPsec technology assigned to the VPN—Regular IPsec, IPsec/GRE, GRE Dynamic IP (sub-technology), DMVPN, Easy VPN, or GETVPN. The topology you select controls what is available in this list.

If you selected IPsec/GRE, you must also specify the type which may be **Standard** (for IPsec/GRE) or **Spokes with Dynamic IP** (to configure GRE Dynamic IP).

• **Discover From**—You can either discover the VPN directly from the network or from Configuration Archive.
  - **Network**—Security Manager connects to all live devices to obtain the device configuration. For Extranet VPN discovery, Security Manager connects to the single managed device that you specify.
  - **Config Archive**—Discovery from Configuration Archive is recommended if you deploy to configuration files instead of live devices. The most recent version of the device configuration in Configuration Archive is used for all devices.

**Step 3**
Click **Next** to open the Discover VPN Policies Wizard—Device Selection Page.

**Step 4**
Select the devices participating in the VPN and their role in the VPN (hub, spoke one, peer two, local device, key server, group member, or simply selected devices for full-mesh VPNs) depending on the topology type. For Easy VPN topologies, servers are hubs and clients are spokes.

If there are two or more IPsec terminators in a hub-and-spoke VPN, use the Up and Down arrow buttons to ensure the primary hub is listed first. When there is only one IPsec terminator, regardless of how many hubs are connected to the same IPsec terminator, it is not possible to designate one hub as the primary hub.

For more detailed information on selecting devices for a VPN, see Selecting Devices for Your VPN Topology, page 23-32.

**Step 5**
Click **Finish** to close the wizard and start the discovery process. The Discovery Status window opens and displays the status of the discovery and indicates whether the discovery of each device has been successful or has failed (see Viewing Policy Discovery Task Status, page 5-20). Error or warning messages are provided to indicate the source of any problems, which may be VPN specific or device specific.

Except for Extranet discovery, when the discovery process completes successfully, and you close the Discovery Status dialog box, the Site-to-Site VPN Manager window opens, displaying summary information for the VPN that was discovered. For Extranet discovery, you must either manually open the Site-to-Site VPN Manager, or select the Site-to-Site VPN policy in Device view, to see the list of discovered Extranet VPNs.

**Step 6**
Verify that the VPN policies are as required. Edit the policies as necessary.

---

**Tip**
When discovering Extranet VPNs, all Extranet VPNs defined on the selected device are discovered. Delete the ones that you do not want to manage in Security Manager.

---

**Defining or Repairing Discovered VPNs with Multiple Spoke Definitions**

If you discover a VPN whose spokes contain different definitions (for example, different client modes for Easy VPN spokes), Security Manager changes the definitions during discovery to create a uniform definition for all spokes. This behavior occurs because VPN topologies in Security Manager can contain only one set of spoke definitions.
If you want to maintain your original definitions, or create a new VPN that has spokes with different definitions, you can choose one of two approaches:

- Define multiple VPN topologies in Security Manager, where each topology includes spokes containing matching spoke definitions.
- Define a FlexConfig policy that contains the specialized definition, then assign the policy to the spokes that require this definition, as described in the following procedure.

**Related Topics**

- Creating a New Shared Policy, page 5-51
- Creating FlexConfig Policy Objects, page 7-27
- Modifying Policy Assignments in Policy View, page 5-51
- Site-To-Site VPN Discovery, page 23-19
- Discovering Site-to-Site VPNs, page 23-24
- VPN Discovery Rules, page 23-21

---

**Step 1** Create a shared FlexConfig policy in Policy view:

- a. Select View > Policy View.
- b. Right-click FlexConfigs in the Policy Type selector, then select New FlexConfigs Policy.
- c. Enter a name for the policy and click OK.

**Step 2** Define the FlexConfig policy by creating and selecting a FlexConfig object:

- a. In the work area of Policy view, click the Add button on the Details tab.
- b. In the FlexConfigs Selector, click the Create button in the lower-left corner of the window to open Add or Edit FlexConfig Dialog Box, page 7-29.
- c. Define an appended FlexConfig object that contains the required client definition. For example, to define the client mode on an Easy VPN spoke, enter the following commands:

```
crypto ipsec client ezvpn CSM_EASY_VPN_CLIENT_1
mode client
exit
```

- d. After you create the FlexConfig object, add it to the FlexConfig policy using the selector.

**Step 3** In the work area of Policy view, use the Assignments tab to select the spokes to which this policy should be assigned, then click Save.

**Step 4** Deploy the policy.

---

**Rediscovering Site-to-Site VPNs**

You can rediscover the configurations of existing VPN topologies that are already managed with Security Manager so that you do not have to recreate policies changes in the application.

The same rules by which Security Manager translates and discovers VPN configurations apply also to rediscovery. However, you can perform rediscovery only on devices that participate in a VPN topology, and you cannot make any changes to the IPsec technology or topology type. Only the configurations of
device specific policies, such as VPN interfaces and protected networks, and any High Availability (HA) policies that are configured on hubs, can be rediscovered. VPN global policies, such as IKE proposals or PKI enrollments, cannot be rediscovered. In addition, you cannot rediscover the following topologies:

- Easy VPN topologies with Dynamic VTI
- Extranet VPNs

This procedure describes how to rediscover the configurations of a Site-to-Site VPN topology that already exists in Security Manager.

Related Topics
- Discovering Site-to-Site VPNs, page 23-24
- Discovering Policies, page 5-12
- Prerequisites for VPN Discovery, page 23-21
- VPN Discovery Rules, page 23-21
- Understanding Devices Supported by Each IPsec Technology, page 23-9
- Including Unmanaged or Non-Cisco Devices in a VPN, page 23-11

Step 1
In the Site-to-Site VPN Manager window, right-click the VPN topology whose configurations you want to rediscover and select Rediscover Peers. This opens the Rediscover VPN Policies Wizard—Name and Technology page.

This page displays the type of topology and IPsec technology used in the VPN, which you cannot change.

Step 2
Specify the following information:

- **VPN Discovery Name**—The name of the rediscover VPN job.
- **Description**—An optional description of the VPN.
- **Discover From**—You can either rediscover the VPN directly from the network or from Configuration Archive.
  - Network—Security Manager connects to all live devices to obtain the device configuration.
  - Config Archive—Rediscovery from Configuration Archive is recommended if you deploy to configuration files instead of live devices. The most recent version of the device configuration in Configuration Archive is used for all devices.

Step 3
Click Next to open the Rediscover VPN Policies Wizard—Device Selection page.

Step 4
Select the devices whose peer level policies need to be rediscovered and their role in the VPN (hub, spoke, peer one, peer two, key server, group member, or simply selected devices for full-mesh VPNs) depending on the topology type. For Easy VPN topologies, servers are hubs and clients are spokes.

If there are two or more IPsec terminators in a hub-and-spoke VPN, use the Up and Down arrow buttons to ensure the primary hub is listed first. When there is only one IPsec terminator, regardless of how many hubs are connected to the same IPsec terminator, it is not possible to designate one hub as the primary hub.

For more detailed information on selecting devices for a VPN, see Selecting Devices for Your VPN Topology, page 23-32.
Creating or Editing VPN Topologies

Security Manager supports three basic types of topologies with which you can create a site-to-site VPN. Use the Create VPN wizard to create a hub-and-spoke, point-to-point, or full mesh VPN topology across multiple device types. For more information about these topologies, see Understanding VPN Topologies, page 23-2.

Tip

If you want to create an Extranet point-to-point VPN, read Creating or Editing Extranet VPNs, page 23-62 instead of this topic.

Creating a VPN topology involves specifying the devices and the networks that make up the site-to-site VPN. You define the devices and their roles (such as hub, spoke, peer, key server, group member), the VPN interfaces that are the source and destination endpoints of the VPN tunnel, and the protected networks that will be secured by the tunnel. When you create a VPN topology, you assign to it the IPsec technology (such as Regular IPSec, IPSec/GRE, GRE Dynamic IP, DMVPN, Large Scale DMVPN, Easy VPN, GET VPN) with which a predefined set of policies is associated. See Understanding Mandatory and Optional Policies for Site-to-Site VPNs, page 23-6.

Note

When you complete the Create VPN wizard, your topology might be immediately deployable, because Security Manager provides defaults for mandatory policies. However, if you use Security Manager defaults, be sure to verify that the settings will work properly in your network. For more information, see Understanding and Configuring VPN Default Policies, page 23-12.

When you edit a VPN topology, the Edit VPN dialog box contains the same pages as the Create VPN wizard (except for the VPN defaults page), but the pages are laid out in a tabbed format rather than being presented as a wizard. The only exception is for GET VPN topologies, where you can edit only the name and description of the topology (you must edit GET VPN policies to change topology attributes, see Configuring GET VPN, page 27-12). Clicking OK on any tab in the dialog box saves your definitions on all the tabs. For all topologies, you must edit mandatory and optional policies originally presented on the VPN defaults page directly.

By editing a VPN topology, you can change its device structure (adding or removing devices), change the VPN interfaces and protected networks defined for a device, or modify the policies that are assigned to the VPN. For example, if your organization frequently opens new sites, you might need to add spokes to an existing hub-and-spoke VPN while applying all policies of the VPN to the new spokes. Or, you might want to increase resiliency by adding a secondary hub to a VPN that has only one hub. While editing a VPN topology, you might also need to modify the policies assigned to it, for example, to change an IKE algorithm to a more secured one, or to change the DES encryption algorithm for a VPN to make it more secure.
After you create a topology you cannot change the technology used in the VPN. Instead, you must delete the old VPN and create a new one using the desired technology.

To start the Create VPN wizard, or to edit an existing VPN topology:

- To open the Create VPN wizard, in the Site-to-Site VPN Manager Window or the Site-to-Site VPN policy page (Device View), click the Create VPN Topology (+) button and select the type of VPN topology you want to create from the options that are displayed—Hub and Spoke, Point to Point, or Full Mesh. Use the Back and Next buttons to move through the pages; when finished, click Finish to create the topology.

- To open the Edit VPN dialog box, select the VPN topology in the Site-to-Site VPN Manager window or the Site-to-Site VPN policy page (Device View) and click the Edit VPN Topology (pencil) button.

The pages or tabs that appear and their sequence depend on the type of VPN topology you are creating, as explained in the following table.

Chapter 23      Managing Site-to-Site VPNs: The Basics

Creating or Editing VPN Topologies

Either during or after you create a VPN topology, you can also create the following advanced configurations when editing endpoints:

- VRF-Aware IPsec on a hub in a hub-and-spoke topology (see Configuring VRF Aware IPsec Settings, page 23-46).
- A VPNSM or VPNSPA/VSPA on a Catalyst 6500/7600 in a hub-and-spoke, point-to-point, or full mesh VPN topology (see Configuring VPNSM or VPN SPA/VSPA Endpoint Settings, page 23-41).
- A Firewall Services Module together with a VPN Services Module or VPN SPA on a Catalyst 6500/7600 device in a hub-and-spoke, point-to-point, or full mesh VPN topology (see Configuring a Firewall Services Module (FWSM) Interface with VPNSM or VPNSPA/VSPA, page 23-45).

You can create a visual representation of your VPN topology with all its elements in the Map view. For more information, see Creating VPN Topologies in Map View, page 33-20.

- Using Wizards, page 1-43

### Defining the Name and IPsec Technology of a VPN Topology

This topic does not apply to Extranet VPNs. For information about configuring the name of an Extranet VPN, see Creating or Editing Extranet VPNs, page 23-62.

Use the Name and Technology page (or tab) of the Create VPN wizard and Edit VPN dialog box to define a name and description for the VPN topology. When creating a new topology, you must select the IPsec technology that will be assigned to it, but you cannot change the technology when editing an existing topology.

For information on opening the Create VPN wizard or Edit VPN dialog box, see Creating or Editing VPN Topologies, page 23-28.

If you are editing an existing VPN, the assigned IPsec technology and type is displayed, but you cannot change them. To change the technology or type, you must delete the topology and create a new one.

Selecting Devices for Your VPN Topology

This topic does not apply to Extranet VPNs. For information about selecting devices in an Extranet VPN, see Creating or Editing Extranet VPNs, page 23-62.

Use the Device Selection page (or tab) of the Create VPN wizard and Edit VPN dialog box to select the devices to include in the VPN topology. The contents of this page differ depending on whether you are creating or editing a hub-and-spoke, large scale DMVPN, point-to-point, or full mesh VPN topology. Also, you cannot use this page to edit the membership in a GET VPN (instead, see Configuring GET VPN Group Members, page 27-20 and Configuring GET VPN Key Servers, page 27-18 when working with an existing GET VPN).

For information on opening the Create VPN wizard or Edit VPN dialog box, see Creating or Editing VPN Topologies, page 23-28.

In most cases, the devices that are listed in the Available Devices list include only those that can be used for the selected VPN topology type, that support the IPsec technology type, and which you are authorized to view. In addition, the available devices depend on the selected IPsec technology—for example, if the IPsec technology is IPsec/GRE, GRE Dynamic IP, or DMVPN, PIX Firewalls and ASA devices are not displayed. However, the lists are not adjusted to account for the IKE versions you are supporting in the topology. For more information, see the supported platforms described in Understanding Devices Supported by Each IPsec Technology, page 23-9.

When selecting devices, you can select a device group to select all of the eligible devices in the group.

The following list explains how to add or remove devices based on the type of topology:

- **To select devices for a full mesh VPN topology with Regular IPSec or IPSec/GRE technology**, select them in the Available Devices list and click >>.

- **To select devices for a full mesh VPN topology that uses the GET VPN technology**:
  - Select the devices that you want to define as key servers and click >> next to the Key Servers field.
    
    If you have more than one key server, use the Up and Down arrow buttons to ensure the primary key server is listed first. Group members register with the first key server in the list. If the first key server cannot be reached, they try to register with the second key server, and so on.

  - Select the devices that you want to define as group members and click >> next to the Group Members field.

- **To select devices for a hub-and-spoke VPN topology**:

  - Select the devices that you want to define as hubs (or servers in an Easy VPN configuration) and click >> next to the Hubs list.

    If you have more than one hub, ensure the hubs list is in priority order with the primary hub listed first. To change the order, select a hub and click the Up and Down arrow buttons until the device is ordered as desired.

- **Note**: You need to select the primary hub only when there are two or more IPsec terminators. When there is only one IPsec terminator, regardless of how many hubs are connected to the same IPsec terminator, it is not possible to designate one hub as the primary hub.
Creating or Editing VPN Topologies

- Select the devices that you want to define as spokes (or clients in an Easy VPN configuration) and click >> next to the Spokes list.
- If you are configuring a Large Scale DMVPN with IPsec Terminator topology, you must also select the Catalyst 6500/7600 devices you want to be IPsec Terminators in your Large Scale DMVPN configuration. If you select more than one IPsec Terminator, use the Up and Down arrow buttons to put them in priority order. For more information, see Configuring Large Scale DMVPNs, page 25-16.

- To select devices for a point-to-point VPN topology:
  - From the Devices list, select a device to be Peer One and click >>.
  - Select another device to be Peer Two and click >>.

- To remove devices (any topology or technology combination), select them from one of the selected devices lists and click << to move them back to the Available Devices list.

If you are editing an existing VPN topology, you can remove devices from the VPN topology, but you cannot save your changes if your device selections result in an invalid VPN configuration. When removing devices, you should be aware of the following:

- You cannot remove a device if it is the only hub in a hub-and-spoke VPN topology, unless you replace it with a different hub.
- You cannot remove a device that is one of the two devices in a point-to-point VPN topology, unless you replace it with a different device.
- In a VPN topology with multiple hub devices, deleting a hub causes the appropriate tunnels to be removed.
- If some, but not all, spokes in a VPN topology are deleted, the hub side crypto statements change to reflect the removal.
- GET VPNs must have at least one key server and one group member.

Defining the Endpoints and Protected Networks

Use the Endpoints page of the Create VPN wizard and Edit VPN dialog box, or the Peers policy, to view the devices in your VPN topology and to define or edit their VPN characteristics and features. You are primarily defining the external or internal VPN interfaces and the protected networks for the devices in the VPN topology. The VPN interfaces are the interfaces that encrypt the data. The protected networks are the networks that are encrypted.

To get to the Endpoints page, do any of the following:

- Open the Create VPN wizard or the Edit VPN dialog box; for the procedure, see Creating or Editing VPN Topologies, page 23-28.
- In the Site-to-Site VPN Manager, select the desired VPN topology (excepting GET VPN topologies) and select the Peers policy.
Tips:

- This configuration applies to all IPsec technology types except GET VPN. To configure GET VPN endpoints when creating the VPN, see Defining GET VPN Peers, page 23-56. For existing GET VPNs, configure endpoints using the Key Servers and Group Members policies; see Configuring GET VPN Key Servers, page 27-18 and Configuring GET VPN Group Members, page 27-20.

- The devices listed on this page are selected in the Device Selection Page (see Selecting Devices for Your VPN Topology, page 23-32). You can change the list only when editing the Peers policy, where you can select a device and click the Delete (trash can) button to remove it. To add devices, you must edit the VPN topology itself.

- Although you can edit the endpoints for an Extranet VPN using the Peers policy, you should instead edit the endpoints through the Edit Extranet VPN dialog box by editing the VPN topology. The Endpoints page does not appear in the Create Extranet VPN wizard.

The table shows the role each device plays in the VPN (hub, spoke, peer, or IPsec Terminator), the device name, and the VPN interface and protected networks. Initially, the VPN interface and protected network is set to the default interface roles defined in the Security Manager Administrative settings for external and internal interfaces (see VPN Policy Defaults Page, page 11-47). The endpoint configuration might include configurations not shown in this table, but the VPN interface and protected network are the only required settings.

- To change the endpoint configuration for a device, select it and click the Edit Row button beneath the table. You can select more than one device to edit at a time, but the devices must serve the same role, and you cannot include Catalyst 6500/7600 devices or VPN service modules when selecting multiple devices. You perform endpoint editing in the Edit Endpoints Dialog Box, whose content differs depending on the selected device type and IPsec technology.

See the following topics for detailed information about the options you can configure in the Edit Endpoints dialog box:

- **VPN Interface tab**—To configure the VPN interface and other required interface settings (see Configuring VPN Interface Endpoint Settings, page 23-35). In some cases, you can also configure dial backup (for more information about dial backup, see Configuring Dial Backup, page 23-38).

  For Catalyst 6500/7600 devices, the VPN Interface tab provides settings that enable you to configure a VPN Services Module (VPNSTM) or a VPNSPA/VSPA blade on the device (which might be an IPsec Terminator in a large scale DMVPN), and are described in Configuring VPNSTM or VPN SPA/VSPA Endpoint Settings, page 23-41.

- **Extranet Device Details**—To configure the endpoint settings for the remote (unmanaged) device in an Extranet VPN. The tab appears in the Peers policy only. Instead of editing the information on this tab, the preferred method is to edit the VPN topology and change the settings there. For more information, see Creating or Editing Extranet VPNs, page 23-62.

- **Hub Interface tab**—If the selected device is a hub in a large scale DMVPN, specify the interface that is connected to the IPsec Terminator. See Configuring Large Scale DMVPNs, page 25-16.

- **Protected Networks tab**—To define the networks that are encrypted (see Identifying the Protected Networks for Endpoints, page 23-44). The protected network can be an interface role, network/host object, or in the case of regular IPsec, an ACL policy object.

- **FWSM tab**—To define the settings that enable you to connect between a Firewall Services Module (FWSM) and an IPsec VPN Services Module (VPNSTM) or VPNSPA/VSPA that is already configured on a Catalyst 6500/7600 device. This is possible only in a hub-and-spoke
Chapter 23      Managing Site-to-Site VPNs: The Basics

Creating or Editing VPN Topologies

- **VRF Aware IPsec tab**—To configure a VRF-Aware IPsec policy on a hub (IPsec Aggregator) in a hub-and-spoke VPN topology. For more information, see Configuring VRF Aware IPsec Settings, page 23-46 and Understanding VRF-Aware IPsec, page 23-14.

- To view the actual interfaces associated with an interface role for each device, select Matching Interfaces in the Show list beneath the table. If there are no matching interfaces, “No Match” is displayed. The default is to show the interface role policy object names. To create a valid VPN, these roles must match to actual interfaces defined on the device.

- Table Columns and Column Heading Features, page 1-44
- Filtering Tables, page 1-44

**Configuring VPN Interface Endpoint Settings**

Use the VPN Interface tab in the Edit Endpoints dialog box to edit the VPN interfaces defined for devices in the Endpoints table. When defining a primary VPN interface for a router device, you can also configure a backup interface to use as a fallback link for the primary route VPN interface, if its connection link becomes unavailable. You can configure a backup interface on a Cisco IOS security router, that is in a point-to-point or full mesh topology, or that is a spoke in a hub-and-spoke topology, or is a remote client in an Easy VPN topology. For more information, see Configuring Dial Backup, page 23-38.

**Tips**
- If the device is a hub in a large scale DMVPN, this tab is called **Hub Interface**. Specify the interface that is connected to the IPsec Terminator in the Hub Interface Toward the IPsec Terminator field. Enter the name of the interface or interface role, or click **Select** to select it from a list. For more information, see Configuring Large Scale DMVPNs, page 25-16.

- If the device is a Catalyst 6500/7600 device, the VPN Interface tab provides settings that enable you to configure a VPN Services Module (VPNSM) or a VPNSPA/VSPA blade on the device. For a description of the elements that appear on the VPN Interface tab for a Catalyst 6500/7600 device, see Configuring VPNSM or VPN SPA/VSPA Endpoint Settings, page 23-41. The table below assumes the device is not a Catalyst 6500/7600 device.

**Navigation Path**

On the Endpoints Page of the Create VPN wizard or Edit VPN dialog box, or on the VPN Peers policy, select a device and click **Edit** to open the Edit Endpoints Dialog Box. Select the VPN Interfaces tab in the Edit Endpoints dialog box. For information on how to access these pages and dialog boxes, see Defining the Endpoints and Protected Networks, page 23-33.

</tr>
<tr>
<td></td>
<td>You can choose therequired interface by clicking Select. A dialog box opens that lists all available predefined interface roles, and in which you can create an interface role object.</td>
</tr>
</tbody>
</table>
### Chapter 23      Managing Site-to-Site VPNs: The Basics

#### Creating or Editing VPN Topologies

If you have enabled the setting to use a unique tunnel source per tunnel interface in the GRE Modes > Tunnel Parameters tab, the **Override Unique Tunnel Source per Tunnel Interface** check box is available. Select this option to specify a different tunnel source for the selected device.

Specifies the tunnel source address to be used by the GRE or DMVPN tunnel on the spoke side. You can select one of the following options:

- **VPN Interface**—Uses the VPN interface as the tunnel source address.
- **Interface**—To use any interface as the tunnel source address, not necessarily a VPN interface. Enter the interface name or click Select to select an interface role that identifies the interface (you can also create a role from the selection dialog box).

**Dial Backup Settings**

Whether to configure a backup interface to use as a fallback link for the primary route VPN interface, if its connection link becomes unavailable.

**Tip** Before configuring a backup interface, you must first configure the dialer interface settings on the device. For more information, see *Dialer Interfaces on Cisco IOS Routers*, page 58-27.

### Table 23-6 Edit Endpoints Dialog Box, VPN Interface Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Tunnel Source            | Available only for IPsec/GRE or DMVPN. If you have enabled the setting to use a unique tunnel source per tunnel interface in the GRE Modes > Tunnel Parameters tab, the **Override Unique Tunnel Source per Tunnel Interface** check box is available. Select this option to specify a different tunnel source for the selected device. Specifies the tunnel source address to be used by the GRE or DMVPN tunnel on the spoke side. You can select one of the following options:  
  - **VPN Interface**—Uses the VPN interface as the tunnel source address.  
  - **Interface**—To use any interface as the tunnel source address, not necessarily a VPN interface. Enter the interface name or click Select to select an interface role that identifies the interface (you can also create a role from the selection dialog box). |
| Dial Backup Settings     |                                                                                                                                                                                                             |
| Enable Backup            | Available if the selected device is an IOS router that is in a point-to-point or full mesh topology, or that is a spoke in a hub-and-spoke topology, or that is a remote client in an Easy VPN topology.  
  Whether to configure a backup interface to use as a fallback link for the primary route VPN interface, if its connection link becomes unavailable.  
  **Tip** Before configuring a backup interface, you must first configure the dialer interface settings on the device. For more information, see *Dialer Interfaces on Cisco IOS Routers*, page 58-27. |
| Dialer Interface         | The logical interface through which the secondary route traffic is directed when the dialer interface is activated. This can be a Serial, Async, or BRI interface. Enter the name of the interface or interface role object, or click Select to select it from a list. |
| Primary Next Hop IP Address | Available only if the selected technology is Regular IPsec, IPsec/GRE, GRE Dynamic IP, or Easy VPN. The IP address to which the primary interface connects when it is active. This is known as the next hop IP address.  
  If you do not specify the next hop IP address, Security Manager configures a static route using the VPN interface name. The VPN interface must be point-to-point or deployment fails.  
  You can choose the required IP address by clicking Select. The Network/Hosts selector opens, in which you can select a network from which the IP address will be allocated. |
Creating or Editing VPN Topologies

| Tracking IP Address | The IP address of the destination device to which connectivity must be maintained from the primary VPN interface connection. This is the device that is pinged by the Service Assurance agent through the primary route to track connectivity. The backup connection is triggered if connectivity to this device is lost.  
If you do not specify an IP address, the primary hub VPN interface is used in a hub-and-spoke or Easy VPN topology. In a point-to-point or full mesh VPN topology, the peer VPN interface is used.  
You can choose the required IP address by clicking Select. The Network/Hosts selector opens, in which you can select a network from which the IP address will be allocated. |
| Advanced button  | Available if the selected technology is Regular IPsec, IPsec/GRE, GRE Dynamic IP, or Easy VPN.  
Click this button to configure additional optional settings using the Dial Backup Settings Dialog Box, page 23-40.                                                                                                      |

### Configuring Dial Backup

You can use dial backup to provide a fallback link for a primary, direct connection when the primary link becomes unavailable. You can configure dial backup on Cisco IOS security routers that participate in a point-to-point, Extranet, or full mesh VPN topology, or that are spokes in a hub-and-spoke topology. You can also configure it on a remote client router running IOS version 12.3(14)T+ in an Easy VPN topology.

Implementation of the dial backup feature is based on the assumption that two static routes exist:

- A primary route through a primary gateway, which has highest priority.
- A secondary route through a secondary gateway, which has lower priority and only appears in the routing table when the primary gateway is down.

Security Manager configures a logical dialer interface on the spoke. The dialer interface is associated with a physical backup interface. When the primary route is down, the dialer interface is activated and traffic is redirected through this backup interface along the secondary route. To ensure that the spoke-hub traffic is encrypted, Security Manager applies a crypto map to the dialer interface. This crypto map is identical to the crypto map on the VPN interface (the primary route interface). In Easy VPN, the backup configuration is attached to the dialer interface.

Depending on the IOS version, Response Time Reporter (RTR) or Service Level Agreement (SLA) IOS technology is used to detect loss of network performance on the primary route. If the assigned IPsec technology is DMVPN, Dialer Watch-List (DWL) is used.

ISDN Basic Rate Interface (BRI) and analog modem interfaces can be configured as backup interfaces to other primary interfaces. In such a case, an ISDN or analog modem connection is made if the primary interface goes down. Should the primary interface and connection go down, the ISDN or analog modem interface immediately dials out to establish a connection so that network services are not lost.
Before You Begin

- Configure the dialer interface settings on the Cisco IOS routers. This requires defining the relationship between the physical BRI and Async interfaces, and the virtual dialer interfaces used when configuring dial backup. For more information, see Dialer Interfaces on Cisco IOS Routers, page 58-27.
- Make sure that the primary route is functioning.
- For Extranet VPNs, you can configure dial backup on the local (managed) device only.

Step 1
For most VPN topologies, you configure dial backup when creating or editing a site-to-site VPN. You can also edit the Peers policy for existing VPN topologies. For Extranet VPNs, you configure dial backup through the Peers policy only.

Do one of the following:
- In the Create VPN wizard, proceed to the Endpoints page (see Creating or Editing VPN Topologies, page 23-28 and Defining the Endpoints and Protected Networks, page 23-33).
- In the Edit VPN dialog box, click the Endpoints tab (see Creating or Editing VPN Topologies, page 23-28 and Defining the Endpoints and Protected Networks, page 23-33).
- For Extranet VPNs, or for editing any other VPN topology, select the Peers policy. For general information on editing endpoints, see Defining the Endpoints and Protected Networks, page 23-33.

Step 2
Select the router on which you want to configure dial backup and click the Edit (pencil) button. If there is more than one router that will have the same dialer configuration, you can select and edit them all at once. This action opens the Edit Endpoints dialog box. Select the VPN Interface tab if it is not already selected.

Step 3
On the VPN Interface tab, configure the following options related to dial backup. If you are creating a new VPN, you need to configure the other settings (such as VPN interface) as well. For detailed reference information for these options, see Configuring VPN Interface Endpoint Settings, page 23-35.

- **Enable Backup**—Select this option.
- **Dialer Interface**—Specify the physical interface through which the secondary route traffic will be directed when the logical dialer interface is activated.
- **Primary Next Hop IP Address**—If the selected IPsec technology is Regular IPsec, IPsec/GRE, GRE Dynamic IP, or Easy VPN, enter the next hop IP address. If you do not enter the next hop IP address, Security Manager configures a static route using the interface name.
- **Tracking IP Address**—Specify the IP address of the destination device to which connectivity must be maintained from the primary VPN interface connection. This is the device that is pinged through the primary route to track connectivity. The backup connection is triggered if connectivity to this device is lost.

If you do not specify an IP address, the primary hub VPN interface is used in a hub-and-spoke or Easy VPN topology. In a point-to-point or full mesh VPN topology, the peer VPN interface is used.

Step 4
If the selected IPsec technology is Regular IPsec, IPsec/GRE, GRE Dynamic IP, or Easy VPN, click Advanced to configure additional (optional) settings in the Dial Backup Settings dialog box. These settings are explained in Dial Backup Settings Dialog Box, page 23-40. Click OK to save your changes.

Step 5
Click OK in the Edit Endpoints dialog box.
Dial Backup Settings Dialog Box

Use the Dial Backup Settings dialog box to define optional settings for configuring a dial backup policy for your site-to-site VPN. These settings are available for Regular IPsec, IPsec/GRE, GRE Dynamic IP, or Easy VPN technologies.

Mandatory settings for dial backup are configured in the VPN Interface tab on the Edit Endpoints dialog box. See Configuring VPN Interface Endpoint Settings, page 23-35.

**Note**

You must configure the dialer interface settings before dial backup can work properly. For more information, see Dialer Interfaces on Cisco IOS Routers, page 58-27.

**Navigation Path**

To open the Dial Backup Settings dialog box, enable dial backup and click Advanced on the VPN Interface tab of the Edit Endpoints dialog box. For information on opening the Edit Endpoints dialog box, see Defining the Endpoints and Protected Networks, page 23-33.

**Related Topics**

Configuring VPNSM or VPN SPA/VSPA Endpoint Settings

When you select a Catalyst 6500/7600 device in the Endpoints table for editing, the VPN Interface tab of the Edit Endpoints dialog box provides settings for configuring Cisco VPN Services Modules (VPNSM), Cisco VPN Shared Port Adapters (VPN SPAs), and Cisco VPN Service Port Adapters (VSPAs) on the device. You can select more than one Catalyst 6500/7600 device at the same time. Your changes are applied to all the selected devices.

The device can be in a point-to-point or full mesh VPN topology, or a hub or spoke in a hub-and-spoke VPN topology managed by Security Manager (except in an Easy VPN configuration, where the device cannot be a spoke). These settings must also be configured if the selected device is an IPsec Terminator in a large scale DMVPN, although not all settings described below are available. See Configuring Large Scale DMVPNs, page 25-16.

General Notes

- A Catalyst 6500/7600 device can contain from 3 to 13 chassis slots. Due to the design of the blades, you can install one VPNSM or two VPNSPA/VSPA per slot. The location of a VPNSPA/VSPA is identified with a slot and subslot number. Security Manager stores this information in its inventory, so that Security Manager can manage the VPN topologies.
- If you are configuring intra-chassis high availability, you cannot use a VPNSM blade and a VPNSPA/VSPA blade on the same device as primary and failover blades.
- In a remote access VPN, you can configure only one failover unit for each IPsec proposal. See VPNSM/VPN SPA/VSPA Settings Dialog Box, page 31-6.
- If the Catalyst 6500/7600 has a Firewall Services Module (FWSM), you can configure it to work with these modules. For more information, see Configuring a Firewall Services Module (FWSM) Interface with VPNSM or VPNSPA/VSPA, page 23-45.
- If you are configuring a VPNSM or VPNSPA/VSPA with VRF-Aware IPsec on a device, the device cannot belong to a different VPN topology in which VRF-Aware IPsec is not configured. For more information, see Configuring VRF Aware IPsec Settings, page 23-46.
- Create an inside VLAN on the Catalyst 6500/7600 device, or edit an existing port or VLAN configuration. If the device is configured with VRF-Aware IPsec, you must create a forwarding VLAN.

Notes for VPNSMs

- Security Manager supports the configuration of multiple VPNSMs on a Catalyst 6500/7600 device, but only one module (or two if you are configuring intra-chassis high availability) can be configured per VPN topology.
- VPNSM configuration requires that its parent Catalyst 6500/7600 device is running Cisco IOS Software release 12.2(18)SXD1 and later.
- You can use only Layer 3 VLANs for VPNSM configuration.

Notes for VPNSPA/VSPAs

- This configuration also applies if you are configuring an IPsec Terminator in a large scale DMVPN configuration. For more information, see Configuring Large Scale DMVPNs, page 25-16.
- The VPN SPA supports the AES encryption algorithm for all key sizes (128-, 192-, and 256-bit), as well as the DES and 3DES encryption algorithms. For more information, see Deciding Which Encryption Algorithm to Use, page 24-6.

In VRF mode, the `crypto engine slot slot/subslot {inside | outside}` command is deployed on the inside and outside VPN interfaces.
• Make sure that the Catalyst 6500/7600 device is running Cisco IOS Software release 12.2(18)SXE2 or later.

• If you plan to use Crypto Connect Alternate mode (whereby encrypted traffic entering the VPNSM/VPN SPA is passed through and clear text traffic is bypassed), the Catalyst 6500 device must be running Cisco IOS Software version 12.2(33)SXH or later, and the 7600 router must be running 12.2(33)SRA or later.

• In the case of a DMVPN topology in which multiple hubs participate, if one hub is configured with a VPN SPA blade, a tunnel key must not be configured on any of the devices, whether they are spokes or hubs. Devices that participate in such a topology must be running Cisco IOS Software version 12.3T and later in order to support tunnels without keys.

Navigation Path
On the Endpoints Page of the Create VPN wizard or Edit VPN dialog box, or on the VPN Peers policy, select a Catalyst 6500/7600 device, then click Edit to open the Edit Endpoints Dialog Box. Select the FWSM tab in the Edit Endpoints dialog box. For information on how to access these pages and dialog boxes, see Defining the Endpoints and Protected Networks, page 23-33.

Field Reference

| Table 23-8 Edit Endpoints Dialog Box, VPN Interface Tab’s VPNSM/VPN SPA/VSPA Settings |
|----------------------------------|--------------------------------------|
| Element | Description |
| Enable the VPN Interface Changes on All Selected Peers | Note: Available if you selected more than one Catalyst 6500/7600 device for editing in the Endpoints page. When selected, applies any changes you make in the VPN interface tab to all the selected devices. |
Creating or Editing VPN Topologies

### Table 23-8  Edit Endpoints Dialog Box, VPN Interface Tab’s VPNSM/VPN SPA/VSPA Settings

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPNSM/VPN SPA/VSPA Settings</td>
<td><em>Use Crypto Connect Alternate</em>—When selected, only encrypted traffic entering the VPNSM/VPN SPA on the Catalyst 6500/7600 is passed through. Clear text traffic does not go through (bypasses) the adapters. To use this option, the Catalyst 6500 must be running version 12.2(33)SXH or later, and the 7600 router must be running 12.2(33)SRA or later. This mode is recommended as an alternate to Crypto connect mode for enterprise customers who have a need to support large VPN topologies (financial institutions, for example) or need to pass large amounts of data over an encrypted channel (remote disaster recovery or backup over the Internet).</td>
</tr>
<tr>
<td></td>
<td><em>Inside VLAN</em>—The VLAN that serves as the inside interface to the service module or adapter. It is also the hub endpoint of the VPN tunnel (unless VRF-Aware IPsec is configured on the device). Enter the name of the VLAN or interface role object, or click Select to select it from a list.</td>
</tr>
<tr>
<td></td>
<td><em>Slot and Subslot</em>—The number designating the slot location of the VPNSM or VPNSPA/VSPA. If you are configuring a VPNSPA/VSPA, the subslot number is also required.</td>
</tr>
<tr>
<td></td>
<td><em>Outside VLAN/External port</em>—The external port or VLAN that connects to the inside VLAN. Enter the name of the VLAN or interface role object, or click Select to select it from a list. You must select an interface or interface role that differs from the one selected for the inside VLAN.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> If VRF-Aware IPsec is configured on the device, the external port or VLAN must have an IP address.</td>
</tr>
<tr>
<td>Tunnel Source</td>
<td><strong>Note</strong> Available only for a hub when the selected technology is IPsec/GRE or DMVPN. Specifies the tunnel source address to be used by the GRE or DMVPN tunnel on the spoke side. You can select one of the following options:</td>
</tr>
<tr>
<td></td>
<td><em>Override Unique Tunnel Source per Tunnel Interface</em>—If you have enabled the setting to use a unique tunnel source per tunnel interface in the GRE Modes &gt;Tunnel Parameters tab, this option is available. Select this option to specify a different tunnel source for the selected device.</td>
</tr>
<tr>
<td></td>
<td><em>Outside VLAN/External Port (When CCA/VRF is Enabled)</em>—When the Use Crypto Connect Alternate check box is selected, this radio button is available. When selected, specifies the outside VLAN/external port as the tunnel source.</td>
</tr>
<tr>
<td></td>
<td><em>Inside VLAN</em>—When selected, uses the interface configured for the inside VLAN as the tunnel source.</td>
</tr>
<tr>
<td></td>
<td><em>Interface</em>—To use any interface as the tunnel source address, not necessarily a VPN interface, enter the interface name or click Select to select an interface role that identifies the interface. You can create new roles from the selection list.</td>
</tr>

Creating or Editing VPN Topologies

Chapter 23 Managing Site-to-Site VPNs: The Basics

Creating or Editing VPN Topologies

Identifying the Protected Networks for Endpoints

Use the Protected Networks tab on the Edit Endpoints dialog box to edit the protected networks that are defined on devices in the Endpoints table. (See Defining the Endpoints and Protected Networks, page 23-33.)

You can specify the protected networks as interface roles whose naming patterns match the internal VPN interface of the device, as network/host group objects containing one or more network or host IP addresses, interfaces, or other network objects, or as access control list objects (if Regular IPsec is the assigned technology).

- If you are editing more than one device at a time, select Enable the Protected Networks Changes on All Selected Peers to apply any changes you make in the Protected Networks tab to all the selected devices.

- To add a protected network, select it from the Available Protected Networks list and click >> to move it to the Selected Protected Networks list. You can use any combination of interface role objects, network/host group objects (listed in the Protected Networks folder), or Access Control List objects to define the protected network for the device. (ACL objects are available only if Regular IPsec is the assigned technology.)

  Note In a hub-and-spoke VPN topology in which Regular IPsec is the assigned technology, when an ACL object is used to define the protected network on a spoke, Security Manager mirrors the spoke’s ACL object on the hub to the matching crypto map entry.

- To remove a selected protected network, select it and click the << button.
If the order of the objects matters, you can adjust the priority order of the selected objects using the Move Up, Move Down buttons to position the objects in the selected list as desired. These buttons are not available if order does not matter.

If an object that you need to define the protected network is not listed, click the Create (+) button to add the object; you are prompted to select the type of object you want to add. You can also modify the definition of an existing object by selecting it and clicking the Edit (pencil) button. For more information, see the following topics:

- Understanding Interface Role Objects, page 6-62 and Creating Interface Role Objects, page 6-63.
- Understanding Network/Host Objects (IPv4 and IPv6), page 6-69 and Creating IPv4 or IPv6 Network/Host Objects, page 6-71.

**Navigation Path**

On the Endpoints Page of the Create VPN wizard or Edit VPN dialog box, or on the Peers policy, select a device and click Edit to open the Edit Endpoints Dialog Box. Select the Protected Networks tab in the Edit Endpoints dialog box. For information on how to access these pages and dialog boxes, see Defining the Endpoints and Protected Networks, page 23-33.

**Configuring a Firewall Services Module (FWSM) Interface with VPNSM or VPNSPA/VSPA**

Security Manager supports the configuration of a Firewall Services Module (FWSM) with an IPsec VPN Services Module (VPNSM) or VPNSPA/VSPA on a Catalyst 6500/7600 device. This feature enables a FWSM to apply firewall policies to untrusted clients, while the VPNSM or VPN SPA/VSPA provides secure access to the internal network.

Use the FWSM tab on the Edit Endpoints dialog box to define the settings that enable you to connect between the FWSM and a VPNSM or VPNSPA/VSPA that is already configured on a Catalyst 6500/7600 device. The FWSM tab is available only in a hub-and-spoke VPN topology when the selected hub is a Catalyst 6500/7600 device.

**Tips**

- Before you can define the FWSM settings, you must add the hosting Catalyst 6500/7600 device to the Security Manager inventory and discover its FWSM and its policies and security contexts. See Adding Devices from the Network, page 3-9 and Managing Security Contexts, page 56-4.
- If an inside interface is not already created on the Catalyst 6500/7600 device, you must create it (see Creating or Editing VLANs, page 64-26). Then, you must assign the FWSM inside interface (VLAN) to the appropriate security context, or directly to the FWSM blade.
- You also must configure the settings on the VPN Interfaces tab related to IPsec VPN Services Module (VPNSM) or VPNSPA/VSPA. For more information, see Configuring VPNSM or VPN SPA/VSPA Endpoint Settings, page 23-41.

**Navigation Path**

On the Endpoints Page of the Create VPN wizard or Edit VPN dialog box, or on the VPN Peers policy, select a Catalyst 6500/7600 device that contains an FWSM, then click Edit to open the Edit Endpoints Dialog Box. Select the FWSM tab in the Edit Endpoints dialog box. For information on how to access these pages and dialog boxes, see Defining the Endpoints and Protected Networks, page 23-33.
Chapter 23 Managing Site-to-Site VPNs: The Basics

Creating or Editing VPN Topologies

Configuring VRF Aware IPsec Settings

Use the VRF-Aware IPsec tab on the Edit Endpoints dialog box to configure a VRF-Aware IPsec policy on a hub in your hub-and-spoke VPN topology. You can configure VRF-Aware IPsec as a one-box or two-box solution. For more information about VRF-Aware IPsec, see Understanding VRF-Aware IPsec, page 23-14.

Tips

- VRF-Aware IPsec can be configured only on hubs in a hub-and-spoke VPN topology.
- In a VPN topology with two hubs, you must configure VRF-Aware IPsec on both devices.
- You cannot configure VRF-Aware IPsec on a device that belongs to another VPN topology in which VRF-Aware IPsec is not configured.
- You cannot configure VRF-Aware IPsec on hubs that have been configured with high availability. See Configuring High Availability in Your VPN Topology, page 23-48.
- Deployment might fail if the IPsec Aggregator is configured with the same keyring CLI command as the existing preshared key (keyring) command, and is not referenced by any other command. In this case, Security Manager does not use the VRF keyring CLI, but generates the keyring with a different name, causing deployment to fail. You must manually remove the preshared key keyring command through the CLI before you can deploy the configuration.

Navigation Path

On the Endpoints Page of the Create VPN wizard or Edit VPN dialog box, or on the VPN Peers policy, select a device that supports VRF-Aware IPsec configuration in a hub-and-spoke topology, and click Edit to open the Edit Endpoints Dialog Box. Select the VRF-Aware IPsec tab in the Edit Endpoints dialog box. For information on how to access these pages and dialog boxes, see Defining the Endpoints and Protected Networks, page 23-33 and Creating or Editing VPN Topologies, page 23-28.
### Field Reference

**Table 23-10  Edit Endpoints Dialog Box, VRF Aware IPsec Tab**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable the VRF Settings Changes on All Selected Peers</td>
<td>Available if you selected more than one device for editing in the Endpoints page. When selected, applies any changes you make in the VRF Settings tab to all the selected devices.</td>
</tr>
<tr>
<td>Enable VRF Settings</td>
<td>Whether to enable the configuration of VRF settings on the device. <strong>Note</strong> You can remove VRF settings that were defined for the VPN topology by deselect this check box. However, if VRF-Aware IPsec is configured on a Catalyst 6500/7600 device, disabling it requires additional steps, as explained in Enabling and Disabling VRF on Catalyst Switches and 7600 Devices, page 23-17.</td>
</tr>
</tbody>
</table>
| VRF Solution | The type of VRF solution you want to configure:  
- 1-Box (IPsec Aggregator + MPLS PE)—In the one-box solution, one device serves as the Provider Edge (PE) router that does the MPLS tagging of the packets in addition to IPsec encryption and decryption from the Customer Edge (CE) devices. For more information, see VRF-Aware IPsec One-Box Solution, page 23-14.  
- 2-Box (IPsec Aggregator Only)—In the two-box solution, the PE device does just the MPLS tagging, while the IPsec Aggregator device does the IPsec encryption and decryption from the CEs. For more information, see VRF-Aware IPsec Two-Box Solution, page 23-15. |
| VRF Name | The name of the VRF routing table on the IPsec Aggregator. The VRF name is case-sensitive. |
| Route Distinguisher | The unique identifier of the VRF routing table on the IPsec Aggregator. This unique route distinguisher maintains the routing separation for each VPN across the MPLS core to the other PE routers.  
The identifier can be in either of the following formats:  
- IP address:X (where X is in the range 0-2147483647).  
- N:X (where N is in the range 0-65535, and X is in the range 0-2147483647). **Note** You cannot override the RD identifier after deploying the VRF configuration to your device. To modify the RD identifier after deployment, you must manually remove it using the device CLI, and then deploy again. |
| Interface Towards Provider Edge (2-Box solution only.) | The VRF forwarding interface on the IPsec Aggregator towards the PE device.  
If the IPsec Aggregator (hub) is a Catalyst VPN service module, you must specify a VLAN.  
Enter the name of the interface or interface role object, or click **Select** to select it from a list or to create a new interface role object. |
Creating or Editing VPN Topologies

Chapter 23  Managing Site-to-Site VPNs: The Basics

Creating or Editing VPN Topologies

Configuring High Availability in Your VPN Topology

Use the High Availability page of the Create VPN wizard and Edit VPN dialog box to define a group of hubs as a high availability (HA) group. Configuring high availability is optional.

For information on opening the Create VPN wizard or Edit VPN dialog box, see Chapter 57, “Managing Routers.”

In a one-box solution, these fields are unavailable as you do not need to specify the routing protocol and AS number. In the one-box solution, only the BGP protocol is supported.

Routing Protocol (2-Box solution only.)

The routing protocol to be used between the IPsec Aggregator and the PE. The options are BGP, EIGRP, OSPF, RIPv2, or Static route. The default is BGP.

If the routing protocol used for the secured IGP differs from the routing protocol between the IPsec Aggregator and the PE, select the routing protocol to use for redistributing the routing to the secured IGP.

For information about protocols, see Chapter 57, “Managing Routers.”

AS Number (2-Box solution, BGP or EIGRP routing only.)

The number that will be used to identify the autonomous system (AS) area between the IPsec Aggregator and the PE. The AS number must be within the range 1-65535.

If the routing protocol used for the secured IGP differs from the routing protocol between the IPsec Aggregator and the PE, enter an AS number that will be used to identify the secured IGP into which the routing will be redistributed from the IPsec Aggregator and the PE. This is relevant only when IPsec/GRE or DMVPN are applied.

Process Number (2-Box solution, OSPF routing only.)

The routing process ID number that will be used to identify the secured IGP if you are using OSPF routing.

The range is 1-65535.

OSPF Area ID (2-Box solution, OSPF routing only.)

The ID number of the area in which the packet belongs. You can enter any number from 0-4294967295.

Note All OSPF packets are associated with a single area, so all devices must have the same area ID number.

Next Hop IP Address (2-Box solution, static routing only.)

The IP address of the Provider Edge (PE) or the interface that is connected to the IPsec Aggregator, if you are using static routing.

Redistribute Static Route (2-Box solution, non-static routing only.)

Whether to have static routes advertised in the routing protocol configured on the IPsec Aggregator towards the PE device.

Table 23-10 Edit Endpoints Dialog Box, VRF Aware IPsec Tab (Continued)
High Availability (HA) policies provide automatic device backup when configured on Cisco IOS routers or Catalyst 6500/7600 devices that run IP over LANs. You can configure high availability in a hub-and-spoke VPN topology that uses Regular IPsec or Easy VPN technologies.

In Security Manager, HA is supported by an HA group made up of two or more hub devices that use Hot Standby Routing Protocol (HSRP) to provide transparent, automatic device failover. By sharing a virtual IP address, the hubs in the HA group present the appearance of a single virtual device or default gateway to the hosts on a LAN. One hub in the HA group is always active and assumes the virtual IP address, while the others are standby hubs. The hubs in the group watch for hello packets from active and standby devices. If the active device becomes unavailable for any reason, a standby hub takes ownership of the virtual IP address and takes over the hub functionality. This transfer is seamless and transparent to hosts on the LAN and to the peering devices.

Keep the following points in mind when working with HA groups:

- You can configure High Availability only on hubs in a hub-and-spoke VPN topology that uses Regular IPsec or Easy VPN technologies.
- You can configure high availability only on Cisco IOS routers or Catalyst 6500/7600 devices; however, an HA group cannot contain both Cisco IOS routers and Catalyst 6500/7600 devices.
- If you want to configure stateful failover, the HA group can contain only two hubs, and they must be Cisco IOS routers. You cannot use Catalyst 6500/7600 devices.
- You cannot configure High Availability on hubs that have been configured with VRF-Aware IPsec. See Understanding VRF-Aware IPsec, page 23-14.
- You cannot configure GRE on an HA group.
- A device in an HA group can belong to more than one hub-and-spoke topology.
- A device configured as a hub in a site-to-site VPN with an HA configuration cannot be configured as a hub in a different site-to-site VPN with an HA configuration using the same outside interface. Similarly, such a device cannot be configured as a remote access VPN server on which HA is configured using the same outside interface.
- The same auto-generated preshared key must be used for authentication on all peers. If you specified not to use this option when configuring a preshared key policy, this is overridden during configuration of High Availability. For more information, see Configuring IKEv1 Preshared Key Policies, page 24-41.
- During generation of configurations, all hubs in the HA group receive the same commands, which must be deployed to the HA group as a unit. You cannot deploy to individual hubs in the group.

The following table describes the options for configuring high availability.

<table>
<thead>
<tr>
<th>Table 23-11 High Availability Page</th>

User Guide for Cisco Security Manager 4.3
Defining GET VPN Group Encryption

Use the GET VPN Group Encryption page to define the group settings and security associations for a GET VPN topology.

The contents of this page differ depending on whether you are using the Create VPN wizard or you are editing the Group Encryption Policy. The wizard page is not tabbed, whereas the policy is tabbed. There is an extra field on the wizard page to allow the security association configuration.

To open the GET VPN Group Encryption page:
- When creating a new GET VPN, use the Create VPN wizard. For information on starting the wizard, see Creating or Editing VPN Topologies, page 23-28.
- (Site-to-Site VPN Manager Window) Select an existing GET VPN topology and then select Group Encryption Policy in the Policies selector.
- (Policy view) Select Site-to-Site VPN > Group Encryption Policy, and then select an existing policy or create a new one.

The following table describes the options you can configure when defining the GET VPN group encryption settings.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Stateful Failover</td>
<td>Whether to enable stateful failover, which uses Stateful SwitchOver (SSO) to ensure that state information is shared between the HSRP devices in the HA group. If a device fails, the shared state information enables the standby device to maintain IPsec sessions without having to re-establish the tunnel or renegotiate the security associations. You can configure stateful failover only on an HA group that contains two hubs that are Cisco IOS routers. This check box is disabled if the HA group contains more than two hubs. In an Easy VPN topology, this check box appears selected and disabled, as stateful failover must always be configured.</td>
</tr>
<tr>
<td></td>
<td><strong>Tips:</strong></td>
</tr>
<tr>
<td></td>
<td>• When deselected in a Regular IPsec topology, stateless failover is configured on the HA group. Stateless failover will also be configured if the HA group contains more than two hubs. You can configure stateless failover on Cisco IOS routers or Catalyst 6500/7600 devices.</td>
</tr>
<tr>
<td></td>
<td>• Stateful failover cannot be used when RSA Signature is the IKE authentication method.</td>
</tr>
<tr>
<td></td>
<td>• Stateful failover can be configured together with PKI configuration, but only on devices with Cisco IOS version 12.3(14)T and later.</td>
</tr>
</tbody>
</table>

</tr>
<tr>
<td></td>
<td>addresses of group members.</td>
</tr>
</tbody>
</table>
Key Distribution
The transport method to be used to distribute keys to each group member, either unicast or multicast. For help deciding which to use, see Choosing the Rekey Transport Mechanism, page 27-6.

If you select unicast, the key server sends a rekey message to each registered group member and waits for an acknowledgment. If you select multicast, the key server sends a rekey message to all group members at once and does not wait for acknowledgment. Rekey messages are retransmitted after the retransmit interval configured in this policy.

If you select multicast, make sure that the router used as the key server is multicast enabled, and also configure the following options:

- **Group IP Address**—The IP address of the multicast group to be used for key distribution.
- **Use Static IGMP Joins on Group Members**—If you select this option, the static Source Specific Multicast (SSM) mappings are enabled, which reveal the source of multicast traffic to the group member. In the case of GET VPN, the group member learns the key server address.

RSA Key Label
The label for the RSA key, which is used to encrypt a variety of messages. This key can either already exist on the device, or it can be an unused new label.

If you are creating a new VPN, you are asked at the end of the Create VPN wizard whether you want this key synchronized among the key servers; if you click Yes, Security Manager generates the key if it does not already exist. If you change this value for an existing GET VPN, you need to synchronize keys from the Key Servers policy. For more detailed information about how this key is used, and the key generation and synchronization process, see Generating and Synchronizing RSA Keys, page 27-13.

Lifetime (KEK)
The number of seconds that the key encryption key (KEK) is valid. This key is used for encrypting rekey messages. Before the end of this lifetime, the key server sends rekey messages to the group, which includes a new KEK encryption key and transforms and new TEK encryption keys and transforms.

The KEK lifetime value should be greater than the TEK lifetime value (it is recommended that the KEK lifetime value be at least three times greater than the TEK lifetime value). The default value of 86,400 seconds is usually appropriate. The TEK lifetime value is configured for each security association (see Add New or Edit Security Association Dialog Box, page 23-55).

Encryption Algorithm
The algorithm used to encrypt the rekey message from the key server to the group member.

Retransmits
The number of times the rekey message can be sent if one or more group members do not receive it.

Interval
The number of seconds between retries.

---

**Table 23-12 GET VPN Group Encryption Policy Page (Continued)**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Distribution</td>
<td>The transport method to be used to distribute keys to each group member, either unicast or multicast. For help deciding which to use, see Choosing the Rekey Transport Mechanism, page 27-6. If you select unicast, the key server sends a rekey message to each registered group member and waits for an acknowledgment. If you select multicast, the key server sends a rekey message to all group members at once and does not wait for acknowledgment. Rekey messages are retransmitted after the retransmit interval configured in this policy. If you select multicast, make sure that the router used as the key server is multicast enabled, and also configure the following options:</td>
</tr>
<tr>
<td>RSA Key Label</td>
<td>The label for the RSA key, which is used to encrypt a variety of messages. This key can either already exist on the device, or it can be an unused new label. If you are creating a new VPN, you are asked at the end of the Create VPN wizard whether you want this key synchronized among the key servers; if you click Yes, Security Manager generates the key if it does not already exist. If you change this value for an existing GET VPN, you need to synchronize keys from the Key Servers policy. For more detailed information about how this key is used, and the key generation and synchronization process, see Generating and Synchronizing RSA Keys, page 27-13.</td>
</tr>
<tr>
<td>Lifetime (KEK)</td>
<td>The number of seconds that the key encryption key (KEK) is valid. This key is used for encrypting rekey messages. Before the end of this lifetime, the key server sends rekey messages to the group, which includes a new KEK encryption key and transforms and new TEK encryption keys and transforms. The KEK lifetime value should be greater than the TEK lifetime value (it is recommended that the KEK lifetime value be at least three times greater than the TEK lifetime value). Add Certificate Filter Dialog Box

Use the Add Certificate Filter dialog box to define a certificate filter for the group encryption policy for GET VPNs. This filter, located on the key server, specifies the attributes and values used to validate whether the group member is authorized to join the group.

Select one of the following filter types:

- **dn**—(Distinguished name.) Specify a comma separated list of name=value pairs in the Subject field. For example, OU=Cisco, C=US. When you configure the Public Key Infrastructure policy, the PKI enrollment object you select should define the same values on the Certificate Subject Name tab (see PKI Enrollment Dialog Box—Certificate Subject Name Tab, page 24-58). Using a distinguished name can let you match multiple devices with a single filter.

- **fqdn**—(Fully-qualified domain name.) Specify the fully qualified domain name of a single device (for example, router1.example.com) in the Domain Name field. When you configure the Public Key Infrastructure policy, the PKI enrollment object you select should have the Include Device’s FQDN option selected. Because each device has a unique name, an FQDN filter matches a single device only.

To configure certificate authorization, you must also configure a Public Key Infrastructure (PKI) policy for the GET VPN. The PKI policy is configured on all devices in the VPN.

### Add New or Edit Security Association Dialog Box

Use the Security Associations table to define security associations for the VPN. The columns in the table summarize the settings for an entry and are explained in Add New or Edit Security Association Dialog Box, page 23-55. When creating a new VPN, the Security Policy field (explained above) is used instead of this tab, which does not appear in the wizard.

To configure security associations:

- Click the **Add** button to add an entry to the table, and fill in the Add New Security Association dialog box.
- Select an entry and click the **Edit** button to edit an existing entry.
- Select an entry and click the **Delete** button to delete it.

### Security Associations Tab

</tr>
</tbody>
</table>

---

**Tip**

To configure certificate authorization, you must also configure a Public Key Infrastructure (PKI) policy for the GET VPN. The PKI policy is configured on all devices in the VPN.

### Navigation Path

From the Group Settings tab on the GET VPN Group Encryption page, select Certificates as the authorization type and click the **Add Row** button under the Authorization Filter table, or select a filter and click the **Edit Row** button. For information on opening the Group Encryption page, see Defining GET VPN Group Encryption, page 23-51.
Add New or Edit Security Association Dialog Box

Use the Add New or Edit Security Association dialog boxes to define an IPSec profile (name and transform set only) and security policy used by the selected GET VPN topology.

Navigation Path

To open the Add New Security Association dialog box, from the Security Associations tab on the GET VPN Group Encryption page, click the Add Row (+) button or select an existing association and click the Edit Row (pencil) button. For information on opening the Group Encryption page, see Defining GET VPN Group Encryption, page 23-51.

Field Reference

Table 23-13 Add New Security Association Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The sequence number of the profile. This number defines the relative priority of the security association (1 being the highest). If you have more than one security association, the ACLs for each are concatenated (and merged) in the order represented by this number, and the group members process the collected ACL as a single ACL. Keep the default number or enter a new one.</td>
</tr>
<tr>
<td>IPSec Profile Name</td>
<td>The name of the IPSec profile.</td>
</tr>
<tr>
<td>Transform Sets</td>
<td>The transform set policy objects (security protocols, algorithms, and other settings) defined for the IPSec profile. Separate multiple entries with commas, and place them in priority order. Click Select to choose from a list of predefined transform sets or to create a new one.</td>
</tr>
<tr>
<td>Security Policy</td>
<td>The access control list policy object defined for the security association. Click Select to choose from a list of predefined ACL objects or to create a new one. For a detailed explanation of the contents of this object and how it relates to the group member security policy, see Understanding the GET VPN Security Policy and Security Associations, page 27-10.</td>
</tr>
</tbody>
</table>

Note: If you are using multicast as the method to distribute the keys, then the ACL policy object must contain a deny rule (ACE) for the multicast address. In this way, the rekey packets sent using multicast will not be encrypted by the TEK. This statement allows the group members to receive rekey packets sent using the multicast protocol.

Creating or Editing VPN Topologies

Chapter 23  Managing Site-to-Site VPNs: The Basics

Creating or Editing VPN Topologies

Defining GET VPN Peers

Use the GET VPN Peers page of the Create VPN wizard to configure peer properties for the key servers and group members in a GET VPN topology. After creating the topology, use the Key Servers and Group Members policies to modify these settings. The policies are the same as the wizard page, except that the key server and group member tables are split into separate policies.

Tip

The list of key servers and group members includes those devices you selected on the Device Selection page of the wizard (see Selecting Devices for Your VPN Topology, page 23-32), however, you can use the Add (+) and Delete (trash can) buttons to add or remove devices from this page.
Examine the list of key servers and group members to determine if the default settings are appropriate for your VPN. You can select Matching Interfaces from the Show field below each table to display the actual interfaces that will be selected by the default interface roles. The interface roles must resolve to actual interfaces on the device for the GET VPN configuration to be valid.

**Before You Begin**

This procedure describes how to define peers for GET VPN when creating a new VPN, and explains just the GET VPN peers configuration. For information on opening the Create VPN wizard, see Creating or Editing VPN Topologies, page 23-28.

**Related Topics**

- Configuring Fail-Close to Protect Registration Failures, page 27-8
- Using Passive Mode to Migrate to GET VPN, page 27-23
- Configuring GET VPN Key Servers, page 27-18
- Configuring GET VPN Group Members, page 27-20

**Step 1**

Configure the key servers if the default settings are not appropriate.

For each key server you want to modify, select it, click the Edit (pencil) button beneath the table, and configure at least following settings. For information on all available settings, see Edit Key Server Dialog Box, page 27-19.

- **Identity Interface**—Select the interface that group members use to identify the key server and register with it. The default is the Loopback interface role, which identifies all Loopback interfaces defined on the key server.

- **Priority**—Define the role of the key server as primary or secondary by entering a priority value between 1-100. The key server with the highest priority becomes the primary key server. If two or more key servers are assigned the same priority value, the device with the highest IP address is used. The default priority is 100 for the first key server, 95 for the second, and so on.

*Note*

There can be more than one primary key server if the network is partitioned.

**Step 2**

Move key servers up or down in the table to specify the order that group members use to register with key servers. Group members register with the first key server in the list. If the first key server cannot be reached, they will register with the second key server, and so on. Note that this order does not define the overall key server priority, which is used to determine which key server is the primary key server.

**Step 3**

Configure the group members if the default settings are not appropriate.

For each group member you want to modify, select it, click the Edit (pencil) button beneath the table, and configure at least the following settings:

- **GET-Enabled Interface**—This is the VPN-enabled outside interface to the provider edge (PE). Traffic originating or terminating on this interface is evaluated for encryption or decryption, as appropriate. You can configure multiple interfaces by selecting an interface role object that resolves to more than one interface. Click Select to select an interface role object or to create a new object.
Creating or Editing VPN Topologies

Chapter 23  Managing Site-to-Site VPNs: The Basics

Assigning Initial Policies (Defaults) to a New VPN Topology

Use the VPN Defaults page of the Create VPN wizard to view and select the shared site-to-site VPN policies that will be assigned to the VPN topology you are creating. The page displays all the available mandatory and optional policies that can be assigned to your VPN topology, according to the selected IPsec technology. (For more information, see Understanding Mandatory and Optional Policies for Site-to-Site VPNs, page 23-6.)

For information on opening the Create VPN wizard, see Creating or Editing VPN Topologies, page 23-28. After you create the topology, you edit these policies directly.

For each policy type, select the shared VPN policy you want to assign to your VPN topology. Only shared policies are available for selection. Use the following tips to guide your selection:

- The initial defaults listed in this page are configured in the Security Manager Administration VPN Policy Defaults Page, page 11-47. If no specific default was configured for a mandatory policy, the Factory Default policy is selected. For more information about configuring default policies, see Understanding and Configuring VPN Default Policies, page 23-12.

- The shared policies listed are only those that have been committed to the database. For example, if you create a new shared IPsec Proposal policy before using the Create VPN wizard, but you do not submit (and have approved, if necessary) the policy beforehand, the new policy does not appear in the list. Ensure that you submit policies before creating a VPN if you need to use the new policies.

- If a policy is mandatory, you must make a selection. If there are no shared policies, Factory Default is your only option. You can always edit the policy after you create the topology.

Note

If you try to select a shared policy that is currently locked by another user, a message is displayed warning you of a lock problem. To bypass the lock, select a different policy or cancel the VPN topology creation until the lock is removed. For more information, see Understanding Policy Locking, page 5-7.

- If a policy is optional, and there are no shared policies, you cannot select anything. If you want the features provided by that policy, configure it after you finish creating the topology.

- To view the contents of the policy in a read-only dialog box, select the policy and click the View Contents button beside the policy list.

- If you are creating a topology that supports IKEv2 only, the Create VPN wizard will still create either an IKEv1 Preshared Key or IKEv1 Public Key Infrastructure policy according to your selection. There are no default configurations for IKEv2 Authentication policies. Whenever you choose to support IKEv2, you must manually edit the IKEv2 Authentication policy after creating the VPN to define at least the global IKEv2 settings. You can also create peer-specific IKEv2 overrides. When supporting IKEv2 only, you can unassign the IKEv1-specific policies created by the wizard.
Creating or Editing VPN Topologies

When you are done, click Finish to create the new VPN topology. The new VPN topology appears in the VPNs selector in the Site-to-Site VPN window, with the VPN Summary page displayed. See Viewing a Summary of a VPN Topology’s Configuration, page 23-59.

Viewing a Summary of a VPN Topology’s Configuration

Use the VPN Summary page to view a summary of the configuration of a selected VPN topology. This includes information about the type of VPN topology, its devices, the assigned technology, and specific policies that are configured in it. The summary page is opened automatically after you create a VPN topology. When creating an Extranet VPN, it is also shown as the final step of the Create Extranet VPN wizard.

To open the VPN Summary page for a VPN topology:

- (Site-to-Site VPN Manager Window, page 23-18) Select the VPN topology, then select VPN Summary from the Policies list.
- (Device view) Select a device that participates in the VPN and select the Site-to-Site VPN policy from the Policies list. Select the VPN topology, then click the Edit VPN Policies button. This opens the Site-to-Site VPN Manager window with the topology selected, where you can select VPN Summary from the Policies list.

The following table describes the information shown on this page.

<table>
<thead>
<tr>
<th>Table 23-14 VPN Summary Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element</strong></td>

</tr>
</tbody>
</table>

**Summary Information for Extranet VPNs**

- **IKE Phase 1 Proposal section**: The parameters for the IKE Phase 1 proposal, which are defined in the IKE Proposal policy object that is assigned to the Extranet. For information about the settings, see the following topics:
  - Configuring IKEv1 Proposal Policy Objects, page 24-10
  - Configuring IKEv2 Proposal Policy Objects, page 24-13

- **IKE Phase 2 Proposal section**: The parameters of the IKE Phase 2 proposal. Most of these parameters are configured in the IPsec transform set policy object assigned to the Extranet. For explanations, see Configuring IPsec IKEv1 or IKEv2 Transform Set Policy Objects, page 24-24.

  The Lifetime attribute parameter is defined in the VPN Global Settings policy, see Configuring VPN Global Settings, page 24-27. The Perfect Forward Secrecy parameter is defined in the IPsec Proposal policy, see Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20.

- **Authentication section**: The preshared key or the PKI enrollment policy object that defines the certificate used to authenticate the connection.

  When using preshared keys, you can click the **Show/Hide Key** button to toggle between showing and masking the key. If you print the summary or generate a PDF, the key is shown or hidden based on your selection here.
Creating or Editing Extranet VPNs

Security Manager provides a simplified method of creating a regular IPsec point-to-point VPN between a device that you are managing in Security Manager and one that is not managed. This type of VPN is called an Extranet.

Typically, an Extranet is a site-to-site VPN connection between your network and the network of a partner or a service provider. However, it can also be a VPN connection within your organization’s network, but between devices managed by different groups, or between a Cisco device and a non-Cisco device (which Security Manager cannot manage).

Use the Create Extranet VPN wizard to create this type of point-to-point VPN topology. Creating an Extranet VPN involves specifying the devices, the VPN interfaces that are the source and destination endpoints of the VPN tunnel, and the protected networks that will be secured by the tunnel. You also specify the IKE and IPsec proposals and preshared key or certificates required to complete a secure connection.
When you edit an Extranet VPN topology, the Edit Extranet VPN dialog box contains the same pages as the Create Extranet VPN wizard, with the exception of the IKE proposal page, but the pages are laid out in a tabbed format rather than being presented as a wizard. Clicking OK on any tab in the dialog box saves your definitions on all the tabs. For IKE proposals, IPsec proposals, preshared keys, and Public Key Infrastructure certificates, you must edit the policies directly.

**Tips**

- VPN default policies do not apply to Extranet VPNs. The settings defined on the Security Manager Administration VPN Defaults page are ignored. If you have shared policies that you want to use in the Extranet VPN configuration, you can assign them to the VPN after you create it with the Create Extranet VPN wizard. Assigning the shared policy replaces the policy created by the wizard.
- You cannot select your pre-defined IKE proposal or IPsec transform set policy objects when creating an Extranet VPN. If you have existing objects that you want to use, you can edit the relevant policies after creating the VPN and select the objects. You can then delete the objects created by the Create Extranet VPN wizard, if desired.
- After creating an Extranet VPN, you cannot convert it to a standard point-to-point VPN, where you are managing both ends of the VPN in Security Manager. Instead, you must delete and recreate the VPN.
- You can configure Extranet VPN connections for regular IPsec point-to-point connections only. For example, you cannot use this method to identify a GET VPN key server that exists in your service provider’s network. To configure all other types of Extranet connections, you must add dummy unmanaged devices to the Security Manager inventory as described in Including Unmanaged or Non-Cisco Devices in a VPN, page 23-11.

**Related Topics**

- Understanding VPN Topologies, page 23-2
- Configuring VPN Topologies in Device View, page 23-19
- Understanding IPsec Technologies and Policies, page 23-5
- Using Wizards, page 1-43

**Step 1**

Do one of the following

- To create a new Extranet VPN, in the Site-to-Site VPN Manager Window or the Site-to-Site VPN policy page (Device View), click the Create VPN Topology (+) button and select Extranet VPN. The Create Extranet VPN wizard starts with the Name and Technology page.
- To edit an existing Extranet VPN, select the VPN topology in the Site-to-Site VPN Manager window or the Site-to-Site VPN policy page (Device View) and click the Edit VPN Topology (pencil) button. The Edit Extranet VPN dialog box opens to the Device Selection tab.

**Step 2**

On the Name and Technology page or tab, configure the following; only the name is required:

- **Name**—A unique name that identifies the VPN topology.
- **Description**—A description of the VPN, up to 1024 characters.
- **Creation Date**—The date on which the VPN was created. When creating the VPN, today’s date is the default. However, you can click the calendar icon beside the edit box and select the desired date.
- **Ticket Number**—If you use a trouble ticket system, and the action you are taking relates to a tracked requirement, enter the number in this field. Security Manager does not use this number; it is for your internal tracking purposes only.
• **Last Modified By**—The name, user ID, email address, or other indicator of the person who last changed the settings for the VPN. Security Manager does not use this field; it is for your internal tracking purposes only.

In the wizard, click **Next**; in the Edit Extranet VPN dialog box, click the **Device Selection** tab.

**Step 3** On the Device Selection page or tab, configure the devices, interfaces, and protected networks for each end of the connection:

- **Local**—This is the device in your managed network. The device must be in the Security Manager inventory. Configure all of these properties:
  - **Device**—Enter the display name of the device or click **Select** to select it from the list of devices in the inventory. You can select ASA 5500 series devices, PIX firewalls, or Cisco IOS routers (including ASRs).
  - **VPN Tunnel Interface**—The name of the interface or interface role that identifies the external interface for the VPN connection. Click **Select** to select an existing interface or interface role, or to create a new interface role.
  
    When you select an interface or role, the IP address for the matching interface appears next to the IP Address display field. If no address appears, Security Manager could not determine the IP address. Check your configuration or object selection.
  
  - **Protected Networks**—The networks that the device is protecting for this VPN. Enter either the name of a network/host policy object, or enter the network addresses directly (such as 10.100.10.0/24). Separate multiple entries with commas. The content of the selected objects is evaluated and displayed beneath the edit box so that you can verify that you selected the desired objects.

  **Note** If you want to specify the protected networks using an interface name, interface role object, or ACL object, you must edit the Peers policy as described in Defining the Endpoints and Protected Networks, page 23-33. When creating the Extranet VPN, use a dummy network, then be sure to edit the Peers policy immediately after finishing the wizard.

- **Remote**—This is the device that you are not managing in Security Manager. Configure all of these properties:
  
    - **Name**—The name of the device, equivalent to the display name used in the Security Manager inventory.
  
    - **IP Address**—The IP address of the VPN interface on the device.
  
    - **Protected Networks**—The networks that the device is protecting for this VPN. Enter either the name of a network/host policy object, or enter the network addresses directly (such as 10.100.10.0/24). Separate multiple entries with commas. The content of the selected objects is evaluated and displayed beneath the edit box so that you can verify that you selected the desired objects.

  **Note** You can also edit the remote device endpoint settings as described in Defining the Endpoints and Protected Networks, page 23-33. However, the settings are identical to these, and you cannot specify the protected networks using an interface name, interface role object, or ACL object.
In the wizard, click **Next**. In the Edit VPN dialog box, you are finished; to edit the remaining characteristics, you must edit the IKE Proposal, IPsec Proposal, IKEv1 Preshared Key, IKEv1 Public Key Infrastructure, IKEv2 Authentication, and VPN Global Settings policies to change the settings described in the next step.

**Step 4** On the IKE Proposal page of the Create Extranet VPN wizard, define the IKE proposal, the IPsec proposal, and either the preshared key or the certificate:

- **Select IKEv1 or IKEv2.** You can use IKEv2 on ASA 5500 series devices running release 8.4(x) only.

  If you want to change IKE versions after creating the Extranet VPN, you must edit all of these policies to unassign or replace the old configuration while configuring options for the desired version: IKE Proposal, IPsec Proposal, IKEv1 Preshared Key, IKEv1 Public Key Infrastructure, IKEv2 Authentication, VPN Global Settings. For information on how IKEv1 and IKEv2 differ, see Comparing IKE Version 1 and 2, page 24-4.

- **Configure the IKE Phase 1 Proposal parameters.** These parameters will be used to create an IKE proposal policy object with the name `ExtranetName_ikeBB`. For an explanation of the parameters, see Configuring IKEv1 Proposal Policy Objects, page 24-10 or Configuring IKEv2 Proposal Policy Objects, page 24-13.

  To edit these values after creating the VPN, you simply need to edit the object. You can edit the object in the Policy Object Manager or directly through the IKE Proposal policy for the VPN.

  **Note** The **DH Group** attribute (for Diffie-Hellman modulus group) is called **Modulus Group** in other policies and policy objects.

- **Configure the IKE Phase 2 (IPsec) Proposal parameters.** Most of these parameters will be used to create an IPsec transform set policy object with the name `ExtranetName_transformSet`. For an explanation of the parameters, see Configuring IPSec IKEv1 or IKEv2 Transform Set Policy Objects, page 24-24. Note that the AH Hash Algorithm setting is available only if the local device is a router.

  To edit these values after creating the VPN, you simply need to edit the object. You can edit the object in the Policy Object Manager or directly through the IPsec Proposal policy for the VPN.

  The following settings are not part of the IPsec transform set object:

  - **Enable Perfect Forward Secrecy, DH Group**—Whether to use a unique session key for each encrypted exchange, which prevents an attacker from decrypting a captured exchange even if the attacker knows the preshared or private keys used by both ends of the tunnel. If you select this option, also select the Diffie-Hellman (DH) modulus group to use for deriving the key. For more information on the modulus group, see Deciding Which Diffie-Hellman Modulus Group to Use, page 24-7.

    To change this option after creating the VPN, edit the IPsec Proposal policy.

  - **Lifetime**—The number of seconds a security association will exist before expiring. The default is 3,600 seconds (one hour).

    To change this option after creating the VPN, edit the VPN Global Settings policy.

  - **If you select Preshared Key** for authentication, enter the key used to authenticate connections with the remote host.
Deleting a VPN Topology

Deleting a VPN topology removes IPsec tunnels between peers and all configurations associated with the VPN topology from the devices and networks assigned to the site-to-site VPN. The actual VPN is not removed from the network until you deploy configurations.

Step 1  Do one of the following:
• Select Manage > Site-To-Site VPNs to open the Site-to-Site VPN Manager Window, page 23-18.
• In Device view, select a device that participates in the VPN you want to delete, then select the Site to Site VPN policy from the policy selector (see Configuring VPN Topologies in Device View, page 23-19).

Step 2  Select the VPN topology you want to delete and click the Delete VPN Topology (trash can) button. You are asked to confirm the deletion.
Configuring IKE and IPsec Policies

This chapter describes how to configure Internet Protocol Security (IPsec) and the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) standards to build site-to-site and remote access IPsec Virtual Private Networks (VPNs). These policies are used in regular IPsec and other types of IPsec-based VPN technologies to build VPN tunnels.

Tunneling makes it possible to use a public TCP/IP network, such as the Internet, to create secure connections between remote users and a private corporate network. Each secure connection is called a tunnel.

IPsec-based VPN technologies use the ISAKMP and IPsec tunneling standards to build and manage tunnels. ISAKMP and IPsec accomplish the following:

- Negotiate tunnel parameters.
- Establish tunnels.
- Authenticate users and data.
- Manage security keys.
- Encrypt and decrypt data.
- Manage data transfer across the tunnel.
- Manage data transfer inbound and outbound as a tunnel endpoint or router.

A device in a VPN functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.

The following topics explain the basic IKE and IPsec policies and how to configure them:

- Overview of IKE and IPsec Configurations, page 24-2
- Understanding IKE, page 24-5
- Understanding IPsec Proposals, page 24-16
- Configuring VPN Global Settings, page 24-27
- Understanding IKEv1 Preshared Key Policies in Site-to-Site VPNs, page 24-40
- Understanding Public Key Infrastructure Policies, page 24-44
- Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59
Overview of IKE and IPsec Configurations

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and to automatically establish IPsec security associations (SAs).

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection.

An IKE proposal is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters will be used to protect subsequent IKE negotiations. For IKE version 1 (IKEv1), IKE proposals contain a single set of algorithms and a modulus group. You can create multiple, prioritized policies at each peer to ensure that at least one policy matches a remote peer’s policy. Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups from which peers can choose during the Phase 1 negotiation, potentially making it possible to create a single IKE proposal (although you might want different proposals to give higher priority to your most desired options). You can define several IKE proposals per VPN.

You must configure several policies to define the settings required to make successful regular IPsec connections in a site-to-site or remote access VPN. The following procedure provides an overview of the steps required to complete the configuration, and points to other topics that provide detailed information for each step.

Related Topics
- Understanding IKE, page 24-5
- Understanding IPsec Proposals, page 24-16
- Understanding IKEv1 Preshared Key Policies in Site-to-Site VPNs, page 24-40
- Understanding Public Key Infrastructure Policies, page 24-44

Step 1 Configure the IKE Proposal policy.

In the IKE Proposal policy, you define the IKE proposal policy objects to use for making VPN connections. When defining the IKE proposal object, you select the algorithms to use for encrypting the IKE negotiation and for integrity checking, and the Diffie-Hellman group to use to operate the encryption algorithm. For IKEv1, you also determine whether you are using preshared keys or Public Key Infrastructure, whereas in IKEv2, the IKE proposal does not include a specification for authentication mode.

The following topics explain how to configure the IKE Proposal policy:
- Configuring an IKE Proposal, page 24-9
  - Configuring IKEv1 Proposal Policy Objects, page 24-10
  - Configuring IKEv2 Proposal Policy Objects, page 24-13
- Configuring the IKE Proposal for GET VPN, page 27-15

Step 2 Complete the authentication mode configuration.

Your selection for authentication mode in the IKEv1 proposal, and your decision on which mode to use for IKEv2, controls what other policies are required to complete the authentication mode configuration:
• Preshared keys—For remote access IKEv1 IPsec VPNs, you define the preshared keys in the Connection Profiles policy; preshared keys are not supported for IKEv2 in remote access VPNs. For site-to-site VPNs, you define the keys in the IKEv1 Preshared Keys or the IKEv2 Authentication policy based on the IKE version you are using.

The following topics explain preshared key configuration:

- IPSec Tab (Connection Profiles), page 29-16
- Configuring IKEv1 Preshared Key Policies, page 24-41
- Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59

• Public Key Infrastructure Certificate Authority servers—If you configure IKE to use Certificate Authority (CA) servers, you must configure the Public Key Infrastructure policy. You also use this policy to define the Public Key Infrastructure for SSL VPNs. For site-to-site VPNs, the policy is IKEv1 Public Key Infrastructure or IKEv2 Authentication, based on the IKE version you are using.

The Public Key Infrastructure policy identifies the PKI enrollment object that identifies the Certificate Authority server. For site-to-site VPNs, you can select a single PKI enrollment object; for remote access VPNs, you can select all objects needed for your remote access connections. These trustpoints are then identified in the remote access Connection Profiles policy (on the Ipsec tab).

The following topics explain public key infrastructure configuration:

- Understanding Public Key Infrastructure Policies, page 24-44
- Configuring IKEv1 Public Key Infrastructure Policies in Site-to-Site VPNs, page 24-47
- Defining Multiple IKEv1 CA Servers for Site-to-Site VPNs, page 24-48
- Configuring Public Key Infrastructure Policies for Remote Access VPNs, page 24-49
- IPSec Tab (Connection Profiles), page 29-16
- Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59

Step 3 Configure the IPSec Proposal policy. The IPSec Proposal policy defines the IPsec transform set policy objects used to create a secure IPsec tunnel for the VPN.

The following topics explain how to configure the IPSec Proposal policy:

- Configuring IPSec Proposals in Site-to-Site VPNs, page 24-20
  - Selecting the IKE Version for Devices in Site-to-Site VPNs, page 24-23
  - Configuring IPSec IKEv1 or IKEv2 Transform Set Policy Objects, page 24-24
- Configuring an IPSec Proposal for Easy VPN, page 26-10
- Configuring an IPSec Proposal on a Remote Access VPN Server (ASA, PIX 7.0+ Devices), page 29-30
- Configuring an IPSec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3

Step 4 Configure the Global Settings policy.

The Global Settings (remote access) and VPN Global Settings (site-to-site) policies define various ISAKMP, IKEv1, IKEv2, IPsec, NAT, fragmentation, and other settings. These settings have default values that are frequently adequate, so normally you need to configure the Global Settings policy only if you want non-default behavior. However, you must configure the policy for remote access IKEv2 IPsec VPNs, because you must specify a remote access global trustpoint on the IKEv2 Settings tab.
Overview of IKE and IPsec Configurations

The following topics explain how to configure the Global Settings policy:

- Configuring VPN Global Settings, page 24-27
  - Configuring VPN Global ISAKMP/IPsec Settings, page 24-27
  - Configuring VPN Global IKEv2 Settings, page 24-31
  - Configuring VPN Global NAT Settings, page 24-35
  - Configuring VPN Global General Settings, page 24-37
- Configuring Global Settings for GET VPN, page 27-17

Step 5

If you are configuring a remote access IKEv2 IPsec VPN, you must also configure several policies for SSL VPN. IKEv2 shares several configuration settings with SSL VPNs. For information on the other policies you need to configure, see Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (ASA and PIX 7.0+ Devices), page 28-24.

Comparing IKE Version 1 and 2

There are two versions of IKE: version 1 (IKEv1) and version 2 (IKEv2). When you configure IKE on a device that supports IKEv2, you have the option of configuring either version alone, or both versions together. When the device attempts to negotiate a connection with another peer, it uses whichever versions you allow and that the other peer accepts. If you allow both versions, the device automatically falls back to the other version if negotiations are unsuccessful with the initially chosen version (IKEv2 is always tried first if it is configured). Both peers must support IKEv2 to use it in a negotiation.

Tip

Security Manager supports IKEv2 on ASA 8.4(1)+ only. For remote access IPsec VPNs, users must use the AnyConnect 3.0+ client to complete IKEv2 connections, and IKEv2 connections use the same license pool that is used for SSL VPN connections. The legacy VPN Client is used for IKEv1 remote access connections on ASAs. For more information about device support in VPNs, see Understanding Devices Supported by Each IPsec Technology, page 23-9.

IKEv2 differs from IKEv1 in the following ways:

- IKEv2 fixes the Photuris style cookie mechanism.
- IKEv2 has fewer round trips in a negotiation than IKEv1, two round trips versus five for IKEv1 for a basic exchange.
- Transform options are OR’ed, which means that you can specify multiple options in a single proposal rather than creating separate unique proposals for each allowed combination.
- Built-in dead peer detection (DPD).
- Built-in configuration payload and user authentication mode.
- Built-in NAT traversal (NAT-T). IKEv2 uses ports 500 and 4500 for NAT-T.
- Improved re-keying and collision handling.
- A single security association (SA) can protect multiple subnets, which improves scalability.
- Asymmetric authentication in site-to-site VPNs, where each side of a tunnel can have different preshared keys, different certificates, or one side a key and the other side a certificate.
For remote access IPsec VPNs, you can configure double authentication for IKEv2 connections in the same way that you configure them for remote access SSL VPNs. IKEv1 does not support double authentication.

Related Topics
- Overview of IKE and IPsec Configurations, page 24-2
- Configuring an IKE Proposal, page 24-9

Understanding IKE

Internet Key Exchange (IKE), also called Internet Security Association and Key Management Protocol (ISAKMP), is the negotiation protocol that lets two hosts agree on how to build an IPsec security association (SA). It provides a common framework for agreeing on the format of SA attributes. This includes negotiating with the peer about the SA, and modifying or deleting the SA. IKE creates the cryptographic keys used to authenticate IPsec peers, negotiates and distributes IPsec encryption keys, and automatically establishes IPsec security associations.

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, creating the first tunnel that enables the peers to communicate securely in Phase 2, protecting later ISAKMP negotiation messages. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec, which protects the data sent between peers. Both phases use proposals when they negotiate a connection.

An IKE proposal is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters will be used to protect subsequent IKE negotiations. In remote access IPsec VPNs, you can define several IKE proposals per VPN to create multiple, prioritized policies at each peer to ensure that at least one policy matches a remote peer’s policy. For site-to-site VPNs, you can create a single IKE proposal.

To define an IKE proposal, you must specify:
- A unique priority (1 through 65,543, with 1 the highest priority).
- An encryption method for the IKE negotiation, to protect the data and ensure privacy. See Deciding Which Encryption Algorithm to Use, page 24-6.
- A Hashed Message Authentication Codes (HMAC) method (called integrity algorithm in IKEv2) to ensure the identity of the sender, and to ensure that the message has not been modified in transit. See Deciding Which Hash Algorithm to Use, page 24-7.
- For IKEv2, a separate pseudo-random function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The options are the same as those used for the hash algorithm; see Deciding Which Hash Algorithm to Use, page 24-7.
- A Diffie-Hellman group to determine the strength of the encryption-key-determination algorithm. The device uses this algorithm to derive the encryption and hash keys. See Deciding Which Diffie-Hellman Modulus Group to Use, page 24-7.
- A limit to the time the device uses an encryption key before replacing it.
Understanding IKE

Tip

(ASA devices only.) With IKEv1 policies, for each parameter, you set one value. For IKEv2, you can configure multiple encryption, integrity, PRF, and Diffie-Hellman options. The ASA orders the settings from the most secure to the least secure and negotiates with the peer using that order. This allows you to potentially send a single proposal to convey all the allowed transforms instead of the need to send each allowed combination as with IKEv1.

When IKE negotiation begins, the peer that initiates the negotiation sends all of its policies to the remote peer, and the remote peer searches for a match with its own policies, in priority order.

A match between IKE policies exists if they have the same encryption, hash (integrity and PRF for IKEv2), authentication, and Diffie-Hellman values, and an SA lifetime less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter lifetime—from the remote peer policy—applies. If no match exists, IKE refuses negotiation and the IKE SA is not established.

The following topics explain how to configure IKE proposals:

- Configuring an IKE Proposal, page 24-9
- Configuring IKEv1 Proposal Policy Objects, page 24-10
- Configuring IKEv2 Proposal Policy Objects, page 24-13
- Configuring the IKE Proposal for GET VPN, page 27-15

Deciding Which Encryption Algorithm to Use

When deciding which encryption and hash algorithms to use for the IKE proposal, your choice is limited to algorithms that are supported by the devices in the VPN.

You can choose from the following encryption algorithms:

- DES (Data Encryption Standard) is a symmetric secret-key block algorithm. It is faster than 3DES and uses less system resources, but it is also less secure. If you do not need strong data confidentiality, and if system resources or speed is a concern, you should choose DES.

- 3DES (Triple DES) is more secure because it processes each block of data three times, each time with a different key. However, it uses more system resources and is slower than DES. 3DES is the recommended encryption algorithm, assuming that the devices support it.

- AES (Advanced Encryption Standard) provides greater security than DES and is computationally more efficient than 3DES. AES offers three different key strengths: 128-, 192- and 256-bit keys. A longer key provides higher security but a reduction in performance. When you configure IKE on a router, the router must use Cisco IOS Software 12.3T or later to use AES.

Note

AES cannot be used in conjunction with a hardware encryption card.

Related Topics

- Understanding IKE, page 24-5
- Configuring an IKE Proposal, page 24-9
Deciding Which Hash Algorithm to Use

You can choose from the following hash algorithms. In IKEv2, the hash algorithm is separated into two options, one for the integrity algorithm, and one for the pseudo-random function (PRF).

- **SHA (Secure Hash Algorithm)** is more resistant to brute-force attacks than MD5. However, it is also more resource intensive than MD5. For implementations that require the highest level of security, use the SHA hash algorithm.

  Standard SHA produces a 160-bit digest.

  The following options, which are even more secure, are available for IKEv2 configurations on ASA 8.4(2+) devices:
  - SHA512—a 512-bit key.
  - SHA384—a 384-bit key.
  - SHA256—a 256-bit key.

- **MD5 (Message Digest 5)** produces a 128-bit digest and uses less processing time for an overall faster performance than SHA, but it is considered to be weaker than SHA.

**Related Topics**

- Understanding IKE, page 24-5
- Configuring an IKE Proposal, page 24-9

Deciding Which Diffie-Hellman Modulus Group to Use

Security Manager supports the following Diffie-Hellman key derivation algorithms to generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus provides higher security, but requires more processing time. You must have a matching modulus group on both peers.

**Tip**

If you select AES encryption, to support the large key sizes required by AES, ISAKMP negotiation should use Diffie-Hellman (DH) Group 5 or higher. ASA devices support groups 1, 2, and 5 only, and these are the only groups available for IKEv2.

- Diffie-Hellman Group 1: 768-bit modulus. Use to generate IPsec SA keys where the prime and generator numbers are 768 bits.
- Diffie-Hellman Group 2: 1024-bit modulus. Use to generate IPsec SA keys where the prime and generator numbers are 1024 bits. Cisco VPN Client Version 3.x or higher requires a minimum of Group 2.
- Diffie-Hellman Group 5: 1536-bit modulus. Use to generate IPsec SA keys where the prime and generator numbers are 2048 bits. Considered good protection for 128-bit keys, but group 14 is better.
- Diffie-Hellman Group 7: Use to generate IPsec SA keys when the elliptical curve field size is 163 characters. Group 7 is not supported on a Catalyst 6500/7600 device with VPNSM or VPN SPA configuration.
Deciding Which Authentication Method to Use

Security Manager supports two methods for peer device authentication in a VPN communication:

- **Preshared Key**—Preshared keys allow for a secret key to be shared between two peers and to be used by IKE during the authentication phase. The same shared key must be configured at each peer or the IKE SA cannot be established.

  To use IKE successfully with this device authentication method, you must define various preshared key parameters. For more information, see the appropriate topic:

  - Site-to-site VPN, IKEv1 configuration—See Configuring IKEv1 Preshared Key Policies, page 24-41.
  - Site-to-site VPN, IKEv2 configuration—See Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59.
  - Remote access IPsec VPN, IKEv1—Configured on the IPsec tab of the connection profile. See IPSec Tab (Connection Profiles), page 29-16.
  - Remote access IPsec VPN, IKEv2—You cannot use preshared keys when using IKEv2 in a remote access IPsec VPN. You must use certificates.

- **Certificate**—An authentication method in which RSA key pairs are used to sign and encrypt IKE key management messages. Certificates provide non-repudiation of communication between two peers, meaning that it can be proved that the communication actually took place. When using this authentication method, peers are configured to obtain digital certificates from a Certification Authority (CA). CAs manage certificate requests and issue certificates to participating IPsec network devices. These services provide centralized key management for the participating devices.

  While the use of preshared keys does not scale well, using a CA does improve the manageability and scalability of your IPsec network. With a CA, you do not need to configure keys between all encrypting devices. Instead, each participating device is registered with the CA, and requests a certificate from the CA. Each device that has its own certificate and the public key of the CA can authenticate every other device within a given CA’s domain.

  To use IKE successfully with the Certificate authentication method, you must define parameters for CA authentication and enrollment. For more information, see the appropriate topic:

  - Site-to-site VPN, IKEv1 configuration—See Understanding Public Key Infrastructure Policies, page 24-44.
  - Site-to-site VPN, IKEv2 configuration—Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59.
  - Remote access IPsec VPN, IKEv1—Configured on the IPsec tab of the connection profile as explained in IPSec Tab (Connection Profiles), page 29-16. You must also configure the Public Key Infrastructure policy with the same trustpoint; see Understanding Public Key Infrastructure Policies, page 24-44.
  - Remote access IPsec VPN, IKEv2—Configure the global trustpoint on the IKEv2 Settings tab of the Global Settings policy as explained in Configuring VPN Global IKEv2 Settings, page 24-31. You must also configure the Public Key Infrastructure policy with the same trustpoint; see Understanding Public Key Infrastructure Policies, page 24-44.
Configuring an IKE Proposal

In Security Manager, an IKE proposal is a mandatory policy when you configure a site-to-site or remote access IPsec VPN. When you use the configuration wizard to create a new IPsec VPN, an IKE Proposal policy is automatically assigned to the VPN; the policy might be the factory default, or it might be a shared policy specifically selected for the VPN. For more information about the IKE (Internet Key Exchange) key management protocol, see Understanding IKE, page 24-5.

Use the IKE Proposal policy to examine the current IKE proposals and to configure new proposals except for GET VPN topologies. For GET VPN, see Configuring the IKE Proposal for GET VPN, page 27-15.

Tips

- For site-to-site VPNs, you can select at most one IKE proposal per IKE version. For remote access IPsec VPNs, you can select multiple proposals for each IKE version; select all IKE proposals that are allowed in the remote access VPN.
- To configure IKEv2 (version 2), the device must be an ASA running ASA Software release 8.4(1) or higher.
- The IPsec Proposal policy must enable IKEv1, IKEv2, or both, to match the IKE proposals you configure in this policy. In cases where you cannot configure IKEv2 in the IPsec proposal, such as in Easy VPN topologies, IKEv2 is not supported. For more information, see Understanding IPsec Proposals, page 24-16.
- The IKEv1 Proposal objects specify whether preshared keys or certificates are used for authentication. You must configure the appropriate policies to configure preshared keys or Public Key Infrastructure settings. For IKEv2, the object does not specify whether preshared keys or certificates are used, but other policies must define the authentication requirements. For more information, see Deciding Which Authentication Method to Use, page 24-8.

Related Topics

- Deciding Which Hash Algorithm to Use, page 24-7
- Deciding Which Diffie-Hellman Modulus Group to Use, page 24-7
- Deciding Which Authentication Method to Use, page 24-8

Step 1

Do one of the following to open the IKE Proposal policy based on the type of VPN you are configuring:

- For remote access VPNs, do one of the following:
  - (Device View) Select Remote Access VPN > IPSec VPN > IKE Proposal from the Policy selector.
  - (Policy View) Select Remote Access VPN > IPSec VPN > IKE Proposal from the Policy Type selector. Select an existing policy or create a new one.
- For site-to-site VPNs, do one of the following:
  - Open the Site-to-Site VPN Manager Window, page 23-18, select a topology (other than GET VPN) in the VPNs selector, then select IKE Proposal in the Policies selector.
Understanding IKE

- (Policy view) Select Site-to-Site VPN > IKE Proposal from the Policy Types selector. Select an existing shared policy or create a new one.

Step 2

In each of the IKEv1 Proposals and IKEv2 Proposals fields, click Select to choose the policy objects that define the settings for an IKE version 1 or version 2 proposal. Configure proposals only for those IKE versions supported in the VPN.

- To select an IKE proposal for site-to-site VPNs, simply highlight it in the available proposals list. For remote access IPsec VPNs, highlight the desired objects in the available proposals list and click >> to move them to the selected proposals list.
- To remove an IKE proposal for remote access IPsec VPNs, highlight it in the selected proposals list and click << to move it to the available proposals list.
- To create a new IKE proposal, click the Create (+) button beneath the available proposals list. The Add IKEv1 or IKEv2 Proposal dialog box opens. For instructions on creating the object, see the following topics:
  - Configuring IKEv1 Proposal Policy Objects, page 24-10
  - Configuring IKEv2 Proposal Policy Objects, page 24-13
- To edit an object, or to view its settings, select it and click the Edit (pencil) button beneath the list.

Configuring IKEv1 Proposal Policy Objects

Use the IKEv1 Proposal dialog box to create, copy, and edit an IKEv1 proposal object.

Internet Key Exchange (IKE) version 1 proposal objects contain the parameters required for IKEv1 proposals when defining remote access and site-to-site VPN policies. IKE is a key management protocol that facilitates the management of IPsec-based communications. It is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs).

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes security associations (SAs) for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. For more information about IKE proposals, see the following topics:

- Overview of IKE and IPsec Configurations, page 24-2
- Comparing IKE Version 1 and 2, page 24-4
- Understanding IKE, page 24-5
- Deciding Which Encryption Algorithm to Use, page 24-6
- Deciding Which Hash Algorithm to Use, page 24-7
- Deciding Which Diffie-Hellman Modulus Group to Use, page 24-7
- Deciding Which Authentication Method to Use, page 24-8

Navigation Path

Select Manage > Policy Objects, then select IKE Proposals > IKEv1 Proposals from the Object Type Selector. Right-click inside the work area, then select New Object or right-click a row, then select Edit Object.
You can also access this dialog box when configuring the IKE Proposal policy as explained in Configuring an IKE Proposal, page 24-9.

</tbody>
</table>
| Modulus Group       | The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time.
|                     | The two peers must have a matching modulus group. Options are:                                                                                                                                       |
|                     | • 1—Diffie-Hellman Group 1 (768-bit modulus).                                                                                                                                                           |
|                     | • 2—Diffie-Hellman Group 2 (1024-bit modulus).                                                                                                                                                           |
|                     | • 5—Diffie-Hellman Group 5 (1536-bit modulus, considered good protection for 128-bit keys, but group 14 is better). If you are using AES encryption, use this group (or higher). The ASA supports this group as the highest group. |
|                     | • 7—Diffie-Hellman Group 7 (163-bit elliptical curve field size).                                                                                                                                       |
|                     | • 14—Diffie-Hellman Group 14 (2048-bit modulus, considered good protection for 128-bit keys).                                                                                                                                                                    |
|                     | • 15—Diffie-Hellman Group 15 (3072-bit modulus, considered good protection for 192-bit keys).                                                                                                                                                                     |
|                     | • 16—Diffie-Hellman Group 16 (4096-bit modulus, considered good protection for 256-bit keys).                                                                                                                                                                     |
| Lifetime            | The lifetime of the security association (SA), in seconds. When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. As a general rule, the shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes. |
|                     | You can specify a value from 60 to 2147483647 seconds. The default is 86400.                                                                                                                           |
Understanding IKE

Configuring IKEv2 Proposal Policy Objects

Use the IKEv2 Proposal dialog box to create, copy, and edit an IKEv2 proposal object. You can use IKEv2 proposals with ASA Software release 8.4(1)+ only.

Internet Key Exchange (IKE) version 2 proposal objects contain the parameters required for IKEv2 proposals when defining remote access and site-to-site VPN policies. IKE is a key management protocol that facilitates the management of IPsec-based communications. It is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs).

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes security associations (SAs) for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups from which peers can choose during the Phase 1 negotiation. For more information about IKE proposals, see the following topics:

- Overview of IKE and IPsec Configurations, page 24-2
- Comparing IKE Version 1 and 2, page 24-4
- Understanding IKE, page 24-5
- Deciding Which Encryption Algorithm to Use, page 24-6
- Deciding Which Hash Algorithm to Use, page 24-7
- Deciding Which Diffie-Hellman Modulus Group to Use, page 24-7

| Encryption Algorithm | The encryption algorithm used to establish the Phase 1 SA for protecting Phase 2 negotiations. Click Select and select all of the algorithms that you want to allow in the VPN:  
  - AES—Encrypts according to the Advanced Encryption Standard using 128-bit keys.  
  - AES-192—Encrypts according to the Advanced Encryption Standard using 192-bit keys.  
  - AES-256—Encrypts according to the Advanced Encryption Standard using 256-bit keys.  
  - DES—Encrypts according to the Data Encryption Standard using 56-bit keys.  
  - 3DES—Encrypts three times using 56-bit keys. 3DES is more secure than DES, but requires more processing for encryption and decryption. It is less secure than AES. A 3DES license is required to use this option.  
  - Null—No encryption algorithm. |
| Integrity (Hash) Algorithm | The integrity portion of the hash algorithm used in the IKE proposal. The hash algorithm creates a message digest, which is used to ensure message integrity. Click Select and select all of the algorithms that you want to allow in the VPN:  
  - SHA (Secure Hash Algorithm)—SHA is more resistant to brute-force attacks than MD5.  
    Standard SHA produces a 160-bit digest.  
    The following options, which are even more secure, are available for IKEv2 configurations on ASA 8.4(2+) devices:  
      - SHA512—A 512-bit key.  
      - SHA384—A 384-bit key.  
      - SHA256—A 256-bit key.  
  - MD5 (Message Digest 5)—Produces a 128-bit digest. MD5 uses less processing time than SHA. |
| Prf Algorithm | The pseudo-random function (PRF) portion of the hash algorithm used in the IKE proposal. In IKEv1, the Integrity and PRF algorithms are not separated, but in IKEv2, you can specify different algorithms for these elements. Click Select and select all of the algorithms that you want to allow in the VPN. The options are described above under Integrity Algorithm. |
Understanding IPsec Proposals

IPsec is one of the most secure methods for setting up a VPN. IPsec provides data encryption at the IP packet level, offering a robust security solution that is standards-based. With IPsec, data is transmitted over a public network through tunnels. A tunnel is a secure, logical communication path between two peers, which can be devices in a site-to-site VPN or a device and user in remote access IPsec VPNs. Traffic that enters an IPsec tunnel is secured by a combination of security protocols and algorithms called a transform set.

An IPsec proposal is used in Phase 2 of an IKE negotiation, as explained in Understanding IKE, page 24-5. The specific content of the proposal varies according to topology type (site-to-site or remote access) and device type, although the proposals are broadly similar and contain many of the same elements, such as IPsec transform sets.

The following topics explain IPsec proposal concepts and procedures in more detail:

Understanding IPsec Proposals for Site-to-Site VPNs

IPsec is one of the most secure methods for setting up a VPN. IPsec provides data encryption at the IP packet level, offering a robust security solution that is standards-based. Pure IPsec configurations cannot use routing protocols—the policy created is used for pure IPsec provisioning. You can configure pure IPsec on Cisco IOS routers, PIX Firewalls, Catalyst VPN Service Modules, and Adaptive Security Appliance (ASA) devices.

With IPsec, data is transmitted over a public network through tunnels. A tunnel is a secure, logical communication path between two peers. Traffic that enters an IPsec tunnel is secured by a combination of security protocols and algorithms called a transform set.

In Security Manager, you use an IPsecProposal policy to define the settings required for a IPsec tunnels. An IPsec proposal is a collection of one or more crypto maps that are applied to the VPN interfaces on the devices. A crypto map combines all the components required to set up IPsec security associations, including transform sets. A crypto map can also be configured with Reverse Route Injection (RRI).

The following topics provide more information:
- Understanding Crypto Maps, page 24-17
- Understanding Transform Sets, page 24-18
- Understanding Reverse Route Injection, page 24-19

Related Topics
- Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20

Understanding Crypto Maps

A crypto map combines all components required to set up IPsec security associations (SA), including IPsec rules, transform sets, remote peers, and other parameters that might be necessary to define an IPsec SA. A crypto map entry is a named series of CLI commands. Crypto map entries with the same crypto map name (but different map sequence numbers) are grouped into a crypto map set, which is applied to the VPN interfaces on relevant devices. All IP traffic passing through the interface is evaluated against the applied crypto map set.

When two peers try to establish an SA, they must each have at least one compatible crypto map entry. The transform set defined in the crypto map entry is used in the IPsec security negotiation to protect the data flows specified by that crypto map’s IPsec rules.

Dynamic crypto map policies are used in site-to-site VPNs when an unknown remote peer tries to initiate an IPsec security association with the local hub. The hub cannot be the initiator of the security association negotiation. Dynamic crypto policies allow remote peers to exchange IPsec traffic with a local hub even if the hub does not know the remote peer’s identity. You can create a dynamic crypto policy on individual hubs or on a device group that contains hubs. The policy is written only to the hubs, not to any spokes that might be contained in the group. A dynamic crypto map policy essentially creates a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer’s requirements. The peer addresses for dynamic or static crypto maps are deduced from the VPN topology.
Dynamic crypto map policies apply only in a hub-and-spoke VPN configuration—in a point-to-point or full mesh VPN topology, you can apply only static crypto map policies.

(Note (Site-to-site VPNs.) Except for Extranet VPNs, Security Manager can manage an existing VPN tunnel only if the tunnel's peers are managed by Security Manager. In such a case, Security Manager uses the same crypto map name for the tunnel on the peers. On subsequent deployments, only Security Manager tunnels are managed (Security Manager maintains a log of all tunnels that were configured).

**Related Topics**
- Understanding IPsec Proposals, page 24-16
- Understanding Transform Sets, page 24-18
- Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20

**Understanding Transform Sets**

A transform set is a combination of security protocols and algorithms that secure traffic in an IPsec tunnel. During the IPsec security association (SA) negotiation, peers search for a transform set that is the same at both peers. When such a transform set is found, it is applied to create an SA that protects data flows in the access list for that crypto map, protecting the traffic in the VPN.

There are separate IPsec transform sets for IKEv1 and IKEv2. With IKEv1 transform sets, for each parameter, you set one value. For IKEv2 transform sets, you can configure multiple encryption and integration algorithms for a single proposal. ASA devices order the settings from the most secure to the least secure and negotiate with the peer using that order. This allows you to potentially send a single proposal to convey all the allowed combinations instead of the need to send each allowed combination individually as with IKEv1.

You can specify a number of transform sets per IPsec proposal policy. If you are defining the policy on a spoke or a group of spokes, you do not usually have to specify more than one transform set. This is because the spoke's assigned hub would typically be a higher performance router capable of supporting any transform set that the spoke supports. However, if you are defining the policy on a hub for dynamic crypto, you should specify more than one transform set to ensure that there will be a transform set match between the hub and the unknown spoke. If more than one of your selected transform sets is supported by both peers, the transform set that provides the highest security is used.

Security Manager provides predefined transform sets that you can use in your tunnel policies. You can also create your own transform sets. For more information, see Configuring IPsec IKEv1 or IKEv2 Transform Set Policy Objects, page 24-24.

**Selecting Tunnel Mode for IKEv1 Transform Sets**

When defining an IKEv1 transform set, you must specify which IPsec mode of operation to use—tunnel mode or transport mode. You can use the AH and ESP protocols to protect an entire IP payload (Tunnel mode) or just the upper-layer protocols of an IP payload (Transport mode).

In tunnel mode (the default), the entire original IP datagram is encrypted, and it becomes the payload in a new IP packet. This mode allows a router to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source’s router encrypts packets and forwards them along the IPsec tunnel. The destination’s router decrypts the original IP datagram and forwards it on to the destination system. The major advantage of tunnel mode is that the end systems do not need to be modified to enjoy the benefits of IPsec. Tunnel mode also protects against traffic analysis. With tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.
In transport mode, only the IP payload is encrypted, and the original IP headers are left intact. This mode has the advantage of adding only a few bytes to each packet. It also allows devices on the public network to see the final source and destination of the packet. However, by passing the IP header in the clear, transport mode allows an attacker to perform some traffic analysis. For example, an attacker could see when a company’s CEO sent many packets to another senior executive. However, the attacker would only know that IP packets were sent; the attacker would not be able to decipher the contents of the packets. With transport mode, the destination of the flow must be an IPsec termination device.

**Note**

You cannot use transport mode for VPN topologies using regular IPsec or Easy VPN.

**Understanding Reverse Route Injection**

Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities. Each route is created on the basis of the remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote VPN router as the next hop, the traffic is forced through the crypto process to be encrypted.

After the static route is created on the VPN router, this information is propagated to upstream devices, allowing them to determine the appropriate VPN router to which to send returning traffic in order to maintain IPsec state flows. This is particularly useful if multiple VPN routers are used at a site to provide load balancing or failover, or if the remote VPN devices are not accessible through a default route. Routes are created in either the global routing table or the appropriate virtual route forwarding (VRF) table.

**Note**

Security Manager automatically configures RRI on devices with High Availability (HA) or on the IPsec Aggregator when VRF-Aware IPsec is configured. You can also configure RRI on a device’s crypto map in a remote access VPN. See Configuring an IPsec Proposal on a Remote Access VPN Server (ASA, PIX 7.0+ Devices), page 29-30 and Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3.

In Security Manager, the following options are available for configuring Reverse Route Injection:

- For dynamic crypto maps, routes are created upon the successful establishment of IPsec security associations (SAs) for those remote proxies. The next hop back to those remote proxies is through the remote VPN router whose address is learned and applied during the creation of the dynamic crypto map template. The routes are deleted after the SAs are deleted.
- The Remote Peer option (available for IOS devices only) enables you to specify an interface or address as the explicit next hop to the remote VPN device. Two routes are created. One route is the standard remote proxy ID and the next hop is the remote VPN client tunnel address. The second route is the actual route to the remote tunnel endpoint, when a recursive lookup is forced to impose that the remote endpoint is reachable via “next-hop.” Creation of the second route for the actual next hop is very important for VRF-Aware IPsec when a default route must be overridden by a more explicit route.
Understanding IPsec Proposals

Note
For devices using a VPN Services Module (VPNSM), the next hop is the interface or subinterface/VLAN on which the crypto map is applied.

- In the case of Remote Peer IP (available for IOS devices only), one route is created to a remote proxy by way of a user-defined next hop. The next hop can be used to override a default route to properly direct outgoing encrypted packets. This option reduces the number of routes created and supports those platforms that do not readily facilitate route recursion.

Configuring IPsec Proposals in Site-to-Site VPNs

Use the IPsec Proposal page to configure the IPsec proposal used during IKE Phase 2 negotiations for site-to-site VPN topologies with the exception of Easy VPN topologies.

IPsec proposals used with Easy VPN topologies, and with remote access VPNs, are significantly different than the basic site-to-site proposal explained in this topic. For information on IPsec proposals in these other topologies, see the following topics:

- Configuring an IPsec Proposal for Easy VPN, page 26-10
- Configuring an IPsec Proposal on a Remote Access VPN Server (ASA, PIX 7.0+ Devices), page 29-30
- Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3

Navigation Path
- (Site-to-Site VPN Manager Window, page 23-18) Select a non-Easy VPN topology in the VPNs selector, then select IPsec Proposal in the Policies selector. If necessary, click the IPsec Proposal tab.
- (Policy view) Select Site-to-Site VPN > IPsec Proposal from the Policy Types selector. Select an existing shared policy or create a new one.

### Understanding IPsec Proposals

#### Table 24-3  IPsec Proposal Page, Site-to-Site VPNs (except Easy VPN)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Crypto Map Type** (Hub and spoke and full mesh topologies only.) | A crypto map combines all the components required to set up IPsec security associations (SA). When two peers try to establish an SA, they must each have at least one compatible crypto map entry. For more information, see Understanding Crypto Maps, page 24-17. Select the type of crypto map you want to generate:  
- Static—Use a static crypto map in a point-to-point or full mesh VPN topology.  
- Dynamic—Dynamic crypto maps can only be used in a hub-and-spoke VPN topology. Dynamic crypto map policies allow remote peers to exchange IPsec traffic with a local hub, even if the hub does not know the remote peer’s identity. |
| **Enable IKEv1** | The IKE versions to use during IKE negotiations. IKEv2 is supported on ASA Software release 8.4(x) only. Select either or both options as appropriate; you must select IKEv1 if any device in the topology does not support IKEv2. |
| **Enable IKEv2** |  
When you select both options in hub-and-spoke or full mesh topologies, Security Manager automatically assigns the IKE version to devices based on the OS type and version used by the device. You can change these assignments by clicking the IKE Version tab, then click the Select button beneath the IKEv1 Enabled Peers or IKEv2 Enabled Peers to change which version is assigned to the device. You can change the assignments for devices that support each version only; other devices are not selectable. For more information, see Selecting the IKE Version for Devices in Site-to-Site VPNs, page 24-23. |
| **Transform Sets** | The transform sets to use for your tunnel policy. Transform sets specify which authentication and encryption algorithms will be used to secure the traffic in the tunnel. The transform sets are different for each IKE version; select objects for each supported version. You can select up to 11 transform sets for each. For more information, see Understanding Transform Sets, page 24-18. If more than one of your selected transform sets is supported by both peers, the transform set that provides the highest security will be used. Click Select to select the IPsec transform set policy objects to use in the topology. If the required object is not yet defined, you can click the Create (+) button beneath the available objects list in the selection dialog box to create a new one. For more information, see Configuring IPSec IKEv1 or IKEv2 Transform Set Policy Objects, page 24-24. |

**Note**  
IKEv1 Transform sets can use tunnel mode or transport mode of IPsec operation. However, you cannot use transport mode in IPsec or Easy VPN topologies.
Understanding IPsec Proposals

<tbody>
<tr>
<td>Enable Perfect Forward Secrecy Modulus Group</td>
<td>Whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list. For an explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use, page 24-7.</td>
</tr>
</tbody>
</table>
| Lifetime (sec) Lifetime (kbytes)           | The global lifetime settings for the crypto IPsec security association (SA). You can specify the IPsec lifetime in seconds, in kilobytes, or both.  
  • Seconds (sec)—The number of seconds an SA will exist before expiring. The default is 3600 seconds (one hour).  
  • Kilobytes (kbytes)—The volume of traffic (in kilobytes) that can pass between IPsec peers using a given SA before it expires. Valid values depend on the device type. Enter a value within the range 10-2147483647 for an IOS router, and 2560-536870912 for an ASA/PIX7.0+ device. The default value is 4,608,000 kilobytes. |
| QoS Preclassify                            | Supported on Cisco IOS routers, except 7600 devices. When selected, enables the classification of packets before tunneling and encryption occur. The Quality of Service (QoS) for VPNs feature enables Cisco IOS QoS services to operate with tunneling and encryption on an interface. The QoS features on the output interface classify packets and apply the appropriate QoS service before the data is encrypted and tunneled, enabling traffic flows to be adjusted in congested environments, and resulting in more effective packet tunneling. |
Understanding IPsec Proposals

Selecting the IKE Version for Devices in Site-to-Site VPNs

Use the IKE Version tab in the IPsec Proposal page to select which version of IKE to use for each device in a hub-and-spoke or full mesh site-to-site VPN. This tab appears only in the Site-to-Site VPN Manager; you cannot configure the options in Policy view, because they are specific to the actual devices in a VPN topology.

The IKE Version tab contains two lists: IKEv1 Enabled Peers and IKEv2 Enabled Peers. When you configure the IPsec proposal, as described in Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20, you select which IKE versions to allow in the VPN (version 1, version 2, or both). Security Manager automatically chooses which IKE version to use for a device based on the OS version used by the device. For example, IOS routers always appear in the IKEv1 Enabled Peers list. If a device supports both IKEv1 and IKEv2, it appears in both lists.

You need to alter the selection only if you are allowing both IKE versions in a VPN and you want to specifically prevent some IKEv2-capable devices from using one of the IKE versions.

To change which IKE version is allowed for a device, click the Select button beneath the list from which you want to remove the device (or to add the device after previously removing it). A selection dialog box opens where you can do the following (click OK to confirm your choices):

- To remove a device, so that it cannot use the IKE version, highlight it in the Selected Peers list and click << to move it to the Available Peers list.
- To add a device, so that it is allowed to use the IKE version, highlight it in the Available Peers list and click >> to move it to the Selected Peers list.
The selection lists include only those devices that support both IKE versions, because you cannot change the version selection for devices that support a single version. IKEv2 is supported on ASA Software 8.4(1+).

**Tip**

The selection lists include only those devices that support both IKE versions, because you cannot change the version selection for devices that support a single version. IKEv2 is supported on ASA Software 8.4(1+).

**Navigation Path**

(Site-to-Site VPN Manager Window, page 23-18) Select an non-Easy VPN topology in the VPNs selector, then select **IPsec Proposal** in the Policies selector. Click the **IKE Version** tab.

## Configuring IPsec IKEv1 or IKEv2 Transform Set Policy Objects

Use the Add or Edit IPsec Transform Set dialog box to configure IPsec transform sets for use in IKE negotiations.

You can create IPsec transform set objects for use in IPsec proposals when defining IPsec-protected traffic in site-to-site and remote access VPNs. During IPsec security association negotiation, the peers agree to use a particular transform set when protecting a particular data flow.

Two different security protocols are included within the IPsec standard:

- Encapsulating Security Protocol (ESP)—Provides authentication, encryption, and anti-replay services. ESP is IP protocol type 50.
- Authentication Header (AH)—Provides authentication and anti-replay services. AH does not provide encryption and has largely been superseded by ESP. It is also supported on routers only. AH is IP protocol type 51.

**Note**

We recommend using both encryption and authentication on IPsec tunnels.

There are separate IPsec transform set objects based on the IKE version, IKEv1 or IKEv2:

- When you create an IPsec IKEv1 transform set object, you select the mode in which IPsec should operate, as well as define the required encryption and authentication types. Additionally, you can select whether to include compression in the transform set. You can select single options for the algorithms, so if you want to support multiple combinations in a VPN, you must create multiple IPsec IKEv1 transform set objects.
- When you create an IPsec IKEv2 transform set object, you can select all of the encryption and hash algorithms that you will allow in a VPN. During IKEv2 negotiations, the peers select the most appropriate options that each support.

**Navigation Path**

Select **Manage > Policy Objects**, then select **IPSec Transform Sets > IPsec IKEv1 Transform Sets** or **IPSec Transform Sets > IPsec IKEv2 Transform Sets** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the policy object. A maximum of 128 characters is allowed.</td>
</tr>
<tr>
<td>Description</td>
<td>A description of the policy object. A maximum of 1024 characters is allowed.</td>
</tr>
<tr>
<td>Mode (IKEv1 only.)</td>
<td>The mode in which the IPSec tunnel operates:</td>
</tr>
<tr>
<td></td>
<td>• Tunnel—Tunnel mode encapsulates the entire IP packet. The IPSec header is added between the original IP header and a new IP header. This is the default. Use tunnel mode when the firewall is protecting traffic to and from hosts positioned behind the firewall. Tunnel mode is the normal way regular IPSec is implemented between two firewalls (or other security gateways) that are connected over an untrusted network, such as the Internet.</td>
</tr>
<tr>
<td></td>
<td>• Transport—Transport mode encapsulates only the upper-layer protocols of an IP packet. The IPSec header is inserted between the IP header and the upper-layer protocol header (such as TCP). Transport mode requires that both the source and destination hosts support IPSec, and can only be used when the destination peer of the tunnel is the final destination of the IP packet. Transport mode is generally used only when protecting a Layer 2 or Layer 3 tunneling protocol such as GRE, L2TP, and DLSW.</td>
</tr>
</tbody>
</table>
### Understanding IPsec Proposals

#### ESP Encryption
The Encapsulating Security Protocol (ESP) encryption algorithm that the transform set should use. For more information on the following options, see *Deciding Which Encryption Algorithm to Use, page 24-6.*  
For IKEv1, select one of the following options. For IKEv2, click **Select** to open a dialog box where you can select all of the options you want to support.
- **(Blank)—** Do not use ESP encryption.
- **DES—** Encrypts according to the Data Encryption Standard using 56-bit keys.
- **3DES—** Encrypts three times using 56-bit keys. 3DES is more secure than DES, but requires more processing for encryption and decryption. A 3DES license is required to use this option.
- **AES-128—** Encrypts according to the Advanced Encryption Standard using 128-bit keys.
- **AES-192—** Encrypts according to the Advanced Encryption Standard using 192-bit keys.
- **AES-256—** Encrypts according to the Advanced Encryption Standard using 256-bit keys.
- **ESP-Null (NULL)—** A null encryption algorithm. Transform sets defined with ESP-Null provide authentication without encryption; this is typically used for testing purposes only.

#### ESP Hash Algorithm (IKEv1)
The hash or integrity algorithm to use in the transform set for authentication. For IKEv1, the default is to use SHA for ESP authentication and to not use AH authentication. For IKEv2, there is no default. The AH hash algorithm is used on routers only.
- **None—** Does not perform ESP or AH authentication.
- **SHA, SHA-1 (Secure Hash Algorithm version 1)—** Produces a 160-bit digest. SHA is more resistant to brute-force attacks than MD5, but requires more processing time.
- **MD5 (Message Digest 5)—** Produces a 128-bit digest. MD5 uses less processing time than SHA, but is less secure.

#### ESP Integration Algorithm (IKEv2)
For IKEv1, select one of the following options. For IKEv2, click **Select** to open a dialog box where you can select all of the options you want to support.
- **None—** Does not perform ESP or AH authentication.
- **SHA, SHA-1 (Secure Hash Algorithm version 1)—** Produces a 160-bit digest. SHA is more resistant to brute-force attacks than MD5, but requires more processing time.
- **MD5 (Message Digest 5)—** Produces a 128-bit digest. MD5 uses less processing time than SHA, but is less secure.

#### AH Hash Algorithm (IKEv1 only)
The hash or integrity algorithm to use in the transform set for authentication. For IKEv1, the default is to use SHA for ESP authentication and to not use AH authentication. For IKEv2, there is no default. The AH hash algorithm is used on routers only.
- **None—** Does not perform ESP or AH authentication.
- **SHA, SHA-1 (Secure Hash Algorithm version 1)—** Produces a 160-bit digest. SHA is more resistant to brute-force attacks than MD5, but requires more processing time.
- **MD5 (Message Digest 5)—** Produces a 128-bit digest. MD5 uses less processing time than SHA, but is less secure.

#### Compression (IKEv1 only, IOS devices only.)
Whether to compress the data in the IPSec tunnel using the Lempel-Ziv-Stac (LZS) algorithm.

#### Category
The category assigned to the object. Categories help you organize and identify rules and objects. See *Using Category Objects, page 6-11.*

Configuring VPN Global Settings

You can define global settings that apply to all devices in your remote access or site-to-site VPN topology. These settings include Internet Key Exchange (IKE), IKEv2, IPsec, NAT, and fragmentation definitions. The global settings typically have defaults that work in most situations, so configuring the Global Settings policy is optional in most cases; configure it only if you need non-default behavior or if you are supporting IKEv2 negotiations in a remote access IPsec VPN.

Note
The VPN Global Settings policy for site-to-site VPNs applies to all technologies except GET VPN. For an explanation of global settings for GET VPN, see Configuring Global Settings for GET VPN, page 27-17.

Step 1
Do one of the following to open the global settings policy based on the type of VPN you are configuring:

- For remote access VPNs, do one of the following:
  - (Device View) Select Remote Access VPN > Global Settings from the Policy selector.
  - (Policy View) Select Remote Access VPN > Global Settings from the Policy Type selector. Select an existing policy or create a new one.

- For site-to-site VPNs, do one of the following:
  - Open the Site-to-Site VPN Manager Window, page 23-18, select a topology in the VPNs selector, then select VPN Global Settings in the Policies selector.
  - (Policy view) Select Site-to-Site VPN > VPN Global Settings from the Policy Types selector. Select an existing shared policy or create a new one.

Step 2
Select the desired tab and configure the settings as needed:

- **ISAKMP/IPsec Settings**—To configure global settings for IKE and IPsec. For detailed information about the options, see Configuring VPN Global ISAKMP/IPsec Settings, page 24-27.

- **IKEv2 Settings**—To configure global settings for IKE version 2 negotiations. For detailed information about the options, see Configuring VPN Global IKEv2 Settings, page 24-31.

- **NAT Settings**—To configure NAT behavior. For detailed information about the options, see Configuring VPN Global NAT Settings, page 24-35. Also see Understanding NAT in VPNs, page 24-34.

- **General Settings**—To configure fragmentation behavior and some other miscellaneous options. For detailed information about the options, see Configuring VPN Global General Settings, page 24-37.

Configuring VPN Global ISAKMP/IPsec Settings

Use the ISAKMP/IPsec Settings tab of the VPN Global Settings page to specify global settings for Internet Key Exchange (IKE) and IPsec.

The Internet Key Exchange (IKE) protocol, also called the Internet Security Association and Key Management Protocol (ISAKMP) is the negotiation protocol that lets two hosts agree on how to build an IPsec security association. Each ISAKMP negotiation is divided into a Phase 1 and Phase 2. Phase 1 creates the first tunnel, which protects ISAKMP negotiation messages. Phase 2 creates the tunnel that protects data.
To set terms for ISAKMP negotiations, you create an IKE proposal. For more information, see Configuring an IKE Proposal, page 24-9.

**About IKE Keepalive**

With IKE keepalive, tunnel peers exchange messages that demonstrate they are available to send and receive data in the tunnel. Keepalive messages transmit at set intervals, and any disruption in that interval results in the creation of a new tunnel, using a backup device.

Devices that rely on IKE keepalive for resiliency transmit their keepalive messages regardless of whether they are exchanging other information. These keepalive messages can therefore create a small but additional demand on your network.

A variation on IKE keepalive called keepalive dead-peer detection (DPD) sends keepalive messages between peer devices only when no incoming traffic is received and outbound traffic needs to be sent. If you want to send DPD keepalive messages when no incoming traffic is received regardless of whether there is any outbound traffic, you can specify this using the Periodic option.

**Navigation Path**

- For remote access VPNs, do one of the following:
  - (Device View) Select Remote Access VPN > Global Settings from the Policy selector. Click the ISAKMP/IPsec Settings tab.
  - (Policy View) Select Remote Access VPN > Global Settings from the Policy Type selector. Select an existing policy or create a new one, then click the ISAKMP/IPsec Settings tab.

- For site-to-site VPNs, do one of the following:
  - Open the Site-to-Site VPN Manager Window, page 23-18, select a topology in the VPNs selector, then select VPN Global Settings in the Policies selector. Click the ISAKMP/IPsec Settings tab.
  - (Policy view) Select Site-to-Site VPN > VPN Global Settings from the Policy Types selector. Select an existing shared policy or create anew one, then click the ISAKMP/IPsec Settings tab.

**Related Topics**

</thead>
<tbody>
<tr>
<td><strong>ISAKMP Settings</strong></td>
<td></td>
</tr>
</tbody>
</table>
| Enable Keepalive      | Whether to configure dead-peer detection (DPD) settings. If the peer fails to respond, a new tunnel is constructed on the assumption that the peer is no longer available. IKE keepalive is defined on the spokes in a hub-and-spoke VPN topology, on both devices in a point-to-point VPN topology, or in remote access VPN configurations. Configure the following options:  
  - Interval—The number of seconds the peer can be idle before beginning keepalive monitoring. The range is 10-3600 seconds. The default is 10, although the ASA device default for remote access groups is 300.  
  - Retry—The interval in seconds between retries after a keepalive response has not been received. The range is 2-10 seconds for ASA, 2-60 for IOS devices. The default is 2 seconds.  
  - Periodic—(Routers running IOS Software version 12.3(7)T and later, except 7600 devices.) Whether to send DPD keepalive messages at regular intervals regardless of IPsec traffic. This changes how the interval value is used.  
  - Infinite—(ASA only.) Whether to ignore the interval and retry settings and allow the peer to be idle indefinitely. |
| Identity              | During Phase I IKE negotiations, peers must identify themselves to each other. Select one of the following:  
  - Address—Use the IP address of the host exchanging ISAKMP identity information. This is the default.  
  - Hostname—Use the fully-qualified domain name of the host exchanging ISAKMP identity information.  
  - Auto/DN—Use automatic selection or distinguished name based on device type:  
    - Distinguished Name (IOS devices only)—Use a distinguished name (DN) to identify a user group name.  
    - Auto (ASA devices only)—Determine ISAKMP negotiation by connection type; IP address for preshared key or certificate distinguished name for certificate authentication. |
| **SA Requests System Limit** | Supported on routers running Cisco IOS Software Release 12.3(8)T and later, except 7600 routers.  
  The maximum number of SA requests allowed before IKE starts rejecting them, from 0 to 99999. The number must equal or exceed the number of peers, or the VPN tunnels might be disconnected. |
| **SA Requests System Threshold** | Supported on Cisco IOS routers and Catalyst 6500/7600 devices.  
  The percentage of system resources that can be used before IKE starts rejecting new SA requests. The default is 75 percent. |

</tr>
<tr>
<td></td>
<td>• 5580, 5585-X (other models)—10000 sessions.</td>
</tr>
</tbody>
</table>
Use the IKEv2 Settings tab of the VPN Global Settings page to specify global settings for Internet Key Exchange (IKE) version 2. These settings apply to ASA 8.4(x) devices only.

Internet Key Exchange (IKE), also called Internet Security Association and Key Management Protocol (ISAKMP), is the negotiation protocol that lets two hosts agree on how to build an IPsec security association (SA).

**Preventing DoS Attacks by Limiting IKEv2 Open SAs**

You can prevent denial-of-service (DoS) attacks for IPsec IKEv2 connections by always cookie challenging incoming security associations (SAs) or by limiting the number of open SAs and cookie challenging any additional connections. By default, the ASA does not limit the number of open SAs and never cookie challenges SAs.

You can also limit the number of SAs allowed, which stops further connections from negotiating to protect against memory or CPU attacks that the cookie-challenge feature may be unable to thwart. Limiting the maximum number of SAs can protect the current connections.
With a DoS attack, an attacker initiates the attack when the peer device sends an SA initiate packet and the ASA sends its response, but the peer device does not respond further. If the peer device does this continually, all the allowed SA requests on the ASA can be used up until it stops responding.

Enabling a threshold percentage for cookie challenges limits the number of open SA negotiations. For example, with the default setting of 50%, when 50% of the allowed SAs are in-negotiation (open), the ASA cookie challenges any additional SA initiate packets that arrive. For the Cisco ASA 5580 with 10,000 allowed IKEv2 SAs, after 5000 SAs become open, any more incoming SAs are cookie-challenged.

If used in conjunction with the **Maximum SAs in Negotiation** option, configure a lower cookie-challenge threshold.

**Navigation Path**
- For remote access VPNs, do one of the following:
  - (Device View) Select **Remote Access VPN > Global Settings** from the Policy selector. Click the **IKEv2 Settings** tab.
  - (Policy View) Select **Remote Access VPN > Global Settings** from the Policy Type selector. Select an existing policy or create a new one, then click the **IKEv2 Settings** tab.
- For site-to-site VPNs, do one of the following:
  - Open the **Site-to-Site VPN Manager Window**, page 23-18, select a topology in the VPNs selector, then select **VPN Global Settings** in the Policies selector. Click the **IKEv2 Settings** tab.
  - (Policy view) Select **Site-to-Site VPN > VPN Global Settings** from the Policy Types selector. Select an existing shared policy or create a new one, then click the **IKEv2 Settings** tab.

</tr>
<tr>
<td>(Remote access VPNs only.)</td>
<td>- Pros—This option allows the master server to do minimal processing and state keeping (using CPU and memory) prior to redirecting the connection.</td>
</tr>
<tr>
<td></td>
<td>- Cons—This option is not as secure as AUTH (even though security risks are minimal) because anyone can get a redirected IP address without authenticating at all.</td>
</tr>
<tr>
<td></td>
<td>- <strong>AUTH</strong> (the default)—Redirect during authentication (during IKE_AUTH). The device still has not identified or authenticated the user at this point, but it allows the client to authenticate the server to make sure it can trust the redirection that it receives.</td>
</tr>
<tr>
<td></td>
<td>- Pros—This option is more secure as the reply is encrypted in the IKEv2 tunnel and it allows the client side to authenticate the server before retrying with the redirected IP address, providing better DoS protection than the INIT option.</td>
</tr>
<tr>
<td></td>
<td>- Cons—This option requires more processing as the IKEv2 tunnel needs to be almost brought up before redirecting, although child SAs and data tunnels do not need to be brought up. The client is not authenticated at all. Note that IKEv1 redirection occurs after group authentication of both sides of the tunnel.</td>
</tr>
</tbody>
</table>

**Understanding NAT in VPNs**

Network Address Translation (NAT) enables devices that use internal IP addresses to send and receive data through the Internet. It converts private, internal LAN addresses into globally routable IP addresses when they try to access data on the Internet. In this way, NAT enables a small number of public IP addresses to provide global connectivity for a large number of hosts.

NAT enhances the stability of your hub-and-spoke VPN tunnels or remote access connections because resources required for VPN connections are not used for other purposes, and the VPN tunnel is kept available for traffic requiring complete security. Sites inside the VPN can use NAT through a split tunnel to exchange non secure traffic with outside devices, and they do not squander VPN bandwidth or overwhelm the hub at the tunnel head-end by directing nonessential traffic through it.

Security Manager supports NAT with dynamic IP addressing only, and applies to it an overload feature that permits what is known as port-level NAT or Port Address Translation (PAT). PAT uses port addressing to associate thousands of private NAT addresses with a small group of public IP address. PAT is used if the addressing requirements of your network exceed the available addresses in your dynamic NAT pool.
When you enable PAT on Cisco IOS routers, an additional NAT rule is implicitly created for split-tunneled traffic on deployment. This NAT rule, which denies VPN-tunneled traffic and permits all other traffic (using the external interface as the IP address pool), is not reflected as a router platform policy. You can remove the NAT rule by disabling this feature. For more information, see NAT Page: Dynamic Rules, page 22-10.

You can configure traffic to bypass NAT configuration on site-to-site VPN traffic. To bypass NAT configuration on Cisco IOS routers, make sure the Do Not Translate VPN Traffic option is selected in the NAT Dynamic Rule platform policy (see NAT Dynamic Rule Dialog Box, page 22-11). To exclude NAT on PIX Firewalls or ASA devices, make sure this option is selected in the NAT Translation Options platform policy (see Translation Options Page, page 22-16).

About NAT Traversal

NAT traversal is used for the transmission of keepalive messages when there is a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow. If the IP address of the VPN interface on the spoke is not globally routable, the NAT on the middle device replaces it with a new globally routable IP address. This change is made in the IPsec header, and violates the checksum of the spoke causing a mismatch with the hub’s checksum calculation. This results in loss of connectivity between the hub and the spoke.

With NAT traversal, the spoke adds a UDP header to the payload. The NAT on the middle device changes the IP address in the UDP header, leaving the IPsec header and checksum intact. On a middle device that uses static NAT, you must provide the static NAT IP address (globally routable) on the inside interface. The static NAT IP address is provided for all traffic through that interface that requires NAT. However, if the middle device uses dynamic NAT where the NAT IP address is unknown, you must define dynamic crypto on the hub to serve any connection request from the spoke. Security Manager generates the required tunnel configuration for the spoke.

NAT traversal is enabled by default on routers running IOS version 12.3T and later. If you want to disable the NAT traversal feature, you must do this manually on the device or using a FlexConfig (see Chapter 7, “Managing FlexConfigs”).

You can define global NAT settings on the NAT Settings tab of the Global VPN Settings page as described in Configuring VPN Global NAT Settings, page 24-35.

Configuring VPN Global NAT Settings

Use the NAT Settings tab of the Global Settings page to define global Network Address Translation (NAT) settings that enable devices that use internal IP addresses to send and receive data through the Internet.

For site-to-site VPNs, if you want to bypass NAT configuration on IOS routers, make sure that the Do Not Translate VPN Traffic option is selected in the NAT Dynamic Rule platform policy (see NAT Dynamic Rule Dialog Box, page 22-11). To exclude NAT on PIX Firewalls or ASA devices, make sure this option is selected in the NAT Translation Options platform policy (see Translation Options Page, page 22-16).
Navigation Path

- For remote access VPNs, do one of the following:
  - (Device View) Select Remote Access VPN > Global Settings from the Policy selector. Click the NAT Settings tab.
  - (Policy View) Select Remote Access VPN > Global Settings from the Policy Type selector. Select an existing policy or create a new one, then click the NAT Settings tab.

- For site-to-site VPNs, do one of the following:
  - Open the Site-to-Site VPN Manager Window, page 23-18, select a topology in the VPNs selector, then select VPN Global Settings in the Policies selector. Click the NAT Settings tab.
  - (Policy view) Select Site-to-Site VPN > VPN Global Settings from the Policy Types selector. Select an existing shared policy or create a new one, then click the NAT Settings tab.

<td>• <strong>End to End MTU Discovery</strong>—Use ICMP messages to determine the maximum MTU. Use this option with IPsec VPNs.</td>
</tr>
<tr>
<td></td>
<td>End-to-end MTU discovery uses Internet Control Message Protocol (ICMP) messages to determine the maximum MTU that a host can use to send a packet through the VPN tunnel without causing fragmentation. The MTU setting for each link in a transmission path is checked to ensure that no transmitted packet exceeds the smallest MTU in that path. The discovered MTU is used to decide whether fragmentation is necessary. If ICMP is blocked, MTU discovery fails and packets are either lost (if the DF bit is set) or fragmented after encryption (if the DF bit is not set).</td>
</tr>
<tr>
<td></td>
<td>• <strong>Local MTU Handling</strong>—Set the MTU locally on the devices. This option is typically used when ICMP is blocked or in site-to-site IPsec/GRE VPNs. If you select this option, specify the local MTU size, which can be between 68 and 65535 bytes depending on the VPN interface.</td>
</tr>
</tbody>
</table>

Note (Site-to-site VPNs) For Catalyst 6500/7600 devices, end-to-end path MTU discovery is supported only on images 12.2(33)SRA, 12.2(33)SRB, 12.2(33)SXH, 12.2(33)SXI or above.
## Table 24-8  VPN Global Settings Page, General Settings Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| DF Bit  | Supported on Cisco IOS routers, Catalyst 6500/7600 devices, PIX 7.0+ and ASA devices.  
A Do Not Fragment (DF) bit within an IP header determines whether a device is allowed to fragment a packet. Select how to handle the DF bit:  
- **Copy**—Copy the DF bit from the encapsulated header in the current packet to all the device’s packets. If the packet’s DF bit is set to fragment, all future packets are fragmented. This is the default option.  
- **Set**—Set the DF bit in the packet you are sending. A large packet that exceeds the MTU is dropped and an ICMP message is sent to the packet’s initiator.  
- **Clear**—Fragment packets regardless of the original DF bit setting. If ICMP is blocked, MTU discovery fails and packets are fragmented only after encryption. |
| Enable Fragmentation Before Encryption | Supported on Cisco IOS routers, Catalyst 6500/7600 devices, PIX 7.0+ and ASA devices.  
When selected, enables fragmentation to occur before encryption if the expected packet size exceeds the MTU.Look ahead Fragmentation (LAF) is used before encryption takes place to calculate the packet size that would result after encryption, depending on the transform sets configured on the IPsec SA. If the packet size exceeds the specified MTU, the packet will be fragmented before encryption. |
| Enable Notification on Disconnection | Supported on ASA and PIX 7.0+ devices.  
When selected, enables the device to notify qualified peers of sessions that are about to be disconnected. The peer receiving the alert decodes the reason and displays it in the event log or in a pop-up window. This feature is disabled by default.  
IPsec sessions might be dropped for several reasons, such as a security appliance shutdown or reboot, session idle timeout, maximum connection time exceeded, or administrator cut-off. |
| Enable Split Tunneling (Site-to-site VPN only.) | When selected (the default), enables you to configure split tunneling in your site-to-site VPN topology.  
Split tunneling allows you to transmit both secured and unsecured traffic on the same interface. Split tunneling requires that you specify exactly which traffic will be secured and what the destination of that traffic is, so that only the specified traffic enters the IPsec tunnel, while the rest is transmitted unencrypted across the public network. |
| Enable Spoke-to-Spoke Connectivity through the Hub | Supported on ASA and PIX 7.0+ devices.  
When selected, enables direct communication between spokes in a hub-and-spoke VPN topology in which the hub is an ASA or PIX 7.0+ device. |
Understanding IKEv1 Preshared Key Policies in Site-to-Site VPNs

If you want to use preshared key as your authentication method for IKEv1 negotiations, you must define a shared key for each tunnel between two peers that will be their shared secret for authenticating the connection. The key will be configured on each peer. If the key is not the same on both peers of the tunnel, the connection cannot be established. The peer addresses that are required for configuring the preshared key are deduced from the VPN topology.

You can also use preshared keys for IKEv2 negotiations, but the configuration is different from the one used for IKEv1, as are the rules and requirements. For information on configuring preshared keys for IKEv2 negotiations, see Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59.

Preshared keys are configured on spokes. In a hub-and-spoke VPN topology, Security Manager mirrors the spoke’s preshared key and configures it on its assigned hub, so that the key on the spoke and hub are the same. In a point-to-point VPN topology, you must configure the same preshared key on both peers. In a full mesh VPN topology, any two devices that are connected must have the same preshared key.

In a preshared key policy, you can use a specific key, or you can use automatically generated keys for peers participating in each communication session. Using automatically generated keys (the default method) is preferred, because security can be compromised if all connections in a VPN use the same preshared key.

There are three methods for negotiating key information and setting up IKE security associations (SAs):

- Main mode address—Negotiation is based on IP address. Main mode provides the highest security because it has three two-way exchanges between the initiator and receiver. This is the default negotiation method.

  This method has three options for creating keys:

  - You can create a key for each peer, based on the unique IP address of each peer, providing high security.

  - You can create a group preshared key on a hub in a hub-and-spoke VPN topology, to be used for communication with any device in a specified subnet. Each peer is identified by its subnet, even if the IP address of the device is unknown. In a point-to-point or full mesh VPN topology, a group preshared key is created on the peers.

  - You can create a wildcard key on a hub in a hub-and-spoke VPN topology, or on a group containing hubs, to be used for dynamic crypto where a spoke does not have a fixed IP address or belong to a specific subnet. All spokes connecting to the hub have the same preshared key, which could compromise security. In a point-to-point or full mesh VPN topology, a wildcard key is created on the peers.

<table>

</tr>
</tbody>
</table>
Chapter 24 Configuring IKE and IPsec Policies

Understanding IKEv1 Preshared Key Policies in Site-to-Site VPNs

Note
If you are configuring DMVPN with direct spoke-to-spoke connectivity, you create a wildcard key on the spokes.

- Main mode fully qualified domain name (FQDN)—Negotiation is based on DNS resolution, with no reliance on IP address. This option can only be used if the DNS resolution service is available for the host. It is useful when managing devices with dynamic IP addresses that have DNS resolution capabilities.

- Aggressive mode—Negotiation is based on hostname (without DNS resolution) and domain name. Aggressive mode is less secure than main mode. However, it provides more security than using group preshared keys if the IP address of the VPN interface on the host is unknown, and the FQDN of the dynamic IP peer is not DNS resolvable. This negotiation method is recommended for use with a GRE Dynamic IP or DMVPN failover and routing policy.

Configuring IKEv1 Preshared Key Policies

Use the IKEv1 Preshared Key page to define the preshared key configuration when using IKEv1 in a site-to-site VPN topology. For information on configuring preshared keys when using IKEv2, see Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59.

Note
The preshared key policy does not apply to Easy VPN topologies.

To open the IKEv1 Preshared Key page:
- (Site-to-Site VPN Manager Window, page 23-18) Select a topology in the VPNs selector, then select IKEv1 Preshared Key in the Policies selector.
- (Policy view) Select Site-to-Site VPN > IKEv1 Preshared Key from the Policy Types selector. Select an existing shared policy or create a new one.

The following table explains the settings you can configure in this policy.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Specification</td>
<td>Select whether to manually define the key (User Defined) or to have the key automatically generated. There are additional options you can configure when using auto generated keys.</td>
</tr>
<tr>
<td>User Defined</td>
<td>When selected, enables you to use a manually defined preshared key. Enter the required preshared key in the Key field, then enter it again in the Confirm field.</td>
</tr>
</tbody>
</table>
### Understanding IKEv1 Preshared Key Policies in Site-to-Site VPNs

Auto Generated

When selected, allocates a random key to the participating peers. This ensures security because a different key is generated for every hub-spoke connection. Auto Generated is the default selection.

Auto generated is not a useful option when you do not manage all nodes in the VPN, for example, in the case of an Extranet VPN.

**Note** The key is allocated during the first deployment to the devices and is used in all subsequent deployments to the same devices, until you select the Regenerate Key (Only in Next Deployment) check box.

Key Length

The required length of the preshared key to be automatically generated, from 1 to 127. The default is 24.

Same Key for All Tunnels

Unavailable in a point-to-point VPN topology.

When selected, enables you to use the same auto-generated key for all tunnels.

**Note** If you do not select this option, different keys are used for the tunnels, except in cases, such as DMVPN configuration, when different multipoint GRE interfaces in the same network must use the same preshared key.

Regenerate Key (Only in Next Deployment)

When selected, enables Security Manager to generate a new key for the next deployment to the devices. This is useful if it is possible that the secrecy of the keys might be compromised.

When you submit the job for deployment, this check box is cleared. It does not remain selected because the new key will only be generated for the upcoming deployment, and not for subsequent deployments (unless you select it again).

### Negotiation Method

Select the type of negotiation method. The methods are explained in more detail in [Understanding IKEv1 Preshared Key Policies in Site-to-Site VPNs](#), page 24-40.

---

**Table 24-9 IKEv1 Preshared Key Page (Continued)**

<table>

</tr>
</tbody>
</table>
Main Mode Address

Use this negotiation method for exchanging key information if the IP address of the devices is known. Negotiation is based on IP address. Main mode provides the highest security because it has three two-way exchanges between the initiator and receiver. Main mode address is the default negotiation method.

Select one of the following options to define the negotiation address type:

- **Peer Address**—Negotiation is based on the unique IP address of each peer. A key is created for each peer, providing high security. This is the default.

- **Subnet**—Creates a group preshared key on a hub in a hub-and-spoke topology to use for communication with any device in a specified subnet, even if the IP address of the device is unknown. Each peer is identified by its subnet. In a point-to-point or full mesh VPN topology, a group preshared key is created on the peers. Enter the subnet in the field provided, for example, `10.10.10.0/24`.

- **Wildcard**—Creates a wildcard key on a hub or on a group of hubs in a hub-and-spoke topology to use when a spoke does not have a fixed IP address or belong to a specific subnet. In this case, all spokes connecting to the hub have the same preshared key, which could compromise security. Use this option if a spoke in your hub-and-spoke VPN topology has a dynamic IP address. In a point-to-point or full mesh VPN topology, a wildcard key is created on the peers.

**Note** When configuring DMVPN with direct spoke-to-spoke connectivity, you create a wildcard key on the spokes.

Main Mode FQDN

Select this negotiation method for exchanging key information if the IP address is not known and DNS resolution is available for the devices. Negotiation is based on DNS resolution, with no reliance on IP address.

Aggressive Mode

Available only in a hub-and-spoke VPN topology.

Select this negotiation method for exchanging key information if the IP address is not known and DNS resolution might not be available on the devices. Negotiation is based on hostname and domain name.

**Note** If direct spoke to spoke tunneling is enabled, you cannot use aggressive mode.

Understanding Public Key Infrastructure Policies

Security Manager supports IPsec configuration with Certification Authority (CA) servers that manage certificate requests and issue certificates to devices in your VPN topology. You can create a Public Key Infrastructure (PKI) policy to generate enrollment requests for CA certificates and RSA keys, and manage keys and certificates, providing centralized key management for the participating devices.

CA servers, also known as trustpoints, manage public CA certificate requests and issue certificates to participating IPsec network devices. When you use Certificates as the authentication method for IKE and IPsec proposal policies, peers are configured to obtain digital certificates from a CA server. With a CA server, you do not have to configure keys between all the encrypting devices. Instead, you individually enroll each participating device with the CA server, which is explicitly trusted to validate identities and create a digital certificate for the device. When this has been accomplished, each participating peer can validate the identities of the other participating peers and establish encrypted sessions with the public keys contained in the certificates.

CAs can also revoke certificates for peers that no longer participate in an IPsec VPN topology. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server, which each peer can check before accepting a certificate from another peer.

PKI enrollment can be set up in a hierarchical framework consisting of multiple CAs. At the top of the hierarchy is a root CA, which holds a self-signed certificate. The trust within the entire hierarchy is derived from the RSA key pair of the root CA. Subordinate CAs within the hierarchy can enroll with either the root CA or with another subordinate CA. Within a hierarchical PKI, all enrolled peers can validate each other’s certificate if the peers share a trusted root CA certificate or a common subordinate CA.

Keep the following in mind:

- PKI policies can be configured on Cisco IOS routers running version 12.3(7)T and later, PIX Firewalls, and Adaptive Security Appliance (ASA) devices for site-to-site and remote access VPNs.
- In site-to-site VPNs, you use the IKEv1 Public Key Infrastructure policy to identify CA servers for IKEv1 negotiations only. For IKEv2 negotiations, you identify the CA servers in the IKEv2 Authentication policy as described in Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59.
- To save the RSA key pairs and the CA certificates between reloads permanently to Flash memory on a PIX Firewall release 6.3, you must configure the `ca save all` command. You can do this manually on the device or using a FlexConfig (see Chapter 7, “Managing FlexConfigs”).

CA Server Authentication Methods

You can authenticate the CA server using one of the following methods:

- Using the Simple Certificate Enrollment Protocol (SCEP) to retrieve the CA’s certificates from the CA server. Using SCEP, you establish a direct connection between your device and the CA server. Be sure your device is connected to the CA server before beginning the enrollment process. Because this method of retrieving CA certificates for routers is interactive, you can deploy your PKI policy to live devices only, not to files.

  **Note** When using SCEP, you must enter the fingerprint for the CA server. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected. You can obtain the CA’s fingerprint by contacting the server directly, or by entering the following address in a web browser: `http://<URLHostName>/certsrv/mscep/mscep.dll`. 
Understanding Public Key Infrastructure Policies

- Manually creating an enrollment request that you can submit to a CA server offline, by copying the CA server's certificates from another device.

  Use this method if your device cannot establish a direct connection to the CA server or if you want to generate an enrollment request and send it to the server at a later time.

  **Note**  This method enables you to deploy the PKI policy either to devices or to files.

  For more information, see PKI Enrollment Dialog Box, page 24-51.

  You can also use Cisco Secure Device Provisioning (SDP) to enroll for a certificate for a router. For more information about using SDP for certificate enrollment, see Secure Device Provisioning on Cisco IOS Routers, page 59-81.

The following topics explain Public Key Infrastructure configuration in more detail:

- Requirements for Successful PKI Enrollment, page 24-45
- Configuring IKEv1 Public Key Infrastructure Policies in Site-to-Site VPNs, page 24-47
- Defining Multiple IKEv1 CA Servers for Site-to-Site VPNs, page 24-48
- Configuring Public Key Infrastructure Policies for Remote Access VPNs, page 24-49
- PKI Enrollment Dialog Box, page 24-51

### Requirements for Successful PKI Enrollment

The following are prerequisites for configuring a PKI policy in your network:

- For IKEv1, the IKE proposal must specify Certificate for the IKE authentication method. See Configuring IKEv1 Proposal Policy Objects, page 24-10.

- The domain name must be defined on the devices for PKI enrollment to be successful (unless you specify the CA server nickname).

- To enroll with the CA server directly, you must specify the server’s enrollment URL.

- To enroll with the CA server by means of a TFTP server, you must ensure that the CA certificates file is saved to the TFTP server. After deployment of the PKI policy, you must copy the certificate request from your TFTP server to the CA server.

- You may specify an RSA public key to use in the enrollment request. If you do not specify an RSA key pair, the Fully Qualified domain Name (FQDN) key will be used.

  If using RSA keys, once the certificate has been granted, the public key is included in the certificate so that peers can use it to encrypt data sent to the device. The private key is kept on the device and used to decrypt data sent by peers, and to digitally sign transactions when negotiating with peers. You can use an existing key pair or generate a new one. If you want to generate a new key pair to use in the certificate for router devices, you must also specify the modulus to determine the size of the key.

  For more information, see PKI Enrollment Dialog Box—Enrollment Parameters Tab, page 24-56.

- If you are making a PKI enrollment request on a Cisco Easy VPN IPsec remote access system, you must configure each remote component (spoke) with the name of the user group to which it connects. You specify this information in the Organization Unit (OU) field in the Certificate Subject Name tab of the PKI Enrollment Editor dialog box.
For more information, see PKI Enrollment Dialog Box—Certificate Subject Name Tab, page 24-58.

- To deploy PKI policies to files (not to live devices), the following prerequisites must be met:
  - Routers must run Cisco IOS Software 12.3(7)T or later.
  - CA authentication certificates must be cut and pasted into the Security Manager user interface (so that CA authentication is not interactive and does not require communication with the live device).
- If you are deploying to live devices, the PKI server must be online.
- Security Manager supports the Microsoft, Verisign, and Entrust PKIs.
- Security Manager supports Cisco IOS Certificate Servers. The Cisco IOS Certificate Server feature embeds a simple certificate server, with limited CA functionality, into the Cisco IOS software. An IOS Certificate Server can be configured as a FlexConfig policy. For more information, see Chapter 7, “Managing FlexConfigs”.
- To configure PKI with AAA authorization that uses the entire subject name on an IOS router, use the predefined FlexConfig object named IOS_PKI_WITH_AAA.

Prerequisites for PKI Enrollment Using TFTP

If you do not have constant direct access to the CA server, you can enroll using TFTP if your devices are routers running Cisco IOS Software 12.3(7)T or later.

On deployment, Security Manager generates the corresponding CA trustpoint command and authenticate command. The trustpoint command is configured with the enrollment URL tftp://<certserver> <file_specification> entry to retrieve the CA certificate using TFTP. If file_specification is not specified, the FQDN of the router is used.

Before using this option, you must make sure that the CA certificates file (.ca) is saved on the TFTP server. To do this, use this procedure:

1. Connect to http://servername/certsrv, where servername is the name of the Windows 2000 web server on which the CA you want to access is located.
2. Select Retrieve the CA certificate or certificate revocation list, then click Next.
3. Select Base64 encoded, then click Download CA certificate.
4. Save the .crt file as a .ca file on the TFTP server using your browser’s Save As function.

After deployment, you must transfer the certificate request generated by Security Manager on the TFTP server to the CA, and then transfer the device’s certificates from the CA to the device.

Transferring the Certificate Request from the TFTP Server to the CA Server

Security Manager creates a PKCS#10 formatted enrollment request (.req) on the TFTP server. You must transfer it to the PKI server using this procedure:

1. Connect to http://servername/certsrv, where servername is the name of the Windows 2000 web server where the CA you want to access is located.
2. Select Request a certificate, then click Next.
3. Select Advanced request, then click Next.
4. Select Submit a certificate request using a base64 encoded PKCS #10 file or a renewal request using a base64 encoded PKCS #7 file, then click Next.
5. Either select browse for a file (and browse to the TFTP server and select the .req file) or open the just received by TFTP .req file with WordPad/Notepad and copy/paste the contents in the first window.

6. Export the .crt file from the CA and put it on the TFTP server.

7. Configure the ‘crypto ca import <label> certificate’ to import the device’s certificates from the tftp server.

### Configuring IKEv1 Public Key Infrastructure Policies in Site-to-Site VPNs

You can create a Public Key Infrastructure (PKI) policy to generate enrollment requests for CA certificates and RSA keys, and to manage keys and certificates. Certification Authority (CA) servers are used to manage these certificate requests and issue certificates to the participating devices in your VPN topology.

In Security Manager, CA servers are predefined as PKI enrollment objects that you can use in your PKI policies. A PKI enrollment object contains the server information and enrollment parameters that are required for creating enrollment requests for CA certificates.

For more information about Public Key Infrastructure policies, see Understanding Public Key Infrastructure Policies, page 24-44.

This procedure describes how to specify the CA server that will be used to create an IKEv1 Public Key Infrastructure (PKI) policy in your VPN topology.

![Tip]

For information on specifying CA servers for use in IKEv2 negotiations, see Configuring IKEv2 Authentication in Site-to-Site VPNs, page 24-59.

### Before You Begin

For important information about successfully configuring PKI, see Requirements for Successful PKI Enrollment, page 24-45.

### Related Topics
- Defining Multiple IKEv1 CA Servers for Site-to-Site VPNs, page 24-48
- Deciding Which Authentication Method to Use, page 24-8
- Filtering Items in Selectors, page 1-41

### Step 1

Do one of the following:

- **(Site-to-Site VPN Manager Window)** Select an existing topology and then select **IKEv1 Public Key Infrastructure** in the Policies selector.

- **(Policy view)** Select **Site-to-Site VPN > IKEv1 Public Key Infrastructure**, and then select an existing policy or create a new one.
The Public Key Infrastructure page opens, displaying the currently selected CA server, if any, in the **Selected** field.

**Step 2** Select the PKI enrollment policy object that defines the desired CA server in the Available CA Servers list. You can do the following to modify the listed objects:

- To add a new PKI enrollment object, click the **Create (+)** button. The Add PKI Enrollment dialog box opens. For detailed information about the attributes of a PKI enrollment object, see **PKI Enrollment Dialog Box**, page 24-51.
- To change the configuration of an existing object, select it and click the **Edit (pencil)** button.

**Note** If you are making a PKI enrollment request on an Easy VPN topology, you must configure each remote component (spoke) with the name of the user group to which it connects. You specify this information in the Organization Unit (OU) field in the Certificate Subject Name tab of the PKI Enrollment dialog box. You do not need to configure the name of the user group on the hub (Easy VPN server). For more information, see **PKI Enrollment Dialog Box—Certificate Subject Name Tab**, page 24-58.

---

**Defining Multiple IKEv1 CA Servers for Site-to-Site VPNs**

You can select only one CA server when defining an IKEv1 Public Key Infrastructure (PKI) policy on a site-to-site VPN. This creates a problem when the devices in the VPN enroll with different CA servers when using IKEv1. For example, the spoke devices might enroll with a different CA server than the hub, or the spokes in one part of the VPN might enroll with a different CA server than the spokes in another part of the VPN.

**Tip** When using IKEv2, you can configure different CA servers for various devices by creating overrides for the IKEv2 Authentication policy global settings rather than creating device-level overrides for PKI enrollment policy objects. However, you can also use device-level overrides for IKEv2 as described in this topic. For information on configuring CA servers for IKEv2, see **Configuring IKEv2 Authentication in Site-to-Site VPNs**, page 24-59.

To define an IKEv1 PKI policy, you select a PKI enrollment object that specifies the CA server to which the devices should enroll. Although by default the policy object refers globally to a single CA server, you can use device-level overrides to have the object refer to a different CA server on selected devices.

For example, if PKI enrollment object PKI_1 refers to a CA server named CA_1, you can create a device-level override for selected devices that has PKI_1 refer to a different CA server, for example, CA_2. Theoretically, you can use overrides to define a different CA server for each device in the VPN.

This procedure describes the basic steps for creating overrides for PKI enrollment objects.

**Note** You can also use device-level overrides when the CA servers are arranged in a PKI hierarchy beneath a common, trusted CA server. To do this, you must ensure that both the global definition of the object and the device-level override specify the trusted CA server in the Trusted CA Hierarchy tab of the PKI Enrollment dialog box. See **PKI Enrollment Dialog Box—Trusted CA Hierarchy Tab**, page 24-59.
Step 1 To create the PKI enrollment object, open the PKI Enrollment dialog box. You can access this dialog box in two ways:
- From the Public Key Infrastructure policy—Click the Create (+) button beneath the Selected field. See Configuring IKEv1 Public Key Infrastructure Policies in Site-to-Site VPNs, page 24-47.
- From the Policy Object Manager (select Manage > Policy Objects)—Select PKI Enrollments from the Object Type selector, then click the New Object (+) button.

Step 2 Define the global definition of the PKI enrollment object, including the CA server to which the object refers. Be sure to select Allow Value Override per Device. This option makes the object overridable on individual devices. See PKI Enrollment Dialog Box, page 24-51.

Base the global definition of the object on the CA server that is used by the most devices in the VPN. Doing this reduces the number of device-level overrides that are required.

Step 3 When you finish defining the PKI enrollment object, click OK. As a result:
- If you accessed the dialog box through the PKI policy, the new object appears in the Selected field of the policy page.
- If you accessed the dialog box using the Policy Object Manager, the new object appears in the work area of the Policy Object Manager window. A green check mark in the Overridable column indicates that device-level overrides can be created for this object. (The check mark does not indicate whether any overrides actually exist.)

Step 4 Create the device-level overrides for the PKI enrollment object. You can do this in one of two ways:
- From Device Properties (with the device selected in Device view, select Tools > Device Properties)—This option is recommended when you want to create a device-level override for a single device. In the device properties, select Policy Object Overrides > PKI Enrollments, select the PKI enrollment object that you want to override, then click the Create Override button. You can then define the content of the override, including the CA server defined by the object.
  For more information, see Creating or Editing Object Overrides for a Single Device, page 6-17.
- From the Policy Object Manager—This option is recommended when you want to create a device-level override for multiple devices at the same time. Double-click the green check mark in the Overridable column, select the devices to which the override should apply, then define the content of the override, including the CA server defined by the object.
  For more information, see Creating or Editing Object Overrides for Multiple Devices At A Time, page 6-17.

Configuring Public Key Infrastructure Policies for Remote Access VPNs

You can create a Public Key Infrastructure (PKI) policy to generate enrollment requests for CA certificates and RSA keys, and to manage keys and certificates. Certification Authority (CA) servers are used to manage these certificate requests and issue certificates to users who connect to your IPsec or SSL remote access VPN.
In Security Manager, CA servers are predefined as PKI enrollment objects that you can use in your PKI policies. A PKI enrollment object contains the server information and enrollment parameters that are required for creating enrollment requests for CA certificates.

For more information about Public Key Infrastructure policies, see Understanding Public Key Infrastructure Policies, page 24-44.

This procedure describes how to specify the CA servers that will be used to create a Public Key Infrastructure (PKI) policy in your remote access VPN.

**Before You Begin**

Keep the following in mind:

- For important information about successfully configuring PKI, see Requirements for Successful PKI Enrollment, page 24-45.
- The IKE Proposal policy for IPsec remote access VPNs should use an IKE Proposal object that requires certificate authorization when configuring IKEv1.
- For remote access VPNs defined on an ASA or PIX 7.x+ device, be aware that the Public Key Infrastructure policy is directly related to the following policies. Any trustpoints defined in these policies must also be selected in the Public Key Infrastructure policy; they are not automatically added to the policy. You might want to first configure these policies to determine which PKI enrollment objects are required in your remote access VPNs.
  - Connection Profiles—When you create a IPsec connection profile for which CA trustpoints should be used, you select the PKI enrollment object that identifies the trustpoint on the IPsec tab.
  - SSL VPN Access—You can configure trustpoints for each interface and also a fallback trustpoint.
  - Global Settings, IKEv2 Settings tab—For IKEv2 IPsec, you must specify a global trustpoint.

**Related Topics**

- Deciding Which Authentication Method to Use, page 24-8
- Filtering Items in Selectors, page 1-41

**Step 1**

Do one of the following:

- (Device view) Select Remote Access VPN > Public Key Infrastructure from the Policy selector.
- (Policy view) Select Remote Access VPN > Public Key Infrastructure from the Policy Type selector. Select an existing policy or create a new one.

The Public Key Infrastructure page opens, displaying the currently available and selected CA servers (PKI enrollment objects), if any.

**Step 2**

Select the PKI enrollment policy objects that define the desired CA servers in the Available CA Servers list and click >> to move them to the Selected CA Servers list. You can remove undesired objects by selecting them in the selected list and clicking <<.

For ASA and PIX 7.x+ devices, the list of selected PKI enrollment objects must include all objects that are specified in the connection profiles defined for the remote access VPN. For more information on connection profiles, see Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6. Also, any trustpoints configured for IKEv2 on the Global Settings policy must be included; see Configuring VPN Global IKEv2 Settings, page 24-31.
You can do the following to modify the listed objects:

- To add a new PKI enrollment object, click the **Create (+)** button below the list of available servers. The Add PKI Enrollment dialog box opens. For detailed information about the attributes of a PKI enrollment object, see **PKI Enrollment Dialog Box, page 24-51**.

- To change the configuration of an existing object, select it in either list and click the **Edit (pencil)** button.

### PKI Enrollment Dialog Box

Use the PKI Enrollment dialog box to view, create, copy, or edit Public-Key Infrastructure (PKI) enrollment objects. A PKI enrollment object represents an external certification authority (CA) server that responds to certificate requests from devices in the network.

You can create PKI enrollment objects to define the properties of a CA server used when devices exchange certificates as part of an IPsec network. When you create a PKI enrollment object, you define a name for the server and the URL for enrollment. You must specify whether the devices you wish to enroll with this server should retrieve the CA server's own certificate using the Simple Certificate Enrollment Process (SCEP) or use a certificate that you have entered manually into the device configuration. You must also select the method of support used by the CA server for revocation checking.

**Note**

You do not have to define enrollment parameters in order to create or import a trustpoint in Security Manager.

In addition, you can optionally define the following:

- Whether the CA server is acting as a Registration Authority (RA) server.
- Enrollment parameters, including retry settings and RSA key pair settings.
- Additional attributes to include in the certificate request.
- The list of trusted CA servers located above this server in the PKI hierarchy.

### Navigation Path

Select **Manage > Policy Objects**, then select **PKI Enrollments** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

**Tip**

You can also open this dialog box from the **Public Key Infrastructure** policy for remote access or site-to-site VPNs.

### Understanding Public Key Infrastructure Policies

**Enrollment URL**

The URL of the CA server to which devices should attempt to enroll. The URL can be in the following formats:
- **SCEP**—Uses an HTTP URL in the form of `http://CA_name:port`, where CA_name is the host DNS name or IP address of the CA server. The port number is mandatory.
- **TFTP**—Uses the format `tftp://certserver/file_specification`. Use this option when you do not have direct access to the CA server. The TFTP server transfers certificate requests and certificates.
- Other supported formats include: bootflash, cns, flash, ftp, null, nvram, rcp, scp, system.

**Note** If the CA cgi-bin script location at the CA is not the default (`/cgi-bin/pkiclient.exe`), you must also include the nonstandard script location in the URL, in the form of `http://CA_name:port/script_location`, where script_location is the full path to the CA scripts.

**CA Certificate Source**

**Fingerprint**

How to obtain the certificate:
- **Retrieve CA Certificate Using SCEP** (the default)—Have the router retrieve the certificate from the CA server using the Simple Certificate Enrollment Process (SCEP). Enter the fingerprint for the CA server in hexadecimal format. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected.

Using the fingerprint to verify the authenticity of the CA's certificate helps prevent an unauthorized party from substituting a fake certificate in place of the real one.

**Tip** You can obtain the CA's fingerprint by contacting the server directly, or by entering the following address in a web browser: `http://URLHostName/certsrv/mscep/mscep.dll`. Using the fingerprint is supported only on Cisco IOS software releases 12.3(12) or higher, 12.3(14)T or higher, 12.4 or higher (including 15.x), 12.2(33)XNA or higher.

- **Enter CA Certificate from CA Server Manually**—Copy and Paste up to three certificates from another device into the Certificate field (using your browser's Paste function or the Ctrl-V keyboard shortcut). Each certificate must begin with the word “certificate” and end with the word “quit”. Use this option when you want the PKI enrollment object to represent predefined certificates.

</tr>
</tbody>
</table>
Revocation Check Support

- Checking Not Performed—This is the default. The device does not perform any revocation checking, even if a CRL is on the device.
- CRL Check Required—The device must check a CRL. If no CRL exists on the device and the device cannot obtain one, certificates are rejected and a tunnel cannot be established.
- OCSP Check Required—The device must check revocation status from an OCSP server. If this check fails, certificates are rejected.
- CRL Check Attempted—The device tries to download the latest CRL from the specified LDAP server. If the download fails, however, certificates are accepted.
- OCSP Check Attempted—The device tries to check revocation status from an OCSP server. If this fails, however, certificates are accepted.
- CRL or OCSP Check Required—The device first checks for a CRL. If a CRL does not exist or cannot be obtained, the device tries to check revocation status from an OCSP server. If both options fail, certificates are rejected.
- OCSP or CRL Check Required—The device first tries to check revocation status from an OCSP server. If this fails, the device checks for a CRL. If both options fail, certificates are rejected.
- CRL and OCSP Checks Attempted—The device first checks for a CRL. If a CRL does not exist or cannot be obtained, the device tries to check revocation status from an OCSP server. If both options fail, however, certificates are accepted.
- OCSP and CRL Checks Attempted—The device first tries to check revocation status from an OCSP server. If this fails, the device tries to download the latest CRL. If both options fail, however, certificates are accepted.
- CRL and OCSP Checks Attempted—The device first checks for a CRL. If a CRL does not exist or cannot be obtained, the device tries to check revocation status from an OCSP server. If both options fail, however, certificates are accepted.

OCSP Server URL

The URL of the OCSP server checking for revocation if you require OCSP checks. This URL must start with http://

CRL Server URL

The URL of the LDAP server from which the CRL can be downloaded if you require CRL checks. This URL must start with ldap://

Note: You must include a port number in the URL when using this AAA server on ASA devices, otherwise LDAP will fail.

Enable Registration Authority Mode (PIX 6.3)

For PIX 6.3 devices, whether the CA server operates in RA (Registration Authority) mode. A Registration Authority is a server that acts as a proxy for the actual CA so that CA operations can continue when the CA server is offline.

Note: Cisco IOS routers configure RA mode automatically, if required.
PKI Enrollment Dialog Box—Enrollment Parameters Tab

Use the Enrollment Parameters tab of the PKI Enrollment dialog box to define the retry settings to use when the device contacts the CA server as well as the settings for generating the RSA key pair to associate with the certificate.

If the PKI enrollment object represents a Microsoft CA, you can define the challenge password required to validate the router’s identity.

Note
You do not have to define enrollment parameters in order to create or import a trustpoint in Security Manager.

Navigation Path
Go to the PKI Enrollment dialog box and click the Enrollment Parameters tab. For information on opening the dialog box, see PKI Enrollment Dialog Box, page 24-51.

Field Reference

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Challenge Password</td>
<td>The password used by the CA server to validate the identity of the device. This password is mandatory for PIX 6.3 devices, but optional for PIX/ASA 7.0+ devices and Cisco IOS routers. You can obtain the password by contacting the CA server directly or by entering the following address in a web browser: <a href="http://URLHostName/certsrv/mscep/mscep.dll">http://URLHostName/certsrv/mscep/mscep.dll</a>. The password is good for 60 minutes from the time you obtain it from the CA server. Therefore, it is important that you deploy the password as soon as possible after you create it. Note Each password is valid for a single enrollment by a single device. Therefore, we do not recommend that you assign a PKI enrollment object where this field is defined to a VPN, unless you first configure a device-level override for each device in the VPN. For more information, see Understanding Policy Object Overrides for Individual Devices, page 6-16.</td>
</tr>
<tr>
<td>Retry Period</td>
<td>The interval between certificate request attempts, in minutes. Values can be 1 to 60 minutes. The default is 1 minute.</td>
</tr>
<tr>
<td>Retry Count</td>
<td>The number of retries that should be made if no certificate is issued upon the first request. Values can be 1 to 100. The default is 10.</td>

</tbody>
</table>
### Table 24-12 PKI Enrollment Dialog Box—Enrollment Parameters Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate Auto-Enrollment</td>
<td>The percentage of the current certificate’s lifetime after which the router requests a new certificate. For example, if you enter 70, the router requests a new certificate after 70% of the lifetime of the current certificate has been reached. Values range from 10% to 100%. If you do not specify a value, the router requests a new certificate after the old certificate expires.</td>
</tr>
<tr>
<td>Include Device’s Serial Number</td>
<td>Whether to include the serial number of the device in the certificate. Tip: The CA uses the serial number to either authenticate certificates or to later associate a certificate with a particular device. If you are in doubt, include the serial number, as it is useful for debugging purposes.</td>
</tr>
<tr>
<td>RSA Key Pair Name</td>
<td>If the key pair you want to associate with the certificate already exists, this field specifies the name of that key pair. If the key pair does not exist, this field specifies the name to assign to the key pair that will be generated during enrollment. Note: If you do not specify an RSA key pair, the fully qualified domain name (FQDN) key pair is used instead. On PIX and ASA devices, the key pair must exist on the device before deployment.</td>
</tr>
<tr>
<td>RSA Key Size</td>
<td>If the key pair does not exist, defines the desired key size (modulus), in bits. If you want a modulus between 512 and 1024, enter an integer that is a multiple of 64. If you want a value higher than 1024, enter 1536 or 2048. The recommended size is 1024. Note: The larger the modulus size, the more secure the key. However, keys with larger modulus sizes take longer to generate (a minute or more when larger than 512 bits) and longer to process when exchanged.</td>
</tr>
<tr>
<td>RSA Encryption Key Size</td>
<td>The size of the second key, which is used to request separate encryption, signature keys, and certificates.</td>
</tr>
<tr>
<td>Source Interface</td>
<td>The source address for all outgoing connections sent to a CA or LDAP server during authentication, enrollment, and when obtaining a revocation list. This parameter may be necessary when the CA server or LDAP server cannot respond to the address from which the connection originated (for example, due to a firewall). If you do not define a value in this field, the address of the outgoing interface is used. Enter the name of an interface or interface role, or click Select to select it. If the object that you want is not listed, click the Create button to create it.</td>
</tr>
</tbody>
</table>
PKI Enrollment Dialog Box—Certificate Subject Name Tab

Use the Certificate Subject Name tab of the PKI Enrollment dialog box to optionally define additional information about the device in certificate requests sent to the CA server. This information is placed in the certificate and can be viewed by any party who receives the certificate from the router.

Enter all information using the standard LDAP X.500 format.

Navigation Path
Go to the PKI Enrollment dialog box and click the Certificate Subject Name tab. For information on opening the dialog box, see PKI Enrollment Dialog Box, page 24-51.

PKI Enrollment Dialog Box—Trusted CA Hierarchy Tab

Use the Trusted CA Hierarchy tab of the PKI Enrollment dialog box to define the trusted CA servers within an hierarchical PKI framework. Within this framework, all enrolled peers can validate each other’s certificates if they share a trusted root CA certificate or a common subordinate CA.

Select the CA servers (as defined as PKI enrollment objects) to include in the hierarchy in the Available Servers list and click >> to move them to the selected list. You can do the reverse to remove servers.

If the PKI enrollment object you need is not yet defined, click the Create (+) button beneath the available servers list to create the object. You can also select an object and click the Edit button to change its definition, if needed.

Navigation Path

Go to the PKI Enrollment dialog box and click the Trusted CA Hierarchy tab. For information on opening the dialog box, see PKI Enrollment Dialog Box, page 24-51.

Configuring IKEv2 Authentication in Site-to-Site VPNs

When you configure IKE version 2 (IKEv2) in a site-to-site VPN, you must configure the IKEv2 Authentication policy to define authentication settings. Unlike IKEv1, authentication settings are not part of the IKEv2 proposal.

In Security Manager, when you configure IKEv2 authentication for a site-to-site VPN, you configure default settings that will be used in the VPN topology. You can then configure exceptions to the default, specifying different preshared keys or trustpoints for specific segments of the VPN. You can use a mixture of preshared keys and trustpoints, for example, configuring a global preshared key, but trustpoints for selected members of the VPN.

IKEv2 allows you to use asymmetric authentication, unlike IKEv1. This means that two peers can have different preshared keys, different trustpoints, or one peer could use a preshared key and the other peer could use a trustpoint. In Security Manager, you can configure asymmetric authentication by doing any of the following:

- On the Global IKEv2 Authentication Settings tab, you can configure different preshared keys if you elect to auto-generate keys and do not select the Same Keys for All Tunnels or the Same Key at Tunnel Endpoints option. A different preshared key is generated for each end of each tunnel.
- On the Override IKEv2 Authentication Settings tab, you can create overrides for the global settings. You add overrides that specify different keys or trustpoints for subsets of local and remote peers. Because you can create more than one override for a device or a specific tunnel, you can configure a set of preshared keys and trustpoints from which peers will authenticate.
Chapter 24  Configuring IKE and IPsec Policies

Chapter 24      Configuring IKE and IPsec Policies

Configuring IKEv2 Authentication in Site-to-Site VPNs

Tip
The IKEv2 Authentication policy is not a shared policy. You must configure the policy for each VPN topology in which you support IKEv2 negotiations. You cannot configure global IKEv2 authentication options for use by all of your VPN topologies. When using the Create VPN wizard, even if you elect to support IKEv2, the IKEv2 Authentication policy is never configured.

Before You Begin
The IKEv2 Authentication policy is used only if you enable IKEv2 in the VPN in the IKE Proposal and IPsec Proposal policies, and if at least some of the devices in the topology support IKEv2.

To configure IKEv2, the device must be an ASA running ASA Software release 8.4(1) or higher. For more information on device support, see Understanding Devices Supported by Each IPsec Technology, page 23-9.

Tip
If you support only IKEv2 in the topology, ensure that you unassign the IKEv1 Preshared Keys and IKEv1 Public Key Infrastructure policies to avoid validation warnings.

Related Topics
- Understanding IKE, page 24-5
- Deciding Which Authentication Method to Use, page 24-8

Step 1
Open the Site-to-Site VPN Manager Window, page 23-18, select a regular IPsec topology (that supports IKEv2) in the VPNs selector, then select IKEv2 Authentication in the Policies selector.

For reference information on the policy, see IKEv2 Authentication Policy, page 24-61.

Step 2
On the Global IKEv2 Authentication Settings tab, configure the authentication type that should be used for devices in the VPN for which no override is configured on the Override IKEv2 Authentication Settings tab. Select the option that is used by most devices in the VPN. You can configure a global preshared key or trustpoint:

- **Global Preshared Keys**—To configure a global preshared key, select Key Specification and then configure one of the following options:
  - User Defined—Enter the desired global key and enter it again in the Confirm field.
  - Auto Generated—Enter the length of the key that should be generated and select whether you want to use the same key for all tunnels or the same key at both ends of a single tunnel. If you select neither of these options, unique keys are generated for every end point.
  
  You can also select Regenerate Key (On Next Deployment) to have new keys generated. This allows you to periodically re-key the VPN. The check box is cleared after the next successful deployment.

- **Global Trustpoint (CA Servers)**—To configure trustpoint certificate authorization, select PKI Specification and enter the name of the PKI enrollment object that identifies the Certificate Authority (CA) server. Click Select to select the object from a list or to create a new object.

Step 3
If you want to override the global IKEv2 authentication configuration for specific devices, click the Override IKEv2 Authentication Settings tab and do any of the following:

- To add an override, click the Add Row (+) button and fill in the IKEv2 Authentication dialog box. You select the local and remote peers for which to create the override, and then specify the preshared key or CA server that should be used. See IKEv2 Authentication (Override) Dialog Box, page 24-63.
To edit an override, select it in the table and click the **Edit Row (pencil)** button.

To delete an override, select it in the table and click the **Delete Row (trash can)** button.

---

### IKEv2 Authentication Policy

Use the IKEv2 Authentication policy to configure the device authentication settings for Internet Key Exchange (IKE) version 2 in site-to-site VPNs. These settings apply to ASA 8.4(1)+ devices only. For more information about configuring IKEv2 authentication, see [Configuring IKEv2 Authentication in Site-to-Site VPNs](#), page 24-59.

The policy contains two tabs:

- **Global IKEv2 Authentication Settings**—The global settings apply to all devices in the VPN unless overrides are configured on the Overrides tab. Configure the global settings to represent the authentication scheme used by most devices in the VPN.

- **Override IKEv2 Authentication Settings**—The override settings apply unique authentication settings to specific tunnels, allowing you to create unique preshared key and trustpoint combinations that are required by various tunnels in the VPN. The settings you configure on this tab are used first and always take precedence over the global settings.

**Navigation Path**

Open the Site-to-Site VPN Manager Window, page 23-18, select a regular IPsec topology (that supports IKEv2) in the VPNs selector, then select **IKEv2 Authentication** in the Policies selector.

This policy is not available as a shared policy.

You can configure Generic Routing Encapsulation (GRE) and Dynamic Multipoint (DM) VPNs that include GRE mode configurations. You can configure IPsec GRE VPNs for hub-and-spoke, point-to-point, and full mesh VPN topologies. DMVPN is available for hub-and-spoke topologies only.

This chapter contains the following topics:

- Understanding the GRE Modes Page, page 25-1
- GRE and Dynamic GRE VPNs, page 25-2
- Dynamic Multipoint VPNs (DMVPN), page 25-9

Understanding the GRE Modes Page

Use the GRE Modes page to define the routing and tunnel parameters for IPsec tunneling with GRE, GRE Dynamic IP, and DMVPN policies.

The content of the policy differs depending on how you access it:

- **(Site-to-Site VPN Manager Window, page 23-18)** When you select a GRE VPN or DMVPN, the GRE Modes policy contains the properties related to the technology and technology type used in the VPN.

- **(Policy view)** When you select Site-to-Site VPN > GRE Modes, and create a new policy or select an existing policy, there is an additional field in the policy called GRE Method. From the GRE Method list, you must select the VPN technology and technology type for which you are defining the policy: IPsec/GRE, GRE Dynamic IP, DMVPN, or Large Scale DMVPN. This option controls which fields are displayed in the policy. You cannot change the GRE Method after you save the policy.

  When you assign a shared GRE Modes policy to a VPN, the GRE Method and the VPN’s technology and type must match or the policy cannot be selected. For example, you cannot assign a shared DMVPN GRE Modes policy to an IPsec/GRE VPN.

The following topics describe the GRE Modes policy in detail based on the selected GRE Methods:

- IPsec/GRE or GRE Dynamic IP—See Configuring GRE Modes for DMVPN, page 25-12.
- DMVPN or Large Scale DMVPN—See Configuring GRE Modes forGRE or GRE Dynamic IP VPNs, page 25-6.
When configuring an IPsec/GRE, GRE Dynamic IP, or DMVPN routing policy, Security Manager adds a routing protocol to all the devices in the secured IGP, on deployment. If you want to maintain this secured IGP, you must create a router platform policy (on each member device) using the same routing protocol and autonomous system (or process ID) number as defined in the GRE Modes policy.

**GRE and Dynamic GRE VPNs**

You can use Generic Routing Encapsulation (GRE) to create VPNs using Cisco IOS security routers and Catalyst 6500/7600 devices in hub-and-spoke, point-to-point, and full mesh VPN topologies.

This section contains the following topics:

- Understanding GRE, page 25-2
- Configuring IPsec GRE VPNs, page 25-5
- Configuring GRE Modes for GRE or GRE Dynamic IP VPNs, page 25-6

**Understanding GRE**

Generic Routing Encapsulation (GRE) is a tunneling protocol that encapsulates a variety of protocol packet types inside IP tunnels, creating a virtual point-to-point connection to devices at remote points over an IP network. With this technology, GRE encapsulates the entire original packet with a standard IP header and GRE header before the IPsec process. Then, IPsec views the GRE packet as an unremarkable IP packet and performs encryption and authentication services, as dictated by the IKE negotiated parameters. Because GRE can carry multicast and broadcast traffic, it is possible to configure a routing protocol for virtual GRE tunnels. The routing protocol detects loss of connectivity and reroutes packets to the backup GRE tunnel, thus providing high resiliency.

For VPN resilience, a spoke must be configured with two GRE tunnels, one to the primary hub and the other to the backup hub. Both GRE tunnels are secured with IPsec: each one has its own IKE security association (SA) and a pair of IPsec SAs. An associated routing protocol automates the failover mechanism, transferring to the backup tunnel if virtual link loss is detected.

**Note**

GRE can be configured on Cisco IOS security routers and Catalyst 6500/7600 devices in hub-and-spoke, point-to-point, and full mesh VPN topologies.

This section contains the following topics:

- Advantages of IPsec Tunneling with GRE, page 25-3
- How Does Security Manager Implement GRE?, page 25-3
- Prerequisites for Successful Configuration of GRE, page 25-3
- Understanding GRE Configuration for Dynamically Addressed Spokes, page 25-5
Advantages of IPsec Tunneling with GRE

The main advantages of IPsec tunneling with GRE are the following:

- GRE uses a routing protocol by which every IPsec peer knows the status of every other peer at all times.
- GRE provides higher resiliency than IKE keepalive.
- Spoke-to-spoke connectivity is supported when you use GRE.
- GRE supports multicast and broadcast transmissions.

Note: GRE does not support the use of dynamic cryptographic tunnels.

How Does Security Manager Implement GRE?

Security Manager implements an additional Interior Gateway Protocol (IGP) solution for GRE. An IGP refers to a group of devices that receive routing updates from one another by a routing protocol, EIGRP, OSPF, or RIP. Each “routing group” is identified by a logical number. For general routing purposes, the interfaces on the routers in your networks belong to an IGP. Security Manager adds an additional IGP that is dedicated for IPsec and GRE-secured communication. This additional IGP is the secured IGP. The existing IGP (unsecured IGP), is used for routing traffic that does not require encryption.

For a GRE tunnel to be established, Security Manager configures a virtual interface on each device. These virtual interfaces are the endpoints of the GRE tunnel. Each virtual interface is unique. The GRE tunnel interface has an IP address (inside tunnel IP address) which is taken from an interface that Security Manager creates. The GRE tunnel points to the source and destination IP addresses of either the physical or loopback interfaces on each device. The GRE virtual interfaces belong to the secured IGP, as do the inside interfaces. Routing updates within the secured IGP are GRE encapsulated and IPsec is applied. A flow whose destination is a secured interface (according to the routing updates of the secured IGP) is directed through the GRE interface where it is GRE encapsulated and then evaluated against the crypto ACL. If it matches the crypto ACL, it is routed through the GRE and VPN tunnels.

Prerequisites for Successful Configuration of GRE

Consider the following prerequisites before using GRE in your network:

- You must identify the inside interfaces on your devices—the physical interfaces on the device that connect the device with its internal subnets and networks.
- You must select a routing protocol (known as an IGP) or a static route, whenever you enable GRE. Security Manager supports the EIGRP, OSPF, and RIPv2 dynamic routing protocols, and GRE static routes.
  - EIGRP—Enhanced Interior Gateway Routing Protocol enables the exchange of routing information within an autonomous system and addresses some of the more difficult issues associated with routing in large, heterogeneous networks. Compared to other protocols, EIGRP provides superior convergence properties and operating efficiency, and combines the advantages of several different protocols. For more information, see EIGRP Routing on Cisco IOS Routers, page 63-8.
  - OSPF—Open Shortest Path First is a link-state, hierarchical protocol that features least-cost routing, multipath routing, and load balancing.
Using OSPF, a host that obtains a change to a routing table or detects a change in the network immediately multicasts the information to all other hosts in the network, so that all will have the same routing table information. For more information, see OSPF Routing on Cisco IOS Routers, page 63-19.

- RIPv2—Routing Information Protocol is a distance-vector protocol that sends routing-update messages at regular intervals and whenever the network topology changes.

Using RIPv2, a gateway host (with a router) sends its entire routing table to its closest neighbor host every 30 seconds, which in turn passes the information on to its next neighbor, and so on, until all hosts within the network have the same knowledge of routing paths. RIPv2 uses a hop count to determine network distance. Each host with a router in the network uses the routing table information to determine the next host to route a packet to for a specified destination.

RIP is considered an effective solution for small homogeneous networks. For larger, more complicated networks, RIP’s transmission of the entire routing table every 30 seconds may put a heavy amount of extra traffic in the network. For more information, see RIP Routing on Cisco IOS Routers, page 63-42.

- Static route—Use a static routing policy to provide a robust, stable IPsec-protected GRE tunnel if there is a fixed, unchanging route between two devices. For each device subnet, a static route is created on the device pointing to the corresponding tunnel interface. For more information, see Static Routing on Cisco IOS Routers, page 63-50.

- You must specify an IGP process number. The IGP process number identifies the IGP process to which the inside interface on the device belongs. When GRE is implemented, this will be the secured IGP. For secure communication, the inside interfaces on the devices in your VPN must use the same IGP process. The IGP process number must be within a specified range. If you have an existing IGP process on the device that is within this range, but is different from the IGP process number specified in your GRE settings, Security Manager removes the existing IGP process. If the existing IGP process matches the one specified in your GRE settings, any networks included in the existing IGP process that do not match the specified inside interfaces are removed.

- If the inside interfaces on your devices are configured to use an IGP process other than the IGP process specified in your GRE settings (meaning that the interfaces belong to an unsecured IGP):
  - For spokes: Manually remove the inside interfaces from the unsecured IGP through the device CLI before configuring GRE.
  - For hubs: If the hub inside interface is used as a network access point for Security Manager, then on deployment, the interface is advertised in both secured and unsecured IGPs. To ensure that the spoke peers use only the secured IGP, manually add the auto-summary command for the unsecured IGP or remove the unsecured IGP for that inside interface.

- You must provide a subnet that is unique yet it can be non-globally-routable for loopback. This subnet must only be used to support the implementation of loopback for GRE. The loopback interfaces are created, maintained, and used only by Security Manager. You should not use them for any other purpose.

- If you are using static routes, not unsecured IGP, make sure you configure static routes on the spokes through to the hub inside interfaces.

**Note**

You can configure the above settings in the GRE Modes page when IPsec/GRE is the selected IPsec technology.
Understanding GRE Configuration for Dynamically Addressed Spokes

When a spoke has a dynamic IP address, there is no fixed GRE tunnel source address (to be used by the GRE tunnel on the spoke side) or destination address (to be used by the GRE tunnel on the hub side). Therefore, Security Manager creates additional loopback interfaces on the hub and the spoke, to be used as the GRE tunnel endpoints. You must specify a subnet from which Security Manager can allocate an IP address for the loopback interfaces.

**Note**
GRE Dynamic IP can only be configured on Cisco IOS routers and Catalyst 6500/7600 devices in hub-and-spoke VPN topologies.

Security Manager uses the Cisco Configuration Engine to retrieve device IP addresses and other information from dynamically addressed devices. Devices that have dynamic IP addresses connect to the Configuration Engine manager at periodic intervals to upgrade device configuration files and to pass device and status information.

For more information, see Adding, Editing, or Deleting Auto Update Servers or Configuration Engines, page 3-33.

**Note**
You can configure the GRE Dynamic IP settings in the GRE Modes page when GRE Dynamic IP is the selected IPsec technology.

**Related Topics**
- Understanding GRE, page 25-2
- Configuring GRE Modes for GRE or GRE Dynamic IP VPNs, page 25-6

Configuring IPsec GRE VPNs

To configure an IPsec GRE (generic routing encapsulation) VPN, use the Create VPN wizard as described in Creating or Editing VPN Topologies, page 23-28. You can also edit the membership of the VPN, or some of its policies, using the described procedures. If you are creating a hub-and-spoke VPN with dynamically addressed spokes, also see Understanding GRE Configuration for Dynamically Addressed Spokes, page 25-5.

If you need to make changes to other policies and settings, open the policies from the Site-to-Site Manager page, as follows:

- For ISAKMP and IPSec settings, select **VPN Global Settings**. See Configuring VPN Global Settings, page 24-27.
- For IPSec proposals, select **IPsec Proposal**. See Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20.
- For preshared key policies, select **IKEv1 Preshared Key**. See Configuring IKEv1 Preshared Key Policies, page 24-41.
- For public key (PKI) policies, select **Public Key Infrastructure**. See Configuring IKEv1 Public Key Infrastructure Policies in Site-to-Site VPNs, page 24-47.
- For Generic Routing Encapsulation configuration, select **GRE Modes**. See Configuring GRE Modes for DMVPN, page 25-12.
Configuring GRE Modes for GRE or GRE Dynamic IP VPNs

Use the GRE Modes policy to define the routing and tunnel parameters for IPsec tunneling in a GRE or GRE Dynamic IP VPN.

To open the GRE Modes policy:

- (Site-to-Site VPN Manager Window, page 23-18) Select an IPsec/GRE or GRE Dynamic IP topology, then select GRE Modes from the policies list.
- (Policy view) Select Site-to-Site VPN > GRE Modes, and create a new policy or select an existing policy. Then, select either IPsec/GRE or Dynamic GRE from the GRE Method list.

The following table describes the elements on the GRE Modes page for configuring IPsec tunneling with GRE or GRE Dynamic IP.

![Note](https://example.com/notes.png)

When configuring a GRE routing policy, Security Manager adds a routing protocol to all the devices in the secured IGP, on deployment. If you want to maintain this secured IGP, you must create a router platform policy (on each member device) using the same routing protocol and autonomous system (or process ID) number as defined in the GRE Modes policy.

<td></td>
<td>The range is between 1 and 65535. The default is 110. Security Manager adds an additional Interior Gateway Protocol (IGP) that is dedicated for IPsec and GRE secured communication. An IGP refers to a group of devices that receive routing updates from one another by means of a routing protocol. Each “routing group” is identified by the process number.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Understanding GRE, page 25-2.</td>
</tr>
<tr>
<td>Hub Network Area ID</td>
<td>The ID number of the area in which the hub’s protected networks will be advertised, including the tunnel subnet. You can specify any number. The default is 0.</td>
</tr>
<tr>
<td>Spoke Protected Network Area ID</td>
<td>The ID number of the area in which the remote protected networks will be advertised, including the tunnel subnet. You can specify any number. The default is 1.</td>
</tr>
<tr>
<td>Authentication</td>
<td>A string that specifies the OSPF or RIPv2 authentication key. The string can be up to eight characters long.</td>
</tr>
<tr>
<td>Cost</td>
<td>The cost of sending a packet on the primary route interface.</td>
</tr>
<tr>
<td></td>
<td>If the selected protocol is OSPF, enter a value in the range 1-65535; the default is 100.</td>
</tr>
<tr>
<td></td>
<td>If the selected protocol is RIPv2, enter a value in the range 1-15; the default is 1.</td>
</tr>
</tbody>
</table>
### Table 25-1  
**GRE Modes Page for GRE or GRE Dynamic IP VPNs (Continued)**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Failover Cost (OSPF or RIPv2 only.) | The cost of sending a packet on the secondary (failover) route interface.  
You can enter a value in the range 1-65535 for OSPF (the default is 125), or in the range 1-15 for RIPv2 (the default is 2). |
| Filter Dynamic Updates on Spokes | When selected, enables the creation of a redistribution list that filters all dynamic routing updates on the spokes. This forces the spoke devices to advertise (populate on the hub device) only their own protected subnets and not other IP addresses. |

**Tunnel Parameters Tab**

<table>
<thead>
<tr>
<th>Tunnel IP</th>
<th>Select the required option to specify the GRE or GRE Dynamic IP tunnel interface IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Use Physical Interface</td>
<td>When selected, uses the private IP address of the tunnel taken from the protected network.</td>
</tr>
</tbody>
</table>
| • Use Subnet | When selected, uses the tunnel IP address taken from an IP range. This is the default.  
In the Subnet field, enter the private IP address including the unique subnet mask (default is 1.1.1.0/24).  
If you are also configuring a dial backup interface, enter its subnet in the Dial Backup Subnet field provided (default is 1.1.2.0/24). |
| Note | In most cases, when you use a subnet to specify a GRE tunnel interface IP address, Security Manager creates a loopback interface on the device which is used for the tunnel IP address.  
If the device belongs to a VPN topology whose configurations were discovered by Security Manager, and you configure an IP address directly on the device’s GRE tunnel, Security Manager keeps that configuration and does not create a loopback interface on the device. However, a loopback is always configured on a hub in a VPN topology; in a hub-and-spoke VPN topology with multiple hubs, a loopback interface is also configured on the spokes.  
• Use Loopback Interface | When selected, uses the tunnel IP address taken from an existing loopback interface. In the Role field, enter the name of the interface role object that defines the loopback interface name, or click Select to select it from a list or to create a new object. |
| Note | To view the new GRE tunnel or loopback interfaces in the Router Interfaces page, you must rediscover the device inventory details after successfully deploying the VPN to the device. |
Dynamic Multipoint VPNs (DMVPN)

Dynamic Multipoint VPN (DMVPN) is a hub-and-spoke VPN technology that enables better scaling of large and small IPsec VPNs by combining generic routing encapsulation (GRE) tunnels, IP Security (IPsec) encryption, and Next Hop Resolution Protocol (NHRP) routing.

This section contains the following topics:

- **Understanding DMVPN**, page 25-10
- **Configuring DMVPN**, page 25-12
- **Configuring GRE Modes for DMVPN**, page 25-12
- **Configuring Large Scale DMVPNs**, page 25-16
- **Configuring Server Load Balancing in Large Scale DMVPN**, page 25-17

### Table 25-1  GRE Modes Page for GRE or GRE Dynamic IP VPNs (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>

<tbody>
<tr>
<td>Configure Unique Tunnel Source for each Tunnel</td>
<td>When enabled, each GRE tunnel interface in the VPN is assigned a unique tunnel source. In the <strong>Tunnel Source IP Range</strong> field, enter a subnet IP to be used as tunnel sources.</td>
</tr>
<tr>
<td>(IPsec/GRE standard only.)</td>
<td><strong>Note</strong>: When enabled, this feature is set for all GRE tunnel interfaces in the VPN. If you want to assign a specific tunnel source for an interface, use the Peers policy to configure the endpoints for the desired devices; see <strong>Defining the Endpoints and Protected Networks</strong>, page 23-33.</td>
</tr>
<tr>
<td>Tunnel Source IP Range</td>
<td>The private IP address including the unique subnet mask that supports the loopback for GRE. The GRE tunnel interface has an IP address (inside tunnel IP address) which is taken from a loopback interface that Security Manager creates specifically for this purpose.</td>
</tr>
<tr>
<td>(GRE Dynamic IP only.)</td>
<td>When a spoke has a dynamic IP address, there is no fixed GRE tunnel source address (to be used by the GRE tunnel on the spoke side) or destination address (to be used by the GRE tunnel on the hub side). Therefore, Security Manager creates additional loopback interfaces on the hub and the spoke to use as the GRE tunnel endpoints. You must specify a subnet from which Security Manager can allocate an IP address for the loopback interfaces.</td>
</tr>
<tr>
<td>Enable IP Multicast</td>
<td>When selected, enables multicast transmissions across your GRE tunnels. IP multicast delivers application source traffic to multiple receivers without burdening the source or the receivers, while using a minimum of network bandwidth.</td>
</tr>
<tr>
<td>Rendezvous Point</td>
<td>Only available if you selected the Enable IP Multicast check box. If required, you can enter the IP address of the interface that will serve as the rendezvous point (RP) for multicast transmission. Sources send their traffic to the RP. This traffic is then forwarded to receivers down a shared distribution tree.</td>
</tr>
</tbody>
</table>
Understanding DMVPN

Dynamic Multipoint VPN (DMVPN) enables better scaling of large and small IPsec VPNs by combining generic routing encapsulation (GRE) tunnels, IP Security (IPsec) encryption, and Next Hop Resolution Protocol (NHRP) routing. (For information about large scale DMVPNs, see Configuring Large Scale DMVPNs, page 25-16.)

Security Manager supports DMVPN using the EIGRP, OSPF, and RIPv2 dynamic routing protocols, and GRE static routes. In addition, On-Demand Routing (ODR) is supported. ODR is not a routing protocol. It may be used in a hub-and-spoke VPN topology when the spoke routers do not connect to any router other than the hub. If you are running dynamic protocols, ODR is not suitable for your network environment.

You can use DMVPN on a hub-and-spoke VPN topology only with devices running Cisco IOS Software release 12.3T devices and later, or ASRs running Cisco IOS XE Software 2.x or later (known as 12.2(33)XNA+ in Security Manager). DMVPN is not supported on Catalyst VPN Services Module devices or on High Availability (HA) groups. If your device does not support DMVPN, use GRE dynamic IP to configure GRE for dynamically addressed spokes. See Understanding GRE Configuration for Dynamically Addressed Spokes, page 25-5.

The following topics provide more overview information on DMVPN:

- Enabling Spoke-to-Spoke Connections in DMVPN Topologies, page 25-10
- Advantages of DMVPN with GRE, page 25-11

The following documents on Cisco.com explain DMVPN in further detail:

- Cisco Dynamic Multipoint VPN: Simple and Secure Branch-to-Branch Communications—Explains DMVPN technology and where and why you would use it. This data sheet explains the technologies used with DMVPN and the benefits derived from those technologies.
- Migrating from Dynamic Multipoint VPN Phase 2 to Phase 3—Explains the difference between phase 2 and phase 3 spoke-to-spoke connections. Creating spoke-to-spoke connections is a configuration option with DMVPN. Phase 3 uses shortcut switching enhancements to increase network performance and scalability.

Enabling Spoke-to-Spoke Connections in DMVPN Topologies

You can use DMVPN to essentially create a full-mesh VPN, in which traditional hub-and-spoke connectivity is supplemented by dynamically-created IPsec tunnels directly between the spokes. With direct spoke-to-speke tunnels, traffic between remote sites does not need to traverse the hub; this eliminates additional delays and conserves WAN bandwidth. Spoke-to-spoke capability is supported in a single-hub or multihub environment. Multihub deployments provide increased spoke-to-spoke resiliency and redundancy.

You can use the 80:20 traffic rule to determine whether to use a pure hub-and-spoke topology or to allow direct spoke-to-speke connections:

- If 80 percent or more of the traffic from the spokes are directed into the hub network itself, deploy the hub-and-spoke model.
- If more than 20 percent of the traffic is meant for other spokes, consider the spoke-to-spoke model.

For networks with a high volume of IP Multicast traffic, the hub-and-spoke model is usually preferred.
When you configure the GRE Modes policy for a DMVPN, you can elect to allow spokes to create these direct connections. You must select the DMVPN phase to use for these connections:

- **Phase 2**—Spoke to spoke connections go through regional hubs and routing protocol updates from hubs to spokes are not summarized.

- **Phase 3** (Default)—Spokes can create direct connections with each other and routing updates from hubs to spokes are summarized. This option allows the greatest scalability and reduces latency. Devices must run IOS Software release 12.4(6)T or higher; ASRs must run IOS XE Software release 2.4 (called 12.2(33)XND) or higher. Security Manager automatically creates a phase 2 configuration for devices running a lower OS version.

For more information on configuring the GRE Modes policy, see *Configuring GRE Modes for DMVPN*, page 25-12.

- Understanding DMVPN, page 25-10
- *Cisco Dynamic Multipoint VPN: Simple and Secure Branch-to-Branch Communications*
- *Migrating from Dynamic Multipoint VPN Phase 2 to Phase 3*

**Advantages of DMVPN with GRE**

Using DMVPN with GRE provides the following advantages:

- **Simplified GRE configuration on the hub**
  
  With GRE, a tunnel is configured on the hub for each connected spoke. With GRE + DMVPN, only one tunnel is configured for all the connected spokes.

- **Support for dynamically addressed spokes**
  
  When using GRE, the physical interface IP address of the spoke routers must be configured as the GRE tunnel destination address, when configuring the hub router. DMVPN enables spoke routers to have dynamic external interface IP addresses, and provides robust configuration that does not have to be redeployed to the device even if the external interface IP address changes. When the spoke comes online, it sends to the hub registration packets that contain the physical interface IP address of the spoke.

- **Dynamic tunnel creation for direct spoke-to-spoke communication**
  
  NHRP enables spoke routers to dynamically learn the external interface IP address of the routers in the VPN network. Using NHRP, the hub maintains an NHRP database of the public interface addresses of all the spokes (the clients). Each spoke registers its real address with the hub when it boots.

  When a spoke wants to transmit a packet to another spoke, it can use NHRP to dynamically determine the required destination address of the destination spoke. The hub acts as the NHRP server, handling the request for the source spoke. This enables the dynamic creation of an IPsec+GRE tunnel directly between spoke routers, without having to go through a hub router, thus reducing the delay of multiple encryption and decryption actions on the hub.
Configuring DMVPN

To configure a hub-and-spoke Dynamic Multipoint VPN, use the Create VPN wizard as described in Creating or Editing VPN Topologies, page 23-28. You can also edit the membership of the VPN, or some of its policies, using the described procedures. If you are creating a Large Scale DMVPN, also see Configuring Large Scale DMVPNs, page 25-16.

If you need to make changes to other policies and settings, open the policies from the Site-to-Site Manager page, as follows:

- For ISAKMP and IPSec settings, select VPN Global Settings. See Configuring VPN Global Settings, page 24-27.
- For IPSec proposals, select IPsec Proposal. See Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20.
- For preshared key policies, select IKEv1 Preshared Key. See Configuring IKEv1 Preshared Key Policies, page 24-41.
- For public key (PKI) policies, select Public Key Infrastructure. See Configuring IKEv1 Public Key Infrastructure Policies in Site-to-Site VPNs, page 24-47.
- For Generic Routing Encapsulation configuration, including the selection of phase 2 or 3 connections between spokes, select GRE Modes. See Configuring GRE Modes for DMVPN, page 25-12.
- For server load balancing policies that are used with Large Scale DMVPN, select Server Load Balance. See Configuring Server Load Balancing in Large Scale DMVPN, page 25-17.

Configuring GRE Modes for DMVPN

Use the GRE Modes policy to define the routing and tunnel parameters for IPsec tunneling in a DMVPN.

To open the GRE Modes policy:

- (Site-to-Site VPN Manager Window, page 23-18) Select a DMVPN or Large Scale DMVPN topology, then select GRE Modes from the policies list.
- (Policy view) Select Site-to-Site VPN > GRE Modes, and create a new policy or select an existing policy. Then, select either DMVPN or Large Scale DMVPN from the GRE Method list.

The following table describes the elements on the GRE Modes page for configuring a DMVPN.

---

**Note**

When configuring a DMVPN routing policy, Security Manager adds a routing protocol to all the devices in the secured IGP, on deployment. If you want to maintain this secured IGP, you must create a router platform policy (on each member device) using the same routing protocol and autonomous system (or process ID) number as defined in the GRE Modes policy.
Table 25-2  GRE Modes Page for DMVPN

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Routing Parameters Tab</strong></td>
<td></td>
</tr>
<tr>
<td>Routing Protocol</td>
<td>Select the required dynamic routing protocol, or static route, to be used in the DMVPN tunnel. Options include the EIGRP, OSPF, and RIPv2 dynamic routing protocols, and GRE static routes. On-Demand Routing (ODR) is also supported. On-Demand Routing is not a routing protocol. It can be used in a hub-and-spoke VPN topology when the spoke routers connect to no other router other than the hub. If you are running dynamic protocols, On-Demand Routing is not suitable for your network environment. For more information, see Understanding GRE, page 25-2.</td>
</tr>
<tr>
<td>AS Number</td>
<td>The number that is used to identify the autonomous system (AS) area to which the EIGRP packet belongs. The range is 1-65535. The default is 110. An autonomous system (AS) is a collection of networks that share a common routing strategy. An AS can be divided into a number of areas, which are groups of contiguous networks and attached hosts. Routers with multiple interfaces can participate in multiple areas. An AS ID identifies the area to which the packet belongs. All EIGRP packets are associated with a single area, so all devices must have the same AS number.</td>
</tr>
<tr>
<td>Hello Interval</td>
<td>The interval between hello packets sent on the interface, from 1 to 65535 seconds. The default is 5 seconds.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
Configuring Large Scale DMVPNs

You can configure DMVPN for large scale deployments that might comprise thousands of spokes. In large scale DMVPN topologies, IPsec Terminators, also referred to as Server Load Balance (SLB) devices, reside between the spokes and the hubs. The hubs must be directly connected to the IPsec Terminator—there can be no other device between them.

The IPsec Terminator, which is a Catalyst 6500/7600 device, performs encryption and decryption while the hubs handle all tasks related to Next Hop Resolution Protocol (NHRP) and multipoint generic routing encapsulation (mGRE). The IPsec Terminator is configured to specifically load balance GRE traffic to the hubs, and is configured with dynamic crypto to accept any spokes with any proxies. When using tunnel protection on spokes, these proxies are automatically set to match GRE traffic. One GRE tunnel is configured on the spokes. All hubs connecting to the same IPsec Terminator will use the same Tunnel IP address, and the tunnel source is the Virtual IP address of the IPsec Terminator.

In Security Manager, you configure a Large Scale DMVPN during the creation of a new hub-and-spoke VPN topology as described in Creating or Editing VPN Topologies, page 23-28. You cannot edit an existing standard DMVPN and convert it to a Large Scale DMVPN. When you create the Large Scale DMVPN, keep the following points in mind:

- When you define the technology of the VPN, select **DMVPN** as the technology, and **Large Scale with IPsec Terminator** as the type. For the procedure, see Defining the Name and IPsec Technology of a VPN Topology, page 23-30.

- When you select the devices for the VPN, select the required IPsec Terminators (Catalyst 6500/7600 devices), the hubs and all the spokes. For the procedure, see Selecting Devices for Your VPN Topology, page 23-32.

There must be direct connectivity between the IPsec Terminators and the hubs.

- When you configure the endpoints, as described Defining the Endpoints and Protected Networks, page 23-33, configure the following in the Edit Endpoints dialog box:
  - For each hub device, in the Hub Interface tab, select the interface that is connected to the IPsec Terminator. Each hub can be connected to only one IPsec Terminator. Also, identify the protected networks. Each hub in the Large Scale DMVPN must identify itself and its protected networks.
  - For each IPsec Terminator in the Large Scale DMVPN, specify a VPN external interface, the crypto engine slot, and the Inside VLAN. No protected networks are configured on an IPsec Terminator.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hold time</td>
<td>The time, in seconds, that routers will keep information provided in authoritative NHRP responses. The cached IP-to-NBMA address mapping entries are discarded after the hold time expires. The default is 300 seconds.</td>
</tr>
<tr>
<td>Authentication</td>
<td>An authentication string that controls whether the source and destination NHRP stations allow intercommunication. All routers within the same network using NHRP must share the same authentication string. The string can be up to eight characters long.</td>
</tr>
</tbody>
</table>
After you create the Large Scale DMVPN topology, a Server Load Balance policy is configured on the IPSec Terminators with all the required parameters, which you can edit if required. Initially, all hubs are given the same priority and number of VPN connections. For information on configuring the Server Load Balance policy, see Configuring Server Load Balancing in Large Scale DMVPN, page 25-17.

**Note**

VRF-Aware IPsec cannot be configured in a Large Scale DMVPN.

**Related Topics**

- Understanding DMVPN, page 25-10
- Configuring DMVPN, page 25-12

### Configuring Server Load Balancing in Large Scale DMVPN

Use the Server Load Balance page to view or edit the server load balance policy configured on the IPSec Terminators in a large scale DMVPN. Server load balancing optimizes performance in multiple hub-and-spoke VPN topologies by sharing the workload among a group of hubs. In large scale DMVPN configurations, the IPSec Terminators perform the traffic load balancing. For more information, see Configuring Large Scale DMVPNs, page 25-16.

A weighted round robin (WRR) scheduling algorithm is used to control the bandwidth allocated to output transmission queues. Weighting is based on the amount of bandwidth used by each transmit queue on an interface. Packets from queues with higher capacity are transmitted more often than those from queues with less capacity.

To open the Server Load Balance policy, in the Site-to-Site VPN Manager Window, select an existing Large Scale DMVPN topology, then select **Server Load Balance** from the Policies list.

The table displays the hubs in the VPN, the hub’s weight relative to other hubs connected to the same IPSec Terminator, and the maximum number of active connections allowed for the hub. To change the weight or maximum connections, select the hub and click the Edit (pencil) button beneath the table to open the **Edit Load Balancing Parameters Dialog Box**, page 25-17.

**Related Topics**

- Configuring Large Scale DMVPNs, page 25-16
- Filtering Tables, page 1-44

### Edit Load Balancing Parameters Dialog Box

Use the Edit Load Balancing Parameters dialog box to change the server load balance parameters configured on a hub that is connected to an IPSec Terminator in a large scale DMVPN.

**Navigation Path**

From the Server Load Balance policy, select a hub and click the **Edit (pencil)** button below the table. For information on opening the Server Load Balance policy, see Configuring Server Load Balancing in Large Scale DMVPN, page 25-17.

**Related Topics**

- Configuring Large Scale DMVPNs, page 25-16

Easy VPN

Easy VPN is a hub-and-spoke VPN topology that can be used with a variety of routers, PIX, and ASA devices. Policies are defined mostly on the hub and pushed to remote spoke VPN devices, ensuring that clients have up-to-date policies in place before establishing a secure connection.

This chapter contains the following topics:

- Understanding Easy VPN, page 26-1
- Configuring Client Connection Characteristics for Easy VPN, page 26-7
- Configuring an IPsec Proposal for Easy VPN, page 26-10
- Configuring a Connection Profile Policy for Easy VPN, page 26-13
- Configuring a User Group Policy for Easy VPN, page 26-14

Understanding Easy VPN

Easy VPN simplifies VPN deployment for remote offices. With Easy VPN, security policies defined at the head end are pushed to remote VPN devices, ensuring that clients have up-to-date policies in place before establishing a secure connection.

Security Manager supports the configuration of Easy VPN policies on hub-and-spoke VPN topologies. In such a configuration, most VPN parameters are defined on the Easy VPN server, which acts as the hub device. The centrally managed IPsec policies are pushed to the Easy VPN client devices by the server, minimizing the remote (spoke) devices configuration.

The Easy VPN Server can be a Cisco IOS router, a PIX Firewall, or an ASA 5500 series device. The Easy VPN client is supported on PIX 501, 506, 506E Firewalls running PIX 6.3, Cisco 800-3900 Series routers, and ASA 5505 devices running ASA Software release 7.2 or later.

Note

Some of the policies used in Easy VPN topologies are similar to those used in remote access VPNs. In remote access VPNs, policies are configured between servers and mobile remote PCs running VPN client software, whereas, in site-to-site Easy VPN topologies, the clients are hardware devices.

This section contains the following topics:

- Easy VPN with Dial Backup, page 26-2
- Easy VPN with High Availability, page 26-2
- Easy VPN with Dynamic Virtual Tunnel Interfaces, page 26-2
Easy VPN with Dial Backup

Dial backup for Easy VPN allows you to configure a dial backup tunnel connection on your remote client device. The backup feature is activated only when real traffic is ready to be sent, eliminating the need for expensive dialup or ISDN links that must be created and maintained even when there is no traffic.

**Note**

Easy VPN dial backup can be configured only on remote clients that are routers running IOS version 12.3(14)T or later.

In an Easy VPN configuration, when a remote device attempts to connect to the server and the tracked IP is no longer accessible, the primary connection is torn down and a new connection is established over the Easy VPN backup tunnel to the server. If the primary hub cannot be reached, the primary configuration switches to the failover hub with the same primary configuration and not to the backup configuration.

Only one backup configuration is supported for each primary Easy VPN configuration. Each inside interface must specify the primary and backup Easy VPN configuration. IP static route tracking must be configured for dial backup to work on an Easy VPN remote device. The object tracking configuration is independent of the Easy VPN remote dial backup configuration. The object tracking details are specified in the spoke’s Edit Endpoints dialog box.

For more information about dial backup, see Configuring Dial Backup, page 23-38.

Easy VPN with High Availability

You can configure High Availability (HA) on devices in an Easy VPN topology. High Availability provides automatic device backup when configured on Cisco IOS routers or Catalyst 6500/7600 devices that run IP over LANs. You can create an HA group made up of two or more hub devices in your Easy VPN that use Hot Standby Routing Protocol (HSRP) to provide transparent, automatic device failover.

For more information, see Configuring High Availability in Your VPN Topology, page 23-48.

Easy VPN with Dynamic Virtual Tunnel Interfaces

The IPsec virtual tunnel interface (VTI) feature simplifies the configuration of GRE tunnels that need to be protected by IPsec for remote access links. A VTI is an interface that supports IPsec tunneling, and allows you to apply interface commands directly to the IPsec tunnels. The configuration of a virtual tunnel interface reduces overhead as it does not require a static mapping of IPsec sessions to a particular physical interface where the crypto map is applied.

IPsec VTIs support both unicast and multicast encrypted traffic on any physical interface, such as in the case of multiple paths. Traffic is encrypted or decrypted when it is forwarded from or to the tunnel interface and is managed by the IP routing table. Dynamic or static IP routing can be used to route the traffic to the virtual interface. Using IP routing to forward traffic to the tunnel interface simplifies IPsec...
VPN configuration compared to the more complex process of using access control lists (ACLs) with a crypto map. Dynamic VTIs function like any other real interface so that you can apply quality of service (QoS), firewall, and other security services as soon as the tunnel is active.

Dynamic VTIs use a virtual template infrastructure for dynamic instantiation and management of IPsec interfaces. In an Easy VPN topology, Security Manager implicitly creates the virtual template interface for the device. If the device is a hub, the user must provide the IP address on the hub that will be used as the virtual template interface—this can be a subnet (pool of addresses) or an existing loopback or physical interface. On a spoke, the virtual template interface is created without an IP address.

Notes
- Dynamic VTI can be configured only in a hub-and-spoke Easy VPN topology on routers running IOS version 12.4(2)T and later, except 7600 devices. It is not supported on PIX Firewalls, ASA devices, or Catalyst 6000 series switches.
- Not all the hubs/spokes require Dynamic VTI configuration during discovery or provision. You can extend the existing Easy VPN topology (including routers not supporting dVTI) to add routers that support dVTI.
- Dynamic VTI is supported on only servers, only clients (if server does not support dVTI), or both clients and servers.
- You cannot configure High Availability on hubs/servers that have been configured with dVTI.
- You can also configure Dynamic VTI in remote access VPNs. For more information, see Configuring Dynamic VTI/VRF Aware IPsec in Remote Access VPNs (IOS Devices), page 31-7.

Easy VPN Configuration Modes

Easy VPN can be configured in three modes—Client, Network Extension, and Network Extension Plus.

- Client mode—The default configuration that allows devices at the client site to access resources at the central site, but disallows access to the central site for resources at the client site. In client mode, a single IP address is pushed to the remote client from the server when the VPN connection is established. This address is typically a routable address in the private address space of the customer network. All traffic passing across the Easy VPN tunnel undergoes Port Address Translation (PAT) to that single pushed IP address.

- Network Extension mode—Allows users at the central site to access the network resources at the client site, and allows the client PCs and hosts direct access to the PCs and hosts at the central site. Network Extension mode specifies that the hosts at the client end of the VPN tunnel should be given IP addresses that are fully routable and reachable by the destination network. The devices at both ends of the connection will form one logical network. PAT is not used, so the hosts at the client end have direct access to the hosts at the destination network. In other words, the Easy VPN server (the hub) gives routable addresses to the Easy VPN client (the spoke), while the whole LAN behind the client will not undergo PAT.

- Network Extension Plus mode—An enhancement to Network Extension mode, which can be configured only on IOS routers. It enables an IP address that is received via mode configuration to be automatically assigned to an available loopback interface. This IP address can be used for connecting to your router for remote management and troubleshooting (ping, Telnet, and Secure Shell). If you select this option and some clients are not IOS routers, those clients are configured in Network Extension mode.
All modes of operation can also support split tunneling, which allows secure access to corporate resources through the VPN tunnel while also allowing Internet access through a connection to an ISP or other service (thereby eliminating the corporate network from the path for web access).

You configure the mode in the Client Connection Characteristics policy as described in Configuring Client Connection Characteristics for Easy VPN, page 26-7.

Easy VPN and IKE Extended Authentication (Xauth)

When negotiating tunnel parameters for establishing IPsec tunnels in an Easy VPN configuration, IKE Extended Authentication (Xauth) adds another level of authentication that identifies the user who requests the IPsec connection. If the VPN server is configured for Xauth, the client waits for a username/password challenge after the IKE security association (SA) has been established. When the end user responds to the challenge, the response is forwarded to the IPsec peers for an additional level of authentication.

The information that is entered is checked against authentication entities using authentication, authorization, and accounting (AAA) protocols such as RADIUS and TACACS+. Token cards may also be used via AAA proxy. During Xauth, a user-specific attribute can be retrieved if the credentials of that user are validated via RADIUS.

VPN servers that are configured to handle remote clients should always be configured to enforce user authentication.

Security Manager allows you to save the Xauth username and password on the device itself so you do not need to enter these credentials manually each time the Easy VPN tunnel is established. The information is saved in the device’s configuration file and used each time the tunnel is established. Saving the credentials in the device’s configuration file is typically used if the device is shared between several PCs and you want to keep the VPN tunnel up all the time, or if you want the device to automatically bring up the tunnel whenever there is traffic to be sent.

Saving the credentials in the device’s configuration file, however, could create a security risk, because anyone who has access to the device configuration can obtain this information. An alternative method for Xauth authentication is to manually enter the username and password each time Xauth is requested. You can select whether to use a web browser window or the router console to enter the credentials. Using web-based interaction, a login page is returned, in which you can enter the credentials to authenticate the VPN tunnel. After the VPN tunnel comes up, all users behind this remote site can access the corporate LAN without being prompted again for the username and password. Alternatively, you can choose to bypass the VPN tunnel and connect only to the Internet, in which case a password is not required.

Easy VPN Tunnel Activation

If the device credentials (Xauth username and password) are stored on the device itself, you must select a tunnel activation method for IOS router clients. Two options are available:
Understanding Easy VPN

- **Auto**—The Easy VPN tunnel is established automatically when the Easy VPN configuration is delivered to the device configuration file. If the tunnel times out or fails, the tunnel automatically reconnects and retries indefinitely. This is the default option.

- **Traffic Triggered Activation**—The Easy VPN tunnel is established whenever outbound local (LAN side) traffic is detected. Traffic Triggered Activation is recommended for use with the Easy VPN dial backup configuration so that backup is activated only when there is traffic to send across the tunnel. When using this option, you must specify the Access Control List (ACL) that defines the “interesting” traffic.

---

**Note**

Manual tunnel activation is configured implicitly if you select to configure the Xauth password interactively. In this case, the device waits for a command before attempting to establish the Easy VPN remote connection. When the tunnel times out or fails, subsequent connections will also have to wait for the command.

You configure the xauth and tunnel activation mode in the Client Connection Characteristics policy as described in [Configuring Client Connection Characteristics for Easy VPN, page 26-7](#).

**Overview of Configuring Easy VPN**

When a remote client initiates a connection to a VPN server, device authentication between the peers occurs using IKE, followed by user authentication using IKE Extended Authentication (Xauth), VPN policy push (in Client, Network Extension, or Network Extension Plus mode), and IPsec security association (SA) creation.

The following provides an overview of this process:

1. The client initiates IKE Phase 1 via aggressive mode if a preshared key is to be used for authentication, or main mode if digital certificates are used. If the client identifies itself with a preshared key, the accompanying user group name (defined during configuration) is used to identify the group profile associated with this client. If digital certificates are used, the organizational unit (OU) field of a distinguished name (DN) is used to identify the user group name. See [PKI Enrollment Dialog Box—Certificate Subject Name Tab, page 24-58](#).

   **Note**
   
   Because the client may be configured for preshared key authentication, which initiates IKE aggressive mode, the administrator should change the identity of the VPN device via the `crypto isakmp identity hostname` command. This will not affect certificate authentication via IKE main mode.

2. The client attempts to establish an IKE SA between its public IP address and the public IP address of the VPN server. To reduce the amount of manual configuration on the client, every combination of encryption and hash algorithms, in addition to authentication methods and D-H group sizes, is proposed.

3. Depending on its IKE policy configuration, the VPN server determines which proposal is acceptable to continue negotiating Phase 1.
Understanding Easy VPN

Note: Device authentication ends and user authentication begins at this point.

4. After the IKE SA is successfully established, and if the VPN server is configured for Xauth, the client waits for a “username/password” challenge and then responds to the challenge of the peer. The information that is entered is checked against authentication entities using authentication, authorization, and accounting (AAA) protocols such as RADIUS and TACACS+. Token cards may also be used via AAA proxy. During Xauth, a user-specific attribute can be retrieved if the credentials of that user are validated via RADIUS.

Note: VPN servers that are configured to handle remote clients should always be configured to enforce user authentication.

5. If the server indicates that authentication was successful, the client requests further configuration parameters from the peer. The remaining system parameters (for example, IP address, DNS, and split tunnel attributes) are pushed to the client using client or network extension mode configuration.

Note: The IP address pool and group preshared key (if Rivest, Shamir, and Adelman [RSA] signatures are not being used) are the only required parameter in a group profile. All other parameters are optional.

6. After each client is assigned an internal IP address via mode configuration, Reverse Route Injection (RRI), if configured, ensures that a static route is created on the device for each client internal IP address.

7. IKE quick mode is initiated to negotiate and create IPsec SAs.

The connection is complete.

Important Notes About Easy VPN Configuration

Before you configure an Easy VPN policy in your topology, you should know the following:

- In an Easy VPN topology configuration, deployment fails if a 72xx series router is used as a remote client device. The Easy VPN client is supported on PIX 501, 506, 506E Firewalls running PIX 6.3, Cisco 800-3900 Series routers, and ASA 5505 devices running ASA Software release 7.2 or later.

- If you try to configure a Public Key Infrastructure (PKI) policy on a PIX 6.3 remote client in an Easy VPN topology configuration, deployment fails. For successful deployment on this device, you must first issue the PKI certificate on the CA server, and then try again to deploy the device. For more information about PKI policies, see Understanding Public Key Infrastructure Policies, page 24-44.

- In some cases, deployment fails on a device that serves as an Easy VPN client if the crypto map is configured on the NAT (or PAT) internal interface instead of the external interface. On some platforms, the inside and outside interfaces are fixed. For example, on a Cisco 1700 series router the VPN interface must be the device’s FastEthernet0 interface. On a Cisco 800 series router the VPN interface could be either the device’s Ethernet0 or Dialer1 interface, depending on the configuration. On a Cisco uBR905/uBR925 cable access router, the VPN interface must be the Ethernet0 interface.
Configuring Client Connection Characteristics for Easy VPN

Use the Client Connection Characteristics page to specify how traffic will be routed in the Easy VPN topology and how the VPN tunnel will be established. The characteristics defined in this policy are configured on the remote clients. Before configuring this policy, read the following topics:

- Easy VPN Configuration Modes, page 26-3
- Easy VPN and IKE Extended Authentication (Xauth), page 26-4

Navigation Path

- (Site-to-Site VPN Manager Window, page 23-18) Select an Easy VPN topology in the VPNs selector, then select Client Connection Characteristics in the Policies selector.
- (Policy view) Select Site-to-Site VPN > Client Connection Characteristics and create a new policy or edit an existing policy.

Configuring Client Connection Characteristics for Easy VPN

Chapter 26      Easy VPN

Table 26-1   Easy VPN Client Connection Characteristics Page (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Xauth Credentials Source | Select how you want to enter the Xauth credentials for user authentication when you establish a VPN connection with the server:  
  - Device Stored Credentials (default)—The username and password are saved on the device itself in the device’s configuration file to be used each time the tunnel is established.  
  - Interactive Entered Credentials—Enables you to manually enter the username and password each time Xauth is requested, in a web browser window or from the router console.  
For more information, see Easy VPN and IKE Extended Authentication (Xauth), page 26-4. |
| Xauth Credentials | Available only if you selected Device Stored Credentials as the Xauth Credentials Source.  
  The credentials policy object that defines the default Xauth credentials. Enter the name of the object or click Select to select it from a list or to create a new object. For more information, see Configuring Credentials Policy Objects, page 26-9.  
Note If you want to configure different Xauth credentials on your remote client, you must configure the credentials policy object to allow overrides (select Allow Value Override per Device in the object definition). |
| Tunnel Activation (IOS) | Available only if you selected the Device Stored Credentials option for the Xauth password source.  
  For IOS router clients, select a tunnel activation method:  
  - Auto (default)—The Easy VPN tunnel is established automatically when the Easy VPN configuration is delivered to the device configuration file. If the tunnel times out or fails, the tunnel automatically reconnects and retries indefinitely.  
  - Traffic Triggered Activation—The Easy VPN tunnel is established whenever outbound local (LAN side) traffic is detected. If you select traffic triggered activation, also enter the name of the Access Control List (ACL) policy object that defines the traffic that should activate the tunnel. Click Select to select the object or to create a new object.  
  Traffic Triggered Activation is recommended for use when Easy VPN dial backup is configured so that backup is activated only when there is traffic to send across the tunnel.  
Note Manual tunnel activation is configured implicitly when you select to configure the Xauth password interactively. |
Configuring Credentials Policy Objects

Use the Credentials dialog box to create, copy and edit Credential objects.

Credential objects are used in Easy VPN configuration during IKE Extended Authentication (Xauth) when authenticating user access to the network and network services. When negotiating tunnel parameters for establishing IPsec tunnels in an Easy VPN configuration, Xauth identifies the user who requests the IPsec connection. If the VPN server is configured for Xauth, the client waits for a “username/password” challenge after the IKE SA has been established. When the end user responds to the challenge, the response is forwarded to the IPsec peers for an additional level of authentication. You can save the Xauth credentials (username and password) on the device itself so you do not need to enter them manually each time the Easy VPN tunnel is established.

Navigation Path
Select Manage > Policy Objects, then select Credentials from the Object Type Selector. Right-click inside the work area and select New Object or right-click a row and select Edit Object.

**Configuring an IPsec Proposal for Easy VPN**

Use the Easy VPN IPsec Proposal page to configure the IPsec proposal used during IKE Phase 2 negotiations for Easy VPN topologies. The IPsec proposal is configured on the IPSec Proposal tab; the options are described below.

In Easy VPN topologies, you can also configure a dynamic virtual interface on the Dynamic VTI tab. For an explanation of dVTI configuration, see Configuring Dynamic VTI for Easy VPN, page 26-12.

**Note**

This topic describes the IPsec Proposal page when the site-to-site VPN technology is Easy VPN. For a description of the IPsec Proposal page when the site-to-site VPN technology is something else, see Configuring IPsec Proposals in Site-to-Site VPNs, page 24-20.

**Navigation Path**

- (Site-to-Site VPN Manager Window, page 23-18) Select an Easy VPN topology in the VPNs selector, then select Easy VPN IPsec Proposal in the Policies selector. Click the IPSec Proposal tab.
- (Policy view) Select Site-to-Site VPN > Easy VPN IPsec Proposal from the Policy Types selector. Select an existing shared policy or create a new one. Click the IPSec Proposal tab.

**Related Topics**

- Understanding Easy VPN, page 26-1

<td>IKEv1 Transform Sets</td>
<td>The transform sets to be used for your tunnel policy. Transform sets specify which authentication and encryption algorithms will be used to secure the traffic in the tunnel. You can select up to 11 transform sets. For more information, see Understanding Transform Sets, page 24-18. Transform sets may use only tunnel mode IPsec operation. If more than one of your selected transform sets is supported by both peers, the transform set that provides the highest security will be used. Click Select to select the IPsec transform set policy objects to use in the topology. If the required object is not yet defined, you can click the Create (+) button beneath the available objects list in the selection dialog box to create a new one. For more information, see Configuring IPSec IKEv1 or IKEv2 Transform Set Policy Objects, page 24-24.</td>
</tr>
</tbody>
</table>
| Reverse Route            | Supported on ASA 5500 series devices, PIX 7.0+ devices, and Cisco IOS routers except 7600 devices. Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint. For more information, see Understanding Reverse Route Injection, page 24-19. Select one of the following options to configure RRI on the crypto map:  
  - **None**—Disables the configuration of RRI on the crypto map.  
  - **Standard**—(ASA, PIX 7.0+, IOS devices) Creates routes based on the destination information defined in the crypto map access control list (ACL). This is the default option.  
  - **Remote Peer**—(IOS devices only) Creates two routes, one for the remote endpoint and one for route recursion to the remote endpoint via the interface to which the crypto map is applied.  
  - **Remote Peer IP**—(IOS devices only) Specifies an address as the explicit next hop to the remote VPN device. Enter the IP address or a network/host object that specifies the address, or click Select to select the network/host object from a list or to create a new object.  
  | **Note** If you use network/host objects, you can select the *Allow Value Override per Device* option in the object to override the IP address, if required, for specific devices that use this object. |
| Enable Network Address Translation Traversal | Supported on PIX 7.0+ and ASA 5500 series devices. Whether to allow Network Address Translation (NAT) traversal. Use NAT traversal when there is a device between a VPN-connected hub and spoke, and that performs Network Address Translation (NAT) on the IPsec traffic. For information about NAT traversal, see Understanding NAT in VPNs, page 24-34 |
Configuring an IPSec Proposal for Easy VPN

Chapter 26      Easy VPN

Configuring an IPsec Proposal for Easy VPN

Use the Dynamic VTI tab of the Easy VPN IPSec Proposal policy to configure a dynamic virtual tunnel interface on a device in a hub-and-spoke Easy VPN topology. For more information, see Easy VPN with Dynamic Virtual Tunnel Interfaces, page 26-2.

Note Dynamic VTI can be configured only on IOS routers running IOS version 12.4(2)T and later, except 7600 devices.

Navigation Path

- (Site-to-Site VPN Manager Window, page 23-18) Select an Easy VPN topology in the VPNs selector, then select Easy VPN IPSec Proposal in the Policies selector. Click the Dynamic VTI tab.
- (Policy view) Select Site-to-Site VPN > Easy VPN IPSec Proposal from the Policy Types selector. Select an existing shared policy or create a new one. Click the Dynamic VTI tab.

</tbody>
</table>
| Virtual Template IP   | If you are configuring Dynamic VTI on a hub in the topology, specify either the subnet address or interface role:  
- **Subnet**—To use the IP address taken from a pool of addresses. Enter the private IP address including the subnet mask, for example 10.1.1.0/24.  
- **Interface Role**—To use a physical or loopback interface on the device. If required, click **Select** to open the Interface selector where you can select the interface role object that identifies the desired interface. If an appropriate object does not already exist, you can create one in the selection dialog box.  
If you are configuring Dynamic VTI on a spoke in the topology, select **None**. |

### Configuring a Connection Profile Policy for Easy VPN

A connection profile consists of a set of records that contain IPsec tunnel connection policies. Connection profiles, or tunnel groups, identify the group policy for a specific connection, and include user-oriented attributes. If you do not assign a particular group policy to a user, the default group policy for the connection applies. For a successful connection, the username of the remote client must exist in the database, otherwise the connection is denied.

In site-to-site VPNs, you configure connection profile policies on an Easy VPN server, which can be a PIX Firewall version 7.0+ or an ASA 5500 series device. The Easy VPN connection profile policy is similar to the one used for remote access VPNs. You can unassign the connection profile policy if none of the Easy VPN servers are ASA or PIX 7.0+ devices.

Creating a connection profile policy involves specifying:
- The group policy—a collection of user-oriented attributes stored either internally on the device or externally on RADIUS/LDAP server.
- Global AAA settings—Authentication, Authorization, and Accounting servers.
- The DHCP servers to be used for client address assignment, and the address pools from which the IP addresses will be assigned.
- Settings for Internet Key Exchange (IKE) and IPsec (such as preshared key).
On the PIX7.0+/ASA Connection Profiles page, you can connection profiles on your Easy VPN server.

Related Topics
- Creating or Editing VPN Topologies, page 23-28
- Understanding IPsec Technologies and Policies, page 23-5
- Understanding Easy VPN, page 26-1

Step 1 Do one of the following:
- (Site-to-Site VPN Manager Window, page 23-18) Select an Easy VPN topology in the VPNs selector, then select Connection Profiles (PIX 7.0/ASA) in the Policies selector.
- (Policy view) Select Site-to-Site VPN > Connection Profiles (PIX 7.0/ASA) from the Policy Types selector. Select an existing shared policy or create a new one.

For information on the policy, see Connection Profiles Page, page 29-8.

Step 2 On the General tab, specify the connection profile name and group policies and select which method (or methods) of address assignment to use. For a description of the available properties, see General Tab (Connection Profiles), page 29-9.

Step 3 Click the AAA tab and specify the AAA authentication parameters for an the connection profile. For a description of the elements on the tab, see AAA Tab (Connection Profiles), page 29-11.

Step 4 Click the IPsec tab and specify IPsec and IKE parameters for the connection profile. For a description of the elements on the tab, see IPSec Tab (Connection Profiles), page 29-16.

Configuring a User Group Policy for Easy VPN

Use the User Group Policy page to create or edit a user group policy on your Easy VPN server. When you configure an Easy VPN server, you create a user group to which remote clients belong. An Easy VPN user group policy can be configured on a Cisco IOS security router, PIX 6.3 Firewall, or Catalyst 6500/7600 device. You can unassign the user group policy if none of the Easy VPN servers are IOS routers, Catalyst 6500/7600 devices, or PIX 6.3 firewalls.

Remote clients must have the same group name as the user group configured on the server in order to connect to the device, otherwise no connection is established. When the remote client establishes a successful connection to the VPN server, the group policies for that particular user group are pushed to all clients belonging to the user group.

Select the user group policy object that you want to use in the policy from the Available User Groups list. You can create a new user group object by clicking the Create (+) button, or edit an existing group by selecting it and clicking the Edit (pencil icon) button. For information about configuring the user group object, see Add or Edit User Group Dialog Box, page 32-54.
Navigation Path

- (Site-to-Site VPN Manager Window, page 23-18) Select an Easy VPN topology in the VPNs selector, then select **User Group Policy** in the Policies selector.

- (Policy view) Select **Site-to-Site VPN > User Group Policy** from the Policy Types selector. Select an existing shared policy or create a new one.

Group Encrypted Transport (GET) VPNs

Cisco Group Encrypted Transport virtual private network (GET VPN) is a full-mesh VPN technology that can be used in a variety of WAN environments, including IP and Multiprotocol Label Switching (MPLS). GET VPN comprises a set of features that are necessary to secure IP multicast group traffic or unicast traffic over a private WAN that originates on or flows through a Cisco IOS device. GET VPN combines the keying protocol Group Domain of Interpretation (GDOI) with IP security (IPsec) encryption to provide users with an efficient method to secure IP multicast or unicast traffic. GET VPN enables the router to apply encryption to nontunneled (that is, “native”) IP multicast and unicast packets and eliminates the requirement to configure tunnels to protect multicast and unicast traffic.

Cisco Group Encrypted Transport VPN provides the following benefits:

- Provides data security and transport authentication, helping to meet security compliance and internal regulation by encrypting all WAN traffic.
- Enables high-scale network meshes and eliminates complex peer-to-peer key management with group encryption keys.
- For Multiprotocol Label Switching (MPLS) networks, maintains network intelligence such as full-mesh connectivity, natural routing path, and Quality of Service (QoS).
- Grants easy membership control with a centralized key server.
- Helps ensure low latency and jitter by enabling full-time, direct communications between sites, without requiring transport through a central hub.
- Reduces traffic loads on customer premises equipment (CPE) and provider-edge (PE) encryption devices by using the core network for replication of multicast traffic, avoiding packet replication at each individual peer site.

Tip
For information about the CLI configuration of GET VPN, see Cisco Group Encrypted Transport VPN on Cisco.com.

Understanding Group Encrypted Transport (GET) VPNs

Networked applications such as voice and video increase the need for instantaneous, branch-interconnected, and QoS-enabled WANs. The distributed nature of these applications results in increased demands for scale. At the same time, enterprise WAN technologies force businesses to trade off between QoS-enabled branch interconnectivity and transport security. As network security risks increase and regulatory compliance becomes essential, Group Encrypted Transport VPN (GET VPN), a WAN encryption technology, eliminates the need to compromise between network intelligence and data privacy.

With GET, Cisco provides tunnelless VPN, which eliminates the need for IPsec tunnels. By removing the need for point-to-point tunnels, meshed networks can scale higher while maintaining network-intelligence features critical to voice and video quality. GET is a standards-based security model that is based on the concept of a trusted group to eliminate point-to-point IPsec tunnels and their associated overlay routing. Trusted group members share a common security association (SA), also known as a group SA. This enables group members to decrypt traffic that was encrypted by any other group member. By using trusted groups instead of point-to-point tunnels, full-mesh networks can scale higher while maintaining network-intelligence features (such as QoS, routing, and multicast), which are critical to voice and video quality.

GET-based networks can be used in a variety of WAN environments, including IP and Multiprotocol Label Switching (MPLS). MPLS VPNs that use this encryption technology are highly scalable, manageable, and cost-effective, and they meet government-mandated encryption requirements. The flexible nature of GET allows security-conscious enterprises either to manage their own network security over a service provider WAN service or to offload encryption services to their providers. GET simplifies securing large Layer 2 or MPLS networks that require partial or full-mesh connectivity.

In addition to leveraging the existing IKE, IPsec and multicast technologies, a GET VPN topology includes these key elements and features:

- **Group members**—The routers that exchange the actual traffic within the VPN are called group members. Group members provide encryption services to the traffic. Encryption policies are defined centrally on the key server and downloaded to the group member at the time of registration. Based on these downloaded policies, a group member decides whether traffic needs to be encrypted or decrypted and what keys to use.

Although group members primarily obtain encryption policies from the key server, you can configure local service policy ACLs on the group members to exclude traffic from encryption based on local requirements. For more information, see Understanding the GET VPN Security Policy and Security Associations, page 27-10.

---

Note

A device can be a group member of more than one group.
• Key servers—The routers that act as key servers are the gatekeepers to the topology. The group member must successfully register with a key server before becoming an active member of the VPN. The key servers control the shared service policy, and generate and transmit keys to group members. Key servers cannot be group members themselves, but a single key server can service more than one topology. For more information, see Understanding the GET VPN Registration Process, page 27-4.

• The Group Domain of Interpretation (GDOI) group key management protocol is used to provide a set of cryptographic keys and policies to a group of devices. In a GET VPN network, GDOI is used to distribute common IPsec keys to a group of enterprise VPN gateways (group members) that must communicate securely. Devices designated as key servers periodically refresh and send out the updated keys to the group members using a process called “rekeying.”

The GDOI protocol uses the Phase 1 Internet Key Exchange (IKE) SA. All participating VPN gateways authenticate themselves to the device providing keys using IKE. All IKE authentication methods, for example, pre-shared keys (PSKs) and public key infrastructure (PKI), are supported for initial authentication. After the VPN gateways are authenticated and provided with the appropriate security keys using the IKE SA, the IKE SA expires and GDOI is used to update the group members in a more scalable and efficient manner. For more information about GDOI, refer to RFC 3547.

• Address preservation—IPsec-protected data packets carry the original source and destination in the outer IP header rather than replacing them with tunnel endpoint addresses. Address preservation allows GET VPN to use the routing functionality present within the core network. Address preservation allows routing to deliver the packets to any customer-edge (CE) device in the network that advertises a route to the destination address. Any source and destination matching the policy for the group will be treated in a similar manner. In the situation where a link between IPsec peers is not available, address preservation also helps combat traffic “black-hole” situations.

Header preservation also maintains routing continuity throughout the enterprise address space and in the WAN. As a result, end host addresses of the campus are exposed in the WAN (for MPLS, this applies to the edge of the WAN). For this reason, GET VPN is applicable only when the WAN network acts as a “private” network (for example, in an MPLS network).

The following figure shows the general operation of a GET VPN topology.

Figure 27-1  General GET VPN Operation

1. Group members register with the key server using the Group Domain of Interpretation (GDOI) protocol. The key server authenticates and authorizes the group members and downloads the IPsec policy and keys that are necessary for them to encrypt and decrypt IP multicast and unicast packets. The registration process can use unicast or multicast communications.
2. Group members exchange IP packets that are encrypted using IPsec. Only the group members are an active part of the VPN.

3. As needed, the key server pushes a rekey message to the group members. The rekey message contains new IPsec policy and keys to use when old IPsec security associations (SAs) expire. Rekey messages are sent in advance of the SA expiration time to ensure that valid group keys are always available.

GET VPN is provisioned using Security Manager with the following caveats:

- GET VPN-aware VRF is not supported.
- DMVPN with GET is not supported, because there is no way to define DMVPN without tunnel protection in Security Manager.
- Manual configuration of a group member to join a multicast group (ip igmp join-group) is not supported. Security Manager only provisions static source-specific multicast (SSM) mappings.

Understanding the GET VPN Registration Process

In GET VPN, group members comprise the VPN topology. Traffic in the VPN is traffic between group members. For a device to become a group member, the device must successfully register with a key server. Key servers maintain the security association (SA) policy and create and maintain the keys for the group. When a group member registers, the key server downloads the policy and the keys to the group member. The key server also rekeys the group before existing keys expire.

The key server has two responsibilities: servicing registration requests and sending rekeys. A group member can register at any time and receive the most current policy and keys. When a group member registers with the key server, the key server verifies the group ID that the group member is attempting to join. If the group ID is valid, the key server sends the security association policy to the group member. After the group member acknowledges that it can handle the downloaded policy, the key server downloads the respective keys.

Communication among the key server and group members is encrypted and secured using two types of keys: the traffic encryption key (TEK) and the key encryption key (KEK). The TEK is downloaded by the key server to all the group members. The downloaded TEK is used by all the group members to communicate securely among each other. This key is essentially the group key that is shared by all the group members. The group policies and IPsec SAs are refreshed by the key server using periodic rekey messages to the group members. The KEK is also downloaded by the key server and is used by the group members to decrypt the incoming rekey messages from the key server.

The key server sends out rekey messages either because of an impending IPsec SA expiration or because the security policy has changed on the key server. A rekey can also happen if the KEK timer has expired (the key server sends out a KEK rekey). Rekey messages might also be retransmitted periodically to account for possible packet loss. If the rekey mechanism is multicast, there is no efficient feedback mechanism by which receivers can indicate that they did not receive a rekey message, so retransmission seeks to bring all receivers up to date. If the rekey mechanism is unicast, the receivers send an acknowledgment message.
The key server generates the group policy and IPsec security associations (SAs) for the GDOI group. The information generated by the key server includes multiple TEK attributes, traffic encryption policy, lifetime, source and destination, a Security Parameter Index (SPI) ID that is associated with each TEK, and the rekey policy (one KEK). Note that the group member might also have a local security policy configured that is merged with the one downloaded; for complete information see Understanding the GET VPN Security Policy and Security Associations, page 27-10.

The following figure illustrates the communication flow between group members and the key server. The key server, after receiving registration messages from a group member, generates the information that contains the group policy and new IPsec SAs. The new IPsec SA is then downloaded to the group member. The key server maintains a table that contains the IP address of each group member per group. When a group member registers, the key server adds its IP address in its associated group table, thus allowing the key server to monitor an active group member. A key server can support multiple groups. A group member can be part of multiple groups.

![Communication Flow Between Group Members and the Key Server](image)

When you configure the GET VPN topology, you can configure the following registration-related features:

- Decide whether to use unicast or multicast for group registration and rekeying. For more information, see Choosing the Rekey Transport Mechanism, page 27-6.

  **Note** If you use multicast, you need to enable multicast on the key servers and group members manually. Security Manager does not provision multicast commands.

- Decide whether to configure more than one key server to provide redundancy and load balancing. For more information, see Configuring Redundancy Using Cooperative Key Servers, page 27-7.

- Decide whether to configure fail-close mode on group members to protect their traffic prior to successful registration with the key server. For more information, see Configuring Fail-Close to Protect Registration Failures, page 27-8.
Understanding the GET VPN Registration Process

- Decide whether to require authorization for group members to join the group. You can use certificate authorization (which requires that you also configure the Public Key Infrastructure policy) or preshared keys. Configuring authorization is required if the key server serves more than one group. For information about the configuration options, see the Authorization Type setting described in Defining GET VPN Group Encryption, page 23-51.

Choosing the Rekey Transport Mechanism

When you configure the rekey settings in the Group Encryption Policy (as described in Defining GET VPN Group Encryption, page 23-51), you must select whether to use multicast or unicast as the rekey transport mechanism. The key server uses this method whenever sending new keys and IPsec security associations (SAs) to group members or each other. There are advantages and disadvantages to each method.

Multicast is the standard choice. Using multicast, the key server sends one copy of each rekey message to all group members at once using a multicast group address, so there is no rekey delay and group members can install the updated security policy essentially simultaneously (not accounting for regular network delay). However, in some networks, multicast is either an extra cost feature, or it is simply not allowed. If you configure multicast, you must supply the multicast address that will be used by the GET VPN topology.

Unicast can be used when multicast is unavailable or undesirable. Using unicast, the key server sends directed rekey and IPsec SAs to group members, and the group member sends an acknowledgment that the message was received. Because unicast requires sending direct messages and receiving acknowledgments, the key server sends the unicast messages to a subset of the group members at a time (unless you have a relatively small VPN, perhaps fewer than 30 group members, in which case all group members might be sent messages at the same time).

Thus, the relative benefits of multicast and unicast include the following:

- With multicast, the key server does not know if a group member receives a message, whereas with unicast, there are acknowledgments. With unicast, if the key server does not receive the acknowledgment, it resends the message.
- Multicast is faster than unicast, especially for large topologies with hundreds of group members. Multicast rekey uses the same low CPU overhead whether there is one group member in the group or a few thousand.
- With unicast, if a group member continuously fails to send acknowledgments, the key server decides the group member is no longer there and stops sending rekey messages. Thus, the key server always has a list of active group members. The unresponsive group member must reregister to rejoin the GET VPN topology. Because multicast does not use acknowledgments, the key server does not know if a group member becomes unresponsive, and it does not maintain a list of active group members.

Tip
To use multicast, you must enable multicast on the key servers and group members. Security Manager does not provision these commands; it only enables multicast rekey, it does not enable the router to send and receive multicast traffic. Therefore, you must manually enable multicast on the device, or use the FlexConfig policy to provision the commands (see Creating FlexConfig Policy Objects, page 7-27).
Chapter 27 Group Encrypted Transport (GET) VPNs

Understanding the GET VPN Registration Process

Fortunately, it is possible to mix multicast and unicast in a single GET VPN topology so long as all key servers support multicast. When deciding which transport mechanism to use, consider the following recommendations:

- If all key servers and group members, and the network, support multicast, use multicast.
- If all of the key servers and most of the group members support multicast, but a small number of group members do not support multicast, use multicast. Group members that do not support multicast will not receive rekey and IPsec SA updates. However, when the lifetime settings for these items are about to expire, unicast group members will reregister with the key server and obtain the new keys and IPsec SAs.
- If no group members, or only a few, support multicast, use unicast. The group members will then receive rekeys and IPsec SA updates from the key server and not need to reregister to get them.

Configuring Redundancy Using Cooperative Key Servers

The key server is the most important entity in the GET VPN network because the key server maintains the control plane. Therefore, a single key server is a single point of failure for an entire GET VPN network. Because redundancy is an important consideration for key servers, GET VPN supports multiple key servers, called cooperative (COOP) key servers, to ensure seamless fault recovery if a key server fails or becomes unreachable.

You can configure a group member to register to any available key server from a list of all COOP key servers. The group member configuration determines the registration order (see Configuring GET VPN Group Members, page 27-20 and Edit Group Member Dialog Box, page 27-21). The key server defined first is contacted first, followed by the second defined key server, and so on. It is a best practice to distribute group member registration to all available COOP key servers to reduce the IKE processing load on a single key server. Note that only the primary key server sends rekey messages.

When COOP key servers boot, all key servers assume a secondary role and begin an election process. One key server, typically the one having the highest priority, is elected as a primary key server. The other key servers remain in the secondary state. The primary key server is responsible for creating and distributing group policies to all group members and to periodically synchronize the COOP key servers.

Cooperative key servers exchange one-way announcement messages (primary to secondary). If a secondary key server does not hear from the primary key server for a certain length of time, the secondary key server tries to contact the primary key server and request updated information. If the primary key server does not respond, or if the secondary key server does not hear from the primary key server, a COOP key server reelection is triggered and a new primary key server is elected.

Up to eight key servers can be defined as COOP key servers, but more than four COOP key servers are seldom required. Because rekey information is generated and distributed from a single primary key server, the advantage of deploying more than two key servers is the ability to handle registration load in case of a network failure and reregistration taking place at the same time. This is especially important when using Public Key Infrastructure (PKI) group member authorization because IKE negotiation using PKI requires a lot more CPU power compared to IKE negotiation using pre-shared keys (PSKs).
Understanding the GET VPN Registration Process

Tips

- The RSA key must be the same on all cooperative key servers. For information on synchronizing the RSA key, see Generating and Synchronizing RSA Keys, page 27-13.
- It is a best practice to enable periodic ISAKMP keepalives between key servers so that the primary key server can track and display the state of the other secondary key servers. IKE Keepalives between group members and the key server is not required and is not supported. For information on configuring keepalives, see Configuring Global Settings for GET VPN, page 27-17.
- The COOP protocol is configured on a per GDOI group basis. A key server that is configured with multiple GDOI groups can maintain multiple unique COOP relationships with disparate key servers.

Configuring Fail-Close to Protect Registration Failures

Group members must register with the key server to become members of the GET VPN. Before a group member successfully registers with the key server, traffic passing through the group member’s GET VPN interface is not encrypted. The period of time in which clear-text transmissions occur can be short (if registration succeeds) or potentially long, if the group member fails to register for any reason.

This default behavior is known as fail-open. If you consider it a violation of your security standards that traffic is sent in clear text at any time, you can configure fail-close mode to protect traffic before (or during) registration. With fail-close mode, all traffic on the interface is dropped except for the traffic you specifically identify in the fail-close ACL. Fail-close mode essentially shuts down the interface until the group member successfully registers with the key server and downloads the required keys and security policy and associations. Note that the use of fail-close mode requires as a minimum Cisco IOS Software release 12.4(22)T or 15.0; you can also configure it on all supported ASRs (see Understanding Devices Supported by Each IPsec Technology, page 23-9).

Fail-close mode is used only during the initial registration. If a group member has already successfully registered, the group member keeps the downloaded policy from the key server even if future registrations fail. However, if you use the clear crypto gdoi command on the group member, the subsequent registration attempt is considered a first-time attempt and fail-close mode is enforced.

You configure fail-close mode on the individual group members as described in Configuring GET VPN Group Members, page 27-20. Thus, you can enable the mode on selected group members rather than on all of them. You must specify a fail-close ACL to ensure that you do not lock yourself (and Security Manager) out of the device, preventing configuration updates and maintenance until registration succeeds.

The fail-close ACL is an extended ACL policy object and is configured as part of a crypto map on the device. You configure the rules from the perspective of the group member. Use the following tips to help you create an appropriate fail-close ACL:

- You can configure both permit and deny statements. In the fail-close ACL, “permit” means “do not send this traffic,” whereas “deny” means “send this traffic in clear text.” This behavior is different from that of the typical crypto map ACL, where the statements have the following meaning:
  - Permit—Means “encrypt this traffic.” Because the group member does not have the IPsec security association required to encrypt the traffic prior to registration, the result is that the traffic is dropped.
  - Deny—Means “do not encrypt this traffic.” In a typical crypto map ACL, a deny statement results in the matching packet being compared to the next crypto map ACL configured on the device (if any). However, if traffic matches a deny statement in the fail-close ACL, all crypto map ACL processing ends and the traffic is allowed in clear text.
The reason deny works this way in fail-close mode is because fail-close includes an implicit ACL statement that gets added at the bottom of the list of crypto map ACLs. This statement is **permit ip any any**, which matches all traffic. Because there is no IPsec security association due to the fact that registration has yet to occur, there is no way to encrypt the remaining traffic and it is dropped.

Note that because of this final permit ip any any statement, you might be able to limit yourself to deny statements in your fail-close ACL.

- The fail-close ACL is processed sequentially after the optional group member security policy ACL. However, all statements in the group member security policy ACL must be deny statements, which indicate that matching traffic should be sent in clear text. Because the security policy is processed according to normal crypto map rules, traffic that matches deny statements is subsequently compared to the fail-close ACL. If the fail-close ACL does not have matching deny statements, the traffic will subsequently be dropped by the implicit final fail-close permit ip any any statement.

Therefore, if you use a group member security policy ACL, and you want the identified traffic to be sent in clear text regardless of the registration status of the group member, your fail-close ACL should contain all of the same statements contained in the security policy ACL at the least. It might even be possible to use the same ACL object for both ACLs.

For more information about group member security policies, see Understanding the GET VPN Security Policy and Security Associations, page 27-10.

- The fail-close ACL is inserted as the final crypto map ACL. Thus, if you configure other features on the GET VPN interface that use crypto maps, any traffic identified on deny statements in those other ACLs will also get trapped (and dropped) by the fail-close ACL and the implicit final permit ip any any statement. Thus, configuring fail-close mode for GET VPN can influence the non-GET VPN services you configure on the interface.

- Upon successful registration, the fail-close ACL and the implicit final permit ip any any statement are removed from the crypto maps. These policies are not persistent.

- You should consider including the following rules in the fail-close ACL policy object. Remember that these rules are from the perspective of the group member:
  - SSH, SSL (HTTPS) traffic—You, and Security Manager, need to be able to access the device to configure it. To ensure that you do not lock down the device, include deny statements for SSH and SSL. For SSH, `deny tcp any eq 22 <host or network address>`. For SSL, `deny tcp any eq 443 <host or network address>`. If you specify host addresses, ensure that the Security Manager server is one of the hosts.
  - Routing traffic—To enable routing, allow the traffic for your routing process. For example, if you are using OSPF, `deny ospf any any`.
  - GDOI traffic—Regardless of the contents of the fail-close ACL, the device looks for GDOI registration messages, so you do not need to explicitly allow them to enable successful registration. However, if a group member (1) is in the path between the key server and another group member (2), a registration failure by group member (1) will prevent successful registration by the blocked group member (2). For registration on group member (2) to succeed, the fail-close ACL on group member (1) would have to allow GDOI traffic to pass. Thus, you might want to make it a general practice to allow GDOI traffic in the fail-close ACL: `deny udp any eq 848 any eq 848`.

Understanding the GET VPN Security Policy and Security Associations

GET VPN uses crypto map access control lists (ACLs) to identify the traffic that needs to be encrypted in the VPN. These ACLs also identify traffic that should be sent as clear text instead of being encrypted (essentially, traffic that lies outside of the VPN). The collection of these ACLs define the security policy for the VPN.

GET VPN provides a multi-layered security policy. You define the general policy for the entire VPN on the key server, but you can also define a separate security policy on group members to account for local variations. The group member security policy always takes priority over the policy received from the key server. When the group member registers with the key server, the group member downloads the key server’s security policy and associations and the group member creates a new, single security policy crypto map ACL by concatenating the individual security policies in this order: first, the group member’s ACL; second, the key server’s first ACL; third, and so forth, any additional ACLs from the key server in the order defined on the key server. It is important to understand that these merged ACLs are treated as a single ACL; they are not searched as separate ACLs. Thus, if traffic matches a deny statement from the group member’s ACL, that traffic is never tested against any ACL rules downloaded from the key server.

**Tip**

If a group member leaves the GET VPN, the ACLs downloaded from the key server are removed, but the group member security policy ACL is retained and remains configured on the device.

In GET VPN security policy ACLs (and crypto map ACLs in general), the permit and deny keywords have special meaning:

- **Permit**—Means “encrypt this traffic.” Permit entries are allowed only in the security policy ACLs defined on the key server (in the **Group Encryption Policy**), because encrypted traffic needs to have a full IPsec security association, which includes the transform set used for encrypting traffic, and anti-replay and IPsec lifetime configurations. If a packet matches a permit entry, but no IPsec SA exists for that packet, the packet is dropped.

  Normally, your permit rules should be symmetric, that is, the source and destination addresses should be the same. If you need to specify different source and destination addresses, you must create two rules; the second rule should be a mirror image of the first rule, with the source and destination address switched.

- **Deny**—Means “do not encrypt this traffic.” In practice, this typically means that the traffic that matches the deny statement is sent in the clear. However, if you configure other features that use crypto maps, “denied” traffic is actually compared to subsequent (lower priority) crypto map ACLs to see if there is a match. IPsec security associations (SAs) are not generated for deny rules.

Following is a summary of the security policies that you can configure, in priority order:

- **Group member security policy**—When you configure the group member, as described in Configuring GETVPN Group Members, page 27-20, you can optionally select an ACL policy object that defines the local group member security policy.

  This group member ACL policy object is allowed to have deny statements only. You use this ACL to identify any traffic that you want to exclude from encryption and send in the clear. For example, if a handful of group members in the group are running a different routing protocol than the usual one, you can configure a local entry to these group members’ security policy ACL to bypass encryption of the routing protocol traffic instead of defining the policy globally at the key server level.
Key server security policies and security associations—When you configure the Group Encryption Policy for the GET VPN, as described in Defining GET VPN Group Encryption, page 23-51, you configure ACLs that identify the traffic that should be encrypted and protected in the VPN.

The security policies on the key server are coupled with transform sets and other settings to define security associations; two IPsec security associations (SAs) are actually configured for every rule within the ACL, and these SAs define how the selected traffic should be encrypted. Thus, all group members use the same group SAs and they do not need to negotiate them with each other.

Because the key server policy is appended to the group member policy, the policy might be as simple as permit ip any any, that is, encrypt all traffic that has not been excluded by the group member policy.

However, you can create more complex sets of security policies and associations, setting up several separate ACL policy objects that are coupled to different transform sets to define different types of encryption.

If you create more than one security association, you must identify their order, and they are appended to the group policy in that order. Remember, the end result is a single ACL, so if you include a deny statement in the first ACL, any permit rules for the same traffic in subsequent security associations are ignored, and the traffic is sent in clear text rather than being encrypted.

Note When you consider the security associations defined in the Group Encryption Policy as a whole, you can define up to 100 ACL permit entries. Each permit entry results in a pair of IPsec SAs; the maximum number of IPsec SAs in a group can not exceed 200. It is a best practice to summarize interesting traffic to as few permit entries as possible, and to build symmetric policies, where the source and destination addresses are the same. Unlike traditional IPSec policies, where source and destination address ranges must be uniquely defined, GET VPN is optimized when the source and destination address range are the same. If you configure a rule that has different source and destination addresses, you must also configure the mirrored rule (where the source and destination address are flipped), meaning that four SAs are consumed.

In addition to these security policies, there is an additional fail-close ACL that influences traffic patterns if you configure fail-close mode on a group member. For a complete discussion, see Configuring Fail-Close to Protect Registration Failures, page 27-8.

Understanding Time-Based Anti-Replay

Anti-replay is an important feature in a data encryption protocol such as IPSec (RFC 2401). Anti-replay prevents a third party from eavesdropping on an IPsec conversation, stealing packets, and injecting those packets into a session at a later time. The time-based anti-replay mechanism helps ensure that invalid packets are discarded by detecting the replayed packets that have already arrived at an earlier time.
GET VPN uses the Synchronous Anti-Replay (SAR) mechanism to provide anti-replay protection for multisender traffic. SAR is independent of real-world Network Time Protocol (NTP) clock or sequential-counter mechanisms (which guarantee packets are received and processed in order). A SAR clock advances regularly. The time tracked by this clock is called pseudotime. The pseudotime is maintained on the key server and is sent periodically to the group members within a rekey message as a timestamp field called pseudoTimeStamp. Group members have to be resynchronized to the pseudotime of the key server periodically. The pseudotime of the key server starts ticking from when the first group member registers. Initially, the key server sends the current pseudotime value of the key server and window size to group members during the registration process. New attributes, such as time-based replay-enabled information, window size, and the pseudotime of the key server, is sent under the SA payload (TEK).

The group members use the pseudotime to prevent replay as follows: the pseudoTimeStamp contains the pseudotime value at which a sender created a packet. A receiver compares the pseudotime value of senders with its own pseudotime value to determine whether a packet is a replayed packet. The receiver uses a time-based anti-replay window to accept packets that contain a timestamp value within that window. The window size is configured on the key server and is sent to all group members.

The following figure illustrates an anti-replay window in which the value PTr denotes the local pseudotime of the receiver, and W is the window size.

You configure anti-replay in the security association definitions in the Group Encryption Policy. For more information, see Defining GET VPN Group Encryption, page 23-51 and Add New or Edit Security Association Dialog Box, page 23-55.

![Figure 27-3 Anti-Replay Window](image)

**Configuring GET VPN**

To configure a full mesh VPN with group encrypted transport (GET), use the Create VPN wizard as described in Creating or Editing VPN Topologies, page 23-28. When you finish the wizard, you are asked if you want to synchronize RSA keys, which is required for normal VPN functioning; for detailed information, see Generating and Synchronizing RSA Keys, page 27-13.

If you select multicast as the rekey transport mechanism, you must enable multicast on all key servers and the desired group members. For more information, see Choosing the Rekey Transport Mechanism, page 27-6.

You can change only the name and description of a GET VPN using the Edit VPN wizard. If you need to make changes to other policies and settings, open the policies from the Site-to-Site Manager page, as follows:

- For ISAKMP and IPSec settings, select Global Settings for GET VPN. See Configuring Global Settings for GET VPN, page 27-17.

For security associations (ACL rules) and IPSec policies, select Group Encryption Policy > Security Associations. See Defining GET VPN Group Encryption, page 23-51.

For preshared key policies, select IKEv1 Preshared Key. See Configuring IKEv1 Preshared Key Policies, page 24-41.

For public key (PKI) policies, select Public Key Infrastructure. See Configuring IKEv1 Public Key Infrastructure Policies in Site-to-Site VPNs, page 24-47.

For group membership and endpoint settings, select Group Members. See Configuring GET VPN Group Members, page 27-20.

Generating and Synchronizing RSA Keys

When you specify the RSA key label in the Group Encryption Policy (as described in Defining GET VPN Group Encryption, page 23-51), the corresponding RSA key (public and private keys) needs to be configured on all key servers in the GET VPN topology. The key can either be a pre-existing key that you defined on the device, or it could be a new key label, and Security Manager can generate the key for you and synchronize all key servers to use the same key.

You can use the following methods to have Security Manager generate and synchronize the RSA key:

- When creating a new GET VPN using the Create VPN wizard, you are asked at the end of the wizard if you want to synchronize the keys. If you click Yes, Security Manager does the key synchronization immediately, and generates a new key if the key does not already exist. For information on using the Create VPN wizard, see Creating or Editing VPN Topologies, page 23-28.

- For an existing GET VPN, you can click the Synchronize Keys button on the Key Servers policy. Use this process whenever you add key servers or generate a new key on the primary key server. For information on configuring key server settings for existing topologies, see Configuring GET VPN Key Servers, page 27-18.
Tip

For existing GET VPN topologies, if you want to generate a new RSA key, it might be easiest to update the Group Encryption Policy to specify a new, unused RSA key label, then click the Synchronize Keys button in the Key Servers policy. Because the key will not exist on any key server, Security Manager will generate the new key and import it into all key servers. You can then manually delete the old key from each key server.

Following are the uses for the RSA key:

- The key server uses the private RSA key to authenticate rekey messages from the group members.
- The key server provides the public RSA key to group members during registration.
- The key server uses the private key to sign the key encryption key (KEK) and traffic encryption key (TEK). The absence of an RSA key prevents the key server from creating the KEK and TEK.
- The RSA key is also used to sign messages between cooperative key servers.

When you start the RSA key synchronization process, the Synchronize Keys dialog box opens and shows you the overall progress as well as the results for each key server. (You can click the Abort button at any time to stop the process.) Security Manager performs the following steps:

1. Logs into all key servers and retrieves the RSA key information from each of them for the RSA key label configured for the VPN.
2. Determines whether any key server has a key with the required label:
   - If no key server has an RSA key with the required label, Security Manager generates the key on the primary key server (the one with the highest priority).
   - If one or more key server does not have the key, but all of the key servers that do have the key have the identical keys, Security Manager uses the existing key on any key server that has it.
   - If more than one key server has the key, but the contents of the key is different among the servers, you are asked if Security Manager can overwrite the keys. If you click Yes, Security Manager uses the existing key on the primary key server.
     If you click No, you can log into the key servers outside of Security Manager and manually adjust the keys according to your requirements. However, all key servers must have the same key contents for the RSA key. See below for an explanation of the process.
3. Creates an exportable version of the key.
4. Imports the key into each of the remaining key servers.

Tip

For the synchronization process to succeed, the devices must be online and reachable and you must have Deploy authorization. If the device connection fails or times out, ensure that you can ping the key server from the Security Manager server. If it is your practice to deploy to file instead of to live devices, you might need to manually generate and synchronize the keys as described below. If you do not have sufficient authorization, you are prevented from initiating the process; someone else must do it.
Manually Generating and Synchronizing the RSA Key

If you do not want Security Manager to generate and synchronize keys, or if for some reason Security Manager cannot complete the process, you can manually generate and synchronize keys using the following sequence in Privileged EXEC (enable) configuration mode:

1. Generate the key on a key server using the following command, where `rekeyrsa` is the name of the key (you can specify a name of your choosing). You must make the key exportable.
   
   ```
   crypto key generate rsa general-keys label rekeyrsa modulus 1024 exportable
   ```

2. Create an exportable copy of the key using the following command, where `passphrase` is a string used to encrypt the key for import (you can specify your own pass phrase):
   
   ```
   crypto key export rsa rekeyrsa pem terminal 3des passphrase
   ```
   This command prints out the public and private keys to the terminal, where you can copy them to the clipboard for import into the other key servers. The keys are demarcated by `----BEGIN/END PUBLIC KEY----` and `----BEGIN/END RSA PRIVATE KEY----`. Note that you can also export to a URL; see the Cisco IOS Security Command Reference on Cisco.com for detailed usage information.

3. Import the key into each of the other key servers using the following command:
   
   ```
   crypto key import rsa rekeyrsa pem exportable terminal passphrase
   ```
   When copying and pasting the keys, include the begin/end lines.

Configuring the IKE Proposal for GET VPN

Use the IKE Proposal for GET VPN page to define the IKE proposal to be used by the GET VPN topology. The IKE proposal is configured on the key servers and the group members.

These settings are for the ISAKMP security association (SA). If you are using a single key server, the ISAKMP SA is not used after initial group member registration. If you are using more than one key server (cooperative key servers), the ISAKMP SA is needed for communications among the key servers.

To open the IKE Proposal for GET VPN page:

- (Site-to-Site VPN Manager Window) Select an existing GET VPN topology and then select IKE Proposal for GET VPN in the Policies selector.
- (Policy view) Select Site-to-Site VPN > IKE Proposal for GET VPN, and then select an existing policy or create a new one.
The following table explains the settings you can configure in this policy.

### Table 27-1  IKE Proposal for GET VPN Policy

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IKE Proposal</td>
<td>The IKE proposal policy object that defines the settings you want to use. There are several predefined objects that you might be able to use as is.</td>
</tr>
<tr>
<td></td>
<td>Click Select to open the list of existing IKE proposal objects. The object you select needs to use the same authorization method you are configuring for the group (for example, an object name with the prefix <code>preshared</code> when using preshared keys, or with the prefix <code>cert</code> when using Public Key Infrastructure (PKI) certificates).</td>
</tr>
<tr>
<td></td>
<td>When you select an object and click OK, the settings defined in the object are displayed in the IKE Proposal Settings display fields. You can also see the settings by editing them in the selection list. If you do not find an appropriate pre-existing object, click the Add (+) button in the selection list and create a new object (see Configuring IKEv1 Proposal Policy Objects, page 24-10 for more information and detailed descriptions of the options).</td>
</tr>
<tr>
<td>IKE Proposal Overrides</td>
<td>The number of seconds that the ISAKMP SA for key servers and group members is valid. When the lifetime is exceeded, the SA expires and must be renegotiated between the peers. Values can be 1 to 86400.</td>
</tr>
<tr>
<td></td>
<td>• If you are using cooperative key servers (more than one key server), set the key server lifetime high. The default 86400 is appropriate.</td>
</tr>
<tr>
<td></td>
<td>• If you are using a single key server, you can set the lifetime low (but not less than 60 seconds) so that the ISAKMP SA is not retained unnecessarily. It is not used after a group member registers.</td>
</tr>
<tr>
<td></td>
<td>• We recommend that you set the group member lifetime low as compared to the key server lifetime, especially when cooperative key servers are configured.</td>
</tr>
</tbody>
</table>

Chapter 27 Group Encrypted Transport (GET) VPNs

Configuring Global Settings for GET VPN

Use the Global Settings for GET VPN page to define global settings for ISAKMP and IPsec that apply to devices in your GET VPN topology.

Note

The lifetime settings in this policy do not apply to the ISAKMP security association lifetime for the key server and group members. Those lifetime values are configured in the IKE Proposal for GET VPN policy. For more information, see Configuring the IKE Proposal for GET VPN, page 27-15.

To open the Global Settings for GET VPN page:

- (Site-to-Site VPN Manager Window) Select an existing GET VPN topology and then select Global Settings for GET VPN in the Policies selector.
- (Policy view) Select Site-to-Site VPN > Global Settings for GET VPN, and then select an existing policy or create a new one.

The following table explains the settings you can configure in this policy.

<table>
<thead>
<tr>
<th>Table 27-2 Global Settings for GET VPN</th>
</tr>

</table>
Configuring GET VPN Key Servers

Use the Key Servers policy to define key servers to be used by a GET VPN topology.

To open the Key Servers policy, in the Site-to-Site VPN Manager Window, select an existing GET VPN topology, then select **Key Servers** from the Policies list.

The table lists the key servers used in the VPN, showing the device name, identity, priority, and registration interface. For detailed information about these attributes, see Edit Key Server Dialog Box, page 27-19.

- To add a key server to the table, click the **Add Row** button and select the device from the list presented. Only devices that can be included as key servers are shown.
- To edit the characteristics of a key server, select it and click the **Edit Row** button. Fill in the Edit Key Server dialog box (see Edit Key Server Dialog Box, page 27-19).
- To delete a key server, select it and click the **Delete Row** button.
- To synchronize the RSA keys among the key servers, so that they all use the identical key, click the **Synchronize Keys** button. For detailed information about the key synchronization process, including when and why you would do it, see Generating and Synchronizing RSA Keys, page 27-13.
To change the order of a key server when using cooperative key servers, select it and click the up or down arrow button. This order does not define which server is the primary key server (this is determined by the Priority value, the higher the value, the higher the likelihood that the server will be elected the primary key server).

Instead, the order determines the default order in which group members will try to register with a key server. Group members register with the first key server in the list. If the first key server cannot be reached, group members register with the second key server, and so on. For more information about key server redundancy, see Configuring Redundancy Using Cooperative Key Servers, page 27-7. Note that you can override this order for individual group members; see Configuring GET VPN Group Members, page 27-20 and Edit Group Member Dialog Box, page 27-21.

You can toggle between showing the interface roles or the actual interfaces defined by those roles in the Identity and interfaces columns using the Show field below the table.

- Filtering Tables, page 1-44

**Add Key Server, Group Member Dialog Box**

Use the Add Key Server and Add Group Member dialog boxes to select key servers or group members to be used in the GET VPN topology. Select the check box next to the desired devices and click OK.

**Navigation Path**
To add key servers or group members to a GET VPN topology, click the Add Row (+) button beneath the Key Server or Group Member table in the GET VPN Peers page of the Create VPN wizard, or for existing topologies, the Key Servers or Group Members policies. For detailed information, see the following topics:
- Defining GET VPN Peers, page 23-56
- Configuring GET VPN Key Servers, page 27-18
- Configuring GET VPN Group Members, page 27-20

**Edit Key Server Dialog Box**

Use the Edit Key Servers dialog box to change the attributes defined for a key server in a GET VPN topology.

**Navigation Path**
- (Create VPN Wizard) Go to the GET VPN Peers Page, select a key server and click the Edit Row button. See Defining GET VPN Peers, page 23-56.
• (Site-to-Site VPN Manager Window, page 23-18) Select the Key Servers policy, select a key server and click the Edit Row button. See Configuring GET VPN Key Servers, page 27-18.

Field Reference

Table 27-3   Edit Key Server Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identity Interface</td>
<td>The interface that group members use to identify the key server and register with it. The default is the Loopback interface role, which identifies all Loopback interfaces.</td>
</tr>
<tr>
<td>Priority</td>
<td>A number between 1-100 that designates the role of the key server, either primary or secondary. The key server with the highest number becomes the primary key server. If two or more key servers are assigned the same priority, the device with the highest IP address is used. The default priority is 100 for the first key server, 95 for the second, and so on. Note There can be more than one primary key server if the network is partitioned.</td>
</tr>
<tr>
<td>Registration Interface</td>
<td>The interface on which group domain of interpretation (GDOI) registrations can be accepted. If you do not specify a registration interface, GDOI registrations can occur on any interface.</td>
</tr>
</tbody>
</table>

Configuring GET VPN Group Members

Use the Group Members policy to define the group members in a GET VPN topology.

To open the Group Members policy, in the Site-to-Site VPN Manager Window, select an existing GET VPN topology, then select Group Members from the Policies list.

The group members table lists the members of the GET VPN, showing the device name, GET-enabled interface, local interface, and security policy. For detailed information about these attributes, see Edit Group Member Dialog Box, page 27-21.

• To add a group member to the table, click the Add Row button and select the device from the list presented. Only devices that can be included as group members are shown.

• To edit the endpoint characteristics of a group member, select it and click the Edit Row button. Fill in the Edit Group Member dialog box (see Edit Group Member Dialog Box, page 27-21).

If you select multiple group members in the table, you can also right-click and select the following commands to edit just these attributes:

– Edit Key Server Order—To change the key server list and priority order for the selected group members.

– Edit Passive SA Mode—To change whether the selected group members use passive SA mode.
• To delete a group member, select it and click the **Delete Row** button.

---

**Tip**

You can toggle between showing the interface roles or the actual interfaces defined by those roles in the interfaces columns using the **Show** field below the table.

---

**Edit Group Member Dialog Box**

Use the Edit Group Members dialog box to change the attributes defined for a group member of a GET VPN topology.

**Tip**

If you selected multiple devices and chose an edit command from the right-click menu, this dialog box shows only those options related to the edit command you chose.

**Navigation Path**

- (Create VPN Wizard) Go to the GET VPN Peers page, select a group member and click the **Edit Row** button. See Defining GET VPN Peers, page 23-56.

- (Site-to-Site VPN Manager Window, page 23-18) Select a GET VPN topology, then select the **Group Members** policy. Select a group member and click the **Edit Row** button. See Configuring GET VPN Group Members, page 27-20.

**Related Topics**

- Understanding Group Encrypted Transport (GET) VPNs, page 27-2

**Field Reference**

**Table 27-4 Edit Group Member Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET-Enabled Interface</td>
<td>The VPN-enabled outside interface to the provider edge (PE). Traffic originating or terminating on this interface is evaluated for encryption or decryption, as appropriate. You can configure multiple interfaces. Enter the name of the interface or interface role, or click <strong>Select</strong> to select it from a list or to create a new interface role.</td>
</tr>
</tbody>
</table>
### Table 27-4  Edit Group Member Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface to be used as local address</td>
<td>The interface whose IP address is used to identify the group member to the key server for sending data, such as rekey information. If GET is enabled on only one interface, you do not need to specify the interface to be used as the local address. If GET is enabled on more than one interface, you must specify the interface to be used as the local address. Enter the name of the interface or interface role, or click Select to select it from a list or to create a new interface role.</td>
</tr>
<tr>
<td>Security Policy</td>
<td>The local group member security ACL used to deny some group member-specific traffic over and above the security ACL downloaded from the key server. Denied traffic is sent in clear text rather than encrypted. For detailed information, see Understanding the GET VPN Security Policy and Security Associations, page 27-10. Enter the name of the ACL object or click Select to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Enable Fail Close</td>
<td>Whether to enable fail-close mode on the device, which prevents the device from transmitting clear text traffic before the device successfully registers with the key server. Fail-close mode requires as a minimum Cisco IOS Software release 12.4(22)T or 15.0; you can also configure it on all supported ASRs. Tip: Fail-close mode is a complex feature, and you must carefully construct the fail-close ACL or you might lock yourself out of the device. Before enabling fail-close mode, read Configuring Fail-Close to Protect Registration Failures, page 27-8. You must select an ACL policy object that identifies allowable clear text traffic (using deny statements), such as SSH and SSL communications with the Security Manager server to allow for configuration updates. Enter the name of the object or click Select to select it or to create a new object.</td>
</tr>
<tr>
<td>Override Key Servers</td>
<td>Whether to override the key server list configured for the GET VPN topology as a whole for this particular group member. If you select this option, you can choose a subset of the key servers configured for the topology to be used by the selected group member, and change their priority order. This can help you load-balance registration activity among a group of cooperative key servers. For more information, see Configuring Redundancy Using Cooperative Key Servers, page 27-7. Click Select to change the key server list and priority order of the key servers using the Key Servers Selection dialog box. A key server must be defined for the GET VPN topology before you can modify its use for a group member.</td>
</tr>
</tbody>
</table>
Chapter 27  Group Encrypted Transport (GET) VPNs

Using Passive Mode to Migrate to GET VPN

If you are migrating an existing VPN to the GET VPN technology, especially a clear-text VPN, you can use two features to help you migrate in a phased approach to help prevent network down-time. The features are essentially the same, and involve the passive acceptance of encrypted traffic, but you configure them on different devices in the GET VPN.

Normally, in a fully-deployed GET VPN, traffic is encrypted in both directions (bidirectional security associations, or SAs). However, during testing, you can use passive mode. In passive mode, the group member installs the SA in the inbound direction only, so that the group member receives encrypted traffic but sends traffic in clear text. You can then test the VPN to ensure that it is performing as expected before turning on full encryption.

Use the following features to configure passive mode in a GET VPN:

- **SA Receive-only mode**—You configure receive-only mode for security associations on the key servers in the topology using the Group Encryption Policy. Thus, the setting applies to the entire topology.

- **Passive SA mode**—You configure passive security association mode on individual group members. This setting overrides the SA receive-only setting; thus, you can turn on full encryption for the entire topology, but leave some group members in passive mode. This lets you test the group members in stages and enable full encryption after you verify each member device.

### Tip

Passive SA mode on group members requires Cisco IOS Software release 12.4(22)T+ or 15.0+, or Release 2.3 (12.2(33)XNC)+ on ASRs.

The following procedure shows an example of the end-to-end migration process you might follow to convert to GET VPN using these passive mode features.

**Using Passive Mode to Migrate to GET VPN**

If you are migrating an existing VPN to the GET VPN technology, especially a clear-text VPN, you can use two features to help you migrate in a phased approach to help prevent network down-time. The features are essentially the same, and involve the passive acceptance of encrypted traffic, but you configure them on different devices in the GET VPN.

Normally, in a fully-deployed GET VPN, traffic is encrypted in both directions (bidirectional security associations, or SAs). However, during testing, you can use passive mode. In passive mode, the group member installs the SA in the inbound direction only, so that the group member receives encrypted traffic but sends traffic in clear text. You can then test the VPN to ensure that it is performing as expected before turning on full encryption.

Use the following features to configure passive mode in a GET VPN:

- **SA Receive-only mode**—You configure receive-only mode for security associations on the key servers in the topology using the Group Encryption Policy. Thus, the setting applies to the entire topology.

- **Passive SA mode**—You configure passive security association mode on individual group members. This setting overrides the SA receive-only setting; thus, you can turn on full encryption for the entire topology, but leave some group members in passive mode. This lets you test the group members in stages and enable full encryption after you verify each member device.

### Tip

Passive SA mode on group members requires Cisco IOS Software release 12.4(22)T+ or 15.0+, or Release 2.3 (12.2(33)XNC)+ on ASRs.

The following procedure shows an example of the end-to-end migration process you might follow to convert to GET VPN using these passive mode features.

**Related Topics**

- Understanding Group Encrypted Transport (GET) VPNs, page 27-2
- Configuring GET VPN, page 27-12
Step 1
Create the new GET VPN topology in Security Manager using the Create VPN wizard. When you are in the wizard, ensure that you make these selections:

- When selecting devices, choose the key servers for the topology, but for group members, select the first set of group members that will be migrated. For more information, see Selecting Devices for Your VPN Topology, page 23-32.

- When configuring the group encryption settings, select Receive Only. This enables the SA receive-only feature for the entire topology. For more information, see Defining GET VPN Group Encryption, page 23-51.

For information about creating VPNs, see Creating or Editing VPN Topologies, page 23-28.

Step 2
Deploy the configurations to all devices in the VPN. The group members should now be able to receive encrypted traffic but not send it. For information on the deployment process, see the following topics based on the Workflow mode you are using:

- Deploying Configurations in Non-Workflow Mode, page 8-27
- Deploying Configurations in Workflow Mode, page 8-32

Step 3
Outside of Security Manager, verify that all of the group members are functioning properly.

For example, you can test whether the group members are able to send and receive encrypted packets using some CLI commands on the group member devices:

- On group member 1, configure the following command, where “groupexample” is the name of the GDOI group for the VPN. This command sets the device to accept encrypted or clear text, but to send only clear text.
  ```bash
  crypto gdoi gm group groupexample ipsec direction inbound only
  ```

- On group member 2, configure the following command. This command sets the device to accept encrypted or clear text, but to send encrypted text.
  ```bash
  crypto gdoi gm group groupexample ipsec direction inbound optional
  ```

- Ping group member 1 from group member 2. Group member 2 should encrypt the packet before sending it, and group member 1 should accept it and decrypt it. If you ping member 2 from member 1, the ping should be sent in clear text and accepted by member 2. Ensure that your ACLs allow pings.

Step 4
In Security Manager, select Manage > Site-to-Site VPNs (see Site-to-Site VPN Manager Window, page 23-18).

Select the GET VPN topology, then select Group Members.

Add the remaining group members that you want to add to the topology (click the Add Group Member (+) button, select the devices, and click OK).

If you want to use passive mode to test the new group members before enabling full encryption, ensure that you select Enable Passive SA Mode when configuring the group members:

- To configure an individual group member, select it and click the Edit Group Member (pencil) button.

- To enable passive mode on more than one device at a time, use Shift+click or Ctrl+click to select multiple devices, then right-click and select Edit Passive SA Mode. You can then select the option and click OK.

For more information on configuring group members, see Configuring GET VPN Group Members, page 27-20.

Step 5
Deploy the configuration changes to all devices in the VPN. All devices should be operating in passive mode at this point.
Step 6  In the Site-to-Site VPN Manager, select the GET VPN topology, then select **Group Encryption Policy**. Deselect **Receive Only**. This turns off SA receive-only mode at the topology level.

Step 7  Deploy the configuration changes to all devices in the VPN. Now the GET VPN should be operating in fully encrypted mode for the original group members that you tested. Any new members that you added with passive SA mode enabled should be receiving encrypted traffic and sending clear text traffic.

Step 8  Use the following process to verify the new devices and to turn off passive mode. You can follow this process for all new devices at once, or you can do smaller groups of them at a time. You can also use this process for new group members as you extend your network. Iterate the following steps as appropriate:

a. Verify that the new group members are functioning properly using the same techniques that you used to verify the original group members.

b. When you are ready to move a set of group members to fully-encrypted mode, in the Site-to-Site VPN Manager, select the GET VPN topology and select **Group Members**.

c. Select all passive mode group members that should use full encryption, right-click and select **Edit Passive SA Mode**. Deselect the **Enable Passive SA Mode** option and click **OK**.

d. Deploy configurations to all devices in the VPN, not just the ones whose passive mode you changed. Normally, you should not deploy to less than all devices in a VPN.

---

**Troubleshooting GET VPN Configurations**

If after provisioning and deploying GET VPN using Security Manager, the GET VPN is not working, check the following:

- Ensure that the RSA key is synchronized among all cooperative key servers (that is, the RSA key is the same). For information on how to synchronize keys, see *Generating and Synchronizing RSA Keys*, page 27-13.

- If desired traffic is not being encrypted, make sure the key server security policy ACL (security association) has a permit ACE for the desired traffic. For asymmetric ACEs (where the source and destination addresses are different), ensure that there is a mirrored ACE (with the source and destination addresses reversed). For more information, see *Understanding the GET VPN Security Policy and Security Associations*, page 27-10.

- For multicast rekey, make sure that the network is multicast enabled and that all key servers and most group members are configured to enable multicast. You must enable multicast on the devices directly; Security Manager does not provision the commands required to enable multicast. For more information, see *Choosing the Rekey Transport Mechanism*, page 27-6.

- When using multicast rekey, check whether there is a deny ACE in the key server security ACL for the multicast group address to prevent encryption of multicast rekey messages.

- Check that the local security ACL on the group member has only deny ACEs. If you include a permit statement in an attempt to identify traffic that should be encrypted, the matching traffic is actually dropped because there is no corresponding IPsec SA. Because the permit entry is defined in the group member, the key server is not aware of it and cannot generate the required IPsec SA. For more information, see *Understanding the GET VPN Security Policy and Security Associations*, page 27-10.

- For group member authorization using certificates, check that the ISAKMP authentication uses certificates and that a PKI policy is configured. ISAKMP identity on the group member and key server should be set to use the distinguished name (dn).
• Normally, network address translation (NAT) is not used in the type of WAN environments where GET VPN is deployed. However, if you use NAT, ensure that the security policy ACL has permit statements for the translated addresses. Also, if you are using Network Address Translation-Traversal (NAT-T), the GDOI protocol port changes to 4500.

• A control plane replay protection mechanism was added to Cisco IOS Software releases 12.4(15)T10, 12.4(22)T3, 12.4(24)T2, 15.0(1)M, and 12.2(33)XNE. This mechanism is not backward-compatible, so if any GET VPN group member in the network is running any of these (or later) releases, you must also upgrade all key servers to one of these (or newer) releases. Otherwise, network disruption might occur because of a failed rekey, which causes one of the following system logging (syslog) messages to appear:
  - %GDOI-3-GDOI_REKEY_SEQ_FAILURE: Failed to process rekey seq # 2 in seq payload for group get-group, last seq # 6
  - %GDOI-3-PSEUDO_TIME_TOO_OLD: Rekey received in group get-group is too old and failed PST check: my_pst is 184 sec, peer_pst is 25 sec, allowable_skew is 10 sec

Tip
For additional troubleshooting tips from the CLI configuration perspective, including information about valuable show commands, see Cisco Group Encrypted Transport VPN on Cisco.com.

Managing Remote Access VPNs: The Basics

Cisco Security Manager lets you configure both remote access IPSec VPNs and remote access SSL VPNs. Security Manager provides flexible configuration and management of remote access VPNs:

- You can discover existing remote access VPN configuration policies from existing live devices or from configuration files. Then, you can change and deploy new or updated policies, as necessary.
- You can use the configuration wizard to help you quickly and easily set up these two types of remote access VPNs with basic functionality.
- If you know the functions and feature your network requires, you can configure remote access VPNs independently. You can also use the wizard to create a basic remote access VPN and then configure additional features that are not included in the wizard separately.

In addition, Cisco Security Manager provides flexibility in how remote access VPN configuration policies are assigned: Device view or Policy view.

For some policies, you can also assign either the factory default policy (a private policy), or a shared policy that you created using Security Manager.

This chapter contains the following topics:

- Understanding Remote Access VPNs, page 28-1
- Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9
- Overview of Remote Access VPN Policies, page 28-10
- Discovering Remote Access VPN Policies, page 28-12
- Using the Remote Access VPN Configuration Wizard, page 28-13

Understanding Remote Access VPNs

Security Manager supports two types of remote access VPNs: IPSec and SSL.

This section contains the following topics:

- Understanding Remote Access IPSec VPNs, page 28-2
- Understanding Remote Access SSL VPNs, page 28-2
Understanding Remote Access IPSec VPNs

Remote access IPSec VPNs permit secure, encrypted connections between a company’s private network and remote users, by establishing an encrypted IPSec tunnel across the Internet using broadband cable, DSL, dial-up, or other connections.

A remote access IPSec VPN consists of a VPN client and a VPN headend device, or VPN gateway. The VPN client software resides on a user’s workstation and initiates the VPN tunnel access to the corporate network. At the other end of the VPN tunnel is the VPN gateway at the edge of the corporate site.

When a VPN client initiates a connection to the VPN gateway device, negotiation consists of authenticating the device through Internet Key Exchange (IKE), followed by user authentication using IKE Extended Authentication (Xauth). Next the group profile is pushed to the VPN client using mode configuration, and an IPsec security association (SA) is created to complete the VPN connection.

Tip

For a remote access IPsec VPN hosted on an ASA 8.4(x) device, you have the option of configuring IKE version 2 (IKEv2). If you decide to use IKEv2, you must configure several SSL VPN policies in addition to the regular IPSec policies. The user also must use the AnyConnect 3.0+ VPN client to make an IKEv2 connection. For more information, see Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (ASA and PIX 7.0+ Devices), page 28-24.

For remote access IPSec VPNs, AAA (authentication, authorization, and accounting) is used for secure access. With user authentication, a valid user name and password must be entered before the connection is completed. User names and passwords can be stored on the VPN device itself, or on an external AAA server that can provide authentication to numerous other databases. For more information on using AAA servers, see Understanding AAA Server and Server Group Objects, page 6-23.

Note

Site-to-site Easy VPN topologies use some of the same policies and policy objects that are used in remote access IPSec VPNs, but the policies are kept distinct from the remote access policies. In Easy VPN, the remote clients are hardware clients, such as routers, whereas in remote access IPSec VPNs, remote clients are workstations or other devices that use VPN client software. For more information, see Understanding Easy VPN, page 26-1.

Understanding Remote Access SSL VPNs

An SSL VPN lets users access enterprise networks from any Internet-enabled location. Users can make clientless connections, which use only a Web browser that natively supports Secure Socket Layer (SSL) encryption, or they can make connections using a full client (such as AnyConnect) or a thin client.
Chapter 28  Managing Remote Access VPNs: The Basics

Understanding Remote Access VPNs

SSL VPN is supported on ASA 5500 devices running software version 8.0 and later, running in single-context and router modes, on Cisco 870, 880, 890, 1800, 2800, 3700, 3800, 7200, and 7301 Series routers running software version 12.4(6)T and later, and on Cisco 1900, 2900, and 3900 Series routers running software version 15.0(1)M and later. For the 880 Series routers, the minimum software version is 12.4(15)XZ, which is mapped to 12.4(20)T in Security Manager.

On IOS devices, remote access is provided through an SSL-enabled VPN gateway. Using an SSL-enabled Web browser, the remote user establishes a connection to the SSL VPN gateway. After the remote user is authenticated to the secure gateway via the Web browser, an SSL VPN session is established and the user can access the internal corporate network. A portal page lets users access all the resources available on the SSL VPN networks.

On ASA devices, remote users establish a secure, remote access VPN tunnel to the security appliance using the Web browser. The SSL protocol provides the secure connection between remote users and specific, supported internal resources that you configure at a central site. The security appliance recognizes connections that need to be proxied, and the HTTP server interacts with the authentication subsystem to authenticate users.

User authentication can be done using usernames and passwords, certificates, or both.

Network administrators provide user access to SSL VPN resources on a group basis instead of on an individual user basis.

This section contains the following topics:

- Remote Access SSL VPN Example, page 28-3
- SSL VPN Access Modes, page 28-4
- Understanding and Managing SSL VPN Support Files, page 28-5
- Prerequisites for Configuring SSL VPNs, page 28-7
- SSL VPN Limitations, page 28-8

Remote Access SSL VPN Example

The following illustration shows how a mobile worker can access protected resources from the main office and branch offices. Site-to-site IPsec connectivity between the main and remote sites is unaltered. The mobile worker needs only Internet access and supported software (Web browser and operating system) to securely access the corporate network.
SSL VPN Access Modes

SSL VPN provides three modes of remote access on IOS routers: Clientless, Thin Client and FullClient. On ASA devices, there are two modes: Clientless (which includes Clientless and Thin Client port forwarding) and AnyConnect Client (a full client).

**Clientless Access Mode**

In Clientless mode, the remote user accesses the internal or corporate network using a Web browser on the client machine. No applet downloading is required.

Clientless mode is useful for accessing most content that you would expect in a Web browser, such as Internet access, databases, and online tools that employ a Web interface. It supports Web browsing (using HTTP and HTTPS), file sharing using Common Internet File System (CIFS), and Outlook Web Access (OWA) email. For Clientless mode to work successfully, the remote user’s PC must be running Windows 2000, Windows XP, or Linux operating systems.

Browser-based SSL VPN users connecting from Windows operating systems can browse shared file systems and perform the following operations: view folders, view folder and file properties, create, move, copy, copy from the local host to the remote host, copy from the remote host to the local host, and delete. Internet Explorer indicates when a Web folder is accessible. Accessing this folder launches another window, providing a view of the shared folder, on which users can perform web folder functions, assuming the properties of the folders and documents permit them.

**Thin Client Access Mode**

Thin Client mode, also called TCP port forwarding, assumes that the client application uses TCP to connect to a well-known server and port. In this mode, the remote user downloads a Java applet by clicking the link provided on the portal page. The Java applet acts as a TCP proxy on the client machine for the services configured on the SSL VPN gateway. The Java applet starts a new SSL connection for every client connection.

The Java applet initiates an HTTP request from the remote user client to the SSL VPN gateway. The name and port number of the internal email server is included in the HTTP request. The SSL VPN gateway creates a TCP connection to that internal email server and port.

Thin Client mode extends the capability of the cryptographic functions of the Web browser to enable remote access to TCP-based applications such as Post Office Protocol version 3 (POP3), Simple Mail Transfer Protocol (SMTP), Internet Message Access protocol (IMAP), Telnet, and Secure Shell (SSH).
Note

The TCP port-forwarding proxy works only with Sun’s Java Runtime Environment (JRE) version 1.4 or later. A Java applet is loaded through the browser that verifies the JRE version. The Java applet refuses to run if a compatible JRE version is not detected.

When using Thin Client mode, you should be aware of the following:

- The remote user must allow the Java applet to download and install.
- For TCP port-forwarding applications to work seamlessly, administrative privileges must be enabled for remote users.
- You cannot use Thin Client mode for applications such as FTP, where the ports are negotiated dynamically. That is, you can use TCP port forwarding only with static ports.

Full Tunnel Client Access Mode

Full Tunnel Client mode enables access to the corporate network completely over an SSL VPN tunnel, which is used to move data at the network (IP) layer. This mode supports most IP-based applications, such as Microsoft Outlook, Microsoft Exchange, Lotus Notes E-mail, and Telnet. Being part of the SSL VPN is completely transparent to the applications run on the client. A Java applet is downloaded to handle the tunneling between the client host and the SSL VPN gateway. The user can use any application as if the client host was in the internal network.

The tunnel connection is determined by the group policy configuration. The SSL VPN client (SVC) or AnyConnect client is downloaded and installed to the remote client, and the tunnel connection is established when the remote user logs in to the SSL VPN gateway. By default, the client software is removed from the remote client after the connection is closed, but you can keep it installed, if required.

Note

Full Tunnel SSL VPN access requires administrative privileges on the remote client.

Understanding and Managing SSL VPN Support Files

SSL VPNs sometimes require supporting files that reside in the device’s flash storage. This is especially true of SSL VPNs configured on ASA devices. Supporting files include Cisco Secure Desktop (CSD) packages, AnyConnect client images, and plug-in files. Security Manager includes many of these files for your use. However, some supporting files, such as graphic files used for portal pages, or client profiles used for AnyConnect clients are not provided by Security Manager.

Typically, you need to create a File Object to specify a supporting file, and you then select the File Object when you create a policy that refers to it. You can create the File Objects that you need when you create the policies, or you can create them before you start defining policies. For more information, see Add and Edit File Object Dialog Boxes, page 32-22.

When you deploy policies to the devices, any supporting files referenced in your policies are copied to the device and placed in flash memory in the \csm folder. For the most part, you do not have to do any manual work to make this happen. The following are some situations where you might need to do some manual work:

- If you are trying to discover existing SSL VPN policies, or rediscover them, file references from the SSL VPN policies must be correct. For detailed information on how supporting files are handled during policy discovery, see Discovering Remote Access VPN Policies, page 28-12.
If you have configured the ASA device in an Active/Failover configuration, you must get the supporting files onto the failover device. The supporting files are not copied over to the failover device during a failover. You have these choices for getting the files onto the failover device:

- Manually copy the files from the `csm` folder on the active unit to the failover unit.
- After deploying the policies to the active unit, force a failover and redeploy the policies to the now-active unit.

If you are using a VPN cluster for load balancing, the same supporting files must be deployed to all devices in the cluster.

Cisco Secure Desktop (CSD) Packages

These packages are for ASA SSL VPNs. You select a package in the Dynamic Access policy. The package you select must be compatible with the ASA operating system version running on the device. When you create a Dynamic Access policy for an ASA device, the version number that is compatible with the device’s operating system is displayed in the Version field.

You can find the CSD packages in Program Files\CSCOpx\files\vms\repository\. The file names are in the form securedesktop-asa_k9-version.pkg or csd_version.pkg, where version is the CSD version number such as 3.5.1077.

Following is the CSD compatibility with ASA versions for the CSD packages shipped with Security Manager:

- csd_3_6_181-3.6.181.pkg—ASA 8.4 or later.
- csd_3_5_2008-3.5.2008.pkg—ASA 8.0(4) or later.
- csd_3_5_2001-3.5.2001.pkg—ASA 8.0(4) or later.
- csd_3_5_1077-3.5.1077.pkg—ASA 8.0(4) or later.
- csd_3_5_841-3.5.841.pkg—ASA 8.0(4) or later.
- csd_3_4_2048-3.4.2048.pkg—ASA 8.0(4) or later.
- csd_3_4_1108-3.4.1108.pkg—ASA 8.0(4) or later.
- csd-3.4.0373.pkg—ASA 8.0(4) or later.
- securedesktop_asa_k9-3.3.0.151.pkg—ASA 8.0(3.1) or later.
- securedesktop_asa_k9-3.3.0.118.pkg—ASA 8.0(3.1) or later.
- securedesktop_asa_k9-3.2.1.126.pkg—ASA 8.0(3) or later.
- securedesktop_asa_k9-3.2.0.136.pkg—ASA 8.0(2) or later.

For more information on creating Dynamic Access policies to specify the CSD, see Configuring Cisco Secure Desktop Policies on ASA Devices, page 30-9.

AnyConnect Client Images

These images are for remote access SSL and IKEv2 IPsec VPNs hosted on an ASA. The AnyConnect client is downloaded to the user’s PC and manages the client’s VPN connection. Security Manager includes several AnyConnect images, which you can find in Program Files\CSCOpx\files\vms\repository\. The package names indicate the workstation operating system and the anyconnect release number in this general pattern: anyconnect-client_OS_information-anyconnect_release.pkg. For example,
anyconnect-win-3.0.0610-k9-3.0.0610.pkg is the AnyConnect 3.0(0610) client for Windows workstations. The k9 indicates that the package includes encryption. In this example, the AnyConnect release number is repeated; in some file names, the release number appears once.

Packages are available for the following workstation operating systems (OS). For specific information on which OS versions that each client supports, see the documentation for the AnyConnect client on Cisco.com.

- Linux—Packages start with anyconnect-linux, or anyconnect-linux-64 for 64-bit versions.
- Mac OS—Packages start with anyconnect-macosx for Mac OS X on i386 workstations, and anyconnect-macosx-powerpc for Mac OS X on Power PC workstations.
- Windows—Packages start with anyconnect-win.

You can also download other AnyConnect client packages to the Security Manager server or your local Security Manager client and use them in remote access policies. However, Security Manager might not be able to configure newer parameters for those clients, although it might be possible to use FlexConfigs to configure newer parameters.

For more information on the AnyConnect client, its profiles, and how to configure policies to load the client onto the device, see the following topics:

- Understanding SSL VPN AnyConnect Client Settings, page 29-49
- Configuring SSL VPN AnyConnect Client Settings (ASA), page 29-50

**Plug-in Files**

These files are used as browser plug-ins. You can find plug-in files in Program Files\CSCOpx\objects\sslvpn\plugin. For complete information on the available files, see Configuring SSL VPN Browser Plug-ins (ASA), page 29-47.

**Prerequisites for Configuring SSL VPNs**

For a remote user to securely access resources on a private network behind an SSL VPN gateway, the following prerequisites must be met:

- A user account (login name and password).
- An SSL-enabled browser (such as Internet Explorer, Netscape, Mozilla, or Firefox).
- An email client (such as Eudora, Microsoft Outlook, or Netscape Mail).
- One of the following operating systems:
  - Microsoft Windows 2000 or Windows XP, with either JRE for Windows version 1.4 or later, or a browser that supports ActiveX controls.
  - Linux with JRE for Linux version 1.4 or later. To access Microsoft shared files from Linux in clientless remote access mode, Samba must also be installed.

**Related Topics**

- SSL VPN Access Modes, page 28-4
- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (ASA Devices), page 28-14
- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (IOS Devices), page 28-30
SSL VPN Limitations

SSL VPN configurations in Security Manager are subject to the following limitations:

- SSL VPN license information cannot be imported into Security Manager. As a result, certain command parameters, such as `vpn sessiondb` and `max-webvpn-session-limit`, cannot be validated.

- You must configure DNS on each device in the topology in order to use clientless SSL VPN. Without DNS, the device cannot retrieve named URLs, but only URLs with IP addresses.

- If you share your Connection Profiles policy among multiple ASA devices, bear in mind that all devices share the same address pool unless you use device-level object overrides to replace the global definition with a unique address pool for each device. Unique address pools are required to avoid overlapping addresses in cases where the devices are not using NAT.

- If the device configuration contains an address pool for SSL VPN with a name that begins CSM_ (the naming convention used by Security Manager), Security Manager cannot detect whether the addresses in that pool overlap with the pool configured in your SSL VPN policy. (This can occur, for example, when the pool was configured by a user on a different installation of Security Manager.) This can lead to errors during deployment. Therefore, we recommend that you configure the same IP address pool as a network/host object in Security Manager and define it as part of the SSL VPN policy. This enables the proper validation to take place.

- The same IP address and port number cannot be shared by multiple SSL VPN gateways on the same IOS device. As a result, deployment errors can occur if a duplicate gateway exists in the device configuration but was not redefined using the Security Manager interface. If such an error occurs, you must choose a different IP address and port number and redeploy.

- If you define AAA authentication or accounting as part of an SSL VPN policy, the `aaa new-model` command is deployed to enable AAA services. Bear in mind that this command is not removed if you later delete the SSL VPN policy, as there might be other parts of the device configuration that require the `aaa new-model` command for AAA services.

  **Note**
  
  In addition, we recommend that you define at least one local user on the device with a privilege level of 15. This ensures that you will not be locked out of the device if the `aaa new-model` command is configured without an associated AAA server.

Related Topics

Understanding Devices Supported by Each Remote Access VPN Technology

There are three types of remote access VPN: IKE version 1 (IKEv1) IPsec, IKE version 2 (IKEv2) IPsec, and SSL. The devices on which you can configure these technologies differs, and broadly speaking, the configuration for each type of VPN differs for ASA/PIX 7.0+ compared to IOS/PIX 6.3 devices.

The following table describes the basic device support. When you select a device, the device type will determine which remote access policies are visible or configurable.

Some device models have NO-VPN versions, which do not support VPN configuration. Thus, although the 3845 model might be supported for a type of VPN, the 3845 NOVPN model is not supported. In addition, the Cisco Catalyst 6500 series ASA Services Module (running software release 8.5(x)) does not support any type of VPN.

Table 28-1 Devices Supported by Each Remote Access Technology

<table>
<thead>
<tr>
<th>Technology</th>
<th>Supported Platforms</th>
</tr>
</thead>
<tbody>
<tr>
<td>IKE version 1 IPsec</td>
<td>• ASA/PIX 7.0+—ASA 5500 series and PIX 515, 515E, 525, or 535 with PIX Software 7.0+ (including 8.0+), running in single context and router modes.</td>
</tr>
<tr>
<td></td>
<td>• IOS/PIX 6.3—Cisco IOS security routers (including Aggregation Service Routers, or ASRs), Catalyst 6500/7600, and PIX Firewalls running PIX Software 6.3 only.</td>
</tr>
<tr>
<td>IKE version 2 IPsec</td>
<td>ASA 5500 series only, running ASA Software 8.4(x) only.</td>
</tr>
<tr>
<td>SSL</td>
<td>• ASA—ASA 5500 series devices running software version 8.0 and later, running in single-context and router modes.</td>
</tr>
<tr>
<td></td>
<td>• IOS—Cisco 870, 880, 890, 1800, 2800, 3700, 3800, 7200, and 7301 Series routers running software version 12.4(6)T and later, and on Cisco 1900, 2900, and 3900 Series routers running software version 15.0(1)M and later. For the 880 Series routers, the minimum software version is 12.4(15)XZ, which is mapped to 12.4(20)T in Security Manager.</td>
</tr>
</tbody>
</table>

Tip: No version of PIX is supported for SSL VPN configuration.

Related Topics
- Understanding Remote Access IPSec VPNs, page 28-2
- Understanding Remote Access SSL VPNs, page 28-2
- Using the Remote Access VPN Configuration Wizard, page 28-13
- Overview of Remote Access VPN Policies for ASA and PIX 7.0+ Devices, page 29-2
- Overview of Remote Access VPN Policies for IOS and PIX 6.3 Devices, page 31-2
Overview of Remote Access VPN Policies

The following list summarizes the various policies used in remote access VPN configuration based on the technology used in the VPN. Possible remote access VPN types are: IKE version 1 (IKEv1) IPsec, IKE version 2 (IKEv2) IPsec, and SSL. Where indicated, many of these policies apply to specific device types only. To see an edited version of this list per device type, see the following topics:

- Overview of Remote Access VPN Policies for ASA and PIX 7.0+ Devices, page 29-2
- Overview of Remote Access VPN Policies for IOS and PIX 6.3 Devices, page 31-2

Note: You cannot configure SSL VPNs on PIX devices; PIX devices support remote access IKEv1 IPsec VPNs only.

- Policies used with remote access IKEv1 and IKEv2 IPsec and SSL VPNs:
  - ASA Cluster Load Balancing (ASA/PIX 7.0+)—In a remote client configuration in which you are using two or more devices connected to the same network to handle remote sessions, you can configure these devices to share their session load. This feature is called load balancing. Load balancing directs session traffic to the least loaded device, thus distributing the load among all devices. Load balancing is effective only on remote sessions initiated with an ASA device. For more information, see Understanding Cluster Load Balancing (ASA), page 29-4.
  - Connection Profiles (ASA/PIX 7.0+)—A connection profile is a set of records that contain VPN tunnel connection policies, including the attributes that pertain to creating the tunnel itself. Connection profiles identify the group policies for a specific connection, which includes user-oriented attributes. For more information, see Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.
  - Dynamic Access (ASA 8.0+)—Multiple variables can affect each VPN connection, for example, intranet configurations that frequently change, the various roles that each user might inhabit within an organization, and logins from remote access sites with different configurations and levels of security. Dynamic access policies (DAP) let you configure authorization that addresses these many variables. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. For more information, see Chapter 30, “Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)”.
  - Global Settings—You can define global settings that apply to all devices in your remote access VPNs. These settings include Internet Key Exchange (IKE), IKEv2, IPsec, NAT, and fragmentation definitions. The global settings typically have defaults that work in most situations, so configuring the Global Settings policy is optional in most cases; configure it only if you need non-default behavior or if you are supporting IKEv2 negotiations. For more information, see Configuring VPN Global Settings, page 24-27.
  - Group Policies (ASA/PIX 7.0+)—You can view the user group policies defined for your remote access VPN connection profiles. From this page, you can specify new ASA user groups and edit existing ones. When you create a connection profile, if you specify a group policy that has not been used on the device, the group policy is automatically added to the Group Policies page; you do not need to add it to this policy before you create the connection profile. For more information, see Configuring Group Policies for Remote Access VPNs, page 29-22.
  - Public Key Infrastructure—You can create a Public Key Infrastructure (PKI) policy to generate enrollment requests for CA certificates and RSA keys, and to manage keys and certificates. Certification Authority (CA) servers are used to manage these certificate requests
Overview of Remote Access VPN Policies

and issue certificates to users who connect to your IPsec or SSL remote access VPN. For more information, see Understanding Public Key Infrastructure Policies, page 24-44 and Configuring Public Key Infrastructure Policies for Remote Access VPNs, page 24-49.

- **Policies used in remote access IPsec VPNs only:**
  
  - **Certificate To Connection Profile Maps, Policy and Rules** (IKEv1 IPsec only, ASA/PIX 7.0+ only.)—Certificate to connection profile map policies let you define rules to match a user’s certificate to a permission group based on specified fields. To establish authentication, you can use any field of the certificate, or you can have all certificate users share a permission group. You can match the group from the DN rules, the Organization Unit (OU) field, the IKE identity, or the peer IP address. You can use any or all of these methods. For more information, see Configuring Certificate to Connection Profile Map Policies (ASA), page 29-26.
  
  - **IKE Proposal**—Internet Key Exchange (IKE), also called ISAKMP, is the negotiation protocol that enables two hosts to agree on how to build an IPsec security association. IKE is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and to automatically establish IPsec security associations (SAs). Use the IKE Proposal policy to define the requirements for phase 1 of the IKE negotiation. For more information, see Configuring an IKE Proposal, page 24-9.
  
  - **IPsec Proposal (ASA/PIX 7.x)**—An IPsec proposal is a collection of one or more crypto maps. A crypto map combines all the components required to set up IPsec security associations (SAs), including IPsec rules, transform sets, remote peers, and other parameters that might be necessary to define an IPsec SA. The policy is used for IKE phase 2 negotiations. For more information, see Configuring an IPsec Proposal on a Remote Access VPN Server (ASA, PIX 7.0+ Devices), page 29-30.
  
  - **IPsec Proposal (IOS/PIX 6.x)**—An IPsec proposal is a collection of one or more crypto maps. A crypto map combines all the components required to set up IPsec security associations (SAs), including IPsec rules, transform sets, remote peers, and other parameters that might be necessary to define an IPsec SA. The policy is used for IKE phase 2 negotiations. For more information, see Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3.
  
  - **High Availability** (IOS/PIX 6.3)—High Availability (HA) is supported by the creation of an HA group made up of two or more hub devices that use Hot Standby Routing Protocol (HSRP) to provide transparent, automatic device failover. For more information, see Configuring High Availability in Remote Access VPNs (IOS), page 31-10.
  
  - **User Groups** (IOS/PIX 6.3)—A user group policy specifies the attributes that determine user access to and use of the VPN. For more information, see Configuring User Group Policies, page 31-13.

- **Policies used in remote access IKEv2 IPsec and SSL VPNs only:**
  
  - **Access** (ASA only.)—An Access policy specifies the security appliance interfaces on which a remote access SSL or IKEv2 IPsec VPN connection profile can be enabled, the port to be used for the connection profile, Datagram Transport Layer Security (DTLS) settings, the SSL VPN session timeout and maximum number of sessions. You can also specify whether to use the AnyConnect VPN Client or AnyConnect Essentials Client. For more information, see Understanding SSL VPN Access Policies (ASA), page 29-33.
  
  - **Other Settings** (ASA only.)—The SSL VPN Other Settings policy defines settings that include caching, content rewriting, character encoding, proxy and proxy bypass definitions, browser plug-ins, AnyConnect client images and profiles, Kerberos Constrained Delegation, and some other advanced settings. For more information, see Configuring Other SSL VPN Settings (ASA), page 29-38.
Discovering Remote Access VPN Policies

Security Manager allows you to import the configurations of remote access IPSec VPN policies during policy discovery. You can also discover SSL VPN policies on ASA devices, but not on IOS devices. To discover remote access VPN policies, select the RA VPN Policies option in the Discover Device settings when adding the device to the inventory or when discovering policies on a device already in the inventory. For more information on adding devices or discovering policies, see the following topics:

- Adding Devices to the Device Inventory, page 3-7
- Discovering Policies on Devices Already in Security Manager, page 5-15

You can discover configurations on devices that are already deployed in your remote access VPN network, so that Security Manager can manage them. These configurations are imported into Security Manager as remote access VPN policies. Remote access VPN policy discovery can be performed by importing the configuration of a live device or by importing a configuration file. However, SSL VPN policies that refer to files in flash storage cannot be discovered from configuration files, therefore, we recommend that you do not discover SSL VPNs from configuration files.

When you initiate policy discovery on a device in a remote access VPN, the system analyzes the configuration on the device and then translates this configuration into Security Manager policies so that the device can be managed. Warnings are displayed if the imported configuration completes only a partial policy definition. If additional settings are required, you must go to the relevant page in the Security Manager interface to complete the policy definition. You can also rediscover the configurations of devices that are already managed with Security Manager.

When discovering SSL VPN policies, files residing in flash storage that are referenced in SSL VPN policies are copied to the Security Manager server to be stored in the /csm directory on the target device when policies are deployed from Security Manager. If the flash storage contains files that you want to use, but they are not referenced by an SSL VPN policy, either configure commands that refer to them or manually copy them to the Security Manager server. Policy discovery fails if an SSL VPN policy on the device refers to a file that has been deleted from flash; in this case, either fix the configuration directly before discovering the device, or deselect the RA VPN Policies option when adding the device and create the desired SSL VPN configuration in Security Manager.

Tips

- You should perform deployment immediately after you discover the policies on a device before you make any changes to policies or unassign policies from the device; otherwise, the changes that you configure in Security Manager might not be deployed to the device.
- For ASA and PIX 7.0+ devices, the default connection profiles and group policy are discovered and added to the Connection Profiles and Group Policies policy. You can modify these default profiles and group, but you cannot delete them:
  - DefaultRAGroup—The default connection profile for remote access IPsec VPNs.
Using the Remote Access VPN Configuration Wizard

You can use the Remote Access VPN Configuration wizard to create the policies required to configure a basic IPSec or SSL VPN. The wizard provides simplified options to configure the basic settings. Thus, after using the wizard, you might need to configure additional settings in the individual remote access VPN policies.

**Tip**

The wizard never creates a valid IKEv2 IPSec VPN. You must always configure additional policies to complete an IKEv2 configuration.

Depending on the device type and VPN type (IPSec or SSL), the wizard takes you through the steps to configure a basic remote access VPN.

To access the Remote Access Configuration wizard:

1. In Device view, select the device to configure as your remote access server from the Device selector.
2. Select **Remote Access VPN > Configuration Wizard** from the Policy selector.
3. Select the radio button corresponding to the type of remote access VPN you want to create: **Remote Access SSL VPN** or **Remote Access IPSec VPN**.
4. Click **Remote Access Configuration Wizard** to open the appropriate wizard.
For detailed information on how to use each version of the wizard, see the following topics:

- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (ASA Devices), page 28-14
- Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (ASA and PIX 7.0+ Devices), page 28-24
- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (IOS Devices), page 28-30
- Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (IOS and PIX 6.3 Devices), page 28-34

Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (ASA Devices)

This procedure describes how to create or edit SSL VPNs on ASA devices using the Remote Access SSL VPN Configuration Wizard.

Related Topics
- Understanding Remote Access SSL VPNs, page 28-2
- Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9

Step 1 In Device view, select the desired ASA device.
Step 2 From the Policy selector, select Remote Access VPN > Configuration Wizard.
Step 3 Select the Remote Access SSL VPN radio button.
Step 4 Click Remote Access Configuration Wizard. The Access page opens. For a description of the elements on this page, see SSL VPN Configuration Wizard—Access Page (ASA), page 28-16.
Step 5 Specify the interfaces on which you want to enable the SSL VPN connections. Click Select to select an interface or an interface role object that identifies the interfaces.
Step 6 Specify the port number you want to use for the SSL VPN sessions. Enter the port number or the name of a port list object that defines the number, or click Select to select the object or to create a new object.
  The default port is 443, for HTTPS traffic. The port number can be 443, or within the range of 1024-65535. If you change the port number, all current SSL VPN connections terminate, and current users must reconnect.
  
  **Note** If HTTP port redirection is enabled, the default HTTP port number is 80.

Step 7 To allow users to select a tunnel group from a list of tunnel group connection profiles configured on the device at login, select the Allow Users to Select Connection Profile in Portal Page option.
Step 8 To allow users to use the AnyConnect VPN client to connect to the SSL VPN, select the Enable AnyConnect Access check box.
Step 9 Click Next. The Connection Profile page opens. For a description of the elements on this page, see SSL VPN Configuration Wizard—Connection Profile Page (ASA), page 28-17.
Step 10  In **Connection Profile Name**, enter the name of the connection profile. This is the name of the tunnel group, and will appear in the Remote Access VPN > Connection Profiles policy. For more information about the connection profile policy, see **Configuring Connection Profiles (ASA, PIX 7.0+)**, page 29-6.

Step 11  On the Connection Profile page, configure these options that will later appear in the General tab of the connection profile (see **General Tab (Connection Profiles)**, page 29-9):

- **Group Policy**—Enter the name of the ASA Group Policy policy object that will be the default group for the connection profile, or click **Select** to select the object. If the required object does not yet exist, click **Select**, then click the Create (+) button in the ASA User Groups Selector dialog box, which opens a wizard to guide you through the creation process as described in **Creating User Groups with the Create Group Policy Wizard**, page 28-19.

  For more about ASA Group Policies objects, see **ASA Group Policies Dialog Box**, page 32-1.

- **Group Policies**—This table lists all group policies currently used on the device, whether for SSL or IPsec VPNs. You can click **Edit** to add other group policies.

- **Global IP Address Pool**—Enter the address pools from which IP addresses are assigned. The server uses these address pools in the order listed. If all addresses in the first pool have been assigned, it uses the next pool, and so on. You can specify up to 6 pools.

  Specify the pools as address ranges or network/host objects that contain address ranges, in the format $Start Address-End Address$, for example, 10.100.10.2-10.100.10.254. Click **Select** to select network/host objects or to create new objects.

Step 12  On the Connection Profile page, configure these options that will later appear in the SSL VPN tab of the connection profile (see **SSL Tab (Connection Profiles)**, page 29-18):

- **Portal Page Customization**—The name of the SSL VPN Customization policy object that defines the default portal page for the VPN. Click **Select** to select the object or to create a new object.

  **Note**  You can set up different login windows for different groups by using a combination of customization profiles and tunnel groups. For example, assuming that you had created a customization profile called salesgui, you can create an SSL VPN tunnel group called sales that uses that customization profile.

- **Connection URL**—The URL of the connection profile. This URL provides users with direct access to the customized portal page. Select a protocol (**http** or **https**) from the list, and specify the URL including the name of the connection profile, in the field provided.

  The URL is made up of the host name or IP address of the ASA device and port number, and the alias used to identify the SSL VPN connection profile.

  **Note**  If you do not specify a URL, you can access the portal page by entering the portal page URL, and then selecting the connection profile alias from a list of configured connection profile aliases configured on the device. See **SSL VPN Configuration Wizard—Access Page (ASA)**, page 28-16.

Step 13  On the Connection Profile page, configure the AAA options for authentication, authorization, and accounting, and secondary authentication, which will later appear on the AAA and Secondary AAA tab of the connection profile (see **AAA Tab (Connection Profiles)**, page 29-11 and **Secondary AAA Tab (Connection Profiles)**, page 29-14).

Step 14  Click **Finish** to save your changes.
SSL VPN Configuration Wizard—Access Page (ASA)

Use the Access page of the SSL VPN Configuration Wizard to configure the security appliance interfaces for SSL VPN sessions. After you complete the wizard, you can later edit these settings in the SSL VPN Access policy; see SSL VPN Access Policy Page, page 29-34.

Navigation Path

(Device view) Open the Remote Access VPN Configuration Wizard for configuring a remote access SSL VPN on an ASA device (see Using the Remote Access VPN Configuration Wizard, page 28-13). The Access page is the first page that appears.

</thead>
<tbody>
<tr>
<td>Interfaces to Enable SSL VPN Service</td>
<td>The interfaces or interface roles that identify the interfaces on which you want to enable SSL VPN connections. Click <strong>Select</strong> to select interfaces or interface roles, or to create new interface roles.</td>
</tr>
</tbody>
</table>
| Port Number                          | The port number to use for the SSL VPN sessions. Enter a port number or port list object name, or click **Select** to select an object that defines the port, or to create a new object.  

  The default port is 443, for HTTPS traffic. The port number can be 443, or within the range of 1024-65535. If you change the port number, all current SSL VPN connections terminate, and current users must reconnect.  

  **Note** If HTTP port redirection is enabled, the default HTTP port number is 80. |
| Portal Page URLs                     | The URLs that users would use to connect to the VPN. The URLs are displayed after you specify the interfaces and port number.                     |
| Allow Users to Select Connection Profile in Portal Page | Whether to present a list of configured connection profiles (tunnel groups) from which the user can select the appropriate profile when the user logs in (for example, in the SSL VPN portal page). If you do not select this option, the user cannot select a profile and must use the default profile for the connection. |
| Enable AnyConnect Access             | Whether to allow the user to use the AnyConnect VPN client to make an SSL or IKEv2 IPSec VPN connection. The option is selected by default. For details about AnyConnect VPN clients, see Understanding SSL VPN AnyConnect Client Settings, page 29-49. |

  **Note** To enable AnyConnect Essentials, go to Remote Access VPN > SSL VPN > Access. For details, see Configuring an Access Policy, page 29-37. |
SSL VPN Configuration Wizard—Connection Profile Page (ASA)

Use the Connection Profile page in the SSL VPN Configuration wizard to configure the tunnel group policies on your security appliance. You can specify a name for the tunnel connection profile policy that you are adding, select the user group policy, specify address pools for this policy, and specify authentication server group settings.

Navigation Path

(Device view) Open the Remote Access VPN Configuration Wizard for configuring a remote access SSL VPN on an ASA device (see Using the Remote Access VPN Configuration Wizard, page 28-13); then click Next until you reach this page.

</table>
Using the Remote Access VPN Configuration Wizard

Creating User Groups with the Create Group Policy Wizard

When you are using the Remote Access SSL VPN Configuration wizard to create an SSL VPN on ASA or IOS devices, you can create new ASA group policy or IOS user group objects using a wizard. The wizard lets you configure select elements of the group, so you might need to edit the object after creating it to configure additional settings.

The Create Group Policy wizard is available only through the Remote Access SSL VPN Configuration wizard. For an explanation of how to start and use the wizard, see the following topics:

The following procedure assumes that you are already in the Remote Access SSL VPN Configuration wizard, as described in the following topics:

- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (ASA Devices), page 28-14
- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (IOS Devices), page 28-30

Related Topics
- SSL VPN Access Modes, page 28-4

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorization Server Group</td>
<td>The name of the authorization server group (LOCAL if the tunnel group is configured on the local device). Enter the name of a AAA server group object or click Select to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Accounting Server Group</td>
<td>The name of the accounting server group. Enter the name of a AAA server group object or click Select to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Secondary Authentication</td>
<td>Whether to enable double authentication, which prompts the user for two sets of credentials (username and password) before completing the remote access VPN connection.</td>
</tr>
<tr>
<td></td>
<td>• Enable Secondary Authentication — Select this option to require double authentication.</td>
</tr>
<tr>
<td></td>
<td>• Authentication Server Group — The name of the authentication server group (LOCAL if the tunnel group is configured on the local device) to be used with the second set of credentials. Enter the name of a AAA server group object or click Select to select it from a list or to create a new object.</td>
</tr>
<tr>
<td></td>
<td>• Use LOCAL if Server Group Fails — Whether to fall back to the local database for authentication if the selected authentication server group fails.</td>
</tr>
</tbody>
</table>
Step 1 When using the Remote Access VPN Configuration wizard for SSL VPNs, proceed to the page where you select group policies. On this page, you can open the selection page for user groups by doing the following:

- ASA devices—On the Connection Profile page of the wizard, click Select next to the Group Policy field, or click Edit next to the Group Policies table.
- IOS devices—On the Gateway and Context page of the wizard, click Edit next to the Group Policies table.

Step 2 In the Group Policy Selector dialog box, click the Create (+) button below the list of available group policies to start the Create Group Policy wizard. The wizard starts at the Group Policy page.

You can also do the following on the Group Policy Selector:

- Select existing groups and click >> to use them in the SSL VPN. When selecting a group for the default group on an ASA (the Group Policy field), you select the object simply by clicking it in the list.
- Select an existing group and click Edit (pencil) to change its properties.

Step 3 On the Group Policy page, configure the following options:

- Name—The name of the user group. Enter up to 128 characters, including uppercase and lowercase characters and most alphanumeric or symbol characters.
- Access Method—Select the required remote access method options, as follows:
  - Full Tunnel—To access to the corporate network completely over an SSL VPN tunnel. This is the recommended option.
  - Clientless—To access the internal or corporate network using a web browser on the client machine.
  - Thin Client—To download a Java applet that acts as a TCP proxy on the client machine.

Step 4 Click Next. The page that opens next depends on which access methods you selected. This procedure assumes that you selected all methods, in which case the Full Client page opens.

Step 5 On the Full Client page, select whether to restrict access to full tunnel only or to allow other methods of access if the full client download fails. Also, specify DNS and WINS server information, and configure split tunneling if you want to allow it. For an explanation of the options, see Create Group Policy Wizard—Full Tunnel Page, page 28-21.

Step 6 Click Next. The Clientless and Thin Client page opens.

Step 7 On the Clientless and Thin Client page, configure these access modes. For an explanation of the options, see Create Group Policy Wizard—Clientless and Thin Client Access Modes Page, page 28-23.

Step 8 Click Finish to create the group policy object.

Step 9 When you complete the wizard, the group policy is added to the available groups list, but it is not selected (unless you are configuring the default group for an ASA). To select it, highlight it in the available groups list and click >> to move it to the selected groups list.

Note To specify a user group as the default user group, select it and click Set As Default. This option is only available for IOS routers.

Step 10 Click OK in the Group Policy Selector page to save your changes and return to the Remote Access SSL VPN Configuration wizard.
Create Group Policy Wizard—Full Tunnel Page

This page is available only if you selected the **Full Client** option in the Group Policy of the Create Group Policy wizard.

In this page, you can configure the mode used to access the corporate network.

**Navigation Path**
For information on starting the Create Group Policy wizard, see Creating User Groups with the Create Group Policy Wizard, page 28-19.

</tbody>
</table>
### Using the Remote Access VPN Configuration Wizard

**Secondary WINS Server**
- The IP address of the primary WINS server for the group. Enter the IP address or the name of a network/host object, or click Select to select an object from a list or to create a new object.

**Split Tunnel Option**
- Whether to allow split tunneling and if so, which traffic should be secured or transmitted unencrypted across the public network:
  - Disabled—(Default) No traffic goes in the clear or to any other destination than the gateway. Remote users reach networks through the corporate network and do not have access to local networks.
  - Tunnel Specified Traffic—Tunnel all traffic from or to the addresses listed in the Networks or Destinations field. Traffic to all other addresses travels in the clear and is routed by the remote user’s Internet service provider.
  - Exclude Specified Traffic—Traffic goes in the clear from and to the addresses listed in the Networks or Destinations field. This is useful for remote users who want to access devices on their local network, such as printers, while they are connected to the corporate network through a tunnel.

**Networks**
- (ASA device only.) If you select Tunnel Specified Traffic or Exclude Specified traffic in the Split Tunnel Option, enter the name of the ACL object that defines the traffic to be tunneled or excluded. Click Select to select the object or to create a new object.

**Destinations**
- (IOS device only.) If you select Tunnel Specified Traffic or Exclude Specified traffic in the Split Tunnel Option, specify the IP addresses that define the traffic to be tunneled or excluded.
  
  Enter network addresses such as 10.100.0.24 or host addresses such as 10.100.10.12. You can also enter the name of a network/host policy object, or click Select to select the object from a list or to create a new object. Separate multiple addresses with commas.

**Exclude Local LANs**
- (IOS device only.) Whether to exclude local LANs from the encrypted tunnel. This option is available only if you selected the Exclude Specified Traffic split tunnel option. By selecting this option, you do not have to enter local LAN addresses into the destinations field to allow users to communicate with systems (such as printers) that are attached to their LAN.
  
  When selected, this attribute disallows a non split-tunneling connection to access the local subnetwork at the same time as the client.

**Split DNS Names**
- A list of domain names to be resolved through the split tunnel to the private network. All other names are resolved using the public DNS server.
  
  Enter up to 10 entries in the list of domains, separated by commas. The entire string can be no longer than 255 characters.

Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (ASA and PIX 7.0+ Devices)

This procedure describes how to create IPSec VPNs on ASA or PIX 7.0+ devices using the Remote Access VPN Configuration Wizard.

Tip

The wizard allows you to select shared policies to use in the VPN on the Defaults page (the final step of the wizard). If you want to use this feature, you must first ensure that all required shared policies are configured and submitted to the database. For information on configuring shared policies and VPN policy defaults, see Understanding and Configuring VPN Default Policies, page 23-12.

Related Topics

- Understanding Remote Access IPSec VPNs, page 28-2
- Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9

Step 1

In Device view, select the desired ASA or PIX 7.0+ device.

Step 2

From the Policy selector, select Remote Access VPN > Configuration Wizard.

Step 3

Select the Remote Access IPSec VPN radio button.

Step 4

Click Remote Access Configuration Wizard. The Connection Profile page opens. For a description of the options that appear on this page, see Remote Access VPN Configuration Wizard—IPSec VPN Connection Profile Page (ASA), page 28-27.

Step 5

On the Connection Profile page, configure these basic options:

- **Connection Profile name**—Enter the name of the connection profile. This is the name of the tunnel group, and will appear in the Remote Access VPN > Connection Profiles policy. For more information about the connection profile policy, see Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.

- **IKE Versions**—Select the IKE versions to use during IKE negotiations between the VPN server and the remote users, version 1, 2 or both. IKEv2 is supported on ASA Software release 8.4(1)+ only.

Step 6

On the Connection Profile page, configure these options that will later appear in the General tab of the connection profile (see General Tab (Connection Profiles), page 29-9):

- **Group Policy**—Enter the name of the ASA Group Policy policy object that will be the default group for the connection profile, or click Select to select the object. If the required object does not yet exist, click Select, then click the Create (+) button in the ASA User Groups Selector dialog box to open the dialog boxes that are used to create these objects.

  When creating a new group policy object, you must select the same IKE versions that you select in the Connection Profile page of the wizard. These options are on the Technology page of the Add ASA Group Policies dialog box: Easy VPN/IPSec IKEv1 and Easy VPN/IPSec IKEv2.

  For more information about ASA Group Policies objects, see ASA Group Policies Dialog Box, page 32-1.

- **Global IP Address Pool**—Enter the address pools from which IP addresses are assigned. The server uses these address pools in the order listed. If all addresses in the first pool have been assigned, it uses the next pool, and so on. You can specify up to 6 pools.
Specify the pools as address ranges or network/host objects that contain address ranges, in the format Start_Address-End_Address, for example, 10.100.10.2-10.100.10.254. Click Select to select network/host objects or to create new objects.

**Step 7**
On the Connection Profile page, configure the AAA options for authentication, authorization, and accounting, which will later appear on the AAA tab of the connection profile (see AAA Tab (Connection Profiles), page 29-11).

**Step 8**
Click Next to move to the IPsec Settings page.

**Step 9**
On the IPsec Settings page, configure the options for IPsec, which will later appear on the IPsec tab of the connection profile (see IPsec Tab (Connection Profiles), page 29-16). Note that some of these settings apply to IKEv1 only.

- **Preshared Key, Confirm**—Enter the IKEv1 preshared key for the tunnel group in each field. The maximum length of a preshared key is 127 characters.

  You cannot configure a preshared key for remote access IKEv2 IPsec VPNs.

- **Trustpoint Name**—Enter the name of the PKI enrollment policy object that defines the trustpoint name, if any trustpoints are configured, for an IKEv1 connection. A trustpoint represents a Certificate Authority (CA)/identity pair and contains the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate. Click Select to select the object from a list or to create a new object.

  For IKEv2, the trustpoint name is not configured here, but on the IKEv2 Settings tab of the Global Settings policy. The configuration is explained later in this procedure.

- The other options (other than the client table) apply to both IKEv1 and IKEv2. Change the settings if you need non-default behavior. For an explanation of the options, including the client software update table, see Remote Access VPN Configuration Wizard—IPSec Settings Page (ASA), page 28-28.

**Step 10**
Click Next to move to the VPN Defaults page.

**Step 11**
On the Defaults page, select the additional shared policies that you want to assign to the VPN. Initially, the policies listed are those chosen on the Security Manager Administration VPN Defaults page.

For more information about selecting these policies, see Remote Access VPN Configuration Wizard—Defaults Page, page 28-29.

**Step 12**
Click Finish to save your changes.

Because the wizard does not configure all possible options, inspect the policies created and configure any additional options that you want to implement.

The remaining steps are required if you selected IKE version 2 as a supported IKE version, or if you specified an IPsec trustpoint.

**Step 13**
(IKEv2 Optional.) Configure group aliases and double authentication if required:

a. Select the Connection Profiles policy.

b. Select the connection profile you configured in the wizard, and click the Edit Row (pencil) button to open the Connection Profiles dialog box.

- If you want to configure double authentication, select the Secondary AAA tab and configure the required settings. For more information, see Secondary AAA Tab (Connection Profiles), page 29-14.

- If you want to configure aliases for the profile, which helps users select the correct profile during login, select the SSL tab and configure the alias table. For more information, see SSL Tab (Connection Profiles), page 29-18.
There are several additional connection profile settings that are not configured in the wizard. Examine the tabs in the Connection Profile dialog box to determine if additional changes are required.

c. Click OK in the Connection Profiles dialog box to save your changes.

Step 14  (IKEv2 Requirement.) Select the Remote Access VPN > SSL VPN > Access policy and configure at least the following. For detailed information about configuring an Access policy, see Understanding SSL VPN Access Policies (ASA), page 29-33.

- Add the remote access VPN interface to the access interfaces table.
- Select Allow Users to Select Connection Profile in Portal Page.
- Select Enable AnyConnect Access.

Step 15  (IKEv2 Requirement.) Select the Remote Access VPN > SSL VPN > Other Settings policy, and click the Client Settings tab.

In the AnyConnect Client Image table, add an AnyConnect 3.0 or higher client image, one that supports IKEv2 negotiations.

For more information on configuring client images, see Configuring SSL VPN AnyConnect Client Settings (ASA), page 29-50.

Step 16  (IKEv2 Requirement.) Select the Remote Access VPN > Global Settings policy, and click the IKEv2 Settings tab.

At minimum, configure the RA Trustpoint for remote access IKEv2 authentication. Enter the name of the PKI enrollment object that identifies the certificate authority (CA) server or click Select to select the object or to create a new one.

For more information on configuring IKEv2 global settings, see Configuring VPN Global IKEv2 Settings, page 24-31.

Step 17  (IKEv1, IKEv2 Requirement.) Select the Remote Access VPN > Public Key Infrastructure policy and ensure that the following PKI enrollment objects are selected:

- (IKEv1) The object specified on the IPSec tab of the connection profile, if a trustpoint is configured.
- (IKEv2) The object specified on the IKEv2 Settings tab of the Global Settings policy.

Note  In the wizard, you might have applied a shared Public Key Infrastructure policy that already specifies these objects.

Step 18  (IKEv2 Optional.) IKEv2 connections require the use of the AnyConnect 3.0+ client. The AnyConnect client might need to download files, such as software upgrades, profiles, localization and customization files, CSD, SCEP, and so forth. The wizard does not enable these types of download.

To enable AnyConnect file downloads:

b. Select the IPSec proposal created by the wizard, and click Edit Row (pencil) to open the IPSec Proposal Editor. For information about the various options, see IPsec Proposal Editor (ASA, PIX 7.0+ Devices), page 29-31.

c. Select the Enable Client Services option, and enter a port number if you do not want to use the default port 443. (You can use the same port number used for SSL VPN or other SSL uses.)

d. Click OK to save your changes.
Remote Access VPN Configuration Wizard—IPSec VPN Connection Profile Page (ASA)

Use the Connection Profile page of the Remote Access VPN Configuration wizard to configure the connection profile policies on your security appliance for a remote access IPSec VPN. You can specify a name for the connection profile policy that you are adding, select the IKE versions to allow during IKE negotiations, select the user group policy, specify address pools for this policy, and specify authentication, authorization, and accounting server group settings.

For more information about using the wizard to configure remote access IPSec VPNs on ASA, see Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (ASA and PIX 7.0+ Devices), page 28-24.

Navigation Path

(Device view) Open the Remote Access VPN Configuration Wizard for configuring a remote access IPSec VPN on an ASA or PIX 7.0+ device (see Using the Remote Access VPN Configuration Wizard, page 28-13). The IPSec Connection Profile page is the first page that appears.

Chapter 28 Managing Remote Access VPNs: The Basics

Using the Remote Access VPN Configuration Wizard

Remote Access VPN Configuration Wizard—IPSec Settings Page (ASA)

Use the IPSec Settings page of the Remote Access VPN Configuration wizard to configure the IPSec settings on your security appliance for a remote access IPSec VPN. Some of these settings apply to IKE version 1 (IKEv1) only; if you are configuring an IKEv2-only VPN, these fields are greyed and unconfigurable.

For more information about using the wizard to configure remote access IPSec VPNs on ASA, see Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (ASA and PIX 7.0+ Devices), page 28-24.

Navigation Path

(Device view) Open the Remote Access VPN Configuration Wizard for configuring a remote access IPSec VPN on an ASA or PIX 7.0+ device (see Using the Remote Access VPN Configuration Wizard, page 28-13); then click Next until you reach this page.

Field Reference

</tr>
</tbody>
</table>

**Remote Access VPN Configuration Wizard—Defaults Page**

Use the Defaults page of the Remote Access VPN Configuration wizard to select the shared policies to assign to the remote access IPSec VPN. Initially, the policies selected are those configured in the Security Manager Administration VPN Defaults for remote access VPNs. For information on how to configure these defaults, see Understanding and Configuring VPN Default Policies, page 23-12.

Required policies must always have a policy selected. If “Factory Default” is shown, then the policy applied is not a shared policy but default policy settings supplied by Security Manager. If you can select the empty option, the policy is optional and you need to configure it only if you want the associated features.

When evaluating which policies to assign (if any), keep the following in mind:

- The drop-down lists for each policy type list the existing shared policies that you can select. You can select only shared policies that have been committed to the Security Manager database (and approved, if you are using Workflow mode with an approver). You cannot create a shared policy and use it before you submit it.
- To view the content of a policy, select it and click the **View Content** button. You are presented with a read-only view of the policy. Use this to help verify that you are selecting the desired policy.
If you try to select a default policy that is currently locked by another user, a message is displayed warning you of a lock problem. To bypass the lock, select a different policy or cancel the VPN creation until the lock is removed. For more information, see Understanding Policy Locking, page 5-7.

Navigation Path

(Device view) Open the Remote Access VPN Configuration Wizard for configuring a remote access IPsec VPN (see Using the Remote Access VPN Configuration Wizard, page 28-13) and click Next until you reach this page.

Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (IOS Devices)

This procedure describes how to create or edit SSL VPNs on IOS devices using the Remote Access SSL VPN Configuration Wizard.

Related Topics

- Understanding Remote Access SSL VPNs, page 28-2
- Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9
Using the Remote Access VPN Configuration Wizard

Step 1  In Device view, select the desired IOS device.

Step 2  From the Policy selector, select Remote Access VPN > Configuration Wizard.

Step 3  Select the Remote Access SSL VPN radio button.

Step 5  Select the gateway to be used as a proxy for connections to the protected resources in your SSL VPN. Options are:

- **Use Existing Gateway**—Lets you use an existing gateway object. If you select this option, specify the name of the SSL VPN Gateway policy object that defines the gateway. Click Select to select the object or to create a new object.
- **Create Using IP Address**—Lets you configure a new gateway object using a reachable (public, static) IP address on the router. Enter the IP address.
- **Create Using Interface**—Lets you configure a new gateway using the public, static IP address of a router interface. Select the interface or interface role object.

If you elected to create a new gateway using an IP address or an interface:

- Specify a gateway name.
- Specify the number of the port that will carry the HTTPS traffic. The default is 443, unless HTTP port redirection is enabled, in which case the default HTTP port number is 80. If you want to use a different port, it must be between 1024 and 65535.

Step 6  Enter the name of the context that defines the virtual configuration of the SSL VPN.

Step 7  Select the user groups that will be used in your SSL VPN policy. User groups define the resources available to users when connecting to an SSL VPN gateway. The table shows whether full client access is enabled for the group. Click Edit to select the desired groups, or to create new groups.

Step 8  Configure the AAA options for authentication, authentication domain, and accounting. For detailed information, see SSL VPN Configuration Wizard—Gateway and Context Page (IOS), page 28-32.

Step 9  Click Next. The Portal Page Customization page opens. For a description of the elements on this page, see SSL VPN Configuration Wizard—Portal Page Customization Page (IOS), page 28-33.

Step 10  On the Portal Customization page, configure the following options. The bottom of the page is a preview of what the portal page will look like based on your selections; use the preview to fine-tune your selections.

- **Title**—The name of the portal page, which appears at the top of the page.
- **Logo**—The graphic to show in the title area of the page: None, Default (the Cisco logo graphic), or Custom. If you select custom, click Select to select the graphic on the Security Manager server. You must copy the custom graphic to the server before you can use it in the portal customization.
  
  The source image file for the logo can be a GIF, JPG, or PNG file, with a file name of up to 255 characters, and up to 100 kilobytes in size.
- **Login Message**—The text that should appear above the login prompt.
- **Title and Text Colors**—The colors to use for the title and login area and the fonts.

Step 11  Click Finish to save your changes.
SSL VPN Configuration Wizard—Gateway and Context Page (IOS)

A gateway and context must be configured on a device before a remote user can access resources on a private network behind the SSL VPN. Use this step of the SSL VPN Configuration wizard to specify a gateway and context configuration, including information that will allow users to access a portal page.

Navigation Path

(Device view) Open the Remote Access VPN Configuration Wizard for configuring a remote access SSL VPN on an IOS device (see Using the Remote Access VPN Configuration Wizard, page 28-13). The Gateway and Context page is the first page that appears.

Related Topics

- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (IOS Devices), page 28-30

<td>- If you selected Use Existing Gateway, click Select to select the object from a list or to create a new object.</td>
</tr>
<tr>
<td></td>
<td>Note After selecting the gateway, the port number and digital certificate required to establish a secure connection are displayed in the relevant fields.</td>
</tr>
<tr>
<td></td>
<td>- If you selected Create Using IP Address or Interface, enter the name of the object that you want to create (up to 128 characters).</td>
</tr>
<tr>
<td>IP Address</td>
<td>Available if you selected to create a gateway using an IP address.</td>
</tr>
<tr>
<td></td>
<td>The IP address on the router that should be used as the gateway address.</td>
</tr>
<tr>
<td>Interface</td>
<td>Available if you selected to create a gateway using an interface.</td>
</tr>
<tr>
<td></td>
<td>The name of the interface, or the interface role object that defines the interface, that should be used as the SSL VPN gateway. Click Select to select the interface or interface role, or to create a new interface role.</td>
</tr>
</tbody>
</table>
The port number used for SSL VPN connections. The default is 443, unless HTTP port redirection is enabled, in which case the default HTTP port number is 80. If you enter a different number, it must be between 1024 and 65535.

- If you selected Use Existing Gateway, this is a read-only field that shows the port number configured in the selected object.
- If you selected Create Using IP Address or Interface, enter the port number or the name of a port list object that specifies the number, or click **Select** to select the port list object.

**Trustpoint**
The digital certificate required to establish the secure connection. A self-signed certificate is generated when an SSL VPN gateway is activated.

**Context Name**
The name of the context that defines the virtual configuration of the SSL VPN.

**Portal Page URL**
The URL for the SSL VPN, which is filled in when you select (or define) a gateway object. Users connect to this URL to enter the VPN.

**Group Policies**
The user groups that will be used in your SSL VPN policy. User groups define the resources available to users when connecting to an SSL VPN gateway. The table shows whether full client access is enabled for the group. Click **Edit** to select the desired groups, or to create new groups.

**Authentication Server Group**
The authentication server groups. The list is in prioritized order. Authentication is attempted using the first group and proceeds through the list until the user is successfully authenticated or denied. Use the LOCAL group if the users are defined on the gateway itself.

Enter the names of the AAA server groups; separate multiple entries with commas. You can click **Select** to select the groups or to create new ones.

**Accounting Server Group**
A list or method for SSL VPN remote user authentication. If you do not specify a list or method, the gateway uses global AAA parameters for remote-user authentication.

**SSL VPN Configuration Wizard—Portal Page Customization Page (IOS)**

Use this step of the SSL VPN Configuration wizard to define the appearance of the portal page that remote users see when connecting to the SSL VPN. The portal page allows remote users access to all websites available on the SSL VPN networks.

**Navigation Path**
(Devicel view) Open the Remote Access VPN Configuration Wizard for configuring a remoteaccess SSL VPN on an ASA device (see Using the Remote Access VPN Configuration Wizard, page 28-13); then click **Next** until you reach this page.

Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (IOS and PIX 6.3 Devices)

This procedure describes how to create or edit IPSec VPNs on IOS and PIX 6.3 devices using the Remote Access VPN Configuration Wizard.

Tip

The wizard allows you to select shared policies to use in the VPN on the Defaults page (the final step of the wizard). If you want to use this feature, you must first ensure that all required shared policies are configured and submitted to the database. For information on configuring shared policies and VPN policy defaults, see Understanding and Configuring VPN Default Policies, page 23-12.

Related Topics

- Understanding Remote Access IPSec VPNs, page 28-2
- Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9

Step 1
In Device view, select the desired IOS or PIX 6.3 device.

Step 2
From the Policy selector, select Remote Access VPN > Configuration Wizard.

Step 3
Select the Remote Access IPSec VPN radio button.

Step 4
Step 5  Select the required user groups from the Available User Groups list and click >>.

- If the required user group is not in the list, click Create (+) to open the Add User Groups dialog box, which enables you to create or edit a user group object. See Add or Edit User Group Dialog Box, page 32-54.

- You can edit an existing user group by selecting it in either list and clicking Edit (pencil).

- To deselect a user group, select it and click <<.

Step 6  Click Next. The Defaults page opens.

Step 7  Select the shared policies to assign to the VPN. Initially, the selected policies are those configured on the Security Manager Administration VPN Defaults page. You can use the defaults or select different policies, if any are available. For more information about these policy defaults, see Remote Access VPN Configuration Wizard—Defaults Page, page 28-29.

Step 8  Click Finish to save your changes.

Inspect the policies created and configure any additional options that you want to implement.
Managing Remote Access VPNs on ASA and PIX 7.0+ Devices

You can configure and manage remote access IPsec on devices running Cisco ASA Software or PIX 7.0+, and SSL VPNs on ASA 8.0+ devices (but not on PIX devices). Additionally, you can use IKE version 2 (IKEv2) negotiations in remote access IPsec VPNs on ASA 8.4(x) devices.

Tip
No VPN configuration is supported on Cisco Catalyst 6500 Series ASA Service Modules and the ASA Software Release 8.5(x) used on the module.

The configuration of these remote access VPNs are the same for these device types. IOS and PIX 6.3+ devices use different configurations for remote access VPNs (as explained in Chapter 31, “Managing Remote Access VPNs on IOS and PIX 6.3 Devices”).

The topics in this chapter explain how to configure policies that are specific to ASA and PIX 7.0+ devices. Additionally, review the following topics for more information about remote access VPNs:

- Understanding Remote Access VPNs, page 28-1
- Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9
- Discovering Remote Access VPN Policies, page 28-12
- Using the Remote Access VPN Configuration Wizard, page 28-13
  - Creating IPSec VPNs Using the Remote Access VPN Configuration Wizard (ASA and PIX 7.0+ Devices), page 28-24
  - Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (ASA Devices), page 28-14
- Chapter 30, “Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)”

This chapter contains the following topics:

- Overview of Remote Access VPN Policies for ASA and PIX 7.0+ Devices, page 29-2
- Understanding Cluster Load Balancing (ASA), page 29-4
- Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6
- Configuring Group Policies for Remote Access VPNs, page 29-22
- Working with IPSec VPN Policies, page 29-26
- Working with SSL and IKEv2 IPSec VPN Policies, page 29-33
- Customizing Clientless SSL VPN Portals, page 29-59
Overview of Remote Access VPN Policies for ASA and PIX 7.0+ Devices

When you configure remote access VPNs on ASA or PIX 7.0+ devices, you use the following policies based on the type of VPN you are configuring. Possible remote access VPN types are: IKE version 1 (IKEv1) IPsec, IKE version 2 (IKEv2) IPsec, and SSL. IKEv2 is supported on ASA 8.4(x) devices only. Table 29-1 explains the conditions under which these policies are required or optional.

Note: You cannot configure SSL VPNs on PIX devices; PIX devices support remote access IKEv1 IPsec VPNs only.

- **Policies used with remote access IKEv1 and IKEv2 IPsec and SSL VPNs:**
  - **ASA Cluster Load Balancing**—In a remote client configuration in which you are using two or more devices connected to the same network to handle remote sessions, you can configure these devices to share their session load. This feature is called load balancing. Load balancing directs session traffic to the least loaded device, thus distributing the load among all devices. Load balancing is effective only on remote sessions initiated with an ASA device. For more information, see Understanding Cluster Load Balancing (ASA), page 29-4.
  - **Connection Profiles**—A connection profile is a set of records that contain VPN tunnel connection policies, including the attributes that pertain to creating the tunnel itself. Connection profiles identify the group policies for a specific connection, which includes user-oriented attributes. For more information, see Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.
  - **Dynamic Access**—Multiple variables can affect each VPN connection, for example, intranet configurations that frequently change, the various roles that each user might inhabit within an organization, and logins from remote access sites with different configurations and levels of security. Dynamic access policies (DAP) let you configure authorization that addresses these many variables. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. For more information, see Chapter 30, “Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)”.
  - **Global Settings**—You can define global settings that apply to all devices in your remote access VPNs. These settings include Internet Key Exchange (IKE), IKEv2, IPsec, NAT, and fragmentation definitions. The global settings typically have defaults that work in most situations, so configuring the Global Settings policy is optional in most cases; configure it only if you need non-default behavior or if you are supporting IKEv2 negotiations. For more information, see Configuring VPN Global Settings, page 24-27.
  - **Group Policies**—You can view the user group policies defined for your remote access VPN connection profiles. From this page, you can specify new ASA user groups and edit existing ones. When you create a connection profile, if you specify a group policy that has not been used on the device, the group policy is automatically added to the Group Policies page; you do not need to add it to this policy before you create the connection profile. For more information, see Configuring Group Policies for Remote Access VPNs, page 29-22.
  - **Public Key Infrastructure**—You can create a Public Key Infrastructure (PKI) policy to generate enrollment requests for CA certificates and RSA keys, and to manage keys and certificates. Certification Authority (CA) servers are used to manage these certificate requests.
and issue certificates to users who connect to your IPsec or SSL remote access VPN. For more information, see Understanding Public Key Infrastructure Policies, page 24-44 and Configuring Public Key Infrastructure Policies for Remote Access VPNs, page 24-49.

- **Policies used in remote access IPsec VPNs only:**
  - **Certificate To Connection Profile Maps, Policy and Rules (IKEv1 IPsec only.)**—Certificate to connection profile map policies let you define rules to match a user’s certificate to a permission group based on specified fields. To establish authentication, you can use any field of the certificate, or you can have all certificate users share a permission group. You can match the group from the DN rules, the Organization Unit (OU) field, the IKE identity, or the peer IP address. You can use any or all of these methods. For more information, see Configuring Certificate to Connection Profile Maps (ASA), page 29-26.
  - **IKE Proposal**—Internet Key Exchange (IKE), also called ISAKMP, is the negotiation protocol that enables two hosts to agree on how to build an IPsec security association. IKE is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and to automatically establish IPsec security associations (SAs). Use the IKE Proposal policy to define the requirements for phase 1 of the IKE negotiation. For more information, see Configuring an IKE Proposal, page 24-9.
  - **IPsec Proposal (ASA/PIX 7.x)**—An IPsec proposal is a collection of one or more crypto maps. A crypto map combines all the components required to set up IPsec security associations (SAs), including IPsec rules, transform sets, remote peers, and other parameters that might be necessary to define an IPsec SA. The policy is used for IKE phase 2 negotiations. For more information, see Configuring an IPsec Proposal on a Remote Access VPN Server (ASA, PIX 7.0+ Devices), page 29-30.

- **Policies used in remote access IKEv2 IPsec and SSL VPNs only:**
  - **Access**—An Access policy specifies the security appliance interfaces on which a remote access SSL or IKEv2 IPsec VPN connection profile can be enabled, the port to be used for the connection profile, Datagram Transport Layer Security (DTLS) settings, the SSL VPN session timeout and maximum number of sessions. You can also specify whether to use the AnyConnect VPN Client or AnyConnect Essentials Client. For more information, see Understanding SSL VPN Access Policies (ASA), page 29-33.
  - **Other Settings**—The SSL VPN Other Settings policy defines settings that include caching, content rewriting, character encoding, proxy and proxy bypass definitions, browser plug-ins, AnyConnect client images and profiles, Kerberos Constrained Delegation, and some other advanced settings. For more information, see Configuring Other SSL VPN Settings (ASA), page 29-38.
  - **Shared License**—Use the SSL VPN Shared License page to configure your SSL VPN Shared License. For more information, see Configuring SSL VPN Shared Licenses (ASA 8.2+), page 29-56.

The following table explains whether a policy is required or optional for a particular type of VPN.

| **Table 29-1** Remote Access VPN Policy Requirements for ASA Devices |
|------------------------|-------------------|
| **Policy**             | **Required, Optional** |
| ASA Cluster Load Balancing | Optional for all VPN types. |
| Connection Profiles     | Required for all VPN types. |
| Dynamic Access          | Optional for all VPN types. |
Chapter 29  Managing Remote Access VPNs on ASA and PIX 7.0+ Devices

Understanding Cluster Load Balancing (ASA)

In a remote client configuration in which you are using two or more devices connected to the same network to handle remote sessions, you can configure these devices to share their session load. This feature is called load balancing. Load balancing directs session traffic to the least loaded device, thus distributing the load among all devices. Load balancing is effective only on remote sessions initiated with an ASA device.

To implement load balancing, you must group two or more devices on the same private LAN-to-LAN network into a virtual cluster. All devices in the virtual cluster carry session loads. One device in the virtual cluster, called the virtual cluster master, directs incoming calls to the other devices, called secondary devices. The virtual cluster master monitors all devices in the cluster, keeps track of how busy each is, and distributes the session load accordingly.

The virtual cluster appears to outside clients as a single virtual cluster IP address. This IP address is not tied to a specific physical device—it belongs to the current virtual cluster master. A VPN client trying to establish a connection connects first to this virtual cluster IP address. The virtual cluster master then sends back to the client the public IP address of the least-loaded available host in the cluster. In a second transaction (transparent to the user), the client connects directly to that host. In this way, the virtual cluster master directs traffic evenly and efficiently across resources.

Table 29-1  Remote Access VPN Policy Requirements for ASA Devices (Continued)
The role of virtual cluster master is not tied to a physical device—it can shift among devices. If a machine in the cluster fails, the terminated sessions can immediately reconnect to the virtual cluster IP address. The virtual cluster master then directs these connections to another active device in the cluster. Should the virtual cluster master itself fail, a secondary device in the cluster immediately takes over as the new virtual session master. Even if several devices in the cluster fail, users can continue to connect to the cluster as long as any one device in the cluster is available.

Understanding Redirection Using a Fully Qualified Domain Name (FQDN)

By default, the ASA sends only IP addresses in load-balancing redirection to a client. If certificates are in use that are based on DNS names, the certificates will be invalid when redirected to a secondary device. As a VPN cluster master, this security appliance can send a fully qualified domain name (FQDN) of a cluster device (another security appliance in the cluster) when redirecting VPN client connections to that cluster device. The security appliance uses reverse DNS lookup to resolve the FQDN of the device to its outside IP address to redirect connections and perform VPN load balancing. All outside and inside network interfaces on the load-balancing devices in a cluster must be on the same IP network.

After you enable load balancing using FQDNs, add an entry for each of your ASA outside interfaces into your DNS server, if such entries are not already present. Each ASA outside IP address should have a DNS entry associated with it for lookups. These DNS entries must also be enabled for Reverse Lookup. Enable DNS lookups on your ASA and define your DNS server IP address on the ASA.

For the procedure to configure cluster load balancing, see Configuring Cluster Load Balance Policies (ASA), page 29-5.

Configuring Cluster Load Balance Policies (ASA)

Use the ASA Cluster Load Balance page to enable load balancing for an ASA device in your remote access VPN. You must explicitly enable load balancing, as it is disabled by default. All devices that participate in a cluster must share the same cluster-specific values: IP address, encryption settings, encryption key, and port. For more information on cluster load balancing, see Understanding Cluster Load Balancing (ASA), page 29-4.

Note

Load balancing requires an active 3DES/AES license and an ASA Model 5510 with a Plus license or an ASA Model 5520 or higher. The ASA device checks for the existence of this crypto license before enabling load balancing. If it does not detect an active 3DES or AES license, the device prevents load balancing, and also prevents internal configuration of 3DES by the load balancing system unless the license permits this usage.

Step 1

Do one of the following:

- (Device View) Select an ASA device; then select **Remote Access VPN > ASA Cluster Load Balance** from the Policy selector.
- (Policy View) Select **Remote Access VPN > ASA Cluster Load Balance** from the Policy Type selector. Select an existing policy or create a new one.

The ASA Cluster Load Balance page opens.

Step 2

Select **Participate in Load Balancing Cluster** to indicate that the device belongs to a load-balancing cluster.

Step 3

Configure the VPN Cluster Configuration options:

- **Cluster IP Address**—Specify the single IP address that represents the entire virtual cluster. Choose an IP address that is in the same subnet as the external interface.
Configuring Connection Profiles (ASA, PIX 7.0+)

A connection profile is a set of records that contain VPN tunnel connection policies, including the attributes that pertain to creating the tunnel itself. Connection profiles identify the group policies for a specific connection, which includes user-oriented attributes. If you do not assign a group policy to a user, the default connection profile for the connection applies. You can create one or more connection profiles specific to your environment. You can configure connection profiles on the local remote access VPN server or on external AAA servers.

When you discover remote access VPN policies on a device, Security Manager adds the default connection profiles to the policy. You can edit these profiles, and the associated DfltGrpPolicy (renamed in Security Manager as <device_display_name>DfltGrpPolicy), but you cannot delete them. The following default connection profiles are supported in Security Manager:

- **DefaultRAGroup**—The default connection profile for remote access IPsec VPNS.
- **DefaultWEBVPNGroup**—The default connection profile for SSL VPNS. This connection profile is discovered only for ASA 8.0+ devices.

If you are configuring a connection profile on an ASA device, you have the option of configuring double authentication. The double authentication feature implements two-factor authentication for remote access to the network, in accordance with the Payment Card Industry Standards Council Data Security Standard. This feature requires that the user enter two separate sets of login credentials at the login page. For example, the primary authentication might be a one-time password, and the secondary authentication might be a domain (Active Directory) credential. If the primary credential authentication fails, the security appliance does not attempt to validate the secondary credentials. If either authentication fails,

- **UDP Port**—Specify the UDP destination port for the virtual cluster to which the device belongs. The port is typically 9023, but if that port is in use by another application, enter the UDP destination port number that you want to use for load balancing.

- **Enable IPSec Encryption, IPSec Shared Secret**—If required, select Enable IPSec Encryption to ensure that all load-balancing information communicated between the devices is encrypted. If you select this option, also enter (and confirm) the shared secret password. This can be a case-sensitive value between 4 and 16 characters, without spaces. The security appliances in the virtual cluster communicate through LAN-to-LAN tunnels using IPsec. This password must match the passwords passed on by the client.

**Step 4** Configure the priority of the server in the cluster. Select one of the following options:

- **Accept default device value**—To accept the default priority value assigned to the device.
- **Configure same priority on all devices in the cluster**—To configure the same priority value to all the devices in the cluster. Then enter the priority number (1-10) to indicate the likelihood of the device becoming the virtual cluster master, either at startup or when the existing master fails.

**Step 5** Specify the public and private interfaces to be used on the server:

- **Public Interfaces**—The public interfaces to be used on the server. Enter the name of an interface or interface role object, or click Select to select the interface or role or to create a new role.
- **Private Interfaces**—The private interfaces to be used on the server. Enter the name of an interface or interface role object, or click Select to select the interface or role or to create a new role.

**Step 6** If required, select Send FQDN to client instead of an IP address when redirecting to enable redirection using fully-qualified domain names. This option is available only for ASA devices running 8.0(2) or later. For more information, see Understanding Cluster Load Balancing (ASA), page 29-4.
the connection is denied. Both the AnyConnect VPN client (SSL VPN or IKEv2 IPSec VPN) and Clientless SSL VPN support double authentication. The AnyConnect client supports double authentication on Windows computers (including supported Windows Mobile devices and Start Before Login), Mac computers, and Linux computers.

This procedure describes how to create or edit connection profiles on your remote access VPN server using the Connection Profile policy.

**Note**  
You can also create connection profiles from the Remote Access VPN Configuration wizard; see Using the Remote Access VPN Configuration Wizard, page 28-13. For information on connection profiles in Easy VPN site-to-site topologies, see Configuring a Connection Profile Policy for Easy VPN, page 26-13.

**Related Topics**
- Discovering Remote Access VPN Policies, page 28-12

---

**Step 1**  
Do one of the following:

- (Device view) With an ASA or PIX 7.0+ device selected, select Remote Access VPN > Connection Profiles from the Policy selector.
- (Policy view) Select Remote Access VPN > Connection Profiles (ASA) from the Policy Type selector. Select an existing policy or create a new one.

The Connection Profiles page opens. The policy lists all connection profiles and shows the group policy used in the profile. For more information, see Connection Profiles Page, page 29-8.

**Step 2**  
Click Add Row (+) beneath the table, or select a profile and click Edit Row (pencil). The Connection Profiles dialog box opens.

**Step 3**  
(All remote access VPN types.) On the General tab, specify the connection profile name and group policies and select which method (or methods) of address assignment to use. For a detailed explanation of the configuration, see General Tab (Connection Profiles), page 29-9.

**Step 4**  
(All remote access VPN types.) Click the AAA tab to specify the AAA authentication parameters for the connection profile. For a detailed explanation of the configuration, see AAA Tab (Connection Profiles), page 29-11.

**Step 5**  
(Remote access IKEv2 IPsec and SSL VPN only.) If you are setting up a connection profile on an ASA device, you can configure secondary authentication. To do so, click the Secondary AAA tab. For a detailed explanation of the configuration, see Secondary AAA Tab (Connection Profiles), page 29-14.

**Step 6**  
(Remote access IPsec VPN only.) Click the IPSec tab to specify IPsec and IKE parameters for the connection profile. Some of these settings apply to IKEv1 but not to IKEv2 connections. For a detailed explanation of the configuration, see IPSec Tab (Connection Profiles), page 29-16.

**Note**  
To configure IKEv2 settings, use the IKEv2 Settings tab of the Global Settings policy; see Configuring VPN Global IKEv2 Settings, page 24-31.
Step 7  (Remote access SSL VPN only.) Click the SSL tab to specify the WINS servers for the connection profile policy, select a customized look and feel for the SSL VPN end-user logon web page, specify DHCP servers to be used for client address assignment, and establish an association between an interface and client IP address pools. For a detailed explanation of the configuration, see SSL Tab (Connection Profiles), page 29-18.

Step 8  Click OK.

Connection Profiles Page

Use the Connection Profiles page to manage connection profile policies for remote access VPN or Easy VPN topologies. Use of this policy differs depending on the type of VPN you are configuring:

- Remote access SSL VPN—The policy is used only for ASA devices. You can create multiple profiles, and configure settings on all tabs of the Connection Profiles dialog box.
- Remote access IPSec VPN—The policy is used for ASA devices and PIX Firewalls running PIX 7.0+ software. You can create multiple profiles, but only the General, AAA, and IPSec tabs on the Connection Profiles dialog box apply to this configuration (in some cases, you will see only these tabs).
- Easy VPN topologies—The policy is used for Easy VPN servers (hubs) that are ASA devices or PIX Firewalls running PIX 7.0+ software. You can create a single profile, so the policy page actually imbeds the Connection Profiles dialog box, so that you have direct access to the tabs that define the profile. Only the General, AAA, and IPSec tabs apply.

For remote access IPSec and SSL VPNs:

- To add a profile, click the Add Row button and fill in the Connection Profiles dialog box.
- To edit an existing profile, select it and click the Edit Row button.
- To delete a profile, select it and click the Delete Row button.

The connection profile consists of the following tabs. Configure them as appropriate for the type of VPN you are configuring:

- General Tab (Connection Profiles), page 29-9
- AAA Tab (Connection Profiles), page 29-11
- Secondary AAA Tab (Connection Profiles), page 29-14 (SSL VPN and IKEv2 IPsec VPN only.)
- IPSec Tab (Connection Profiles), page 29-16 (IKEv1 IPsec VPN only, does not apply to SSL or IKEv2 IPsec VPNs.)
- SSL Tab (Connection Profiles), page 29-18 (SSL VPN only)

Navigation Path

Remote access VPNs:

- (Device View) Select a ASA or PIX 7+ device and select Remote Access VPN > Connection Profiles from the Policy selector.
- (Policy View) Select Remote Access VPN > Connection Profiles (ASA) from the Policy Type selector. Select an existing policy or create a new one.
Easy VPN:

- From the Site-to-Site VPN Manager Window, page 23-18, select the Easy VPN topology and then select Connection Profiles (PIX7.0/ASA).
- (Device view) Select a device that participates in the Easy VPN topology and select Site to Site VPN from the Policy selector. Select the Easy VPN topology and click Edit VPN Policies to open the Site-to-Site VPN Manager Window, page 23-18, where you can select the policy.
- (Policy view) Select Site-to-Site VPN > Connection Profiles (PIX7.0/ASA). Select an existing policy or create a new one.

This section contains the following topics:

- General Tab (Connection Profiles), page 29-9
- AAA Tab (Connection Profiles), page 29-11
- Secondary AAA Tab (Connection Profiles), page 29-14
- IPSec Tab (Connection Profiles), page 29-16
- SSL Tab (Connection Profiles), page 29-18

### General Tab (Connection Profiles)

Use the General tab of the Connection Profiles dialog box to configure the basic properties for a VPN Connection Profile policy. These properties are used in remote access IPsec and SSL VPNs and site-to-site Easy VPN topologies.

**Navigation Path**

- Remote Access VPNs—From the Connection Profiles page (see Connection Profiles Page, page 29-8), click the Add Row (+) button, or select a profile and click the Edit Row (pencil) button, to open the Connection Profiles dialog box. Click the General tab if necessary.

- Easy VPN topologies—Select the site-to-site VPN Connection Profiles policy in either Policy view or in the Site-to-Site VPN Manager with an Easy VPN topology selected (see Connection Profiles Page, page 29-8). Click the General tab if necessary.

<td>Enable Notification Upon Password Expiration to Allow User to Change Password</td>
<td>Whether to have the security appliance notify the remote user at login that the current password is about to expire or has expired, and to then offer the user the opportunity to change the password.</td>
</tr>
<tr>
<td>Enable Notification Prior to Expiration Notify Prior to Expiration</td>
<td>If you want to give the user prior warning of an impending password expiration, select Enable Notification Prior to Expiration and specify the number of days prior to expiration that you want to start notifications (1 to 180 days). You can use this option with AAA servers that support such notification—RADIUS, RADIUS with an NT server, and LDAP servers. There is no prior notification for other types of servers.</td>
</tr>
</tbody>
</table>
| Distinguished Name (DN) Authorization Settings | How you want to use the distinguished name for authorization. A distinguished name (DN) is a unique identification, made up of individual fields, that can be used as the identifier when matching users to a tunnel group. DN rules are used for enhanced certificate authentication. Select from the following options to determine how the DN is used during authorization:  
  - Use Entire DN as the Username—Use the entire DN; do not focus on any one field.  
  - Specify Individual DN fields as the Username—Focus on specific fields. Select a primary field, and optionally, a secondary field. The default is to use the common name (CN) as primary and the organization unit (OU) as secondary. |
| Interface-Specific Authentication Server Groups table | If you want to configure separate authentication server groups for specific interfaces, so that clients connecting through that interface use a server group different from the global group, add the interface to this table and configure the separate group. Any interface not listed here uses the global authentication server group. The table shows the server group and whether you are falling back to local authentication if the server group is not available.  
  - To add an interface-specific authentication group to the list, click the Add Row button and fill in the Add/Edit Interface Specific Authentication Server Groups Dialog Box, page 29-13.  
  - To edit an interface setting, select it and click the Edit Row button.  
  - To delete an interface setting, select it and click the Delete Row button. |
Navigation Path

Open the AAA or Secondary AAA tabs in the Connection Profiles dialog box (see AAA Tab (Connection Profiles), page 29-11 or Secondary AAA Tab (Connection Profiles), page 29-14), then click Add Row below the Interface-Specific Address Pools table, or select a row in the table and click Edit Row.

<tr>
<td>Interface</td>
<td>The name of the interface or interface role (that identifies the interfaces) for which you are configuring an authentication server group. Click Select to select an interface or interface role or to create a new interface role.</td>
</tr>
</tbody>
</table>
| Server Group                   | The name of the authentication server group (LOCAL if the tunnel group is configured on the local device). Enter the name of a AAA server group object or click Select to select it from a list or to create a new object.  
When you are configuring secondary AAA, this group is used specifically for the second credentials. You can specify different server groups for primary and second credentials. |
| Use LOCAL if Server Group Fails| Whether to fall back to the local database for authentication if the selected authentication server group fails.                                |
| Use Primary Username (Secondary authentication only; remote access SSL or IKEv2 IPSec VPN on ASA 8.2+ only.) | Whether to use the same username for the secondary credentials that was used for the primary credentials. If you select this option, after users authenticate with their primary credentials, they are prompted for the secondary password only. If you do not select this option, the secondary prompt requires both a username and password. |

Secondary AAA Tab (Connection Profiles)

Use the Secondary AAA tab to configure the secondary AAA authentication parameters for a remote access SSL VPN connection profile policy for use with ASA 8.2+ devices, or a remote access IKEv2 IPSec VPN connection profile policy for use with an ASA 8.4(1)+ device. These settings do not apply to remote access IKEv1 IPSec VPNs or Easy VPN topologies or to other device types.

Navigation Path

Remote Access VPNs only—From the Connection Profiles page (see Connection Profiles Page, page 29-8), click the Add Row (+) button, or select a profile and click the Edit Row (pencil) button, to open the Connection Profiles dialog box. Click the Secondary AAA tab.

IPSec Tab (Connection Profiles)

Use the IPSec tab of the Connection Profiles page to specify IPsec and IKE parameters for the connection policy. The preshared key, trustpoint, and client software table apply to IKE version 1 only and do not apply to IKE version 2 (IKEv2).

Note

To configure IKEv2 settings, use the IKEv2 Settings tab of the Global Settings policy; see Configuring VPN Global IKEv2 Settings, page 24-31.

Navigation Path

- Remote Access VPNs—From the Connection Profiles page (see Connection Profiles Page, page 29-8), click the Add Row (+) button, or select a profile and click the Edit Row (pencil) button, to open the Connection Profiles dialog box. Click the IPSec tab.
- Easy VPN topologies—Select the site-to-site VPN Connection Profiles policy in either Policy view or in the Site-to-Site VPN Manager with an Easy VPN topology selected (see Connection Profiles Page, page 29-8). Click the IPSec tab.

Field Reference

Table 29-9  Connection Profile SSL Tab

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WINS Servers List</td>
<td>The name of the WINS (Windows Internet Naming Server) servers list to use for CIFS name resolution. Click <strong>Select</strong> to select the WINS servers list policy object or to create a new object. SSL VPN uses the CIFS protocol to access or share files on remote systems. When you attempt a file-sharing connection to a Windows computer by using its computer name, the file server you specify corresponds to a specific WINS server name that identifies a resource on the network. A WINS servers list defines a list of WINS servers, which are used to translate Windows file server names to IP addresses. The security appliance queries the WINS servers to map WINS names to IP addresses. You must configure at least one, and up to three WINS servers for redundancy. The security appliance uses the first server on the list for WINS/CIFS name resolution. If the query fails, it uses the next server.</td>
</tr>
<tr>
<td>DNS Group</td>
<td>The DNS group to use for the SSL VPN tunnel group. The DNS group resolves the hostname to the appropriate DNS server for the tunnel group. Select the desired group from the list; the DefaultDNS group is the default group that is always available on the device. Tip The DNS groups are defined in the <strong>Platform &gt; Device Admin &gt; Server Access &gt; DNS</strong> policy. Use the DNS policy to change the servers defined in a group or to add or remove groups. See <strong>DNS Page</strong>, page 50-11.</td>
</tr>
<tr>
<td>Portal Page Customization</td>
<td>The name of the SSL VPN Customization policy object that defines the default portal page for the VPN. This profile defines the appearance of the portal page that allows the remote user access to all resources available on the SSL VPN. Click <strong>Select</strong> to select the object or to create a new object. Note You can set up different login windows for different groups by using a combination of customization profiles and groups. For example, assuming that you had created a customization profile called salesgui, you can create an SSL VPN group called sales that uses that customization profile. You would then specify the SSL VPN customization object in the group policy object on the SSL VPN &gt; Settings tab; see <strong>ASA Group Policies SSL VPN Settings</strong>, page 32-14.</td>
</tr>
</tbody>
</table>
Chapter 29  Managing Remote Access VPNs on ASA and PIX 7.0+ Devices

Table 29-9  Connection Profile SSL Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Override SVC Download</td>
<td>Whether you want clientless users logging in under specific tunnel groups to not have to wait for the download prompt to expire before being presented with the clientless SSL VPN home page. Instead, these users are immediately presented with the clientless SSL VPN home page.</td>
</tr>
<tr>
<td>Reject Radius Message</td>
<td>Whether you want to display to remote users a RADIUS message about their authentication failure.</td>
</tr>
<tr>
<td>Connection Aliases table</td>
<td>A list of alternate names by which the tunnel group can be referred to. The status indicates whether the name is enabled for use or disabled (cannot be used). A group alias creates one or more alternate names by which a user can refer to a tunnel group. This feature is useful when the same group is known by several common names (such as “Devtest” and “QA”). If you want the actual name of the tunnel group to appear on this list, you must specify it as an alias. The group alias that you specify here appears on the login page. Each tunnel group can have multiple aliases or no alias.</td>
</tr>
<tr>
<td>Group URLs table</td>
<td>A list of URLs associated with the tunnel group connection profile. The status indicates whether the URL is enabled for use. When enabled, the user can use the URL, which eliminates the need to select a group during login. You can configure multiple URLs (or no URLs) for a tunnel group. Each URL can be enabled or disabled individually. You must use a separate specification for each URL, specifying the entire URL using either the HTTP or HTTPS protocol.</td>
</tr>
<tr>
<td>Disable CSD</td>
<td>Whether to disable Cisco Secure Desktop (CSD) for this connection profile. In many cases, this option is disabled. Configure CSD in the Dynamic Access policy.</td>
</tr>
</tbody>
</table>

Add/Edit Connection Alias Dialog Box

Use the Add/Edit Connection Alias dialog box to create or edit a connection alias for an SSL or IKEv2 IPsec VPN connection profile. Specifying the connection alias creates one or more alternate names by which the user can refer to a tunnel group.
Navigation Path
Open the SSL tab in the Connection Profiles dialog box (see SSL Tab (Connection Profiles), page 29-18), and click Add Row beneath the Connection Alias table, or select an alias from the table and click Edit Row.

Field Reference

**Table 29-10 Add/Edit Connection Alias Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Whether to enable the connection alias. You must enable the alias for users to use it.</td>
</tr>
<tr>
<td>Connection Alias</td>
<td>The alternative name for the connection profile. The connection alias that you specify here appears in a list on the user’s login page.</td>
</tr>
</tbody>
</table>

Add/Edit Connection URL Dialog Box

Use this dialog box to specify incoming URLs for the tunnel group. If a connection URL is enabled in a tunnel group, when the user connects using that URL, the security appliance selects the associated tunnel group and presents the user with only the username and password fields in the login window.

**Tips**
- You can configure multiple URLs or addresses (or none) for a group. Each URL or address can be enabled or disabled individually.
- You cannot associate the same URL or address with multiple groups. The security appliance verifies the uniqueness of the URL or address before accepting the URL or address for a tunnel group.

Navigation Path
Open the SSL tab in the Connection Profiles dialog box (see SSL Tab (Connection Profiles), page 29-18), and click Add Row beneath the Group URLs table, or select a URL from the table and click Edit Row.

Field Reference

**Table 29-11 Add/Edit Connection URL Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Whether to enable the connection alias. You must enable the alias for users to use it.</td>
</tr>
<tr>
<td>Connection URL</td>
<td>Select a protocol (http or https) from the list, and specify the incoming URL for the connection.</td>
</tr>
</tbody>
</table>
Configuring Group Policies for Remote Access VPNs

In the Group Policies page, you can view the user group policies defined for your ASA remote access VPN connection profiles. From this page, you can specify new ASA user groups and edit existing ones. When you create a connection profile, if you specify a group policy that has not been used on the device, the group policy is automatically added to the Group Policies page; you do not need to add it to this policy before you create the connection profile. For information on creating connection profiles, see Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.

For more information about group policies, see Understanding Group Policies (ASA), page 29-23.

Tip
Dynamic Access policies take precedence over Group policies. If a setting is not specified in a Dynamic Access policy, an ASA device checks for Group policies that specify the setting.

Each row in the table represents an ASA group policy object, displaying the name of the policy object assigned to the remote access VPN connection profile, whether it is stored on the ASA device itself (Internal) or on a AAA server (External), and whether the group is for IKEv1 (IPsec), IKEv2 (IPsec), SSL, or all types of VPN. For external groups, the protocol is unknown and listed as N/A.

- To add an ASA group policy object, click the Add Row button. This opens an object selector, from which you can select an existing policy object or click the Create button to create a new object. For more information about creating group policies, see Creating Group Policies (ASA, PIX 7.0+), page 29-24.

Note
You cannot create more than one group policy that includes DfltGrpPolicy in its name. DfltGrpPolicy is the default policy defined on the device; if Security Manager discovers the group during remote access policy discovery, the group appears in the list under the name <device_display_name>DfltGrpPolicy. When you deploy the configuration to the device, the display name prefix is removed so that DfltGrpPolicy is updated correctly. For more information, see Discovering Remote Access VPN Policies, page 28-12.

- To edit an object, select it and click the Edit Row button to open the ASA Group Policies Dialog Box, page 32-1.

- To delete an object from the policy, select it and click the Delete Row button. The associated policy objects are not deleted, they are only removed from this policy.

Note
You cannot delete the default group policy.

Navigation Path
- (Device view) Select an ASA device, then select Remote Access VPN > Group Policies from the Policy selector.
- (Policy view) Select Remote Access VPN > Group Policies (ASA) from the Policy selector. Select an existing policy or create a new one.
Understanding Group Policies (ASA)

When you configure a remote access IPSec or SSL VPN connection, you must create user groups to which remote clients will belong. A user group policy is a set of user-oriented attribute/value pairs for remote access VPN connections that are stored either internally (locally) on the device or externally on an AAA server. The connection profile uses a user group policy that sets terms for user connections after the connection is established. Group policies let you apply whole sets of attributes to a user or a group of users, rather than having to specify each attribute individually for each user.

Tip

Dynamic Access policies take precedence over Group policies. If a setting is not specified in a Dynamic Access policy, an ASA device checks for Group policies that specify the setting.

An ASA user group comprises the following attributes:

- Group policy source—Identifies whether the user group’s attributes and values are stored internally (locally) on the security appliance or externally on an AAA server. If the user group is an external type, no other settings need to be configured for it. For more information, see ASA Group Policies Dialog Box, page 32-1.
- Client Configuration settings, which specify the Cisco client parameters for the user group in an Easy VPN or remote access VPN. For more information, see ASA Group Policies Client Configuration Settings, page 32-4.
- Client Firewall Attributes, which configure the firewall settings for VPN clients in an Easy VPN or remote access VPN. For more information, see ASA Group Policies Client Firewall Attributes, page 32-5.
- Hardware Client Attributes, which configure the VPN 3002 Hardware Client settings in an Easy VPN or remote access VPN. For more information, see ASA Group Policies Hardware Client Attributes, page 32-7.
- IPSec settings, which specify tunneling protocols, filters, connection settings, and servers for the user group in an Easy VPN or remote access VPN. For more information, see ASA Group Policies IPSec Settings, page 32-8.
- Clientless settings, which configure the Clientless mode of access to the corporate network in an SSL VPN, for the ASA user group. For more information, see ASA Group Policies SSL VPN Clientless Settings, page 32-10.
- Full Client settings, which configure the Full Client mode of access to the corporate network in an SSL VPN, for the ASA user group. For more information, see ASA Group Policies SSL VPN Full Client Settings, page 32-12.
- General settings that are required for Clientless/Port Forwarding in an SSL VPN. For more information, see ASA Group Policies SSL VPN Settings, page 32-14.
- DNS/WINS settings that define the DNS and WINS servers and the domain name that should be pushed to remote clients associated with the ASA user group. For more information, see ASA Group Policies DNS/WINS Settings, page 32-17.
- Split tunneling that lets a remote client conditionally direct packets over an IPSec or SSL VPN tunnel in encrypted form or to a network interface in clear text form. For more information, see ASA Group Policies Split Tunneling Settings, page 32-18.
- Remote access or SSL VPN session connection settings for the ASA user group. For more information, see ASA Group Policies Connection Settings, page 32-19.
Creating Group Policies (ASA, PIX 7.0+)

Use the Group Policies page to create group policies for ASA or PIX 7.0+ devices used in remote access IPSec VPNs, or ASA devices used in remote access SSL VPNs. For information about group policies, see:

- Understanding Group Policies (ASA), page 29-23
- Configuring Group Policies for Remote Access VPNs, page 29-22

Step 1
Do one of the following:

- (Device view) With an ASA or PIX 7.0+ device selected, select Remote Access VPN > Group Policies from the Policy selector.

- (Policy view) Select Remote Access VPN > Group Policies (ASA) from the Policy Type selector. Select an existing policy or create a new one.

The Group Policies page opens. The table lists the existing group policies, whether they are defined internally on the device or externally on a AAA server, and the protocol for the group: IKEv1 (IPsec), IKEv2 (IPsec), or SSL.

Step 2
Click Add Row (+) to open a dialog box from which you can select a user group from a list of predefined ASA user group objects, or create new ones if necessary. To create a new group, click the Create (+) button in the dialog box.

Step 3
Select the required ASA user group from the list and click OK. If the required group already exists, you are finished.

If the required ASA user group does not exist, create it by clicking Create (+). The Add ASA User Group dialog box appears, displaying a list of settings that you can configure for the ASA user group object. For a description of the elements on this dialog box, see ASA Group Policies Dialog Box, page 32-1.

Step 4
Enter a name for the object and optionally a description of the object.

Step 5
Select whether to store the ASA user group’s attributes and values locally on the device, or on an external server.

Note
If you selected to store the ASA user group’s attributes on an external server, you do not need to configure any Technology settings. After you specify the AAA server group that will be used for authentication and a password to the AAA server, click OK and then select the group in the object selector and click OK to add it to the policy.

Step 6
If you selected to store the ASA user group’s attributes locally on the device, select the type of VPN for which you are creating the ASA user group from the Technology list:

- Easy VPN/IPSec IKEv1—For remote access IPsec VPNs that use IKE version 1 negotiations.
- Easy VPN/IPSec IKEv2—(ASA only.) For remote access IPsec VPNs that use IKE version 2 negotiations.
- SSL Clientless—(ASA only.) For SSL VPNs, all access modes (not just clientless).
Step 7 To configure the user group for Easy VPN/IPSec IKEv1 and Easy VPN/IPSec IKEv2, from the Easy VPN/IPSec VPN folder in the Settings pane:

   a. Select Client Configuration to configure the Cisco client parameters. For a description of these settings, see ASA Group Policies Client Configuration Settings, page 32-4.

   b. Select Client Firewall Attributes to configure the firewall settings for VPN clients. For a description of these settings, see ASA Group Policies Client Firewall Attributes, page 32-5.

   c. Select Hardware Client Attributes to configure the VPN 3002 Hardware Client settings. For a description of these settings, see ASA Group Policies Hardware Client Attributes, page 32-7.

   d. Select IPsec to specify tunneling protocols, filters, connection settings, and servers. For a description of these settings, see ASA Group Policies IPsec Settings, page 32-8.

Step 8 To configure the user group for an SSL VPN, from the SSL VPN folder in the Settings pane:

   a. Select Clientless to configure the Clientless mode of access to the corporate network in an SSL VPN. For a description of these settings, see ASA Group Policies SSL VPN Clientless Settings, page 32-10.

   b. Select Full Client to configure the Full Client mode of access to the corporate network in an SSL VPN. For a description of these settings, see ASA Group Policies SSL VPN Full Client Settings, page 32-12.

   c. Select Settings to configure the general settings that are required for clientless and thin client (port forwarding) access modes in an SSL VPN. For a description of these settings, see ASA Group Policies SSL VPN Settings, page 32-14.

Step 9 Specify the following settings for an ASA user group in an Easy VPN/IPSec IKEv1 or IKEv2 VPN and SSL VPN configuration, in the Settings pane:

   a. Select DNS/WINS to define the DNS and WINS servers and the domain name that should be pushed to clients associated with the ASA user group. For a description of these settings, see ASA Group Policies DNS/WINS Settings, page 32-17.

   b. Select Split Tunneling to allow a remote client to conditionally direct encrypted packets through a secure tunnel to the central site and simultaneously allow clear text tunnels to the Internet through a network interface. For a description of these settings, see ASA Group Policies Split Tunneling Settings, page 32-18.

   c. Select Connection Settings to configure the SSL VPN connection settings for the ASA user group, such as the session and idle timeouts, including the banner text. For a description of these settings, see ASA Group Policies Connection Settings, page 32-19.

Step 10 Click OK.

Step 11 Select the ASA user group from the list and click OK.
Working with IPSec VPN Policies

Certain policies need to be configured for IPSec VPNs. The topics listed below explain these remote access IPSec VPN policies, with the exception of the IKE Proposal policy, which is explained in Configuring an IKE Proposal, page 24-9.

This section contains the following topics:

- Configuring Certificate to Connection Profile Map Policies (ASA), page 29-26
- Configuring an IPSec Proposal on a Remote Access VPN Server (ASA, PIX 7.0+ Devices), page 29-30

Configuring Certificate to Connection Profile Map Policies (ASA)

Certificate to connection profile map policies are used for enhanced certificate authentication on ASA devices in remote access IKEv1 IPSec VPNs. They are not used in remote access IKEv2 IPSec or SSL VPNs.

Certificate to connection profile map policies let you define rules to match a user’s certificate to a permission group based on specified fields. To establish authentication, you can use any field of the certificate, or you can have all certificate users share a permission group. You can match the group from the DN rules, the Organization Unit (OU) field, the IKE identity, or the peer IP address. You can use any or all of these methods.

To match user permission groups based on DN fields of the certificate, you define rules that specify the fields to match for a group and then enable each rule for that selected group. A connection profile must already exist in the configuration before you can create a rule for it.

This procedure describes how to configure a Certificate to Connection Profile Map policy for a remote client trying to connect to an ASA server device.

**Step 1**

Do one of the following:

- (Device View) Select an ASA device; then select **Remote Access VPN > IPSec VPN > Certificate to Connection Profile Maps > Policies** from the Policy selector.
- (Policy View) Select **Remote Access VPN > IPSec VPN > Certificate to Connection Profile Maps > Policies** from the Policy Type selector. Select an existing policy or create a new one.

The Certificate to Connection Profile Map Policies page opens.

**Step 2**

Select any, or all, of the following options to establish authentication and to determine to which connection profile (tunnel group) to map the client:

- **Use Configured Rules to Match a Certificate to a Group**—To use the rules defined in the Certificate to Connection Profile Maps > Rules policy. For information on configuring the rules, see Configuring Certificate to Connection Profile Map Rules (ASA), page 29-27.
- **Use Certificate Organization Unit (OU) Field to Determine the Group**—To use the organizational unit (OU) field of the client certificate.
- **Use IKE Identity to Determine the Group**—To use the IKE identity.
- **Use Peer IP address to Determine the Group**—To use the peer’s IP address.
Configuring Certificate to Connection Profile Map Rules (ASA)

If you configure certificate to connection profile maps, and select the option to Use Configured Rules to Match a Certificate to a Group (as explained in Configuring Certificate to Connection Profile Map Policies (ASA), page 29-26), you need to configure the rules required to match a user to a connection profile based on the user certificate.

To match user permission groups based on fields of the certificate, you define rules that specify the fields to match for a group and then enable each rule for that selected group. You must first define a connection profile (tunnel group) before you can create and map a rule to it.

This procedure describes how to configure the Certificate to Connection Profile Map rules and parameters for any remote client trying to connect to an ASA server device.

Tip

Certificate to connection profile map policies apply to remote access IKEv1 IPSec VPNs only. They do not apply to IKEv2 or SSL VPNs.

Before You Begin

- Make sure the connection profiles for which you are creating mapping rules has been configured on the device. See Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.

Step 1

(Device view only) With an ASA device selected, select Remote Access VPN > IPSec VPN > Certificate to Connection Profile Maps > Rules from the Policy selector.

The Certificate to Connection Profile Map Rules page is displayed. The policy has two tables:

- **Maps table (upper table)**—The upper table lists all connection profiles for which you are defining certificate to connection map rules. Each row is a profile map, which includes the name of the connection profile that is being mapped, the priority of the map (lower numbers have higher priority), and the map name. You can configure more than one map for the same connection profile.
  - To configure rules for a map, select it and then use the rules table to create, edit, and delete the rules.
  - To add a map, click the Add Row button and fill in the Map Rule Dialog Box (Upper Table), page 29-28.
  - To edit map properties (not rules), select it and click the Edit Row button.
  - To delete an entire map, select it and click the Delete Row button.

- **Rules table (lower table)**—The rules for the map selected in the upper table. You must ensure that the map is actually selected in the upper table: the group title above the rules table should say “Details for (Connection Profile Name).”
When you select a map, the table shows all rules configured for the map, including the field (subject or issuer), certificate component, matching operator, and the value that the rule is looking for. The remote user must match all configured rules in a map for the device to use the mapped connection profile.

- To add a rule, click the **Add Row** button and fill in the Map Rule Dialog Box (Lower Table), page 29-29.
- To edit a rule, select it and click the **Edit Row** button.
- To delete a rule, select it and click the **Delete Row** button.

**Step 2**

To add a rule to a map:

a. Select the map in the upper table.

   If the map does not already exist, create it by clicking the **Add Row (+)** button beneath the upper table and fill in the Map Rule dialog box for creating maps. In the dialog box, you must select the connection profile for the map, assign a relative priority between 1 and 65535 (lower numbers have higher priority), and a unique map name.

b. Ensure that the map is actually selected. Highlighting the map in the table is not sufficient. The heading above the lower table should be “Details for (Connection Profile Name),” and unless the map is new, the table should show some rules.

c. To add a new certificate to connection profile matching rule that must be satisfied in order for a remote client to connect to the device using the profile in this map, click the **Add Row (+)** button beneath the lower table. This opens the Map Rule dialog box with different fields.

   **Note**
   
   If you get the error message “Missing Settings, A value ID required for Mapping field, Please select a Mapping,” it means that you have not successfully selected a map in the upper table. Click on the desired map again.

d. From the **Field** list, select whether the rule should examine the Subject or Issuer field of the client certificate.

e. From the **Component** list, select the component of the client certificate to use for the matching rule.

f. From the **Operator** field, select how the component should be compared to the Value field: Equals (exact match is required), Contains (the entire value must appear), Does Not Equal, Does Not Contain.

g. In the **Value** field, specify the value to match, then click **OK** to save the rule.

h. Add additional rules to the map as desired.

**Step 3**

In the **Default Connection Profile** field, select the connection profile that should be used for users who do not meet any of the map rules.

**Map Rule Dialog Box (Upper Table)**

Use the Map Rule dialog box, when opened for the maps table in the upper part of the Certificate to Connection Profile Maps > Rules policy, to configure maps for which you can then configure rules in the lower table of the Rules policy. For a detailed explanation of configuring these maps and their associated rules, see Configuring Certificate to Connection Profile Map Rules (ASA), page 29-27.
Navigation Path

(Device View only) Select an ASA device; then select Remote Access VPN > IPSec VPN > Certificate to Connection Profile Maps > Rules from the Policy selector. Click the Add Row button beneath the upper table, or select a map in the upper table and click Edit Row.

Field Reference

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Profile</td>
<td>Select the connection profile for which you are creating matching rules. Clients attempting to connect to this connection profile must satisfy the associated matching rule conditions to connect to the device.</td>
</tr>
<tr>
<td>Priority</td>
<td>The priority number of the matching rule, between 1 and 65535. A lower number has a higher priority. For example, a matching rule with a priority number of 2, has a higher priority than a matching rule with a priority number of 5. If you create multiple maps, they are processed in priority order, and the first matching rule determines to which profile the user is mapped.</td>
</tr>
<tr>
<td>Map Name</td>
<td>The name of the connection profile map.</td>
</tr>
</tbody>
</table>

Map Rule Dialog Box (Lower Table)

Use the Map Rule dialog box, when opened for the rules table in the lower part of the Certificate to Connection Profile Maps > Rules policy, to configure rules for the map selected in the maps table (upper table of the Rules policy). For a detailed explanation of configuring these rules, see Configuring Certificate to Connection Profile Map Rules (ASA), page 29-27.

Navigation Path

(Device View only) Select an ASA device; then select Remote Access VPN > IPSec VPN > Certificate to Connection Profile Maps > Rules from the Policy selector. Click the Add Row button beneath the lower table, or select a rule in the lower table and click Edit Row.

Configuring an IPsec Proposal on a Remote Access VPN Server (ASA, PIX 7.0+ Devices)

This procedure describes how to create or edit an IPsec proposal for your remote access VPN server when the server is an ASA or PIX 7.0+ device. If you are configuring an IPsec proposal for IOS or PIX 6.3 devices, including Catalyst 6500/7600 devices, see Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3

An IPsec proposal is a collection of one or more crypto maps. A crypto map combines all the components required to set up IPsec security associations (SAs), including IPsec rules, transform sets, remote peers, and other parameters that might be necessary to define an IPsec SA.

When configuring an IPsec proposal, you must define the external interface through which the remote access clients connect to the server, the IKE version to use during IKE negotiation, and the encryption and authentication algorithms that protect the data in the VPN tunnel. You can also enable reverse route injection and NAT traversal.

For more information on IPsec tunnel concepts, see Understanding IPsec Proposals, page 24-16.

Related Topics
- Table Columns and Column Heading Features, page 1-44

Step 1  Do one of the following:

- (Device view) Select Remote Access VPN > IPSec VPN > IPsec Proposal (ASA/PIX 7.x) from the Policy selector.
- (Policy view) Select Remote Access VPN > IPSec VPN > IPsec Proposal (ASA/PIX 7.x) from the Policy Type selector. Select an existing policy or create a new one.
The IPsec Proposal page opens and lists the configured proposals, including the VPN endpoint, IPsec transform set, and whether reverse route injection is configured for the proposal.

**Step 2**

Do any of the following:

- To add a new IPsec proposal, click the **Add Row (+)** button and fill in the IPsec Proposal Editor dialog box. For detailed information on the available options, see **IPsec Proposal Editor (ASA, PIX 7.0+ Devices)**, page 29-31.

- To edit an existing proposal, select it and click the **Edit Row (pencil)** button.

- To delete a proposal, select it and click the **Delete Row (trash can)** button.

---

**IPsec Proposal Editor (ASA, PIX 7.0+ Devices)**

Use the IPsec Proposal Editor to create or edit an IPsec proposal for an ASA or PIX 7.0+ device.

The elements in this dialog box differ according to the selected device. The table below describes the elements on the General tab in the IPsec Proposal Editor dialog box when an ASA or PIX 7.0+ device is selected.

**Note**

For a description of the elements in the dialog box when a PIX 7.0+ or ASA device is selected is selected, see **IPsec Proposal Editor (IOS, PIX 6.3 Devices)**, page 31-4.

**Navigation Path**

- (Device view) Select **Remote Access VPN > IPSec VPN > IPsec Proposal (ASA/PIX 7.x)** from the Policy selector. Click the Add Row (+) or Edit Row (pencil) buttons.

- (Policy view) Select **Remote Access VPN > IPSec VPN > IPsec Proposal (ASA/PIX 7.x)** from the Policy Type selector. Select an existing policy or create a new one. Click the Add Row (+) or Edit Row (pencil) buttons.

Working with SSL and IKEv2 IPSec VPN Policies

Certain policies need to be configured for SSL VPNs. These policies are also used with remote access IKEv2 IPSec VPNs. The topics listed below explain these remote access VPN policies.

This section contains the following topics:

- Understanding SSL VPN Access Policies (ASA), page 29-33
- Configuring Other SSL VPN Settings (ASA), page 29-38
- Configuring SSL VPN Shared Licenses (ASA 8.2+), page 29-56

Understanding SSL VPN Access Policies (ASA)

An Access policy specifies the security appliance interfaces on which a remote access SSL or IKEv2 IPSec VPN connection profile can be enabled, the port to be used for the connection profile, Datagram Transport Layer Security (DTLS) settings, the SSL VPN session timeout and maximum number of sessions. You can also specify whether to use the AnyConnect VPN Client or AnyConnect Essentials Client.

For more information about the Anyconnect VPN Client, see Understanding SSL VPN AnyConnect Client Settings, page 29-49. The remainder of this topic explains DTLS and AnyConnect Essentials in more detail.

Datagram Transport Layer Security (DTLS)

Enabling Datagram Transport Layer Security (DTLS) allows the AnyConnect client establishing an SSL VPN connection to use two simultaneous tunnels—an SSL tunnel and a DTLS tunnel. Using DTLS avoids latency and bandwidth problems associated with SSL connections and improves the performance of real-time applications that are sensitive to packet delays. By default, DTLS is enabled when SSL VPN access is enabled on an interface. If you disable DTLS, SSL VPN connections connect with an SSL VPN tunnel only.

Note

In order for DTLS to fall back to a TLS connection, you must specify a fallback trustpoint. If you do not specify a fallback trustpoint and the DTLS connection experiences a problem, the connection terminates instead of falling back to the specified trustpoint.

AnyConnect Essentials VPN Client

AnyConnect Essentials is a separately licensed VPN client for SSL or IKEv2 IPSec, entirely configured on the adaptive security appliance, that provides the full AnyConnect capability, with the following exceptions:

- No CSD (including HostScan/Vault/Cache Cleaner)
- No clientless SSL VPN
- Optional Windows Mobile Support

The AnyConnect Essentials client provides remote end users running Microsoft Windows Vista, Windows Mobile, Windows XP or Windows 2000, Linux, or Macintosh OS X, with the benefits of a Cisco VPN client. If this feature is disabled, the full AnyConnect VPN client is used. This feature is disabled by default.
This license cannot be used at the same time as the shared license for SSL VPN.

This section contains the following topics:

- SSL VPN Access Policy Page, page 29-34
- Configuring an Access Policy, page 29-37

SSL VPN Access Policy Page

Use the SSL VPN Access Policy page to configure access parameters for your remote access SSL or IKEv2 IPsec VPN. For more information about configuring an Access policy, see Configuring an Access Policy, page 29-37.

Tip

Any trustpoints that you specify in this policy must also be selected in the Public Key Infrastructure policy. For more information, see Configuring Public Key Infrastructure Policies for Remote Access VPNs, page 24-49.

Navigation Path

- (Device View) Select Remote Access VPN > SSL VPN > Access from the Policy selector.
- (Policy View) Select Remote Access VPN > SSL VPN > Access (ASA) from the Policy Type selector. Select an existing policy or create a new one.

<td>The Access Interface table lists the interfaces that are configured for remote access SSL or IKEv2 IPsec VPN connections. The table displays the access settings for each interface: whether the interface is enabled to allow VPN access, whether DTLS is enabled, whether client certificates are required, and the trustpoints used by the interface.</td>
</tr>
<tr>
<td></td>
<td>• To configure access on an interface, click the Add row (+) button (see Access Interface Configuration Dialog Box, page 29-36).</td>
</tr>
<tr>
<td></td>
<td>• To edit access settings for an interface, select the interface and click the Edit Row (pencil) button (see Access Interface Configuration Dialog Box, page 29-36).</td>
</tr>
<tr>
<td></td>
<td>• To delete access settings for an interface, select the interface and click the Delete Row (trash can) button.</td>
</tr>
</tbody>
</table>
### Table 29-15  SSL VPN Access Policy Page (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port Number</td>
<td>The port to use for VPN sessions. The default port is 443, for HTTPS traffic. If HTTP port redirection is enabled, the default HTTP port number is 80. To specify a non-default port, the range is 1024 through 65535. Enter the port number or the name of a port list object, or click Select to select a port list object or to create a new object. <strong>Note</strong> If you change the port number, all current SSL VPN connections terminate (upon configuration deployment), and current users must reconnect.</td>
</tr>
<tr>
<td>DTLS Port Number</td>
<td>The UDP port to use for DTLS connections. The default port is 443. For details about DTLS, see Understanding SSL VPN Access Policies (ASA), page 29-33. Enter the port number or the name of a port list object, or click Select to select a port list object or to create a new object.</td>
</tr>
<tr>
<td>Fallback Trustpoint</td>
<td>The trustpoint (Certificate Authority, or CA server) to use for interfaces that do not have an assigned trustpoint. Enter the name of a PKI enrollment object, or click Select to select the object from a list or to create a new object.</td>
</tr>
<tr>
<td>Default Idle Timeout</td>
<td>The amount of time, in seconds, that an SSL or IKEv2 IPSec VPN session can be idle before the security appliance terminates it. This value applies only if the Idle Timeout value in the group policy for the user is set to zero (0), which means there is no timeout value; otherwise the group policy Idle Timeout value takes precedence over the timeout you configure here. The minimum value you can enter is 60 seconds (1 minute). The default is 30 minutes (1800 seconds). The maximum is 24 hours (86400 seconds). We recommend that you set this attribute to a short time period. This is because a browser set to disable cookies (or one that prompts for cookies and then denies them) can result in a user not connecting but nevertheless appearing in the sessions database. If the Simultaneous Logins attribute for the group policy is set to one, the user cannot log back in because the database indicates that the maximum number of connections already exists. Setting a low idle timeout removes such phantom sessions quickly, and lets a user log in again.</td>
</tr>
</tbody>
</table>
| Max Session Limit | The maximum number of SSL or IKEv2 IPSec VPN sessions allowed. Be aware that the different ASA models have different maximum session limits:  
  - ASA 5505—25.  
  - ASA 5510—250.  
  - ASA 5520—750.  
  - ASA 5540—2500.  
  - ASA 5550, 5585-X with SSP-10—5000.  
  - ASA 5580, 5585-X (other models)—10,000. |

Configuring an Access Policy

This procedure describes how to configure an Access policy on an ASA device. Access policies are required for remote access SSL and IKEv2 IPSec VPN connections. For more information about access policies, see Understanding SSL VPN Access Policies (ASA), page 29-33.

Step 1
Do one of the following:

- (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Access from the Policy selector.
- (Policy view) Select Remote Access VPN > SSL VPN > Access (ASA) from the Policy Type selector. Select an existing policy or create a new one.

The Access page opens. For a description of the elements on this page, see SSL VPN Access Policy Page, page 29-34.

Step 2
In the interface table at the top of the policy, configure all of the interfaces on which you will allow remote access SSL or IKEv2 IPSec VPN connections:

- To add an interface, click the Add Row (+) button beneath the table and fill in the Add Access Interface Configuration dialog box. You must specify the interface name (or an interface role object that identifies the desired interfaces) and whether to allow access on the interface.

  You can also specify the PKI enrollment object that identifies the Certificate Authority (CA) server trustpoint for the interface (and a load balancing trustpoint if you use load balancing), whether to enable DTLS connections, and whether to require that the client have a valid certificate to complete a connection. For details about the options, see Access Interface Configuration Dialog Box, page 29-36.

- To edit the settings for an interface, select it and click the Edit Row (pencil) button.

- To delete an interface, select it and click the Delete Row button. Keep in mind that you can edit the interface settings to disallow access, so you should delete an interface only if you want to permanently remove it from VPN use.

Step 3
Configure the remaining settings. The settings are described in detail in SSL VPN Access Policy Page, page 29-34. The following are the settings that are of particular interest:

- **Fallback Trustpoint**—The Certificate Authority (CA) server trustpoint to use if an interface does not have a trustpoint configured in the table. Enter the name of a PKI enrollment object, or click Select to select one or to create a new object.
• **Allow Users to Select Connection Profile in Portal Page**—If you have multiple tunnel groups, selecting this option allows the user to select the correct tunnel group during login. You must select this option for IKEv2 IPSec VPNs.

• **Enable AnyConnect Access**—The AnyConnect VPN client is a full client; you must enable AnyConnect access if you want to allow full client access to the VPN. You must select this option for IKEv2 IPSec VPNs.

  For more information about AnyConnect, including AnyConnect Essentials, see [Understanding SSL VPN AnyConnect Client Settings](#), page 29-49.

• **Enable AnyConnect Essentials**—Select this option if you are using AnyConnect Essentials clients, which you can use with remote access SSL or IKEv2 IPSec VPNs.

### Step 4

Any trustpoints that you specify in this policy must also be selected in the **Public Key Infrastructure** policy. For more information, see [Configuring Public Key Infrastructure Policies for Remote Access VPNs](#), page 24-49.

---

## Configuring Other SSL VPN Settings (ASA)

The SSL VPN Other Settings policy for ASA devices defines settings that include caching, content rewriting, character encoding, proxy and proxy bypass definitions, browser plug-ins, AnyConnect client images and profiles, Kerberos Constrained Delegation, and some other advanced settings.

To configure the Other Settings policy, do one of the following:

- (Device View) Select **Remote Access VPN > SSL VPN > Other Settings** from the Policy selector.
- (Policy View) Select **Remote Access VPN > SSL VPN > Other Settings (ASA)** from the Policy Type selector. Select an existing policy or create a new one.

You can then configure the settings on the following tabs:

- **Performance tab**—To configure caching to improve SSL VPN performance. See [Configuring SSL VPN Performance Settings (ASA)](#), page 29-39.

- **Content Rewrite tab**—To create rules that permit users to browse certain sites and applications without going through the security appliance itself. See [Configuring SSL VPN Content Rewrite Rules (ASA)](#), page 29-40.

- **Encoding tab**—To configure non-default encoding for web pages delivered from CIFS servers. Encoding is normally determined by the remote user’s browser. See [Configuring SSL VPN Encoding Rules (ASA)](#), page 29-42.

- **Proxy tab**—To define HTTP or HTTPS proxy servers, if your network requires them, and proxy bypass rules. See [Configuring SSL VPN Proxies and Proxy Bypass (ASA)](#), page 29-44.

- **Plug In tab**—To define browser plug-ins, which are separate programs that a web browser invokes to perform a dedicated function. See [Configuring SSL VPN Proxies and Proxy Bypass (ASA)](#), page 29-44.

- **Client Settings tab**—To configure AnyConnect client images and profiles for downloading to clients. See the following topics:
  - [Understanding SSL VPN AnyConnect Client Settings](#), page 29-49
  - [Configuring SSL VPN AnyConnect Client Settings (ASA)](#), page 29-50
• Microsoft KCD Server—To configure Kerberos Constrained Delegation (KCD) for use with clientless SSL VPN connections. See the following topics:
  – Understanding Kerberos Constrained Delegation (KCD) for SSL VPN (ASA), page 29-52
  – Configuring Kerberos Constrained Delegation (KCD) for SSL VPN (ASA), page 29-54
• Advanced tab—To configure the memory, on-screen keyboard, and internal password features. See Configuring SSL VPN Advanced Settings (ASA), page 29-55.

Tip
You must also configure a connection profile policy on the device. See Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.

Configuring SSL VPN Performance Settings (ASA)

Caching enhances SSL VPN performance. It stores frequently reused objects in the system cache, which reduces the need to perform repeated rewriting and compressing of content. It reduces traffic between SSL VPN and both the remote servers and end-user browsers, with the result that many applications run much more efficiently.

This procedure describes how to enable caching on your ASA security appliance.

Related Topics
• Configuring Other SSL VPN Settings (ASA), page 29-38

Step 1
Do one of the following:
• (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Other Settings from the Policy selector. Click the Performance tab if it is not already selected.
• (Policy view) Select Remote Access VPN > SSL VPN > Other Settings (ASA) from the Policy Type selector. Select an existing policy or create a new one. Click the Performance tab if it is not already selected.

Step 2
Select Enable to enable caching on the security appliance.
If you deselect this option, the cache settings configured on the security appliance do not take effect.

Step 3
Configure the following options:
• Minimum Object Size—The minimum size of an HTTP object that can be stored in the cache on the security appliance, in kilobytes. The range is 0-10,000 KB. The default is 0 KB.
• Maximum Object Size—The maximum size of an HTTP object that can be stored in the cache on the security appliance, in kilobytes. The range is 0-10,000 KB. The default is 1000 KB. The maximum size must be larger than the minimum size.
• Last Modified Factor—An integer to set a revalidation policy for caching objects that have only the last-modified timestamp, and no other server-set expiration values. The range is 1-100. The default is 20.

The Expires response from the origin web server to the security appliance request, which indicates the time that the response expires, also affects caching. This response header indicates the time that the response becomes stale and should not be sent to the client without an up-to-date check (using a conditional GET operation).

The security appliance can also calculate an expiration time for each web object before it is written to disk. The algorithm to calculate an object’s cache expiration date is as follows:
Expiration date = (Today’s date - Object’s last modified date) * Freshness factor

After the expiration date has passed, the object is considered stale and subsequent requests causes a fresh retrieval of the content by the security appliance. Setting the last modified factor to zero is equivalent to forcing an immediate revalidation, while setting it to 100 results in the longest allowable time until revalidation.

- **Expiration Time**—The amount of time (in minutes) that the security appliance caches objects without revalidating them. The range is 0-900 minutes. The default is one minute.

  Revalidation consists of rejecting the objects from the origin server before serving the requested content to the client browser when the age of the cached object has exceeded its freshness lifetime. The age of a cached object is the time that the object has been stored in the security appliance’s cache without the security appliance explicitly contacting the origin server to check if the object is still fresh.

- **Cache Static Content**—Whether to cache static content on the security appliance. Each web page can include static and dynamic objects. The security appliance caches individual static objects, such as image files (*.gif, *.jpeg), java applets (.js), and cascading style sheets (*.css).

**Configuring SSL VPN Content Rewrite Rules (ASA)**

SSL VPN processes application traffic through a content transformation/rewriting engine that includes advanced elements (such as, JavaScript, VBScript, Java, and multi-byte characters) to proxy HTTP traffic depending on whether the user is using an application within or independently of an SSL VPN device.

If you do not want some applications and web resources, such as public web sites, to go through the security appliance, you can create rewrite rules that permit users to browse certain sites and applications without going through the security appliance itself. This is similar to split tunneling in an IPsec VPN connection.

In the Content Rewrite tab of the SSL VPN Other Settings page, you can configure multiple content rewrite rules. The Content Rewrite tab lists all applications for which content rewrite is enabled or disabled.

The security appliance searches rewrite rules by order number, starting with the lowest, and applies the first rule that matches.

This procedure shows you how to create or edit content rewrite rules.

**Related Topics**

- [Configuring Other SSL VPN Settings (ASA), page 29-38](#)

**Step 1**

Do one of the following:

- (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Other Settings from the Policy selector.

- (Policy view) Select Remote Access VPN > SSL VPN > Other Settings (ASA) from the Policy Type selector. Select an existing policy or create a new one.

**Step 2**

On the Other Settings page, click the Content Rewrite tab. The Content Rewrite tab displays all applications for which content rewrite is enabled or disabled.
The security appliance searches rewrite rules by order number, starting with the lowest, and applies the first rule that matches. The resource mask defines the application string to which the rule is matched. If a rule does not have a number, it is evaluated after all of the numbered rules.

**Step 3**

Do any of the following:

- To add a rule, click the **Add Row** button beneath the table and fill in the Add Content Rewrite dialog box. The options are described in detail in Add/Edit Content Rewrite Dialog Box, page 29-41.
- To edit a rule, select it, click the **Edit Row** button, and make your changes in the Edit Content Rewrite dialog box.
- To delete a rule, select it and click the **Delete Row** button. You are asked to confirm the deletion.

**Add/Edit Content Rewrite Dialog Box**

Use the Add or Edit Content Rewrite dialog box to configure the rewriting engine that includes advanced elements such as JavaScript, VBScript, Java, and multi-byte characters to proxy HTTP traffic over a SSL VPN connection. For more information about content rewrite rules, see Configuring SSL VPN Content Rewrite Rules (ASA), page 29-40.

**Navigation Path**

From the Content Rewrite tab of the SSL VPN Other Settings policy for ASA devices, click the **Add Row** button, or select a rule and click the **Edit Row** button. For detailed information on opening the tab, see Configuring SSL VPN Content Rewrite Rules (ASA), page 29-40.

<td><strong>Element</strong></td>
</tr>
<tr>
<td>Enable</td>
</tr>
<tr>
<td>Rule Number</td>
</tr>
<tr>
<td>Rule Name</td>
</tr>
</tbody>
</table>
Use the Encoding tab of the SSL VPN Other Settings page to specify the character set to encode in SSL VPN portal pages to be delivered to remote users. By default, the encoding type set on the remote browser determines the character set for SSL VPN portal pages, so you need to set the character encoding only if it is necessary to ensure proper encoding on the browser.

Character encoding is the pairing of raw data (such as 0’s and 1’s) with characters to represent the data. The language determines the character encoding method to use. Some languages use the same method, while others do not. Usually, the geographic region determines the default encoding method used by the browser, but the remote user can change this. The browser can also detect the encoding specified on the page, and render the document accordingly.

The encoding attribute lets you specify the value of the character encoding method in the SSL VPN portal page to ensure that the browser renders it properly, regardless of the region in which the user is using the browser, or any changes made to the browser.

The character encoding attribute is a global setting that, by default, all SSL VPN portal pages inherit. However, you can override the file-encoding attribute for Common Internet File System (CIFS) servers that use character encoding that differs from the value of the character-encoding attribute. You can use different file-encoding values for CIFS servers that require different character encodings.

The SSL VPN portal pages downloaded from the CIFS server to the SSL VPN user encode the value of the SSL VPN file-encoding attribute identifying the server, or if one does not, they inherit the value of the character encoding attribute. The remote user’s browser maps this value to an entry in its character encoding set to determine the proper character set to use. The SSL VPN portal pages do not specify a value if SSL VPN configuration does not specify a file encoding entry for the CIFS server and the character encoding attribute is not set. The remote browser uses its own default encoding if the SSL VPN portal page does not specify the character encoding, or if it specifies a character encoding value that the browser does not support.
In the Encoding tab of the SSL VPN Global Settings page, you can view the currently configured character sets associated with the CIFS server to be encoded in the portal pages. From this tab, you can create or edit the character sets, as described in the following procedure.

**Related Topics**
- Configuring Other SSL VPN Settings (ASA), page 29-38

**Step 1**
Do one of the following:
- (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Other Settings from the Policy selector.
- (Policy view) Select Remote Access VPN > SSL VPN > Other Settings (ASA) from the Policy Type selector. Select an existing policy or create a new one.

**Step 2**
On the Other Settings page, click the Encoding tab. The Encoding tab displays the default encoding and a list of CIFS servers for which encoding rules are configured.

**Step 3**
From the Global SSL VPN Encoding Type list, select the attribute that determines the character encoding that all SSL VPN portal pages inherit, except for those from the CIFS servers listed in the table.

**Note**
If you choose none or specify a value that the browser on the SSL VPN client does not support, the browser uses its own default encoding. The default global encoding is none.

You can select from the following encoding types:
- big5
- gb2312
- ibm-850
- iso-8859-1
- shift_jis

**Note**
If you are using Japanese Shift_jis Character encoding, click Do not specify in the Font Family area of the associated Select Page Font pane to remove the font family.

- unicode
- windows-1252
- none

**Step 4**
Do any of the following:
- To add a rule, click the Add Row button beneath the table and configure the following settings in the Add File Encoding dialog box:
  - CIFS Server IP, CIFS Server Host—Select one of these options to specify the CIFS server either by IP address or hostname. If you select IP address, you can either enter the IP address or the name of a network/host object that specifies one or more individual IP addresses.
    If you specify a hostname, the security appliance retains the case you specify, although it ignores the case when matching the name to a server.
  - Encoding Type—Select the encoding type. The options are the same as for the global setting described above.
To edit a rule, select it, click the **Edit Row** button, and make your changes in the Edit File Encoding dialog box.

To delete a rule, select it and click the **Delete Row** button. You are asked to confirm the deletion.

### Configuring SSL VPN Proxies and Proxy Bypass (ASA)

Use the Proxy tab of the SSL VPN Other Settings page to configure the security appliance to terminate HTTPS connections and forward HTTP/HTTPS requests to HTTP and HTTPS proxy servers. On this tab, you can also configure the security appliance to perform minimal content rewriting and to specify the types of content to rewrite—external links, XML, or neither.

The security appliance can terminate HTTPS connections and forward HTTP/HTTPS requests to HTTP and HTTPS proxy servers. These servers act as intermediaries between users and the Internet. Requiring all Internet access through a server you control provides another opportunity for filtering to assure secure Internet access and administrative control.

**Note**
The HTTP/HTTPS proxy does not support connections to personal digital assistants.

You can specify a proxy auto-configuration (PAC) file to download from an HTTP proxy server; however, you cannot use proxy authentication when specifying the PAC file.

You can configure the security appliance to use proxy bypass when applications and web resources work better with the content rewriting this feature provides. Proxy bypass is an alternative method of content rewriting that makes minimal changes to the original content. It is useful with custom web applications.

You can configure multiple proxy bypass entries. The order in which you configure them is unimportant. The interface and path mask or interface and port uniquely identify a proxy bypass rule.

If you configure proxy bypass using ports rather than path masks, depending on your network configuration, you might need to change your firewall configuration to allow these ports access to the security appliance. Use path masks to avoid this restriction. Be aware, however, that path masks can change, so you might need to use multiple path mask statements to exhaust the possibilities.

This procedure shows you how to define proxies and proxy bypass rules for your SSL VPN.

**Related Topics**
- Configuring Other SSL VPN Settings (ASA), page 29-38

**Step 1**
Do one of the following:

- *(Device view)* With an ASA device selected, select **Remote Access VPN > SSL VPN > Other Settings** from the Policy selector.

- *(Policy view)* Select **Remote Access VPN > SSL VPN > Other Settings (ASA)** from the Policy Type selector. Select an existing policy or create a new one.

**Step 2**
On the Other Settings page, click the **Proxy** tab. The Proxy tab displays any currently defined proxies and proxy rules.

**Step 3**
From the **Proxy Type** field, select the type of external proxy server to use for SSL VPN connections:

- **HTTP/HTTPS Proxy Server**—To specify proxy servers to handle HTTP or HTTPS requests.
Chapter 29  Managing Remote Access VPNs on ASA and PIX 7.0+ Devices

Working with SSL and IKEv2 IPSec VPN Policies

- **Proxy Using PAC**—To specify a proxy auto-configuration (PAC) file to download from an HTTP proxy server to the user’s browser. Once downloaded, the PAC file uses a JavaScript function to identify a proxy for each URL.

  If you select this option, enter the URL for the PAC file in the **Specify Proxy Auto Config file URL** field. The URL must begin with **http://** or the security appliance will not use the PAC file.

**Step 4**

If you select HTTP/HTTPS Proxy Server for the proxy type, configure the settings for the HTTP and HTTPS proxy servers. There are separate settings for the HTTP and HTTPS server, allowing you to use different servers, or to specify only one type of proxy. Configure the following options:

- **Enable HTTP Proxy Server, Enable HTTPS Proxy Server**—Select either or both of these options to configure the proxy server.

- **HTTP Proxy Server, HTTPS Proxy Server**—Enter the IP address, or the name of a network/host object that contains the single proxy server’s IP address, for each type of proxy server you are configuring. You can click **Select** to select the object from a list or to create a new object.

  The default ports are 80 for HTTP and 443 for HTTPS.

- **HTTP Proxy Port, HTTPS Proxy Port**—Enter the port on the proxy server to which HTTP or HTTPS requests will be forwarded. You can also enter the name of a port list object that defines the port, or click **Select** to select an object or to create a new one.

- **Exception Address List**—A URL or a comma-delimited list of several URLs to exclude from those that should be sent to the HTTP or HTTPS proxy servers. The string does not have a character limit, but the entire command cannot exceed 512 characters. You can specify literal URLs or use the following wildcards:
  - * to match any string, including slashes (/) and periods (.). You must accompany this wildcard with an alphanumeric string.
  - ? to match any single character, including slashes and periods.
  - [x-y] to match any single character in the range of x and y, where x represents one character and y represents another character in the ANSI character set.
  - [!x-y] to match any single character that is not in the range.

- **Authentication User Name, Authentication Password, Confirm**—If the proxy server requires user authentication, enter a valid user name and password.

**Step 5**

If necessary, configure proxy bypass rules in the Proxy Bypass table at the bottom of the tab. Proxy bypass rules specify the ASA interface, port, and target URL configured for proxy bypass. Do any of the following:

- To create a proxy bypass rule, click the **Add Row** button and fill in the Add Proxy Bypass dialog box. For specific information on the attributes of a proxy bypass rule, see **Add or Edit Proxy Bypass Dialog Box, page 29-46**.

- To edit a proxy bypass rule, select the rule and click the **Edit Row** button.

- To delete a rule, select it and click the **Delete Row** button. You are asked to confirm the deletion.

Tip  If you configure proxy bypass rules, you must also configure the SSL VPN Access policy. For more information, see **Configuring an Access Policy, page 29-37**.
Add or Edit Proxy Bypass Dialog Box

Use the Add or Edit Proxy Bypass dialog box to set proxy bypass rules when the security appliance should perform little or no content rewriting.

Navigation Path

From the Proxy tab of the SSL VPN Other Settings policy for ASA devices, click the Add Row button, or select a rule and click the Edit Row button. For detailed information on opening the tab, see Configuring SSL VPN Encoding Rules (ASA), page 29-42.

Field Reference

Table 29-18  Add or Edit Proxy Bypass Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
<td>The interface on the security appliance that is used for proxy bypass. Enter the name of the interface or the interface role object, or click Select to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Bypass On Port</td>
<td>Select this option to use a port number for proxy bypass. Valid port numbers are 20000-21000. Enter the ports or the name of a port list object, or click Select to select an object or to create a new one. Note: If you configure proxy bypass using ports rather than path masks, depending on your network configuration, you might need to change your firewall configuration to allow these ports access to the security appliance. Use path masks to avoid this restriction.</td>
</tr>
</tbody>
</table>
| Bypass Matching Specific Pattern | Select this option to use a URL path mask to match for proxy bypass. A path is the text in a URL that follows the domain name. For example, in the URL www.mycompany.com/hrbenefits, hrbenefits is the path. You can use the following wildcards:  
• *—Matches everything. You cannot use this wildcard by itself. It must accompany an alphanumeric string.  
• ?—Matches any single character.  
• [x-y]—Matches any character in the sequence.  
• ![x-y]—Matches any character not in the sequence. The maximum is 128 bytes. Note: Path masks can change, so you might need to use multiple path mask statements to exhaust the possibilities. |
| URL                   | Select the http or https protocol, then enter a URL to which you want to apply proxy bypass. URLs used for proxy bypass allow a maximum of 128 bytes. The port for HTTP is 80 and for HTTPS it is 443, unless you specify another port. |
| Rewrite XML           | Whether to rewrite XML sites and applications to be bypassed by the security appliance.                                                        |
| Rewrite Hostname      | Whether to rewrite external links to be bypassed by the security appliance.                                                                  |
Configuring SSL VPN Browser Plug-ins (ASA)

A browser plug-in is a separate program that a web browser invokes to perform a dedicated function, such as connect a client to a server within the browser window. The security appliance lets you import plug-ins for download to remote browsers in clientless SSL VPN sessions.

Cisco redistributes the following open-source, Java-based components to be accessed as plug-ins for web browsers in Clientless SSL VPN sessions. Cisco tests the plug-ins it redistributes, and in some cases, tests the connectivity of plug-ins we cannot redistribute. These files are available in the \objects\sslvpn\plugin folder in the product installation folder (usually C:\Program Files\CSCOpx) on the Security Manager server. The actual file names include release numbers:

- **ssh-plugin.jar**—The Secure Shell-Telnet plug-in lets the remote user establish a Secure Shell or Telnet connection to a remote computer. The web site containing the source of the redistributed plug-in is [http://javassh.org/](http://javassh.org/).

  **Note** The ssh-plugin.jar provides support for both SSH and Telnet protocols. The SSH client supports SSH Version 1.0.

- **vnc-plugin.jar**—The Virtual Network Computing plug-in lets the remote user use a monitor, keyboard, and mouse to view and control a computer with remote desktop sharing turned on. The web site containing the source of the redistributed plug-in is [http://www.tightvnc.com](http://www.tightvnc.com).

  **Note** Per the GNU General Public License (GPL), Cisco redistributes plug-ins without having made any changes to them. Per the GPL, Cisco cannot directly enhance these plug-ins.

The security appliance does the following when you install a plug-in onto the flash device:

- (Cisco-distributed plug-ins only) Unpacks the jar file specified in the URL.
- Writes the file to the csco-config/97/plugin directory on the security appliance file system.
- Enables the plug-in for all future clientless SSL VPN sessions, and adds a main menu option and an option to the drop-down menu next to the Address field of the portal page.

When the user in a clientless SSL VPN session clicks the associated menu option on the portal page, the portal page displays a window to the interface and displays a help pane. The user can select the protocol displayed in the drop-down menu and enter the URL in the Address field to establish a connection.

  **Note** Some Java plug-ins might report a status of connected or online even when a session to the destination service is not set up. The open-source plug-in reports the status, not the security appliance.

In the Plug-in tab of the SSL VPN Global Settings page, you can view the currently configured browser plug-ins for clientless SSL VPN browser access. From this tab, you can create or edit the plug-in files, as described in the following procedure.
Plug-in Requirements and Restrictions

Clientless SSL VPN must be enabled on the security appliance to provide remote access to the plug-ins. The minimum access rights required for remote use belong to the guest privilege mode. The plug-ins automatically install or update the Java version required on the remote computer. A stateful failover does not retain sessions established using plug-ins. Users must reconnect following a failover.

Before installing a plug-in, prepare the security appliance as follows:

- Make sure clientless SSL VPN is enabled on an interface on the security appliance.
- Install an SSL certificate onto the security appliance interface to which remote users use a fully-qualified domain name (FQDN) to connect.

**Note**
Do not specify an IP address as the common name (CN) for the SSL certificate. The remote user attempts to use the FQDN to communicate with the security appliance. The remote PC must be able to use DNS or an entry in the System32\drivers\etc\hosts file to resolve the FQDN.

Related Topics

- Understanding and Managing SSL VPN Support Files, page 28-5
- Configuring Other SSL VPN Settings (ASA), page 29-38

---

**Step 1**
Do one of the following:

- (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Other Settings from the Policy selector.
- (Policy view) Select Remote Access VPN > SSL VPN > Other Settings (ASA) from the Policy Type selector. Select an existing policy or create a new one.

**Step 2**
On the Other Settings page, click the **Plug-in** tab. The Plug-in tab lists all configured plug-ins, including the type of plug-in and the name of the File policy object that defines the actual plug-in file.

**Step 3**
Do any of the following:

- To add a plug-in, click the **Add Row** button beneath the table and fill in the Add Plug-In Entry dialog box as follows:
  - **Plug-in**—Select the type of plug-in that you are adding:
    - Remote Desktop (RDP) or RDP2—For Remote Desktop Protocol services.
    - Secure Shell (SSH), Telnet—For Secure Shell and Telnet services.
    - VNC—For Virtual Network Computing services.
    - Citrix (ICA)—For Citrix MetaFrame services.
    - Post—For post services.
  - **Plug-in File**—The name of the File policy object that defines the plug-in file. Enter the name of the File object or click **Select** to select an object or to create a new one. For more information on creating File Objects, see Add and Edit File Object Dialog Boxes, page 32-22.
- To edit a plug-in, select it, click the **Edit Row** button, and make your changes in the Edit Plug-In Entry dialog box.
- To delete a plug-in, select it and click the **Delete Row** button. You are asked to confirm the deletion.
Understanding SSL VPN AnyConnect Client Settings

The Cisco AnyConnect VPN Client provides secure SSL and IKEv2 IPsec connections to the security appliance for remote users. The client gives remote users the benefits of an SSL or IKEv2 IPsec VPN client without the need for network administrators to install and configure clients on remote computers.

IKEv2 IPsec connections require AnyConnect 3.0 or higher clients.

Without a previously installed client, remote users enter the IP address in their browser of an interface configured to accept SSL or IKEv2 IPsec VPN connections. Unless the security appliance is configured to redirect http:// requests to https://, users must enter the URL in the form https://<address>.

After the user enters the URL, the browser connects to that interface and displays the login screen. If the user satisfies the login authentication, and the security appliance identifies the user as requiring the client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure connection and either remains or uninstalls itself (depending on the security appliance configuration) when the connection terminates.

In the case of a previously installed client, when the user authenticates, the security appliance examines the revision of the client and upgrades the client as necessary.

When the client negotiates a connection with the security appliance, it connects using Transport Layer Security (TLS), and optionally, Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

The AnyConnect client can be downloaded from the security appliance, or it can be installed manually on the remote workstation by the system administrator. For more information about installing the client manually, see the Cisco AnyConnect Secure Mobility Client Administrator Guide. AnyConnect documentation is available at http://www.cisco.com/en/US/products/ps10884/tsd_products_support_series_home.html. You can find general information about AnyConnect at http://www.cisco.com/go/anyconnect.

The security appliance downloads the client based on the group policy or username attributes of the user establishing the connection. You can configure the security appliance to automatically download the client, or you can configure it to prompt the remote user about whether to download the client. In the latter case, if the user does not respond, you can configure the security appliance to either download the client after a timeout period or present the login page.

AnyConnect Client Profiles

An AnyConnect client profile is a group of configuration parameters, stored in an XML file, that the client uses to configure the connection entries that appear in the client user interface. These parameters (XML tags) include the names and addresses of host computers and settings to enable additional client features.

The AnyConnect client installation includes a profile template, named AnyConnectProfile.tmpl, that you can edit with a text editor and use as a basis to create other profile files. You can also set advanced parameters that are not available through the user interface. The installation also includes a complete XML schema file, named AnyConnectProfile.xsd.

You can add the profile to the Client Settings tab in the Other Settings policy to have it loaded onto the security appliance and subsequently downloaded to the client workstations based on group policies and username attributes.

Configuring SSL VPN AnyConnect Client Settings (ASA)

This procedure shows you how to define SSL and IKEv2 IPsec VPN client images and profiles. For a detailed explanation of AnyConnect images and profiles, see Understanding SSL VPN AnyConnect Client Settings, page 29-49.

Tip
Ensure that you add AnyConnect images of the required releases. For example, if you are configuring an IKEv2 IPsec VPN, you must include an AnyConnect 3.0 or higher image. In general, the image versions must support the features you are deploying in the remote access VPN.

Related Topics
- Understanding and Managing SSL VPN Support Files, page 28-5
- Configuring Other SSL VPN Settings (ASA), page 29-38

Step 1
Do one of the following:
- (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Other Settings from the Policy selector.
- (Policy view) Select Remote Access VPN > SSL VPN > Other Settings (ASA) from the Policy Type selector. Select an existing policy or create a new one.

Step 2
On the Other Settings page, click the Client Settings tab. The tab has two tables listing the configured AnyConnect clients and profiles separately.

The AnyConnect images include an order number. The security appliance downloads portions of the AnyConnect images to the remote computer until it achieves a match with the operating system, starting with the highest order number. Therefore, you should give the highest number to the image used by the most commonly-encountered operating system.

Because mobile users have slower connection speeds, you should load the AnyConnect image for Windows Mobile at the top of the list. Alternatively, you can decrease the connection time by specifying the regular expression Windows CE to match the user agent on Windows Mobile devices. When the browser on the mobile device connects to the ASA, it includes the User-Agent string in the HTTP header. The ASA, receiving the string, immediately downloads AnyConnect for Windows Mobile without ascertaining whether the other AnyConnect images are appropriate.

Step 3
To add an AnyConnect client image or make changes to the existing list, do any of the following:
- To add an AnyConnect image, click the Add Row button beneath the table and fill in the Add AnyConnect Client Image dialog box. You need to specify the name of the File object that defines the image and the priority order of the image. You can also specify a regular expression for the connecting client to speed up the download. For detailed information about the options, see Add/Edit AnyConnect Client Image Dialog Box, page 29-51.
- To edit an image, select it, click the Edit Row button, and make your modifications in the Edit AnyConnect Client Image dialog box.
- To delete an image, select it and click the Delete Row button. You are asked to confirm the deletion.
Step 4  To add an AnyConnect profile or make changes to the existing list, do any of the following:

- To add an AnyConnect profile, click the **Add Row** button beneath the table and configure these options in the Add AnyConnect Client Profile dialog box:
  - **AnyConnect Profile Name**—The name of the profile.
    
    To use this profile, ensure that you specify the profile name in an ASA Group Policy object assigned to the security appliance (in the Full Client settings page as described in ASA Group Policies SSL VPN Full Client Settings, page 32-12). Configure the ASA Group Policy object through the remote access Connection Profiles policy for the device as described in Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.
  - **AnyConnect Client Profile**—The name of the File object that identifies the Anyconnect client profile XML file. Click **Select** to select the object or to create a new one. For more information about File objects, see Add and Edit File Object Dialog Boxes, page 32-22.

- To edit a profile, select it, click the **Edit Row** button, and make your modifications in the Edit AnyConnect Client Profile dialog box.

- To delete a profile, select it and click the **Delete Row** button. You are asked to confirm the deletion.

**Add/Edit AnyConnect Client Image Dialog Box**

Use the Add or Edit AnyConnect Client Image dialog box to create or edit a package file as the client image, and establish the order that the security appliance downloads the image to the remote workstation.

**Navigation Path**

From the Client Settings tab of the SSL VPN Other Settings policy for ASA devices, click the **Add Row** button for the AnyConnect Client Image table, or select an image and click the **Edit Row** button. For detailed information on opening the tab, see Configuring SSL VPN AnyConnect Client Settings (ASA), page 29-50.

**Related Topics**

Understanding Kerberos Constrained Delegation (KCD) for SSL VPN (ASA)

There are many ways to protect network resources through the use of authentication. Many organizations want to use Kerberos to protect certain web applications while using other authentication techniques, such as username and password, digital certificates, RSA SecureID, or SmartCards, to control access to an SSL VPN. However, a restriction in the Kerberos protocol prevents Kerberos authentication if the user has already used another technique to authenticate to the VPN.

Microsoft overcomes this limitation in Kerberos starting with Windows Server 2003. Using protocol transition and constrained delegation, the ASA can authenticate to the Kerberos Key Distribution Center (KCD) on the Windows domain controller and obtain impersonate tickets for users who have authenticated to the ASA using non-Kerberos protocols. The ASA can use the impersonate ticket to obtain other Kerberos service tickets for remote users.

To configure the domain controller so that Kerberos constrained delegation works, you must do the following:

- Each instance of a service that uses Kerberos authentication must have a service principle name (SPN) defined so that clients can identify it on the network. Register the SPN in the Active Directory Service-Principal-Name attribute of the Windows account under which the instance of the service is running. When a service needs to authenticate to another service running on a specific computer, it uses that service’s SPN to differentiate it from other services running on that computer.

  The SPN syntax is `service_class/host_name:port`. where:
  - `service_class` identifies the service. It can be a built-in service, such as http, or a user defined service.
  - `host_name` identifies the fully-qualified domain name or NetBIOS name of the server that hosts the service, but it cannot be an IP address.
  - `port` identifies the port on which the service runs. You can omit the port if you use the default service port.

- Create a service account username and password that the ASA can use. Configure the account to allow Kerberos constrained delegation to any authentication protocol. In addition, the user account must not be marked as a sensitive account that cannot be delegated.
To configure the ASA to allow KCD, once the ASA joins the domain, an entry should appear under the Users and Computers list on the domain controller for the ASA. In the Properties dialog box, on the Delegation tab, select \textbf{Trust this computer for delegation to specified services only}, and then select \textbf{Use any authentication protocol}. In the table of authorized services, add all services for which the ASA is delegated for authentication on behalf of users.

\textbf{Tip}

For definitive information on configuring this feature on the Windows domain controller, refer to the Microsoft documentation.

For the ASA to use Kerberos constrained delegation, you must configure the ASA as described in \textbf{Configuring Kerberos Constrained Delegation (KCD) for SSL VPN (ASA), page 29-54}. The feature is available on ASA Software release 8.4 and higher only.

Following is an example that explains how Kerberos constrained delegation works with a clientless SSL VPN hosted on an ASA.

\textbf{Figure 29-1} \hspace{1em} \textbf{Kerberos Constrained Delegation Example}

After verifying the identity of an SSL VPN user with the configured authentication mechanism, the ASA uses protocol transition to switch to the Kerberos protocol for authentication on behalf of the user and then sends a Kerberos service ticket instead of the user’s credentials to a published Web server that accepts Kerberos for authentication. Following are the steps:

1. An SSL VPN user session is authenticated by the ASA using the authentication mechanism configured for the user. For example, in case of Smartcard credentials, the ASA extracts the required information (the user’s principle name) from the digital certificate and performs LDAP authorization against Windows Active Directory.

2. After successful authentication, the user logs into the ASA SSL VPN portal page. The VPN user accesses a web service by entering a URL in the portal page or by clicking on a bookmark. If the access requires authentication, the server challenges the ASA for credentials and along with the challenge sends a list of authentication mechanisms supported by the server. Based on the HTTP headers in the challenge, the ASA deduces whether the server requires Kerberos authentication. If connecting to a backend server requires Kerberos authentication, then the ASA requests an impersonate ticket, for itself on behalf the user, from the KDC.
3. The KDC returns the requested tickets to the ASA. Even though these tickets are passed to the ASA, they contain the user’s authorization data.

**Note** These first steps comprise protocol transition; after these steps, a user who authenticated to the ASA using a non-Kerberos authentication protocol is transparently authenticated to the KDC using Kerberos.

4. The ASA now requests a service ticket from the KDC for the specific service that the user wants to access. The service ticket request contains the SPN (the unique identifier) of the service.

5. The KDC returns a service ticket for the specific service to the ASA.

6. The ASA uses the service ticket to request access to the web service, in the above scenario this is sent to the web server in a HTTP GET request.

7. The web server authenticates the Kerberos service ticket and grants access to the service. An authentication failure will display an appropriate error message after acknowledgment of which the portal will be displayed.

**Configuring Kerberos Constrained Delegation (KCD) for SSL VPN (ASA)**

Use the Microsoft KCD Server tab of the SSL VPN Other Settings page to configure Kerberos Constrained Delegation (KCD) for clientless SSL VPNs hosted on an ASA.

KCD addresses a limitation of Kerberos. If a user authenticates to the SSL VPN using a method other than Kerberos, the user cannot access Kerberos-protected resources. This prevents a remote access device, such as ASA, from authenticating users using non-Kerberos methods and still provide single sign-on access to Kerberos-authenticated web applications in the enterprise.

If this limitation applies to your network, you can configure KCD to get around the limitation. KCD offloads the Kerberos authentication to the ASA. Users log into the corporate network using the SSL VPN portal, and from then on, access Kerberos-protected services in a transparent fashion.

**Tips**

- KCD requires ASA release 8.4+. If you configure KCD for other releases, the configuration is ignored.
- The feature is used with clientless SSL VPN access only.
- Microsoft Windows Server (2003 or 2008), configured as domain controllers, are required for KCD.
- If you use SSL VPN Bookmark policy objects to define bookmarks to include on the SSL VPN portal page, you might need to add explicit service principle name (SPN) parameters to bookmarks if a service uses a non-default port. For services that use Kerberos authentication, an SPN must be defined in the Service-Principal-Name attribute of the account under which the service runs.

Bookmarks need to reflect this configuration. The SPN is a parameter on the URL: http://<url>?SPN=<spn> or http://<url>?SPN=<spn>. For example, http://owa.example.com?SPN=http/owa:444. For more details about the SPN syntax, see Understanding Kerberos Constrained Delegation (KCD) for SSL VPN (ASA), page 29-52.

- To configure this feature, you must also configure the Hostname, DNS, and NTP policies. Configure both hostname and domain name in the Hostname policy.
Chapter 29  Managing Remote Access VPNs on ASA and PIX 7.0+ Devices

Working with SSL and IKEv2 IPSec VPN Policies

- Kerberos authentication requires that the clock between the hosts to be synchronized with a maximum drift of 5 minutes (this is the default setting). This restriction is applicable to the clocks on the ASA, the domain controller, and the application servers. Configuring the same NTP server for all servers should address the requirement.

Related Topics
- Configuring Other SSL VPN Settings (ASA), page 29-38
- Understanding AAA Server and Server Group Objects, page 6-23

Step 1  Do one of the following:
- (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Other Settings from the Policy selector.
- (Policy view) Select Remote Access VPN > SSL VPN > Other Settings (ASA) from the Policy Type selector. Select an existing policy or create a new one.

Step 2  On the Other Settings page, click the Microsoft KCD Server tab.

Step 3  Select Configure KCD and configure the following options:
- **KCD Server**—The AAA server group object that identifies the Microsoft KCD server (the domain controller) to use for Kerberos Constrained Delegation. Enter the name of the object or click Select to select it from a list or to create a new object. The object must use a Kerberos AAA server policy object to identify the domain controller.
- **Username, Password, Confirm**—A user account that the ASA can use to join the Active Directory domain.

For the ASA to use Kerberos protocol transition and constrained delegation, and obtain service tickets on behalf of the remote access users, the account used by the ASA to authenticate with the domain controller must be configured in Active Directory and configured to allow Kerberos constrained delegation to any authentication protocol. In addition, the user account must not be marked as a sensitive account that cannot be delegated. For more information about Active Directory configuration requirements, see Understanding Kerberos Constrained Delegation (KCD) for SSL VPN (ASA), page 29-52.

---

Configuring SSL VPN Advanced Settings (ASA)

Use the Advanced tab of the SSL VPN Other Settings page to configure the memory, on-screen keyboard, and internal password features on ASA devices. All of these settings are optional.

Related Topics
- Configuring Other SSL VPN Settings (ASA), page 29-38

Step 1  Do one of the following:
- (Device view) With an ASA device selected, select Remote Access VPN > SSL VPN > Other Settings from the Policy selector.
- (Policy view) Select Remote Access VPN > SSL VPN > Other Settings (ASA) from the Policy Type selector. Select an existing policy or create a new one.

Step 2  On the Other Settings page, click the Advanced Tab.
Step 3  In the **Memory Size** field, specify the amount of memory you want to allocate to SSL VPN sessions. The default is 50%.

To change the setting, select one of the following options and enter the desired number:

- **% of Total Physical Memory**—As a percentage of total memory. Default is 50%.
- **Kilobytes**—In kilobytes. 20KB is the minimum setting allowed. Cisco recommends that you do not specify memory in terms of KB because different ASA models have different total amounts of memory, for example:

  Note  When you change the memory size, the new setting takes effect only after the system reboots.

Step 4  In the **Enable On-Screen Keyboard** field, select one of the following options:

- **Disabled**—The on-screen keyboard is not displayed. Users must input their credentials using the standard keyboard. This is the default.
- **On All Pages**—Allows a user to input credentials using an on-screen keyboard, which is displayed whenever logon credentials are required.
- **On Logon Page Only**—Allows a user to input credentials using an on-screen keyboard, which is displayed on the logon page but not on any other pages that require credentials.

Step 5  Select **Allow Users to Enter Internal Password** to require an additional password when accessing internal sites. This feature is useful if you require that the internal password be different from the SSL VPN password. For example, you can use a one-time password for authentication to ASA and another password for internal sites.

### Configuring SSL VPN Shared Licenses (ASA 8.2+)

Use the SSL VPN Shared License page to configure your SSL VPN Shared License.

You can purchase a shared license with a large number of SSL or remote access IKEv2 IPsec VPN sessions and share the sessions as needed among a group of ASA devices by configuring one of the ASA devices as a shared license server, and the rest as clients. For the server license, you can share 500-50,000 licenses in increments of 500 and 50,000-1,040,000 licenses in increments of 1000.

A license is consumed by each remote access user that makes an SSL or IKEv2 IPsec connection.

  Note  The shared license cannot be used at the same time as the AnyConnect Essentials license.

The following topics explain the procedure for configuring shared licenses:

- **Configuring an ASA Device as a Shared License Client**, page 29-58
- **Configuring an ASA Device as a Shared License Server**, page 29-59

**Navigation Path**

- (Device View) Select an ASA device using version 8.2 or higher, and select **Remote Access VPN > SSL VPN > Shared License** from the Policy selector.
- (Policy View) Select **Remote Access VPN > SSL VPN > Shared License (ASA 8.2+)** from the Policy Type selector. Select an existing policy or create a new one.

This section contains the following topics:

- Configuring an ASA Device as a Shared License Client, page 29-58
- Configuring an ASA Device as a Shared License Server, page 29-59

Configuring an ASA Device as a Shared License Client

This procedures describes how to configure an ASA device as a shared license client.

Tip
You must ensure that the SSL VPN Shared License Client activation key is present on the device.

Step 1
Do one of the following:

• (Device view) With an ASA device selected, select **Remote Access VPN > SSL VPN > Shared License** from the Policy selector.

• (Policy view) Select **Remote Access VPN > SSL VPN > Shared License (ASA 8.2+)** from the Policy Type selector. Select an existing policy or create a new one.

The SSL VPN Shared License page appears (see Configuring SSL VPN Shared Licenses (ASA 8.2+), page 29-56).

Step 2
Select **Shared License Client** as the role of the device.

Step 3
In the Shared Secret field, enter and confirm a case-sensitive string (4-128 characters) used for communicating with the shared license server.

Step 4
In the License Server field, enter the IP address or the name of a network/host object that identifies the ASA device configured as the license server.

Step 5
In the License Server Port field, enter the number of the TCP port on which the license server communicates.

Step 6
Select the role of the client:

• **Client Only**—When selected, the client acts only as the client. In this case, you can specify another device as a backup server.
• **Backup Server**—When selected, the client also acts as the backup server. In this case, you must also specify the interfaces to be used for this purpose.

---

### Configuring an ASA Device as a Shared License Server

This procedures describe how to configure an ASA device as a shared license server.

**Tip**
You must ensure that the SSL VPN Shared License Server activation key is present on the device.

**Step 1**
Do one of the following:

- (Device view) With an ASA device selected, select **Remote Access VPN > SSL VPN > Shared License** from the Policy selector.
- (Policy view) Select **Remote Access VPN > SSL VPN > Shared License (ASA 8.2+)** from the Policy Type selector. Select an existing policy or create a new one.

The SSL VPN Shared License page appears (see Configuring SSL VPN Shared Licenses (ASA 8.2+), page 29-56).

**Step 2**
Select **Shared License Server** as the role of the device.

**Step 3**
In the Shared Secret field, enter and confirm a case-sensitive string (4-128 characters) used for communicating with the shared license server.

**Step 4**
In the License Server Port field, enter the number of the TCP port on which the license server communicates.

**Step 5**
In the Refresh Interval field, enter a value between 10-300 seconds to be used as the refresh interval. Default is 30 seconds.

**Step 6**
In the Interfaces field, enter or select the interfaces to be used for communicating with clients.

**Step 7**
(Optional.) Select **Configure Backup shared SSL VPN License Server** to configure a backup server for the shared license server, then configure the following:

- **Backup License Server**—The IP address, or network/host object that contains the address, of the server to act as a backup license server if the current one is unavailable.
- **Backup Server Serial Number**—The serial number of the backup license server.
- **HA Peer Serial Number**—(Optional) The serial number of the backup server of a failover pair.

---

### Customizing Clientless SSL VPN Portals

You can customize the web site and its contents that you use for the portal page for a browser-based clientless SSL VPN. ASA devices allow much more customization than IOS devices. You can create several policy objects that define the look of the web pages the user sees when logging into or out of the VPN and the home page for the portal, as well as the bookmarks and smart tunnels available to the user.
This section contains the following topics:

- Configuring ASA Portal Appearance Using SSL VPN Customization Objects, page 29-60
- Localizing SSL VPN Web Pages for ASA Devices, page 29-62
- Creating Your Own SSL VPN Logon Page for ASA Devices, page 29-64
- Configuring SSL VPN Bookmark Lists for ASA and IOS Devices, page 29-65
- Using the Post URL Method and Macro Substitutions in SSL VPN Bookmarks, page 29-66
- Configuring SSL VPN Smart Tunnels for ASA Devices, page 29-68
- Configuring WINS/NetBIOS Name Service (NBNS) Servers To Enable File System Access in SSL VPNs, page 29-70

Configuring ASA Portal Appearance Using SSL VPN Customization Objects

An SSL VPN Customization object describes the appearance of browser-based clientless SSL VPN web pages displayed to users. This includes the Logon page displayed when they connect to the ASA security appliance, the Home page displayed after authentication, and the Logout page displayed when users log out of the SSL VPN service.

You use SSL VPN Customization objects when defining ASA group objects or Remote Access VPN Connection policies for ASA devices. You can create several customization objects and define multiple ASA group or connection profiles so that each user group sees web pages designed specifically for their use. Customization can include localizing the web pages in the languages appropriate for each group. For more information about localization, see Localizing SSL VPN Web Pages for ASA Devices, page 29-62.

Initially, when a user first connects, the default customization object identified in the connection profile determines how the logon screen appears. If the user selects a different group from the connection profile list on the logon page, and that group has its own customization, the screen changes to reflect the customization object for the selected group. After the remote user is authenticated, the screen appearance is determined by the customization object that has been assigned to the group policy.

After you create the SSL VPN customization object as described in this procedure, you can use the object to specify the portal characteristics in these policies:

- On the SSL VPN > Settings page in an ASA group policy object (see ASA Group Policies SSL VPN Settings, page 32-14), which you then select in one of these policies:
  - Remote Access VPN > Group Policies
  - Remote Access VPN > Connection Profiles on the General tab
- In the Remote Access VPN > Connection Profiles policy, you can also specify the SSL VPN customization object on the SSL tab (see SSL Tab (Connection Profiles), page 29-18).

Related Topics

- Localizing SSL VPN Web Pages for ASA Devices, page 29-62
- Creating Policy Objects, page 6-8
- Add and Edit SSL VPN Customization Dialog Boxes, page 32-32
Step 1
Select Manage > Policy Objects to open the Policy Object Manager (see Policy Object Manager Window, page 6-4).

Tip
You can also create SSL VPN Customization objects when defining policies or objects that use this object type. For more information, see Selecting Objects for Policies, page 6-2.

Step 2
Select SSL VPN Customization from the Object Type selector. The SSL VPN Customization page opens, displaying a list of the existing SSL VPN Customization objects.

Step 3
Right-click in the work area and select New Object.

The Add SSL VPN Customization dialog box appears (see Add and Edit SSL VPN Customization Dialog Boxes, page 32-32).

Step 4
Enter a name for the object and optionally a description of the object.

Step 5
Before you configure settings for the various pages, use the Preview button to view the default settings. Clicking Preview opens a browser window to display the current settings for the Logon page, Portal page, or Logout page, whichever one is selected in the table of contents (selecting a page within one of these folders is the same as selecting the parent folder).

Tip
Click Preview after making any changes to settings to verify that the changes are what you desire.

Step 6
Configure the settings for the Logon page. This web page is the one users see first when connecting to the SSL VPN portal. It is used for logging into the VPN. Select the following items in the Logon Page folder in the table of contents on the left of the dialog box to view and change the settings:

- **Logon Page**—Specify the title of the web page, which is displayed in the browser’s title bar.

- **Title Panel**—Determine whether the Logon page will have a title displayed in the web page itself. If you enable the title panel, you can specify the title, font, font size and weight, styles, and colors used. You can also select a File object that identifies a logo graphic. For more information about the settings, see SSL VPN Customization Dialog Box—Title Panel, page 32-35.

- **Language**—If you want to configure translation tables for other languages on the ASA device and use them, you can configure the supported languages and allow users to choose their language. For more information about translation tables and localization support, see Localizing SSL VPN Web Pages for ASA Devices, page 29-62. For more information about the settings, see SSL VPN Customization Dialog Box—Language, page 32-36.

- **Logon Form**—Configure the labels and colors used in the form that accepts user logon information. For more information about the settings, see SSL VPN Customization Dialog Box—Logon Form, page 32-38.

- **Informational Panel**—If you want to provide extra information to the user, you can enable an informational panel and add text and a logo graphic. For more information about the settings, see SSL VPN Customization Dialog Box—Informational Panel, page 32-39.

- **Copyright Panel**—If you want to include copyright information on the logon page, you can enable the copyright panel and enter your copyright statement. For more information about the settings, see SSL VPN Customization Dialog Box—Copyright Panel, page 32-40.
Customizing Clientless SSL VPN Portals

- **Full Customization**—If you do not want to use the security appliance’s built-in logon page, even customized, you can instead enable full customization and supply your own web page. For information on creating the required file, see *Creating Your Own SSL VPN Logon Page for ASA Devices*, page 29-64. For more information about the settings, see *SSL VPN Customization Dialog Box—Full Customization*, page 32-41.

**Step 7** Configure the settings for the Portal page. This is the home page for the SSL VPN portal, and is displayed after the users log in. Select the following items in the Portal Page folder in the table of contents on the left of the dialog box to view and change the settings:

- **Portal Page**—Specify the title of the web page, which is displayed in the browser’s title bar.
- **Title Panel**—Determine whether the Portal page will have a title displayed in the web page itself. If you enable the title panel, you can specify the title, font, font size and weight, styles, and colors used. You can also select a File object that identifies a logo graphic. For more information about the settings, see *SSL VPN Customization Dialog Box—Title Panel*, page 32-35.
- **Toolbar**—Determine whether the Portal page will have a toolbar, which contains a field for entering a URL to browse. For more information about the settings, see *SSL VPN Customization Dialog Box—Toolbar*, page 32-41.
- **Applications**—Determine which application buttons will appear on the page. For more information about the settings, see *SSL VPN Customization Dialog Box—Applications*, page 32-42.
- **Custom Panes**—Determine how you want to organize the body of the Portal page. The default is a single column with no internal panes. You can create a multiple-column layout, create internal panes that display text or references to URLs, and determine in which column and row to place the panes. For more information about the settings, see *SSL VPN Customization Dialog Box—Custom Panes*, page 32-42.
- **Home Page**—Determine how and whether to display URL lists on the home page, and whether to use your own web page for the main body of the Portal page. For more information about the settings, see *SSL VPN Customization Dialog Box—Home Page*, page 32-44.

**Step 8** Select *Logout Page* to configure the settings of the page displayed when a user logs out of the SSL VPN. You can configure the title, message text, fonts, and colors. For more information about the settings, see *SSL VPN Customization Dialog Box—Logout Page*, page 32-45.

**Step 9** (Optional) Under Category, select a category to help you identify this object in the Objects table. See *Using Category Objects*, page 6-11.

**Step 10** (Optional) Select *Allow Value Override per Device* to allow the properties of this object to be redefined on individual devices. See *Allowing a Policy Object to Be Overridden*, page 6-16.

**Step 11** Click **OK** to save the object.

---

**Localizing SSL VPN Web Pages for ASA Devices**

Localization is the process of providing text in a language that is appropriate for the target users. When you create an SSL VPN Customization object for defining the look of browser-based clientless SSL VPN web pages hosted on an ASA device, you can configure the pages to use the desired language.

To see localized web pages correctly, users must configure their browsers to use UTF-8 encoding (for example, in Internet Explorer, select **View > Encoding > Unicode (UTF-8)**). They also must install the required fonts or language support files for their language using the Regional and Language Options control panel. On the Languages tab, click Details to install the desired languages, and select the
appropriate supplemental language settings for East Asian, complex scripting, and right-left languages. On the Advanced tab, select the desired code page conversion tables. If users do not configure the browser correctly, they might see boxes instead of characters.

There are two techniques you can use to localize SSL VPN web pages that are hosted on an ASA device. These techniques are not mutually exclusive; you can use both of them. These are the techniques:

- **Configure the SSL VPN Customization object using the desired language**—When you create the SSL VPN Customization object, you can enter text for labels and messages in non-English, non-ASCII languages in UTF-8 encoding. To enter non-ASCII languages in UTF-8 encoding, you must configure Windows with the correct locale setting and have the required fonts installed. Use the Regional and Language Options control panel to configure your system and install files required for complex script or East Asian languages. If you want to type in text directly, you also need to install an appropriate keyboard; otherwise, you can use a text editor that supports the language’s characters and copy and paste text from a document that contains the text you want to use.

  You can also enter non-ASCII languages into SSL VPN Bookmarks objects.

- **Configure translation tables on the ASA device to support the languages you want to make available**—To enable the security appliance to provide language translation for the portal and screens displayed to users, you must define the necessary languages in a translation table and import the table into the security appliance. The software image package for the security appliance includes a translation table template. Every language you list in an SSL VPN Customization object must have a corresponding translation table on the device. Conversely, translation tables for languages that are not listed in the SSL VPN Customization object are ignored.

  If you use this technique, you must use the ASA CLI or ASDM to configure and upload the translation tables. You cannot manage the translation tables with Security Manager. However, the SSL VPN Customization object includes settings that allow you to configure automatic browser language selection and to enable users to select their desired language. Thus, if you install translation tables for ten languages, the pages defined in the SSL VPN Customization object will be available to users in all of those languages. For more information on these settings, see SSL VPN Customization Dialog Box—Language, page 32-36.

Although both of the following features require translation tables, they are separate and complementary:

- **Automatic Browser Language Selection**—Automatic browser language selection attempts to select the appropriate language based on the user’s browser settings. This technique does not ask for user input. In the SSL VPN Customization object, you create a list of languages that will be used in the negotiation with the browser. During a connection, the security appliance receives a list of languages (and their priorities) from the browser, and looks through your list of languages top to bottom until a match is found. If there is no match, then the language you defined in the list as the default language is used. If you do not specify a default language, English is used.

  The languages on the security appliance are labels for the translation tables. The languages must mirror those of the browser, and can consist of groups of up to 8 alphanumeric characters (starting from alpha characters), separated by hyphens. For example, fr-FR-paris-univ8.

  However, when you add a language to the list in Security Manager, only the first two characters are available.

  When looking for a match, the security appliance starts with the longest language name, and if it does not match, it discards the rightmost group of the name. For example, if the preferred language on the browser is fr-FR-paris-univ8, and the security appliance supports fr-FR-paris-univ8, fr-FR-paris, fr-FR, and fr, it matches fr-FR-paris-univ8 and uses the translated strings from that translation table. If fr is the only language on the security appliance, the security appliance considers it a match also, and uses that translation table.
For more information about setting up translation tables, see the user documentation for the
ASA device and operating system or the ASDM online help.

– **Language Selector**—By enabling the language selector, you provide the user with the ability
to actively select the desired language from a list of languages that you support. This technique
does not rely on the browser language settings being configured correctly. The language selector
is displayed on the logon page.

### Creating Your Own SSL VPN Logon Page for ASA Devices

You can create your own custom SSL VPN Logon page rather than use the page provided by the security
appliance for browser-based clientless SSL VPNs. This is called full customization, and replaces the
settings you can configure in the SSL VPN Customization policy object.

To provide your own Logon page, you must create the page, copy it to the Security Manager server, and
identify the page on the Full Customization page of the SSL VPN Customization object dialog box. For
information on creating SSL VPN Customization objects, see Configuring ASA Portal Appearance
Using SSL VPN Customization Objects, page 29-60.

When you enable full customization, all other settings for the Logon page configured in the policy object
are ignored. When you deploy your configuration to the ASA device, Security Manager copies your
custom page to the device.

The Logon page you create must include all of the HTML code required to present the page correctly,
and include special Cisco HTML code that provides the functions for the login form and the Language
Selector drop-down list. Keep the following in mind when you create the HTML file:

- The file extension must be `.inc`.
- All images in the custom Logon page must be present on the security appliance. Replace the file
  path with the keyword `/+CSCOU+/`, which is an internal directory on the ASA device. When you
  upload an image to the device, it is saved in this directory.
- Use the `esco_ShowLoginForm('lform')` Javascript function to add the login form to the page. This
  form prompts for the username, passwords, and group information. You must include this function
  somewhere on the page.
- Use the `esco_ShowLanguageSelector('selector')` Javascript function to add the Language Selector
  drop-down list to the page. You do not have to use this function if you are not supporting the use of
  more than one language.

Configuring SSL VPN Bookmark Lists for ASA and IOS Devices

When you configure a browser-based clientless SSL VPN, you can define a list of bookmarks, or URLs, to include on the SSL VPN portal page. Use SSL VPN bookmarks policy objects to define bookmark lists.

You can create SSL VPN bookmark objects for SSL VPNs hosted on IOS devices or ASA devices. However, these device types allow different bookmark configurations, the ASA device allowing more configuration options than IOS devices. Besides allowing more configuration options, you can also create bookmarks for ASA devices in non-English, non-ASCII languages. For more information on localizing the bookmarks and portal for ASA devices, see Localizing SSL VPN Web Pages for ASA Devices, page 29-62.

After you create the SSL VPN bookmark object as described in this procedure, you can use the object to specify the bookmark object in the Portal Web Pages or Bookmarks fields in these policies:

- **ASA devices**—On the SSL VPN > Clientless page in an ASA group policy object (see ASA Group Policies SSL VPN Clientless Settings, page 32-10), which you then select in one of these policies:
  - Remote Access VPN > Group Policies
  - Remote Access VPN > Connection Profiles on the General tab
- **ASA devices**—In the Remote Access VPN > Dynamic Access policy, you can specify the SSLVPN bookmark object on the Main > Bookmarks tab (see Main Tab, page 30-13).
- **IOS devices**—On the Clientless page in a user group policy object configured for SSL VPN (see User Group Dialog Box—Clientless Settings, page 32-63), which you then select in the Remote Access VPN > SSL VPN policy on the General tab.

Related Topics

- Creating Group Policies (ASA, PIX 7.0+), page 29-24
- Configuring Dynamic Access Policies, page 30-2
- Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6
- Configuring an SSL VPN Policy (IOS), page 31-14
- Creating Policy Objects, page 6-8
- Policy Object Manager Window, page 6-4

**Step 1** Select Manage > Policy Objects to open the Policy Object Manager (see Policy Object Manager Window, page 6-4).

**Tip** You can also create SSL VPN bookmark objects when you define policies or objects that use this object type. For more information, see Selecting Objects for Policies, page 6-2.

**Step 2** Select SSL VPN Bookmarks from the Object Type selector. The SSL VPN Bookmarks page opens, displaying a list of the existing SSL VPN bookmark objects.

**Step 3** Right-click in the work area, then select New Object.

The Add SSL VPN Bookmark dialog box appears (see Add or Edit Bookmarks Dialog Boxes, page 32-29).

**Step 4** Enter a name for the object and optionally a description of the object.
Step 5  If you are creating the object for an SSL VPN hosted on an IOS device, you can enter a name for the heading that is displayed above the bookmarks list in the **Bookmarks Heading (IOS)** field.

Step 6  The Bookmarks table displays any URLs that are defined for the object. To add a bookmark, click the **Add Row** button below the table; to edit an existing bookmark, select it and click the **Edit Row** button. The Add/Edit SSL VPN Bookmark Entry dialog box opens. For more information about the fields on this dialog box, see **Add and Edit Bookmark Entry Dialog Boxes**, page 32-30.

- In the **Bookmark Option** field, select whether you are defining a bookmark (**Enter Bookmark**) or adding bookmarks from another SSL VPN bookmark object (**Include Existing Bookmarks**). If you are including an existing object, enter the object's name or click **Select** to select it from a list of existing objects.

- If you are creating the object for use on an IOS device, enter the title of the bookmark, which is displayed to users, and the URL. Be careful to select the correct protocol for the URL. Click **OK** to add the bookmark to the table of bookmarks.

- If you are creating the object for use on an ASA device, you have many more options. Besides the title and the URL, you can define a subtitle and image icon for the bookmark plus other options.

**Tip**  If you choose the protocols RDP, SSH, Telnet, VNC, or ICA, you must configure the plug-in for the protocol in the **Remote Access VPN > SSL VPN > Other Settings** policy (see **Configuring SSL VPN Browser Plug-ins (ASA)**, page 29-47).

You can also configure the bookmark to use the Post method rather than the Get method. If you use Post, you must configure the post parameters by clicking **Add Row** beneath the Post Parameters table. For more information on Post parameters, see these topics:

- **Using the Post URL Method and Macro Substitutions in SSL VPN Bookmarks**, page 29-66

- **Add and Edit Post Parameter Dialog Boxes**, page 32-32

Click **OK** to add the bookmark to the table of bookmarks.

Step 7  *(Optional)*  Under Category, select a category to help you identify this object in the Objects table. See **Using Category Objects**, page 6-11.

Step 8  *(Optional)*  Select **Allow Value Override per Device** to allow the properties of this object to be redefined on individual devices. See **Allowing a Policy Object to Be Overridden**, page 6-16.

Step 9  Click **OK** to save the object.

### Using the Post URL Method and Macro Substitutions in SSL VPN Bookmarks

One of the options you have for configuring bookmarks on an SSL VPN hosted on an ASA device is the method used by a URL, either Get or Post. The Get method is the standard method; a user clicks the URL and is taken to the web page. The Post method is useful when processing the data might involve changes to it, for example, storing or updating data, ordering a product, or sending e-mail.

If you choose the Post URL method, you must configure Post parameters for bookmark entries. Because these are often personalized resources that contain the user ID and password or other input parameters, you might need to define clientless SSL VPN macro substitutions.
Clientless SSL VPN macro substitutions let you configure users for access to personalized resources that contain the user ID and password or other input parameters. Examples of such resources include bookmark entries, URL lists, and file shares.

**Note**

For security reasons, password substitutions are disabled for file access URLs (cifs://). Also for security reasons, use caution when introducing password substitutions for web links, especially for non-SSL instances.

You can use the following macro substitutions:

- **Logon Information Substitutions**—The security appliance obtains values for these substitutions from the SSL VPN Logon page. It recognizes these strings in user requests, and replaces them with the value specific to the user before it passes the request on to a remote server.

These are the available macro substitutions:

- **CSCO_WEBVPN_USERNAME**
  The username used to log into the SSL VPN.

- **CSCO_WEBVPN_PASSWORD**
  The password used to log into the SSL VPN.

- **CSCO_WEBVPN_INTERNAL_PASSWORD**
  The internal resource password entered when logging into the SSL VPN.

- **CSCO_WEBVPN_CONNECTION_PROFILE**
  The connection profile associated with the user group selected when logging into the SSL VPN.

For example, if a URL list contains the link `http://someserver/homepage/CSCO_WEBVPN_USERNAME.html`, the security appliance translates it to the following unique links:

- For USER1 the link becomes `http://someserver/homepage/USER1.html`
- For USER2 the link is `http://someserver/homepage/USER2.html`

In the following example, cifs://server/users/CSCO_WEBVPN_USERNAME lets the security appliance map a file drive to specific users:

- For USER1 the link becomes cifs://server/users/USER1
- For USER2 the link is cifs://server/users/USER2

- **RADIUS/LDAP Vendor-Specific Attributes (VSAs)**—These substitutions let you set substitutions configured on either a RADIUS or an LDAP server. These are the available macro substitutions:

  - **CSCO_WEBVPN_MACRO1**
  - **CSCO_WEBVPN_MACRO2**

For information on configuring bookmarks, see Configuring SSL VPN Bookmark Lists for ASA and IOS Devices, page 29-65.
Configuring SSL VPN Smart Tunnels for ASA Devices

A smart tunnel is a connection between an application running on a user’s workstation and a private site. The connection uses a clientless (browser-based) SSL VPN session with the security appliance as the pathway and proxy server. Smart tunnels do not require the user to connect the application to the local port, so the application can gain access to the network without giving the user administrative privileges, as is required for full tunnel support. If you do not otherwise configure the network to allow access to an application, you can create a smart tunnel for those applications that you want to support.

You can configure smart tunnel access to an application under the following conditions:

- The application is a Winsock 2, TCP-based application and there is a browser plug-in for the application. Cisco distributes plug-ins for some applications for use in clientless SSL VPN, including SSH (for both SSH and Telnet sessions), RDP, and VNC. You must supply or obtain plug-ins for any other applications. Configure plug-ins in the Remote Access VPN > SSL VPN > Other Settings policy on the Plug-Ins tab.
- The user’s workstation is a supported platform. See the Cisco ASA 5500 Series Adaptive Security Appliances documentation that corresponds with your ASA version for supported platforms, http://www.cisco.com/en/US/products/ps6120/products_installation_and_configuration_guides_list.html.
- Users of Microsoft Windows Vista who use smart tunnels (or port forwarding) must add the URL of the ASA device to the Trusted Site zone. Configure the Trusted Site zone in Internet Explorer (Tools > Internet Options, Security tab).
- The user’s browser must be enabled with Java, Microsoft ActiveX, or both.
- If the user’s workstation requires a proxy server to reach the security appliance, the URL of the terminating end of the connection must be in the list of URLs excluded from proxy services. In this configuration, smart tunnels support only basic authentication.

### Tip
A stateful failover does not retain smart tunnel connections. Users must reconnect following a failover.

You configure smart tunnel access for an application by creating an SSL VPN smart tunnel list policy object and including that object in an ASA group policy object. You then assign the ASA group policy object to a device in the Remote Access VPN > Group Policies policy.

#### Related Topics
- Understanding Group Policies (ASA), page 29-23
- Creating Policy Objects, page 6-8
- Policy Object Manager Window, page 6-4

#### Step 1
Create an SSL VPN smart tunnel list policy object:

**a.** Select Manage > Policy Objects to open the Policy Object Manager (see Policy Object Manager Window, page 6-4), and select SSL VPN Smart Tunnel Lists from the table of contents.

### Tip
You can also create SSL VPN smart tunnel list objects when you create or edit the ASA group policy object. For more information, see Selecting Objects for Policies, page 6-2.

**b.** Click the Add Object button to open the Add and Edit Smart Tunnel List Dialog Boxes, page 32-48.
Customizing Clientless SSL VPN Portals

Step 2 (Optional) Create an SSL VPN smart tunnel auto sign-on list policy object:

a. Select Manage > Policy Objects to open the Policy Object Manager (see Policy Object Manager Window, page 6-4), and select SSL VPN Smart Tunnel Auto Signon Lists from the table of contents.

Tip You can also create SSL VPN smart tunnel auto sign-on list objects when you create or edit the ASA group policy object. For more information, see Selecting Objects for Policies, page 6-2.

b. Click the Add Object button to open the Add and Edit Smart Tunnel Auto Signon List Dialog Boxes, page 32-51.

c. Enter a name for the object, up to 64 characters.

d. To the table of smart tunnel auto sign-on entries, add the servers for which to automate the submission of login credentials during smart tunnel setup (click the Add Row button to open the Add and Edit Smart Tunnel Auto Signon Entry Dialog Boxes, page 32-52).

e. You can also incorporate other SSL VPN smart tunnel auto sign-on list objects into the object. This allows you to create a core set of smart tunnel auto sign-on list objects that you can use repeatedly in other objects.

f. Click OK to save the object.

Step 3 Configure the ASA group policy object to use the SSL VPN smart tunnel list object:

a. Edit (or create) the ASA group policy object either from the Policy Object Manager Window, page 6-4 or the Remote Access VPN > Group Policies policy. The object must be configured to support SSL VPNs. (You can also edit these objects from the Remote Access VPN > Connection Profiles policy from an individual profile.)

b. Select the SSL VPN > Clientless folder from the table of contents to open ASA Group Policies SSL VPN Clientless Settings, page 32-10.

c. Enter the name of the SSL VPN smart tunnel list object in the Smart Tunnel field.
**Customizing Clientless SSL VPN Portals**

Chapter 29      Managing Remote Access VPNs on ASA and PIX 7.0+ Devices

**d.** Select **Auto Start Smart Tunnel** to automatically start smart tunnels for the applications when the user connects to the SSL VPN portal.

If you do not select this option, users must start smart tunnel access using the **Application Access > Start Smart Tunnels** button on the clientless SSL VPN portal page.

**e.** Enter the name of the SSL VPN smart tunnel auto sign-on list object in the **Smart Tunnel Auto Signon Server List** field.

**f.** If the universal naming convention (domain\username) is required for authentication, specify the Windows domain to add it to the username during auto sign-on in the **Domain Name** field. For example, enter CISCO to specify CISCO\qa_team when authenticating for the username qa_team. You must also check the Use Domain option when configuring associated entries in the auto sign-on server list.

---

**Configuring WINS/NetBIOS Name Service (NBNS) Servers To Enable File System Access in SSL VPNs**

Clientless SSL VPN uses WINS and the Common Internet File System (CIFS) protocol to access or share files, printers, and other machine resources on remote systems. The ASA or IOS device uses a proxy CIFS client to provide this access transparently; users appear to have direct access to the file systems (subject to individual file and user permissions).

When users attempt a file-sharing connection to a Windows computer by using its computer name, the file server they specify corresponds to a specific WINS name that identifies a resource on the network. The security appliance queries WINS or NetBIOS name servers to map WINS names to IP addresses. SSL VPN requires NetBIOS to access or share files on remote systems.

You use WINS server list policy objects to configure the list of WINS servers that are used to resolve these Microsoft file-directory share names. The WINS server list objects define the NetBIOS Name Service (NBNS) server list on the device (using the `nbns-list` and `nbns-server` commands) for Common Internet File System (CIFS) name resolution.

After creating the WINS server list policy object, you can configure it in the following policies and policy objects, and also select the file access services that you want to allow:

- **ASA devices**—In the **Remote Access VPN > Connection Profiles** policy, specify the WINS server list object on the **SSL** tab (see **SSL Tab (Connection Profiles)**, page 29-18).

  Select the file access options on the **SSL VPN > Clientless** page in an ASA group policy object (see **ASA Group Policies SSL VPN Clientless Settings**, page 32-10), which you then select in one of these policies:
  - **Remote Access VPN > Group Policies**
  - **Remote Access VPN > Connection Profiles** on the **General** tab

- **IOS devices**—On the **Clientless** page in a user group policy object configured for SSL VPN (see **User Group Dialog Box—Clientless Settings**, page 32-63), which you then select in the **Remote Access VPN > SSL VPN** policy on the **General** tab.

---

**Related Topics**

- **Creating Policy Objects**, page 6-8

---

**Step 1**  
Select **Manage > Policy Objects** to open the **Policy Object Manager Window**, page 6-4.
Step 2  Select **WINS Server Lists** from the Object Type selector.

The WINS Server List page opens, displaying the currently defined WINS server list objects.

Step 3  Right-click in the work area and select **New Object** to open the Add or Edit WINS Server List Dialog Box, page 32-70.

Step 4  Enter a name for the object and optionally a description of the object.

Step 5  Click the **Add Row** button below the table, or select a server in the table and click **Edit Row**, to configure the WINS servers defined in the object. Configure these settings:

- **Server**—The IP address of the WINS server. You can select a network/host object or enter the address directly.
- **Set as Master Browser**—Select this option if the server is a master browser, which maintains the list of computers and shared resources.

Other fields are optional; change them if you want non-default values. For more information, see Add or Edit WINS Server Dialog Box, page 32-71.

Click **OK** to save your changes.

Step 6  (Optional) Under Category, select a category to help you identify this object in the Objects table. See Using Category Objects, page 6-11.

Step 7  (Optional) Select **Allow Value Override per Device** to allow the properties of this object to be redefined on individual devices. See Allowing a Policy Object to Be Overridden, page 6-16.

Step 8  Click **OK** to save the object.
Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)

This chapter explains Dynamic Access Policies (DAP) for assigning remote access users to connection profiles (tunnel groups). You can configure these policies for remote access IKEv1 IPsec on ASA 8.0+ devices, IKEv2 IPsec on ASA 8.4(x) devices, and SSL VPNs on ASA 8.0+ (except 8.5) devices.

For information on configuring other remote access policies for ASA and PIX 7.0+ devices, see Chapter 29, “Managing Remote Access VPNs on ASA and PIX 7.0+ Devices”.

This chapter contains the following topics:

- Understanding Dynamic Access Policies, page 30-1
- Configuring Dynamic Access Policies, page 30-2
- Dynamic Access Page (ASA), page 30-10

Understanding Dynamic Access Policies

Multiple variables can affect each VPN connection, for example, intranet configurations that frequently change, the various roles each user may inhabit within an organization, and logins from remote access sites with different configurations and levels of security. The task of authorizing users is much more complicated in a VPN environment than it is in a network with a static configuration.

Dynamic access policies (DAP) on a security appliance let you configure authorization that addresses these many variables. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. These attributes address issues of multiple group membership and endpoint security. That is, the security appliance grants access to a particular user for a particular session based on the policies you define. It generates a DAP at the time the user connects by selecting and/or aggregating attributes from one or more DAP records. It selects these DAP records based on the endpoint security information of the remote device and the AAA authorization information for the authenticated user. It then applies the DAP record to the user tunnel or session. The DAP system includes the following components that require your attention:

- DAP Selection Configuration File—A text file containing criteria that the security appliance uses for selecting and applying DAP records during session establishment. It is stored on the security appliance. You can use Security Manager to modify it and upload it to the security appliance in XML data format. DAP selection configuration files include all of the attributes that you configure. These can include AAA attributes, endpoint attributes, and access policies as configured in network and web-type ACL filter, port forwarding, and URL lists.
Configuring Dynamic Access Policies

This procedure describes how to create or edit a dynamic access policy.

Related Topics
- Understanding Dynamic Access Policies, page 30-1
- Understanding DAP Attributes, page 30-3
- Configuring Cisco Secure Desktop Policies on ASA Devices, page 30-9

Step 1
Do one of the following:
- (Device view) With an ASA device selected, select **Remote Access VPN > Dynamic Access** from the Policy selector.
- (Policy view) Select **Remote Access VPN > Dynamic Access (ASA)** from the Policy Type selector. Select an existing policy or create a new one.

The Dynamic Access page opens. For a description of the elements on this page, see **Dynamic Access Page (ASA)**, page 30-10.

Step 2
Click **Create** or select a policy in the table and click **Edit**.

The Add/Edit Dynamic Access Policy dialog box opens, with the Main tab open by default. For a description of the elements in this dialog box, see **Table 30-4 on page 30-13**.

Step 3
Enter the name of the DAP record (up to 128 characters).
Step 4 Specify a priority for the DAP record. The security appliance applies access policies in the order you set here, highest number having the highest priority.

Step 5 Enter a description for the DAP record.

Step 6 In the **Main** tab, configure the DAP attributes and the type of remote access method supported by the DAP system on your security appliance. For a detailed description of the elements on this tab, see Table 30-5 on page 30-14.

a. Click **Create** below the table, or select a DAP entry in the table and click **Edit**. The Add/Edit DAP Entry dialog box opens. For a description of the elements on this dialog box, see Add/Edit DAP Entry Dialog Box, page 30-17.

   For a full description of the procedure to define the DAP attributes, see Configuring DAP Attributes, page 30-7.

b. Select the type of remote access permitted by the DAP system.

c. Select the **Network ACL** tab to select and configure network ACLs to apply to this DAP record. This tab is available only if you selected an access method other than Web Portal.

d. Select the **WebType ACL** tab to select and configure Web-type ACLs to apply to this DAP record. This tab is available only if you selected an access method other than AnyConnect Client.

e. Select the **Functions** tab to configure file server entry and browsing, HTTP proxy, and URL entry for the DAP record. This tab is available only if you selected an access method other than AnyConnect Client.

f. Select the **Port Forwarding** tab to select and configure port forwarding lists for user sessions. This tab is available only if you selected an access method other than AnyConnect Client.

g. Select the **URL List** tab to select and configure URL lists for user sessions. This tab is available only if you selected an access method other than AnyConnect Client.

h. Select the **Action** tab to configure the type of remote access permitted. This tab is available for all types of access methods.

Step 7 Select the **Logical Operators** tab to create multiple instances of each type of endpoint attribute. For a description of the elements on this tab, see Table 30-21 on page 30-34.

Step 8 Select the **Advanced Expressions** tab to set additional attributes for the DAP using free-form LUA. For a description of the elements on this tab, see Table 30-22 on page 30-36.

Step 9 Click **OK**.

---

**Understanding DAP Attributes**

DAP records include all of the attributes that you configure. These can include AAA attributes, endpoint attributes, and access policies as configured in network and web-type ACL filter, port forwarding and URL lists.
DAP and AAA Attributes

DAP complements AAA services. It provides a limited set of authorization attributes that can override those AAA provides. The security appliance selects DAP records based on the AAA authorization information for the user and posture assessment information for the session. The security appliance can select multiple DAP records depending on this information, which it then aggregates to create DAP authorization attributes.

You can specify AAA attributes from the Cisco AAA attribute hierarchy, or from the full set of response attributes that the security appliance receives from a RADIUS or LDAP server.

AAA Attribute Definitions

Table 30-1 defines the AAA selection attribute names that are available for DAP use. The Attribute Name field shows you how to enter each attribute name in a LUA logical expression, which you might do on the Advanced tab of the Add/Edit Dynamic Access Policy dialog box.

### Table 30-1 AAA Attribute Definitions

</tbody>
</table>

DAP and Endpoint Security

The security appliance obtains endpoint security attributes by using posture assessment methods that you configure. These include Cisco Secure Desktop and NAC. You can use a match of a prelogin policy, Basic Host Scan entry, Host Scan Extension, or any combination of these and any other policy attributes to assign access rights and restrictions. At minimum, configure DAPs to assign to each prelogin policy and Basic Host Scan entry.

Endpoint Assessment, a Host Scan extension, examines the remote computer for a large collection of antivirus and antispyware applications, associated definitions updates, and firewalls. You can use this feature to combine endpoint criteria to satisfy your requirements before the security appliance assigns a specific DAP to the session.

DAP and Anti-Virus, Anti-Spyware, and Personal Firewall Programs

The security appliance uses a DAP policy when the user attributes matches the configured AAA and endpoint attributes. The Prelogin Assessment and Host Scan modules of Cisco Secure Desktop return information to the security appliance about the configured endpoint attributes, and the DAP subsystem uses that information to select a DAP record that matches the values of those attributes. Most, but not all, anti-virus, anti-spyware, and personal firewall programs support active scan, which means that the programs are memory-resident, and therefore always running. Host Scan checks to see if an endpoint has a program installed, and if it is memory-resident as follows:
- If the installed program does not support active scan, Host Scan reports the presence of the software. The DAP system selects DAP records that specify the program.
- If the installed program does support active scan, and active scan is enabled for the program, Host Scan reports the presence of the software. Again the security appliance selects DAP records that specify the program.
- If the installed program does support active scan and active scan is disabled for the program, Host Scan ignores the presence of the software. The security appliance does not select DAP records that specify the program. Further, the output of the `debug trace` command, which includes a lot of information about DAP, does not indicate the program presence, even though it is installed.

**Endpoint Attribute Definitions**

Table 30-2 on page 30-5 defines the endpoint selection attribute names that are available for DAP use. The Attribute Name field shows you how to enter each attribute name in a LUA logical expression, which you might do on the Advanced tab of the Add/Edit Dynamic Access Policy dialog box. The *label* variable identifies the application, filename, process, or registry entry.

### About Advanced Expressions for AAA or Endpoint Attributes

In the text box you enter free-form LUA text that represents AAA and/or endpoint selection logical operations. ASDM does not validate text that you enter here; it just copies this text to the DAP policy file, and the security appliance processes it, discarding any expressions it cannot parse.
This option is useful for adding selection criteria other than what is possible in the AAA and endpoint attribute areas above. For example, while you can configure the security appliance to use AAA attributes that satisfy any, all, or none of the specified criteria, endpoint attributes are cumulative, and must all be satisfied. To let the security appliance employ one endpoint attribute or another, you need to create appropriate logical expressions in LUA and enter them here.

Examples of DAP Logical Expressions

Study these examples for help in creating logical expressions in LUA.

- This AAA LUA expression tests for a match on usernames that begin with "b". It uses the string library and a regular expression:
  ```lua
  not(string.find(aaa.cisco.username, "^b") == nil)
  ```

- This endpoint expression tests for a match on CLIENTLESS OR CVC client types:
  ```lua
  endpoint.application.clienttype=="CLIENTLESS" or endpoint.application.clienttype=="CVC"
  ```

- This endpoint expression tests for Norton Antivirus versions 10.x but excludes 10.5.x:
  ```lua
  (endpoint.av.NortonAV.version > "10" and endpoint.av.NortonAV.version < "10.5") or
  endpoint.av.NortonAV.version > "10.6"
  ```

DAP Connection Sequence

The following sequence outlines a typical remote access connection establishment.

1. A remote client attempts a VPN connection.
2. The security appliance performs posture assessment, using configured NAC and Cisco Secure Desktop Host Scan values.
3. The security appliance authenticates the user via AAA. The AAA server also returns authorization attributes for the user.
4. The security appliance applies AAA authorization attributes to the session, and establishes the VPN tunnel.
5. The security appliance selects DAP records based on the user AAA authorization information and the session posture assessment information.
6. The security appliance aggregates DAP attributes from the selected DAP records, and they become the DAP policy.
7. The security appliance applies the DAP policy to the session.

Configuring DAP Attributes

The attributes you must define for a DAP policy include specifying the authorization attributes and endpoint attributes. You can also configure network and webtype ACLs, file browsing, file server entry, HTTP proxy, URL entry, port forwarding lists and URL lists.

This procedure describes how to create or edit the AAA and endpoint attributes required for a DAP policy.
Chapter 30  Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)

Related Topics
- Understanding DAP Attributes, page 30-3
- Understanding Dynamic Access Policies, page 30-1
- Configuring Dynamic Access Policies, page 30-2

Step 1  Do one of the following:
- (Device view) With an ASA device selected, select Remote Access VPN > Dynamic Access from the Policy selector.
- (Policy view) Select Remote Access VPN > Dynamic Access (ASA) from the Policy Type selector. Select an existing policy or create a new one.

The Dynamic Access page opens. For a description of the elements on this page, see Dynamic Access Page (ASA), page 30-10.

Step 2  Click Create on the Dynamic Access policy page, or select the row of a policy in the table on the page, and click Edit.

The Add/Edit Dynamic Access Policy dialog box opens, displaying the Main tab. For a description of the elements on the Main tab, see Main Tab, page 30-13.

Step 3  Click Create below the table, or select a DAP entry in the table and click Edit. The Add/Edit DAP Entry dialog box opens. For a description of the elements on this dialog box, see Add/Edit DAP Entry Dialog Box, page 30-17.

Step 4  Select the attribute type from the Criterion list, then enter the appropriate values. The dialog box values vary based on your selection. Options are:
- AAA Attributes Cisco; see Table 30-6 on page 30-19.
- AAA Attributes LDAP; see Table 30-7 on page 30-21.
- AAA Attributes RADIUS; see Table 30-8 on page 30-22.
- Anti-Spyware; see Table 30-9 on page 30-23.
- Anti-Virus; see Table 30-10 on page 30-24.
- AnyConnect Identity; see Table 30-11 on page 30-25.
- Application; see Table 30-12 on page 30-26.
- Device; see Table 30-13 on page 30-26.
- File; see Table 30-14 on page 30-27.
- NAC; see Table 30-15 on page 30-28.
- Operating System; see Table 30-16 on page 30-29.
- Personal Firewall; see Table 30-17 on page 30-30.
- Policy; see Table 30-18 on page 30-31.
- Process; see Table 30-19 on page 30-32.
- Registry; see Table 30-20 on page 30-33.

Step 5  Click OK.
Configuring Cisco Secure Desktop Policies on ASA Devices

Cisco Secure Desktop (CSD) provides a reliable means of eliminating all traces of sensitive data by providing a single, secure location for session activity and removal on the client system. CSD provides a session-based interface where sensitive data is shared only for the duration of an SSL VPN session. All session information is encrypted, and all traces of the session data are removed from the remote client when the session is terminated, even if the connection terminates abruptly. This ensures that cookies, browser history, temporary files, and downloaded content do not remain on a system.

When the session closes, CSD overwrites and removes all data using a U.S. Department of Defense (DoD) sanitation algorithm to provide endpoint security protection.

A complete explanation of the capabilities and configuration of the Cisco Secure Desktop program is beyond the scope of this document. For information about configuring CSD, and what CSD can do for you, see the materials available online at http://www.cisco.com/en/US/products/ps6742/tsd_products_support_configure.html. Select the configuration guide for the CSD version you are configuring.

This procedure describes how to configure the Cisco Secure Desktop feature on an ASA device.

Before You Begin

- Make sure a connection profile policy has been configured on the device. See Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.

Related Topics

- Understanding and Managing SSL VPN Support Files, page 28-5

Step 1

Do one of the following:

- (Device view) With an ASA device selected, select Remote Access VPN > Dynamic Access from the Policy selector.
- (Policy view) Select Remote Access VPN > Dynamic Access (ASA) from the Policy Type selector. Select an existing policy or create a new one.

The Dynamic Access page opens. For a description of the elements on this page, see Dynamic Access Page (ASA), page 30-10.

Step 2

In the Cisco Secure Desktop section, select Enable CSD to enable CSD on the ASA device.

Step 3

In the CSD Package field, specify the name of the File Object that identifies the Cisco Secure Desktop package you want to upload to the device. Click Select to select an existing File Object or to create a new one. For more information, see Add and Edit File Object Dialog Boxes, page 32-22.

Note

The package version must be compatible with the ASA operating system version. When you create a local policy in Device view, the Version field indicates the CSD package version you should select. (The version is included in the package file name. For example, securedesktop-asak9-3.3.0.118.pkg is CSD version 3.3.0.118.) When you create a shared policy in Policy view, the Version field indicates the version of the CSD file you selected. For more information on version compatibility, see Understanding and Managing SSL VPN Support Files, page 28-5.
Step 4  (Optional) In the **Hostscan Package** field, specify the name of the File Object that identifies the Host Scan package you want to upload to the device. Click **Select** to select an existing File Object or to create a new one. For more information, see *Add and Edit File Object Dialog Boxes*, page 32-22.

Step 5  Click **Configure** to open the Cisco Secure Desktop Manager (CSDM) Policy Editor that lets you configure CSD on the security appliance. This application is independent of Security Manager; read the CSD documentation cited above for an explanation of how to use the policy editor.

The editor contains these main items (select them in the table of contents):

- Prelogin Policies—This is a decision tree. When a user attempts a connection, the user’s system is evaluated against your rules and the first rule that matches is applied. Typically, you create policies for secure locations, home locations, and insecure public locations. You can make your checks based on registry information, the presence of specific files or certificates, the workstation’s operating system, or IP address.

All editing is done through the right-click menu. Right click on boxes or + signs to activate related settings, if any.

For end nodes, you can select these options:

- Access Denied—Workstations that match your criteria are prevented from accessing the network.
- Policy—You want to define a specific admission policy at this point. After naming the policy, it is added to the table of contents. Select each item in the policy and configure its settings.
- Subsequence—You want to perform additional checks. Enter the name of the next decision tree that you want to evaluate for this workstation.

- Host scan—You can specify a set of registry entries, file names, and process names, which form a part of the basic host scan. The host scan occurs after the prelogin assessment but before the assignment of a dynamic access policy. Following the basic host scan, the security appliance uses the login credentials, the host scan results, prelogin policy, and other criteria you configure to assign a dynamic access policy. You can also enable:

  - Endpoint Assessment—The remote workstation scans for a large collection of antivirus, antispyware, and personal firewall applications, and associated updates.
  - Advanced Endpoint Assessment—Includes all of the Endpoint Assessment features, and lets you configure an attempt to update noncompliant workstations to meet the version requirements you specify. You must purchase and install a license for this feature before you can configure it.

---

**Dynamic Access Page (ASA)**

Use the Dynamic Access page to view the dynamic access policies (DAP) defined on the security appliance. From this page, you can create, edit, or delete DAPs.

Use the Cisco Secure Desktop section to enable and download the Cisco Secure Desktop (CSD) software on the selected ASA device. Cisco Secure Desktop provides a single, secure location for session activity and removal on the client system, ensuring that sensitive data is shared only for the duration of an SSL VPN session.

>Note

The CSD client software must be installed and activated on a device in order for an SSL VPN policy to work properly.
Dynamic Access policies take precedence over Group policies. If a setting is not specified in a Dynamic Access policy, an ASA device checks for Group policies that specify the setting.

**Navigation Path**
- (Device View) Select an ASA device; then select **Remote Access VPN > Dynamic Access (ASA)** from the Policy selector.
- (Policy View) Select **Remote Access VPN > Dynamic Access (ASA)** from the Policy Type selector. Select an existing policy or create a new one.

### Table 30-5  Add/Edit Dynamic Access Policy Dialog Box > Main Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| File Server Browsing     | Specify the file server browsing setting to be configured on the portal page:<br>  
  - **Unchanged**—Uses values from the group policy that applies to this session.  
  - **Enable**—Enables CIFS browsing for file servers or shared features.  
  - **Disable**—Disables CIFS browsing for file servers or shared features.  
  **Note** Browsing requires NBNS (Master Browser or WINS). If that fails or is not configured, we use DNS.  
  The CIFS browse feature does not support internationalization. |
| File Server Entry        | Specify the file server entry setting to be configured on the portal page:<br>  
  - **Unchanged**—Uses values from the group policy that applies to this session.  
  - **Enable**—Enables a user from entering file server paths and names on the portal page.  
    When enabled, places the file server entry drawer on the portal page. Users can enter pathnames to Windows files directly. They can download, edit, delete, rename, and move files. They can also add files and folders. Shares must also be configured for user access on the applicable Windows servers. Users might have to be authenticated before accessing files, depending on network requirements.  
  - **Disable**—Disables a user from entering file server paths and names on the portal page. |
| HTTP Proxy               | Specify how you want to configure the security appliance to terminate HTTPS connections and forward HTTP/HTTPS requests to HTTP and HTTPS proxy servers:<br>  
  - **Unchanged**—Uses values from the group policy that applies to this session.  
  - **Enable**—Allows the forwarding of an HTTP applet proxy to the client.  
    The proxy is useful for technologies that interfere with proper content transformation, such as Java, ActiveX, and Flash. It bypasses mangling while ensuring the continued use of the security appliance. The forwarded proxy modifies the browser’s old proxy configuration and redirects all HTTP and HTTPS requests to the new proxy configuration. It supports virtually all client side technologies, including HTML, CSS, JavaScript, VBScript, ActiveX, and Java. The only browser it supports is Microsoft Internet Explorer.  
  - **Disable**—Disables the forwarding of an HTTP applet proxy to the client.  
  - **Auto-start**—Enables HTTP proxy and to have the DAP record automatically start the applets associated with these features. |
Dynamic Access Page (ASA)

Chapter 30  Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)

[Image 145x285 to 159x298]

Dynamic Access Page (ASA)

URL Entry Using SSL VPN does not ensure that communication with every site is secure. SSL VPN ensures the security of data transmission between the remote user’s PC or workstation and the security appliance on the corporate network. If a user then accesses a non-HTTPS web resource (located on the Internet or on the internal network), the communication from the corporate security appliance to the destination web server is not secured.

In a clientless VPN connection, the security appliance acts as a proxy between the end user web browser and target web servers. When a user connects to an SSL-enabled web server, the security appliance establishes a secure connection and validates the server SSL certificate. The end user browser never receives the presented certificate, so therefore cannot examine and validate the certificate. The current implementation of SSL VPN does not permit communication with sites that present expired certificates. Neither does the security appliance perform trusted CA certificate validation. Therefore, users cannot analyze the certificate an SSL-enabled web-server presents before communicating with it.

Specify how the URL entry setting must be configured on the portal page:

- **Unchanged**—Uses values from the group policy that applies to this session.
- **Enable**—Allows a user from entering HTTP/HTTPS URLs on the portal page. If this feature is enabled, users can enter web addresses in the URL entry box, and use clientless SSL VPN to access those websites.
- **Disable**—Disables a user from entering HTTP/HTTPS URLs on the portal page.

**Note**  To limit Internet access for users, select **Disable** for the URL Entry field. This prevents SSL VPN users from surfing the Web during a clientless VPN connection.

**Port Forwarding tab**—Lets you select and configure port forwarding lists for user sessions.

**Note**  Port Forwarding does not work with some SSL/TLS versions.

**Caution**  Make sure Sun Microsystems Java Runtime Environment (JRE) 1.4+ is installed on the remote computers to support port forwarding (application access) and digital certificates.

- **Unchanged**—Removes the attributes from the running configuration.
- **Enable**—Enables port forwarding on the device.
- **Disable**—Disables port forwarding on the device.
- **Auto-start**—Enables port forwarding, and to have the DAP record automatically start the port forwarding applets associated with its port forwarding lists.
Chapter 30   Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)

Dynamic Access Page (ASA)

Add/Edit DAP Entry Dialog Box

Use the Add/Edit DAP Entry dialog box to specify the authorization attributes and endpoint attributes for a dynamic access policy. The security appliance selects the dynamic access policy based on the endpoint security information of the remote device and the AAA authorization information for the authenticated user. It then applies the dynamic access policy to the user tunnel or session.

For detailed information about dynamic access policy attributes, see Understanding DAP Attributes, page 30-3.

Table 30-5   Add/Edit Dynamic Access Policy Dialog Box > Main Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port Forwarding List</td>
<td>The Port Forwarding List, that defines the mapping of the port number on the client machine to the application’s IP address and port behind the SSL VPN gateway. You can click Select to open the Port Forwarding List Selector from which you can select the required Port Forwarding List from list of Port Forwarding List objects. A Port Forwarding List object defines the mappings of port numbers on the remote client to the application’s IP address and port behind the SSL VPN gateway.</td>
</tr>
<tr>
<td>Bookmark tab— Lets you enable and configure SSL VPN bookmarks. When enabled, users who successfully log into the SSL VPN are presented with the portal page containing the list of defined bookmarks. These bookmarks enable users to access resources available on SSL VPN websites in Clientless access mode.</td>
<td>Enable Bookmarks When selected, enables bookmarks on the SSL VPN portal page. Bookmarks A list of websites that will be displayed on the portal page as a bookmark to enable users to access the resources available on the SSL VPN websites. You can click Select to open the Bookmarks Selector from which you can select the required bookmark from a list or create a new bookmark, as desired.</td>
</tr>
</tbody>
</table>
| Action tab— Specifies special processing to apply to a specific connection or session. | Terminate When selected, terminates the session. By default, the access policy attributes are applied to the session and it is running. User Message Enter a text message to display on the portal page when this DAP record is selected. Maximum 128 characters. A user message displays as a yellow orb. When a user logs on it blinks three times to attract attention, and then it is still. If several DAP records are selected, and each of them has a user message, all user messages display. 

**Note** You can include in such messages URLs or other embedded text, which require that you use the correct HTML tags. For example: All contractors please read &lt;a href=’http://wwwin.abc.com/procedure.html’&gt; Instructions&lt;/a&gt; for the procedure to upgrade your antivirus software. |
The content of the dialog box differs based on the criterion that you select. The criterion is the authorization or endpoint attribute that serves as the selection criterion that the security appliance uses for selecting and applying dynamic access policies during session establishment. You can select from the following criteria:

- **AAA Attributes Cisco**—Refers to user authorization attributes that are stored in the AAA hierarchical model. See Add/Edit DAP Entry Dialog Box > AAA Attributes Cisco, page 30-19.

- **AAA Attributes LDAP**—Sets the LDAP client stores all native LDAP response attribute value pairs in a database associated with the AAA session for the user. See Add/Edit DAP Entry Dialog Box > AAA Attributes LDAP, page 30-20.

- **AAA Attributes RADIUS**—Sets the RADIUS client stores all native RADIUS response attribute value pairs in a database associated with the AAA session for the user. See Add/Edit DAP Entry Dialog Box > AAA Attributes RADIUS, page 30-21.

- **Anti-Spyware**—Creates an endpoint attribute of type Anti-Spyware. You can use the Host Scan modules of Cisco Secure Desktop to scan for antispyware applications and updates that are running on the remote computer. See Add/Edit DAP Entry Dialog Box > Anti-Spyware, page 30-22.

- **Anti-Virus**—Creates an endpoint attribute of type Anti-Virus. You can use the Host Scan modules of Cisco Secure Desktop to scan for antivirus applications and updates that are running on the remote computer. See Add/Edit DAP Entry Dialog Box > Anti-Virus, page 30-23.

- **AnyConnect Identity**—Creates an endpoint attribute of type AnyConnect Identity. See Add/Edit DAP Entry Dialog Box > AnyConnect Identity, page 30-24.

- **Application**—Indicates the type of remote access connection. See Add/Edit DAP Entry Dialog Box > Application, page 30-25.

- **Device**—Creates an endpoint attribute of type Device. The Device Criterion lets you provide specific device information for use during the associated prelogin policy checking. See Add/Edit DAP Entry Dialog Box > Device, page 30-26.

- **File**—Creates an endpoint attribute of type File. Filename checking to be performed by Basic Host Scan must be explicitly configured using Cisco Secure Desktop Manager. See Add/Edit DAP Entry Dialog Box > File, page 30-27.

- **NAC**—Creates an endpoint attribute of type NAC. NAC protects the enterprise network from intrusion and infection from worms, viruses, and rogue applications by performing endpoint compliancy. We refer to these checks as posture validation. See Add/Edit DAP Entry Dialog Box > NAC, page 30-28.

- **Operating System**—Creates an endpoint attribute of type Operating System. The prelogin assessment module of the CSD can check the remote device for the OS version, IP address, and Microsoft Windows registry keys. See Add/Edit DAP Entry Dialog Box > Operating System, page 30-28.

- **Personal Firewall**—Creates an endpoint attribute of type Personal Firewall. You can use the Host Scan modules of Cisco Secure Desktop to scan for personal firewall applications and updates that are running on the remote computer. For a description of the elements in the dialog box, see Add/Edit DAP Entry Dialog Box > Personal Firewall, page 30-29.

- **Policy**—Creates an endpoint attribute of type Policy. See Add/Edit DAP Entry Dialog Box > Policy, page 30-30.

- **Process**—Process name checking to be performed by Basic Host Scan must be explicitly configured using Cisco Secure Desktop Manager. See Add/Edit DAP Entry Dialog Box > Process, page 30-31.

- **Registry**—Creates an endpoint attribute of type Registry. Registry key scans apply only to computers running Windows Microsoft Windows operating systems. See Add/Edit DAP Entry Dialog Box > Registry, page 30-32.
Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

**Navigation Path**

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed.

**Related Topics**

<td>Connection Profiles</td>
<td>Select the check box, select the matching criteria (for example, is) from the drop-down list, and select the connection profile from a list of all the SSL VPN Connection Profile policies defined on the security appliance. An SSL VPN connection profile comprises a set of records that contain VPN tunnel connection profile policies, including the attributes that pertain to creating the tunnel itself. <strong>Note</strong> For a description of the procedure to configure an SSL VPN Connection Profiles policy, see Configuring Connection Profiles (ASA, PIX 7.0+), page 29-6.</td>
</tr>
</tbody>
</table>

Add/Edit DAP Entry Dialog Box > AAA Attributes LDAP

The LDAP client stores all native LDAP response attribute value pairs in a database associated with the AAA session for the user. The LDAP client writes the response attributes to the database in the order in which it receives them. It discards all subsequent attributes with that name. This scenario might occur when a user record and a group record are both read from the LDAP server. The user record attributes are read first, and always have priority over group record attributes.

To support Active Directory group membership, the AAA LDAP client provides special handling of the LDAP memberOf response attribute. The AD memberOf attribute specifies the DN string of a group record in AD. The name of the group is the first CN value in the DN string. The LDAP client extracts the group name from the DN string and stores it as the AAA memberOf attribute, and in the response attribute database as the LDAP memberOf attribute. If there are additional memberOf attributes in the LDAP response message, then the group name is extracted from those attributes and is combined with the earlier AAA memberOf attribute to form a comma separated string of group names, also updated in the response attribute database.
Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

**Navigation Path**

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed. Select AAA Attributes LDAP as the Criterion.

Add/Edit DAP Entry Dialog Box > Anti-Spyware

You can use the Host Scan feature of the Cisco Secure Desktop feature to enable Endpoint Assessment, a scan for antivirus, personal firewall, and antispyware applications and updates that are running on the remote computer. Following the configuration of the prelogin policies and host scan options, you can configure a match of any one or any combination of the Host Scan results to assign a dynamic access policy following the user login.

Note

Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

Navigation Path

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed. Select Anti-Spyware as the Criterion.

</tbody>
</table>

Add/Edit DAP Entry Dialog Box > AnyConnect Identity

To configure AnyConnect Identity attributes as selection criteria for dynamic access policies, set AnyConnect Identity as the selection criterion in the Add/Edit DAP Entry dialog box. The ASA generates DAP endpoint attributes based on the AnyConnect Identification attributes received from the AnyConnect mobile client. You are not required to enable Cisco Secure Desktop to configure these specific attributes using Security Manager.

For the purposes of assigning a dynamic access policy, if you configure more than one AnyConnect Identity attribute for a particular DAP entry, the entry will be considered a match if any of the attributes values are true. There is no limit for the number of AnyConnect Identity attributes for each dynamic access policy.

Note

Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

Navigation Path

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed. Select AnyConnect Identity as the Criterion.

</tr>
<tr>
<td>Client Type</td>
<td>Select the check box, then select the matching criteria (for example, is or isn’t) from the drop-down list, and specify the type of remote access connection from the list: AnyConnect, Clientless, Cut-through Proxy, IPsec, or L2TP.</td>
</tr>
<tr>
<td>Note</td>
<td>If you select AnyConnect as the client type, make sure to enable Cisco Secure Desktop. If it is not enabled, Security Manager generates an error.</td>
</tr>
</tbody>
</table>

Add/Edit DAP Entry Dialog Box > Device

The DAP Device Criterion lets you provide specific device information for use during the associated prelogin policy checking. You can provide one or more of the following attributes for a device—host name, MAC address, port number, Privacy Protection selection—and indicate whether each is or isn’t to be matched.

Note that isn’t is exclusionary. For example, if you specify the criterion Host Name isn’t zulu_2, all devices not named zulu_2 will match.

Navigation Path

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed. Choose Device as the Criterion.

Add/Edit DAP Entry Dialog Box > NAC

NAC protects the enterprise network from intrusion and infection from worms, viruses, and rogue applications by performing endpoint compliancy and vulnerability checks as a condition for production access to the network. We refer to these checks as posture validation. You can configure posture validation to ensure that the anti-virus files, personal firewall rules, or intrusion protection software on a host with an AnyConnect or Clientless SSL VPN session are up-to-date before providing access to vulnerable hosts on the intranet. Posture validation can include the verification that the applications running on the remote hosts are updated with the latest patches. NAC occurs only after user authentication and the setup of the tunnel. NAC is especially useful for protecting the enterprise network from hosts that are not subject to automatic network policy enforcement, such as home PCs. The security appliance uses Extensible Authentication Protocol (EAP) over UDP (EAPoUDP) messaging to validate the posture of remote hosts.

The establishment of a tunnel between the endpoint and the security appliance triggers posture validation. You can configure the security appliance to pass the IP address of the client to an optional audit server if the client does not respond to a posture validation request. The audit server, such as a Trend server, uses the host IP address to challenge the host directly to assess its health. For example, it may challenge the host to determine whether its virus checking software is active and up-to-date. After the audit server completes its interaction with the remote host, it passes a token to the posture validation server, indicating the health of the remote host.

Note

Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

Navigation Path

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed. Select NAC as the Criterion.

</tbody>
</table>

Add/Edit DAP Entry Dialog Box > Operating System

The prelogin assessment includes a check for the OS attempting to establish a VPN connection. When the user attempts to connect, however, Cisco Secure Desktop checks for the OS, regardless of whether you insert an OS prelogin check.
If the prelogin policy assigned to the connection has Secure Desktop (Secure Session) enabled and if the remote PC is running Microsoft Windows XP or Windows 2000, it installs Secure Session, regardless of whether you insert an OS prelogin check. If the prelogin policy has Secure Desktop enabled and the operating system is Microsoft Windows Vista, Mac OS X 10.4, or Linux, Cache Cleaner runs instead. Therefore, you should make sure the Cache Cleaner settings are appropriate for a prelogin policy on which you have configured Secure Desktop or Cache Cleaner to install. Although Cisco Secure Desktop checks for the OS, you may want to insert an OS prelogin check as a condition for applying a prelogin policy to isolate subsequent checks for each OS.

**Note**
Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

**Navigation Path**
Open the *Add/Edit Dynamic Access Policy Dialog Box*, page 30-12 with the Main tab selected, then click **Create**, or select a dynamic access policy in the table and click **Edit**. The Add/Edit DAP Entry dialog box is displayed. Select **Operating System** as the Criterion.

Add/Edit DAP Entry Dialog Box > Policy

Windows locations let you determine how clients connect to your virtual private network, and protect it accordingly. For example, clients connecting from within a workplace LAN on a 10.x.x.x network behind a NAT device are an unlikely risk for exposing confidential information. For these clients, you might set up a Cisco Secure Desktop Windows Location named Work that is specified by IP addresses on the 10.x.x.x network, and disable both the Cache Cleaner and the Secure Desktop function for this location. Cisco Secure Desktop checks locations in the order listed on the Windows Location Settings window, and grants privileges to client PCs based on the first location definition they match.

Note
Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

Navigation Path
Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed. Select Policy as the Criterion.

Add/Edit DAP Entry Dialog Box > Process

You can specify a set of process names, which form a part of Basic Host Scan. The host scan, which includes Basic Host Scan and Endpoint Assessment, or Advanced Endpoint Assessment, occurs after the prelogin assessment but before the assignment of a dynamic access policy. Following the Basic Host Scan, the security appliance uses the login credentials, the host scan results, prelogin policy, and other criteria you configure to assign a DAP.

Note

Duplicate entries are not allowed. If you configure a dynamic access policy with no AAA or endpoint attributes, the security appliance always selects it since all selection criteria are satisfied.

Navigation Path

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12 with the Main tab selected, then click Create, or select a dynamic access policy in the table and click Edit. The Add/Edit DAP Entry dialog box is displayed. Select Process as the Criterion.

When you configure Host Scan, the configuration displays in this pane, so you can select it and specify the same index when you assign this entry as an endpoint attribute when configuring a DAP, reducing the possibility of errors in typing or syntax.</td>
</tr>
</tbody>
</table>
**Logical Operations Tab**

Use the Logical Operations tab of the Add/Edit Dynamic Access Policy dialog box to configure multiple instances of the AAA and each type of endpoint attribute that you defined in the DAP Entry dialog box. On this tab, set each type of endpoint or AAA attribute to require only one instance of a type (Match Any = OR) or to have all instances of a type (Match All = AND).

- If you configure only one instance of an endpoint category, you do not need to set a value.
- For some endpoint attributes, it is not useful to configure multiple instances. For example, no users have more than one running OS.
- You are configuring the Match Any/Match All operation within each endpoint type. The security appliance evaluates each type of endpoint attribute, and then performs a logical AND operation on all of the configured endpoints. That is, each user must satisfy the conditions of ALL of the endpoints you configure, as well as the AAA attributes.
Navigation Path
Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12, then click the Logical Operations tab.

Field Reference

| Table 30-21 Add/Edit Dynamic Access Policy Dialog Box > Logical Operations Tab |
|-----------------------------|--------------------------------------------------------------------------------|
| Element | Description |
| AAA | Select one of the following options if you defined the AAA attribute in the dynamic access policy: |
| | - **Match Any**—Creates an OR relationship among the attributes. Attributes matching any of your criteria are included in the filter. The security appliance grants access to a particular user for a particular session even if any one of the attributes is matching all your criteria. |
| | - **Match All**—Creates an AND relationship among the attributes. The security appliance grants access to a particular user for a particular session only if the attributes are matching all your criteria. |
| | - **Match None**—Creates a NOT relationship among the attributes. The dynamic access policy specifies that none of the attributes of the user need to match to be granted access to a session. |
| Anti-Spyware | Select one of the following options if you defined Anti-Spyware as an endpoint attribute: |
| | - **Match Any**—Creates an OR relationship among the attributes. Policies matching any instance of your criteria are used to authorize users. |
| | - **Match All**—Creates an AND relationship among the attributes. Only those attributes matching all your criteria are used to authorize users. |
| Anti-Virus | Select one of the following options if you defined Anti-Virus as an endpoint attribute: |
| | - **Match Any**—Set to require that user authorization attributes match any of the values in the Antivirus endpoint attributes you are configuring. |
| | - **Match All**—Set to require that user authorization attributes match all of the values in the endpoint attributes you are configuring, as well as satisfying the AAA attribute. |
| Application | Select one of the following options if you defined Application as an endpoint attribute: |
| | - **Match Any**—Set to require that user authorization attributes match any of the values in the Antivirus endpoint attributes you are configuring. |
| | - **Match All**—Set to require that user authorization attributes match all of the values in the endpoint attributes you are configuring, as well as satisfying the AAA attribute. |
Chapter 30  Managing Dynamic Access Policies for Remote Access VPNs (ASA 8.0+ Devices)

Use the Advanced Expressions tab of the Add/Edit Dynamic Access Policy dialog box to set additional attributes for the dynamic access policy. You can configure multiple instances of each type of endpoint attribute. Be aware that this is an advanced feature that requires knowledge of LUA (www.lua.org).

Note

For detailed information about advanced expressions, see About Advanced Expressions for AAA or Endpoint Attributes and Examples of DAP Logical Expressions.

Navigation Path

Open the Add/Edit Dynamic Access Policy Dialog Box, page 30-12, then click the Advanced Expressions tab.

Table 30-21  Add/Edit Dynamic Access Policy Dialog Box > Logical Operations Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| File      | Select one of the following options if you defined File as an endpoint attribute:  
  - **Match Any**—Set to require that user authorization attributes match any of the values in the Antivirus endpoint attributes you are configuring.  
  - **Match All**—Set to require that user authorization attributes match all of the values in the endpoint attributes you are configuring, as well as satisfying the AAA attribute. |
| Personal Firewall | Personal firewall rules let you specify applications and ports for the firewall to allow or block. Select one of the following options if you defined Personal Firewall as an endpoint attribute:  
  - **Match Any**—Set to require that user authorization attributes match any of the values in the Antivirus endpoint attributes you are configuring.  
  - **Match All**—Set to require that user authorization attributes match all of the values in the endpoint attributes you are configuring, as well as satisfying the AAA attribute. |
| Process   | Select one of the following options if you defined Process as an endpoint attribute:  
  - **Match Any**—Set to require that user authorization attributes match any of the values in the Antivirus endpoint attributes you are configuring.  
  - **Match All**—Set to require that user authorization attributes match all of the values in the endpoint attributes you are configuring, as well as satisfying the AAA attribute. |
| Registry  | Registry key scans apply only to computers running Windows Microsoft Windows operating systems. Basic Host Scan ignores registry key scans if the computer is running Mac OS or Linux. Select one of the following options if you defined Registry as an endpoint attribute:  
  - **Match Any**—Set to require that user authorization attributes match any of the values in the Antivirus endpoint attributes you are configuring.  
  - **Match All**—Set to require that user authorization attributes match all of the values in the endpoint attributes you are configuring, as well as satisfying the AAA attribute. |

</tr>
<tr>
<td></td>
<td>- Basic OR Advanced—Creates an OR relationship between the basic and advanced expressions. Users are granted access to a session if either the basic or advanced expressions in the dynamic access policy are matched with the user policy.</td>
</tr>
<tr>
<td></td>
<td>- Basic Only—Only the basic expressions defined in the DAP entry are used to determine whether the security appliance grants users access to a particular session.</td>
</tr>
<tr>
<td></td>
<td>- Advanced Only—Only the advanced expressions defined in the DAP entry are used to authorize users for an SSL VPN session.</td>
</tr>
<tr>
<td>Advanced Expressions</td>
<td>Enter one or more logical expressions to set AAA or endpoint attributes other than what is possible in the AAA and Endpoint areas above. Enter free-form LUA text that defines new AAA and/or endpoint selection attributes. Security Manager does not validate text that you enter here; it just copies this text to the dynamic access policy XML file, and the security appliance processes it, discarding any expressions it cannot parse.</td>
</tr>
</tbody>
</table>

Cisco Secure Desktop Manager Policy Editor Dialog Box

Using the Cisco Secure Desktop Manager (CSDM) Policy Editor dialog box, you can configure prelogin policies, specify the checks to be performed between the time the user establishes a connection with the security appliance and the time the user enters the login credentials, and configure host scans. For an explanation of configuring CSD on an ASA device, see Configuring Cisco Secure Desktop Policies on ASA Devices, page 30-9.
The Cisco Secure Desktop Manager Policy Editor is an independent program. For information about configuring CSD, and what CSD can do for you, see the materials available online at http://www.cisco.com/en/US/products/ps6742/tsd_products_support_configure.html. Look specifically for information on configuring prelogin policies and host scan. Select the configuration guide for the CSD version you are configuring.

Navigation Path
Open the Dynamic Access Page (ASA), page 30-10, then click **Configure** from the Cisco Secure Desktop section (you must first specify a CSD package). The CSDM Policy Editor dialog box is displayed.

Managing Remote Access VPNs on IOS and PIX 6.3 Devices

You can configure and manage remote access IPsec on devices running Cisco IOS Software or PIX 6.3, and SSL VPNs on IOS 12.4(6)T or higher devices (but not on PIX devices). For more information on the specific device models supported, see Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9.

The configuration of these remote access VPNs are the same for these device types. ASA and PIX 7.0+ devices use different configurations for remote access VPNs (as explained in Chapter 29, “Managing Remote Access VPNs on ASA and PIX 7.0+ Devices”).

The topics in this chapter explain how to configure policies that are specific to IOS and PIX 6.3 devices. Additionally, review the following topics for more information about remote access VPNs:

- Understanding Remote Access VPNs, page 28-1
- Understanding Devices Supported by Each Remote Access VPN Technology, page 28-9
- Discovering Remote Access VPN Policies, page 28-12
- Using the Remote Access VPN Configuration Wizard, page 28-13
  - Creating IPsec VPNs Using the Remote Access VPN Configuration Wizard (IOS and PIX 6.3 Devices), page 28-34
  - Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (IOS Devices), page 28-30

This chapter contains the following topics:

- Overview of Remote Access VPN Policies for IOS and PIX 6.3 Devices, page 31-2
- Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3
- Configuring High Availability in Remote Access VPNs (IOS), page 31-10
- Configuring User Group Policies, page 31-13
- Configuring an SSL VPN Policy (IOS), page 31-14
Overview of Remote Access VPN Policies for IOS and PIX 6.3 Devices

When you configure remote access VPNs on IOS or PIX 6.3 devices, you use the following policies based on the type of VPN you are configuring. Note that you cannot configure SSL VPNs on PIX 6.3 devices.

- **Policies used with both IPsec and SSL remote access VPNs:**
  - **Global Settings**—You can define global settings that apply to all devices in your remote access VPNs. These settings include Internet Key Exchange (IKE), IPsec, NAT, and fragmentation definitions. The global settings typically have defaults that work in most situations, so configuring the Global Settings policy is optional; configure it only if you need non-default behavior. For more information, see Configuring VPN Global Settings, page 24-27.
  - **Public Key Infrastructure**—You can create a Public Key Infrastructure (PKI) policy to generate enrollment requests for CA certificates and RSA keys, and to manage keys and certificates. Certification Authority (CA) servers are used to manage these certificate requests and issue certificates to users who connect to your IPsec or SSL remote access VPN. For more information, see Understanding Public Key Infrastructure Policies, page 24-44 and Configuring Public Key Infrastructure Policies for Remote Access VPNs, page 24-49.

- **Policies used in remote access IPsec VPNs only:**
  - **IKE Proposal**—Internet Key Exchange (IKE), also called ISAKMP, is the negotiation protocol that enables two hosts to agree on how to build an IPsec security association. IKE is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and to automatically establish IPsec security associations (SAs). Use the IKE Proposal policy to define the requirements for phase 1 of the IKE negotiation. For more information, see Configuring an IKE Proposal, page 24-9.
  - **IPsec Proposal (IOS/PIX 6.x)**—An IPsec proposal is a collection of one or more crypto maps. A crypto map combines all the components required to set up IPsec security associations (SAs), including IPsec rules, transform sets, remote peers, and other parameters that might be necessary to define an IPsec SA. The policy is used for IKE phase 2 negotiations. For more information, see Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3.
  - **High Availability**—High Availability (HA) is supported by the creation of an HA group made up of two or more hub devices that use Hot Standby Routing Protocol (HSRP) to provide transparent, automatic device failover. For more information, see Configuring High Availability in Remote Access VPNs (IOS), page 31-10.
  - **User Groups (IOS/PIX 6.x)**—A user group policy specifies the attributes that determine user access to and use of the VPN. For more information, see Configuring User Group Policies, page 31-13.

- **Policies used in remote access SSL VPNs only:**
  - **SSL VPN**—The SSL VPN policy table lists all of the contexts that define the virtual configurations of the SSL VPN. Each context has a gateway, domain or virtual hostname, and user group policies. For more information, see Configuring an SSL VPN Policy (IOS), page 31-14.
Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices)

This procedure describes how to create or edit an IPsec proposal for your remote access VPN server when the server uses Cisco IOS Software or PIX release 6.3.

An IPsec proposal is a collection of one or more crypto maps. A crypto map combines all the components required to set up IPsec security associations (SAs), including IPsec rules, transform sets, remote peers, and other parameters that might be necessary to define an IPsec SA.

When configuring an IPsec proposal, you must define the external interface through which the remote access clients connect to the server, and the encryption and authentication algorithms that protect the data in the VPN tunnel. You can also select a group authorization (Group Policy Lookup) method that defines the order in which group policies are searched (on the local server or on external AAA servers) and a user authentication (Xauth) method that defines the order in which user accounts are searched.

For more information on IPsec tunnel concepts, see Understanding IPsec Proposals, page 24-16.

When you create or edit an IPsec proposal, you can also configure:

- A VPN Services Module (VPNSM) interface IPsec VPN Shared Port Adapter (VPN SPA) on a Catalyst 6500/7600 device (see VPNSM/VPN SPA/VSPA Settings Dialog Box, page 31-6).
- A dynamic virtual interface on an IOS router running Cisco IOS Software version 12.4(2)T or later, except 7600 device. For more information, see Configuring Dynamic VTI/VRF Aware IPsec in Remote Access VPNs (IOS Devices), page 31-7.
- VRF-Aware IPsec on a router or Catalyst 6500/7600 device (see Configuring Dynamic VTI/VRF Aware IPsec in Remote Access VPNs (IOS Devices), page 31-7).

Related Topics

- Understanding VRF-Aware IPsec, page 23-14
- VPNSM/VPN SPA/VSPA Settings Dialog Box, page 31-6
- Table Columns and Column Heading Features, page 1-44

---

Step 1
Do one of the following:

- (Policy view) Select Remote Access VPN > IPSec VPN > IPsec Proposal (IOS/PIX 6.x) from the Policy Type selector. Select an existing policy or create a new one.

The IPsec Proposal page opens and lists the configured proposals, including the VPN endpoint, IPsec transform set, and whether reverse route injection is configured for the proposal. You can add other columns to the default display to show the AAA, VRF, and dVTI configuration.

Step 2
Do any of the following:

- To add a new IPsec proposal, click the Add Row (+) button and fill in the IPsec Proposal Editor dialog box. For detailed information on the available options, see IPsec Proposal Editor (IOS, PIX 6.3 Devices), page 31-4.
- To edit an existing proposal, select it and click the Edit Row (pencil) button.
- To delete a proposal, select it and click the Delete Row (trash can) button.
Chapter 31  Managing Remote Access VPNs on IOS and PIX 6.3 Devices

IPsec Proposal Editor (IOS, PIX 6.3 Devices)

Use the IPsec Proposal Editor to create or edit an IPsec proposal for an IOS or PIX 6.3 device, including Catalyst 6500/7600, in your remote access VPN. The editor has two tabs—General and Dynamic VTI/VRF Aware IPsec. This topic explains the basic settings on the General tab. For an explanation of Dynamic VTI/VRF Aware IPsec settings, see Configuring Dynamic VTI/VRF Aware IPsec in Remote Access VPNs (IOS Devices), page 31-7.

The elements in this dialog box differ according to the selected device. The table below describes the elements on the General tab in the IPsec Proposal Editor dialog box when a Cisco IOS router, Catalyst 6500/7600, or PIX 6.3 device is selected.

Note
For a description of the elements in the dialog box when a PIX 7.0+ or ASA device is selected, see IPsec Proposal Editor (ASA, PIX 7.0+ Devices), page 29-31.

Navigation Path

• (Device view) Select Remote Access VPN > IPSec VPN > IPsec Proposal (IOS/PIX 6.x) from the Policy selector. Click the Add Row (+) or Edit Row (pencil) buttons.

• (Policy view) Select Remote Access VPN > IPSec VPN > IPsec Proposal (IOS/PIX 6.x) from the Policy Type selector. Select an existing policy or create a new one. Click the Add Row (+) or Edit Row (pencil) buttons.

</thead>
<tbody>
<tr>
<td>IKEv1 Transform Sets</td>
<td>The transform sets to be used for your tunnel policy. Transform sets specify which authentication and encryption algorithms will be used to secure the traffic in the tunnel. You can select up to nine transform sets. For more information, see Understanding Transform Sets, page 24-18. If more than one of your selected transform sets is supported by both peers, the transform set that provides the highest security will be used. Click <strong>Select</strong> to select the IPsec transform set policy objects to use in the topology. If the required object is not yet defined, you can click the <strong>Create (+)</strong> button beneath the available objects list in the selection dialog box to create a new one. For more information, see Configuring IPSec IKEv1 or IKEv2 Transform Set Policy Objects, page 24-24.</td>
</tr>
</tbody>
</table>
| Reverse Route Injection        | Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint. For more information, see Understanding Reverse Route Injection, page 24-19. Select one of the following options to configure RRI on the crypto map:  
  - **None**—Disables the configuration of RRI on the crypto map.  
  - **Standard**—Creates routes based on the destination information defined in the crypto map access control list (ACL). This is the default option.  
  - **Remote Peer**—Creates two routes, one for the remote endpoint and one for route recursion to the remote endpoint via the interface to which the crypto map is applied.  
  - **Remote Peer IP**—Specifies an address as the explicit next hop to the remote VPN device. Enter the IP address or a network/host object that specifies the address, or click **Select** to select the network/host object from a list or to create a new object.  
    **Note**  
    If you use network/host objects, you can select the **Allow Value Override per Device** option in the object to override the IP address, if required, for specific devices that use this object. |
| Group Policy Lookup/AAA        | The AAA authorization method list that will be used to define the order in which the group policies are searched. Group policies can be configured on both the local server or on an external AAA server. Remote users are grouped, so that when the remote client establishes a successful connection to the VPN server, the group policies for that particular user group are pushed to all clients belonging to the user group. Click **Select** to open a dialog box that lists all available AAA group servers, and in which you can create AAA group server objects. Select all that apply and use the up and down arrow buttons to put them in priority order.

VPNSM/VPN SPA/VSPA Settings Dialog Box

Note

This dialog box is available only if the selected device is a Catalyst 6500/7600.

Use the VPNSM/VPN SPA/VSPA Settings dialog box to specify the settings for configuring a VPN Services Module (VPNSM), a VPN Shared Port Adapter (VPN SPA), or a Cisco VPN Service Port Adapters (VSPAs) on a Catalyst 6500/7600 device.

Notes

- Before you define the settings, you must import your Catalyst 6500/7600 device to the Security Manager inventory and discover its interfaces. For more information, see Configuring VPNSM or VPN SPA/VSPA Endpoint Settings, page 23-41.
- Before you configure VPNSM or VPN SPA with VRF-Aware IPsec on a device, verify that an IPsec proposal with VRF-Aware IPsec and an IPsec proposal without VRF-Aware IPsec were not configured on the device.

Navigation Path

In the General tab of the IPsec Proposal Editor Dialog Box (for Catalyst 6500/7600 Devices), click Select next to the Inside VLAN field. For more information about opening the IPsec Proposal Editor, see IPsec Proposal Editor (IOS, PIX 6.3 Devices), page 31-4.

Configuring Dynamic VTI/VRF Aware IPsec in Remote Access VPNs (IOS Devices)

The Dynamic VTI/VRF Aware IPsec tab is available only when the selected device is a Cisco IOS router or Catalyst 6500/7600.

Use the Dynamic VTI/VRF Aware IPsec tab of the IPsec Proposal Editor to configure VRF Aware IPsec settings (on a Cisco IOS router or Catalyst 6500/7600 device), configure a dynamic virtual interface on a Cisco IOS router, or do both, in your remote access VPN.

IOS devices allow dynamic virtual template interfaces (VTIs), which provide highly secure and scalable connectivity for remote-access VPNs, replacing dynamic crypto maps and the dynamic hub-and-spoke method for establishing tunnels. You can use dynamic VTIs for both the server and remote configuration. The tunnels provide an on-demand separate virtual access interface for each VPN session. The configuration of the virtual access interfaces is duplicated from a virtual template configuration, which includes the IPsec configuration and any features configured on the virtual template interface. Dynamic VTIs provide efficiency in the use of IP addresses and provide secure connectivity. They enable dynamically downloadable per-group and per-user policies to be configured on a RADIUS server. Dynamic VTI simplifies VRF-Aware IPsec deployment, as the VRF is configured on the interface.
When this feature is enabled, Security Manager implicitly creates the virtual template interface for the selected device in a remote access VPN. All you must do is provide the IP address on the server that will be used as the virtual template interface, or use an existing loopback interface. The virtual template interface is created on the remote client without an IP address.

Notes
- You can configure dynamic VTI only on routers running Cisco IOS Release 12.4(2)T and later, except 7600 devices.
- You can configure dynamic VTI with or without VRF-Aware IPsec. For more information about VRF-Aware IPsec, see Understanding VRF-Aware IPsec, page 23-14.
- You can also configure dynamic VTI in a site-to-site Easy VPN topology. For more information, see Easy VPN with Dynamic Virtual Tunnel Interfaces, page 26-2.

Navigation Path
In the IPsec Proposal Editor Dialog Box (for IOS routers and Catalyst 6500/7600 devices), click the Dynamic VTI/VRF Aware IPsec tab. For more information, see IPsec Proposal Editor (IOS, PIX 6.3 Devices), page 31-4.

</tr>
</tbody>
</table>
### Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices)

#### Virtual Template IP Type
Available if you selected Enable Dynamic VTI. Specify the virtual template interface to use:
- **IP**—To use an IP address as the virtual template interface. Specify the private IP address.
- **Use Loopback Interface**—To use the IP address taken from an existing loopback interface as the virtual template interface. Click Select to select the interface or interface role object, or to create a new object that identifies the loopback interface.

#### VRF Solution
Available if you selected Enable VRF Settings. Select the VRF solution:
- **1-Box (IPsec Aggregator + MPLS PE)**—One device serves as the Provider Edge (PE) router that does the MPLS tagging of the packets in addition to IPsec encryption and decryption from the Customer Edge (CE) devices. For more information, see VRF-Aware IPsec One-Box Solution, page 23-14.
- **2-Box (IPsec Aggregator Only)**—The PE device does only the MPLS tagging, while the IPsec Aggregator device does the IPsec encryption and decryption from the CEs. For more information, see VRF-Aware IPsec Two-Box Solution, page 23-15.

#### VRF Name
The name of the VRF routing table on the IPsec Aggregator. The VRF name is case-sensitive.

#### Route Distinguisher
The unique identifier of the VRF routing table on the IPsec Aggregator. This unique route distinguisher maintains routing separation for each VPN across the MPLS core to the other PE routers. The identifier can be in either of the following formats:
- **IP address:X**, where X is in the range of 0-999999999.
- **N:X**, where N is in the range of 0-65535, and X is in the range of 0-999999999.

**Note** You cannot override the RD identifier after deploying the VRF configuration to your device. To modify the RD identifier after deployment, you must manually remove it through the device CLI and then deploy again.

#### Interface Towards Provider Edge
Available only for 2-Box VRF. The VRF forwarding interface on the IPsec Aggregator towards the PE device. Click Select to select the interface or interface role object, or to create a new object that identifies the interface.

**Note** If the IPsec Aggregator (hub) is a Catalyst VPN service module, you must specify a VLAN.
Configuring High Availability in Remote Access VPNs (IOS)

Use the High Availability page to configure a High Availability (HA) policy on a Cisco IOS router or Cisco Catalyst switch in a remote access VPN.

In Security Manager, High Availability (HA) is supported by the creation of an HA group made up of two or more devices that use Hot Standby Routing Protocol (HSRP) to provide transparent, automatic device failover. By sharing a virtual IP address, the devices in the HA group present the appearance of a single virtual device or default gateway to the remote access users. One device in the HA group is

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routing Protocol</td>
<td>Available only for 2-Box VRF. Select the routing protocol to use between the IPsec Aggregator and the PE. The options are BGP, EIGRP, OSPF, RIPv2, or Static route. If the routing protocol for the secured IGP differs from the routing protocol between the IPsec Aggregator and the PE, select the routing protocol for redistributing the routing to the secured IGP.</td>
</tr>
<tr>
<td>AS Number</td>
<td>Available only for 2-Box VRF with BGP or EIGRP routing. The number to use to identify the autonomous system (AS) area between the IPsec Aggregator and the PE. The AS number must be between 1 and 65535. If the routing protocol for the secured IGP differs from the routing protocol between the IPsec Aggregator and the PE, enter an AS number that identifies the secured IGP into which the routing will be redistributed from the IPsec Aggregator and the PE. This is relevant only if GRE or DMVPN are applied.</td>
</tr>
<tr>
<td>Process Number</td>
<td>Available only for 2-Box VRF with OSPF routing. The routing process ID number to use to configure the routing between the IPsec Aggregator and the PE. The process number must be between 1 and 65535.</td>
</tr>
<tr>
<td>OSPF Area ID</td>
<td>Available only for 2-Box VRF with OSPF routing. The ID number of the area in which the packet belongs. You can enter any number from 0 to 4294967295. Note: All OSPF packets are associated with a single area, so all devices must have the same area ID number.</td>
</tr>
<tr>
<td>Redistribute Static Route</td>
<td>Available only for 2-Box VRF with any routing protocol other than Static route. When selected, enables static routes to be advertised in the routing protocol configured on the IPsec Aggregator towards the PE device. Note: If this check box is deselected and Enable Reverse Route Injection is enabled (default) for the IPsec proposal, static routes are still advertised in the routing protocol on the IPsec Aggregator.</td>
</tr>
<tr>
<td>Next Hop IP Address</td>
<td>Available only for 2-Box VRF with Static routing. The IP address of the provider edge device (or the interface that is connected to the IPsec aggregator).</td>
</tr>
</tbody>
</table>
always active and assumes the virtual IP address, while the others are standby devices. The devices in the group watch for hello packets from active and standby devices. If the active device becomes unavailable for any reason, a standby device takes ownership of the virtual IP address and takes over the remote access VPN. This transfer is seamless and transparent to remote access users.

Stateful SwitchOver (SSO) is used to ensure that state information is shared between the HSRP devices in the HA group. If a device fails, the shared state information enables the standby device to maintain IPsec sessions without having to re-establish the tunnel or renegotiate the security associations.

**Tips**
- When configuring an HA group, you must provide an inside virtual IP that matches the subnet of one of the interfaces on the device, in addition to a VPN virtual IP that matches the subnet of one of the device’s interfaces and is configured with an IPsec proposal. See Configuring an IPsec Proposal on a Remote Access VPN Server (IOS, PIX 6.3 Devices), page 31-3.
- A remote access VPN server device on which HA is configured cannot be configured as a hub in a site-to-site VPN topology on which HA is configured, using the same outside interface that was used for the remote access VPN server.

---

**Step 1**
Do one of the following:

- (Device view) With an IOS device selected, select **Remote Access VPN > IPSec VPN > High Availability** from the Policy selector.
- (Policy view) Select **Remote Access VPN > IPSec VPN > High Availability** from the Policy Type selector. Select an existing policy or create a new one.

The High Availability page opens.

**Step 2**
Configure the options explained in the following table.
### Table 31-4  High Availability Page, Remote Access VPNs

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inside Virtual IP</td>
<td>The IP address that is shared by the devices in the HA group and that represents the inside interface of the HA group. The virtual IP address must be on the same subnet as the inside interfaces of the devices in the HA group, but must not be identical to the IP address of any of these interfaces. You must provide an inside virtual IP that matches the subnet of one of the interfaces on the device, in addition to a VPN virtual IP that matches the subnet of one of the device’s interfaces and is configured with an IPsec proposal. <strong>Note</strong> If there is an existing standby group on the device, make sure that the IP address you provide is different from the virtual IP address already configured on the device.</td>
</tr>
<tr>
<td>Inside Mask</td>
<td>The subnet mask for the inside virtual IP address.</td>
</tr>
<tr>
<td>VPN Virtual IP</td>
<td>The IP address that is shared by the devices in the HA group and represents the VPN interface of the HA group. This IP address serves as the endpoint of the VPN tunnel. <strong>Note</strong> If there is an existing standby group on the device, make sure that the IP address you provide is different from the virtual IP address already configured on the device.</td>
</tr>
<tr>
<td>VPN Mask</td>
<td>The subnet mask for the VPN virtual IP address.</td>
</tr>
<tr>
<td>Hello Interval</td>
<td>The duration in seconds (within the range of 1-254) between each hello message sent by a device to the other devices in the group to indicate status and priority. The default is 5 seconds.</td>
</tr>
<tr>
<td>Hold Time</td>
<td>The duration in seconds (within the range of 2-255) that a standby device will wait to receive a hello message from the active device before concluding that the device is down. The default is 15 seconds.</td>
</tr>
<tr>
<td>Standby Group Number (Inside)</td>
<td>The standby number of the inside device interface that matches the internal virtual IP subnet for the devices in the HA group. The number must be within the range of 0-255. The default is 1.</td>
</tr>
<tr>
<td>Standby Group Number (Outside)</td>
<td>The standby number of the outside device interface that matches the external virtual IP subnet for the devices in the HA group. The number must be within the range of 0-255. The default is 2. <strong>Note</strong> The outside standby group number must be different to the inside standby group number.</td>
</tr>
<tr>
<td>Failover Server</td>
<td>The IP address or network/host policy object that identifies the inside interface of the remote peer failover servers. Enter the IP address or network/host object name, or click <strong>Select</strong> to select an object or to create a new object.</td>
</tr>
<tr>
<td>Enable Stateful Failover</td>
<td>Enables SSO for stateful failover. This option is always selected and you cannot deselect it for remote access VPNs.</td>
</tr>
</tbody>
</table>
Configuring User Group Policies

Use the User Groups (IOS/PIX 6.x) policy to specify user groups for your remote access IPSec VPN server. You can configure user groups on a Cisco IOS router, PIX 6.3 Firewall, or Catalyst 6500/7600 device.

When you configure a remote access VPN server, you must create user groups to which remote clients will belong. A user group policy specifies the attributes that determine user access to and use of the VPN. User groups simplify system management, enabling you to quickly configure VPN access for large numbers of users.

For example, in a typical remote access VPN, you might allow a finance group to access one part of a private network, a customer support group to access another part, and an MIS group to access other parts. In addition, you might allow specific users within MIS to access systems that other MIS users cannot access. User group policies provide the flexibility to do so securely.

Remote clients must have the same group name as the user group configured on the VPN server so that they can connect to the device; otherwise, a connection cannot be established. When a remote client establishes a connection to the VPN server, the group policies for that user group are pushed to all clients belonging to the same user group. You can configure user groups on the local remote access VPN server and external AAA servers.

Notes

- You can also specify user groups using the Remote Access VPN Configuration Wizard. For more information, see Using the Remote Access VPN Configuration Wizard, page 28-13.
- To specify group policies for an SSL VPN on an IOS device, use the SSL VPN policy as explained in Configuring an SSL VPN Policy (IOS), page 31-14.

Related Topics

- Understanding Remote Access IPSec VPNs, page 28-2

Step 1

Do one of the following:

- (Device view) With an IOS router, Catalyst 6500/7600, or PIX 6.3 device selected, select Remote Access VPN > IPSec VPN > User Groups (IOS/PIX 6.x) from the Policy selector.
- (Policy view) Select Remote Access VPN > IPSec VPN > User Groups (IOS/PIX6.x) from the Policy Type selector. Select an existing policy or create a new one.

The User Groups page opens.

The page contains two lists: Available User Groups lists all existing User Group policy objects that are configured for remote access IPSec VPNs; Selected User Groups lists all of the User Group policy objects that will be configured on the device.

Step 2

Ensure that the list of selected user groups contains the desired User Group policy objects:

- To create a new User Group policy object, click the Create (+) button beneath the available user groups list to open the Add User Group dialog box. For instructions on creating the object, see Add or Edit User Group Dialog Box, page 32-54.
  After you create the group, it is added to the available list, and you must add it to the selected list if you want to use it.
- To add a User Group to the selected list, select it in the available list and click >>.
To remove a User Group, select it in the selected list and click <<. If the group is already configured on the device, it will be removed during the next deployment.

You can edit the properties of a User Group object by selecting it in either list and clicking the Edit button.

---

**Configuring an SSL VPN Policy (IOS)**

Use the SSL VPN policy to configure the SSL VPN connection policies for an IOS router. From this page, you can create, edit, or delete SSL VPN policies.

**Related Topics**
- Understanding Remote Access SSL VPNs, page 28-2
- Creating SSL VPNs Using the Remote Access VPN Configuration Wizard (IOS Devices), page 28-30
- Filtering Tables, page 1-44

**Step 1**
Do one of the following:
- (Device view) With an IOS device selected, select Remote Access VPN > SSL VPN from the Policy selector.
- (Policy view) Select Remote Access VPN > SSL VPN > SSL VPN Policy (IOS) from the Policy Type selector. Select an existing policy or create a new one.

The SSL VPN page appears.

The table lists all of the contexts that define the virtual configurations of the SSL VPN. Each context has a gateway, domain or virtual hostname, and user group policies. The status of the context is also shown, either In Service or Out of Service.

**Step 2**
Do either of the following:
- To add a context, click the Add Row button to open the SSL VPN Context Editor Dialog Box (IOS), page 31-15.
- To edit a context, select it and click the Edit Row button.

**Note** To delete a context, select it and click the Delete Row button.

**Step 3**
Configure at least the following general settings for the policy. For information on other fields, see General Tab, page 31-16.

- **Name, Domain**—For new policies, the name of the context that defines the virtual configuration of the SSL VPN. To simplify the management of multiple context configurations, make the context name the same as the domain or virtual hostname.
- **Gateway**—The SSL VPN gateway policy object that identifies the gateway device to which users will connect, including interface and port configuration. Click Select to select the object from a list or to create a new object.

When you select the object, the Portal Page URL field shows the URL to which users connect.
- **Authentication Server Group**—A prioritized list of AAA server group objects that identify the AAA servers to use for authenticating users.

- **User Groups**—The user groups that will be used in your SSL VPN policy. User groups define the resources available to users when connecting to an SSL VPN gateway.

  To add a user group, click **Add Row** to open a list of existing user group policy objects from which you can select the group. If the desired group does not already exist, click the **Create** button below the available groups list and create it. For more information about user group objects, see **Add or Edit User Group Dialog Box**, page 32-54.

**Step 4**

Click the **Portal Page** tab and customize the design of the login page. You can customize the title, the logo graphic, the message that appears above the login prompt, and the background and text colors.

If you want to select a different graphic, you must first copy the graphic onto the Security Manager server. You cannot select it from your workstation’s hard drive.

**Step 5**

Click the **Secure Desktop** tab to configure Cisco Secure Desktop (CSD) software. CSD policies define entry requirements for client systems and provide a single, secure location for session activity and removal on the client system, ensuring that sensitive data is shared only for the duration of an SSL VPN session.

If you want to use CSD, select **Enable Cisco Secure Desktop** and click **Select** to select a Secure Desktop Configuration policy object, which defines the rules you want to use to control VPN access and host scanning. You can create a new object from the selection list. For information about configuring these objects, see **Creating Cisco Secure Desktop Configuration Objects**, page 31-18.

**Note**

You must install and activate the Secure Desktop Client software on a device for your configuration to work.

**Step 6**

Click the **Advanced** tab to configure a maximum number of simultaneous users for the context or if you are using VRF, the name of the VRF instance that is associated with the SSL VPN context.

**Step 7**

Click **OK** to save your changes.

### SSL VPN Context Editor Dialog Box (IOS)

Use this dialog box to create or modify a context that defines the virtual configuration of an SSL VPN. For more information, see **Configuring an SSL VPN Policy (IOS)**, page 31-14.

**Navigation Path**

Open the SSL VPN (IOS) policy, then click **Add Row** (+), or select a context in the table and click **Edit Row**. For information on opening the SSL VPN policy, see **Configuring an SSL VPN Policy (IOS)**, page 31-14.

Creating Cisco Secure Desktop Configuration Objects

Cisco Secure Desktop (CSD) Configuration objects define the settings you want to use if you enable Secure Desktop in an SSL VPN policy for an IOS device (see Configuring an SSL VPN Policy (IOS), page 31-14). For ASA devices, the feature is set up as part of the Dynamic Access Policy (see Understanding Dynamic Access Policies, page 30-1 and Configuring Cisco Secure Desktop Policies on ASA Devices, page 30-9).

Cisco Secure Desktop (CSD) provides a reliable means of eliminating all traces of sensitive data by providing a single, secure location for session activity and removal on the client system. CSD provides a session-based interface where sensitive data is shared only for the duration of an SSL VPN session. All session information is encrypted, and all traces of the session data are removed from the remote client when the session is terminated, even if the connection terminates abruptly.

About Windows Locations

Windows locations let you determine how clients connect to your virtual private network, and protect it accordingly. For example, clients connecting from within a workplace LAN on a 10.x.x.x network behind a NAT device are an unlikely risk for exposing confidential information. For these clients, you might set up a CSD Windows Location named Work that is specified by IP addresses on the 10.x.x.x network, and disable both the Cache Cleaner and the Secure Desktop function for this location.

In contrast, users’ home PCs might be considered more at risk to viruses due to their mixed use. For these clients, you might set up a location named Home that is specified by a corporate-supplied certificate that employees install on their home PCs. This location would require the presence of antivirus software and specific, supported operating systems to grant full access to the network.

Alternatively, for untrusted locations such as Internet cafes, you might set up a location named “Insecure” that has no matching criteria (thus making it the default for clients that do not match other locations). This location would require full Secure Desktop functions, and include a short timeout period to prevent access by unauthorized users. If you create a location and do not specify criteria, make sure it is the last entry in the Locations list.
### Configuring an SSL VPN Policy (IOS)

**Related Topics**
- Creating Policy Objects, page 6-8

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Select <strong>Manage &gt; Policy Objects</strong> to open the Policy Object Manager (see Policy Object Manager Window, page 6-4).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Select <strong>Cisco Secure Desktop Configuration</strong> from the Object Type selector.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Right-click in the work area and select <strong>New Object</strong> to open the Add or Edit Secure Desktop Configuration Dialog Box, page 32-20.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Enter a name for the object and optionally a description of the object.</td>
</tr>
</tbody>
</table>
| Step 5 | Select **Windows Location Settings** to create locations (such as Work, Home, or Insecure), and define the location-based settings (also called adaptive policies) for CSD.  
  
a. For each location you want to configure, enter its name in the **Location to Add** field and click **Add** to move it to the Locations field. You can reorder the locations using the Move Up and Move Down buttons. When users connect, these locations are evaluated in order and the first one that matches is used to define the policies for the user.  
  
  When you add a location, a folder for the location is added to the table of contents. The folder and its subfolders define the policies for the location.  
  
b. If you want all the open browser windows to close after the Secure Desktop installation, make sure to select the corresponding check box.  
  
c. Select the required check boxes to configure a VPN Feature policy that enables web browsing, file access, port forwarding, and full tunneling, if installation or location matching fails. |
| Step 7 | Select **Windows CE** to configure a VPN feature policy to enable or restrict web browsing and remote server file access for remote clients running Microsoft Windows CE. |
| Step 8 | Select **Mac and Linux Cache Cleaner** to configure the Cache Cleaner and a VPN Feature Policy for these clients, such as enabling or restricting web browsing, remote server file access, and port forwarding. |
| Step 9 | (Optional) Under Category, select a category to help you identify this object in the Objects table. See Using Category Objects, page 6-11. |
| Step 10 | Click **OK** to save the object. |
Configuring Policy Objects for Remote Access VPNs

There are several policy objects that you use primarily or exclusively with remote access VPNs. Some of these objects, the ASA Group Policies and User Group objects, are also used with Easy VPN site-to-site topologies. This reference explains the configuration of these policy objects.

This chapter contains the following topics:

- ASA Group Policies Dialog Box, page 32-1
- Add or Edit Secure Desktop Configuration Dialog Box, page 32-20
- Add and Edit File Object Dialog Boxes, page 32-22
- Add or Edit Port Forwarding List Dialog Boxes, page 32-25
- Add or Edit Single Sign On Server Dialog Boxes, page 32-27
- Add or Edit Bookmarks Dialog Boxes, page 32-29
- Add and Edit SSL VPN Customization Dialog Boxes, page 32-32
- Add or Edit SSL VPN Gateway Dialog Box, page 32-46
- Add and Edit Smart Tunnel List Dialog Boxes, page 32-48
- Add and Edit Smart Tunnel Auto Signon List Dialog Boxes, page 32-51
- Add or Edit User Group Dialog Box, page 32-54
- Add or Edit WINS Server List Dialog Box, page 32-70

**ASA Group Policies Dialog Box**

Use the Add or Edit ASA Group Policies dialog box to create, copy, and edit an ASA user group policies object.

ASA group policies are configured on ASA security appliances in Easy VPN topologies, remote access IPSec VPNs, and remote access SSL VPNs. When you configure an Easy VPN or remote access VPN, you must create group policies to which remote clients will belong. A group policy is a set of user-oriented attribute/value pairs for VPN connections that are stored either internally (locally) on the device or externally on a AAA server. The tunnel group uses a group policy that sets terms for user connections after the tunnel is established. Group policies let you apply whole sets of attributes to a user or a group of users rather than having to specify each attribute individually for each user.
ASA Group Policies Dialog Box

Note
You must select the technology for which you are creating the object. Depending on the selected technology, the appropriate settings are available for configuration. If you select the IKEv1 or IKEv2 options, the IKE Proposal and IPSec Proposal policies must also be configured to support the selected IKE version.

Navigation Path
Select ASA Group Policies in the Policy Object Manager Window, page 6-4. Right-click inside the work area and select New Object or right-click a row and select Edit Object.

Tip
You can also create objects while configuring policies that use this type of object, including Connection Profile policies for remote access and Easy VPN, or the Group Policies policy for remote access VPNs.

Related Topics

</table>

Settings Pane
The body of the dialog box is a pane with a table of contents on the left and settings related to the item selected in the table of contents on the right.

You must first configure technology settings, then you can select items from the table of contents on the left and configure the options you require. Your selections on the Technology page control which options are available on these pages and in the table of contents.

The top folders in the table of contents represent the VPN technologies or other settings that you can configure, and are explained next.
### Technology settings

These settings control what you can define in the group policy:

- **Group Policy Type**—Whether you are storing the group policy on the ASA device itself (Internal) or on a AAA server (External). You cannot change this option when editing an object.
  
  If you select **External**, the only attributes you can configure are the name of the AAA server group object that identifies the AAA server and its password.

- **Technology**—The types of VPN for which this object defines group policies. Select all that apply:
  - Easy VPN/IPSec IKEv1—For Easy VPN topologies or remote access IPsec VPNs that allow IKEv1 negotiations.
  - Easy VPN/IPSec IKEv2—For remote access IPsec VPNs that allow IKEv2 negotiations. IKEv2 is not supported in Easy VPN topologies.
  - SSL Clientless—For remote access SSL VPNs of all types, not just clientless.

- **External Server Group**—If you are storing the group policy attributes on an external AAA server, specify the AAA server group that will be used for authentication. Click **Select** to select the object from a list or to create a new object.

  After you select an external server group, the **Password** and **Confirm** fields become active. Enter the alphanumeric password to use for authenticating with the server in both fields. The password can be a maximum of 128 characters; spaces are not allowed.

### DNS/WINS

The DNS and WINS servers and the domain name that should be pushed to clients associated with the group. See ASA Group Policies DNS/WINS Settings, page 32-17.

### Split Tunneling

Settings to allow a remote client to conditionally direct encrypted packets through a secure tunnel to the central site and simultaneously allow clear text tunnels to the Internet through a network interface. See ASA Group Policies Split Tunneling Settings, page 32-18.

### Easy VPN/IPSec VPN

Settings for Easy VPN and remote access IPsec VPNs:

- **Client Configuration**—The Cisco client parameters for the group. See ASA Group Policies Client Configuration Settings, page 32-4.

- **Client Firewall Attributes**—The firewall settings for VPN clients for the group. See ASA Group Policies Client Firewall Attributes, page 32-5.

- **Hardware Client Attributes**—The VPN 3002 Hardware Client settings for the group. See ASA Group Policies Hardware Client Attributes, page 32-7.

- **IPSec**—The tunneling protocols, filters, connection settings, and servers for the group. See ASA Group Policies IPSec Settings, page 32-8.

#### Table 32-3  ASA Group Policies Client Firewall Attributes

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firewall Mode</td>
<td>The firewall requirements for client systems for the group:</td>
</tr>
<tr>
<td></td>
<td>- <strong>No Firewall</strong>—Do not use a firewall. You cannot configure any other options on the page.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Firewall Required</strong>—All users in this group must use the designated firewall. The security appliance drops any session that attempts to connect without the designated firewall installed and running. In this case, the security appliance notifies the VPN client that its firewall configuration does not match.</td>
</tr>
<tr>
<td>Note</td>
<td>Make sure the group does not include any clients other than Windows VPN Clients. Any other clients in the group (including VPN 3002 Hardware Clients) are unable to connect if you require a client firewall.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Firewall Optional</strong>—Users can use a firewall but it is not required. This option allows all users in the group to connect. Those who have a firewall can use it; users that connect without a firewall receive a warning message. This setting is useful if you are creating a group in which some users have firewalls and others do not. For example, you might have clients with systems that do not run Microsoft windows, or your clients have not all had the opportunity to install firewall software.</td>
</tr>
<tr>
<td>Firewall Type</td>
<td>The type of firewall that you are making required or optional. The list shows all of the supported firewall software, which includes software from Cisco, Network ICE, Sygate, and Zone Labs.</td>
</tr>
<tr>
<td></td>
<td>- If you select Custom Firewall, you must fill in the fields in the Custom Firewall group. You also need to configure the policy source; select options only if they are supported by the vendor.</td>
</tr>
<tr>
<td></td>
<td>- Some firewall types require you to specify the source of the policy implemented by the firewall.</td>
</tr>
<tr>
<td>Policy Source</td>
<td>Some types of firewall allow you to configure where the client firewall should obtain its policies:</td>
</tr>
<tr>
<td></td>
<td>- Get Policy From Remote Firewall—The policy is configured in the client firewall application. This is how most client firewalls work.</td>
</tr>
<tr>
<td></td>
<td>- Use Specified Policy—The policy you specify should be pushed to the client firewall application, which should use your policy.</td>
</tr>
<tr>
<td></td>
<td>You must enter the name of an extended access control list policy object, or click <strong>Select</strong> to select one from a list or to create a new one, in both the <strong>Inbound Traffic Policy</strong> and <strong>Outbound Traffic Policy</strong> fields.</td>
</tr>
</tbody>
</table>
ASA Group Policies Hardware Client Attributes

Use the Hardware Client Attributes settings to configure the VPN 3002 Hardware Client settings for the ASA group policy in an Easy VPN or remote access IPSec VPN.

Navigation Path
Select Easy VPN/IPSec VPN > Hardware Client Attributes from the table of contents in the ASA Group Policies Dialog Box, page 32-1.

Field Reference

Table 32-3 ASA Group Policies Client Firewall Attributes (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom Firewall</td>
<td>The attributes that define the required or optional firewall if you select custom firewall as the firewall type:</td>
</tr>
<tr>
<td></td>
<td>• Vendor ID—The number that identifies the vendor of the custom firewall. Values are 1-255.</td>
</tr>
<tr>
<td></td>
<td>• Product ID—The number that identifies the product or model of the custom firewall. Values are 1-32 or 255. Multiple ranges are allowed, for example, 4-12, 24-32. Use 255 for all supported products.</td>
</tr>
<tr>
<td></td>
<td>• Description—An optional description of the custom firewall, for example, the name of the vendor and product.</td>
</tr>
</tbody>
</table>

Table 32-4 ASA Group Policies Hardware Client Attributes

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Require Interactive Client Authentication</td>
<td>Whether to enable secure unit authentication, which provides additional security by requiring VPN hardware clients to authenticate with a username and password each time that the client initiates a tunnel. The hardware client does not have a saved username and password.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Secure unit authentication requires that you have an authentication server group configured for the tunnel group the hardware clients use. If you require secure unit authentication on the primary security appliance, be sure to configure it on any backup servers as well.</td>
</tr>
<tr>
<td>Require Individual User Authentication</td>
<td>Whether to require that individual users behind a hardware client authenticate to gain access to the network across the tunnel. Individual users authenticate according to the order of authentication servers that you configure. If you do not select this option, the security appliance allows inheritance of a value for user authentication from another group policy.</td>
</tr>
<tr>
<td>Enable Cisco IP Phone Bypass</td>
<td>Whether to allow IP phones behind hardware clients to connect without undergoing a user authentication processes. Secure unit authentication remains in effect for other users.</td>
</tr>
</tbody>
</table>
ASA Group Policies IPSec Settings

Use the IPsec settings to specify tunneling protocols, filters, connection settings, and servers for the ASA group policy for Easy VPN or remote access IPSec VPN. This creates security associations that govern authentication, encryption, encapsulation, and key management.

Navigation Path
Select Easy VPN/IPSec VPN > IPsec from the table of contents in the ASA Group Policies Dialog Box, page 32-1.
Field Reference

Table 32-5   ASA Group Policies IPSec Settings

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Re-Authentication on IKE Re-Key</td>
<td>Whether the security appliance should prompt the user to enter a username and password during initial Phase 1 IKE negotiation and also prompt for user authentication whenever an IKE rekey occurs, providing additional security. Reauthentication fails if no user is at the other end of the connection.</td>
</tr>
<tr>
<td>Enable IPsec Compression</td>
<td>Whether to enable data compression, which speeds up transmission rates for remote dial-in users connecting with modems.</td>
</tr>
<tr>
<td></td>
<td><strong>Caution</strong> Data compression increases the memory requirement and CPU usage for each user session and consequently decreases the overall throughput of the security appliance. For this reason, it is recommended that you enable data compression only for remote users connecting with a modem. Design a group policy specific to modem users and enable compression only for them.</td>
</tr>
<tr>
<td>Enable Perfect Forward Secrecy (PFS)</td>
<td>Whether to enable the use of Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. In IPsec negotiations, PFS ensures that each new cryptographic key is unrelated to any previous key.</td>
</tr>
<tr>
<td>Tunnel Group Lock</td>
<td>Tunnel group lock restricts users by checking if the group configured in the VPN client is the same as the tunnel group to which the user is assigned. If it is not, the security appliance prevents the user from connecting. If you do not specify a tunnel name, the security appliance authenticates users without regard to the assigned group. Group locking is disabled by default.</td>
</tr>
<tr>
<td>Client Access Rules table</td>
<td>The access rules for clients. These rules control which types of clients are denied access, if any. You can have up to 25 rules, and combined they are limited to 255 characters.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip</strong> If you define any rule, an implicit deny all rule is added. Thus, if a client matches no permit rule, the client is denied access. If you create rules, ensure that you have permit rules for all allowed clients. You can use * as a wildcard to match partial strings.</td>
</tr>
<tr>
<td></td>
<td>The rule with the lowest integer has the highest priority. Therefore, the rule with the lowest integer that matches a client type or version is the rule that applies. If a lower priority rule contradicts, the security appliance ignores it.</td>
</tr>
<tr>
<td></td>
<td>• To add a rule, click the <strong>Add Row</strong> button to open the <strong>Add or Edit Client Access Rules Dialog Box</strong>, page 32-10.</td>
</tr>
<tr>
<td></td>
<td>• To edit a rule, select it and click the <strong>Edit Row</strong> button.</td>
</tr>
<tr>
<td></td>
<td>• To delete a rule, select it and click the <strong>Delete</strong> button.</td>
</tr>
</tbody>
</table>
Add or Edit Client Access Rules Dialog Box

Use the Client Access Rules dialog box to create or edit the priority, action, VPN client type and VPN client version for a client access rule.

Navigation Path
From ASA Group Policies IPSec Settings, page 32-8, click the Add Row button beneath the Client Access Rules table, or select a rule and click the Edit Row button.

Field Reference

Table 32-6  Add or Edit Client Access Rules Dialog Box

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>• 5 Permit VPN3002 * is a priority 5 rule that allows VPN3002 clients of</td>
</tr>
<tr>
<td></td>
<td>all software versions.</td>
</tr>
<tr>
<td></td>
<td>• 255 Permit *** is a priority 255 rule that allows all types and versions</td>
</tr>
<tr>
<td></td>
<td>of clients. This is useful if you are only trying to deny specific types</td>
</tr>
<tr>
<td></td>
<td>of clients without wanting to create permit rules for all the other types.</td>
</tr>
</tbody>
</table>

ASA Group Policies SSL VPN Clientless Settings

Use the Clientless settings to configure the clientless mode of access to the corporate network in a remote access SSL VPN for the ASA group policy object.

When a user connects to the SSL VPN in clientless mode, the user logs into the SSL VPN portal page. From the portal page, the user can access all available HTTP sites, access web e-mail, and browse Common Internet File System (CIFS) file servers, depending on how you configure the portal.

Navigation Path
Select SSL VPN > Clientless from the table of contents in the ASA Group Policies Dialog Box, page 32-1.
### Field Reference

**Table 32-7  ASA Group Policies SSL VPN Clientless Settings**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portal Page Websites</td>
<td>The name of the SSL VPN bookmarks policy object that includes the website URLs to display on the portal page. These websites help users access desired resources. Enter the name of the object or click <strong>Select</strong> to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Allow Users to Enter Websites</td>
<td>Whether to allow the remote user to enter website URLs directly into the browser. If you do not select this option, the user can access only those URLs included on the portal.</td>
</tr>
<tr>
<td>Enable File Server Browsing</td>
<td>Whether to allow the remote user to browse for file shares on the CIFS file servers.</td>
</tr>
<tr>
<td>Enable File Server Entry</td>
<td>Whether to allow the remote user to locate file shares on the CIFS file servers by entering the names of the file shares.</td>
</tr>
<tr>
<td>Enable Hidden Shares</td>
<td>Whether to make hidden CIFS shares visible, and thus accessible, to users.</td>
</tr>
<tr>
<td>HTTP Proxy</td>
<td>The type of access you want to allow to the external HTTP proxy server to which the security appliance forwards HTTP connections. You can enable access, disable access, or select Auto Start, which starts the proxy automatically upon user login.</td>
</tr>
<tr>
<td>Filter ACL</td>
<td>The name of the web type access control list policy object to use to restrict user access to the SSL VPN. Enter the name of the object or click <strong>Select</strong> to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Enable ActiveX Relay</td>
<td>Whether to enable ActiveX relay, which allows users to start ActiveX programs from the portal page. This allows users to start Microsoft Office applications from the web browser and upload and download Office documents.</td>
</tr>
<tr>
<td>UNIX Authentication Group ID</td>
<td>The UNIX authentication group ID.</td>
</tr>
<tr>
<td>UNIX Authentication User ID</td>
<td>The UNIX authentication user ID.</td>
</tr>
<tr>
<td>Smart Tunnel</td>
<td>The name of the smart tunnel list policy object assigned to this group. Click <strong>Select</strong> to select it from a list or to create a new object. A smart tunnel is a connection between a Winsock 2, TCP-based application and a private site. The connection uses a clientless (browser-based) SSL VPN session with the security appliance as the pathway, and the security appliance as a proxy server. Thus, smart tunnels do not require users to have administrator privileges. For more information, see Configuring SSL VPN Smart Tunnels for ASA Devices, page 29-68.</td>
</tr>
</tbody>
</table>

ASA Group Policies SSL VPN Full Client Settings

Use the Full Client settings to configure the full client mode of access to the corporate network in a remote access SSL VPN for the ASA group policy object.

Full client mode enables access to the corporate network completely over an SSL VPN tunnel. In full client access mode, the tunnel connection is determined by the group policy configuration. The full client software, SSL VPN Client (SVC) or AnyConnect, is downloaded to the remote client, so that a tunnel connection is established when the remote user logs in to the SSL VPN gateway.

To enable full client access, you must configure the Remote Access VPN > SSL VPN > Other Settings policy on the device to identify AnyConnect image packages to install on the device. The images must be on the device so that users can download them. For more information, see Understanding SSL VPN AnyConnect Client Settings, page 29-49 and Add and Edit File Object Dialog Boxes, page 32-22.

Navigation Path
Select SSL VPN > Full Client from the table of contents in the ASA Group Policies Dialog Box, page 32-1.
### ASA Group Policies SSL VPN Full Client Settings

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Full Client</td>
<td>Whether to enable full client mode.</td>
</tr>
<tr>
<td>Mode</td>
<td>The mode in which to operate the SSL VPN:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Use Other Access Modes if AnyConnect Client Download Fails</strong>—If the full client fails to download to the remote user, allow the user to make clientless or thin client access to the VPN.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Full Client Only</strong>—Prohibit clientless or thin client access. The user must have the full client installed and functional to connect to the VPN.</td>
</tr>
<tr>
<td>Keep AnyConnect Client on</td>
<td>Whether to leave the AnyConnect client installed on the client system after the client disconnects. If you do not leave the client installed, it must be download each time the user connects to the gateway.</td>
</tr>
<tr>
<td>Client System</td>
<td></td>
</tr>
<tr>
<td>Enable Compression</td>
<td>Whether to enable data compression, which speeds up transmission rates for remote dial-in users connecting with modems.</td>
</tr>
<tr>
<td><strong>Caution</strong></td>
<td>Data compression increases the memory requirement and CPU usage for each user session and consequently decreases the overall throughput of the security appliance. For this reason, it is recommended that you enable data compression only for remote users connecting with a modem. Design a group policy specific to modem users and enable compression only for them.</td>
</tr>
<tr>
<td>Enable Keepalive Messages</td>
<td>Whether to exchange keepalive messages between peers to demonstrate that they are available to send and receive data in the tunnel. Keepalive messages transmit at set intervals, and any disruption in that interval results in the creation of a new tunnel using a backup device. If you select this option, enter the time interval (in seconds) that the remote client waits between sending IKE keepalive packets in the <strong>Interval</strong> field.</td>
</tr>
<tr>
<td>Client Dead Peer Detection</td>
<td>The time interval, in seconds, that the DeadPeer Detection (DPD) timer is reset each time a packet is received over the SSL VPN tunnel from the remote user. DPD is used to send keepalive messages between peer devices only when no incoming traffic is received and outbound traffic needs to be sent.</td>
</tr>
<tr>
<td>Timeout (sec)</td>
<td></td>
</tr>
<tr>
<td>Gateway Dead Peer Detection</td>
<td>The time interval, in seconds, that the DeadPeer Detection (DPD) timer is reset each time a packet is received over the SSL VPN tunnel from the gateway.</td>
</tr>
<tr>
<td>Timeout (sec)</td>
<td></td>
</tr>
</tbody>
</table>
### ASA Group Policies SSL VPN Settings

Use the SSL VPN Settings to configure attributes that are required for clientless and port forwarding (thin client) access modes to work, including auto signon rules for user access to servers. Auto Signon configures the security appliance to automatically pass SSL VPN user login credentials (username and password) on to internal servers. You can configure multiple auto signon rules.

#### Table 32-8 ASA Group Policies SSL VPN Full Client Settings (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Renegotiation Method</td>
<td>The method by which the tunnel key is refreshed for the remote user group client:</td>
</tr>
<tr>
<td></td>
<td>• Disabled—Disables the tunnel key refresh.</td>

</tbody>
</table>

ASA Group Policies Split Tunneling Settings

Use the Split Tunneling settings to configure a secure tunnel to the central site and simultaneous clear text tunnels to the Internet. These settings apply to Easy VPN and remote access IPSec and SSL VPN configurations.

Split tunneling lets a remote client conditionally direct packets over an IPsec or SSL VPN tunnel in encrypted form or to a network interface in clear text form. With split tunneling enabled, packets not bound for destinations on the other side of the tunnel do not have to be encrypted, sent across the tunnel, decrypted, and then routed to a final destination. The split tunneling policy is applied to specific networks.

Tip
For optimum security, we recommend that you not enable split tunneling.

Navigation Path
Select Split Tunneling from the table of contents in the ASA Group Policies Dialog Box, page 32-1.

Field Reference

Table 32-12 ASA Group Policies Split Tunneling Settings

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS Names</td>
<td>A list of domain names to be resolved through the split tunnel. All other names are resolved using the public DNS server. If you do not enter a list, the list is inherited from the default group policy. Separate multiple entries with spaces or commas. The entire string can be a maximum of 255 characters.</td>
</tr>
<tr>
<td>Send all DNS traffic through the tunnel</td>
<td>Whether the AnyConnect client should resolve all DNS addresses through the VPN tunnel (SSL or IPsec/IKEv2). If DNS resolution through the tunnel fails, the address remains unresolved and the AnyConnect client does not try to resolve the address through public DNS servers. If you do not select this option, the client sends DNS queries over the tunnel according to the split tunnel policy specified by the Tunnel Option setting.</td>
</tr>
</tbody>

Chapter 32  Configuring Policy Objects for Remote Access VPNs

ASA Group Policies Dialog Box

Use the Connection Settings to configure the connection characteristics for the ASA group policy, including access control and session timeouts. These settings are used for Easy VPN and remote access IPsec or SSL VPN sessions.

Navigation Path
Select Connection Settings from the table of contents in the ASA Group Policies Dialog Box, page 32-1.

Field Reference

**Table 32-12 ASA Group Policies Split Tunneling Settings (Continued)**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel Option</td>
<td>The policy you want to enable for split tunneling:</td>
</tr>
<tr>
<td></td>
<td>• Disabled—(Default) No traffic goes in the clear or to any other destination than the security appliance. Remote users reach networks through the corporate network and do not have access to local networks.</td>
</tr>
<tr>
<td></td>
<td>• Tunnel Specified Traffic—Tunnel all traffic from or to the networks permitted in the network ACL. Traffic to all other addresses travels in the clear and is routed by the remote user’s Internet service provider.</td>
</tr>
<tr>
<td></td>
<td>• Exclude Specified Traffic—Traffic goes in the clear from and to the networks permitted in the network ACL. This is useful for remote users who want to access devices on their local network, such as printers, while they are connected to the corporate network through a tunnel. This option applies only to the Cisco VPN Client.</td>
</tr>
<tr>
<td>Networks</td>
<td>The name of a standard access control list policy object that identifies the networks that require traffic to travel across the tunnel and those that do not require tunneling. How permit and deny are interpreted depends on your selection for Tunnel Option.</td>
</tr>
<tr>
<td></td>
<td>Enter the name of the object, or click Select to select it from a list or to create a new object. If you do not specify an ACL, the network list is inherited from the default group policy.</td>
</tr>
</tbody>
</table>

**ASA Group Policies Connection Settings**

Use the Connection Settings to configure the connection characteristics for the ASA group policy, including access control and session timeouts. These settings are used for Easy VPN and remote access IPsec or SSL VPN sessions.

Navigation Path
Select Connection Settings from the table of contents in the ASA Group Policies Dialog Box, page 32-1.

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter ACL</td>
<td>The name of the extended access control list (ACL) policy object to use for filtering traffic on the VPN connection. The ACL determines which traffic is permitted or denied. Enter the name of the object or click Select to select it from a list or to create a new object.</td>
</tr>
<tr>
<td></td>
<td>This ACL does not apply to clientless SSL VPN connections.</td>
</tr>
<tr>
<td>Banner Text</td>
<td>The banner, or welcome text, to display on remote clients when they connect to the VPN. You can enter up to 500 characters.</td>
</tr>
</tbody>
</table>
Add or Edit Secure Desktop Configuration Dialog Box

Use the Add or Edit Cisco Secure Desktop Configuration dialog box to create, copy, and edit Cisco Secure Desktop Configuration objects for IOS routers. You can configure the settings required for Windows clients who are connecting from different location types, enable or restrict web browsing and file access for Windows CE clients, and configure the cache cleaner for Macintosh and Linux clients.

Cisco Secure Desktop (CSD) secures network endpoints by providing a reliable means of eliminating all traces of sensitive data by providing a single, secure location for session activity and removal on the client system.

This policy object uses the Secure Desktop Manager application to configure the settings. For an example of configuring settings, see Cisco Secure Desktop on IOS Configuration Example Using SDM at http://www.cisco.com/en/US/products/ps6496/products_configuration_example09186a008072aa7b.shtml. The first part of the configuration example explains setting up SDM, which you can ignore. Instead, look for the sections that describe setting up Windows locations midway through the example. The screen shots will help you identify when you are looking at CSD configuration.

### Table 32-13 ASA Group Policies Connection Settings (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access hours</td>
<td>The name of a time range policy object that specifies the times that users are allowed to access the VPN. If you do not specify a time range, users can access the VPN at all times. Specify a time range if you want to limit access to the network to certain hours, such as the typical work days and work hours for your organization. Enter the name of the object or click Select to select it from a list or to create a new object. For more information, see Configuring Time Range Objects, page 6-60.</td>
</tr>
<tr>
<td>Max Simultaneous Logins</td>
<td>The number of simultaneous logins a single user is allowed. Values are 0-2147483647. The default is 3. Specify 0 to disable logins and prevent user access.</td>
</tr>
</tbody>
</table>
| Max Connection Time | The maximum amount of time a user is allowed to be connected to the VPN. Select one of the following:  
  - Specified Connection time—Use the maximum time value that you enter. Values are 1-35791394 minutes. After the time is exceeded, the security appliance closes the connection.  
  - Unlimited Connection time—The security appliance does not close connections based on connection time. |
| Idle Timeout       | The amount of time a user is allowed to be connected to the VPN while the connection is idle, that is, there is no communication activity. Select one of the following:  
  - Specified Timeout—Use the time out value you enter. Values are 1-4473924 minutes. When the idle time is exceeded, the security appliance closes the connection. The default is 30 minutes.  
  - Unlimited Timeout—The security appliance does not close idle connections. |
Navigation Path
Select Manage > Policy Objects, then select Cisco Secure Desktop (Router) from the Object Type Selector. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

Add and Edit File Object Dialog Boxes

Use the Add and Edit File Object dialog boxes to create, copy, and edit file objects. File objects represent files that are used in device configurations, typically for remote access VPN policies and policy objects. Such files include Anyconnect client profile and image files, image (graphic) files, plug-in jar files, and Cisco Secure Desktop package files.

When you create a file object, Security Manager makes a copy of the file in its storage system. These files are backed up whenever you create a backup of the Security Manager database, and they are restored if you restore the database. When you deploy configurations that specify a file object, the associated file is downloaded to the device in the appropriate directory.

After you create a file object, you typically should not edit it. If you need to replace the file, edit the file object to select the new file, or create a new file object. If the file is editable, you can edit the file object to identify the file’s location in the file repository, and use the desired editor to open and edit the file.

### Table 32-14  Add or Edit Secure Desktop Configuration Dialog Box (Continued)

<table>
<thead>
<tr>

<td>Whether to set a global timeout after which CSD launches the cache cleaner. Select a timeout (the default is 30 minutes), and select whether to allow the user to reset the timeout value.</td>
</tr>
<tr>
<td>Launch Cleanup Upon Exiting of Browser</td>
<td>Whether to start the cache cleaner when the user closes all web browser windows.</td>
</tr>
<tr>
<td>Enable Canceling of Cleaning</td>
<td>Whether to allow the remote user to cancel the cleaning of the cache.</td>
</tr>
<tr>
<td>Secure Delete</td>
<td>The number of passes for CSD to perform a secure cleanup. The default is 1 pass. CSD encrypts and writes the cache to the remote client’s disk. Upon termination of the Secure Desktop, CSD converts all bits occupied by the cache to all 0’s, then to all 1’s, and then to randomized 0’s and 1’s.</td>
</tr>
<tr>
<td>Enable Web Browsing if Mac or Linux Installation Fails</td>
<td>Whether to allow web browsing (but not other remote access features) if the cache cleaner installation fails.</td>
</tr>
<tr>
<td>VPN Feature Policy</td>
<td>Whether to allow web browsing, remote server file access, and port forwarding for Macintosh and Linux clients. Port forwarding permits the use of the Secure Desktop to connect a client application installed on the local PC to the TCP/IP port of a peer application on a remote server.</td>
</tr>
<tr>
<td>Category</td>
<td>The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects, page 6-11.</td>
</tr>
</tbody>
</table>
outside of Security Manager. The file repository is the \CSCOpx\MDC\FileRepository folder in the installation directory (typically, C:\Program Files). The files are organized in subfolders named for the file type.

For all file types except Image files, you can add a file from the Security Manager server or from the local Security Manager client by selecting the appropriate tab on the Choose a file dialog box. You cannot select files from a network server. You can control the ability to add files from the Security Manager client from Tools > Security Manager Administration > Customize Desktop. For more information, see Customize Desktop Page, page 11-6.

**Tip**
If you are copying a file to the Security Manager server so that it can be used in a file object, do not copy the file directly to the file repository.

When you delete a file object, the associated file is not deleted from the file repository.

**Navigation Path**
Select Manage > Policy Objects, then select File Objects from the Object Type Selector. Right-click inside the work area, then select New Object or right-click a row, then select Edit Object.

Add and Edit File Object Dialog Boxes

File Object — Choose a file Dialog Box

Use the File Object — Choose a file dialog box to select the file to use for the file object you are adding or editing. The available files are managed using Image Manager. For more information, see Image Manager Supported Image Types, page 69-3.

Table 32-15 Add and Edit File Object Dialog Boxes (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| File           | The name and full path of the file. Click Browse to select the file. The following file types are managed using Image Manager. For more information, see Image Manager Supported Image Types, page 69-3.  
- Cisco Secure Desktop Package  
- Plug-In—For browser plug-in files.  
- AnyConnect Image  
- Hostscan Image  
For AnyConnect Profile and Image files, you can add a file from the Security Manager server. You cannot select files from a network server.  
Tip You can control the ability to add files from the Security Manager client from Tools > Security Manager Administration > Customize Desktop. For more information, see Customize Desktop Page, page 11-6.  
For file objects that you are editing, the path indicates the location in the Security Manager file repository. |
| File Name on Device | The file name you want to use when the file is downloaded to the device when you deploy policies. The default is to use the same file name as the original file.  
If the object was created by discovering policies from the device, this field uses the original name of the file as it existed on the device. This might not be the same name as it exists on the Security Manager server if the original name duplicated existing file names on the server. |
| Category | The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects, page 6-11. |

File Object — Choose a file Dialog Box

Use the File Object — Choose a file dialog box to select the file to use for the file object you are adding or editing. The available files are managed using Image Manager. For more information, see Image Manager Supported Image Types, page 69-3.

Navigation Path

Select Manage > Policy Objects, then select File Objects from the Object Type Selector. Add or Edit a file object and from the Add or Edit File Object dialog box, click Browse to open the File Object — Choose a file dialog box.

Related Topics

- Configuring SSL VPN Browser Plug-ins (ASA), page 29-47
Add or Edit Port Forwarding List Dialog Boxes

Use the Port Forwarding List dialog box to create, copy and edit port forwarding list policy objects. You can create port forwarding list objects to use when you are configuring the thin client access mode for SSL VPN.

Port forwarding allows users to access applications (such as Telnet, e-mail, VNC, SSH, and Terminal services) inside the enterprise through an SSL VPN session. When port forwarding is enabled, the hosts file on the SSL VPN client is modified to map the application to the port number configured in the forwarding list. A port forwarding list object defines the mappings of port numbers on the remote client to the application's IP address and port behind the SSL VPN gateway.

Navigation Path
Select Manage > Policy Objects, then select Port Forwarding List from the Object Type Selector. Right-click inside the work area and select New Object or right-click a row and select Edit Object.

</table>

Add or Edit A Port Forwarding Entry Dialog Box

Use the Add or Edit A Port Forwarding Entry dialog boxes to create a new port forwarding list entry or edit an existing one.

Navigation Path

Go to the Add or Edit Port Forwarding List Dialog Boxes, page 32-25 and click the Add Row button or select an entry and click the Edit Row button beneath the Port Forwarding List table.
Add or Edit Single Sign On Server Dialog Boxes

Use the Add or Edit Single Sign On Server dialog box to create, copy, and edit single sign on (SSO) server objects for use with SSL VPNs (as configured in ASA group policy objects). For information on how to configure SSO servers in an ASA group policy, see ASA Group Policies SSL VPN Settings, page 32-14.

Single sign-on lets users access different secure services on different servers without entering a username and password more than once. In the authentication, the security appliance acts as a proxy for the SSL VPN user to the SSO server. You can configure this object to identify either a Computer Associates SiteMinder SSO server or a Security Assertion Markup Language (SAML) Browser Post Profile version 1.1 server.

The SSO mechanism starts as part of the AAA process or just after successful user authentication to an AAA server. The SSL VPN server running on the security appliance acts as a proxy for the user to the authenticating server. When a user logs in, the SSL VPN server sends an SSO authentication request, including username and password, to the authenticating server. If the server approves the authentication request, it returns an SSO authentication cookie to the SSL VPN server. The security appliance keeps this cookie on behalf of the user and uses it to authenticate the user to secure web sites within the domain protected by the SSO server.

If you want to configure SSO for an SSL VPN group, you must also configure a AAA server, such as a RADIUS or LDAP server.

The SAML Browser Artifact profile method of exchanging assertions is not supported.

**Navigation Path**

Select Single Sign On Servers in the Policy Object Manager Window, page 6-4. Right-click inside the work area and select New Object or right-click a row and select Edit Object.

You can also create the object when configuring an ASA user group object for SSL VPN (see ASA Group Policies SSL VPN Settings, page 32-14).

<td>The object name, which must be 4 to 31 characters. Object names are not case-sensitive. For more information, see <a href="#">Creating Policy Objects, page 6-8</a>.</td>
</tr>
<tr>
<td>Description</td>
<td>An optional description of the object.</td>
</tr>
<tr>
<td>Authentication Type</td>
<td>The type of SSO server to use with clientless SSL VPN connections. The other attributes on the page change based on your selection.</td>
</tr>
<tr>
<td></td>
<td>• SiteMinder—Computer Associates SiteMinder SSO server.</td>
</tr>
<tr>
<td></td>
<td>• SAML POST—Security Assertion Markup Language (SAML) Browser Post Profile server.</td>
</tr>
<tr>
<td>URL (SiteMinder only.)</td>
<td>The URL of the SiteMinder SSO server to which the security appliance makes authentication requests. Select whether to use HTTP or HTTPS and enter the URL. <strong>Tip</strong> For HTTPS communication, make sure that the SSL encryption settings match on both the security appliance and the SiteMinder server. On the security appliance, you can verify this with the <code>ssl encryption</code> command.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The key used to encrypt authentication communications with the SiteMinder server, if any. The key can contain any alphanumeric characters. There is no minimum or maximum number of characters. Enter the same key in both fields. <strong>Tip</strong> If you enter a secret key, you must configure the same key in the SiteMinder server using the Cisco Java plug-in authentication scheme.</td>
</tr>
<tr>
<td>Assertion URL (SAML POST only.)</td>
<td>The URL for the SAML-type SSO assertion consumer service. Select whether to use HTTP or HTTPS and enter the URL, which must be fewer than 255 characters.</td>
</tr>
<tr>
<td>Assertion Issuer (SAML POST only.)</td>
<td>The name of the security device that is sending assertions to a SAML-type SSO server. This is usually the name of the security appliance, for example, asa.example.com. The name must be fewer than 65 characters.</td>
</tr>
<tr>
<td>Trustpoint (SAML POST only.)</td>
<td>The name of the PKI enrollment policy object that identifies the certificate authority (CA) server that acts as the trustpoint that contains the certificate to use to sign the SAML-type browser assertion. Enter the name or click Select to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Max Retries</td>
<td>The number of times the security appliance retries a failed SSO authentication attempt before the authentication times out. The range is 1 to 5 retries, and the default is 3 retries.</td>
</tr>
<tr>
<td>Request Timeout</td>
<td>The number of seconds before a failed SSO authentication attempt times out. The range is 1 to 30 seconds, and the default is 5 seconds.</td>
</tr>
<tr>
<td>Category</td>
<td>The category assigned to the object. Categories help you organize and identify rules and objects. See <a href="#">Using Category Objects, page 6-11</a>.</td>
</tr>
</tbody>
</table>
Add or Edit Bookmarks Dialog Boxes

Use the Add and Edit Bookmarks dialog boxes to configure browser-based clientless SSL VPN bookmarks (URL lists) for an SSL VPN Bookmark object. From this dialog box, you can change the order of the bookmark entries within the table, create, copy, edit, and delete SSL VPN Bookmark objects.

An SSL VPN Bookmark object defines the URLs that are displayed on the portal page after a successful login.

Navigation Path
Select Manage > Policy Objects, then select SSL VPN Bookmarks from the Object Type Selector. Right-click inside the work area, then select New Object or right-click a row, then select Edit Object.

</tr>
<tr>
<td></td>
<td>If you allow device overrides, you can click the Edit button to create, edit, and view the overrides. The Overrides field indicates the number of devices that have overrides for this object.</td>
</tr>
</tbody>
</table>

Add and Edit Bookmark Entry Dialog Boxes

Use the Add and Edit Bookmark Entry dialog boxes to create or edit a bookmark to be included in an SSL VPN Bookmark object.

You can use non-English, non-ASCII languages for the text to display for bookmarks if you are configuring the object for use on an ASA device. For more information about how you can configure the SSL VPN portal in local languages, see Localizing SSL VPN Web Pages for ASA Devices, page 29-62.

Navigation Path

In the Policy Object Manager, from the Add or Edit Bookmarks Dialog Boxes, right-click inside the Bookmarks table, then select Add Row or right-click a row, then select Edit Row.

</tr>
</tbody>
</table>
Add and Edit SSL VPN Customization Dialog Boxes

Use the Add and Edit SSL VPN Customization dialog boxes to create, copy, and edit SSL VPN Customization objects. An SSL VPN Customization policy object describes how to customize web pages for a browser-based clientless SSL VPN hosted on an ASA 8.x device. For more information, see Configuring ASA Portal Appearance Using SSL VPN Customization Objects, page 29-60.

You can use non-English, non-ASCII languages for the text to display on these pages. For more information about how you can configure the SSL VPN portal in local languages, see Localizing SSL VPN Web Pages for ASA Devices, page 29-62.

Settings Pane
The body of the dialog box is a pane with a table of contents on the left and settings related to the item selected in the table of contents on the right. Before configuring settings, click the Preview button to see the default settings to help you determine what, if anything, you want to change.

The top folders in the table of contents represent the SSL VPN web pages that you can customize, and are explained next.
Chapter 32  Configuring Policy Objects for Remote Access VPNs

Add and Edit SSL VPN Customization Dialog Boxes

Logon Page

The Logon web page is the one users see first when connecting to the SSL VPN portal. It is used for logging into the VPN. Select the following items in the Logon Page folder in the table of contents to view and change the settings:

- **Logon Page**—The Browser Window Title field defines the title of the web page, which is displayed in the browser’s title bar.

- **Title Panel**—The title displayed in the web page itself. For more information about the settings, see SSL VPN Customization Dialog Box—Title Panel, page 32-35.

- **Language**—The languages you will support for the Logon, Portal, and Logout pages. For more information about the settings, see SSL VPN Customization Dialog Box—Language, page 32-36.

- **Logon Form**—The labels and colors used in the form that accepts user logon information. For more information about the settings, see SSL VPN Customization Dialog Box—Logon Form, page 32-38.

- **Informational Panel**—An extra informational panel for conveying information to users. For more information about the settings, see SSL VPN Customization Dialog Box—Informational Panel, page 32-39.

- **Copyright Panel**—The copyright information on the logon page. For more information about the settings, see SSL VPN Customization Dialog Box—Copyright Panel, page 32-40.

- **Full Customization**—If you do not want to use the security appliance’s built-in logon page, even customized, you can instead enable full customization and supply your own web page. For more information about creating a custom Logon page and the settings, see Creating Your Own SSL VPN Logon Page for ASA Devices, page 29-64 and SSL VPN Customization Dialog Box—Full Customization, page 32-41.

Tip
For more information about CSS, visit the World Wide Web Consortium (W3C) website at www.w3.org.

Tip
The image file can be a GIF, JPG, or PNG file, and it can be up to 100 kilobytes in size.

For more information about File objects, see Add and Edit File Object Dialog Boxes, page 32-22.

SSL VPN Customization Dialog Box—Language

Use the Language page of the SSL VPN Customization dialog box identify the languages you will support on the browser-based clientless SSL VPN portal. If you want to configure translation tables for other languages on the ASA device and use them, you can configure the supported languages and allow users to choose their language. Before you configure these settings, read Localizing SSL VPN Web Pages for ASA Devices, page 29-62.

Navigation Path

From the Add and Edit SSL VPN Customization Dialog Boxes, select Logon Page > Language in the table of contents.

Table 32-25  SSL VPN Customization Dialog Box—Language

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic Browser Language Selection</td>
<td>This table lists the languages you will support on the web pages for automatic browser language selection. Automatic browser language select allows the ASA device to negotiate with the user’s web browser to determine the language in which to present the web pages. You must configure a translation table on the ASA device for any language you list here. For more detailed information about automatic browser language selection, see Localizing SSL VPN Web Pages for ASA Devices, page 29-62. Languages are listed by their abbreviation in the table. The languages are evaluated top to bottom until a match is found. The language that is indicated as the default language (indicated as True in the table) is used if the device is unable to negotiate a different language with the browser. If you do not specify a default, English is the default. • To add a language, click the Add Row button below the table. • To edit a language, select it and click the Edit Row button. • To delete a language, select it and click the Delete Row button.</td>
</tr>
<tr>
<td>Enable Language Selector</td>
<td>Whether to display the Language Selector on the Logon page. The Language Selector allows users to select their preferred language. The Language Selector is complementary to the automatic browser language selection capability.</td>

<td>Whether to restrict the encryption algorithms used for the connection, or to specify a different order of use. The default is to make all algorithms available in this order of preference: 3DES and SHA1, AES and SHA1, RC4 and MD5. Select the priority order for the algorithms. Select None to eliminate one or two algorithms.</td>
</tr>
<tr>
<td>Redirect HTTP Traffic</td>
<td>Whether to have the gateway redirect HTTP traffic over secure HTTP (HTTPS). Traffic that comes to this port is redirected to the port you specify in the Port field.</td>
</tr>
<tr>
<td>HTTP Port</td>
<td>Enter the port number for HTTP traffic in the <strong>HTTP Port</strong> field. You can enter a number or the name of a port list object, or click <strong>Select</strong> to select an object from a list or to create a new object. The HTTP port is normally 80. However, you can enter any other number that is used in your network between 1025-65535.</td>
</tr>
<tr>
<td>Hostname</td>
<td>The hostname for the gateway.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Do Not Specify</strong>—No hostname is assigned; the IP address to the gateway is used.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Use the host and domain names of the device</strong>—These are defined in the <strong>Platform &gt; Device Admin &gt; Hostname</strong> policy.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Use the Object</strong>—The hostname is the value defined in a text policy object. Enter the name of the object or click <strong>Select</strong> to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Category</td>
<td>The category assigned to the object. Categories help you organize and identify rules and objects. See <strong>Using Category Objects</strong>, page 6-11.</td>
</tr>
</tbody>
</table>
Add and Edit Smart Tunnel List Dialog Boxes

Use the Add and Edit Smart Tunnel Lists dialog boxes to create, copy, and edit SSL VPN smart tunnel objects.

An SSL VPN smart tunnel list object lists the applications that are eligible for smart tunnel access to a private site. You can configure the clientless settings of an ASA group policy with a smart tunnel list to allow users to access the specified applications through the SSL VPN portal. For an explanation of the types of applications that support smart tunnel access, see Configuring SSL VPN Smart Tunnels for ASA Devices, page 29-68.

You can include other SSL VPN smart tunnel list objects in an object. Thus, you can create a smaller set of objects that identify your basic list of applications, then create other objects that create the required combination of applications. For example, you might want all three of your ASA group policies to allow smart tunnel access to applications A and B, but the remaining applications are unique for each group. By creating a single object that specifies A and B, you can include that object in each of the SSL VPN smart tunnel list objects for the group policies, and these objects need only specify their unique applications in the applications table.

Navigation Path

Select Manage > Policy Objects, then select SSL VPN Smart Tunnel Lists from the Object Type selector. Right-click inside the work area and select New Object, or right-click a row and select Edit Object.

Related Topics

<td>App Path</td>
<td>The filename and optionally, the path, of the application. This entry can be up to 128 characters. Use one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Filename—For example, <code>outlook.exe</code>. By only specifying the file name, it does not matter where users install the application on their workstations. However, the file name must match exactly.</td>
</tr>
<tr>
<td></td>
<td>• Full path and filename—For example, <code>C:\Program Files\Microsoft Office\OFFICE11\OUTLOOK.EXE</code>. This allows the application smart tunnel access only if it is installed in the specified directory, which you can use to enforce organizational standards.</td>
</tr>
<tr>
<td></td>
<td><strong>Tips</strong></td>
</tr>
<tr>
<td></td>
<td>• If you specify the full path, and the smart tunnel application stops working after it had been working for a while, it is likely that a product upgrade changed the installation path. Add a new entry that accounts for the new path.</td>
</tr>
<tr>
<td></td>
<td>• If you are granting smart tunnel access to an application that is started from the command line, create one entry for <code>cmd.exe</code> (the Windows command line), and another entry for the application.</td>
</tr>
</tbody>
</table>
Add and Edit Smart Tunnel Auto Signon List Dialog Boxes

Use the Add and Edit Smart Tunnel Auto Signon Lists dialog boxes to create, copy, and edit SSL VPN smart tunnel auto sign-on objects.

Smart Tunnel Auto Sign-on is a single sign-on method for Clientless SSL VPN users. It passes the login credentials (username and password) to internal servers for authentication using NTLM authentication, HTTP Basic authentication, or both. Smart Tunnel Auto Sign-on is supported on ASA 5500 devices running software version 7.1(1) and later.

An SSL VPN smart tunnel auto sign-on list object identifies the servers for which to automate the submission of login credentials during smart tunnel setup. You can configure the clientless settings of an ASA group policy with a smart tunnel auto sign-on list if you want to reissue the user credentials when the user establishes a smart tunnel connection to a server. For an explanation of the types of applications that support smart tunnel access, see Configuring SSL VPN Smart Tunnels for ASA Devices, page 29-68.

Table 32-39 Add and Edit Smart Tunnel Entry Dialog Boxes (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hash Value</td>
<td>(Optional) The hash value for the application. By specifying a hash value, you can ensure that the user does not rename another application to use a supported filename and thus start an unsupported and undesired application over the smart tunnel. To obtain the hash value, enter the checksum of the application (that is, the checksum of the executable file) into a utility that calculates a hash using the SHA-1 algorithm. One example of such a utility is the Microsoft File Checksum Integrity Verifier (FCIV), which is available at <a href="http://support.microsoft.com/kb/841290/">http://support.microsoft.com/kb/841290/</a>. Place a temporary copy of the application to be hashed on a path that contains no spaces (for example, c:\temp) and then enter <code>fciv.exe -sha1</code> application at the command line (for example, <code>fciv.exe -sha1 c:\msimn.exe</code>) to display the SHA-1 hash. Copy and paste the value into this field. The SHA-1 hash is always 40 hexadecimal characters. Before authorizing an application for smart tunnel access, clientless SSL VPN calculates the hash of the application matching the App Name. It qualifies the application for smart tunnel access if the result matches the value of hash. Because the checksum varies with each version or patch of an application, the hash you enter can match only one version or patch on the remote host. To specify a hash for more than one version of an application, create a unique smart tunnel entry for each hash value. Tip: Hash values require maintenance. You must update the smart tunnel list if you want to support future versions or patches of an application for which you supply a hash value. A sudden problem with smart tunnel access might be an indication that the application list containing hash values is not up-to-date with an application upgrade. You can avoid this problem by not entering a hash.</td>
</tr>
</tbody>
</table>
You can include other SSL VPN smart tunnel auto sign-on list objects in an object. Thus, you can create a set of objects that identify your basic list of servers and include those objects in another object that expands upon that list of servers.

**Navigation Path**
Select **Manage > Policy Objects**, then select **SSL VPN Smart Tunnel Auto Signon Lists** from the Object Type selector. Right-click inside the work area and select **New Object**, or right-click a row and select **Edit Object**.

<tr>
<td>Authentication Realm</td>
<td>The realm for the authentication. The Authentication Realm is associated with the protected area of the website and is passed back to the browser either in the authentication prompt or in the HTTP headers during authentication. After auto sign-on is configured and a realm string is specified, users can configure the realm string on a web application (such as Outlook Web Access) and access web applications without signing on.</td>
</tr>
<tr>
<td>Use Domain</td>
<td>Select this option to add the Windows domain to the username if authentication requires it. If you use this option, be sure to specify the domain name when assigning the smart tunnel list to one or more group policies.</td>
</tr>
</tbody>
</table>
Add or Edit User Group Dialog Box

Use the Add or Edit User Group dialog box to create or edit a user group object. User group objects are used in Easy VPN topologies, remote access VPNs, and SSL VPNs for IOS devices.

When you configure a remote access VPN, SSL VPN, or Easy VPN server, you can create user groups to which remote clients belong. The remote clients must be configured with the same group name as the user group on the VPN server in order to connect to the server; otherwise, no connection is established.

When the remote client connects to the VPN server successfully, the group policies for that particular user group are pushed to all remote clients belonging to the user group.

For more information about user groups, see:
- Configuring User Group Policies, page 31-13
- Configuring a User Group Policy for Easy VPN, page 26-14
- Configuring an SSL VPN Policy (IOS), page 31-14

Note

You must select the technology (Easy VPN/Remote Access VPN, or SSL VPN) for which you are creating the user group object. If you are editing an existing user group object, the technology is already selected and you cannot change it. Depending on the selected technology, the appropriate settings are available for configuration.

Navigation Path

Select Manage > Policy Objects, then select User Groups from the Object Type Selector. Right-click inside the work area and select New Object or right-click a row and select Edit Object.

Tip

You can also access this dialog box from the Remote Access VPN > IPSec VPN > User Groups or the Remote Access VPN > SSL VPN policies.

</tr>
</tbody>
</table>

Preshared Key

The preshared key that will be used to authenticate the clients associated to the user group.

You do not have to enter a preshared key if you are using digital certificates for group authentication.

In regular IPsec VPNs, preshared keys allow for one or more peers to use individual shared secrets to authenticate encrypted tunnels. A preshared key must be configured on each participating peer. If one of the participating peers is not configured with the same preshared key, the IKE SA cannot be established.

In Easy VPN authentication, the same Easy VPN server key is used for the spoke configuration to ensure that the server/client keys match.

In remote access IPSec VPN authentication, the same key is used to negotiate a VPN connection between the remote access VPN server and the remote clients.

IP Address Pool Subnet/Ranges

The IP address ranges for a local pool that will be used to allocate an internal IP address to a client. Remote clients are assigned IP addresses from this pool. Separate multiple entries with commas. The default is 172.16.0.1-172.16.4.254.

Backup Servers IP Address

The IP address of the servers to be used as backups for the Easy VPN or remote access IPSec VPN server. The router tries to connect to these servers if the primary connection to the Easy VPN or remote access VPN server fails. Separate multiple entries with commas.
Add or Edit User Group Dialog Box

Chapter 32      Configuring Policy Objects for Remote Access VPNs

Configure the DNS/WINS settings for your user group to define the DNS and WINS servers and the domain name that should be pushed to clients associated with the user group.

Note

The DNS/WINS settings you configure for a user group apply in Easy VPN, remote access VPN, and SSL VPN configurations.

Navigation Path
Select DNS/WINS from the table of contents in the Add or Edit User Group Dialog Box, page 32-54.

</tbody>
</table>
User Group Dialog Box—Split Tunneling

Split tunneling lets a remote client conditionally direct packets over an IPsec or SSL VPN tunnel in encrypted form or to a network interface in clear text form. With split tunneling enabled, packets not bound for destinations on the other side of the tunnel do not have to be encrypted, sent across the tunnel, decrypted, and then routed to a final destination.

The split tunneling policy is applied to a specific network. When you configure split tunneling, you can transmit both secured and unsecured traffic on the same interface. You must specify which traffic will be secured and what the destination of that traffic is, so that you have a secure tunnel to the central site, while the clear (unsecured) traffic is transmitted across the public network.

Tip
For optimum security, we recommend that you not enable split tunneling.

Note
Split tunneling can be applied in Easy VPN, remote access VPN, and SSL VPN configurations. For information about configuring split tunneling for SSL VPN, see User Group Dialog Box—SSL VPN Split Tunneling, page 32-67.

Navigation Path
Select Split Tunneling from the table of contents in the Add or Edit User Group Dialog Box, page 32-54 when configuring Easy VPN/Remote Access IPSec VPN.

User Group Dialog Box—Advanced PIX Options

The Advanced PIX Options are specifically for PIX 6.3 Firewalls in your user group.

Note
These settings apply in Easy VPN and remote access VPN configurations.

Navigation Path
Select Advanced Options (PIX) from the table of contents in the Add or Edit User Group Dialog Box, page 32-54.

Field Reference

Table 32-49  User Group Dialog Box—Advanced PIX Options

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Idle Timeout (sec)</td>
<td>The length of time that a VPN tunnel can remain open without user activity, in seconds. Values range from 60-86400 seconds.</td>
</tr>
<tr>
<td>User Authentication Server</td>
<td>The AAA server to which remote devices send user authentication requests. Enter the name of the server group or click Select to select it from a list or to create a new group. See Understanding AAA Server and Server Group Objects, page 6-23.</td>
</tr>
</tbody>
</table>
User Group Dialog Box—Clientless Settings

Use the Clientless settings to configure the clientless mode of access to the corporate network in an SSL VPN.

In clientless access mode, once a user is authenticated and a session is established, an SSL VPN portal page and toolbar is displayed on the user’s web browser. From the portal page, the user can access all available HTTP sites, access web e-mail, and browse Common Internet File System (CIFS) file servers.

Navigation Path
Select Clientless from the table of contents in the Add or Edit User Group Dialog Box, page 32-54.

Related Topics
- Create Group Policy Wizard—Clientless and Thin Client Access Modes Page, page 28-23
Field Reference

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portal Page Websites</td>
<td>The name of the SSL VPN bookmarks policy object that includes the web site URLs to display on the portal page. These web sites help users access desired resources. Enter the name of the object or click <strong>Select</strong> to select it from a list or to create a new object.</td>
</tr>
<tr>
<td>Allow Users to Enter Websites</td>
<td>Whether to allow the remote user to enter web site URLs directly into the browser. If you do not select this option, the user can access only those URLs included on the portal.</td>
</tr>
</tbody>
</table>
| Enable Common Internet File System (CIFS) | In Clientless mode, files and directories created on Microsoft Windows servers can be accessed by the remote client through the web browser. When you enable the Common Internet File System (CIFS), a list of file server and directory links are displayed on the portal page after login. The CIFS protocol lets you customize permissions on the SSL VPN gateway to allow shared files to be accessed or modified by the remote client, as follows:  
  - **Enable File Browsing**—Whether to allow the remote user to browse for file shares on the CIFS file servers.  
  - **Enable File Entry**—Whether to allow the remote user to locate file shares on the CIFS file servers by entering the names of the file shares. |
| WINS Server List              | The name of the WINS server list policy object that identifies the WINS/NetBIOS servers to use for resolving file server names. You should supply an object if you enable CIFS. Enter the name of the object or click **Select** to select it from a list or to create a new object. |
| Enable Citrix                 | Whether to enable remote clients to run Citrix-enabled applications, such as Microsoft Word or Excel, through the SSL VPN as if the application were locally installed, without the need for client software. The Citrix software must be installed on one or more servers on a network that the router can reach. |

User Group Dialog Box—Thin Client Settings

Use the Thin Client settings to enable the thin client, or port forwarding, mode of access to the corporate network in an SSL VPN. Port forwarding allows users to access applications (such as Telnet, e-mail, VNC, SSH, and Terminal services) inside the enterprise through an SSL VPN session. A port forwarding list object defines the mappings of port numbers on the remote client to the application’s IP address and port behind the SSL VPN gateway.

In thin client access mode, the remote user downloads a Java applet that acts as a TCP proxy on the client machine for the services configured on the SSL VPN gateway. The proxy provides the port forwarding services.

**Navigation Path**

Select **Thin Client** from the table of contents in the *Add or Edit User Group Dialog Box, page 32-54.*
Related Topics

</tbody>
</table>

**User Group Dialog Box—SSL VPN Full Tunnel Settings**

Use the SSL VPN Full Tunnel settings to enable the full tunnel client access mode in your SSL VPN. When you enable full tunnel access, you should also define DNS/WINS server settings, browser proxy settings, and split tunneling for the user group.

In full tunnel client access mode, the tunnel connection is determined by the group policy configuration. The full tunnel client software, SSL VPN Client (SVC), must be downloaded to the remote client so that a tunnel connection can be established when the remote user logs in to the SSL VPN gateway.

**Tip**

For full tunnel client access to work, you must install the client software on the gateway. The user downloads the client when connecting to the gateway.

**Navigation Path**

Select Full Tunnel > Settings from the table of contents in the Add or Edit User Group Dialog Box, page 32-54.

**Related Topics**

- Create Group Policy Wizard—Full Tunnel Page, page 28-21

</tr>
</tbody>
</table>
User Group Dialog Box—SSL VPN Split Tunneling

Use the Split Tunneling settings to configure a secure tunnel to the central site and simultaneous clear text tunnels to the Internet for SSL VPNs.

Split tunneling lets a remote client conditionally direct packets over an IPsec or SSL VPN tunnel in encrypted form or to a network interface in clear text form. With split tunneling enabled, packets not bound for destinations on the other side of the tunnel do not have to be encrypted, sent across the tunnel, decrypted, and then routed to a final destination. The split tunneling policy is applied to specific networks.

Tip For optimum security, we recommend that you not enable split tunneling.

Navigation Path
Select Full Tunnel > Split Tunneling from the table of contents in the Add or Edit User Group Dialog Box, page 32-54.

Field Reference

Table 32-53 User Group Dialog Box—Split Tunneling Settings

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel Option</td>
<td>Whether to allow split tunneling and if so, which traffic should be secured or transmitted unencrypted across the public network:</td>
</tr>
<tr>
<td></td>
<td>• Disabled—(Default) No traffic goes in the clear or to any other destination than the gateway. Remote users reach networks through the corporate network and do not have access to local networks.</td>
</tr>
<tr>
<td></td>
<td>• Tunnel Specified Traffic—Tunnel all traffic from or to the addresses listed in the Destinations field. Traffic to all other addresses travels in the clear and is routed by the remote user’s Internet service provider.</td>
</tr>
<tr>
<td></td>
<td>• Exclude Specified Traffic—Traffic goes in the clear from and to the addresses listed in the Destinations field. This is useful for remote users who want to access devices on their local network, such as printers, while they are connected to the corporate network through a tunnel.</td>
</tr>
<tr>
<td>Destinations</td>
<td>The IP addresses for hosts or networks that identify the networks that require traffic to travel across the tunnel and those that do not require tunneling. Whether traffic to these addresses is encrypted and tunneled to the gateway, or sent in the clear, is determined by your selection for Tunnel Option.</td>
</tr>

</tbody>
</table>

User Group Dialog Box—Browser Proxy Settings

Use the Browser Proxy settings to configure proxy bypass for full tunnel access in an SSL VPN.

A security appliance can terminate HTTPS connections and forward HTTP/HTTPS requests to HTTP and HTTPS proxy servers, which act as intermediaries between users and the Internet. Proxy bypass is an alternative method of content rewriting that makes minimal changes to the original content. It is useful with custom web applications.

Tip

The browser proxy settings work only for Microsoft Internet Explorer; they do not work for other types of browsers.

Navigation Path

Select Full Tunnel > Browser Proxy Settings from the table of contents in the Add or Edit User Group Dialog Box, page 32-54.

</tbody>
</table>

User Group Dialog Box—SSL VPN Connection Settings

Use this SSL VPN Connection Settings page to configure the SSL VPN session connection settings for the user group, including the banner text. An SSL VPN session is disconnected if the client is connected longer than the session timeout or if it is idle longer than the idle timeout.

Navigation Path
Select Connection Settings from the table of contents in the Add or Edit User Group Dialog Box, page 32-54.

Field Reference

Table 32-55 User Group Dialog Box—Connection Settings

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Idle Timeout</td>
<td>The idle timeout period for the SSL VPN session. The session is disconnected if the client is idle longer than the specified idle timeout. Values range from 0-3600 seconds.</td>
</tr>
</tbody>
</table>
Add or Edit WINS Server List Dialog Box

Use the WINS Server Lists dialog box to create, copy, and edit WINS server list objects. A WINS Server List object defines a list of Windows Internet Naming Server (WINS) servers, which are used to translate Windows file server names to IP addresses.

**Navigation Path**
Select Manage > Policy Objects, then select WINS Server Lists from the Object Type Selector. Right-click inside the work area and select New Object or right-click a row and select Edit Object.

**Related Topics**
- Configuring WINS/NetBIOS Name Service (NBNS) Servers To Enable File System Access in SSL VPNs, page 29-70
- Policy Object Manager Window, page 6-4

CHAPTER 33

Using Map View

The following topics describe how to use the Map view:

- Understanding Maps and Map View, page 33-1
- Working With Maps, page 33-7
- Displaying Your Network on the Map, page 33-13
- Managing VPNs in Map View, page 33-20
- Managing Device Policies in Map View, page 33-21

Understanding Maps and Map View

The Security Manager Map view provides a graphical view of your VPN and Layer 3 network topology. Using the map view, you can investigate details of your VPN configuration graphically. Topological display of tunnels enables you to easily derive the relationship among multiple VPN configurations (for example, a hierarchical VPN). You can group devices to achieve a more complete picture of your VPN configuration. This is useful in situations where a hub failover pair is a peer with hundreds of spokes.

You can represent your Layer 3 network topology graphically, populating it with managed devices (called device nodes). You can make the picture of the topology more complete by adding unmanaged objects (called map objects) such as devices, clouds, and networks. For large networks, you can choose to simplify the topology graph by incorporating only a portion of the overall topology. You can save the topology maps for future use.

You can save multiple topology maps to reflect your network’s geographical or functional organization. You can link a saved map to a node on a parent map, so that from the parent map you can drill down to the linked map with more detailed information (for more information, see Using Linked Maps, page 33-12). Saved maps are shared among all users who have the necessary access privileges.

You can launch other Security Manager features from the map view. In some cases, you can simplify the use of features by selecting nodes from the map before you start another feature. For example, you can select multiple nodes, then create a VPN that includes those nodes as members.

Tip

The network data that is displayed on maps is typically updated as this data changes. However, to be certain that a map displays current network data, you can refresh it manually by selecting Map > Refresh Map.
This section contains the following topics:

- Understanding the Map View Main Page, page 33-2
- Map Toolbar, page 33-3
- Using the Navigation Window, page 33-4
- Maps Context Menus, page 33-4
- Access Permissions for Maps, page 33-7

**Understanding the Map View Main Page**

Map view enables you to create customized, visual topology maps of your network, within which you can view connections between your devices and easily configure VPNs and access control settings. The following figure identifies the functional areas of the Map view.

To open the Map view main page, click the Map View button in the toolbar.

You can undock the map window, which enables you to use other product features while keeping the map open. To undock the map, select Map > Undock Map View. To dock the map window, select Map > Dock Map View.

Map Toolbar

The following table describes the buttons on the map toolbar.

<table>
<thead>
<tr>
<th>Toolbar Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Select Button" /></td>
<td>Selects objects on the map. Click the button, then click items on the map.</td>
</tr>
<tr>
<td><img src="image" alt="Pan Button" /></td>
<td>Pans the map. Click the button, click and hold on the map, then drag the cursor.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom In Button" /></td>
<td>Zooms in on the map.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom Out Button" /></td>
<td>Zooms out from the map.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom Rectangle Button" /></td>
<td>Zooms the map to fill a rectangle that you draw.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom Entire Map Button" /></td>
<td>Zooms the map to include the entire map.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom Actual Size Button" /></td>
<td>Zooms the map to actual size.</td>
</tr>
<tr>
<td><img src="image" alt="Add Device Button" /></td>
<td>Creates a new Security Manager-managed node. After you create the new device in the inventory, it is added to the active map as a device node.</td>
</tr>
<tr>
<td><img src="image" alt="Add Map Object Button" /></td>
<td>Adds a new map object to the map.</td>
</tr>
<tr>
<td><img src="image" alt="Add Link Button" /></td>
<td>Adds a new link to the map.</td>
</tr>
<tr>
<td><img src="image" alt="Add VPN Button" /></td>
<td>Creates a new VPN connection between nodes on the map.</td>
</tr>
<tr>
<td><img src="image" alt="Select Devices Button" /></td>
<td>Select devices to show on the map as device nodes.</td>
</tr>
<tr>
<td><img src="image" alt="Select VPNs Button" /></td>
<td>Select VPNs to show on the map.</td>
</tr>
</tbody>
</table>
Using the Navigation Window

The navigation window displays a smaller version of the entire active map. The shaded rectangle defines the area of the map that is currently displayed.

Use the navigation window to select the portion of the map to view and to change the map zoom level.

- To toggle the display of the navigation window, select **Map > Show/Hide Navigation Window**.
- To pan the navigation control to select which portion of the map to display, click within the shaded rectangle and drag it to a new location.
- To change the zoom level, click one of the resizing handles in the corners of the shaded rectangle, then drag it to increase or decrease the area of the map to display. The map zooms to display the area covered by the map indicator.

The title bar in the navigation window displays the name of the map. If the map has unsaved changes, an asterisk (*) appears next to the map name.

For information on other ways to pan and zoom maps, see *Panning, Centering, and Zooming Maps*, page 33-11.

Maps Context Menus

The following topics describe the menus that contain maps commands. To open the context menus, right-click map elements.

- **Managed Device Node Context Menu**, page 33-4
- **Multiple Selected Nodes Context Menu**, page 33-5
- **VPN Connection Context Menu**, page 33-6
- **Layer 3 Link Context Menu**, page 33-6
- **Map Object Context Menu**, page 33-6
- **Map Background Context Menu**, page 33-7

Managed Device Node Context Menu

The Managed Device Node context menu opens when you right-click a map node that represents a managed device. The commands that you see depend on the type of device you select. The following table lists all commands that you might see.

<table>
<thead>
<tr>
<th>Menu Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edit Firewall Policies</td>
<td>Edits firewall policies on the device. Select a firewall policy type from the submenu to edit it.</td>
</tr>
<tr>
<td>Edit Firewall Settings</td>
<td>Edits firewall settings on the device. Select a setting from the submenu to edit it.</td>
</tr>
<tr>
<td>Edit VPN Peers</td>
<td>Edits peers in VPNs in which the device participates.</td>
</tr>
<tr>
<td>Edit VPN Policies</td>
<td>Edits VPN policies on the device.</td>
</tr>
<tr>
<td>Device Properties</td>
<td>Displays device properties.</td>
</tr>
</tbody>
</table>
Chapter 33  Using Map View

Understanding Maps and Map View

Multiple Selected Nodes Context Menu

The Multiple Selected Device Node context menu opens when you select more than one map node, then right-click on a selected node.

If all of the selected nodes are not VPN-capable, the commands to configure VPNs do not appear.

### Table 33-3  Multiple Selected Nodes Context Menu

<table>
<thead>
<tr>

</tbody>
</table>

Access Permissions for Maps

Access to maps is controlled based on two systems of user privileges:

- Device privileges—You must have at least read privileges to all the devices in a map to open the map.
- Map privileges—Access to maps is based on your Security Manager user role. There are two levels of map access:
  - Read-only—You can open maps, but you cannot modify them. If you have this map privilege level, the features for modifying maps are not available.
  - Read-write—You can modify maps. All map modification features are available.

Working With Maps

A map is a representation of a portion of your network. You can create and save multiple maps to address your network management needs. To work with any map, you must be in Map view (select View > Map View).
After you create and save a map, the map is available to all users on the system that have at least read privileges to all the devices on the map. Users that do not have read privileges to a device on a map do not see the map in the list of existing maps when they try to open a map. For more information, see Access Permissions for Maps, page 33-7.

You can only have one map open at a time. If a map is open and you create a new map or open an existing map, you are prompted to save or discard any unsaved changes that you made to the current map.

Multiple users can open and modify a map at the same time. When a user saves changes to a map, any other users who are using the map are notified and have the option to do one of the following:

- Update their map to the version saved by the other user, losing any changes they have made.
- Save their version of the map as a new map, preserving any changes they made.

This section contains the following topics:

- Creating New or Default Maps, page 33-8
- Opening Maps, page 33-9
- Saving Maps, page 33-9
- Deleting Maps, page 33-10
- Exporting Maps, page 33-10
- Arranging Map Elements, page 33-10
- Panning, Centering, and Zooming Maps, page 33-11
- Selecting Map Elements, page 33-11
- Searching for Map Nodes, page 33-12
- Using Linked Maps, page 33-12
- Setting the Map Background Properties, page 33-12

## Creating New or Default Maps

You have two options for creating a new map:

- Create an empty map—To create a new empty map, select Map > New Map. You must already be in Map view (select View > Map View). If you currently have a map open with unsaved changes, you are asked if you want to save it. For information about adding elements to a map see Displaying Your Network on the Map, page 33-13.

- Create a new map containing all managed devices and VPNs in the inventory—This is called the default map. Generating the default map is a good way to create a map. After generating the map, save it with a unique name to make it a standard map and modify it as desired.

You can generate the default map whenever you want to, and it contains the inventory as it exists at the time you generate it. You cannot specifically save the default map as the default map; it is regenerated every time you select it.

The following procedure explains how to create a new map using the default map.

**Tips**

- If you refresh the map (select Map > Refresh Map), items that you added to the inventory after generating the default map are not added to the map. You must reopen the default map to see new devices.
Chapter 33 Using Map View

Working With Maps

Step 1 In Map view, select **Map > Open Map**.

Step 2 Select **Default Map** from the Available Maps list, then click **OK**.

**Note** If you do not have sufficient access rights to all devices in the inventory, the default map that opens shows only the subset of devices for which you do have access rights. For more information, see Access Permissions for Maps, page 33-7.

Step 3 To save the default map as a standard map, select **Map > Save Map** or **Map > Save Map As**, enter a name for the map and click **OK**.

Opening Maps

To open an existing map, select **Map > Open Map**, select the desired map from the list of available maps, and click **OK**. You must already be in Map view (select **View > Map View**). If you currently have a map open with unsaved changes, you are asked if you want to save it.

The list of available maps includes a special map called the **Default Map**. This map contains all of the managed devices and VPNs in the inventory. You are essentially creating a new map each time you open it. For more information about the default map, see Creating New or Default Maps, page 33-8.

**Tip** You can open any map that you have created or the default map. You can also open any map that another user has created provided you have the requisite permission settings with regard to the devices shown on that map (see Access Permissions for Maps, page 33-7).

Related Topics

- Working With Maps, page 33-7
- Understanding Map Elements, page 33-13

Saving Maps

To save the active map, select **Map > Save Map**. Any changes that you made since you last saved it are saved. If you did not save the map previously, the Save Map As dialog box opens, enabling you to assign a name to the map and save it.

To save a map under a new name, select **Map > Save Map As**. The map name can be as long as 256 characters, but cannot be the reserved names “Default Map” or “New Map.”

If you close a map that contains unsaved changes, you are prompted to save the changes.

If your Security Manager session closes automatically because of inactivity when a map is open with unsaved changes, the current version of the map is saved if it has a name. If you have not yet saved the map, the map is discarded. For example, if you generate the default map, or create a new map, and do not save it before your session times out, you cannot retrieve that map.
Deleting Maps

If you no longer need a map, you can delete it (presuming that you have edit permission). Deleting a map does not delete any devices or VPNs shown on the map, nor does it delete or modify their configurations; only the map is deleted.

When you delete a map, it is permanently deleted from the server. Other users cannot use the deleted map.

To delete a map, select Map > Delete Map, select the map you want to delete from the available maps list and click OK. You are asked to confirm the deletion.

You must already be in Map view (select View > Map View) to delete a map.

Exporting Maps

When viewing a map, you can export the map to a scalable vector graphics (SVG) image file for use outside of Security Manager.

Related Topics
- Working With Maps, page 33-7
- Understanding Map Elements, page 33-13

Step 1 Select Map > Export Map. The Export Topology Map to SVG dialog box opens.
Step 2 Browse to the location in which to save the file.
Step 3 Enter a filename in the File name field. The correct file extension will be added for you.
Step 4 Click Save.

Arranging Map Elements

To move a map element, click and hold, then drag it to the desired position. Attached links move automatically, but the other end of the link remains where it is.

You can also automatically arrange the network nodes on the map in several predefined layouts. Only nodes that are already displayed on the map are arranged. Any nodes that you later add do not follow the layout.

To select a map layout, right-click the map background, then select one of the following layouts from the map context menu:
- Hierarchical Layout—Arranges the nodes in a hierarchical layout.
- Radial Layout—Arranges the nodes in a radial layout.
- Circular Layout—Arranges the nodes in a circular layout.
Panning, Centering, and Zooming Maps

There are many options for navigating maps. You can pan the map (move around in the map without changing the zoom level), pan a map so that a particular map element is centered in your view, or zoom in or out to see a different map extent.

To pan a map without changing the zoom level:
- Click the Pan Map toolbar button, then click and hold anywhere on the map and drag the cursor.
- Use the vertical and horizontal scroll bars that are available if the entire map does not fit in the visible page.
- Click and drag the shaded rectangle in the navigation window.
- To center the display of the map on a particular map element, right-click the element, then select Move to Center.

To zoom in or out of a map:
- To change the zoom level of the map in predefined increments:
  - To zoom in on the map, select Map > Zoom In, or click the Zoom In toolbar button.
  - To zoom out from the map, select Map > Zoom Out, or click the Zoom Out toolbar button.
- To zoom into a specific area of the map, click Zoom Rectangle in the map toolbar, then click the map and drag a rectangle around the area. When you release the mouse button, the map zooms to display the area defined by the rectangle.
- Alternatively, to zoom in to or out of a specific area of the map, click and drag the corner of the shaded rectangle in the navigation window.
- To display the entire map, select Map > Fit to Window.
- To display the map at actual size, select Map > Display Actual Size.

Related Topics
- Using the Navigation Window, page 33-4

Selecting Map Elements

The following table describes how to select map elements. If the selected element contains other elements (for example, a Catalyst switch that contains an FWSM), the containment relationship is shown. For more information, see Showing Containment of Catalyst Switches, Firewalls, and Adaptive Security Appliances, page 33-16.

<table>
<thead>
<tr>
<th>Table 33-8</th>
<th>Selecting Network Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>To select...</td>
<td>Do the following</td>
</tr>
<tr>
<td>A single map element</td>
<td>Click the element.</td>
</tr>
<tr>
<td>Multiple noncontiguous map elements</td>
<td>Ctrl+click each element.</td>
</tr>
<tr>
<td>Multiple contiguous map elements</td>
<td>Click the map and drag a rectangle that includes the elements.</td>
</tr>
</tbody>
</table>
Searching for Map Nodes

To search for a map node to help you find it in the active map, select Map > Find Map Node. This command opens the Find Node dialog box.

The Find Node dialog box initially lists all objects on the map. Use the fields above the list to filter it (the list shows only objects that satisfy all filter criteria). When you find the desired node, select it in the list and click OK to have the node centered and selected in the map.

To filter the list, you can:

- Select a node type from the Type list to show only objects of that type.
- Enter the name, or at least the initial characters of the name, in the Name field. The list is filtered as you type. Your search term must be from the start of the object name. You cannot use wildcard characters.
- Enter all or part of the IP address or subnet mask. The list is filtered as you enter information.

Using Linked Maps

A linked map is a map that you associate with a map element on another map. Because it is not practical to include all the nodes on a large network in a single map, you can use linked maps to create a hierarchical topology of your network.

You cannot link a node to the another node in the same map.

**Before You Begin**

You must create the map to link to before you can link to it.

**Step 1**
Right-click the map element to which to link a map, then select Set Linked Map. The Set Linked Map dialog box opens.

**Step 2**
Select a map to associate with the selected map element, then click OK.

**Step 3**
To open the linked map, right-click the linked node, then select Open Linked Map. The current map closes and the linked map opens.

Setting the Map Background Properties

You can change the background of a map by changing the color or by configuring an image. A suggested use for a background image is to use an image that represents a geographic area. Then you can position map elements according to their geographic locations.

Some background images are included with Security Manager. You can also transfer images to the server to use as background images. You can use background images of the following file formats: JPEG, GIF, PNG, IVL, and SVG. If you want to use a new image, copy the image file to the Security Manager server file system by connecting directly to the server. For security reasons, Security Manager does not provide a method of transferring files to the server.

To configure the map background, in Map view, select Map > Map Properties to open the Map Settings dialog box.
To configure a background image, select it in the file list. (Select **none** to remove the map’s background image.)

If the image is not listed, click **Add** and browse to the file you placed on the server using the Import Background Image dialog box. Click **OK** to have Security Manager add it to the list of available background images.

If you no longer need a listed image, select it and click **Delete**.

---

**Tip**

You can control the position and scale of the image using the X and Y coordinates and scale settings. The X,Y source point is the upper left corner of the image. You can use positive or negative numbers. You must experiment to get the results you desire. The scale setting is in percentage.

---

To change the background color, click **Select** next to the background color field and choose the desired color.

---

**Displaying Your Network on the Map**

You use the map view to represent your network topology by creating maps. A map is a visual representation of your network, or a portion of it if it is too large to fit on a single map. Maps consist of map elements that represent devices, links, and other objects in your network. For more information about maps, see Working With Maps, page 33-7.

The following topics describe how to create maps:

- **Understanding Map Elements**, page 33-13
- **Displaying Managed Devices on the Map**, page 33-15
- **Showing Containment of Catalyst Switches, Firewalls, and Adaptive Security Appliances**, page 33-16
- **Using Map Objects To Represent Network Topology**, page 33-16
- **Creating and Managing Layer 3 Links on the Map**, page 33-18

---

**Understanding Map Elements**

All objects that can appear on a map are map elements. You display map elements on a map to create a representation of a portion of your network. For more information about maps, see Working With Maps, page 33-7. To open a map, see Opening Maps, page 33-9.

The following tables describe the elements that can appear on a map:

- **Table 33-9 on page 33-14** describes the device nodes that can appear on a map. These elements are managed by Security Manager.
- **Table 33-10 on page 33-14** describes the map objects that can appear on a map. These elements are not managed by Security Manager.
- **Table 33-11 on page 33-15** describes the map element indicators that can appear with a device node.

Displaying Your Network on the Map

A device node represents a device that is managed by Security Manager. You add a device node to a map by selecting the device from the Security Manager inventory.

When you add a device node to a map, its layer 3 connectivity to other nodes on the map is created automatically. For more information, see Creating and Managing Layer 3 Links on the Map, page 33-18.

You can add, remove, or show managed nodes by the following means:

- **To add devices that are already in the Security Manager inventory**—Select Map > Show Devices on Map to open a device selector. Select the desired devices from the list of available devices and click >> to move them to the selected devices list. You can select device groups to move all devices in the group. Click OK when the list of selected devices has the desired nodes. Only those devices in the selected list are shown on the map.

  You can remove devices by selecting them in the selected list and clicking <<.

- **To add a new device to the map and the device inventory**—Click the New Device button in the map toolbar or right-click the map background and select New Device. The New Device dialog box opens. Follow the procedures for adding new devices described in Adding Devices to the Device Inventory, page 3-7.

- **To remove a managed node**—Right-click the node and select Remove from Map.

- **To locate a device on the open map when in Device view**—Right-click the device in the device selector and select Show in Map View. If the device is shown on the active map, it is shown centered and highlighted on the undocked map. You are told that the device cannot be found if the device is not shown on the active map.

- **To locate a device in Device view from the map**—Right-click the device and select Show in Device View. Device view is opened with the device selected so that you can edit its policies.
Displaying Your Network on the Map

Chapter 33      Using Map View

Showing Containment of Catalyst Switches, Firewalls, and Adaptive Security Appliances

The containment relationship between Catalyst and Adaptive Security Appliance (ASA) devices and their service modules and security contexts, between PIX 7.x+ devices and FWSM and their security contexts, or between IPS devices and their virtual sensors, is displayed in maps as follows:

- When you select a Catalyst device, nodes that represent its Firewall Services Modules (FWSM) are highlighted.
- When you select an ASA, nodes that represent its Security Service Modules are highlighted.
- When you select a service module, the device that contains it is highlighted.
- When you select an IPS device, the nodes that represent virtual sensors defined on the device are highlighted.
- You can view a list of the security contexts contained in an ASA, firewall, or FWSM device, or the virtual sensors contained in an IPS device, by right-clicking the node and selecting Show Containment. This command also shows the service modules in a device that has them.
- When you select a security context node, all its ancestor device nodes are highlighted.
- When you select a virtual sensor, the device on which it is defined is highlighted.

Using Map Objects To Represent Network Topology

You can add map elements to a map that represent objects (such as devices and links) that Security Manager does not manage. These nodes are called map objects. You can use map objects to create a more useful representation of your network topology. (If you want to add a managed device, see Displaying Managed Devices on the Map, page 33-15.)

You can add layer 3 links between any map elements, whether they are device nodes, map nodes, or a combination of both types.

Tip

To delete a map object, right-click the object and select Delete Map Object.

Step 1

Select Map > Add Map Object. The Add Map Object dialog box appears (see Add Map Object and Node Properties Dialog Boxes, page 33-17).

Step 2

Do one of the following:

- If you are adding a map object based on the definition of an Security Manager policy object, click Copy Policy Object to open the Select Policy Object Dialog Box, page 33-18. Then, select the type of object (AAA server, network/host, PKI enrollment), click Select to choose the object, then click OK in the Select Policy Object dialog box. Information from the policy object is entered in the Add Map Object dialog box.

  The name of the object is used as the map object name, but you can edit this if desired.
Step 3  Select the type of object that the node represents from the Type list. If you selected a policy object, the type is pre-selected, but you can change the selection.

Step 4  (Optional) Add interfaces to the node by doing the following for each interface:
   a. Click Add to open the Interface Properties Dialog Box, page 33-18. If items already appear in the list, you can select them and click Edit to change them.
   b. Enter an interface name, IP address, and network mask, then click OK.

Step 5  Click OK. The map object is added to the center of the map. Move it to the desired location.

Add Map Object and Node Properties Dialog Boxes

For unmanaged map objects, the Add Map Object and Node Properties dialog boxes are the same. Use the Add Map Object dialog box to add an object to the map. Use the Node Properties dialog box to view or edit map object properties. For more information, see Using Map Objects To Represent Network Topology, page 33-16.

For managed map objects (such as a managed device), the Node Properties dialog box is read-only. It displays the object name, type, and list of interface names and IP addresses (if any are defined in Security Manager for the device). The reference information below does not apply to this version of the Node Properties dialog box.

Navigation Path

- To open the Add Map Object dialog box, select Map > Add Map Object.
- To open the Node Properties dialog box, right-click a map object or managed device and select Node Properties.

Field Reference

Table 33-12  Add Map Object and Node Properties Dialog Boxes for Unmanaged Nodes

<tr>
<td></td>
<td>• To delete an interface, select it and click the Delete (trash can) button.</td>
</tr>
</tbody>
</table>
Displaying Your Network on the Map

Select Policy Object Dialog Box

Use the Select Policy Object dialog box to add an object to the map that is defined in a policy object. Select the type of object that defines the node you want to add to the map from the Select a Policy Object list, then click Select to select the specific policy object. If you know the object’s name, you can type it into the text box instead of clicking Select.

For more information, see Using Map Objects To Represent Network Topology, page 33-16.

Navigation Path

To open this dialog box, click Copy Policy Object in the Add Map Object dialog box (see Add Map Object and Node Properties Dialog Boxes, page 33-17).

Interface Properties Dialog Box

Use the Interface Properties dialog box to add and edit interfaces on map objects. For more information, see Using Map Objects To Represent Network Topology, page 33-16.

Navigation Path

To open this dialog box, click the Add or Edit button in the Add Map Object and Node Properties Dialog Boxes, page 33-17.

</table>

Creating and Managing Layer 3 Links on the Map

A layer 3 link is a line on the map that represents a network connection between two device interfaces. Layer 3 connectivity information is automatically added to the map when you add map elements that have interface information. When you add a map element that has interface information, one of the following happens:

- If the interface is on a network that is not represented on the map as a network map object, a network map object is added to the map with a layer 3 link to the new map element.
- If the interface is on a network that is represented on the map as a network map object, a layer 3 link is added between the new map element and the network map object.

When you remove a node interface that is a layer 3 link endpoint, the link is also removed.

You can add additional layer 3 links between device nodes and map objects to illustrate your network’s connectivity. Adding Layer 3 links to a map does not configure any network devices. Layer 3 links are just visual elements on the map.
You create layer 3 links to connect any two interfaces on a map. Depending on the interfaces that you choose, the layer 3 link might include intermediary networks or network clouds. In some cases, you have the option to select which intermediary networks and networks clouds are inserted between the connected interfaces.

The following procedure explains how to manually create a new layer 3 link.

**Tips**

- The automatic addition of network objects and links is called Autolink. You can configure Autolink to not automatically add private or certain reserved network addresses. To configure these settings, select Tools > Security Manager Administration, then click Autolink.
- To view the properties of a link, right-click the layer 3 link and select Link Properties.
- To delete a layer 3 link, right-click the layer 3 link to be removed and select Delete Link. Deleting a layer 3 link does not delete any intermediary network or network clouds between map elements.

**Step 1**

In Map view, click Map > Add Link or the Add Link button in the toolbar.

**Step 2**

Click one of the map elements to connect, then click the other map element to connect.

**Step 3**

If the map elements contain interfaces, select the source and destination interfaces for the link in the Select Interfaces and Link Properties Dialog Boxes, then click OK.

The Add Link dialog box might open, depending on which interfaces you select.

**Step 4**

If the Add Link Dialog Box opens, select which intermediary objects and network clouds to insert, then click OK.

---

**Select Interfaces and Link Properties Dialog Boxes**

The Select Interfaces and Link Properties dialog boxes are used with layer 3 links on maps. These dialog boxes show information about the source and destination devices for the link (the source being the first device you clicked when making the link).

If you are creating a link, the Select Interfaces dialog box is used. If there are interfaces defined for the device in Security Manager, select the desired source and destination interfaces for the link you are creating from the Source/Destination Interface list.

**Tip**

When creating a link, if there are no interfaces defined for either device, the Interface lists are greyed out. If one device has interfaces defined, both fields are active, but empty for the device that does not have interfaces defined for it. You cannot change the interface when viewing link properties.

**Navigation Path**

For information on how to create layer 3 links or view their properties, see Creating and Managing Layer 3 Links on the Map, page 33-18.
Add Link Dialog Box

Use the Add Link dialog box to select how to represent the layer 3 link that you are adding to the map. The contents of the Add Link dialog box vary according to which nodes and interfaces you are connecting. Select the check boxes for each intermediary map object (network or cloud) that you want to insert between the connected nodes. If desired, you can change the names of the map objects.

Navigation Path

This dialog box might open when you add a link between nodes, depending on which interfaces you select to connect. For the procedure, see Creating and Managing Layer 3 Links on the Map, page 33-18.

Managing VPNs in Map View

The following topics describe how to manage VPNs in the Map view:

- Displaying Existing VPNs on the Map, page 33-20
- Creating VPN Topologies in Map View, page 33-20
- Editing VPN Policies or Peers From the Map, page 33-21

Displaying Existing VPNs on the Map

To display an existing VPN on the map, select Map > Show VPNs on Map. You are prompted with a list of existing VPNs. Select the ones you want from the available VPNs list and click >> to move them to the selected list.

Tip

You can also remove a VPN using this command. Select the VPNs you want to remove from the selected VPNs list and click <<. When you remove a VPN, only the VPN tunnels are removed. The device nodes remain on the map.

When you display a VPN, all of its member devices are added to the map as device nodes, and all of its tunnels are highlighted. However, devices that you removed from the map previously are not added, even if they are members of a VPN that you display. You can add such devices to the map manually, and their VPN connectivity is displayed.

A VPN tunnel is a line on the map that represents a VPN connection between two devices. VPN tunnels are not added to the map automatically when you add a device node that is a member of a VPN. However, if the VPN was already selected to be shown on the map, adding a device in the VPN to the map will also display the tunnel.

For an explanation of the icons used in the map, see Understanding Map Elements, page 33-13.

Creating VPN Topologies in Map View

You can create VPN connections between VPN-capable managed device nodes that are displayed on the map. You cannot create Extranet VPNs, however.

To create a VPN, do one of the following:
• Click the **New VPN** button in the toolbar and select the type of VPN you want to configure: point-to-point, hub and spoke, or full mesh.

• Select the devices that you want to participate in the VPN (use Ctrl+click to select multiple devices), and either right click and select the command for the desired type of VPN, or click the **New VPN** button and select the VPN type.

Consider the following tips:

– Select only 2 devices to create a point-to-point VPN.

– If you create a hub-and-spoke VPN, the device you right-click is initially defined as the hub, but you can change that in the wizard.

– While in the wizard, you can add or remove devices. You are not restricted to the devices you selected on the map.

Using either technique, the Create VPN wizard opens, where you can create the VPN. For more information, see **Creating or Editing VPN Topologies**, page 23-28 or click the Help button in the wizard. The VPN is displayed on the map when you are finished with the wizard.

**Related Topics**

• **Selecting Map Elements**, page 33-11

---

**Editing VPN Policies or Peers From the Map**

You can edit VPN policies, or the peers that participate in a VPN, from map view. To edit policies or peers, right-click a VPN tunnel or device node and select one of these commands:

• **Edit VPN Policies**—To open the Site-to-Site VPN Manager, where you can edit the policies that define the VPN. For more information, see **Site-to-Site VPN Manager Window**, page 23-18.

• **Edit VPN Peers**—To open a dialog box that allows you to configure the peers that participate in the VPN. Click the **Help** button in the dialog box for more information.

• **Show VPN Peers**—To see which devices participate in a VPN without editing the list (VPN Peers dialog box).

If the device participates in more than one VPN, you are first prompted to select the desired VPN (with the Select VPN to Configure dialog box) before the appropriate dialog box is opened.

---

**Managing Device Policies in Map View**

You can perform only basic policy management and configure firewall services policies in Map view. You cannot configure other types of policies. The following topics describe how to manage policies from the Map view:

• **Performing Basic Policy Management in Map View**, page 33-22

• **Managing Firewall Policies in Map View**, page 33-22

• **Managing Firewall Settings in Map View**, page 33-23
Performing Basic Policy Management in Map View

You can perform some basic policy management tasks in Map view. Right click the device and select one of the following commands:

- **Copy Policies Between Devices**—To copy local device policies from one device to another. For more information on copying policies, see *Copying Policies Between Devices*, page 5-31.
- **Share Device Policies**—To create shared policies from local device policies. For more information on sharing policies, see *Sharing Multiple Policies of a Selected Device*, page 5-39.
- **Clone Device**—To create a copy of a device, including its policies. For more information on cloning devices, see *Cloning a Device*, page 3-50.
- **Preview Configuration**—To view the configuration file that will be generated for the device, including the changes from the previous deployment. For more information on previewing configurations, see *Previewing Configurations*, page 8-42.
- **Discover Policies on Device**—To discover the policies defined on the device and configure them in Security Manager, wiping out whatever policies are defined in Security Manager for the device. For more information on device discovery, see *Discovering Policies on Devices Already in Security Manager*, page 5-15.

**Related Topics**
- Chapter 8, “Managing Deployment”
- Chapter 3, “Managing the Device Inventory”
- Chapter 5, “Managing Policies”

Managing Firewall Policies in Map View

You can configure firewall policies on a device in Map view. These policies are local to the device rather than being shared policies (you must use Policy view to configure shared policies).

**Tip**

If you want to assign a shared policy to a device, see *Performing Basic Policy Management in Map View*, page 33-22.

To configure local firewall policies on a device in Map view, right click the device and select one of the following commands:

- **Edit Firewall Policies > AAA Rules**—To configure AAA policies, which control who is allowed access to the device and what services they are allowed to use once they have access. For more information on configuring AAA rules, see *AAA Rules Page*, page 14-9.
- **Edit Firewall Policies > Access Rules**—To configure Access Rules policies, which control the traffic that flows through a device. For more information on configuring access rules, see *Access Rules Page (IPv4 or IPv6)*, page 15-9.
- **Edit Firewall Policies > Inspection Rules**—To configure Inspection Rules policies, which analyze traffic at the application layer and track TCP and UDP sessions to perform refined access control. For more information on configuring inspection rules, see *Inspection Rules Page*, page 16-7.
- **Edit Firewall Policies > Botnet Traffic Filter Rules**—(ASA 8.2 and higher only) To configure Botnet Traffic Filter Rules policies, which monitor web traffic. For more information on configuring botnet traffic filter rules, see *Botnet Traffic Filter Rules Page*, page 18-9.
• **Edit Firewall Policies > Transparent Rules**—To configure Transparent Rules policies, which define EtherType rules for transparent firewalls. For more information on configuring inspection rules, see *Transparent Rules Page*, page 21-3.

• **Edit Firewall Policies > Web Filter Rules**—To configure Web Filter Rules policies, which define rules for web access. For more information on configuring web filter rules, see *Web Filter Rules Page (ASA/PIX/FWSM)*, page 17-3 or *Web Filter Rules Page (IOS)*, page 17-12.

• **Edit Firewall Policies > Zone Based Firewall Rules**—(IOS 12.4(6)T and higher only) To configure Zone Based Firewall Rules policies, which configure inspection and web filtering using security zones. For more information on configuring zone based firewall rules, see *Zone-based Firewall Rules Page*, page 20-55.

**Related Topics**

- Chapter 12, “Introduction to Firewall Services”

### Managing Firewall Settings in Map View

You can configure firewall settings policies on a device in Map View. These policies are local to the device rather than being shared policies (you must use Policy View to configure shared policies).

If you want to assign a shared policy to a device, see *Performing Basic Policy Management in Map View*, page 33-22.

To configure local firewall settings policies on a device in Map View, right click the device and select one of the following commands:

- **Edit Firewall Settings > AAA Firewall**—(ASA/PIX/FWSM only) To configure AAA Firewall settings policies, which configures proxy, authentication challenge, MAC exempt lists, and other general AAA settings. For more information on configuring AAA firewall settings, see *AAA Firewall Settings Page, Advanced Setting Tab*, page 14-18 and *AAA Firewall Page, MAC-Exempt List Tab*, page 14-21.

- **Edit Firewall Settings > Access Control**—To configure Access Control settings policies, which configures optimization and other general access control settings. For more information on configuring access control settings, see *Access Control Settings Page (IPv4 and IPv6)*, page 15-19.

- **Edit Firewall Settings > AuthProxy**—(IOS devices only) To configure AuthProxy settings policies, which configure general settings for authorization proxies. For more information on configuring authorization proxies, see *AAA Page*, page 14-23.

- **Edit Firewall Settings > Inspection**—(IOS devices only) To configure Inspection settings policies, which configure timeout and session settings for inspection rules. For more information on configuring inspection settings, see *Configuring Settings for Inspection Rules for IOS Devices*, page 16-82.

- **Edit Firewall Settings > Web Filter**—To configure Web Filter settings policies, which configure the server used for web filtering. For more information on configuring web filter settings, see *Web Filter Settings Page*, page 17-16.

- **Edit Firewall Settings > Zone Based Firewall**—(IOS 12.4(6)T and higher devices) To configure Zone Based Firewall settings policies, which configure zones and Trend web filter server settings.
PART 4

IPS Configuration
Getting Started with IPS Configuration

Cisco Intrusion Prevention System (IPS) Sensors are network devices that perform real-time monitoring of network traffic for suspicious activities and active network attacks. The IPS sensor analyzes network packets and flows to determine whether their contents appear to indicate an attack against your network.

Using Cisco Security Manager, you can configure and manage sensors, which can be dedicated stand-alone network appliances, Catalyst 6500 switch modules, service modules running in supported ASA devices or routers, and IPS-enabled Cisco IOS Software images running on integrated services routers. For a full list of supported IPS devices and software versions, see the Supported Devices and Software Versions for Cisco Security Manager document for this version of the product.

This chapter contains the following topics:

- Understanding IPS Network Sensing, page 34-1
- Overview of IPS Configuration, page 34-5
- Identifying Allowed Hosts, page 34-7
- Configuring SNMP, page 34-8
- Managing User Accounts and Password Requirements, page 34-13
- Identifying an NTP Server, page 34-21
- Identifying DNS Servers, page 34-22
- Identifying an HTTP Proxy Server, page 34-23
- Configuring the External Product Interface, page 34-23
- Configuring IPS Logging Policies, page 34-27
- Configuring IPS Security Settings, page 34-27

Understanding IPS Network Sensing

Network sensing can be accomplished using Cisco IPS sensors (appliances, switch modules, network modules, and SSMs) and Cisco IOS IPS devices (Cisco IOS routers with IPS-enabled images and Cisco ISRs). These sensing platforms are components of the Cisco Intrusion Prevention System and can be managed and configured through Cisco Security Manager. These sensing platforms monitor and analyze network traffic in real time. They do this by looking for anomalies and misuse on the basis of network flow validation, an extensive embedded signature library, and anomaly detection engines. However, these platforms differ in how they can respond to perceived intrusions.
Tip
Cisco IPS sensors and Cisco IOS IPS devices are often referred to collectively as IPS devices or simply sensors. However, Cisco IOS IPS does not run the full dedicated IPS software, and its configuration does not include IPS device-specific policies. Additionally, the amount of sensing that you can perform with Cisco IOS IPS is more limited. The following sections focus on using dedicated IPS devices, including service modules installed in IOS routers, rather than Cisco IOS IPS. For a discussion focused on Cisco IOS IPS, see Intrusion Prevention System (IPS) Cisco IOS Intrusion Prevention System Deployment Guide on Cisco.com and Chapter 43, “Configuring IOS IPS Routers”. Also, see http://www.cisco.com/go/iosips.

When an IPS device detects unauthorized network activity, it can terminate the connection, permanently block the associated host, and take other actions.

Note
For more overview information on IPS sensors, including a comparison of the available appliances and service modules and details about device interfaces, see Introducing the Sensor in Installing Cisco Intrusion Prevention System Appliances and Modules. A list of these documents for each IPS release is available at http://www.cisco.com/en/US/products/hw/vpndevc/ps4077/prod_installation_guides_list.html.

This section contains the following topics:

- Capturing Network Traffic, page 34-2
- Correctly Deploying the Sensor, page 34-4
- Tuning the IPS, page 34-4

Capturing Network Traffic

The sensor can operate in either promiscuous or inline mode. The following illustration shows how you can deploy a combination of sensors operating in both inline (IPS) and promiscuous (IDS) modes to protect your network.
The command and control interface is always Ethernet. This interface has an assigned IP address, which allows it to communicate with the manager workstation or network devices (Cisco switches, routers, and firewalls). Because this interface is visible on the network, you should use encryption to maintain data privacy. SSH is used to protect the CLI and TLS/SSL is used to protect the manager workstation. SSH and TLS/SSL are enabled by default on the manager workstations.

When responding to attacks, the sensor can do the following:

- Insert TCP resets via the sensing interface.

  **Note**  You should select the TCP reset action only on signatures associated with a TCP-based service. If selected as an action on non-TCP-based services, no action is taken. Additionally, TCP resets are not guaranteed to tear down an offending session because of limitations in the TCP protocol.

- Make ACL changes on switches, routers, and firewalls that the sensor manages.

  **Note**  ACLs may block only future traffic, not current traffic.
• Generate IP session logs, session replay, and trigger packets display.
  IP session logs are used to gather information about unauthorized use. IP log files are written when events occur that you have configured the appliance to look for.
• Implement multiple packet drop actions to stop worms and viruses.

**Correctly Deploying the Sensor**

Before you deploy and configure your sensors, you should understand the following about your network:
• The size and complexity of your network.
• Connections between your network and other networks, including the Internet.
• The amount and type of traffic on your network.

This knowledge will help you determine how many sensors are required, the hardware configuration for each sensor (for example, the size and type of network interface cards), and how many managers are needed.

You should always position the IPS sensor behind a perimeter-filtering device, such as a firewall or adaptive security appliance. The perimeter device filters traffic to match your security policy thus allowing acceptable traffic in to your network. Correct placement significantly reduces the number of alerts, which increases the amount of actionable data you can use to investigate security violations. If you position the IPS sensor on the edge of your network in front of a firewall, your sensor will produce alerts on every single scan and attempted attack even if they have no significance to your network implementation. You will receive hundreds, thousands, or even millions of alerts (in a large enterprise environment) that are not really critical or actionable in your environment. Analyzing this type of data is time consuming and costly.

**Tuning the IPS**

Tuning the IPS ensures that the alerts you see reflect true actionable information. Without tuning the IPS, it is difficult to do security research or forensics on your network because you will have thousands of benign events, also known as false positives. False positives are a by-product of all IPS devices, but they occur much less frequently in Cisco IPS devices because Cisco IPS devices are stateful, normalized, and use vulnerability signatures for attack evaluation. Cisco IPS devices also provide risk rating, which identifies high risk events, and policy-based management, which lets you deploy rules to enforce IPS signature actions based on risk rating.

Follow these tips when tuning your IPS sensors:
• Place your sensor on your network behind a perimeter-filtering device.
  Proper sensor placement can reduce the number of alerts you need to examine by several thousands a day.
• Deploy the sensor with the default signatures in place.
  The default signature set provides you with a very high security protection posture. The Cisco signature team has spent many hours on testing the defaults to give your sensor the highest protection. If you think that you have lost these defaults, you can restore them.
• Make sure that the event action override is set to drop packets with a risk rating greater than 90.
  This is the default and ensures that high risk alerts are stopped immediately.
Overview of IPS Configuration

There are a wide variety of devices on which you can configure the Intrusion Prevention System. From a configuration point-of-view, you can separate the devices into two groups: dedicated appliances and service modules (for routers, switches, and ASA devices) that run the full IPS software; and IPS-enabled routers running Cisco IOS Software 12.4(11)T and later (Cisco IOS IPS).

The following procedure is an overview of IPS configuration on dedicated appliances and service modules. For Cisco IOS IPS devices (which does not include IPS service modules installed in a router), see Overview of Cisco IOS IPS Configuration, page 43-3.

Step 1
Install and connect the device to your network. Install the device software and perform basic device configuration. Install the licenses required for all of the services running on the device. The amount of initial configuration that you perform influences what you will need to configure in Security Manager. Follow the instructions in the Installing Cisco Intrusion Prevention System Appliances and Modules document for the IPS version you are using.

Step 2
Add the device to the Security Manager device inventory (see Adding Devices to the Device Inventory, page 3-7).

Tip
You can discover router and Catalyst switch modules when adding the device in which the module is installed. For ASA devices, you must add the service module separately.

Step 3
Configure the interfaces as described in Configuring Interfaces, page 35-6. You must enable the interfaces connected to your network for the device to function.

For certain types of service module, there are additional policies to configure:

- Router-hosted service modules—Configure the IPS Module interface settings policy on the router. For more information, see IPS Module Interface Settings on Cisco IOS Routers, page 58-22.

Filter out known false positives caused by specialized software, such as vulnerability scanner and load balancers by one of the following methods:

- You can configure the sensor to ignore the alerts from the IP addresses of the scanner and load balancer.
- You can configure the sensor to allow these alerts and then use Event Viewer to filter out the false positives.

Filter the Informational alerts.
These low priority events notifications could indicate that another device is doing reconnaissance on a device protected by the IPS. Research the source IP addresses from these Informational alerts to determine what the source is.

Analyze the remaining actionable alerts:

- Research the alert.
- Fix the attack source.
- Fix the destination host.
- Modify the IPS policy to provide more information.
• **IDSM**—Configure the **IDSM Settings** Catalyst platform policy. For more information, see **IDSM Settings**, page 64-43.

• **IPS modules on ASA devices**—Configure the **Platform > Service Policy Rules > IPS, QoS, and Connection Rules** policy on the host ASA to specify the traffic that should be inspected. For more information, see **About IPS Modules on ASA Devices**, page 55-12 and **IPS, QoS, and Connection Rules Page**, page 55-5.

**Step 4** Use the **Virtual Sensors** policy to assign interfaces to the virtual sensors, including the base vs0 virtual sensor that exists for all IPS devices. For information about virtual sensor settings and assigning interfaces to a virtual sensor, see **Defining A Virtual Sensor**, page 36-5.

If the device supports it, and you have a need for it, you can also create user-defined virtual sensors so that a single device acts like multiple sensors. Most of the IPS configuration is done on the parent device, but you can configure unique settings per virtual sensor for signatures, anomaly detection, and event actions. For more information, see **Chapter 36, “Configuring Virtual Sensors”**.

**Step 5** Configure basic device access platform policies. These policies determine who can log into the device:

- **AAA**—Configure this policy if you want to use a RADIUS server to control access to the device. You can use AAA control in conjunction with local user accounts defined in the User Accounts policy. See **Configuring AAA Access Control for IPS Devices**, page 34-19.

- **Allowed Hosts**—The addresses of hosts who are allowed access. Ensure that the Security Manager server is included as an allowed host, or you cannot configure the device using Security Manager. See **Identifying Allowed Hosts**, page 34-7.

- **SNMP**—Configure this policy if you want to use an SNMP application to manage the device. See **Configuring SNMP**, page 34-8.

- **Password Requirements**—You can define the acceptable characteristics of a user password. See **Configuring User Password Requirements**, page 34-18.

- **User Accounts**—The user accounts defined on the device. See **Configuring IPS User Accounts**, page 34-16.

**Step 6** Configure basic server access platform policies. These policies identify the servers to which the device can connect:

- **External Product Interface**—If you use Management Center for Cisco Security Agents, configure this policy to allow the sensor to download host postures from the application. See **Configuring the External Product Interface**, page 34-23.

- **NTP**—Configure this policy if you want to use a Network Time Protocol server to control the device time. See **Identifying an NTP Server**, page 34-21.

- **DNS, HTTP Proxy**—The DNS and HTTP Proxy policies are required only if you configure global correlation. They identify a server that can resolve DNS names to IP addresses. Use the HTTP Proxy policy if your network requires the use of a proxy to make Internet connections; otherwise, use the DNS policy. See **Identifying DNS Servers**, page 34-22 or **Identifying an HTTP Proxy Server**, page 34-23.

**Step 7** Configure the Logging policy if you want non-default logging. See **Configuring IPS Logging Policies**, page 34-27.

**Step 8** Configure IPS signatures and event actions. Event action policies are easier to configure than creating custom signatures, so try to use event action filters and overrides to modify signature behavior before trying to edit specific signatures. For more information, see the following topics:

- **Chapter 38, “Configuring Event Action Rules”**

- **Configuring Signatures**, page 37-4
Chapter 34      Getting Started with IPS Configuration

Identifying Allowed Hosts

Use the Allowed Hosts policy to identify which hosts or networks have permission to access the IPS sensor. By default, no hosts are permitted to access a sensor, so you must add hosts or networks to this policy.

Step 9  If you use any of the Request Block or Request Rate Limit event actions, configure blocking or rate limiting hosts. See Configuring IPS Blocking and Rate Limiting, page 41-7.

Step 10 Configure other desired advanced IPS services. See the following topics:

- Chapter 40, “Configuring Global Correlation”
- Configuring Anomaly Detection, page 39-6

Step 11 Maintain the device:

- Update and redeploy configurations as necessary.
- Apply updated signature and engine packages. For information about checking for updates, applying them, and setting up regular automated updates, see Managing IPS Updates, page 42-4.
- Manage the device licenses. You can update and redeploy licenses, or automate license updates. For more information, see the following topics:
  - Updating IPS License Files, page 42-1
  - Redeploying IPS License Files, page 42-2
  - Automating IPS License File Updates, page 42-3
- Manage the certificates required for SSL (HTTPS) communication. These certificates expire, so you need to regenerate them approximately every 2 years. For information on regenerating certificates and ensuring that the certificates defined on the device are synchronized with those stored in the Security Manager certificate store, see Managing IPS Certificates, page 42-10.

Step 12 Monitor the device:

- Use the Event Viewer application to view alerts generated from the device. You can open Event Viewer from the Launch menu in Configuration Manager or Report Manager, or from the Windows Start menu.
  - For information on using Event Viewer, see Chapter 65, “Viewing Events”.
  - For an example of how to filter IPS alerts, see Removing False Positive IPS Events from the Event Table, page 65-58.
- Use the Report Manager application to generate reports on IPS usage, including comparisons of inline vs. promiscuous mode, and global correlation vs. traditional inspection. You can also analyze top attackers, victims, signatures, blocked signatures, and perform target analysis. The following topics explain Report Manager and the IPS reports in more detail:
  - Chapter 66, “Managing Reports”
  - Understanding General IPS Reports, page 66-17
  - Understanding IPS Top Reports, page 66-16
  - Opening and Generating Reports, page 66-18
Specifically, you must add either the IP address of the Security Manager server, or its network address, or Security Manager cannot configure the device. Also add the addresses of all other management hosts that you use, such as CS-MARS.

**Tip**
If you add host addresses only, you will be limited to using those workstations to access the device. Instead, you can specify network addresses to allow all hosts connected to specific “safe” networks access.

---

**Step 1**
Do one of the following to open the Allowed Hosts policy:

- (Device view) Select **Platform > Device Admin > Device Access > Allowed Hosts** from the Policy selector.
- (Policy view) Select **IPS > Platform > Device Admin > Allowed Hosts**, then select an existing policy or create a new one.

**Step 2**
Do one of the following:

- To add an entry, click the **Add Row** button and fill in the Access List dialog box.
  You can add up to 512 entries.
- To edit an entry, select it and click the **Edit Row** button.
- To delete an entry, select it and click the **Delete Row** button.

**Step 3**
When adding or editing an entry, specify the host or network address in the Add or Modify Access List dialog box, then click **OK**. You can enter addresses using the following formats:

- Host address—A simple IP address, such as 10.100.10.10.
- Network address—A network address and mask, such as 10.100.10.0/24 or 10.100.10.0/255.255.255.0.
- A network/host policy object—Click **Select** to select an existing object or to create a new one. To use the object in this policy, it must have a single value, either a single network or a single host.

---

**Configuring SNMP**

SNMP is an application layer protocol that facilitates the exchange of management information between network devices. SNMP enables network administrators to manage network performance, find and solve network problems, and plan for network growth.

SNMP is a simple request/response protocol. The network-management system issues a request, and managed devices return responses. This behavior is implemented by using one of four protocol operations: Get, GetNext, Set, and Trap.

You can configure the sensor for monitoring by SNMP. SNMP defines a standard way for network management stations to monitor the health and status of many types of devices, including switches, routers, and sensors.

You can configure the sensor to send SNMP traps. SNMP traps enable an agent to notify the management station of significant events by way of an unsolicited SNMP message.
Trap-directed notification has the following advantage—if a manager is responsible for a large number of devices, and each device has a large number of objects, it is impractical to poll or request information from every object on every device. The solution is for each agent on the managed device to notify the manager without solicitation. It does this by sending a message known as a trap of the event.

After receiving the event, the manager displays it and can take an action based on the event. For example, the manager can poll the agent directly, or poll other associated device agents to get a better understanding of the event.

Tip

Trap-directed notification results in substantial savings of network and agent resources by eliminating frivolous SNMP requests. However, it is not possible to totally eliminate SNMP polling. SNMP requests are required for discovery and topology changes. In addition, a managed device agent cannot send a trap if the device has had a catastrophic outage.

This procedure describes how to configure SNMP on an IPS sensor so that you can manage the sensor with an SNMP management station, including the configuration of traps.

Step 1

Do one of the following to open the SNMP policy:

- (Device view) Select Platform > Device Admin > Device Access > SNMP from the Policy selector.
- (Policy view) Select IPS > Platform > Device Admin > Device Access > SNMP, then select an existing policy or create a new one.

Step 2

On the General Configuration tab, configure at least the following options. For a complete description of all available options, see General SNMP Configuration Options, page 34-10.

- Enable SNMP Gets/Sets—Select this option to enable the SNMP management workstation to obtain (get) information, and to modify (set) values on the IPS sensor. If you do not enable this option, the management workstation cannot manage this sensor.
- Read-Only Community String—The community string required for read-only access to the sensor. SNMP get requests from the management station must supply this string to get responses from the sensor. This string gives access to all SNMP get requests.
- Read-Write Community String—The community string required for read-write access to the sensor. SNMP set requests from the management station must supply this string to get responses from the sensor; it can also be used on get requests. This string gives access to all SNMP get and set requests.

Step 3

If you want to configure SNMP traps, click the SNMP Trap Configuration tab and configure at least the following options. For a complete description of all available options, see SNMP Trap Configuration Tab, page 34-11.

- Enable Notifications—Select this option to allow the sensor to send SNMP traps.
- Trap Destinations—Add the SNMP management stations that should be trap destinations. Click the Add Row (+) button to add a new destination, or select a destination and click the Edit Row (pencil) button to change its configuration.

When adding or editing a trap destination, the trap community string that you enter overrides the default community string entered on the SNMP Trap Configuration tab. The community string appears in the traps sent to this destination and is useful if you are receiving multiple types of traps from multiple agents. For example, a router or sensor could be sending the traps, and if you put something that identifies the router or sensor specifically in your community string, you can filter the traps based on the community string.

To remove a destination, select it and click the Delete Row (trash can) button.
Step 4 If you configure trap destinations, you must also ensure that the desired alerts include the **Request SNMP Trap** action. You have the following options for adding this action:

- **(Easy way.)** Create an event action override to add the Request SNMP Trap action to all alerts of a specified risk rating ([IPS > Event Actions > Event Action Overrides](#)) policy. For example, you could generate traps for all alerts with a risk rating between 85-100. Event action overrides let you add an action without individually editing each signature. For more information, see **Configuring Event Action Overrides**, page 38-12.

- **(Precise way.)** Edit the Signatures policy ([IPS > Signatures > Signatures](#)) to add the Request SNMP Trap action to the signatures for which you want to send trap notifications. Traps are sent only for signatures that you configure to send traps.

  **Note** If the signature has Default for the source, you have to change the source to the Local source before you can change the action. However, if you right-click the Action cell in the signatures table and select **Edit Actions**, then select Request SNMP Trap (along with any other desired action) and click **OK**, the source is automatically changed to Local.

Step 5 Add the SNMP management stations to the Allowed Hosts policy. The management stations must be allowed hosts to access the sensor. See **Identifying Allowed Hosts**, page 34-7.

---

**General SNMP Configuration Options**

Use the General Configuration tab on the SNMP page to configure general SNMP parameters and apply them to IPS sensors. For the procedure, see **Configuring SNMP**, page 34-8.

**Navigation Path**

- **(Device view)** Select **Platform > Device Admin > Device Access > SNMP** from the Policy selector. Select the General Configuration tab.

- **(Policy view)** Select **IPS > Platform > Device Admin > Device Access > SNMP**, then select an existing policy or create a new one. Select the General Configuration tab.

**Field Reference**

| **Table 34-1 General Configuration Tab, SNMP Policy for IPS Sensors** |
|---|---|
| **Element** | **Description** |
| Enable SNMP Gets/Sets | Whether to enable the SNMP management workstation to obtain (get) information, and modify (set) values on the IPS sensor. If you do not enable this option, the management workstation cannot manage this sensor; the sensor will not respond to SNMP requests. |
| Read-Only Community String | The community string required for read-only access to the sensor. SNMP get requests from the management station must supply this string to get responses from the sensor. This string gives access to all SNMP get requests. Use the string to help identify the sensor. |
Table 34-1  General Configuration Tab, SNMP Policy for IPS Sensors (Continued)

<tbody>
<tr>
<td>Read-Write Community String</td>
<td>The community string required for read-write access to the sensor. SNMP set requests from the management station must supply this string to get responses from the sensor; it can also be used on get requests. This string gives access to all SNMP get and set requests. Use the string to help identify the sensor.</td>
</tr>
<tr>
<td>Sensor Contact</td>
<td>The network administrator or contact point who is responsible for this sensor.</td>
</tr>
<tr>
<td>Sensor Location</td>
<td>The physical location of the sensor, such as building address, name, and room number.</td>
</tr>
<tr>
<td>Sensor Agent Port</td>
<td>The port to use for SNMP get/set communication with the sensor. The default is 161. The valid range is 1 to 65535. Enter a port number or the name of a port list object, or click Select to select a port list object from a list or to create a new object. The port list object must identify a single port.</td>
</tr>
<tr>
<td>SNMP Agent Protocol</td>
<td>The protocol you are using for SNMP, either UDP (the default) or TCP. Select the protocol used by your SNMP management station.</td>
</tr>
</tbody>
</table>

**SNMP Trap Configuration Tab**

Use the SNMP Trap Communication tab on the SNMP page to configure traps and apply them to sensors and to identify recipients that the traps should be sent to. For the procedure, see Configuring SNMP, page 34-8.

**Navigation Path**

- (Device view) Select Platform > Device Admin > Device Access > SNMP from the Policy selector. Select the SNMP Trap Configuration tab.
- (Policy view) Select IPS > Platform > Device Admin > Device Access > SNMP, then select an existing policy or create a new one. Select the SNMP Trap Configuration tab.

**Field Reference**

<td>The community string used for the traps if no specific string has been set for the trap destination in the Trap Destinations table.</td>
</tr>
<tr>
<td>Trap Destinations table</td>
<td>The SNMP management stations that will be sent trap notifications. The table shows the IP address of the management station, the community string added to traps from this sensor, and the port to which traps are sent.</td>
</tr>
</tbody>
</table>

- To add a destination, click the **Add Row** button and fill in the Add SNMP Trap Communication dialog box (see **SNMP Trap Communication Dialog Box, page 34-12**).
- To edit a destination, select it, click the **Edit Row** button and make your changes.
- To delete a destination, select it and click the **Delete Row** button.

### SNMP Trap Communication Dialog Box

Use the Add or Modify SNMP Trap Communication dialog box to configure SNMP trap destinations. These are the SNMP management stations that should receive traps from the IPS sensor.

**Navigation Path**

Go to the **IPS Platform > Device Admin > Device Access > SNMP** policy, select the **SNMP Trap Configuration** tab, and click the **Add Row** button beneath the Trap Destinations table, or select a destination in the table and click the **Edit Row** button. For more information, see **SNMP Trap Communication Tab, SNMP Policy for IPS Sensors** (Continued).

**Field Reference**

**Table 34-3  SNMP Trap Communication Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Address</td>
<td>The IP address of the SNMP management station that should receive trap notifications. Enter the IP address or the name of a network/host object, or click <strong>Select</strong> to select the object from a list or to create a new object. The network/host object must specify a single host IP address.</td>
</tr>
</tbody>
</table>
Managing User Accounts and Password Requirements

You can configure user accounts and passwords, and general password requirements, for your IPS devices. You can configure local users (defined directly on the device), use a RADIUS AAA server, or use them both in conjunction. The policies used are the AAA, User Accounts, and Password Requirements policies in the Platform > Device Admin > Device Access folder.

When you create or edit a local user account in Security Manager, the password you enter must satisfy the requirements defined in the Password Requirements policy. This ensures that new passwords meet your security requirements.

If you change the password requirements, and then make changes to any local user account, the new requirements must be met by all user accounts that have passwords managed by Security Manager. This is because Security Manager reconfigures the passwords for all managed accounts if any single account needs to be reconfigured.

The User Accounts policy allows you to centrally manage the local user accounts for your IPS devices. Using a shared policy can help you ensure that all IPS devices contain the same accounts with the same passwords. However, it is important to understand that passwords are encrypted, so Security Manager cannot discover the actual passwords defined on the device. Security Manager manages the passwords for an account only if you define that password in Security Manager. Security Manager does not manage any user accounts defined in a RADIUS AAA server.

The following topics describe IPS user accounts, and Security Manager discovery and deployment considerations, in more detail:

- Understanding IPS User Roles, page 34-14
- Understanding Managed and Unmanaged IPS Passwords, page 34-14
- Understanding How IPS Passwords are Discovered and Deployed, page 34-15
- Configuring IPS User Accounts, page 34-16
- Configuring User Password Requirements, page 34-18
- Configuring AAA Access Control for IPS Devices, page 34-19

### Table 34-3   SNMP Trap Communication Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trap Community String</td>
<td>The community string of the trap. If you do not enter a trap string, the default trap string defined on the SNMP Trap Communication tab is used for traps sent to this destination.</td>

<td>The port used by the SNMP management station to receive traps. Enter the port number or the name of a port list object, or click Select to select the object from a list or to create a new one. The port list object must identify a single port.</td>
</tr>
</tbody>
</table>
Understanding IPS User Roles

There are four user roles for IPS user accounts:

- **Viewer**—Users can view the device configuration and events, but they cannot modify any configuration data except their user passwords.

- **Operator**—Users can view everything and they can modify the following options:
  - Signature tuning (priority, disable or enable).
  - Virtual sensor definition.
  - Managed routers.
  - Their user passwords.

- **Administrator**—Users can view everything and they can modify all options that Operators can modify in addition to the following:
  - Sensor addressing configuration.
  - List of hosts allowed to connect as configuration or viewing agents.
  - Assignment of physical sensing interfaces.
  - Enable or disable control of physical interfaces.
  - Add and delete users and passwords.
  - Generate new SSH host keys and server certificates.

- **Service**—Only one user with service privileges can exist on a sensor. The service user cannot log in to IDM or IME. The service user logs in to a bash shell rather than the CLI. The service role is a special role that allows you to bypass the CLI if needed.

**Note**

The purpose of the Service account is to provide Cisco Technical Support access to troubleshoot unique and unusual problems. It is not needed for normal system configuration and troubleshooting. You should carefully consider whether you want to create a service account. The service account provides shell access to the system, which makes the system vulnerable. However, you can use the service account to create a password if the administrator password is lost. Analyze your situation to decide if you want a service account existing on the system.

Understanding Managed and Unmanaged IPS Passwords

Every IPS local user account has a password, which allows secure user login to the device. These user passwords are encrypted on the IPS device. Thus, when you add an IPS device to the Security Manager inventory, Security Manager cannot read the actual user passwords.

Because Security Manager cannot read the password, it is unable to deploy newly-discovered user account passwords to the device. To avoid putting user accounts into a state where the passwords are unknown and unusable, Security Manager marks discovered user account passwords as unmanaged. The status of a password is indicated in the Is Password Managed? column of the Platform > Device Admin > Device Access > User Accounts policy:

- If No is indicated, the password for this account is not configured in Security Manager. When you deploy this policy, Security Manager will not attempt to configure the password for this user account.
If Yes is indicated, the password for this account was configured or updated in Security Manager. When you deploy this policy, Security Manager reconfigures the passwords for all managed accounts, not just the passwords that changed since the last deployment.

Because Security Manager configures even unchanged passwords, all managed passwords must satisfy the password requirements defined in the Password Requirements policy.

Thus, you can have a mix of managed and unmanaged account passwords. For example, you can have a set of shared user accounts that are centrally managed, and manage these account passwords in Security Manager. Other accounts might be unique to individuals; if you never edit these account passwords in Security Manager, the user can manage these passwords individually on the device.

**Tip**

If you do not want to manage any user accounts in Security Manager, ensure that the User Accounts policy is empty, or simply unassign the policy (right-click the policy and select **Unassign Policy**). Security Manager will not modify user account configurations.

---

### Understanding How IPS Passwords are Discovered and Deployed

Because user passwords are encrypted on IPS devices, Security Manager has to handle them with special care when discovering policies on the device or deploying configurations. When discovering or deploying user accounts on IPS devices, Security Manager does the following:

- **Discovery**—When you add an IPS device to the inventory, or rediscover policies on it, Security Manager determines the current status of each user account, updates the User Account policy with each discovered username and associated role, and marks the user password as unmanaged (as described in Understanding Managed and Unmanaged IPS Passwords, page 34-14).

  You cannot view the account status through Security Manager, because it is dynamic and can change. However, the Discovery Status window displays the status at discovery. Accounts can have these statuses:

  - **Active**—This state indicates that the account is available for use. Active accounts can be accessed using an authentication token if one has been assigned to the account.
  - **Expired**—This state indicates that the account’s authentication token has expired and the account can not be accessed using a token until the token has been updated.
  - **Locked**—This state indicates that logins to the account have been disabled due to too many failed authentication attempts. You should update the password for these accounts.

- **Deployment**—You are warned if any deployed user accounts are in the Expired or Locked state. Any unmanaged passwords are not deployed to the device. Also, keep in mind the following points:

  - If you make changes to any user account on the device, all user accounts with managed passwords are reconfigured. If you also changed the Password Requirements policy, all passwords are compared to the new policy and must meet the new requirements.
  - If you change the password of the user account you defined in the device’s properties for Security Manager to use when configuring the device, after successful deployment, Security Manager updates the password in the device properties to the new password. You do not need to manually update the password. To see device properties, select **Tools > Device Properties**.

This behavior assumes that you selected **Security Manager Device Credentials** for the Connect to Device Using option on the **Tools > Security Manager Administration > Device Communication** page. If you are using the logged-in users credentials for deployment, after successful deployment, the overall deployment is marked as failed, and a message explains how to reestablish connection. See **Device Communication Page, page 11-15**.
Managing User Accounts and Password Requirements

- If you use out-of-band change detection, changes to passwords are not detected. However, changes to usernames and roles are detected. For more information about out-of-band change detection, see Detecting and Analyzing Out of Band Changes, page 8-44.

- When previewing configurations, you can see changes to the user accounts by selecting to IPS (Delta – User Passwords). However, passwords are masked. For more information, see Previewing Configurations, page 8-42.

- If you are rolling back configurations, the user accounts are never rolled back. The current status and configuration of user accounts does not change.

**Tip**
The IPS sensor can accept public keys for RSA authentication when logging into the device through an SSH client. Each user has an associated list of authorized keys. Users can use these keys instead of passwords. Security Manager ignores these keys during discovery and deployment. Thus, if keys are configured, Security Manager does not remove the configuration.

**Configuring IPS User Accounts**

Use the User Accounts policy to configure local user accounts for IPS devices. Users can use these accounts to log into the device. You can create new users, modify user privileges and passwords, and delete users.

The user accounts policy should have at least these accounts:

- **cisco**—An account named “cisco” must exist on the device and you cannot delete it.
- An administrator account that Security Manager can use—Security Manager must be able to log into the device to configure it. Typically, you create an account for this purpose. However, you have the option of having Security Manager use the user account of the person deploying configurations to log into the device. You can configure this using the Connect to Device Using option on the Tools > Security Manager Administration > Device Communication page. See Device Communication Page, page 11-15.

IPS user account configuration is more complicated than it seems. Before you configure IPS user accounts, read the following topics:

- Managing User Accounts and Password Requirements, page 34-13
- Understanding IPS User Roles, page 34-14
- Understanding Managed and Unmanaged IPS Passwords, page 34-14
- Understanding How IPS Passwords are Discovered and Deployed, page 34-15
- Configuring User Password Requirements, page 34-18
- Configuring AAA Access Control for IPS Devices, page 34-19
Tips

- Cisco IOS IPS devices use the same user accounts that are defined for the router. This procedure
does not apply to Cisco IOS IPS configurations.

- If you change the password for the user defined in the device properties, which Security Manager
uses to deploy configurations to the device, Security Manager uses the existing credentials defined
in the device properties to log into the device and deploy changes. After successful deployment, the
device properties are then changed to use your new settings. For more information on credentials in
device properties, see Device Credentials Page, page 3-41.

Related Topics

- Filtering Tables, page 1-44
- Table Columns and Column Heading Features, page 1-44

---

Step 1

Do one of the following to open the User Accounts policy:

- (Device view) Select **Platform > Device Admin > Device Access > User Accounts** from the Policy
  selector.
- (Policy view) Select **IPS > Platform > Device Admin > Device Access > User Accounts**, then
  select an existing policy or create a new one.

The policy shows existing user accounts, including the username, role, and whether the password is
managed by Security Manager (as explained in Understanding Managed and Unmanaged IPS Passwords,
page 34-14).

Step 2

Do one of the following:

- To add a user account, click the **Add Row (+)** button. This opens the Add User dialog box. Enter the
  information required to define the account. For detailed information on the settings, see Add User
- To edit a user account, select it and click the **Edit Row (pencil)** button and make the required
  changes in the Edit User dialog box.
  
  You cannot change a user role to or from the Service role.
- To delete a user account, select it and click the **Delete Row (trash can)** button. You cannot delete
  the account named cisco.

Tip

All password changes must meet the requirements of the Password Requirements policy. If you
change the requirements policy, all new user accounts, or edited accounts, are tested against the
new requirements. Although the passwords for existing unedited user accounts are not tested,
they too must meet the password requirements if you change any user account defined in this
policy, because Security Manager will deploy all of the accounts during the next configuration
deployment. Passwords are checked for conformity when you validate policies, which typically
happens when you submit changes to the database. For more information, see Understanding
How IPS Passwords are Discovered and Deployed, page 34-15.
Add User and Edit User Credentials Dialog Boxes

Use the Add User or Edit User Credentials dialog boxes to add or edit IPS device user accounts.

Navigation Path

From the IPS platform User Accounts policy, click the Add Row (+) button to create a new account, or select an existing account and click the Edit Row (pencil) button. For information on accessing the User Accounts policy, see Configuring IPS User Accounts, page 34-16.

Field Reference

Table 34-4 Add or Edit User Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Name</td>
<td>The username for the account. The name can be 1 to 64 characters, including uppercase and lowercase letters and numbers, plus the special characters ( ) + : , _ / - . You cannot change the username when editing an account.</td>
</tr>
<tr>
<td>Password</td>
<td>The password for this user account. Enter the password in both fields. The password must conform to the Password Requirements policy for IPS devices; see Configuring User Password Requirements, page 34-18.</td>
</tr>
<tr>
<td>Confirm</td>
<td>The role for this user. For an explanation of these roles, see Understanding IPS User Roles, page 34-14. When editing a user account, you cannot select the Service role. When editing an account assigned to the Service role, you cannot change the role.</td>
</tr>
</tbody>
</table>

Configuring User Password Requirements

Use the IPS platform Password Requirements policy to configure the rules for passwords for local IPS device user accounts. All user-created sensor passwords must conform to the requirements defined in this policy. You can configure password requirements for sensor running IPS software version 6.0 or higher.

The requirements you define here determine what is considered an acceptable password in the User Accounts policy (see Configuring IPS User Accounts, page 34-16). If you change this policy, it can be applied even to unchanged user accounts. For more information about the implications of deploying changes to this policy, see Understanding How IPS Passwords are Discovered and Deployed, page 34-15.

To configure IPS password requirements, select one of the following policies:

- (Device view) Select Platform > Device Admin > Device Access > Password Requirements from the Policy selector.
- (Policy view) Select IPS > Platform > Device Admin > Password Requirements from the Policy Type selector, then select an existing policy or create a new one.
The following table explains the password requirement options that you can configure.

<table>
<thead>

**Configuring AAA Access Control for IPS Devices**

Use the AAA policy to configure AAA access control for your IPS devices. The device must use IPS Software release 7.0(4) or above or 7.1.3 or above to configure AAA; for example, neither 7.1.1 nor 7.1.2 supports AAA.

You can configure the IPS device to use a RADIUS AAA server to authenticate user access to the device. By configuring AAA, you can reduce the number of local users defined on the device and take advantage of your existing RADIUS setup. If you configure a AAA server, you can configure the device to allow local user accounts as a fallback mechanism if the RADIUS servers are unavailable.

When configuring AAA, you identify the RADIUS server using a AAA server policy object. You can create the object while configuring the policy, or you can create it in the Policy Object Manager. When you configure the AAA server object, you must adhere to the following restrictions:

- **Host**—You must specify the IP address; you cannot use a DNS name.
- **Timeout**—If you enter a timeout value, it must be from 1 to 512 seconds. The generic AAA server object allows higher numbers, but IPS has a more limited timeout range. The default is 3.
- **Protocol**—RADIUS is the only supported protocol.
• **Key**—You must specify the shared secret key that is defined on the RADIUS server. Although this field is optional for a generic AAA server object, IPS requires a key.

• **Port**—Ensure that the RADIUS Authentication/Authorization port is correct. Note that the default port in the AAA server object is different from the IPS default, which is 1812. You will need to change the port if you want to use the IPS default.

For more information about configuring AAA server objects, see *Creating AAA Server Objects, page 6-28.*

---

**Tip**

You must ensure that the user account configured in the device properties exists in the RADIUS server or as a local user account, depending on the authorization method that you use. If you switch between local and AAA modes, or change AAA servers, you must ensure that the account is defined in whatever user account database you are using. If you are using AAA with local fallback, the account should be defined in all databases. This account must exist, with the same password defined in the Security Manager device properties for the device, or deployment to the device will fail. The user account used for discovery and deployment must have administrator privileges.

**Related Topics**

- Managing User Accounts and Password Requirements, page 34-13
- Configuring IPS User Accounts, page 34-16

---

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > AAA** from the Policy selector.
- (Policy view) Select **IPS > Platform > Device Admin > AAA**, then select an existing policy or create a new one.

**Step 2**

Configure the following basic properties:

- **Authentication Mode**—Whether to use Local or AAA mode. Local mode uses user accounts defined on the IPS device only. With AAA mode, the RADIUS servers are the primary means of user authentication, and you can configure local user accounts as a fallback mechanism. The default is Local. You must select AAA to configure any other options in this policy.

- **Primary RADIUS Server, Secondary RADIUS Server**—The main (primary) AAA server and a backup server, if any. Enter the name of the AAA server policy object that identifies the RADIUS server, or click **Select** to select it from a list of objects or to create a new object.

  When authenticating users, the IPS device sends the user authentication attempt to the primary server. The secondary server is contacted only if the request to the primary server times out.

**Step 3**

Configure the following optional properties if you want non-default values:

- **Console Authentication**—How you want to authenticate users who access the IPS device through the console:
  - Local—Users connected through the console port are authenticated through local user accounts.
  - Local and RADIUS—Users connected through the console port are authenticated through RADIUS first. If RADIUS fails, local authentication is attempted.
  - RADIUS—Users connected through the console port are authenticated by RADIUS. If you also select Enable Local Fallback, then users can also be authenticated through the local user accounts.
• **RADIUS NAS ID**—The Network Access ID, which identifies the service requesting authentication. The value can be no NAS-ID, cisco-ips, or a NAS-ID already configured on the RADIUS server. The default is cisco-ips.

• **Enable Local Fallback**—Whether you want to fall back to local user account authentication if all RADIUS servers are unavailable. This option is selected by default. Note that local authentication is not attempted if the RADIUS server responds negatively to the logon attempt; local authentication is tried only if no response is received from the RADIUS server.

• **Default User Role**—The role to assign to users who do not have a role assigned in the RADIUS server. You can make Viewer, Operator, or Administrator the default roles, but not Service; select Unspecified to assign no default role (this is the default). For an explanation of user roles, see Understanding IPS User Roles, page 34-14.

  __Note__

User role configuration is very important. If you do not assign a role to the user, either through the default user role or in the RADIUS server, the sensor prevents user login even if the RADIUS server accepted the username and password.

To assign roles specifically to users on the RADIUS server, you configure the Accept Message for those accounts as either ips-role=administrator, ips-role=operator, ips-role=viewer, or ips-role=service. You configure the Accept Message individually for each user account. An example of a Reply attribute for a given user could be configured to return “Hello <user> your ips-role=operator.”

If you configure a service account in the RADIUS server, you must also configure an identical service account locally on the device. For service accounts, both the RADIUS and Local accounts are checked during login.

---

**Identifying an NTP Server**

Use the NTP policy to configure a Network Time Protocol (NTP) server as the time source for the IPS device. Using NTP helps ensure synchronized time among your network devices, which can aid event analysis. NTP is the recommended way to configure time settings on an IPS device.

For detailed information on how to set the time on a sensor, including how to set up a Cisco IOS router as an NTP server, refer to Configuring Time in Configuring the Cisco Intrusion Prevention System Sensor Using the Command Line Interface Version 7.0.

**Tip**

Check the time on your IPS sensor if you are having trouble updating your IPS software. If the time on the sensor is ahead of the time on the associated certificate, the certificate is rejected, and the sensor software update fails.

**Step 1**

Do one of the following to open the NTP policy:

• (Device view) Select **Platform > Device Admin > Server Access > NTP** from the Policy selector.

• (Policy view) Select **IPS > Platform > Device Admin > Server Access > NTP**, then select an existing policy or create a new one.
Step 2  In the NTP Server IP Address field, enter the IP address of the NTP server. You can also enter the name of a network/host object that identifies the single host address of the server, or click Select to select the object from a list or to create a new one.

Step 3  If the NTP server does not require authentication, deselect the Authenticated NTP checkbox.

If the NTP server requires authentication, configure the following options:

- **Authenticated NTP**—Select this option to enable authenticated connections.
- **Key, Confirm**—The key value of the NTP server. The key is an MD5 type of key (either numeric or character); it is the key that was used to set up the NTP server.
- **Key ID**—The key ID value of the NTP server, a numeric value between 1 and 65535.

**Tip**  The key and key ID are configured on the NTP server; you must obtain them from the NTP server configuration.

---

**Identifying DNS Servers**

If you configure global correlation on an IPS 7.0+ sensor, the sensor must be able to resolve domain names to successfully connect to the update server when downloading global correlation updates. Use the DNS policy to identify the Domain Name System (DNS) servers that the sensor can use to resolve domain names to IP addresses.

**Tip**  If your network requires HTTP proxies when making Internet connections, configure the HTTP Proxy policy instead of the DNS policy. See Identifying an HTTP Proxy Server, page 34-23.

**Note**  The AIP-SSC-5 service module does not support DNS servers.

Step 1  Do one of the following to open the HTTP Proxy policy:

- (Device view) Select Platform > Device Admin > Server Access > DNS from the Policy selector.
- (Policy view) Select IPS > Platform > Device Admin > Server Access > DNS, then select an existing policy or create a new one.

Step 2  Specify the IP addresses of up to three DNS servers in the Primary, Secondary, and Tertiary Address fields. The sensor uses the servers in the order listed; if one server does not respond, the next server is contacted.

You can enter an IP address or the name of a network/host object that contains a server address. Click Select to select a network/host object from a list or to create a new one. The network/host object must specify a single host address.
Identifying an HTTP Proxy Server

If you configure global correlation on an IPS 7.0+ sensor, and your network requires the use of HTTP proxies to connect to the Internet, you need to configure the HTTP Proxy policy to identify a proxy that the IPS sensor can use. When downloading global correlation updates, the IPS sensor connects to the update server using this proxy. The proxy must be able to resolve DNS names.

**Tip**
If you do not use HTTP proxies, configure DNS servers so that the IPS sensor can resolve the address of the update server. See Identifying DNS Servers, page 34-22.

**Note**
The AIP-SSC-5 service module does not support HTTP proxy servers.

**Step 1**
Do one of the following to open the HTTP Proxy policy:
- (Device view) Select **Platform > Device Admin > Server Access > HTTP Proxy** from the Policy selector.
- (Policy view) Select **IPS > Platform > Device Admin > Server Access > HTTP Proxy**, then select an existing policy or create a new one.

**Step 2**
Configure the following options:
- **Enable Proxy**—Select this option to tell the device to connect through the configured proxy server.
- **IP Address**—Enter the IP address of the proxy server, or the name of the network/host object that contains the server’s IP address. Click **Select** to select a network/host object from a list or to create a new one. The network/host object must contain a single host IP address.
- **Port**—Enter the port number used for HTTP connections to the proxy server. The default is 80.

Configuring the External Product Interface

Use the External Product Interface policy to configure the way that Security Manager works with Management Center for Cisco Security Agents (CSA MC).

In general, the external product interface is designed to receive and process information from external security and management products. These external security and management products collect information that can be used to automatically enhance the sensor configuration information. Management Center for Cisco Security Agents is the only external product that can be configured to communicate with the IPS. At most two Management Center for Cisco Security Agents servers can be configured per IPS device.

**Tip**
Management Center for Cisco Security Agents is no longer an active product. Configure this policy only if you are still using that application. For more information, see About CSA MC in Installing and Using Cisco Intrusion Prevention System Device Manager 6.0 and http://www.cisco.com/en/US/products/sw/cscowork/ps5212/index.html.
Management Center for Cisco Security Agents enforces a security policy on network hosts. It has two components:

- Agents that reside on and protect network hosts.
- A management console, which is an application that manages agents. It downloads security policy updates to agents and uploads operational information from agents.

**Before You Begin**

Add the external product as an allowed host so that Security Manager allows the sensor to communicate with the external product. For more information, see Identifying Allowed Hosts, page 34-7.

**Step 1**

Do one of the following to open the External Product Interface policy:

- (Device view) Select **Platform > Device Admin > Server Access > External Product Interface** from the Policy selector.
- (Policy view) Select **IPS > Platform > Device Admin > Server Access > External Product Interface**, then select an existing policy or create a new one.

The **Management Center for Cisco Security Agents** tab shows any existing definitions, including the IP address (or network/host object), URL, and port of the external application, the username and password used to log into it, and whether the connection is enabled. The interface type is always Extended SDEE.

**Step 2**

Do one of the following:

- To add a server, click the **Add Row (+)** button. This opens the External Product Interface dialog box. Enter the information required to identify the server and configure the posture ACLs. For detailed information on the settings, see **External Product Interface Dialog Box, page 34-24**.
  
  You can add at most two servers.

- To edit a server, select it and click the **Edit Row (pencil)** button and make the required changes in the External Product Interface dialog box.

- To delete a server, select it and click the **Delete Row (trash can)** button.

**External Product Interface Dialog Box**

Use the Add or Edit External Product Interface dialog box to add or modify interfaces between Management Center for Cisco Security Agents (CSA MC) and the IPS device and the related posture ACLs.

**Navigation Path**

From the External Product Interface IPS platform policy, click **Add Row** or select an entry and click **Edit Row**. For information on opening the External Product Interface policy, see Configuring the External Product Interface, page 34-23.
### Field Reference

</tr>
<tr>
<td>Allow unreachable hosts' postures</td>
<td>Whether to allow the receipt of host posture information for hosts that are not reachable by the CSA MC.</td>
</tr>
<tr>
<td></td>
<td>A host is not reachable if the CSA MC cannot establish a connection with the host on any IP addresses in the host’s posture. This option is useful in filtering the postures whose IP addresses may not be visible to the IPS sensor or that might be duplicated across the network. This filter is most applicable in network topologies where hosts that are not reachable by the CSA MC are also not reachable by the IPS, for example if the IPS and CSA MC are on the same network segment.</td>
</tr>
</tbody>
</table>
Posture ACL Dialog Box

Use the Add or Modify Posture ACL dialog box to configure posture ACLs for Management Center for Security Agents. Posture ACLs are network addresses for which host postures are allowed or denied. Use posture ACLs to filter postures that have IP addresses that might not be visible to the IPS or that might be duplicated across the network.

Configure the following fields to define a posture ACL:

- **Network Address**—Enter the IP address of a host or network, or the name of a network/host object that specifies one. You can click Select to select the object from a list or to create a new object.
- **Action**—Whether host postures will be permitted or denied from the hosts on the network address.

**Navigation Path**

From the External Product Interface dialog box (see External Product Interface Dialog Box, page 34-24), click the Add Row (+) button underneath the Posture ACL table, or select a posture ACL and click the Edit Row (pencil) button.
Configuring IPS Logging Policies

Use the IPS platform Logging policy to configure traffic flow notifications and Analysis Engine global variables. These settings apply to the general operation of the IPS sensor.

Traffic flow notifications have to do with the flow of traffic across the interface of a sensor. You can configure the sensor to monitor the flow of packets across an interface and send notification if that flow changes (starts and stops) during a specified interval. You can configure the missed packet threshold within a specific notification interval and also configure the interface idle delay before a status event is reported.

The Analysis Engine performs packet analysis and alert detection. It monitors traffic that flows through specified interfaces. For the Analysis Engine, there is only one global variable: Maximum Open IP Log Files.

Navigation Path
- (Device view) Select Platform > Logging from the Policy selector.
- (Policy view) Select IPS > Platform > Logging, then select an existing policy or create a new one.

Field Reference

Table 34-7 IPS Logging Page

<table>

Configuring IPS Security Settings

Use the IPS Security Settings policy to configure two items that are important to the security of your IPS devices:

- **Permit packet capture logging**—With this feature, IPS devices can prevent users from arbitrarily executing packet capture/display/iplog commands. In previous versions of Security Manager, such actions leave no trace of who executed the command.

- **Configurable idle timeout**—When configured, this feature terminates the connection to an IPS device after a period of time that you specify. Its purpose is to increase the security of a CLI session.
Note

These settings are available for devices operating with IPS 7.1.3 and later.

To configure IPS security settings, select one of the following policies:

- (Device view) Select **Platform > Security > Settings** from the Policy selector.
- (Policy view) Select **IPS > Platform > Security > Settings** from the Policy Type selector, then select an existing policy or create a new one.

The following table explains the IPS security settings that you can configure.

<table>
<thead>
<tr>
<th>Table 34-8</th>
<th>IPS Security Settings Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element</strong></td>
<td><strong>Description</strong></td>

</tbody>
</table>
Managing IPS Device Interfaces

Dedicated IPS appliances and service modules have their own interface configuration, whereas Cisco IOS IPS devices are configured using the regular router interface policies. This chapter explains how to configure interfaces for dedicated IPS appliances and service modules only.

This chapter contains the following topics:

- Understanding Interfaces, page 35-1
- Understanding Interface Modes, page 35-2
- Configuring Interfaces, page 35-6

Understanding Interfaces

Tip

This topic is an overview of IPS interfaces. For more detailed information, including the specific interface names and locations for each type of appliance and service module, supported roles, configuration restrictions, and hardware considerations, refer to the “Configuring Interfaces” chapter of the *Installing and Using Cisco Intrusion Prevention System Device Manager* for the IPS software version you are using on Cisco.com. The information is also in the IME and CLI guides. For general information, see http://www.cisco.com/go/ips.

The sensor interfaces are named according to the maximum speed and physical location of the interface. For example, GigabitEthernet2/1 supports a maximum speed of 1 Gigabit and is the second-from-the-right interface in the second-from-the-bottom expansion slot.

There are three interface roles:

- **Command and control**—The command and control interface has an IP address and is used for configuring the sensor. It receives security and status events from the sensor and queries the sensor for statistics.

  The command and control interface is permanently enabled. It is permanently mapped to a specific physical interface, which depends on the specific model of sensor. You cannot use the command and control interface as either a sensing or alternate TCP reset interface. See the IPS document cited above for a list of command and control interfaces by device type.

- **Sensing**—Sensing interfaces are used by the sensor to analyze traffic for security violations. A sensor has one or more sensing interfaces depending on the sensor. Sensing interfaces can operate individually in promiscuous mode or you can pair them to create inline interfaces. In promiscuous
mode, packets do not flow through the sensor; the sensor analyzes a copy of the monitored traffic. In inline mode, the IPS is in the traffic flow and can directly affect the traffic. For more information about sensing modes, see Understanding Interface Modes, page 35-2.

**Note**
On appliances, all sensing interfaces are disabled by default. You must enable them to use them. On modules, the sensing interfaces are permanently enabled. See the IPS document cited above for a list of sensing interfaces by device type.

- **Alternate TCP reset**—You can configure sensors to send TCP reset packets to try to reset a network connection between an attacker host and its intended target host. In some installations when the interface is operating in promiscuous mode, the sensor may not be able to send the TCP reset packets over the same sensing interface on which the attack was detected. In such cases, you can associate the sensing interface with an alternate TCP reset interface and any TCP resets that would otherwise be sent on the sensing interface when it is operating in promiscuous mode are instead sent out on the associated alternate TCP reset interface.

If a sensing interface is associated with an alternate TCP reset interface, that association applies when the sensor is configured for promiscuous mode but is ignored when the sensing interface is configured for inline mode (interface or VLAN pair), because TCP resets are always sent on the sensing interfaces in those modes.

**Note**
With the exception of IDSM-2, any sensing interface can serve as the alternate TCP reset interface for another sensing interface. The alternate TCP reset interface on IDSM-2 is fixed because of hardware limitation. However, there is only one sensing interface on IPS modules (on routers or ASA devices), so you cannot specify an alternate TCP reset interface on them. See the IPS document cited above for a list of eligible alternate TCP reset interfaces by device type, and for more information about the conditions under which you would use one.

---

**Understanding Interface Modes**

Sensing interfaces can operate in various modes. The mode configured for an interface determines the traffic it can inspect and how it can respond to events.

This section contains the following topics:

- **Promiscuous Mode**, page 35-2
- **Inline Interface Mode**, page 35-3
- **Inline VLAN Pair Mode**, page 35-3
- **VLAN Group Mode**, page 35-4

**Promiscuous Mode**

In promiscuous mode, packets do not flow through the sensor. The sensor analyzes a copy of the monitored traffic rather than the actual forwarded packet. The advantage of operating in promiscuous mode is that the sensor does not affect the packet flow with the forwarded traffic. The disadvantage of operating in promiscuous mode, however, is the sensor cannot stop malicious traffic from reaching its intended target for certain types of attacks, such as atomic attacks (single-packet attacks). The response actions implemented by promiscuous sensor devices are post-event responses and often require
assistance from other networking devices, for example, routers and firewalls, to respond to an attack. While such response actions can prevent some classes of attacks, in atomic attacks the single packet has the chance of reaching the target system before the promiscuous-based sensor can apply an ACL modification on a managed device (such as a firewall, switch, or router).

By default, all sensing interfaces are in promiscuous mode. To change an interface from inline interface mode to promiscuous mode, delete any inline interface that contains that interface and delete any inline VLAN pair subinterfaces of that interface from the interface configuration.

Related Topics
- Understanding Interfaces, page 35-1
- Configuring Physical Interfaces, page 35-9

Inline Interface Mode

Operating in inline interface pair mode puts the IPS directly into the traffic flow and affects packet-forwarding rates making them slower by adding latency. This allows the sensor to stop attacks by dropping malicious traffic before it reaches the intended target, thus providing a protective service. Not only is the inline device processing information on Layers 3 and 4, but it is also analyzing the contents and payload of the packets for more sophisticated embedded attacks (Layers 3 to 7). This deeper analysis lets the system identify and stop or block attacks that would normally pass through a traditional firewall device.

In inline interface pair mode, a packet comes in through the first interface of the pair on the sensor and out the second interface of the pair. The packet is sent to the second interface of the pair unless that packet is being denied or modified by a signature.

Notes:
- If the paired interfaces are connected to the same switch, you should configure them on the switch as access ports with different access VLANs for the two ports. Otherwise, traffic does not flow through the inline interface.
- You can configure IPS modules for routers and ASA devices to operate inline even though these modules have only one sensing interface.

Related Topics
- Understanding Interfaces, page 35-1
- Configuring Inline Interface Pairs, page 35-13

Inline VLAN Pair Mode

You can associate VLANs in pairs on a physical interface. This is known as inline VLAN pair mode. Packets received on one of the paired VLANs are analyzed and then forwarded to the other VLAN in the pair.

Inline VLAN pair mode is an active sensing mode where a sensing interface acts as an 802.1q trunk port, and the sensor performs VLAN bridging between pairs of VLANs on the trunk. The sensor inspects the traffic it receives on each VLAN in each pair, and can either forward the packets on the other VLAN in the pair, or drop the packet if an intrusion attempt is detected. You can configure an IPS sensor to simultaneously bridge up to 255 VLAN pairs on each sensing interface. The sensor replaces the VLAN
ID field in the 802.1q header of each received packet with the ID of the egress VLAN on which the sensor forwards the packet. The sensor drops all packets received on any VLANs that are not assigned to inline VLAN pairs.

Notes:
- You cannot use the default VLAN as one of the paired VLANs in an inline VLAN pair.
- Inline VLAN pairs are not supported on IPS modules for routers or ASA devices.

Related Topics
- Understanding Interfaces, page 35-1
- Configuring Inline VLAN Pairs, page 35-14

### VLAN Group Mode

You can divide each physical interface or inline interface into VLAN group subinterfaces, each of which consists of a group of VLANs on that interface. If you configure multiple virtual sensors, each of them can monitor one or more of these interfaces. This lets you apply multiple policies to the same sensor. The advantage is that now you can use a sensor with only a few interfaces as if it had many interfaces.

Note
You cannot divide physical interfaces that are in inline VLAN pairs into VLAN groups.

VLAN group subinterfaces associate a set of VLANs with a physical or inline interface. No VLAN can be a member of more than one VLAN group subinterface. Each VLAN group subinterface is identified by a number between 1 and 255. Subinterface 0 is a reserved subinterface number used to represent the entire unvirtualized physical or logical interface. You cannot create, delete, or modify subinterface 0 and no statistics are reported for it.

When you create a VLAN group, it is either promiscuous or inline:

- Promiscuous VLAN group—If you configure a VLAN group on a physical interface, the VLAN group is promiscuous, as described in Promiscuous Mode, page 35-2.
- Inline VLAN group—If you configure a VLAN group on an inline interface pair (a logical interface), the VLAN group is inline, as described in Inline Interface Mode, page 35-3.

Thus, VLAN groups augment the operation of promiscuous mode interfaces or inline interfaces by confining their operation to selected VLANs. Once you assign a VLAN group to an interface (physical or inline interface), the interface is no longer a plain promiscuous or inline interface pair and can only be used for inline VLAN groups.

An unassigned VLAN group is maintained that contains all VLANs that are not specifically assigned to another VLAN group. You cannot directly specify the VLANs that are in the unassigned group. When a VLAN is added to or deleted from another VLAN group subinterface, the unassigned group is updated.

Packets in the native VLAN of an 802.1q trunk do not normally have 802.1q encapsulation headers to identify the VLAN number to which the packets belong. A default VLAN variable is associated with each physical interface and you should set this variable to the VLAN number of the native VLAN or to 0. The value 0 indicates that the native VLAN is either unknown or you do not care if it is specified. If the default VLAN setting is 0, the following occurs:

- Any alerts triggered by packets without 802.1q encapsulation have a VLAN value of 0 reported in the alert.
Non-802.1q encapsulated traffic is associated with the unassigned VLAN group and it is not possible to assign the native VLAN to any other VLAN group.

**Note**

You can configure a port on a switch as either an access port or a trunk port. On an access port, all traffic is in a single VLAN called the access VLAN. On a trunk port, multiple VLANs can be carried over the port, and each packet has a special header called the 802.1q header that contains the VLAN ID. This header is commonly referred to as the VLAN tag. However, a trunk port has a special VLAN called the native VLAN. Packets in the native VLAN do not have the 802.1q headers attached. IDSM-2 can read the 802.1q headers for all nonnative traffic to determine the VLAN ID for that packet. However, IDSM-2 does not know which VLAN is configured as the native VLAN for the port in the switch configuration, so it does not know what VLAN the native packets are in. Therefore, you must tell IDSM-2 which VLAN is the native VLAN for that port. Then IDSM-2 treats any untagged packets as if they were tagged with the native VLAN ID.

**Related Topics**

- Deploying VLAN Groups, page 35-5
- Understanding Interfaces, page 35-1
- Configuring VLAN Groups, page 35-15

**Deploying VLAN Groups**

Because a VLAN group of an inline pair does not translate the VLAN ID, an inline paired interface must exist between two switches to use VLAN groups on a logical interface. For an appliance, you can connect the two pairs to the same switch, make them access ports, and then set the access VLANs for the two ports differently. In this configuration, the sensor connects between two VLANs, because each of the two ports is in access mode and carries only one VLAN. In this case the two ports must be in different VLANs, and the sensor bridges the two VLANs, monitoring any traffic that flows between the two VLANs. IDSM-2 also operates in this manner, because its two data ports are always connected to the same switch.

You can also connect appliances between two switches. There are two variations. In the first variation, the two ports are configured as access ports, so they carry a single VLAN. In this way, the sensor bridges a single VLAN between the two switches.

In the second variation, the two ports are configured as trunk ports, so they can carry multiple VLANs. In this configuration, the sensor bridges multiple VLANs between the two switches. Because multiple VLANs are carried over the inline interface pair, the VLANs can be divided into groups and each group can be assigned to a virtual sensor. The second variation does not apply to IDSM-2 because it cannot be connected in this way.

Configuring Interfaces

Use the Interfaces policy for IPS appliances and service modules to configure the interface settings for the device. The following topics explain how to configure the various types of settings. These topics do not apply to Cisco IOS IPS devices, which use the standard router interface policies.

- Understanding the IPS Interfaces Policy, page 35-6
- Configuring Physical Interfaces, page 35-9
- Configuring Bypass Mode, page 35-12
- Configuring CDP Mode, page 35-12
- Configuring Inline Interface Pairs, page 35-13
- Configuring Inline VLAN Pairs, page 35-14
- Configuring VLAN Groups, page 35-15
- Viewing a Summary of IPS Interface Configuration, page 35-8

Understanding the IPS Interfaces Policy

Use the Interfaces policy to configure the physical interfaces, inline pairs, VLAN pairs, and VLAN groups on IPS appliances and service modules. This policy does not apply to Cisco IOS IPS devices.

You can configure any single physical interface to run in promiscuous mode, inline pair mode, inline VLAN pair mode, promiscuous VLAN group, or inline VLAN group, but you cannot configure an interface in a combination of these modes.

Tip

The contents of this policy differ depending on the device type and IPS software version. For example, some devices display the physical interfaces tab only; creating the other types of configurations is not supported. If a tab or option described below does not appear on the policy you are configuring, it does not apply to the device.

Navigation Path

(Device view only) Select IPS > Interfaces from the Policy selector.

Configuring Interfaces

Chapter 35      Managing IPS Device Interfaces

Viewing a Summary of IPS Interface Configuration

The Summary tab of the Interfaces policy contains a table summarizing how you have configured the sensing interfaces— the interfaces you have configured for promiscuous mode, the interfaces you have configured as inline pairs, and the interfaces you have configured as inline VLAN pairs. The content of this table changes when you change your interface configuration.

You can configure any single physical interface to run in promiscuous mode, inline pair mode, or inline VLAN pair mode, but you cannot configure an interface in a combination of these modes.

### Table 35-1  IPS Interfaces Policy (Continued)

<td>The VLAN ID for the first and second VLANs for VLAN pairs. VLAN numbers can be from 1 to 4095.</td>
</tr>
<tr>
<td>VLAN B</td>
<td>The range of VLAN IDs belonging to the VLAN group, for example, 100-200. If the VLAN group is configured to apply to all unassigned VLANs, the field is empty.</td>
</tr>
</tbody>
</table>

Configuring Physical Interfaces

The Physical Interfaces tab of the IPS Interfaces policy lists the existing physical interfaces on your sensor and their associated settings. You cannot add or delete physical interfaces in this policy; instead, you must use policy discovery to obtain the current list of interfaces from the device. Thus, if you add or remove interface cards (available for some appliances), you must rediscover the device as described in Discovering Policies on Devices Already in Security Manager, page 5-15.
To configure the sensor to monitor traffic, you must enable the interface using this procedure. When you initialized the sensor using the `setup` command (using the command line interface on the IPS), you assigned the interface or the inline pair to a virtual sensor, and enabled the interface or inline pair. If you need to change your interfaces settings, you can do so on the Physical Interfaces tab. To assign an interface to a virtual sensor, select the Virtual Sensors policy and add or edit the virtual sensor, as appropriate.

**Tip**

Each physical interface can be divided into VLAN group subinterfaces, each of which consists of a group of VLANs on that interface. For more information, see Configuring VLAN Groups, page 35-15.

**Related Topics**

- Understanding Interfaces, page 35-1

- Configuring CDP Mode, page 35-12
- Configuring Inline Interface Pairs, page 35-13

**Step 1** (Device view) Select Interfaces from the Policy selector, then click the Physical Interfaces tab (if necessary).

**Step 2** Select the interface whose configuration you want to change and click the Edit Row button. The Modify Physical Interface Map dialog box appears.

**Step 3** Make the desired configuration changes and click **OK**. Following are the settings you are most likely to want to change; for a description of all options, see Modify Physical Interface Map Dialog Box, page 35-10.

- **Enabled**—Whether the interface is enabled (Yes or No). Select Yes to make the interface functional. The value of this option is shown in the Administrative State column in the Physical Interfaces tab.
- **Default VLAN**—The VLAN to which the interface is assigned.
- **Specify Interface for TCP Reset**—If you want to assign an alternate TCP reset interface, as described in Understanding Interfaces, page 35-1, select this option, then select the alternate interface from the `interface-name` list.

**Modify Physical Interface Map Dialog Box**

Use the Modify Physical Interface Map dialog box to change the configuration of the physical interfaces of an IPS sensor. For the procedure, see Configuring Physical Interfaces, page 35-9.

**Navigation Path**

(Device view) Select Interfaces from the Policy selector. On the Physical Interfaces tab, select an interface and click the **Edit Row** button.

</tbody>
</table>
Configuring Bypass Mode

You can use inline bypass as a diagnostic tool and a failover protection mechanism. Normally, the sensor Analysis Engine performs packet analysis. When inline bypass is activated, Analysis Engine is bypassed, allowing traffic to flow through the inline interfaces and inline VLAN pairs without inspection. Inline bypass ensures that packets continue to flow through the sensor when the sensor processes are temporarily stopped for upgrades or when the sensor monitoring processes fail. There are three modes: on, off, and automatic. By default, bypass mode is set to automatic.

Keep the following factors in mind before deciding which bypass mode to use:

- There are security consequences when you put the sensor in bypass mode. When bypass mode is on, the traffic bypasses the sensor and is not inspected; therefore, the sensor cannot prevent malicious attacks.
- The inline bypass functionality is implemented in software, so it functions only when the operating system is running. If the sensor is powered off or shut down, inline bypass does not work—traffic does not flow through the sensor.
- When the sensor applies a signature or global correlation update, it might trigger bypass. Whether bypass is triggered depends on the traffic load of the sensor and the size of the signature or global correlation update. If bypass mode is turned off, an inline sensor stops passing traffic while the update is being applied.

To change the bypass mode setting, follow these steps:

Step 1 (Device view) Select the Interfaces policy from the Policy selector.
Step 2 In the Bypass Mode field at the bottom of the policy, select the desired option:

- Off (Always inspect inline traffic)—Disables bypass mode. Traffic flows through the sensor for inspection. If the monitoring process of the sensor is down, traffic stops flowing. This means that inline traffic is always inspected.
- On (Never inspect inline traffic)—Traffic bypasses the Analysis Engine and is not inspected. This means that inline traffic is never inspected.
- Auto (Bypass inspection when analysis engine is stopped)—Traffic flows through the sensor for inspection unless the monitoring process of the sensor is down. This is the default. If the monitoring process of the sensor is down, traffic bypasses the sensor until the sensor is running again. The sensor then inspects the traffic. Auto mode is useful during sensor upgrades to ensure that traffic is still flowing while the sensor is being upgraded. Auto mode also helps to ensure traffic continues to pass through the sensor if the monitoring process fails.

Configuring CDP Mode

You can configure the IPS sensor to enable or disable the forwarding of Cisco Discovery Protocol (CDP) packets. The CDP configuration applies globally to all interfaces on the device, however, it has an effect only on inline interfaces (both inline interfaces and inline VLAN pairs).
Cisco Discovery Protocol is a media- and protocol-independent device-discovery protocol that runs on all Cisco-manufactured equipment, including routers, access servers, bridges, and switches. Using CDP, a device can advertise its existence to other devices and receive information about other devices on the same LAN or on the remote side of a WAN. CDP runs on all media that support SNAP, including LANs, Frame Relay, and ATM media.

**Tip**
The CDP Mode setting is not available on all IPS appliances and service modules. If the CDP Mode field does not appear on the Interfaces policy, the setting does not apply to the device you are configuring.

To change the CDP mode setting on a device, follow these steps:

**Step 1** (Device view) Select the **Interfaces** policy from the Policy selector.

**Step 2** In the **CDP Mode** field at the bottom of the policy, select the desired option:
- **Forward CDP packets**—To allow CDP packets to pass through the sensor.
- **Drop CDP packets**—To have the sensor drop all CDP packets and not allow them to pass through the sensor. This is the default setting.

### Configuring Inline Interface Pairs

You can pair interfaces on your sensor if your sensor is capable of inline monitoring. For more information about inline pairs, see Inline Interface Mode, page 35-3.

**Tip**
IPS modules for routers and ASA devices do not need an inline pair for monitoring. You only need to add the physical interface to a virtual sensor.

### Related Topics
- Understanding Interfaces, page 35-1
- Configuring Bypass Mode, page 35-12
- Configuring CDP Mode, page 35-12
- Configuring Physical Interfaces, page 35-9
- Configuring VLAN Groups, page 35-15
- Defining A Virtual Sensor, page 36-5
- Editing Policies for a Virtual Sensor, page 36-9
- Assigning Interfaces to Virtual Sensors, page 36-4

**Step 1** (Device view) Select **Interfaces** from the Policy selector, then click the **Inline Pairs** tab.

**Step 2** Do one of the following:
- To add a pair, click the **Add Row** button. The Add Interface Pair dialog box opens.
- To edit a pair, select it and click the **Edit Row** button. The Edit Interface Pair dialog box opens.
Chapter 35 Managing IPS Device Interfaces

Configuring Interfaces

Tip
You can also delete a pair by selecting it and clicking the Delete Row button. You cannot delete an inline pair if there is an inline VLAN group. First delete the inline VLAN group from the VLAN Groups tab, and then delete the inline pair.

Step 3
In the Add or Edit Inline Pairs dialog box, configure the following options:

- **Inline Interface Name**—The name you want to give to this inline pair. The name cannot be longer than 32 characters; alphanumeric and underscore characters are allowed. You cannot edit this name after you create the pair.
- **Interface 1 and 2**—Select the two physical interfaces that you want to form a pair. The lists include only those interfaces that are defined on the Physical Interfaces tab and that are not already part of an inline pair, VLAN pair, or VLAN group.
- **Description**—An optional description for the pair.

Step 4
Click OK to save your changes.

Configuring Inline VLAN Pairs

Use the VLAN Pairs tab of the IPS Interfaces policy to configure the VLAN pairs for physical interfaces. The summary table displays the existing VLAN pairs for each physical interface. You can create multiple VLAN pairs on a single physical interface. For more information about inline VLAN pair mode, see Inline VLAN Pair Mode, page 35-3.

Tips

- You cannot create a VLAN pair for an interface if it is already part of an inline interface pair; create VLAN groups for inline interface pairs.
- To create an inline VLAN pair for an interface that is in promiscuous mode and assigned to a virtual sensor, you must first remove the interface from the virtual sensor (using the Virtual Sensors policy) and then create the inline VLAN pair.
- You cannot use the default VLAN as one of the paired VLANs in an inline VLAN pair.
- If your sensor does not support inline VLAN pairs, the VLAN Pairs pane is not displayed. IPS modules on routers and ASA devices do not support inline VLAN pairs.
- When using inline VLAN pairs, you should configure UniDirectional Link Detection (UDLD) on the connected switch that is hosting the VLANs. UDLD can help switches prevent spanning-tree forwarding loops and single direction links. For detailed information, see Configuring UDLD in Installing and Using Intrusion Prevention System Device Manager.

Related Topics

- Understanding Interfaces, page 35-1
- Configuring Bypass Mode, page 35-12
- Configuring CDP Mode, page 35-12
- Configuring Physical Interfaces, page 35-9
- Configuring VLAN Groups, page 35-15
Configuring Interfaces

Step 1  
(Device view) Select Interfaces from the Policy selector, then click the VLAN Pairs tab.

Step 2  
Do one of the following:

- To add a pair, click the Add Row button. The Add VLAN Pair dialog box opens.
- To edit a pair, select it and click the Edit Row button. The Edit VLAN Pair dialog box opens.

Tip  
You can also delete a pair by selecting it and clicking the Delete Row button. You cannot delete an inline VLAN pair if it is assigned to a virtual sensor. First remove the assignment to the virtual sensor using the Virtual Sensors policy, and then delete the inline VLAN pair.

Step 3  
In the Add or Edit VLAN Pairs dialog box, configure the following options:

- Physical Interfaces—Select the physical interface on which you are creating this VLAN pair. The list includes only those interfaces that are defined on the Physical Interfaces tab and that are not already part of an inline interface pair or VLAN group. However, you can create multiple VLAN pairs on a single interface.
- Subinterface Number—Enter a number to assign as a subinterface. The number must be unique on the interface, that is, it cannot already be assigned to another VLAN pair on the selected physical interface. Subinterface numbers can be from 1 to 255.
- Description—An optional description for the pair.
- VLAN A, B—The numbers of the two VLANs that you want to join as a pair. VLAN numbers are from 1 to 4095. You must enter different numbers, and the numbers must not already be part of another VLAN pair on the selected physical interface.

Step 4  
Click OK to save your changes.

Configuring VLAN Groups

Use the VLAN Groups tab of the IPS Interfaces policy to configure the VLAN groups for physical interfaces and inline interface pairs (logical interfaces). The summary table displays the existing VLAN groups. You can create multiple VLAN groups on a single physical interface or inline interface pair. For more information about VLAN group mode, see VLAN Group Mode, page 35-4.

A VLAN group consists of a group of VLAN IDs that exist on an interface. Each VLAN group consists of at least one VLAN ID. You can have up to 255 VLAN groups per interface (logical or physical). Each group can contain any number of VLAN IDs.

After you assign the VLAN IDs to the VLAN group, you must assign the VLAN group to a virtual sensor for it to be operational. You can assign a single group to at most one virtual sensor. Use the Virtual Sensors policy to make the assignment.

Note  
VLAN groups are supported in IPS 6.0 and later only. Not all IPS appliances or service modules support VLAN groups. If the VLAN Groups tab does not appear in the Interfaces policy, the device you are configuring does not support the feature.

Related Topics

- Understanding Interfaces, page 35-1
Step 1  (Device view) Select Interfaces from the Policy selector, then click the VLAN Groups tab.

The table shows the existing VLAN groups, including the interface for which the group is defined, the subinterface number, description (if any), and the VLANs assigned to the group. If the VLANs cell is empty, the group is defined for all unassigned VLANs on the interface.

Step 2  Do one of the following:

- To add a pair, click the Add Row button. The Add VLAN Group dialog box opens.
- To edit a pair, select it and click the Edit Row button. The Edit VLAN Group dialog box opens.

Tip  You can also delete a group by selecting it and clicking the Delete Row button. You cannot delete a VLAN group if it is assigned to a virtual sensor. First remove the assignment to the virtual sensor using the Virtual Sensors policy, and then delete the VLAN group.

Step 3  In the Add or Edit VLAN Group dialog box, configure the following options:

- **Physical and Logical Interfaces**—Select the physical interface or inline interface pair for which you are creating this VLAN group. The list includes only unpaired physical interfaces (defined on the Physical Interfaces tab) that do not already have inline VLAN pairs defined, or inline interface pairs that are defined on the Inline Pairs tab. You can create multiple VLAN groups on a single interface. Keep the following in mind:
  - If you select a physical interface, you are creating a promiscuous VLAN group.
  - If you select a logical interface, you are creating an inline VLAN group.

- **Subinterface Number**—Enter a number to assign as a subinterface. The number must be unique on the interface, that is, it cannot already be assigned to another VLAN group on the selected interface. Subinterface numbers can be from 1 to 255.

- **Description**—An optional description for the group.

- **VLAN assignment**—Select one of the following options:
  - **All Unassigned VLAN IDs**—The group contains all VLANs that are not assigned to other VLAN groups. This is the default option
  - **Range of free VLAN IDs**—The group contains specific VLANs. In the Range box, enter any combination of single VLAN IDs or ranges (separate starting and ending ID with a hyphen), and separate multiple entries with commas. For example, 10, 12-25, 33-49. VLAN numbers are from 1 to 4095.

The VLAN ID cannot already be in another VLAN group for the selected interface. The VLANs also must be configured on the connected switch or there will be no traffic to inspect.

Step 4  Click OK to save your changes.
Configuring Virtual Sensors

All IPS devices and service modules have a base virtual sensor named vs0. When you configure the IPS appliance or service module, you must configure the base vs0 sensor to assign interfaces to it. This assignment tells the device which interfaces to inspect. There are also other settings that are configured on virtual sensors.

In addition to the base vs0 virtual sensor, many IPS appliances and service modules allow you to create user-defined virtual sensors. You can use these virtual sensors to create separate policies for traffic, so that a single physical sensor can act as if it were multiple sensors. A virtual sensor is a logical grouping of sensing interfaces and the configuration policy for the signature engines and event action filters to apply.

This chapter contains the following topics:

- Understanding the Virtual Sensor, page 36-1
- Defining A Virtual Sensor, page 36-5

Understanding the Virtual Sensor

The sensor can receive data inputs from one or many monitored data streams. These monitored data streams can either be physical interface ports or virtual interface ports. For example, a single sensor can monitor traffic from in front of the firewall, from behind the firewall, or from in front of and behind the firewall concurrently. A single sensor can monitor one or more data streams. In this situation a single sensor policy or configuration is applied to all monitored data streams.

With virtual sensors, you can create separate policies to apply to specific traffic feeds. For example, if you want to create a policy for a data center and a second much different policy for the campus network, yet run both policies on the same hardware device, you can configure separate virtual sensors to implement these policies.

You configure the following policies and settings separately for a virtual sensor:

- Signature and signature settings (policies in the IPS > Signatures folder).
- Event action policies (policies in the IPS > Event Actions folder).
- Anomaly detection policies (the IPS > Anomaly Detection policy) and the anomaly detection mode (in the Virtual Sensors policy).
- The promiscuous interfaces, inline interface pairs, inline VLAN pairs, inline VLAN groups, or promiscuous VLAN groups that the virtual sensor monitors.
Understanding the Virtual Sensor

Note

No packet is processed by more than one virtual sensor; you cannot assign the same physical or logical interface to more than one sensor. Packets from interfaces, inline interface pairs, inline VLAN pairs, and VLAN groups that are not assigned to any virtual sensor are disposed of according to the inline bypass configuration that you define in the Interfaces policy.

- The inline TCP session tracking and Normalizer modes (in the Virtual Sensors policy).

Note

If you create a policy instance on an IPS device for signatures, event actions, or anomaly detection but do not assign it to any of the virtual sensors on that device (that is, you do not use that policy instance), then that policy instance is deleted by Security Manager during deployment.

All other policies and settings are configured on the parent device that hosts the virtual sensor. For example, if you want to use global correlation, you configure it on the parent device and the virtual sensors share that configuration.

You can configure up to four virtual sensors on one appliance, but you can add only three user-defined virtual sensors. The first virtual sensor, vs0, is the base sensor and you cannot delete it. In Security Manager, virtual sensors are presented as follows:

- The device selector in Device view contains the parent device, which doubles as the base virtual sensor, vs0. Select this device to configure all device-level policies and to create virtual sensors in the Virtual Sensors policy.
- Any user-defined virtual sensors are also shown in the device selector in Device view. The display name of the real device is prepended to the beginning of the name of the virtual sensor. In most cases, the result is that the virtual sensors appear next to the parent (real) device that the virtual sensor is on. For example, on the host (real device) named “bob,” the virtual sensor with the name “vs1” will appear in the device list as “bob_vs1.”

To configure the signature, anomaly detection, and event action policies for a virtual sensor, you must select it in the device selector. You cannot configure these policies by selecting the parent device; those policies on the parent device are for the vs0 base sensor.

The following topics explain more about virtual sensors:

- Advantages and Restrictions of Virtualization, page 36-3
- Inline TCP Session Tracking Mode, page 36-4
- Understanding Normalizer Mode, page 36-4
- Assigning Interfaces to Virtual Sensors, page 36-4
- Identifying the Virtual Sensors for a Device, page 36-5
- Defining A Virtual Sensor, page 36-5
- Editing Policies for a Virtual Sensor, page 36-9
- Deleting A Virtual Sensor, page 36-10
Advantages and Restrictions of Virtualization

An advantage of using virtual sensors is that you can operate more than one virtual sensor on one appliance while configuring each virtual sensor differently with regard to signature behavior and traffic feed. For example, if you want to create a policy for a data center and a second much different policy for the campus network, yet run both policies on the same hardware device, you can configure separate virtual sensors to implement these policies.

Virtualization has the following advantages:

- You can apply different configurations to different sets of traffic.
- You can monitor two networks with overlapping IP spaces with one sensor.
- You can monitor both inside and outside a firewall or NAT device.

Virtualization has the following restrictions:

- You must assign both sides of asymmetric traffic to the same virtual sensor.
- Using VACL capture or SPAN (promiscuous monitoring) is inconsistent with regard to VLAN tagging, which causes problems with VLAN groups.
  - When using Cisco IOS software, a VACL capture port or a SPAN target does not always receive tagged packets even if it is configured for trunking.
  - When using the MSFC, fast path switching of learned routes changes the behavior of VACL captures and SPAN.
- Persistent store is limited.
- Not all IPS sensors support multiple virtual sensors. The Virtual Sensors policy appears for all IPS appliances and service modules, because you must use it to assign interfaces to the base vs0 sensor. If the Add button in the policy is disabled for a device, and you have not configured user-defined virtual sensors, then the device does not support virtualization. Examples of devices that do not support virtualization include the Cisco IPS 4215, NM-CIDS, AIM-IPS, NME-IPS, and AIP-SSC. IDSM2 supports virtualization, but it does not support VLAN groups or inline interface pairs.
- You must use IPS 6.0+ software. Older software versions do not support virtualization.
- Cisco IOS IPS devices do not support virtualization. Use the IPS > Interface Rules policy to specify the interfaces that IPS should monitor.

Virtualization has the following traffic capture requirements:

- The virtual sensor must receive traffic that has 802.1q headers (other than traffic on the native VLAN of the capture port).
- The sensor must see both directions of traffic in the same VLAN group in the same virtual sensor for any given sensor.

Understanding the Virtual Sensor

Inline TCP Session Tracking Mode

When you choose to modify packets inline, if the packets from a stream are seen twice by the Normalizer engine, it cannot properly track the stream state and often the stream is dropped. This situation occurs most often when a stream is routed through multiple VLANs or interfaces that are being monitored by the IPS. A further complication in this situation is the necessity of allowing asymmetric traffic to merge for proper tracking of streams when the traffic for either direction is received from different VLANs or interfaces.

To deal with this situation, you can set the mode so that streams are perceived as unique if they are received on separate interfaces or VLANs (or the subinterface for VLAN pairs).

The following inline TCP session tracking modes apply:

- **Interface and VLAN**—All packets with the same session key (AaBb) in the same VLAN (or inline VLAN pair) and on the same interface belong to the same session. Packets with the same key but on different VLANs are tracked separately.

- **VLAN Only**—All packets with the same session key (AaBb) in the same VLAN (or inline VLAN pair) regardless of the interface belong to the same session. Packets with the same key but on different VLANs are tracked separately.

- **Virtual Sensor**—All packets with the same session key (AaBb) within a virtual sensor belong to the same session. This is the default and almost always the best option to choose.

You configure the inline TCP session tracking mode as a property of the virtual sensor as described in Defining A Virtual Sensor, page 36-5.

Understanding Normalizer Mode

Normalizer mode applies only when the sensor is operating in inline mode. The default is strict evasion protection, which is full enforcement of TCP state and sequence tracking. The Normalizer enforces duplicate packets, changed packets, out-of-order packets, and so forth, which helps prevent attackers from evading the IPS.

Asymmetric mode disables most of the Normalizer checks. Use Asymmetric mode only when the entire stream cannot be inspected, because in this situation, attackers can now evade the IPS.

You configure the Normalizer mode as a property of the virtual sensor as described in Defining A Virtual Sensor, page 36-5.

Assigning Interfaces to Virtual Sensors

An IPS sensor monitors traffic that traverses interfaces, interface pairs, or VLAN pairs assigned to a virtual sensor.

You can assign one or more of the following types of interfaces to a virtual sensor:

- **Promiscuous interface**—A physical interface that does not have VLAN groups and which is not part of an inline interface pair.

- **Inline interface pair**—A logical interface composed of two physical interfaces.

- **Inline VLAN pair**—A logical interface composed of two VLANs.

- **Promiscuous VLAN group**—A VLAN group that is assigned to a subinterface on a physical interface.
The physical interface cannot already be used for an inline interface or VLAN pair. There can be many promiscuous VLAN groups on the same promiscuous interface, but the VLANs assigned cannot overlap. Once a VLAN group is assigned to a promiscuous interface, it is no longer a plain promiscuous interface and can only be used for promiscuous VLAN groups.

- Inline VLAN group—A VLAN group that is assigned to a subinterface of an inline interface pair.

There can be many inline VLAN groups on the same inline interface pair, but the VLANs assigned cannot overlap. Once a VLAN group is assigned to an inline interface pair it is no longer a plain inline interface pair and can only be used for inline VLAN groups.

VLAN groups cannot be assigned to inline VLAN pairs.

You must configure the interfaces before you can assign them to virtual sensors. For more information about configuring all of these types of interfaces, see Configuring Interfaces, page 35-6. For information on assigning interfaces to virtual sensors, see Defining A Virtual Sensor, page 36-5.

**Identifying the Virtual Sensors for a Device**

If you configure user-defined virtual sensors on an IPS appliance or service module, the virtual sensor appears in the device selector in Device view.

Normally, the display name of a virtual sensor is in the form `device-name_virtual-sensor-name`, where `device-name` is the name of the parent device, and `virtual-sensor-name` is the name of the virtual sensor. For example, the virtual sensor vs1 on device 10.100.10.10 would be 10.100.10.10-vs1.

Thus, under normal conditions, the virtual sensors for a device should appear immediately after the parent device in the device selector. However, you can change the virtual sensor's display name by editing the device properties. If you alter the default name, the virtual sensors might not appear anywhere near the parent device in the device selector.

You can use the following techniques to identify the virtual sensors defined on a device, or to identify the parent device of a virtual sensor:

- To see a list of virtual sensors defined on an IPS device, select the Virtual Sensors policy on the device. The table shows all virtual sensors, including the base vs0 sensor. Note that the vs0 sensor does not appear separately in the device selector; it is represented by the parent device itself.

  Unless you radically alter the display names of virtual sensors, the virtual sensor name, along with the parent device’s display name, should help you find the virtual sensor in the device selector.

- To determine which IPS device is the host of a virtual sensor, right-click the virtual sensor in the device selector and select Device Properties. The Hostname display-only field on the General tab shows the host device display name plus the virtual sensor name as defined on the device.

**Defining A Virtual Sensor**

Use the Virtual Sensors policy to configure virtual sensors on your Cisco IPS devices. Even if your IPS device does not support multiple virtual sensors, you must use this policy to assign interfaces to the base sensor, vs0, and configure properties that are associated with the virtual sensor.

For Cisco IOS IPS devices, you configure the interfaces that the IPS examines in the IPS > Interface Rules policy. You cannot configure virtual sensors in an IOS IPS device.
Before You Begin

Configure the interfaces on the sensor, including inline interface pairs, inline VLAN pairs, and promiscuous and inline VLAN groups. The interface configurations must exist before you can assign them to a virtual sensor. For information on interfaces, interface modes, and how to configure them, see Chapter 35, “Managing IPS Device Interfaces”.

Related Topics
- Understanding Interfaces, page 35-1
- Understanding Interface Modes, page 35-2
- Advantages and Restrictions of Virtualization, page 36-3
- Inline TCP Session Tracking Mode, page 36-4
- Understanding Normalizer Mode, page 36-4
- Assigning Interfaces to Virtual Sensors, page 36-4
- Identifying the Virtual Sensors for a Device, page 36-5
- Editing Policies for a Virtual Sensor, page 36-9

Step 1 (Device view only.) Select Virtual Sensors from the Policies selector to open the Virtual Sensors policy. The policy lists all existing virtual sensors, including the base vs0 sensor, which you cannot delete. The information for each sensor shows the interfaces assigned to the sensor, anomaly detection mode, inline TCP tracking mode, normalizer mode, and a description, if any. If the Assignments cell is empty, no interfaces are assigned to the virtual sensor, which means the virtual sensor cannot analyze any traffic.

Step 2 Do one of the following:
- To add a virtual sensor, click the Add Row button. The Add Virtual Sensor dialog box opens. You can add at most three sensors. The device supports four virtual sensors, including the base vs0 sensor. If the Add Row button is disabled, you either have configured the maximum number of sensors, or your device does not support multiple virtual sensors.
- To edit a virtual sensor, select it and click the Edit Row button. The Edit Virtual Sensor dialog box opens.

Tip You can also delete a virtual sensor by selecting it and clicking the Delete Row button. You cannot delete the base vs0 sensor. For more information about deleting virtual sensors, see Deleting A Virtual Sensor, page 36-10.

Step 3 In the Add or Edit Virtual Sensor dialog box, configure at least the following options. The defaults for the other options are appropriate in most cases. For detailed information on all available options, see Virtual Sensor Dialog Box, page 36-7.
- Virtual Sensor Name—The name of the virtual sensor. The virtual sensor name can be up to 64 characters and it cannot contain spaces.
- Interface assignments (Available, Assigned lists)—The promiscuous interfaces, inline interface pairs, inline VLAN pairs, promiscuous VLAN groups, or inline VLAN groups that you want this virtual sensor to use. The list of available interfaces shows only those interfaces that are configured in the Interfaces policy and that are not yet assigned to another virtual sensor.
  - To assign interfaces, select them in the available list and click >>.
To remove an assignment, select the interface in the assigned list and click <<. You must remove an assignment before you can assign an interface to a different virtual sensor.

**Tip:** If you are not sure about the content of a specific interface, for example, its mode or assigned VLANs, close the dialog box, go to the Interfaces policy, and examine the various tabs.

**Step 4** Click **OK** to save your changes and add them to the Virtual Sensors policy.

**Step 5** Click **Save** to save the Virtual Sensors policy.

**Step 6** If you created a new virtual sensor, you must submit your changes to the database for the new virtual sensor to appear in the device selector in Device view.

- Non-Workflow mode—Select **File > Submit**.
- Workflow mode—Select **Activities > Approve Activity**, or if you are operating with an activity approver, **Activities > Submit Activity**. The activity must be approved before the virtual sensor appears in the device selector.

**Note** In the device selector, the display name of the real device is prepended to the beginning of the name of the virtual sensor. In most cases, the result is that the virtual sensors appear next to the parent (real) device that the virtual sensor is on. For example, on the host (real device) named “bob,” the virtual sensor with the name “vs1” will appear in the device list as “bob_vs1.”

**Step 7** To configure the policies associated with a virtual sensor, select it in the device selector in Device view. You can then configure the associated policies. See the following topics:

- Chapter 37, “Defining IPS Signatures”
- Chapter 38, “Configuring Event Action Rules”
- Configuring Anomaly Detection, page 39-6

---

**Virtual Sensor Dialog Box**

Use the Add or Edit Virtual Sensor dialog box to configure the properties for a virtual sensor.

**Navigation Path**

(Device view only.) Select **Virtual Sensors** from the Policy selector. Click the **Add Row** button, or select an existing virtual sensor and click the **Edit Row** button.

<td>The name of the virtual sensor. The virtual sensor name can be up to 64 characters and it cannot contain spaces. The name of the default virtual sensor is vs0. You cannot change the name after you create the virtual sensor. To change a virtual sensor name, delete the sensor and create a new sensor with the desired name. If you already configured local policies for the sensor (that is, signature, event action, and anomaly detection policies), first save the policies as shared policies, delete the sensor, create the new sensor, then assign the shared policies to the new virtual sensor. For more information about creating shared policies from local policies, see Sharing a Local Policy, page 5-38.</td>
</tr>
</tbody>
</table>
| Interface Assignments (Available, Assigned) | The promiscuous interfaces, inline interface pairs, inline VLAN pairs, promiscuous VLAN groups, or inline VLAN groups that you want this virtual sensor to use. The list of available interfaces shows only those interfaces that are configured in the Interfaces policy and that are not yet assigned to another virtual sensor.  
  - To assign interfaces, select them in the available list and click `>>`.  
  - To remove an assignment, select the interface in the assigned list and click `<<`. You must remove an assignment before you can assign an interface to a different virtual sensor.  
  **Tip** If you are not sure about the content of a specific interface, for example, its mode or assigned VLANs, close the dialog box, go to the Interfaces policy, and examine the various tabs. |
| Anomaly Detection Mode          | The mode that you want the anomaly detection policy to operate in for this virtual sensor: Detect, Inactive, Learn. The default and normal operational mode is Detect. However, if you are using asymmetric normalizer mode, you might want to set the anomaly detection mode to Inactive. For detailed information about these modes, see Anomaly Detection Modes, page 39-2. |
| Inline TCP Session Tracking Mode | The mode used to segregate multiple views of the same stream if the same stream passes through the sensor more than once. The default mode is Virtual Sensor. For more information, see Inline TCP Session Tracking Mode, page 36-4. Select one of the following:  
  - Interface and VLAN—All packets with the same session key (AaBb) in the same VLAN (or inline VLAN pair) and on the same interface belong to the same session. Packets with the same key but on different VLANs are tracked separately.  
  - VLAN Only—All packets with the same session key (AaBb) in the same VLAN (or inline VLAN pair) regardless of the interface belong to the same session. Packets with the same key but on different VLANs are tracked separately.  
  - Virtual Sensor—All packets with the same session key (AaBb) within a virtual sensor belong to the same session. |
Chapter 36  Configuring Virtual Sensors

Editing Policies for a Virtual Sensor

Virtual sensors have two types of policies: the virtual sensor’s properties, and policies assigned to the virtual sensor. You use a different approach to edit these items.

- To edit the properties of a virtual sensor, select the virtual sensor’s parent device in the device selector in Device view. Then, select the Virtual Sensors policy. You can then select the virtual sensor in the table and click the Edit Row button.

Using the Virtual Sensors policy, you can change the interfaces assigned to a sensor, the anomaly detection mode, inline TCP session tracking mode, and Normalizer mode. For more information, see the following topics:
  - Defining A Virtual Sensor, page 36-5
  - Virtual Sensor Dialog Box, page 36-7

- To edit the policies assigned to a virtual sensor, select the virtual sensor in the device selector in Device view. A virtual sensor’s name is in the form device-name_virtual-sensor-name, where device-name is the name of the parent device, and virtual-sensor-name is the name of the virtual sensor. For example, the virtual sensor vs1 on device 10.100.10.10 would be 10.100.10.10_vs1.

<table>

Note The base virtual sensor, vs0, is integrated with the parent device and does not appear separately in the device selector. To configure the base virtual sensor, select the parent device.

You can then select the policies in the Policies selector and configure them. For more information, see the following topics:
  - Chapter 37, “Defining IPS Signatures”

Table 36-1  Add or Edit Virtual Sensor Dialog Box (Continued)
Deleting A Virtual Sensor

Virtual sensors appear in the device selector in Device view. However, you cannot delete them from the selector using the same command used for other devices. Instead, you must delete the virtual sensor from the Virtual Sensors policy of the parent device, that is, the device on which the virtual sensor is defined. The following procedure explains how to delete a user-defined virtual sensor.

**Tip**

The base virtual sensor, vs0, does not appear in the device selector. Instead, it is represented by the parent IPS sensor; it is considered to be the base IPS device. To delete the base vs0 sensor, you delete the entire device from the inventory. For information on deleting devices from the inventory, see Deleting Devices from the Security Manager Inventory, page 3-51.

**Before You Begin**

When you delete a virtual sensor, you also delete the policies defined for the sensor, such as signature, event action, and anomaly detection policies. If you configured non-default local policies, and you want to preserve them for use on other virtual sensors, you must first convert the local policies to shared policies. Then, after you delete the virtual sensor, the policies continue to exist as unassigned shared policies. You can then assign them to another virtual sensor. For more information on creating a shared policy from a local policy, see Sharing a Local Policy, page 5-38.

Using this technique is ideal if you are deleting a virtual sensor simply as a means to change the virtual sensor’s name. Because you cannot change a virtual sensor’s name, you must delete it and create a new virtual sensor with the desired name. If you created shared policies, you could then assign those shared policies to your new sensor, and it will have the same configuration as the sensor had under the old name.

**Step 1**
(Device view only.) Select **Virtual Sensors** from the Policies selector to open the Virtual Sensors policy.

**Step 2**
Select the user-defined virtual sensor that you want to delete and click the **Delete Row** button.

**Step 3**
You are asked for a two-step confirmation. First, you are warned that you must save the policy to keep the policy and device synchronized. Click **OK** to continue, and you are also asked to confirm that you want to delete the node.

If you confirm, the virtual sensor is removed from both the policy and the device selector. It will take a few moments before the device view is updated and the virtual sensor disappears from the list of devices.
Defining IPS Signatures

You can use Security Manager to configure IPS signatures for dedicated IPS appliances and service modules or Cisco IOS IPS devices. When configuring signatures for Cisco IOS IPS, keep in mind that the router cannot use as many signatures as a dedicated appliance or service module.

This chapter contains the following topics:
- Understanding Signatures, page 37-1
- Configuring Signatures, page 37-4
- Configuring Signature Settings, page 37-27

Understanding Signatures

Network intrusions are attacks on, or other misuses of, network resources. Cisco IPS sensors and Cisco IOS IPS devices use a signature-based technology to detect network intrusions. A signature specifies the types of network intrusions that you want the sensor to detect and report. As sensors scan network packets, they use signatures to detect known types of attacks, such as denial of service (DoS) attacks, and respond with actions that you define.

On a basic level, signature-based intrusion detection technology can be compared to virus-checking programs. Cisco IPS contains a set of signatures that the sensor compares with network activity. When a match is found, the sensor takes some action, such as logging the event or sending an alarm to the Security Manager Event Viewer.

Signatures can produce false positives, because certain normal network activity can be construed as malicious. For example, some network applications or operating systems may send out numerous ICMP messages, which a signature-based detection system might interpret as an attempt by an attacker to map out a network segment. You can minimize false positives by editing your signature parameters (tuning your signatures).

To configure a sensor to monitor network traffic for a particular signature, you must enable the signature. By default, the most critical signatures are enabled when you install the signature update. When an attack is detected that matches an enabled signature, the sensor generates an alert, which is stored in the event store of the sensor. The alerts, as well as other events, may be retrieved from the event store by web-based clients such as Event Viewer. By default the sensor logs all Informational alerts or higher.

Some signatures have subsignatures, that is, the signature is divided into subcategories. When you configure a subsignature, changes made to the parameters of one subsignature apply only to that subsignature. For example, if you edit signature 3050 subsignature 1 and change the severity, the severity change applies to only subsignature 1 and not to 3050 2, 3050 3, and 3050 4.
Cisco IPS contains over 10,000 built-in default signatures. You cannot rename or delete signatures from the list of built-in signatures, but you can retire signatures to remove them from the sensing engine. You can later activate retired signatures; however, this process requires the sensing engines to rebuild their configuration, which takes time and could delay the processing of traffic. You can tune built-in signatures by adjusting several signature parameters. Built-in signatures that have been modified are called tuned signatures.

**Note**

We recommend that you retire any signatures that you are not using. This improves sensor performance.

You can create signatures, which are called custom signatures. Custom signature IDs begin at 60000. You can configure them for several things, such as matching of strings on UDP connections, tracking of network floods, and scans. Each signature is created using a signature engine specifically designed for the type of traffic being monitored.

For more about signatures, see:
- Obtaining Detailed Information About a Signature, page 37-2
- Understanding Signature Inheritance, page 37-3

**Related Topics**
- Configuring Signatures, page 37-4
- Chapter 40, “Configuring Global Correlation”

**Obtaining Detailed Information About a Signature**

You can find detailed information about each signature from the Cisco Security Intelligence Operations web site. The web site includes a wealth of information and best practice recommendations for network security, and you can set up IntelliShield alerts. There is education on advanced security topics to help you protect your network, prioritize remediation, and structure your systems to reduce organizational risk.

When you edit the Signatures policy in Security Manager (see Signatures Page, page 37-4), the signature ID is linked directly into the Cisco Security Intelligence Operations database of IPS signatures. Clicking a signature ID opens a page containing information about the signature, including a description, the vulnerabilities on which the signature is based, when the signature was created, and so forth. You can search this database yourself at [http://tools.cisco.com/security/center/search.x?search=Signature](http://tools.cisco.com/security/center/search.x?search=Signature). (The database was formerly called the Cisco Network Security Database or NSDB.)

If you do not have access to Cisco.com, then the signature ID is linked to a local copy of the signature database information. Security Manager detects whether you have access to Cisco.com and makes the appropriate link for you without your having to set a preference.

The database includes information only for built-in, default signatures. You cannot find information about custom (user-defined) signatures.
Understanding Signature Inheritance

Signature inheritance for IPS devices is different than for any other Security Manager rules-based policy. Inheritance refers to the capability of Security Manager to enforce hierarchical lists of first-match, rule-based policies such as access rules. Signature inheritance is different because for IPS devices, Security Manager allows inheritance on a per-signature basis.

This example shows what is meant by inheritance on a per-signature basis:

**Step 1** In Policy View, select **IPS > Signatures > Signatures**.

**Step 2** Create a policy named test1.

**Step 3** Create a second policy, named test2.

**Step 4** Right-click **test 2** and select **Inherit Signatures**. The Inherit Rules—test 2 dialog box appears.

**Step 5** Select **test1** and click the **OK** button.

**Step 6** Select **test1** and edit a signature. Note the edit that you made and save your change.

**Step 7** Select **test2** and select the signature that you just edited. Observe that test2 inherited the editing that you did on test1.

IPS Signature Purge

Beginning with Security Manager 4.1, old signature versions (defined as being older than the lowest signature level deployed) are purged during a periodic purge operation, the purpose of which is to optimize the database.

**Note** As a result of the purge operation, you may notice the deletion of some of your unused tuning contexts.

Some of the purged signatures may be restored during your next download of IPS signature packages from Cisco.com.

IPS signature purge is disabled by default. To enable IPS signature purge,

**Step 1** Stop the Cisco Security Manager Daemon Manager: At the command prompt, enter `net stop crmdmgtd`.

**Step 2** Navigate to `NMSROOT\MDC\ips\etc\sensorupdate.properties` file, where `NMSROOT` is the path to the Security Manager installation directory. The default is `C:\Program Files\CSCOpx`.

**Step 3** In `sensorupdate.properties`, change `purgeUnusedSignautesEntriesinDB:false` to `purgeUnusedSignautesEntriesinDB:true`.

**Step 4** Re-start the Cisco Security Manager Daemon Manager: At the command prompt, enter `net start crmdmgtd`.

IPS signature purge now runs at midnight every day.
Configuring Signatures

The Signatures policy is where you configure signatures for Cisco IPS sensors and Cisco IOS IPS devices.

This section contains the following topics:

- Signatures Page, page 37-4
- Viewing Signature Update Levels, page 37-9
- Enabling and Disabling Signatures, page 37-10
- Editing Signatures, page 37-11
- Adding Custom Signatures, page 37-15
- Cloning Signatures, page 37-18
- Editing Signature Parameters (Tuning Signatures), page 37-18

Signatures Page

Use the Signatures page to display the signature summary table, in which you can add, edit, and delete IPS signatures. From this page you can tune the active signature set in a policy by enabling or disabling signatures. You can also use this page to unload signatures from the engine.

Tips

- Disabled signatures are shown with hash marks covering the table row. When you deploy the configuration, disabled signatures are removed from the device. For more information, see Enabling and Disabling Signatures, page 37-10.
- For many columns, you can right-click the column and edit the property directly. Your edits apply to all rows that you have selected. If you select multiple rows, the options that you can select are limited to those that are valid for all selected rows. The contents of the right-click menu differ based on the cell that you right click. For more information on the available commands, see Signature Shortcut Menu, page 37-7.

Navigation Path

- (Device view) Select IPS > Signatures > Signatures from the Policy selector.
- (Policy view, IPS appliances and service modules) Select IPS > Signatures > Signatures, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select IPS (Router) > Signatures, then select an existing policy or create a new one.

Field Reference

Table 37-1 Signature Policy

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The signature ID, which is the unique numerical value assigned to this signature. This value lets the sensor identify a particular signature. Click the ID number to open a page in your web browser with detailed information about the signature, as explained in Obtaining Detailed Information About a Signature, page 37-2.</td>
</tr>
<tr>
<td>Sub</td>
<td>The subsignature ID, which is the unique numerical value assigned to this subsignature. A Subsignature ID identifies a more granular version of a broad signature.</td>
</tr>
<tr>
<td>Name</td>
<td>The name assigned to the signature.</td>
</tr>
<tr>
<td>Action</td>
<td>The actions the sensor takes when this signature fires.</td>
</tr>
<tr>
<td>Severity</td>
<td>The severity level that the signature reports: High, Medium, Low, or Informational.</td>
</tr>
<tr>
<td>Fidelity</td>
<td>The weight associated with how well this signature might perform in the absence of specific knowledge of the target.</td>
</tr>
<tr>
<td>Source</td>
<td>The lowest policy in the inheritance hierarchy that overrides the settings for a signature. Values can be:</td>
</tr>
<tr>
<td></td>
<td>• Default—The signature uses the default Cisco-defined settings.</td>
</tr>
<tr>
<td></td>
<td>• Local—The signature is defined specifically for the selected device (Device view only.)</td>
</tr>
<tr>
<td></td>
<td>• Policy name—The lowest shared policy in the inheritance hierarchy. You can see policy names in Policy view, or in Device view if you assign a shared signature policy to the device.</td>
</tr>
<tr>
<td>Enabled</td>
<td>Whether the signature is enabled in this policy; true signifies that it is enabled, false that it is disabled. A signature must be enabled for the sensor to protect against the traffic specified by the signature.</td>
</tr>
<tr>
<td>Base Risk Rating</td>
<td>The base risk rating value of the signature.</td>
</tr>

</table>
Chapter 37  Defining IPS Signatures

Configuring Signatures

Retired

The conditions under which the signature is retired, if any. A retired signature is removed from the signature engine. You can activate a retired signature to place it back in the signature engine.

Timesaver

Use the retired field to unload disabled signatures on your IOS-IPS device to achieve the most favorable memory consumption of that device.

If the engine level of a signature policy is less than E-4, the Retired field has two possible values: false and true. False means that the signature is not retired; true means that the signature is retired.

If the engine level of a signature policy is equal to E-4, the Retired field has four possible values:

- **false**—The signature is not retired.
- **low-mem-retired**—The signature should be retired on low-memory platforms. A low-memory device is one that has 2 MB RAM or less.
- **med-mem-retired**—The signature should be retired on both low-end and medium platforms. A medium-memory device is one that has 4 MB RAM or less, but more than 2 MB RAM. (Any device with more than 4 MB RAM is considered a high-memory platform.)
- **true**—The signature is retired on all platforms.

When you select low-mem-retired or med-mem-retired, Security Manager configures the device with those signatures. Whether the signature is actually retired on the device depends on amount of memory installed on the device; the device makes the decision on which signatures are actually retired.

**Tip**  The term *engine level* used here is not the same as the term *engine* in the row above.

Obsolete

Whether the signature is obsolete. An obsolete signature is removed from the signature engine. It cannot be re-activated. This column is read only.

Engine

The engine that parses and inspects the traffic specified by this signature.

View Update Level button

(Device view only.)  
Click this button view the signature update level for this device. For more information, see Viewing Signature Update Levels, page 37-9.

Export to File button

Click this button to export the signature summary for the current device to a comma-separated values (CSV) file. You are prompted to select the folder on the Security Manager server and to specify a file name.

Add button

Click this button to add a custom signature. For more information, see the following topics:

- Adding Custom Signatures, page 37-15
- Edit Signature or Add Custom Signature Dialog Boxes, page 37-12
### Signature Shortcut Menu

Right-clicking inside the signature summary table in the Signatures policy displays a shortcut menu for performing various functions on the selected signatures. Some commands appear only if you select a single signature, while some commands can be used on more than one signature at a time; your changes apply to all selected signatures. For more information about the Signatures policy, see Signatures Page, page 37-4.

Additionally, the available commands differ depending on which cell you right click. Some commands are available when right-clicking any cell, while others are specific to a single cell.

**Tip**

When you use a right-click command to change the value in a cell of a Default signature, the signature is converted to a Local signature in Device view or a shared-policy-specific signature in Policy view.

The following table explains the available commands.

#### Table 37-2 Signature Shortcut Menu

<table>
<thead>

<tr>
<td>Replace Actions With</td>
<td>Replace the current set of actions for the selected signature with the single action selected. If you want to select more than one action, select More from the submenu, then use Ctrl+click to select the desired actions.</td>
</tr>
<tr>
<td>Edit Actions</td>
<td>Opens the Edit Actions dialog box, where you can select the desired actions for the signature. Your selection replaces the current list of actions for the signature. For more information, see Edit, Add, Replace Action Dialog Boxes, page 37-8.</td>
</tr>
</tbody>
</table>

**Severity Cell Commands**

- High
- Medium
- Low
- Informational

Changes the severity level of the signature to the level you select.

**Fidelity Cell Commands**

<table>
<thead>
<tr>
<th>Menu Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edit Fidelity</td>
<td>Changes the fidelity rating of the signature, which is the weight associated with how well this signature might perform in the absence of specific knowledge of the target.</td>
</tr>
</tbody>
</table>

**Retired Cell Commands**

- Retire
- Activate
- Retire on Low Memory
- Retire on Medium Memory

Changes the retired status of the signature to the selected status. For more information about the retired status categories, see Edit Signature or Add Custom Signature Dialog Boxes, page 37-12.

**Edit, Add, Replace Action Dialog Boxes**

Use the Edit, Add, or Replace Action dialog boxes to change the actions defined for a signature. These dialog boxes are available only when you edit the Action cell using the right click menu as explained in Signature Shortcut Menu, page 37-7. The behavior differs depending on the dialog box name:

- Add Actions—The actions that you select are added to those already defined in the signature. To open this dialog box, right-click the Actions cell of a signature and select Add to Actions > More.
Configuring Signatures

- **Replace Actions**—The actions that you select completely replace those defined in the signature. To open this dialog box, right-click the Actions cell of a signature and select **Replace Actions With** > **More**.

- **Edit Actions**—The actions that you select completely replace those defined in the signature. To open this dialog box, right-click the Actions cell of a signature and select **Edit Actions**.

For an explanation of the available actions, see *Understanding IPS Event Actions*, page 38-2. You can select multiple actions using Ctrl+click.

**Note**

When you open dialog box, the list of actions that you see varies. The list of actions depends upon whether you right-click in only one signature row in the Actions column or select more than one signature row before right-clicking in the Actions column. If you right-click in only one signature row in the Actions column, the list of actions is that of the engine for that signature. If you select more than one signature row before right-clicking in the Actions column, the list of actions is that which is available for each affected engine. (It is the list of common actions, not the union of actions.)

**Edit Fidelity Dialog Box**

Use the Edit Fidelity dialog box to make changes in the Fidelity Rating for a particular signature. The Fidelity Rating, or Signature Fidelity Rating (SFR), identifies the weight associated with how well this signature might perform in the absence of specific knowledge of the target. This rating can be any number from 0 to 100, with 100 indicating the most confidence in the signature.

**Navigation Path**

In the Signatures policy, right-click the Fidelity cell in a signature and select Edit Fidelity. For information on opening the Signatures policy, see *Signatures Page*, page 37-4. For more information on the signature shortcut menu, see *Signature Shortcut Menu*, page 37-7.

**Viewing Signature Update Levels**

In Device view, you can determine the current signature update packages applied to the device in Security Manager and compare it to the one deployed on the device.

Differences between the applied and deployed update levels can occur when:

- The device is updated outside of Security Manager.
- An update is applied to the policy in Security Manager but not yet published to the device.
- During initial Security Manager deployment before the devices are under Security Manager control.

To view the signature update level, select the **IPS > Signatures > Signatures** policy for an IPS device in Device view. Then, click the **View Update Level** button to open the Update Level dialog box.

The following table describes the information displayed in the dialog box.
You can enable and disable individual signatures. Your change takes effect when you redeploy the configuration to the device.

If a signature is disabled, it appears in the table overlain with hash marks. When you deploy the configuration, disabled signatures are removed from the device.

Disabling signatures is useful when you want to reduce the number of signatures used by a device, or if you want to temporarily stop using a custom signature without deleting it. You can later reenable a signature that you disabled.

You can enable a signature that is retired, but it then is not used to scan traffic, because it is not in the signature micro-engine. If you want a sensor to scan network traffic for a particular signature, you must enable it and not retire it. The AIP-SSC-5 does not support enabling a signature that is retired.

### Step 1
Do one of the following:

- (Device view) Select **IPS > Signatures** from the Policy selector.
- (Policy view, IPS appliances and service modules) Select **IPS > Signatures** from the Policy selector, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Signatures** from the Policy selector, then select an existing policy or create a new one.

The Signature page appears; see **Signatures Page**, page 37-4.
Step 2 Right-click the signature whose enabled status you want to change and select Enable or Disable, as appropriate.

Editing Signatures

You can edit signatures to change their behavior. For example, you can change the action that should be taken when a signature fires, or the severity and fidelity ratings used to calculate the risk rating of the signature.

Some signatures have special requirements. For example, to configure a sensor to detect ACL violation signatures, you must first configure one or more Cisco IOS routers to log ACL violations. Then, you must configure those routers to communicate with the sensor. Finally, you must configure the sensor to accept syslog traffic from those routers.

Tip This procedure describes how to edit an entire signature. You can also selectively edit individual properties of a signature using the right-click menu in the Signatures policy. For information on the available commands, see Signature Shortcut Menu, page 37-7.

Related Topics
- Understanding Signatures, page 37-1
- Understanding IPS Event Actions, page 38-2
- Enabling and Disabling Signatures, page 37-10
- Cloning Signatures, page 37-18
- Configuring Event Action Filters, page 38-5
- Chapter 38, “Configuring Event Action Rules”

Step 1 Do one of the following:
- (Device view) Select IPS > Signatures > Signatures from the Policy selector.
- (Policy view, IPS appliances and service modules) Select IPS > Signatures > Signatures, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select IPS (Router) > Signatures, then select an existing policy or create a new one.

The Signature page appears; see Signatures Page, page 37-4.

Step 2 Right-click the signature you want to edit and select Edit Row. You can also select the signature and click the Edit Row (pencil) button beneath the signatures table. The Edit Signature dialog box opens.

Tip Use the filter fields above the table to help you find the desired signature. For information on filtering tables, see Filtering Tables, page 1-44.

Step 3 Make the desired changes to the signature. For specific details about each option, see Edit Signature or Add Custom Signature Dialog Boxes, page 37-12.
When editing signatures, keep the following in mind:

- You cannot edit a Default signature. Default signatures are the Cisco-defined version of a signature. Before you can edit a Default signature, you must convert it either to a Local signature (one defined specifically on the selected device) or a shared-policy-specific signature (one defined in a shared policy). You must select either Local or the shared policy name from the Source Policy field before you can change any field on the Edit Signature dialog box.
- You cannot change every characteristic of a signature. For example, you cannot change the signature or subsignature IDs. These fields are read-only.
- If you want to change the detailed parameters of a signature, follow the procedure described in Editing Signature Parameters (Tuning Signatures), page 37-18.

**Step 4** Click OK to save your changes.

---

**Edit Signature or Add Custom Signature Dialog Boxes**

The Edit Signature and Add Custom Signature dialog boxes are essentially the same. Most of the fields are identical, although there are some layout differences. Use these dialog boxes as follows:

- Use the Edit Signature dialog box to edit the characteristics of a non-default signature (you can only view the characteristics of a default signature in read-only mode).
  - You cannot edit default signatures. To make any changes to a signature, you must select something other than Default in the Source Policy field at the top of the dialog box.
- Use the Add Custom Signature dialog box to create a custom signature. In the Add Custom Signature dialog box, you enter a name and then select an existing engine from a drop-down list. The signature ID and subsignature ID are assigned by Security Manager. After you finish selecting the remaining parameters, the new signature is added to the Signatures page in the appropriate numerical location, and it is selected.

**Navigation Path**

From the Signatures page:

- To edit a signature, right-click the policy you want to edit and select **Edit Row**.
- To add a custom signature, click the **Add Row (+)** button beneath the table, or right-click any row and select **Add Row**.

For information on opening the Signature page, see **Signatures Page**, page 37-4.

### Chapter 37      Defining IPS Signatures

#### Configuring Signatures

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Source Policy</strong></td>
<td>The policy in which you are editing the signature:</td>
</tr>
</tbody>
</table>
| *(Edit signature only.)*         | - Default—The default Cisco-defined signature, which you cannot edit. You must select something other than Default to edit the signature.  
                                    - Local—The signature is a local signature defined specifically for the selected device. This option is not available in Policy view.  
                                    - Policy name (variable)—The name of a shared policy. In Device view, a policy name is available only if you assign a shared policy to the device. In Policy view, this is the name of the policy you are editing. Select the policy name to edit the signature and to have your edits reflected on all devices that are assigned the shared policy. |
| **Name**                         | The name of the signature. |
| *(Add only.)*                    | You cannot change the name after you create the signature. If you want to change the name, you must create a clone of the signature. |
| **Inheritance Mandatory**        | When selected, forces any policy that inherits from this policy to use the signature settings defined. |
| *(Edit signature only.)*         | Whether the signature is enabled. |
| **Severity**                     | The severity level that the signature will report: High, Medium, Low, or Informational. |
| **Fidelity Rating**              | The weight associated with how well this signature might perform in the absence of specific knowledge of the target. |
| **Actions**                      | The actions that the sensor will take when this signature fires. For a complete list of actions, see the Understanding IPS Event Actions, page 38-2.  
                                    Use Ctrl+click to select multiple actions. |
| **Base Risk Rating**             | The base risk rating value of the signature, which is calculated by multiplying the fidelity rating and the severity factor and dividing them by 100 (Fidelity Rating x Severity Factor /100). This value is read only; you cannot directly change it. To change the value, alter the Severity and Fidelity fields.  
                                    The Severity Factor has the following values based on what you select in the Severity field:  
                                    - High = 100  
                                    - Medium = 75  
                                    - Low = 50  
                                    - Informational = 25 |

<td>Identifies whether the signature is obsolete. An obsolete signature is removed from the signature engine. It cannot be re-activated.</td>
</tr>
</tbody>
</table>
Adding Custom Signatures

If you want to look for traffic patterns that are not identified by the built-in signatures, you can create your own custom signatures to define the traffic patterns.

Even if a built-in signature covers the traffic pattern, you might want to create a custom signature to edit the detailed signature parameters without altering the default signature. If you are creating a custom signature that is similar to an existing signature, the easiest way to do it is to clone the signature as described in Cloning Signatures, page 37-18.

Note

The AIP-SSC-5 does not support custom signatures.

Step 1

Do one of the following:

- (Device view) Select IPS > Signatures > Signatures from the Policy selector.
- (Policy view, IPS appliances and service modules) Select IPS > Signatures > Signatures, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select IPS (Router) > Signatures, then select an existing policy or create a new one.

The Signature page appears; see Signatures Page, page 37-4.

Step 2

Click the Add Row (+) button beneath the signature table to open the Add Custom Signature dialog box.

Step 3

Configure the desired settings. For specific details about each option, see Edit Signature or Add Custom Signature Dialog Boxes, page 37-12.

When creating signatures, keep the following in mind:

- You cannot change the signature name after you define the signature. If you later want to change the name, you must clone the signature and change it while creating the clone.
- Select the appropriate signature engine for the signature. For a description of the signature engines, see Engine Options, page 37-16. You cannot change the engine after you create the signature; if you select the wrong engine and click OK to save the signature, you must start over and create an entirely new signature.
- The default is to create an enabled signature, but you can deselect the Enabled check box to initially create a disabled signature. You might want to disable the signature if you have not finished editing its parameters.
Follow the procedure described in Editing Signature Parameters (Tuning Signatures), page 37-18 to define the detailed signature parameters. You must select the desired engine before you edit the parameters, because many of the parameters are determined by the signature engine.

Whether you can save the signature before configuring parameters differs based on the engine that you select. At minimum, you must click Edit Parameters to open the Edit Signature Parameters dialog box, and then click OK in the Edit Signature Parameters dialog box, before you can save the signature definition. However, to create a meaningful signature, you will need to configure the parameters to identify the desired traffic pattern.

**Step 4**

Click OK to save your changes.

The custom signature is added to the end of the table and given the next available signature ID starting at 60000.

### Engine Options

The following list identifies the options you can specifying in the Engine field of the Edit Signature Parameters dialog box. For detailed information about each engine, and the parameters available, see the “Signature Engines” section in the Installing and Using Cisco Intrusion Prevention System Device Manager document for the IPS Software release you are using.

- **AIC FTP**—Inspects FTP traffic and lets you control the commands being issued.
- **AIC HTTP**—Provides granular control over HTTP sessions to prevent abuse of the HTTP protocol.
- **Atomic ARP**—Inspects Layer-2 ARP protocol. The Atomic ARP engine is different because most engines are based on Layer-3-IP.
- **atomic-ip**—Inspects IP protocol packets and associated Layer-4 transport protocols.
- **Atomic IPv6**—Detects IOS vulnerabilities that are stimulated by malformed IPv6 traffic.
- **Flood Host**—Detects ICMP and UDP floods directed at hosts.
- **Flood Net**—Detects ICMP and UDP floods directed at networks.
- **Meta**—Defines events that occur in a related manner within a sliding time interval. This engine processes events rather than packets.
- **multi-string**—Defines signatures that inspect Layer 4 transport protocol (ICMP, TCP, and UDP) payloads using multiple string matches for one signature. You can specify a series of regular expression patterns that must be matched to fire the signature.
- **normalizer**—Configures how the IP and TCP normalizer functions and provides configuration for signature events related to the IP and TCP normalizer. Allows you to enforce RFC compliance.
- **service-dns**—Inspects DNS (TCP and UDP) traffic.
- **service-ftp**—Inspects FTP traffic.
- **Service Generic**—Decodes custom service and payload.

The Service Generic engine allows programmatic signatures to be issued in a config-file-only signature update. It has a simple machine and assembly language that is defined in the configuration file. It runs the machine code (distilled from the assembly language) through its virtual machine, which processes the instructions and pulls the important pieces of information out of the packet and runs them through the comparisons and operations specified in the machine code. It is intended as a rapid signature response engine to supplement the String and State engines.

You cannot use the Service Generic engine to create custom signatures.
Service Generic Advanced—Generically analyzes network protocols.
Service H225—Inspects VoIP traffic.
service-http—Inspects HTTP traffic. The WEBPORTS variable defines inspection port for HTTP traffic.
Service IDENT—Inspects IDENT (client and server) traffic.
Service MSRPC—Inspects MSRPC traffic.
Service MSSQL—Inspects Microsoft SQL traffic.
Service NTP—Inspects NTP traffic.
service-rpc—Inspects RPC traffic.
Service SMB—Inspects SMB traffic.
Service SMB Advanced—Processes Microsoft SMB and Microsoft RPC over SMB packets.
Service SNMP—Inspects SNMP traffic.
Service SSH—Inspects SSH traffic.
Service TNS—Inspects TNS traffic.
state—Stateful searches of strings in protocols such as SMTP.
string-icmp—Searches on Regex strings based on ICMP protocol.
string-tcp—Searches on Regex strings based on TCP protocol.
string-udp—Searches on Regex strings based on UDP protocol.
Sweep—Analyzes sweeps of ports, hosts, and services, from a single host (ICMP and TCP), from destination ports (TCP and UDP), and multiple ports with RPC requests between two nodes.
Sweep Other TCP—Analyzes TCP flag combinations from reconnaissance scans that are trying to get information about a single host. The signatures look for flags A, B, and C. When all three are seen, an alert is fired.
Traffic ICMP—Analyzes nonstandard protocols, such as TFN2K, LOKI, and DDOS. There are only two signatures with configurable parameters.
Traffic Anomaly—Analyzes TCP, UDP, and other traffic for worm-infested hosts.
Trojan Bo2k—Analyzes traffic from the nonstandard protocol BO2K. There are no user-configurable parameters in this engine.
Trojan Tfn2k—Analyzes traffic from the nonstandard protocol TFN2K. There are no user-configurable parameters in this engine.
Trojan UDP—Analyzes traffic from the UDP protocol. There are no user-configurable parameters in this engine.
Cloning Signatures

If you want to create a custom signature that is similar to an existing signature, you can create a clone, or copy, of the signature. You can then edit the parameters to make the clone perform according to your requirements.

For example, you might want to create a clone of a Cisco-defined signature to customize it to your needs. You might find this preferable to converting the Cisco signature to a Local or shared policy signature and directly editing its parameters.

To clone a signature, follow these steps:

**Step 1**  Do one of the following:
- (Device view) Select **IPS > Signatures > Signatures** from the Policy selector.
- (Policy view, IPS appliances and service modules) Select **IPS > Signatures > Signatures**, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Signatures**, then select an existing policy or create a new one.

The Signature page appears; see Signatures Page, page 37-4.

**Step 2**  Right-click the signature that you want to clone and select **Clone**.

Security Manager takes some time to make the copy, and might warn you that some attributes are read-only and cannot be copied. If you receive a warning, click **OK**. The Add Custom Signature dialog box then appears.

**Step 3**  Edit the properties of the cloned signature, as described in Adding Custom Signatures, page 37-15.

**Step 4**  Click **OK**. The clone appears in the summary table on the Signatures page as the last signature.

Cloned signatures are enabled and active by default.

Editing Signature Parameters (Tuning Signatures)

If you cannot alter the behavior of a signature to fit your needs using the Event Action Filters and Overrides policies, or by changing the actions associated with a signature, you might need to fine-tune the signature parameters. You should considered editing parameters to be your last option, however, because these parameters can be complex and frequently require that you have a deep understanding of packet characteristics.

The reason you would want to edit parameters is to reduce false positives and false negatives:

- **A false positive** occurs when legitimate network activity, such as virus scanning, is interpreted and reported as an attack. This happens when network activity meets criteria that were specified to identify an attack before the attack occurred. You can decrease the number false positives by tuning your sensor configurations.

- **A false negative** occurs when an attack was not detected. Tuning your sensor configurations will help you decrease the number of false negatives.
Tip

You cannot edit the parameters of a default signature. Before editing the parameters of a default signature, you must convert the signature to a local- or shared-policy signature. In some cases, such as regular expression editing, you must clone the signature and convert it to a custom signature.

This procedure describes how to edit signature parameters to tune a signature.

Related Topics

- Editing Signatures, page 37-11
- Understanding Signatures, page 37-1
- Configuring Event Action Filters, page 38-5
- Configuring Event Action Overrides, page 38-12

Step 1

Do one of the following:

- (Device view) Select IPS > Signatures > Signatures from the Policy selector.
- (Policy view, IPS appliances and service modules) Select IPS > Signatures > Signatures, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select IPS (Router) > Signatures, then select an existing policy or create a new one.

The Signature page appears; see Signatures Page, page 37-4.

Step 2

Right-click the signature whose parameters you want to edit and select Edit Row. The Edit Signature dialog box appears (see Edit Signature or Add Custom Signature Dialog Boxes, page 37-12).

Step 3

If the Source Policy field shows Default, you must change it to Local or to the name of a shared policy before you can edit the parameters. The Local option is available in Device view only, and makes your changes apply to the device you are editing and to no other devices. If you select the name of a shared policy, your changes apply to all devices that are assigned the policy.

Step 4

Click Edit Parameters. The Edit Signature Parameters dialog box appears.

The Edit Signature Parameters dialog box contains a folder tree structure, with the parameter names in the left side tree, and the values of the parameters shown on the right side.

Values that you can change contain a little box in the name; this is a check box. An empty check box indicates that the default value is being used for the parameter. Check the check box to configure that parameter. Click the value field to change the parameter. A green check indicates that a user-defined value is being used. Click the green check to change the value back to the default. (Editing the field typically adds a check mark to the box.)

To change a parameter, click in the associated field in the right side. The behavior of clicking on a parameter differs based on the parameter type:

- Read-only parameters—Many parameters are read-only and cannot be changed, such as signature ID. Clicking these parameters typically has no effect, although parameter lists will open a dialog box (such as the Obsoletes list).
- Text or Numeric parameters—When you click a parameter that requires that you type in a value, whether alphanumeric or numeric, the field becomes an edit box. Type in the desired value and either press enter or click outside the edit box.
- Predefined value parameters—Many parameters have a small set of possible values, such as Yes/No. When you click these parameters, you activate a drop-down list. Select the desired option and click outside the field.
List parameters—Some parameters contain a list of items. These parameters are represented by a pencil icon in the parameter value along with a word, such as Set or List. When you click in the field, a dialog box opens where you can configure the list associated with the item. The Meta engine component list is an example; for more information, see Editing the Component List for Meta Engine Signatures, page 37-25.

Variable parameters—Some parameters allow you to select policy objects to identify the contents of the parameters. For example, you can select port list objects to identify ports in some signature engines. When you click these parameters, an edit box with a Select button appears. You can type the items directly into the edit box, including the name of the policy object, or click Select to select the policy object from a list or to create a new object.

For more information about the Edit Signature Parameters dialog box, see Edit Signature Parameters Dialog Box, page 37-20.

Step 5 Change the settings as desired, then click OK to save your changes. You are returned to the Edit Signature dialog box.

Step 6 Click OK in the Edit Signature dialog box to save your changes to the signature.

Tip If you decide that your edits did not have the desired effect, or you suspect that you made a mistake, you can click the Restore Defaults button in the Edit Signature dialog box to erase your changes. You can then start over.

Edit Signature Parameters Dialog Box

Use the Edit Signature Parameters dialog box to edit (also called tune) the built-in micro-engine parameters for a particular signature. Different engines have different parameters, so the appearance of the Edit Signature Parameters dialog box varies. For more information about editing signature parameters, see Editing Signature Parameters (Tuning Signatures), page 37-18.

The Edit Signature Parameters dialog box contains a folder tree structure, with the parameter names in the left side tree, and the values of the parameters shown on the right side.

Values that you can change contain a little box in the name; this is a check box. An empty check box indicates that the default value is being used for the parameter. Check the check box to configure that parameter. Click the value field to change the parameter. A green check indicates that a user-defined value is being used. Click the green check to change the value back to the default. (Editing the field typically adds a check mark to the box.)

To change a parameter, click in the associated filed in the right side. The behavior of clicking on a parameter differs based on the parameter type:

- Read-only parameters—Many parameters are read-only and cannot be changed, such as signature ID. Clicking these parameters typically has no effect, although parameter lists will open a dialog box (such as the Obsoletes list).
- Text or Numeric parameters—When you click a parameter that requires that you type in a value, whether alphanumeric or numeric, the field becomes an edit box. Type in the desired value and either press enter or click outside the edit box.
- Predefined value parameters—Many parameters have a small set of possible values, such as Yes/No. When you click these parameters, you activate a drop-down list. Select the desired option and click outside the field.
• List parameters—Some parameters contain a list of items. These parameters are represented by a pencil icon in the parameter value along with a word, such as Set or List. When you click in the field, a dialog box opens where you can configure the list associated with the item. The Meta engine component list is an example; for more information, see Editing the Component List for Meta Engine Signatures, page 37-25.

• Variable parameters—Some parameters allow you to select policy objects to identify the contents of the parameters. For example, you can select port list objects to identify ports in some signature engines. When you click these parameters, an edit box with a Select button appears. You can type the items directly into the edit box, including the name of the policy object, or click Select to select the policy object from a list or to create a new object.

Navigation Path
From the Edit Signature or Add Custom Signature dialog boxes, click the Edit Parameters button. For information on opening these dialog boxes, see Edit Signature or Add Custom Signature Dialog Boxes, page 37-12.

Tip
If the button is not active, you must first select Local or the name of a shared policy from the Source Policy field, or clone the signature to create a custom policy. The Local option is available in Device view only, and makes your changes apply to the device you are editing and to no other devices. If you select the name of a shared policy, your changes apply to all devices that are assigned the policy.
### Field Reference

#### Table 37-5  Edit Signature Parameters Dialog Box

<table>
<thead>
<tr>
<th>Elements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuning Context (Policy view only)</td>
<td>Displays the information needed by Security Manager to uniquely describe how the signature parameters were edited (tuned) for a particular signature policy. The Tuning Context field is a character string that contains the following items:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Context</strong>—The identification given by the Security Manager server for the unique definition of this micro-engine.</td>
</tr>
<tr>
<td></td>
<td>• <strong>SigLevel (IPS) or Version (IOS IPS)</strong>—For IPS policies, the range of signature update levels to which this definition of the signature micro-engine applies. For IOS IPS, this is the IOS IPS version.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Engine</strong>—The name of the IPS engine.</td>
</tr>
<tr>
<td><strong>Tip</strong></td>
<td>As an example, the Tuning Context field could contain the following character string: Context:9, SigLevel:302-449, Engine:atomic-ip.</td>
</tr>
<tr>
<td></td>
<td>For any particular signature policy, the Tuning Context field can contain one or many tuning contexts:</td>
</tr>
<tr>
<td></td>
<td>• The tuning context with the highest signature level is pre-pended with &quot;Reference context.&quot;</td>
</tr>
<tr>
<td></td>
<td>• If you modify the shared policy that is pre-pended with &quot;Reference context,&quot; Security Manager may ask you if you want to copy the policy to other applicable contexts. (A particular device may appear in more than one context.)</td>
</tr>
<tr>
<td></td>
<td>• If you choose to copy the policy to other applicable contexts, an error message informs you if some parameters cannot be copied.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Beginning with Security Manager 4.1, old signature versions (defined as being older than the lowest signature level deployed) are purged during a periodic purge operation, the purpose of which is to optimize the database. As a result, you may notice the deletion of some of your unused tuning contexts.</td>
</tr>
<tr>
<td>Signature ID</td>
<td>The unique numerical value assigned to this signature. This value lets the sensor identify a particular signature. The value is 1000 to 65000.</td>
</tr>
<tr>
<td>SubSignature ID</td>
<td>The unique numerical value assigned to this subsignature. The subsignature ID identifies a more granular version of a broad signature. The value is 0 to 255.</td>
</tr>
<tr>
<td>Promiscuous Delta</td>
<td>Modifies the seriousness of an alert when operating in promiscuous mode. The value is subtracted from an alert’s overall risk rating. The promiscuous delta is ignored when operating in inline mode. The value can be 0 to 30.</td>
</tr>
</tbody>
</table>
### Table 37-5 Edit Signature Parameters Dialog Box (Continued)

<table>
<thead>
<tr>

</tbody>
</table>
Editing the Component List for Meta Engine Signatures

Use the Edit Signature Parameter—Component List dialog box to edit the component list for a meta engine signature.

The Meta engine defines events that occur in a related manner within a sliding time interval. This engine processes events rather than packets. As signature events are generated, the Meta engine inspects them to determine if they match any or several Meta definitions. The Meta engine generates a signature event after all requirements for the event are met.

All signature events are handed off to the Meta engine by the Signature Event Action Processor. The Signature Event Action Processor hands off the event after processing the minimum hits option. Summarization and event action are processed after the Meta engine has processed the component events.

The Meta engine is different from other engines in that it takes alerts as input where most engines take packets as input. Thus, in a Meta engine signature, you must identify the signatures that the Meta signature should be looking for. This list of signatures is contained in the Component list.

The Component list is part of the signature parameters. To edit the parameters, follow the procedure described in Editing Signature Parameters (Tuning Signatures), page 37-18. When you open the Edit Signature Parameters dialog box for a signature that uses the Meta engine, look for the Engine > Component List parameter. The parameter value contains a pencil icon and the word List. Click List to open the Edit Signature Parameter—Component List dialog box.

The dialog box is divided into two lists, an Inactive list (on the left) and an active list (on the right). The active list defines the signatures that the Meta engine signature is looking for.

To modify the components list:

- **Add new components**—Click the Add Entry (+) button to the left of the inactive list. The Add Signature Parameter—List Entry dialog box opens. Configure the following values:
  - **Entry Key**—A name for the component.
  - **Component Sig ID**—The signature ID of the signature you are looking for.
  - **Component SubSig ID**—The subsignature ID; enter 0 if there are no subsignatures.
- **Component Count**—The number of times this signature must fire before the Meta signature is triggered.

- **Is a Not Component**—This field lets you create negative entries; thus, you can identify a list where some signatures must fire, and some signatures must not fire. Select No for signatures that must fire, and Yes for signatures that must not fire.

When you click OK in the Add Signature Parameter—List Entry dialog box, the new component is added to the inactive list. Select it and click the >> button to move it to the active list. Then, use the Up and Down arrow buttons to position the component in the active component list; a third button is available to reset the order to the previously saved order.

- **Edit an existing component**—Select the component (in either list) and click the Edit Entry (pencil) button that is between the lists. The Edit Signature Parameter—List Entry dialog box opens. The parameters are the same as for adding a new entry, except that you cannot change the component name.

- **Delete a component**—Select the component in the inactive list and click the Delete Entry (trash can) button that is to the left of the inactive list. If you want to delete an active component, you must first select it in the active list and click the << button to move it to the inactive list.

- **Restore defaults**—If you want to restore the default values of a component, select it and click Restore.

### Obsoletes Dialog Box

Use the Obsoletes dialog box to identify obsolete signatures associated with a particular signature. In many cases, this information is read-only. In some cases, it is read-write; for example, you can edit the list for IOS IPS signature policies for Local or shared-policy-specific signatures.

If you can edit the list:

- Click the Add Entry (+) button to add the signature and subsignature ID of a signature that is made obsolete by the signature you are editing.

- Select an entry and click the Delete Entry (trash can) button to remove it from the list of obsoleted signatures.

### Navigation Path

The Obsoletes list is part of the signature parameters. To edit the parameters, follow the procedure described in **Editing Signature Parameters (Tuning Signatures)**, page 37-18. When you open the Edit Signature Parameters dialog box, look for the Status > Obsoletes parameter. The parameter value contains a pencil icon and the word Set (when the parameter is not read-only). Click the pencil or word to open the Obsoletes dialog box.
### Configuring Signature Settings

Use the Signature Settings page to define settings for IPS appliances and service modules (but not Cisco IOS IPS devices). These settings define the following policies:

- **Application policy**—Enable or disable HTTP, determine and specify the maximum number of HTTP requests, specify AIC web ports, and enable or disable FTP.
- **Fragment reassembly policy**—Configure the sensor to reassemble a datagram that has been fragmented over more than one packet by selecting the IP reassembly mode.
- **Stream reassembly policy**—Configure the sensor to monitor only TCP sessions that have been established by a complete three-way handshake by specifying whether a TCP handshake is required and by selecting the TCP reassembly mode.
- **IP logging policy**—Configure the sensor to generate an IP session log when the sensor detects an attack by determining and selecting the maximum allowable number of log packets, the IP log time and the maximum allowable size of the IP log.

All of these settings have default values, so configure this policy only if you need to use a non-default value.

To configure the Signature Settings policy, do one of the following:

- (Device view) Select **IPS > Signatures > Settings** from the Policy selector.
- (Policy view) Select **IPS > Signatures > Settings**, then select an existing policy or create a new one.

You can then configure the options that are explained in the following table.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable HTTP</td>
<td>Enables protection for web services. Select Yes to require the sensor to</td>
</tr>
<tr>
<td></td>
<td>inspect HTTP traffic for compliance with the RFC.</td>
</tr>
<tr>
<td>Max HTTP Requests</td>
<td>The maximum number of outstanding HTTP requests per connection.</td>
</tr>
<tr>
<td>AIC Web Ports</td>
<td>The ports on which to look for AIC traffic. Enter a comma-separated list of</td>
</tr>
<tr>
<td></td>
<td>port numbers or port list objects that define the ports. You can click</td>
</tr>
<tr>
<td></td>
<td>Select to select a port list object from a list or to create a new object.</td>
</tr>
<tr>
<td>Enable FTP</td>
<td>Enables protection for FTP services. Select Yes to require the sensor to</td>
</tr>
<tr>
<td></td>
<td>inspect FTP traffic.</td>
</tr>
<tr>
<td>IP Reassembly Mode</td>
<td>The method the sensor uses to reassemble the fragments, based on the</td>
</tr>
<tr>
<td></td>
<td>operating system.</td>
</tr>
<tr>
<td>TCP Handshake Required</td>
<td>Whether the sensor should only track sessions for which the three-way</td>
</tr>
<tr>
<td></td>
<td>handshake is completed.</td>
</tr>
</tbody>
</table>
### Configuring Signature Settings

#### TCP Reassembly Mode
The mode the sensor should use to reassemble TCP sessions with the following options:
- **Asymmetric**—May only be seeing one direction of bidirectional traffic flow. **Note**: Asymmetric mode lets the sensor synchronize state with the flow and maintain inspection for those engines that do not require both directions. Asymmetric mode lowers security because full protection requires both sides of traffic to be seen.
- **Loose**—Use in environments where packets might be dropped.
- **Strict**—If a packet is missed for any reason, all packets after the missed packet are not processed.

<table>
<thead>
<tr>

<td>The maximum number of bytes you want logged.</td>
</tr>
</tbody>
</table>
CHAPTER 38

Configuring Event Action Rules

An IPS event is an IPS message that contains an alert, a block request, a status message, or an error message. An event action is the sensor’s response to an event. An event action happens only if the event is not filtered. Possible event actions are TCP reset, block host, block connection, IP logging, and capturing the alert trigger packet. Event actions were known as alarms in Cisco IPS versions earlier than 5.x.

The IPS Event Actions folder is where you configure settings for the event action processing component of the sensor. These settings define the actions for the sensor to take when an event is detected.

Note

This chapter contains the following topics:

- Understanding the IPS Event Action Process, page 38-1
- Understanding IPS Event Actions, page 38-2
- Configuring Event Action Filters, page 38-5
- Configuring Event Action Overrides, page 38-12
- Configuring IPS Event Action Network Information, page 38-14
- Configuring Settings for Event Actions, page 38-20

Understanding the IPS Event Action Process

The IPS event action rules dictate the actions that the sensor performs when an event occurs. Although each signature is configured with specific actions that should be taken, the actual actions performed also depend on other factors.

Following is the general process that occurs when inspection identifies a signature event:

1. A signature alert occurs with actions specified by the signature. A risk rating for the alert is calculated.

For a detailed explanation of how risk rating is calculated, see Calculating the Risk Rating in Installing and Using Cisco Intrusion Prevention System Device Manager 7.0 on Cisco.com.

You can influence risk ratings by configuring target value ratings and OS mappings; see Configuring IPS Event Action Network Information, page 38-14.
2. The **Event Action Overrides** policy is processed. If the risk rating of the event matches an override rule, the actions identified in the override rule are **added** to the actions defined in the signature. The overrides do not replace the actions specified in the signature.

   For information on configuring overrides, see Configuring Event Action Overrides, page 38-12.

3. The **Event Action Filters** policy is processed. If rules apply to the event, the rules **subtract** actions from the event. Thus, an action you added in a signature policy or override rule might be removed by one of your filter rules.

   For information on creating filter rules, see Configuring Event Action Filters, page 38-5.

4. Event summarization occurs, unless you turn off the summarization feature as described in Configuring Settings for Event Actions, page 38-20.

5. The actions are performed. For an explanation of possible actions, see Edit, Add, Replace Action Dialog Boxes, page 37-8.

6. A list of denied attackers is maintained, and subsequent access prevented, based on configurable settings. To change the default settings, see Configuring Settings for Event Actions, page 38-20.

---

**Understanding IPS Event Actions**

When you configure an event action filter or override, or a signature, you specify an action for events that meet the rule. For signatures and overrides, you are specifying an action to add to the event; for filters, you are specifying an action to remove from the event.

The most common action is Produce Alert, which generates an alert that you can view in your network management system, such as the Security Manager Event Viewer or CS MARS. However, there are a wide variety of actions that you can assign to an event. When looking over the possible actions, keep the following in mind:

- Many actions produce alerts in addition to the other action performed. The description for each action explains whether an alert is also produced.

- Cisco IOS IPS supports fewer actions for event action override or filter rules. The actions supported are Deny Attacker Inline, Deny Connection Inline, Deny Packet Inline, Product Alert, and Reset TCP Connection.

- Not all actions are necessarily available on all combinations of IPS software version and device type. Whenever you need to select an action, only those actions that are valid are available for selection.

- For deny and block actions, use the event actions settings policy to set the period of time for which addresses or packets are denied. For more information, see Configuring Settings for Event Actions, page 38-20.
The following table explains the possible actions.

<table>
<thead>
<tr>
<th>Menu Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deny Attacker Inline</td>
<td>Terminates the current packet and future packets from this attacker address for a specified period of time. The IPS must be operating in inline mode. For Cisco IOS IPS devices, no connection can be established from the attacker to the router until the shun time expires. <strong>Tip</strong> This is the most severe of the deny actions. It denies current and future packets from a single attacker address. For IPS appliances and service modules, you can use the IPS Device Manager to see a list of denied attackers and clear the list if necessary.</td>
</tr>
<tr>
<td>Deny Attacker/Service Pair Inline</td>
<td>Does not transmit this packet and future packets on the attacker address victim port pair for a specified period of time. The IPS must be operating in inline mode.</td>
</tr>
<tr>
<td>Deny Attacker/Victim Pair Inline</td>
<td>Does not transmit this packet and future packets on the attacker/victim address pair for a specified period of time. The IPS must be operating in inline mode.</td>
</tr>
<tr>
<td>Deny Connection Inline</td>
<td>Terminates the current packet and future packets on this TCP flow. Other connections from the attacker can be established. The IPS must be operating in inline mode.</td>
</tr>
<tr>
<td>Deny Packet Inline</td>
<td>Terminates the packet. The IPS must be operating in inline mode. For Cisco IOS IPS devices, this action discards the packet without sending a reset. Cisco recommends using “drop and reset” in conjunction with alarm. <strong>Tip</strong> For IPS appliances and service modules, there is an event action override that adds this action to high risk events. You cannot delete the override. If you do not want to use it, disable the override. For more information, see Configuring Event Action Overrides, page 38-12.</td>
</tr>
<tr>
<td>Log Attacker Packets</td>
<td>Starts IP logging on packets that contain the attacker address and sends an alert. This action causes an alert to be written to the Event Store, even if Produce Alert is not selected.</td>
</tr>
<tr>
<td>Log Pair Packets</td>
<td>Starts IP Logging on packets that contain the attacker/victim address pair. This action causes an alert to be written to the Event Store, even if Produce Alert is not selected.</td>
</tr>
<tr>
<td>Log Victim Packets</td>
<td>Starts IP Logging on packets that contain the victim address and sends an alert. This action causes an alert to be written to the Event Store, even if Produce Alert is not selected.</td>
</tr>
</tbody>
</table>
### Understanding IPS Event Actions

**Related Topics**

User Guide for Cisco Security Manager 4.3

38-4

OL-26838-01
Configuring Event Action Filters

You can configure event action filters to remove specific actions from an event or to discard an entire event and prevent further processing by the sensor.

Filters let the sensor perform certain actions in response to the event without requiring the sensor to perform all actions or remove the entire event. Filters work by removing actions from an event. A filter that removes all actions from an event effectively consumes the event. Before configuring filter rules, read Tips for Managing Event Action Filter Rules, page 38-6.

**Note**

When filtering sweep signatures, we recommend that you do not filter the destination addresses. If there are multiple destination addresses, only the last address is used for matching the filter.

Related Topics

- Understanding the IPS Event Action Process, page 38-1

### Step 1

Do one of the following to open the Event Action Filters policy:

- (Device view) Select **IPS > Event Actions > Event Action Filters** from the Policy selector.
- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Event Action Filters**, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Event Action Filters**, then select an existing policy or create a new one.

The table shows the existing filter rules organized into sections. The Local section is for rules defined specifically for a selected device (in Device view). For shared or inherited policies, there are also sections for mandatory and default rules. For more information about the contents of this policy, see Event Action Filters Page, page 38-7.

### Step 2

Select the row after which you want to create the filter rule and click the **Add Row** button or right-click and select **Add Row**. This opens the Add Filter Item dialog box. For detailed information about the options in this dialog box, see Filter Item Dialog Box, page 38-9.

**Tips**

- If you do not select a row, the new rule is added at the end of the local scope.
- You can also select an existing row and edit either the entire row (by clicking the **Edit Row** button) or specific cells. To edit a specific cell, right-click the cell and select the **Edit** command related to the cell from the top of the context menu.
- You can delete a rule by selecting it and clicking the **Delete Row** button.
- You can export the entire list of filter rules to a comma-separated values (CSV) file. Click **Export to File**, navigate to an appropriate folder on the Security Manager server, change the file name if you do not like the default name, and click **Save**.

### Step 3

Configure the filter rule. Following are the highlights of what you typically need to configure. For specific information on configuring the fields, and for information on fields not mentioned here, see Filter Item Dialog Box, page 38-9.

- **Name**—You must enter a name for the rule. Use a name that is meaningful to you.
- **Signature, Subsignature ID**—If the filter should apply to all signatures, use the default values. If you are targeting a specific signature, enter its signature and subsignature identifiers. You can obtain these values by finding the signature in the Signatures policy (see Signatures Page, page 37-4).
• Attacker and Victim Addresses and Ports—If the filter should apply no matter who is attacking, or who is the victim, use the default values. If you are creating a filter specific to an attacker or victim, update these fields to match the appropriate address and port.

• Risk Rating—You are most likely to want to change this value. The filter is applied to events that are within the minimum-maximum range you configure here. The default value, 0-100, will apply the filter rule to all events. If you configure a specific signature ID, the rating applies only to events for that signature (in which case the default risk rating might be acceptable).

For example, you might want to target only high-risk events, such as 90-100.

• Actions to Subtract—Select the actions that you want to subtract from the event. Use Ctrl+click to select more than one action. If you select an action that is not actually assigned to an event, the filter rule essentially has no effect on the event. For more information about the actions, see Edit, Add, Replace Action Dialog Boxes, page 37-8.

• Stop on Match—Whether to define this filter rule as a stop rule. This setting determines how the remaining rules in the event action filter rules table are processed:
  – If you select this option, and an event meets the conditions of the rule, this rule is the final rule tested for the event. The actions identified by this rule are removed from the event, and the device moves on to perform all remaining actions assigned to the event.
  – If you do not select this option, then events that meet the conditions of this filter rule are also compared to subsequent rules in the event actions filters table. Subsequent rules are tested until either all rules are tested, or the event matches a stop rule.

Click OK when you are finished defining your filter rule.

Step 4
If you did not select the right row before adding the rule, select the new rule and use the up and down arrow buttons to position the rule appropriately. Ensure that stop rules are placed after other rules that you want applied prior to the stop.

Tips for Managing Event Action Filter Rules

Following are some tips that might help you effectively manage your event action filter rules:

• Disabled rules are shown with hash marks covering the table row. To change the enabled/disabled status of a rule, right-click the rule and select Enable or Disable as appropriate. You can also change the status when editing the rule.

  Disabling a rule is useful if you want to stop using the rule, but you might want to start using it again in the future. Disabled rules remain in the table so that you do not need to recreate them.

• For existing rules, you can edit most of the fields directly from the event actions filter rules table by right-clicking the cell and selecting the appropriate Edit command from the top portion of the context menu. For example, you can right-click the Attacker Ports cell and select Edit Attacker Ports.

  Many of these right-click commands open a version of the Edit Filter Item dialog box that contains only the selected property. Other commands simply change a value, or open a sub-menu from which you can select a value to add or remove. For example, right-clicking the Action cell provides four commands:

  – Add to Actions—Select from a list of actions to add to those already defined in the rule.

  – Delete from Actions—Select from a list of actions defined in the rule to remove from the rule.
--- **Replace Actions With**—Select from a list the action that you want to completely replace those defined in the rule.

--- **Edit Actions**—Opens a dialog box where you can select all actions for the rule. Your selection replaces the cell contents.

- Although filter rules are configured as an ordered list, the rules are not processed as a “first match wins” list, even though they are processed and applied top to bottom. Instead, each rule has a Stop property: the rule is either a stop rule or it is not a stop rule. Processing ends only if an event matches a stop rule. If an event matches a non-stop rule, the event is compared to subsequent filter rules. Thus, more than one filter rule can apply to an event. If you decide to create stop rules, ensure that you place them below all other rules that you want processed for an event.

If you define no stop rules, each event is compared to all filter rules, and all matching rules are applied to the event in top-to-bottom order.

- You can inherit event action filter rules policies. Thus, you could configure a shared policy in Policy view that includes filter rules that you want to share among all of your devices, inherit that rule for each device (in Device view), and in Device view configure local filter rules that are unique to each device. For more information on inheriting policies, see:
  - Creating a New Shared Policy, page 5-51
  - Inheritance vs. Assignment, page 5-6
  - Inheriting or Uninheriting Rules, page 5-43

--- **Event Action Filters Page**

Use the Event Actions Filters page to configure event action filter rules. Filter rules can remove specific actions from an event or they can discard an entire event and prevent further processing by the sensor.

Event action filters are processed as an ordered list and you can move filters up or down in the list. Filters let the sensor perform certain actions in response to the event without requiring the sensor to perform all actions or remove the entire event. Filters work by removing actions from an event. A filter that removes all actions from an event effectively consumes the event.

Before configuring event action filter rules, read the following topics:

- Configuring Event Action Filters, page 38-5
- Tips for Managing Event Action Filter Rules, page 38-6
- Understanding the IPS Event Action Process, page 38-1

--- **Tip**

Disabled rules are shown with hash marks covering the table row. To change the enabled/disabled status of a rule, right click the rule and select **Enable** or **Disable** as appropriate. You can also change the status when editing the rule.
Navigation Path

- (Device view) Select **IPS > Event Actions > Event Action Filters** from the Policy selector.

- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Event Action Filters**, then select an existing policy or create a new one.

- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Event Action Filters**, then select an existing policy or create a new one.

### Configuring Event Action Filters

**Chapter 38** Configuring Event Action Rules

**Up Row and Down Row buttons (arrow icons)**

Click these buttons to move the selected rules up or down within a scope. Filter rules are processed in order top to bottom for each event. If the conditions of an event match those defined for a filter, and the filter has the Stop field set to Yes, that filter is applied and no additional filters are considered. Ensure that stop rules are placed after the other rules you want applied to an event. You should order the more restrictive rules before general rules in the table.

**Export to File button**

Click this button to export the event action filters summary to a comma-separated values (CSV) file. You are prompted to select the folder on the Security Manager server and specify a file name.

**Add Row button**

Click this button to add a filter rule to the table after the selected row using the Add Filter Item dialog box (see Filter Item Dialog Box, page 38-9). If you do not select a row, the rule is added at the end of the local scope.

**Edit Row button**

Click this button to edit the selected rule. You can also edit individual cells by right-clicking the cell and selecting the appropriate Edit command.

**Delete Row button**

Click this button to delete the selected rule. Instead of removing the rule, you can right-click the rule and select Disable. This prevents the rule from being used, but leaves it in the table in case you want to use it again at a later time.

---

### Filter Item Dialog Box

Use the Add or Edit Filter Item dialog box to configure an event action filter rule.

**Tip**

For existing rules, you can edit most of these fields directly from the event actions filter rules table by right-clicking the cell and selecting the appropriate command from the top portion of the context menu. For example, you can right-click the Attacker Ports cell and select Edit Attacker Ports. Many of these right-click commands open a version of the Edit Filter Item dialog box that contains only the selected property. When seeking help for these context-editing dialog boxes, look for the property description in the table below.

---

### Navigation Path

From the Event Action Filters page (see Event Action Filters Page, page 38-7), click the Add Row button, or select a filter rule and click the Edit Row button.

</tr>
<tr>
<td>Victim Port</td>
<td>The port of the host being attacked (the recipient of the offending packet). This is the port to which the offending packet was sent. You can also enter a range of ports. The default value is a range of all ports (0-65535).</td>
</tr>
<tr>
<td>Risk Rating Min. and Max.</td>
<td>The risk rating range, between 0 and 100, that should be used to trigger this event action filter. The default value is the complete range (0-100). If an event occurs with a risk rating that falls within the minimum-maximum range you configure here, the event is processed against the rules of this event filter.</td>
</tr>
<tr>
<td>OS Relevance</td>
<td>Indicates whether the alert is relevant to the OS that has been identified for the victim. Possible values include one or more of the following: Not Relevant, Relevant, Unknown. Use Ctrl+click to select multiple values. The default is all values selected. <strong>Note</strong> OS Relevance is applicable only to appliances and service modules running IPS 6.x+ software. For Cisco IOS IPS devices, this field is read-only and cannot be edited, and for IPS 5.x devices, this field is blank.</td>
</tr>
<tr>
<td>Comments</td>
<td>The user comments associated with this filter, such as an explanation of the purpose of the rule.</td>
</tr>
</tbody>
</table>

**Note**: OS Relevance is applicable only to appliances and service modules running IPS 6.x+ software. For Cisco IOS IPS devices, this field is read-only and cannot be edited, and for IPS 5.x devices, this field is blank.
Configuring Event Action Overrides

You can add an event action override to change the actions associated with an event based on the risk rating of that event. Event action overrides are a way to add event actions globally without having to configure each signature individually.

Table 38-3  Filter Item Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Actions to Subtract| The actions that should be removed from the event, should the conditions of the event meet the criteria of the event action filter. You can select one or more actions in this list box. All selected actions are removed from the event. Use Ctrl+click to select multiple values. For more information about the possible actions, see Edit, Add, Replace Action Dialog Boxes, page 37-8. For IOS IPS devices, the possible values are restricted to the following:  
  • Deny Attacker Inline blocks the attacker’s source IP address completely. No connection can be established from the attacker to the router until the shun time expires. You can configure this time in the Event Actions Settings policy as described in Configuring Settings for Event Actions, page 38-20.  
  • Deny Connection Inline blocks the appropriate TCP flow from the attacker. Other connections from the attacker can be established to the router.  
  • Deny Packet Inline discards the packet without sending a reset. Cisco recommends using “drop and reset” in conjunction with alarm.  
  • Produce Alert sends a notification about the attack through syslog or SDEE.  
  • Reset TCP Connection is effective for TCP-based connections and sends a reset to both the source and destination addresses. For example, in case of a half-open SYN attack, Cisco IOS IPS can reset the TCP connections.  
  % to Deny | The percentage of packets to deny for deny attacker features. The range is 0 to 100. The default is 100 percent.  
  Note | For IOS IPS devices, this field is read only and cannot be edited.  
  Stop on Match | Whether to define this filter rule as a stop rule. This setting determines how the remaining rules in the event action filter rules table are processed:  
  • If you select this option, and an event meets the conditions of the rule, this rule is the final rule tested for the event. The actions identified by this rule are removed from the event, and the device moves on to perform all remaining actions assigned to the event.  
  • If you do not select this option, then events that meet the conditions of this filter rule are also compared to subsequent rules in the event actions filters table. Subsequent rules are tested until either all rules are tested, or the event matches a stop rule. |
Each event action has an associated risk rating range. If a signature event occurs and the risk rating for that event falls within the range for an event action, that action is added to the event. For example, if you want any event with a risk rating of 85 or more to generate an SNMP trap, you can create an event action override for Request SNMP Trap with the risk rating 85-100.

Tip
If you want to prevent the use of action overrides, you can disable the entire event action override component as described in Configuring Settings for Event Actions, page 38-20.

Related Topics
- Understanding the IPS Event Action Process, page 38-1

---

**Step 1**
Do one of the following to open the Event Action Overrides policy:
- (Device view) Select **IPS > Event Actions > Event Action Overrides** from the Policy selector.
- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Event Action Overrides**, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Event Action Overrides**, then select an existing policy or create a new one.

The table shows the existing overrides, including the action, the risk rating of the alerts the action will be added to, and whether the rule is enabled. The order of the rules does not matter: all overrides that apply to an alert add the associated actions.

The table can have at most a single entry for each possible action.

**Step 2**
Configure the desired overrides:
- To add a new override, click the **Add Row (+)** button beneath the table and fill in the Add Event Action Override dialog box. In the dialog box, select the action you want to add, enter the rating range of the alerts to which you are adding the action (for example, 90-100), and click **OK**. For more information, see Event Action Override Dialog Box, page 38-14.
  
  The risk rating range must be between 0 and 100. Separate the low and high of the range with a hyphen, for example, 80-90.

  - To edit an override, to disable it or to change the risk rating, select the override and click the **Edit Row (pencil)** button. You cannot change the event action.
  - To remove an override, select it and click the **Delete Row** button.

Note
Policies for IPS appliances and service modules include a default override for Deny Packet Inline, which you cannot delete. If you do not want to use that override, disable it.

- To export the entire list of overrides to a comma-separated values (CSV) file, click **Export to File**, navigate to an appropriate folder on the Security Manager server, change the file name if you do not like the default name, and click **Save**.
Event Action Override Dialog Box

Use the Add or Edit Event Action Override dialog box to configure an event action override that acts globally (rather than per signature) to add actions associated with an event based on the risk rating of that event.

Navigation Path

From the Event Action Overrides policy, click the Add Row button beneath the overrides table, or select a row in the table and click the Edit Row button. For information on opening the Event Action Overrides policy, see Configuring Event Action Overrides, page 38-12.

Field Reference

<td></td>
<td>You cannot edit the action of an existing override rule.</td>
</tr>
<tr>
<td>Enabled</td>
<td>Whether the override rule is enabled. Deselect this option to temporarily disable an override without deleting it.</td>
</tr>
<tr>
<td>Risk Rating</td>
<td>The risk rating range between 0 and 100 that should be used to trigger this event action override. Separate the low and high values with a hyphen, for example, 90-100.</td>
</tr>
<tr>
<td></td>
<td>If an event occurs with a risk rating that falls within the minimum-maximum range, the event action is added to the event.</td>
</tr>
</tbody>
</table>

Configuring IPS Event Action Network Information

Use the Event Actions Network Information policy to configure these features:

- **Target value ratings (IPv4 Target Value Ratings tab and IPv6 Target Value Ratings tab)**—You can configure the target value ratings of your network assets. The sensor uses these ratings when calculating the overall risk rating of an alert. By identifying your mission-critical assets, you can trigger more severe signature event actions. As the names indicate, you can use IPv4 or IPv6 by selecting the appropriate tab.
  
  Target value rating is available on IPS appliances, service modules, and Cisco IOS IPS devices.
  
  For more information, see Configuring Target Value Ratings, page 38-15.

- **Passive OS fingerprinting and OS mappings (OS Identification tab)**—You can enable the sensor to use information about the operating system running on a device to determine the attack relevance rating, which is a component of the overall risk rating.

  Passive OS fingerprinting and OS mappings are available on devices running IPS 6.x+ software only, and are not available on Cisco IOS IPS devices.
For more information, see:
  – Understanding Passive OS Fingerprinting, page 38-17
  – Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only), page 38-18

To open the Network Information policy, do one of the following:

- (Device view) Select **IPS > Event Actions > Network Information** from the Policy selector.
- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Network Information**, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Network Information**, then select an existing policy or create a new one.

---

## Configuring Target Value Ratings

You can assign target value ratings to your network assets. The target value rating is one of the factors used to calculate the risk rating value for each alert. It identifies the perceived importance of a network asset, which you identify by its IP address.

You can develop a security policy that is more stringent for valuable corporate resources and looser for less important resources. For example, you could assign a target value rating to the company web server that is higher than the target value rating you assign to a desktop node. In this example, attacks against the company web server have a higher risk rating than attacks against the desktop node. Events with a higher risk rating trigger more severe signature event actions.

You can configure four value ratings. From highest value to lowest: Mission Critical, High, Medium, Low, No Value (zero value).

For a detailed explanation of how risk rating is calculated, see Calculating the Risk Rating in Installing and Using Cisco Intrusion Prevention System Device Manager 7.0 on Cisco.com.

**Tip**

If you are configuring target value ratings on a device that uses IPS 6.0 software lower than 6.0(5), you might also want to update the OS Identification tab of the Network Information policy to get around a software bug, even if you do not need to create OS maps. For detailed information, see Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only), page 38-18.

---

**Step 1**

Do one of the following to open the Network Information policy:

- (Device view) Select **IPS > Event Actions > Network Information** from the Policy selector, then click the **IPv4 Target Value Ratings** tab or the **IPv6 Target Value Ratings** tab.
- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Network Information**, then select an existing policy or create a new one. Click the **IPv4 Target Value Ratings** tab or the **IPv6 Target Value Ratings** tab.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Network Information**, then select an existing policy or create a new one. Click the **IPv4 Target Value Ratings** tab.
The tab shows the target value ratings that are already configured, showing the IP addresses associated with each configured ratings category. The table can have at most five entries, one per rating category.

**Step 2** Configure the desired target value ratings categories:

- To add a new ratings category, click the **Add Row (+)** button beneath the table and fill in the Add Target Value Rating dialog box. In the dialog box, select the rating you want to add, enter the host, network, and address ranges to associate with the category, and click **OK**. For more information, see **Target Value Rating Dialog Box**, page 38-16.

  For IPv4 addresses, you can specify a single network/host object, or a comma-separated list of host, network, or address ranges, such as 10.10.10.10, 10.10.10.0/24, or 10.10.10.2-10.10.10.254. Addresses that you enter in the network format are converted to address ranges. For IPv6 addresses, use IPv6 addressing conventions.

- To edit the IP addresses in an existing ratings category, select the category and click the **Edit Row (pencil)** button. You cannot change the value rating.

- To remove a rating, select it and click the **Delete Row** button.

---

**Target Value Rating Dialog Box**

Use the Add or Edit Target Value Rating dialog box to associate the IP addresses of your assets to a ratings category. IP addresses are IPv4 when you open the Target Value Rating dialog box from the IPv4 Target Value Ratings tab; they are IPv6 from the IPv6 tab.

**Navigation Path**

From the IPv4 Target Value Rating tab or the IPv6 Target Value Rating tab of the IPS Event Actions Network Information policy, click the **Add Row** button beneath the Target Value Ratings table, or select a row in the table and click the **Edit Row** button. For information on opening the IPv4 Target Value Rating tab or the IPv6 Target Value Rating tab, see **Configuring Target Value Ratings**, page 38-15.

</tr>
</tbody>
</table>
User-configurable OS identification.
You can configure OS host mappings, which take precedence over learned OS mappings.

• Computation of attack relevance rating and risk rating.
The sensor uses OS information to determine the relevance of the attack signature to the targeted host. The attack relevance is the attack relevance rating component of the risk rating value for the attack alert.

There are three sources of OS information. The sensor ranks the sources of OS information in the following order:

1. Configured OS mappings—OS mappings that you enter on the OS Identification tab of the Event Actions Network Information policy. You can configure different mappings for each virtual sensor. For more information, see Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only), page 38-18.
We recommend configuring OS mappings to define the identity of the OS running on critical systems. It is best to configure OS mappings when the OS and IP address of the critical systems are unlikely to change.

2. Imported OS mappings—OS mappings imported from Management Center for Cisco Security Agents (CSA MC).

   Imported OS mappings are global and apply to all virtual sensors. For information on configuring the sensor to use CSA MC, see Configuring the External Product Interface, page 34-23.

3. Learned OS mappings—OS mappings observed by the sensor through the fingerprinting of TCP packets with the SYN control bit set.

   Learned OS mappings are local to the virtual sensor that sees the traffic.

When the sensor needs to determine the OS for a target IP address, it consults the configured OS mappings. If the target IP address is not in the configured OS mappings, the sensor looks in the imported OS mappings. If the target IP address is not in the imported OS mappings, the sensor looks in the learned OS mappings. If it cannot find it there, the sensor treats the OS of the target IP address as unknown.

You can configure Event Action Filter rules to use the OS relevancy value of the target, and configure signatures to identify the OSes vulnerable to a signature.

### Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only)

Use the OS Identification tab on the Event Actions Network Information policy to configure operating system (OS) host mappings, which take precedence over learned OS mappings. On the OS Identifications tab you can add, edit, and delete configured OS maps. You can move them up and down in the list to change the order in which the sensor computes the attack relevance rating and risk rating for that particular IP address and OS type combination.

**Note**

OS Identification applies to IPS 6.0+ sensors only and does not apply to Cisco IOS IPS devices.

You can also move them up and down in the list to change the order in which the sensor resolves the OS associated with a particular IP address. Configured OS mappings allow for ranges, so for network 192.168.1.0/24 you might define the following:

<table>
<thead>
<tr>
<th>IP Address Range Set</th>
<th>OS</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.1.1</td>
<td>IOS</td>
</tr>
<tr>
<td>192.168.1.2-192.168.1.10,192.168.1.25</td>
<td>UNIX</td>
</tr>
<tr>
<td>192.168.1.1-192.168.1.255</td>
<td>Windows</td>
</tr>
</tbody>
</table>

More specific mappings should be at the beginning of the list. Overlap in the IP address range sets is allowed, but the entry closest to the beginning of the list takes precedence.

**Tip**

There is a bug in IPS 6.0 versions lower than 6.0(5) related to the Network Information policy. Even if you change nothing on the OS Identification tab, but you make configuration changes to the Threat Value Ratings tab, Security Manager configures the device to use the any variable for restricting OS mappings to addresses. This can result in your monitoring application showing “any” as the event locality for all events. The solution is to upgrade the IPS version on your sensor. The workaround is to enter a
non-default value in the **Restrict to these IP Addresses** field on the OS Identification tab, even if you are not configuring specific OS mappings. For example, enter 0.0.0.1-255.255.255.255 instead of “any” or 0.0.0.0-255.255.255.255.

**Navigation Path**

- (Device view) Select **IPS > Event Actions > Network Information** from the Policy selector, then click the **OS Identification** tab.

- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Network Information**, then select an existing policy or create a new one. Click the **OS Identification** tab.

<tbody>
<tr>
<td>Enable Passive OS Fingerprinting</td>
<td>When selected, lets the sensor perform passive OS analysis. You must enable this option for any of the maps configured on this page to be used. Passive OS fingerprinting functions as part of the sensor. As the sensor analyzes network traffic between hosts, the sensor stores the identity of the OS running on the hosts alongside the IP addresses of the hosts. The sensor determines the identity of the OSes on the hosts by inspecting characteristics of the packets exchanged on the network. The sensor then uses the target system’s OS information to compute the ARR (Attack Relevance Rating) component for the RR (Risk Rating). The RR can then be used to drop suspicious packets. For more information about passive OS fingerprinting, see Understanding Passive OS Fingerprinting, page 38-17.</td>
</tr>
</tbody>
</table>
| Restricted to these IP Addresses | Restricts attack relevance rating calculation to the specified addresses. You can specify addresses using the following techniques:
- Enter the name of a single network/host object, or click **Select** to select an object from a list or to create a new one. The object can contain a group of networks, hosts, and address ranges.
- A comma-separated list of host or network addresses or address ranges. For example, 10.10.10.0/24, 10.10.10.10, 10.10.10.2-10.10.254. |
| OS Maps table | The list of OS mappings, showing the IP addresses of the hosts and the operating systems to which they are mapped. When looking for a match, the sensor goes from top to bottom and selects the first rule that matches the IP address.
- To add a mapping, click the **Add Row** button and fill in the Add OS Map dialog box (see OS Map Dialog Box, page 38-20).
- To edit a mapping, select the rule and click the **Edit Row** button.
- To delete a map, select it and click the **Delete Row** button.
- To change the priority of a rule, select it and click the **Up** or **Down** arrow buttons until the rule is positioned correctly. |
Chapter 38      Configuring Event Action Rules

OS Map Dialog Box

Use the Add or Edit OS Map dialog box to map a host through its IP address to an OS type. Create mappings only if you want to statically assign an OS type to an IP address. Because the sensor uses passive OS fingerprinting to discover the OS associated with an IP address, you might not want to create any mappings, or create mappings only for mission-critical devices that have static IP addresses. Update any mappings that you create if you install devices with different operating systems on the address.

Navigation Path

From the OS Identification tab of the IPS Event Actions Network Information policy, click the Add Row button beneath the OS Maps table, or select a row in the table and click the Edit Row button. For information on opening the OS Identification tab, see Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only), page 38-18.

Field Reference

Table 38-7 OS Map Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Addresses</td>
<td>The IP addresses for this mapping. You can specify addresses using the following techniques:</td>
</tr>
<tr>
<td></td>
<td>• Enter the name of a single network/host object, or click Select to select an object from a list or to create a new one. The object can contain a group of networks, hosts, and address ranges.</td>
</tr>
<tr>
<td></td>
<td>• A comma-separated list of host or network addresses or address ranges. For example, 10.10.10.0/24, 10.10.10.10, 10.10.10.2-10.10.10.254.</td>
</tr>
<tr>
<td>OS Type</td>
<td>The operating system running on the identified hosts. Select the most appropriate option from the list. You can select multiple options (using Ctrl+click) to indicate that there is more than one possible OS.</td>
</tr>
</tbody>
</table>

Tip

Because these mappings take precedence over learned mappings, you probably are better off not assigning General OS, Other, or Unknown OS. The sensor might be able to learn the actual OS through passive OS fingerprinting and provide a better matching. For more information, see Understanding Passive OS Fingerprinting, page 38-17.

Configuring Settings for Event Actions

Use the Event Actions Settings policy to configure general settings that apply globally to event action rules. The defaults for these options are appropriate for most situations, so change them only if you are certain that your situation requires non-default behavior.

To configure the Event Actions Settings policy, do one of the following:

• (Device view) Select IPS > Event Actions > Settings from the Policy selector.
• (Policy view, IPS appliances and service modules) Select IPS > Event Actions > Settings, then select an existing policy or create a new one.
• (Policy view, Cisco IOS IPS devices) Select IPS (Router) > Event Actions > Event Action Settings, then select an existing policy or create a new one.
The following table describes the options you can configure. Note that the options available for Cisco IOS IPS devices are more limited than those available for IPS appliances and service modules.

Table 38-8  Event Actions Settings Policy

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Event Action Override</td>
<td>When selected, enables override rules as defined on the Event Action Overrides page. You can add an event action override to add actions to an event based on specific details about that event. For configuring override rules, see Configuring Event Action Overrides, page 38-12.</td>
</tr>
<tr>
<td>(All device types.)</td>
<td></td>
</tr>
<tr>
<td>Enable Event Action Filters</td>
<td>When selected, enables the filter rules as defined on the Event Action Filters page. You can configure event action filters to remove specific actions from an event or to discard an entire event and prevent further processing by the sensor. For configuring event action filters rules, see Configuring Event Action Filters, page 38-5.</td>
</tr>
<tr>
<td>(All device types.)</td>
<td></td>
</tr>
<tr>
<td>Enable Event Action Summarizer</td>
<td>When selected, enables the Summarizer component. The Summarizer groups events into a single alert, thus decreasing the number of alerts the sensor sends out.</td>
</tr>
<tr>
<td>(IPS appliances and service modules only.)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>By default, the Summarizer is enabled. If you disable it, all signatures are set to Fire All with no summarization. If you configure individual signatures to summarize, this configuration is ignored when the Summarizer is not enabled.</td>
</tr>
<tr>
<td></td>
<td>The Report Manager component of Cisco Security Manager reports events individually. The Event Viewer component of Cisco Security Manager displays alerts. As stated above, the Summarizer groups events into a single alert, thus decreasing the number of alerts the sensor sends out.</td>
</tr>
</tbody>
</table>
|                              | Tip  
Cisco IPS Manager Express (IME) and Cisco Security Manager do not summarize events in precisely the same way.                                                                                       |
| Enable Meta Event Generator  | When selected, enables the Meta Event Generator. The Meta Event Generator processes the component events, which lets the sensor watch for suspicious activity transpiring over a series of events. |
| (IPS appliances and service modules only.) |                                                                                                                                                                                                             |
|                              | By default, the Meta Event Generator is enabled. If you disable the Meta Event Generator, all Meta engine signatures are disabled.                                                                         |
### Table 38-8 Event Actions Settings Policy (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Enable Threat Rating Adjustment              | When selected, enables threat rating adjustment, which adjusts the risk rating. If disabled, risk rating is equal to threat rating. Available in sensors running IPS 6.0+ software only. The Threat Rating feature provides a single view of the threat environment of the network. Threat Rating minimizes alarms and events through a customized view that shows only events with a high Threat Rating value. The Threat Rating value is derived as follows:  
  - Dynamic adjustment of event Risk Rating based on success of response action  
  - If response action was applied, Risk Rating is deprecated (Threat Rating < Risk Rating)  
  - If response action was not applied, Risk Rating remains unchanged (Threat Rating = Risk Rating)  
  The result is a single value by which the threat risk is determined. |
| Deny Attacker Duration in seconds            | The number of seconds to deny the attacker inline. The range is 0 to 518400. The default is 3600. |
| Block Attack Duration in minutes             | The number of minutes to block a host or connection. The range is 0 to 10000000. The default is 30. |
| Maximum Number of Denied Attackers          | Limits the number of denied attackers possible in the system at any one time. The range is 0 to 100000000. The default is 10000. |
| Enable One Way TCP Reset                     | When selected, enables a one-way TCP reset for deny packet inline actions for TCP-based alerts. Available only for sensors running IPS 6.1+ software. The one-way TCP reset operates for inline mode only and is an automatic addition to the deny packet inline actions. It sends a TCP reset to the victim of the alert, thus creating a black hole for the attacker and clearing the TCP resources of the victim. |

### Tips
- In inline mode, all packets entering or leaving the network must pass through the sensor.
- An inline sensor denies packets for any alert with a risk rating of greater than or equal to 90. It also issues a one-way TCP reset on TCP alerts with a risk rating of greater than or equal to 90.
Managing IPS Anomaly Detection

Anomaly detection is designed to recognize network congestion caused by worm traffic that exhibits scanning behavior. Anomaly detection also will identify infected hosts on the network that are scanning for other vulnerable hosts.

Anomaly detection is enabled by default, but there are some configuration settings you should adjust to use it effectively.

Note

The sensor must use IPS software version 6.x or higher to configure anomaly detection. In addition, Cisco IOS IPS and the AIP-SSC-5 do not support anomaly detection.

This chapter contains the following topics:

- Understanding Anomaly Detection, page 39-1
- Configuring Anomaly Detection, page 39-6

Understanding Anomaly Detection

The anomaly detection component of the sensor detects worm-infected hosts. This enables the sensor to be less dependent on signature updates for protection against worms and scanners, such as Code Red and SQL Slammer and so forth. The anomaly detection component lets the sensor learn normal activity and send alerts or take dynamic response actions for behavior that deviates from what it has learned as normal behavior.

Note

Anomaly detection does not detect email-based worms, such as Nimda.

Anomaly detection detects the following two situations:

- When the network starts on the path of becoming congested by worm traffic.
- When a single worm-infected source enters the network and starts scanning for other vulnerable hosts.

The following topics explain anomaly detection in more detail:

- Worm Viruses, page 39-2
- Anomaly Detection Modes, page 39-2
- Anomaly Detection Zones, page 39-3
Worm Viruses

Worm viruses are automated, self-propagating, intrusion agents that make copies of themselves and then facilitate their spread. Worm viruses attack a vulnerable host, infect it, and then use it as a base to attack other vulnerable hosts. They search for other hosts by using a form of network inspection, typically a scan, and then propagate to the next target. A scanning worm virus locates vulnerable hosts by generating a list of IP addresses to probe, and then contacts the hosts. Code Red worm, Sasser worm, Blaster worm, and the Slammer worm are examples of worms that spread in this manner.

Anomaly detection identifies worm-infected hosts by their behavior as a scanner. To spread, a worm virus must find new hosts. It finds them by scanning the Internet using TCP, UDP, and other protocols to generate unsuccessful attempts to access different destination IP addresses. A scanner is defined as a source IP address that generates events on the same destination port (in TCP and UDP) for too many destination IP addresses.

The events that are important for TCP are non-established connections, such as a SYN packet that does not have its SYN-ACK response for a given amount of time. A worm-infected host that scans using TCP generates non-established connections on the same destination port for an anomalous number of IP addresses.

The events that are important for UDP are unidirectional connections, such as a UDP connection where all packets are going in only one direction. A worm-infected host that scans using UDP generates UDP packets but does not receive UDP packets on the same IP address within a time-out period on the same destination port for multiple destination IP addresses.

The events that are important for other protocols, such as ICMP (protocol number 1), are from a source IP address to many different destination IP addresses, that is, packets that are received in only one direction.

---

Caution

If a worm virus has a list of IP addresses it should infect and does not have to use scanning to spread itself (for example, it uses passive mapping—listening to the network as opposed to active scanning), it will not be detected by anomaly detection worm policies. Worm viruses that receive a mailing list from probing files within the infected host and email this list will not be detected, because no Layer 3 or Layer 4 anomaly is generated.

Anomaly Detection Modes

Anomaly detection initially conducts a “peacetime” learning process when the most normal state of the network is reflected. Anomaly detection then derives a set of policy thresholds that best fit the normal network. This is done in two phases: an initial learning mode phase, followed by the ongoing operational detect mode phase.
Anomaly detection has the following modes:

- **Learning accept mode (initial setup)**

  Although anomaly detection is in detect mode by default, it conducts an initial learning accept mode for the default period of 24 hours. We assume that during this phase no attack is being carried out. Anomaly detection creates an initial baseline, known as a knowledge base, of the network traffic. The default interval value for periodic schedules is 24 hours and the default action is rotate, meaning that a new knowledge base is saved and loaded, and then replaces the initial knowledge base after 24 hours.

Keep the following in mind:

- Anomaly detection does not detect attacks when working with the initial knowledge base, which is empty. After the default of 24 hours, a knowledge base is saved and loaded and now anomaly detection also detects attacks.

- Depending on your network complexity, you may want to have anomaly detection in learning accept mode for longer than the default 24 hours. You configure the mode in the Virtual Sensors policy; see Defining A Virtual Sensor, page 36-5. After your learning period has finished, edit the virtual sensor and change the mode to Detect.

- **Detect mode**

  For ongoing operation, the sensor should remain in detect mode. This is for 24 hours a day, 7 days a week. Once a knowledge base is created and replaces the initial knowledge base, anomaly detection detects attacks based on it. It looks at the network traffic flows that violate thresholds in the knowledge base and sends alerts. As anomaly detection looks for anomalies, it also records gradual changes to the knowledge base that do not violate the thresholds and thus creates a new knowledge base. The new knowledge base is periodically saved and takes the place of the old one thus maintaining an up-to-date knowledge base.

- **Inactive mode**

  You can turn anomaly detection off by putting it in inactive mode. Under certain circumstances, anomaly detection should be in inactive mode, for example, if the sensor is running in an asymmetric environment. Because anomaly detection assumes it gets traffic from both directions, if the sensor is configured to see only one direction of traffic, anomaly detection identifies all traffic as having incomplete connections, that is, as scanners, and sends alerts for all traffic flows.

The following example summarizes the default anomaly detection configuration. If you add a virtual sensor at 11:00 pm and do not change the default anomaly detection configuration, anomaly detection begins working with the initial knowledge base and only performs learning. Although it is in detect mode, it cannot detect attacks until it has gathered information for 24 hours and replaced the initial knowledge base. At the first start time (10:00 am by default), and the first interval (24 hours by default), the learning results are saved to a new knowledge base and this knowledge base is loaded and replaces the initial knowledge base. Because the anomaly detection is in detect mode by default, now that anomaly detection has a new knowledge base, the anomaly detection begins to detect attacks.

### Anomaly Detection Zones

By subdividing the network into zones, you can achieve a lower false negative rate. A zone is a set of destination IP addresses. There are three zones, each with its own thresholds: internal, illegal, and external.

The external zone is the default zone with the default Internet range of 0.0.0.0-255.255.255.255. By default, the internal and illegal zones contain no IP addresses. Packets that do not match the set of IP addresses in the internal or illegal zone are handled by the external zone.
We recommend that you configure the internal zone with the IP address range of your internal network. If you configure it in this way, the internal zone is all the traffic that comes to your IP address range, and the external zone is all the traffic that goes to the Internet.

You can configure the illegal zone with IP address ranges that should never be seen in normal traffic, for example, unallocated IP addresses or part of your internal IP address range that is unoccupied. An illegal zone can be very helpful for accurate detection, because we do not expect any legal traffic to reach this zone. This allows very low thresholds, which in turn can lead to very quick worm virus detection.

### Knowing When to Turn Off Anomaly Detection

Anomaly detection assumes that it gets traffic from both directions. If the sensor is configured to see only one direction of traffic, you should turn off anomaly detection. Otherwise, when anomaly detection is running in an asymmetric environment, it identifies all traffic as having incomplete connections, that is, as scanners, and sends alerts for all traffic flows.

You turn off anomaly detection in the Virtual Sensors policy. Edit the virtual sensor for which you are disabling anomaly detection, and change the Anomaly Detection Mode to Inactive. For information on editing virtual sensors, see Editing Policies for a Virtual Sensor, page 36-9.

### Configuring Anomaly Detection Signatures

The Traffic Anomaly engine contains nine anomaly detection signatures covering three protocols (TCP, UDP, and other). Each signature has two subsignatures, one for the scanner and the other for the worm-infected host (or a scanner under worm attack). When anomaly detection discovers an anomaly, it triggers an alert for these signatures. All anomaly detection signatures are enabled by default and the alert severity for each one is set to high.

When a scanner is detected but no histogram anomaly occurred, the scanner signature fires for that attacker (scanner) IP address. If the histogram signature is triggered, the attacker addresses that are doing the scanning each trigger the worm signature (instead of the scanner signature). The alert details state which threshold is being used for the worm detection now that the histogram has been triggered. From that point on, all scanners are detected as worm-infected hosts.

The following anomaly detection event actions are possible:

- Produce alert—Writes the event to the Event Store.
- Deny attacker inline—(Inline only) Does not transmit this packet and future packets originating from the attacker address for a specified period of time.
- Log attacker packets—Starts IP logging for packets that contain the attacker address.
- Deny attacker service pair inline—Blocks the source IP address and the destination port.
- Request SNMP trap—Sends a trap notification to an SNMP trap destination. To use this action, you must configure SNMP trap hosts as described in Configuring SNMP, page 34-8.
- Request block host—Sends a request to ARC to block this host (the attacker). To use this action, you must configure blocking devices as described in Configuring IPS Blocking and Rate Limiting, page 41-7.

You can add actions to the signatures either directly, in the Signatures policy, or to events generated by the signatures based on risk rating in the Event Actions Overrides policy.
The following table lists the anomaly detection worm signatures.

<table>
<thead>
<tr>
<th>Signature ID</th>
<th>Subsignature ID</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
Configuring Anomaly Detection

Use the Anomaly Detection policy to configure anomaly detection settings. The Virtual Sensors policy also contains a setting important for anomaly detection.

This procedure explains the overall configuration of anomaly detection. Before configuring these settings, read the following topics:

- Understanding Anomaly Detection, page 39-1
- Worm Viruses, page 39-2
- Anomaly Detection Modes, page 39-2
- Anomaly Detection Zones, page 39-3
- Knowing When to Turn Off Anomaly Detection, page 39-4
- Configuring Anomaly Detection Signatures, page 39-4

**Step 1**

Do one of the following to open the Anomaly Detection policy you want to modify:

- (Device view) Select IPS > Anomaly Detection from the Policy selector.
- (Policy view) Select IPS > Anomaly Detection from the Policy selector. Select an existing policy or create a new one.

The Anomaly detection policy includes these tabs:

- **Operation Settings**—Defines the worm timeout and identifies any IP addresses that should be ignored by anomaly detection.
- **Learning Accept Mode**—The configuration for learning mode, including how the knowledge base is handled.
- **Internal Zone, Illegal Zone, External Zone**—The zones of your network that you define. You can configure unique settings for each zone. For an explanation of the zones, see Anomaly Detection Zones, page 39-3.

### Table 39-1 Anomaly Detection Worm Signatures (Continued)

<table>
<thead>
<tr>
<th>Signature ID</th>
<th>Subsignature ID</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Identified a worm attack over an Other protocol in the illegal zone; the Other histogram threshold was crossed and a scanner over an Other protocol was identified.</td>
</tr>
</tbody>
</table>
Chapter 39      Managing IPS Anomaly Detection

Configuring Anomaly Detection

Step 2 Click the **Operation Settings** tab, if necessary, and configure the following:

- **Worm Timeout**—The time in seconds for the worm termination timeout. The range is 120 to 10,000,000 seconds. The default is 600 seconds. For an explanation of how this timeout is used, see **Understanding Anomaly Detection Thre sholds and Histograms**, page 39-10.

- **Enable Ignored Addresses and Source/Destination Addresses to Ignore**—Whether you are configuring a list of addresses that should be ignored while anomaly detection is processing. You can specify a list of source addresses (those that initiate a scan) or destination addresses (the hosts that are scanned).

  The addresses can be single host (such as 10.100.10.1), a range of addresses (such as 10.100.10.0-10.100.10.255), or network/host objects that contain single hosts, address ranges, or a combination of hosts and ranges. Click **Select** to select objects from a list or to create new objects.

Step 3 Click the **Learning Accept Mode** tab and define how the knowledge base will be generated and used. For detailed information, see **Configuring Anomaly Detection Learning Accept Mode**, page 39-8.

Step 4 Configure the internal, illegal, and external zones:

- Define the internal and illegal zones—The internal zones are the IP addresses of your internal network, the network that you manage. The illegal zone should represent IP address ranges that should never be seen in normal traffic, for example, unallocated IP addresses or part of your internal IP address range that is unoccupied.

  Click the **Internal Zone** and **Illegal Zone** tabs in turn and configure the following on the **General** tab:

    - **Enable this zone**—Whether the zone will be processed by anomaly detection.
    - **Service Subnets**—The IP addresses that comprise the zone. The default (0.0.0.0) is that no address is included in the zone. Replace 0.0.0.0 to define addresses for the zone.

      The addresses can be single host (such as 10.100.10.1), a range of addresses (such as 10.100.10.0-10.100.10.255), or network/host objects that contain single hosts, address ranges, or a combination of hosts and ranges. Click **Select** to select objects from a list or to create new objects.

- Decide whether to enable the external zone—The external zone comprises all IP addresses that are not configured for the internal or illegal zones. You do not explicitly assign addresses to this zone. On the **External Zone** tab, **General** sub-tab, you can enable or disable the zone using the **Enable this zone** checkbox. The external zone is enabled by default.

- Configure scanner thresholds and histograms—Each zone has sub-tabs for TCP Protocol, UDP Protocol, and Other Protocols. On these tabs, you can configure non-default settings for specific services that override the learned histograms. For detailed information about configuring these settings, see **Configuring Anomaly Detection Thresholds and Histograms**, page 39-11.

At this point, you have finished configuring the basic anomaly detection settings.

Step 5 (Device view only.) Configure the anomaly detection mode. This setting is defined in the **Virtual Sensors** policy. Consider the following tips to select the correct policy:

- If you configured the anomaly detection policy on a virtual sensor (other than vs0, which is represented by the parent IPS device), you must select the parent IPS device, then select the Virtual Sensors policy.

- If you configured the Anomaly Detection policy as a shared policy in Policy view, select the IPS device to which the policy is assigned, or that hosts a virtual sensor to which the policy is assigned.
Then, complete the following steps in the Virtual Sensors policy:

a. Select the desired virtual sensor in the table and click the **Edit Row** button.

b. In the Modify Virtual Sensors dialog box, select the appropriate option for the Anomaly Detection Mode setting: Detect, Inactive, Learn. The default and normal operational mode is Detect. However, if you are using asymmetric normalizer mode, you might want to set the anomaly detection mode to Inactive. For detailed information about these modes, see Anomaly Detection Modes, page 39-2. For information about the other settings in this dialog box, see Virtual Sensor Dialog Box, page 36-7.

c. If you placed anomaly detection in Learning mode, remember to change the mode to Detect after the desired learning period has completed.

**Step 6**
Add additional actions to the anomaly detection signatures, if desired. For example, you might want to add a deny action so that attacks are dropped. You can alternatively configure event action overrides to add actions based on risk rating. For more information, see Configuring Anomaly Detection Signatures, page 39-4.

**Step 7**
Manage the knowledge base, if necessary.

If you configured the knowledge base to automatically rotate (on the Learning Accept Mode tab), then the knowledge base is refreshed automatically and manual intervention is not necessary.

If you configured anomaly detection to only save new databases, and not use them, then you need to manually load updated knowledge bases periodically. You cannot do this in Security Manager; use the IPS Device Manager (IDM) instead.

Using IDM (or IME), you can load, delete, and rename knowledge bases, and upload them to or download them from an external server. For more information about what you can do, see the online help for IDM or IME.

---

**Configuring Anomaly Detection Learning Accept Mode**

Use the Learning Accept Mode tab of the Anomaly Detection policy to configure whether you want the sensor to create a new knowledge base every so many hours. You can configure whether the knowledge base is created and loaded (Rotate) or saved (Save Only). You can schedule how often and when the knowledge base is loaded or saved.

The default generated filename is YYYY-Mon-dd-hh_mm_ss (that is, year-month-day-hour_minute_second), where Mon is a three-letter abbreviation of the current month.

The knowledge base has a tree structure and contains the following information:

- Knowledge base name
- Zone name
- Protocol
- Service

The knowledge base holds a scanner threshold and a histogram for each service. If you have learning accept mode set to automatic and the action set to rotate, a new knowledge base is created every 24 hours and used in the next 24 hours. If you have learning accept mode set to automatic and the action is set to save only, a new knowledge base is created but not loaded, and the current knowledge base is used. If you do not have learning accept mode set to automatic, no knowledge base is created.
Tip
Although you can use Security Manager to configure how knowledge bases are generated, you cannot manage the knowledge bases themselves. Use the IPS Device Manager (IDM), or IPS Manager Express (IME) instead. Using IDM (or IME), you can load, delete, and rename knowledge bases, and upload them to or download them from an external server. For more information about what you can do, see the online help for IDM or IME.

Related Topics
- Anomaly Detection Modes, page 39-2
- Configuring Anomaly Detection, page 39-6
- Understanding Anomaly Detection Thresholds and Histograms, page 39-10

Step 1
Do one of the following to open the Anomaly Detection policy you want to modify:
- (Device view) Select IPS > Anomaly Detection from the Policy selector.
- (Policy view) Select IPS > Anomaly Detection from the Policy selector. Select an existing policy or create a new one.

Step 2
Click the Learning Accept Mode tab and configure the following options:
- Automatically accept learning knowledge base—Whether to have the sensor automatically update the knowledge base. If you do not select this option, anomaly detection does not automatically create a new knowledge base, and you cannot configure the other options on this tab.
- Action—Whether to rotate or save the knowledge base when it is created.
  If you choose Rotate (the default), the new knowledge base is created and loaded according to the schedule you define. If you choose Save Only, the new knowledge base is created but not loaded. You can examine it and decide whether to load it into anomaly detection using IDM or IME.

Step 3
In the Schedule field, select the schedule for generating a new knowledge base. The default schedule is periodic starting at 10 AM and running for 24 hours. Options are:
- Periodic—Base the schedule on a recurring period. Configure the following options:
  - Start Time—The starting time for the learning window in hh:mm:ss format (24-hour clock).
  - Learning Interval in hours—How long you want anomaly detection to learn from the network before creating a new knowledge base.
- Calendar Schedule—Base the schedule on specific times of day and days of the week. The dialog box changes to show Time of Day and Days of the Week tables. These times apply to every day selected; you cannot specify different times for different days.
  - To add a time or day, click the Add Row (+) button beneath the appropriate table. The time is in hh:mm:ss format (24-hour clock). For day, select the day from the list.
  - To edit an existing time or day, select it and click the Edit Row (pencil) button.
  - To delete a time or day, select it and click the Delete Row (trash can) button. Ensure that you have at least one time and one day configured.
Chapter 39  Managing IPS Anomaly Detection

Understanding Anomaly Detection Thresholds and Histograms

Anomaly detection uses thresholds and histograms to determine if scanning behavior is an attack.

During learning mode, anomaly detection develops histograms for each TCP and UDP port, and for other protocols, to create a baseline of the normal behavior of your network (see Anomaly Detection Modes, page 39-2). For example, the histogram for a TCP port lists the “normal” number of source addresses that make incomplete connections to a certain number of destination addresses during a minute. The histograms contain three buckets: low number of destination addresses (5), medium number (20), and high number (100). (The destination buckets are a fixed number.) Separate histograms are kept for each service and zone (see Anomaly Detection Zones, page 39-3).

For example, learning mode might develop the following histogram for TCP port 80:

<table>
<thead>
<tr>
<th>Number of Destination Addresses</th>
<th>Number of Source Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low (5)</td>
<td>18</td>
</tr>
<tr>
<td>Medium (20)</td>
<td>6</td>
</tr>
<tr>
<td>High (100)</td>
<td>2</td>
</tr>
</tbody>
</table>

In addition to these learned histograms, the anomaly detection scanner has a threshold setting that you configure. You configure a general scanner threshold, and you can override the threshold (configuring a different value) for any specific service (TCP port, UDP port, or other protocol). Each zone has its own thresholds.

When anomaly detection moves to detect mode, where it is actively scanning for worms, the thresholds and histograms are used as follows:

- Histograms are ignored until the threshold for the service is exceeded. For example, consider the above table for TCP/80 traffic. If the threshold is set at 200 (the default), a scanner must scan 200 hosts in a minute to trigger a scanner alert. If 7 source addresses scanned 50 hosts (which is an anomaly in the histogram, which expects no more than 6 hosts scanning 20-99 destinations), but a single scanner scanned only 100 addresses, no alert is generated, and no anomaly is detected.
- When the scanner threshold is exceeded, anomaly detection uses the histogram to determine if the service is under worm attack. In this example, if a source scans more than 200 destinations, anomaly detection evaluates the collected activity in the network. Because 7 hosts have scanned 50 hosts, a worm alert is generated.

When under worm attack, anomaly detection stops learning and clears the current learning information. It also temporarily lowers the thresholds.

- When a worm attack is detected, the worm timeout counter is started. When the timeout is reached, the scanner is reset. If the worm attack continues, new alerts are generated. You configure the worm timeout on the Operation Settings tab of the Anomaly Detection policy.

If you leave the defaults in place, anomaly detection generates histograms based on what it learns about your network from the network’s actual behavior. However, if you understand your network you can fine-tune these histograms to reduce false positives, creating your own definition of expected (or desired or tolerated) behavior for each TCP/UDP port or other protocol, for each zone. You can create your own histograms for only those services that interest you, and leave the defaults for all other ports.

Additionally, you can configure the general scanner threshold for each zone, and configure different thresholds for specific services.

For information on configuring thresholds and histograms, see Configuring Anomaly Detection Thresholds and Histograms, page 39-11.
Chapter 39  Managing IPS Anomaly Detection

Configuring Anomaly Detection Thresholds and Histograms

Anomaly detection uses thresholds and histograms to determine if scanning behavior is an attack. In most cases, you can use the default thresholds and the histograms that anomaly detection generates during learning mode (see Anomaly Detection Modes, page 39-2). However, you might want to fine-tune these settings. Changing the thresholds is a more likely change than creating your own histograms.

Before you configure these settings, read Understanding Anomaly Detection Thresholds and Histograms, page 39-10. You must understand how thresholds and histograms are used together to configure them.

Step 1  Do one of the following to open the Anomaly Detection policy you want to modify:

- (Device view) Select IPS > Anomaly Detection from the Policy selector.
- (Policy view) Select IPS > Anomaly Detection from the Policy selector. Select an existing policy or create a new one.

Step 2  Click the tab for the zone whose thresholds or histograms you want to change. You configure separate values for each zone: Internal Zone, Illegal Zone, External Zone. For an explanation of the zones, see Anomaly Detection Zones, page 39-3.

The tabs for each zone contain four sub-tabs: General, TCP Protocol, UDP Protocol, and Other Protocols. The General tab defines the IP addresses for the zone and whether the zone is enabled (the External zone includes all IP addresses not specified for the other zones, you do not configure specific addresses for the External zone).

The other tabs are where you define thresholds and histograms.

Step 3  Select the tab for the protocol for which you want to modify thresholds or histograms: TCP Protocol, UDP Protocol, Other Protocol.

On each tab, configure the following options:

- Enabled—Whether anomaly detection is enabled for the protocol. You can turn off detection for all of TCP, UDP, or for all non-TCP/UDP protocols with this option. If you deselect the option, any other settings configured on the tab are ignored.

- Destination Port Map or Protocol Number Map table—This table lists the TCP/UDP ports, or other protocols, for which you are configuring non-default mappings. By default, all ports and protocols are enabled and use the default scanner threshold.

Add items to this table only if you want to: disable detection for a port or protocol; set a different threshold value for a port or protocol; or configure an explicit histogram for a port or protocol, which will be used instead of the learned histogram.

- To add a mapping, click the Add Row (+) button and fill in the Add Dest or Protocol Map dialog box. For detailed information, see Dest Port or Protocol Map Dialog Box, page 39-12.

- To edit a mapping, select it and click the Edit Row (pencil) button.

- To delete a mapping, select it and click the Delete Row (trash can) button. Deleting a mapping returns the service to the default settings.

- Scanner Threshold—The threshold for all TCP, UDP, or other protocols. This threshold is used for all services except those for which you configured a scanner override in the mapping table. The range is 5 to 1000. The default is 200.

- Threshold Histogram—The default histogram for all TCP, UDP, or other protocols. This histogram is used for all services except those for which you configured a scanner override in the mapping table.
Chapter 39      Managing IPS Anomaly Detection

Configuring Anomaly Detection

Step 4
Repeat the process for each combination of zone and protocol for which you are defining non-default settings.

Dest Port or Protocol Map Dialog Box

Use the Add or Modify Dest Port Map dialog box to add or modify destination port scanner settings for TCP or UDP, and the Add or Modify Protocol Map dialog box to add or modify scanner settings for other protocols.

Before you configure these settings, read the following topics:

- Understanding Anomaly Detection Thresholds and Histograms, page 39-10
- Configuring Anomaly Detection Thresholds and Histograms, page 39-11

Tip
You do not need to add a port or protocol to have anomaly detection look for worm attacks against it. By default, all ports and protocols are processed. You need to configure specific settings only if you want to turn off detection on a specific port or protocol, or if you want non-default thresholds or histograms.

Navigation Path
In the Anomaly Detection policy, on the TCP Protocol, UDP Protocol, or Other Protocol sub tabs on the Internal Zone, Illegal Zone, or External Zone tabs, click the Add Row button beneath the Destination Port Map or Protocol Number Map tables, or select a row and click the Edit Row button. For more information on the steps required to get here, see Configuring Anomaly Detection Thresholds and Histograms, page 39-11.

<td>• To add a threshold, click the <strong>Add Row</strong> button and fill in the Histogram Dialog Box, page 39-13. The Add button is disabled if you already have three rows.</td>
</tr>
<tr>
<td></td>
<td>• To edit a threshold, select it and click the <strong>Edit Row</strong> button. You cannot change the destination bucket to one that is already defined in the table.</td>
</tr>
<tr>
<td></td>
<td>• To delete a threshold, select it and click the <strong>Delete Row</strong> button. Any buckets not included in the table use the default histogram for the bucket.</td>
</tr>
</tbody>
</table>

**Histogram Dialog Box**

Use the Histogram dialog box to create or modify entries in a histogram. The histograms you create or modify override the default histograms that anomaly detection generates. For detailed information about how these histograms are used, see:

- Understanding Anomaly Detection Thresholds and Histograms, page 39-10
- Configuring Anomaly Detection Thresholds and Histograms, page 39-11

**Navigation Path**

Do one of the following from the Anomaly Detection policy (see Configuring Anomaly Detection, page 39-6):

- On the TCP Protocol, UDP Protocol, or Other Protocol sub tabs on the Internal Zone, Illegal Zone, or External Zone tabs, select a row in the Threshold Histogram table and click the **Edit Row** button.
- On the Add or Modify Dest or Protocol Map dialog boxes, click the **Add Row** button, or select a row and click the **Edit Row** button. For information on opening the map dialog boxes, see Dest Port or Protocol Map Dialog Box, page 39-12.
### Table 39-3  Histogram Dialog Box

</tbody>
</table>
Configuring Global Correlation

You can configure global correlation so that your sensors are aware of network devices with a reputation for malicious activity and can take action against them. Global correlation allows you to dynamically use information about malicious activity collected from networks around the globe to change the risk rating of events that have known bad devices as their source.

To configure global correlation, your sensor must be running IPS 7.0+ software. Global correlation is not available on Cisco IOS IPS devices.

This chapter contains the following topics:

- Understanding Global Correlation, page 40-1
- Configuring Global Correlation Inspection and Reputation, page 40-5
- Configuring Network Participation, page 40-7

**Understanding Global Correlation**

You can configure global correlation so that your sensors are aware of network devices with a reputation for malicious activity and can take action against them. Participating IPS devices in a centralized Cisco threat database, the SensorBase, receive and absorb global correlation updates. The reputation data contained in the global correlation updates is factored into the analysis of network traffic, which increases IPS efficacy, because traffic is denied or allowed based on the reputation of the source IP address. The participating IPS devices send data back to the Cisco SensorBase Network, which results in a feedback loop that keeps the updates current and global.

---

**Tip**

The Botnet Traffic Filter feature of adaptive security appliances (ASA) is another dynamic feature you can deploy in your network to defend against malicious activity. Configuring global correlation on IPS devices, and Botnet Traffic Filtering on ASA firewalls, can be an effective combined security implementation. For more information about Botnet Traffic Filtering, see Chapter 18, “Managing Firewall Botnet Traffic Filter Rules”.

There are three main features of global correlation:

- Global Correlation Inspection—The IPS uses the global correlation reputation knowledge of attackers to influence alert handling and to deny actions when attackers with a bad score are seen on the sensor. For more information about reputation, see Understanding Reputation, page 40-2.
- Reputation Filtering—Applies automatic deny actions to packets from known malicious sites.
Understanding Global Correlation

- Network Participation—The sensor sends alert and TCP fingerprint data to the SensorBase Network so that other users can share in the community knowledge. For more information, see Understanding Network Participation, page 40-3.

Global correlation has the following goals:

- Dealing intelligently with alerts thus improving efficacy.
- Improving protection against known malicious sites.
- Sharing telemetry data with the SensorBase Network to improve visibility of alerts and sensor actions on a global scale.
- Simplifying configuration settings.
- Automatic handling of the uploads and downloads of the information.

Tip

You can use Report Manager to generate reports comparing the number of alerts generated by global correlation to those generated by traditional IPS inspection. For information on the Inspection/Global Correlation report, see Understanding General IPS Reports, page 66-17. For information on generating reports, see Opening and Generating Reports, page 66-18.

For information on how to configure global correlation, see the following topics:

- Global Correlation Requirements and Limitations, page 40-4
- Configuring Global Correlation Inspection and Reputation, page 40-5
- Configuring Network Participation, page 40-7

Understanding Reputation

Similar to human social interaction, reputation is an opinion toward a device on the Internet. Reputation indicates the probability that a particular attacker IP address will initiate malicious behavior based on its known past activity. Reputation enables the installed base of IPS sensors to collaborate using the existing network infrastructure and identify network devices that are likely to be malicious or infected.

By collecting data about devices and assigning reputation scores to them, the global correlation database provides important data that the IPS sensor can use to adjust the risk rating of an attack. Risk rating is the probability that a network event is malicious. Each signature has an associated risk rating. If you enable global correlation, the IPS sensor computes a score based on the reputation of an attacker and adds this score to the risk rating of the event. The updated risk rating is then used by your event action override and filter policies to help determine what actions to take for the event.

Thus, you might have an event that is initially configured to simply produce an alert. But, if the attacker has a bad reputation, the IPS might increase the risk rating to a number high enough that it triggers an event action override rule that adds the Deny Packet Inline action. Thus, for some source devices, the event simply produces an alert, but for others, the event drops the packet in addition to producing the alert.

Tip

The Produce Alert action is added to an event whenever global correlation raises the risk rating of the event, or when global correlation adds the Deny Packet Inline or Deny Attacker Inline actions.

Because the global correlation database changes rapidly, the sensor must periodically download global correlation updates from the global correlation servers.
Using reputation scores to adjust the risk rating of an event improves the efficacy of the sensor by improving the following metrics:

- False positives as a percentage of actionable events.
- False negatives as a percentage of threats that do not result in actionable events.
-Actionable events as a percentage of all events.

- Configuring Global Correlation Inspection and Reputation, page 40-5
- Configuring Network Participation, page 40-7

Understanding Network Participation

Network participation lets Cisco collect nearly real-time data from sensors around the world. Sensors installed at customer sites can send data to the SensorBase Network. These data feed into the global correlation database to increase reputation fidelity. Communication between sensors and the SensorBase Network involves an HTTPS request and response over TCP/IP.

There are three modes for Network Participation:

- **Off**—The Network Participation server does not collect data, track statistics, or try to contact the Cisco SensorBase network.

- **Partial Participation**—The Network Participation server collects data, tracks statistics, and communicates with the SensorBase network. Data considered to be potentially sensitive is filtered out and never sent.

  **Note** Configuring the sensor for partial network participation limits a third party from extracting reconnaissance information about your internal network from the global correlation database.

- **Full Participation**—The Network Participation server collects data, tracks statistics, and communicates with the SensorBase network. All data collected is sent.

If you select partial or full participation, you are prompted to accept a participation agreement. You must accept the agreement to participate or you cannot change the participation mode.

The following table explains the data collected and the purpose of collecting it.
Understanding Global Correlation

To configure network participation, the IPS device requires at least 100 MB of available memory, a network connection to the sensor, and a network connection to the Internet. For information on configuring network participation, see Configuring Network Participation, page 40-7.

Global Correlation Requirements and Limitations

The following list explains the requirements that you must meet to configure and successfully use global correlation on IPS devices. It also explains some limitations.

- **Valid license**—You must have a valid sensor license for global correlation features to function. You can still configure and display statistics for the global correlation features, but the global correlation databases are cleared and no updates are attempted. Once you install a valid license, the global correlation features are reactivated. For information on configuring licenses, see Updating IPS License Files, page 42-1.

- **Agree to Network Participation disclaimer**—If you decide to configure network participation, you must accept the disclaimer. For more information, see Understanding Network Participation, page 40-3 and Configuring Network Participation, page 40-7.

- **External connectivity for sensor and a DNS server or HTTP proxy**—Global correlation requires the sensor to connect to the Cisco SensorBase Network. Domain name resolution is also required for these features to function. You can either configure the sensor to connect through an HTTP proxy server that has a DNS client running on it, or you can assign an Internet routeable address to the management interface of the sensor and configure the sensor to use a DNS server. For more information, see Identifying DNS Servers, page 34-22 and Identifying an HTTP Proxy Server, page 34-23.

- **Sensor in inline mode**—The sensor must operate in inline mode so that the global correlation features can increase efficacy by being able to use the inline deny actions.

- **Sensor and IPS version that supports the global correlation features**—The sensor must run IPS 7.0+ software. You cannot configure global correlation on Cisco IOS IPS devices.

- **Sufficient available memory**—To configure network participation, the IPS device requires at least 100 MB of available memory.

<table>

</tbody>
</table>

Table 40-1   Network Participation Data Sharing and Usage
- **Firewall access for port 80, 443 traffic**—Because global correlation updates occur through the sensor management interface, any firewall that lies between the sensor and the internet must allow traffic on ports 80 and 443. You can also use an HTTP proxy (see Identifying an HTTP Proxy Server, page 34-23).

- **Exposure to external traffic**—The global correlation database contains external IP addresses only, so if you position a sensor in an internal lab that has no interaction with outside networks, you might never receive global correlation information. The feature will have no effect.

- **Bypass mode might be triggered during global correlation updates**—As with signature updates, when the sensor applies a global correlation update, it might trigger bypass. Whether bypass is triggered depends on the traffic load of the sensor and the size of the signature or global correlation update. If bypass mode is turned off, an inline sensor stops passing traffic while the update is being applied.

- **No IPv6 address support**—Global correlation inspection and the reputation filtering deny features do not support IPv6 addresses. For global correlation inspection, the sensor does not receive or process reputation data for IPv6 addresses. The risk rating for IPv6 addresses is not modified for global correlation inspection. Similarly, network participation does not include event data for attacks from IPv6 addresses. And finally, IPv6 addresses do not appear in the deny list.

## Configuring Global Correlation Inspection and Reputation

Use the Inspection/Reputation policy to configure the sensor to use updates from the SensorBase Network to adjust the risk rating of events. The global correlation client on the sensor determines which updates are available and applicable to the sensor by communicating with the global correlation update server and a file server. The global correlation update server provides the server manifest document to the sensor, which identifies which updates are available and how to obtain them from a file server. The sensor downloads the update files from the file server using the information in the server manifest.

When you configure global correlation, updates are automatic and happen at regular intervals, approximately every five minutes by default, but this interval can be modified by the global correlation server. The sensor initially gets a full update and then applies an incremental update periodically.

If you turn on global correlation, you can choose how aggressively you want the deny actions to be enforced against malicious hosts. You can then enable reputation filtering to deny access to known malicious hosts. If you only want a report of what could have happened, you can enable Test Global Correlation. This puts the sensor in Audit mode, and actions the sensor would have performed are generated in the events.
When you view IPS events in Event Viewer, there are several columns specific to global correlation that you can add to the event table; these columns are not shown by default, so you must add them to your view. To monitor global correlation in general, use the IPS device manager (IDM) and look at the Sensor Health gadget. Use either the full IDM or open a read-only copy from Security Manager by right-clicking the device in Device view and selecting Device Manager.

Before You Begin

- You must also configure a DNS server or HTTP proxy for global correlation to function. For details, see Identifying DNS Servers, page 34-22 or Identifying an HTTP Proxy Server, page 34-23.
- There are several configuration requirements and limitations that you should be aware of before configuring global configuration. For details, see Global Correlation Requirements and Limitations, page 40-4.

Related Topics

- Understanding Global Correlation, page 40-1
- Understanding Reputation, page 40-2
- Configuring Network Participation, page 40-7

Step 1

Do one of the following to open the Inspection/Reputation policy:

- (Device view) Select IPS > Global Correlation > Inspection/Reputation from the Policy selector.
- (Policy view) Select IPS > Global Correlation > Inspection/Reputation from the Policy Type selector. Select an existing policy or create a new one.

Step 2

Configure the following settings:

- **Global Correlation Inspection**—Whether to enable global correlation inspection. When turned on, the sensor uses updates from the SensorBase Network to adjust the risk rating. Deselect this option to disable inspection.
- **Global Correlation Influence**—How aggressively the sensor uses global correlation information to initiate deny actions. Select one of the following:
  - Permissive—Has the least aggressive effect on deny actions.
  - Standard—(The default.) Has a moderately aggressive effect on deny actions.
  - Aggressive—Has a very aggressive effect on deny actions.
- **Reputation Filtering**—Select whether you want reputation filtering on or off. When turned on, the sensor denies access to malicious hosts that are listed in the global correlation database.
- **Test Global Correlation**—Whether to place global correlation in audit mode. In audit mode, reputation filtering does not deny access to known malicious hosts; only a report of what could have happened is generated.

Audit mode allows you to test the global correlation features without actually denying any hosts. If you decide the effects are desirable, you can deselect this option to activate reputation filtering.
Configuring Network Participation

Use the Network Participation policy to configure the sensor to send data to the SensorBase Network. You can configure the sensor to fully participate and send all data to the SensorBase Network, or you can configure the sensor to collect the data but to omit potentially sensitive data, such as the destination IP address of trigger packets. For detailed information about network participation and the data that is collected, see Understanding Network Participation, page 40-3.

Related Topics
- Understanding Global Correlation, page 40-1
- Understanding Reputation, page 40-2
- Global Correlation Requirements and Limitations, page 40-4
- Configuring Global Correlation Inspection and Reputation, page 40-5

Step 1
Do one of the following to open the Network Participation policy:
- (Device view) Select **IPS > Global Correlation > Network Participation** from the Policy selector.
- (Policy view) Select **IPS > Global Correlation > Network Participation** from the Policy Type selector. Select an existing policy or create a new one.

Step 2
Select the level of participation from the **Network Participation** list:
- **Off**—No data is contributed to the SensorBase network.
- **Partial**—Data is contributed to the SensorBase network but potentially sensitive information is withheld.

Note
Configuring the sensor for partial network participation limits a third party from extracting reconnaissance information about your internal network from the Global Correlation database.

- **Full**—All data is contributed to the SensorBase network.

Step 3
If you select Full or Partial, when you click Save, the Network Participation Disclaimer dialog box opens, prompting you to read and accept a disclaimer. Carefully read the disclaimer. Click **Agree** if you agree to it.

If you click **Disagree**, you cannot enable network participation. Change the setting to Off and save the policy.
Configuring Attack Response Controller for Blocking and Rate Limiting

You can configure an IPS device to implement blocks or rate limits to control attacks. Blocking and rate limiting are primarily of use when operating in promiscuous mode. When operating in inline mode, it is much more efficient to have the IPS drop traffic itself. Blocking and rate limiting are actions that other devices implement at the request of the IPS; thus, configuring blocking and rate limiting is a more complex configuration than simple inline denies.

To configure blocking or rate limiting, you must identify the network device that performs the blocking. A network device that performs blocking is called a blocking device. Many network devices can be used to support blocking: Cisco IOS routers and Catalyst 6500 switches, Cisco security appliances (ASA, PIX, and FWSM), and Catalyst 6500/7600 devices running the Catalyst operating system. You can also configure another IPS device to act as a master blocking sensor.

Note
IPS blocking and rate limiting works only for IPS appliances and service modules. You cannot configure it for Cisco IOS IPS.

This chapter contains the following topics:

- Understanding IPS Blocking, page 41-1
- Configuring IPS Blocking and Rate Limiting, page 41-7
- Blocking Page, page 41-8

Understanding IPS Blocking

The Attack Response Controller (ARC) component of the IPS is responsible for managing network devices in response to suspicious events by blocking access from attacking hosts and networks. ARC blocks the IP address on the devices it is managing. It sends the same block to all the devices it is managing, including any other master blocking sensors. ARC monitors the time for the block and removes the block after the time has expired.

Note
ARC is formerly known as Network Access Controller. Although the name has been changed, the IPS documentation and configuration interfaces contain references to Network Access Controller, nac, and network-access.
ARC completes the action response for a new block in no more than 7 seconds. In most cases, it completes the action response in less time. To meet this performance goal, you should not configure the sensor to perform blocks at too high a rate or to manage too many blocking devices and interfaces. We recommend that the maximum number of blocks not exceed 250 and the maximum number of blocking items not exceed 10. To calculate the maximum number of blocking items, a security appliance counts as one blocking item per blocking context. A router counts as one blocking item per blocking interface/direction. A switch running Catalyst software counts as one blocking item per blocking VLAN. If the recommended limits are exceeded, ARC might not apply blocks in a timely manner or might not be able to apply blocks at all.

For security appliances configured in multiple-context mode, Cisco IPS does not include VLAN information in the block request. Therefore you must make sure the IP addresses being blocked are correct for each security appliance. For example, the sensor is monitoring packets on a security appliance customer context that is configured for VLAN A, but is blocking on a different security appliance customer context that is configured for VLAN B. Addresses that trigger blocks on VLAN A might refer to a different host on VLAN B.

**Note**

Blocking is not supported on the FWSM on the admin context in multiple-context mode.

There are three types of blocks:

- **Host block**—Blocks all traffic from a given IP address.

  To configure the IPS to initiate automatic host blocks when a signature is triggered, add the **Request Block Host** event action to a signature, or add it to events based on risk rating using the event action override policy. See Configuring Event Action Overrides, page 38-12 and Configuring Signatures, page 37-4.

- **Connection block**—Blocks traffic from a given source IP address to a given destination IP address and destination port. Multiple connection blocks from the same source IP address to either a different destination IP address or destination port automatically switch the block from a connection block to a host block.

  To configure the IPS to initiate automatic connection blocks when a signature is triggered, add the **Request Block Connection** event action to a signature, or add it to events based on risk rating using the event action override policy.

- **Network block**—Blocks all traffic from a given network.

  You can initiate host and connection blocks manually or automatically when a signature is triggered. You can only initiate network blocks manually. You cannot initiate network blocks from within Security Manager; use the IPS Device Manager instead.

**Tip**

Connection blocks and network blocks are not supported on security appliances (firewalls). Security appliances only support host blocks with additional connection information.

**Note**

Do not confuse blocking with the ability of the sensor to drop packets. The sensor can drop packets when the following actions are configured for a sensor in inline mode: deny packet inline, deny connection inline, and deny attacker inline.
On Cisco IOS Software devices (routers and Catalyst 6500 series switches), ARC creates blocks by applying ACLs; on Catalyst 6500/7600 devices that run the Catalyst operating system, ARC creates blocks by applying VACLs. ACLs and VACLs permit or deny passage of data packets through interface directions or VLANs. Each ACL or VACL contains permit and deny conditions that apply to IP addresses. The security appliances use the `shun` command instead of ACLs.

For a list of the specific devices and operating system versions that you can configure as blocking devices, see the supported device information in the chapter “Configuring Attack Response Controller for Blocking and Rate Limiting” in the *Installing and Using Cisco Intrusion Prevention System Device Manager* publication for your IPS software version. These publications are available on Cisco.com at [http://www.cisco.com/en/US/products/hw/vpndevc/ps4077/products_installation_and_configuration_guides_list.html](http://www.cisco.com/en/US/products/hw/vpndevc/ps4077/products_installation_and_configuration_guides_list.html).

The following topics explain more about IPS blocking:

- Strategies for Applying Blocks, page 41-3
- Understanding Rate Limiting, page 41-4
- Understanding Router and Switch Blocking Devices, page 41-4
- Understanding the Master Blocking Sensor, page 41-6
- Configuring IPS Blocking and Rate Limiting, page 41-7
- Blocking Page, page 41-8

### Strategies for Applying Blocks

Blocking is performed only when an event occurs and the event includes the Request Block Connection or Request Block Host event actions. These event actions are not typically needed when you operate the IPS in inline mode, where you use Deny actions to drop undesired traffic.

The following are situations in which you might want to implement blocking actions:

- **Promiscuous mode**—When running in promiscuous mode, the IPS cannot implement Deny actions. Thus, if you want to prevent traffic from a host, you must implement blocking.

- **Inline mode**—In inline mode, you can implement Deny actions to immediately drop undesired traffic. However, you might want to add blocking actions to protect other segments of your network.

For example, suppose that your network consists of five subnets, A, B, C, D, and E, and that each of these segments has an inline IPS device monitoring it. If the IPS for subnet A identifies an attack, the IPS can use Deny actions to protect subnet A, but also use Request Block actions to configure the firewalls that protect B, C, D, and E to shun the attacker before the attack can target those other subnets. In this example, you would want to designate a single IPS as the master blocking sensor and have the other four IPS sensors perform blocking through the master blocking sensor.

Use the following techniques to add the request block actions to an event:

- **Event Action Override policy**—Configure an event action override rule to add the action to all events based on the event’s risk rating. This is a simple approach. You could add the request block action for the same risk ratings used for adding Deny actions. For more information, see [Configuring Event Action Overrides, page 38-12](#).
• Signatures policy—You can add the request block actions to individual signatures. This requires editing each signature to add the action. This can be a time-consuming approach, but it allows you to configure blocking for just the types of events that concern you most. For more information, see Configuring Signatures, page 37-4.

• Blocking Page, page 41-8

Understanding Rate Limiting

Attack Response Controller (ARC) is responsible for rate limiting traffic in protected networks. Rate limiting lets sensors restrict the rate of specified traffic classes on network devices. Rate limit responses are supported for the Host Flood and Net Flood engines, and the TCP half-open SYN signature. ARC can configure rate limits on network devices running Cisco IOS 12.3 or later. Master blocking sensors can also forward rate limit requests to blocking forwarding sensors.

To add a rate limit to a signature, you must add the Request Rate Limit action. You can then edit the signature parameters to set the percentage for these signatures in the Event Actions Settings folder.

Tip
You can also manually implement rate limits, but you cannot do so using Security Manager; use the IPS Device Manager instead.

On the blocking device, you must not apply a service policy to an interface/direction that is configured for rate limiting. If you do so, the rate limit action will fail. Before configuring rate limits, confirm that there is no service policy on the interface/direction, and remove it if one exists. ARC does not remove the existing rate limit unless it is one that ARC had previously added.

Rate limits use ACLs, but not in the same way as blocks. Rate limits use ACLs and class-map entries to identify traffic, and policy-map and service-policy entries to police the traffic.

Understanding Router and Switch Blocking Devices

You can use routers or Catalyst 6500/7600 devices running Cisco IOS Software, or Catalyst 6500/7600 devices running the Catalyst operating system, to implement IPS blocking in your network. When you use routers or switches, Attack Response Controller (ARC) configures extended ACLs (on IOS devices) or VLAN ACLs (on Catalyst OS devices) to implement the blocks. These ACLs and VACLs are created and managed in the same way.

Rate limits also use ACLs, but not in the same way as blocks. Rate limits use ACLs and class-map entries to identify traffic, and policy-map and service-policy entries to police the traffic.

Tip
IPS considers Catalyst 6500/7600 devices that run Cisco IOS Software to be equivalent to routers. When you add these devices as blocking devices, add them as routers.
When you configure a router interface or switch VLAN as a blocking interface, you can optionally specify the names of pre- and post-ACLs or VACLs. Although specifying ACL or VACL names is optional, if you have configured ACLs or VACLs on the interface or VLAN, you must identify them to the IPS or ARC will remove them from your device configuration.

The pre- and post-ACL/VACL have the following uses:

- The Pre-Block ACL/VACL is mainly used for permitting what you do not want the sensor to ever block. When a packet is checked against the ACL/VACL, the first line that gets matched determines the action. If the first line matched is a permit line from the Pre-Block ACL/VACL, the packet is permitted even though there may be a deny line (from an automatic block) listed later in the ACL/VACL. The Pre-Block ACL/VACL can override the deny lines resulting from the blocks.

- The Post-Block ACL/VACL is best used for additional blocking or permitting that you want to occur on the same interface or direction. If you have an existing ACL on the interface or direction that the sensor will manage, that existing ACL can be used as a Post-Block ACL/VACL. If you do not have a Post-Block ACL/VACL, the sensor inserts permit ip any any at the end of the new ACL/VACL.

If you are managing the IOS Software blocking device in Security Manager, you can identify the ACL name by selecting the blocking device, then selecting Tools > Preview Config. Look for the `ip access-group` command in the interface configuration, and check the direction. For example, the following lines show that there is an ACL named CSM_FW_ACL_GigabitEthernet0/1 in the In direction attached to the GigabitEthernet0/1 interface.

```
interface GigabitEthernet0/1
  ip access-group CSM_FW_ACL_GigabitEthernet0/1 in
```

In this example, if you configure GigabitEthernet0/1 in the In direction as a blocking interface, ensure that you specify CSM_FW_ACL_GigabitEthernet0/1 as a pre- or post-ACL. In most cases, you should specify the ACL as the post-ACL, so that the relatively short IPS blocking ACL first filters out undesirable traffic before the blocking device implements your other access rules.

Because Security Manager does not manage Catalyst OS devices, you must examine a Catalyst OS device configuration outside of Security Manager to determine VACL names. Keep in mind that a Catalyst 6500/7600 device that runs IOS Software can also have VACLs, but the IPS does not do VLAN blocking on Catalyst 6500/7600 VLANs when the device is running IOS Software.

When the sensor starts up, it reads the contents of the two ACL/VACLs. It creates a third ACL/VACL with the following entries in this order, and this combined ACL/VACL is applied to the interface or VLAN:

1. A `permit` line with the sensor IP address or, if specified, the NAT address of the sensor.
   If you select the Allow Sensor IP address to be Blocked option on the General tab of the Blocking policy, this permit entry is not added. For more information, see General Tab, IPS Blocking Policy, page 41-10.

2. Pre-Block ACL/VACL, if specified.

3. Any active blocks generated by the IPS (deny statements).

4. The Post-Block ACL/VACL, if specified.
   If you do not specify a Post-Block ACL/VACL, a `permit ip any any` entry is added to allow all unfiltered traffic. Note that this negates the normal implicit deny any that ends interface ACLs.

   When using Catalyst OS, IDSM-2 inserts `permit ip any any capture` at the end of the new VACL.
If ARC is managing a device and you need to configure the ACL/VACLs on that device, you should disable blocking first. You want to avoid a situation in which both you and ARC could be making a change at the same time on the same device. This could cause the device or ARC to fail. If you need to modify the Pre-Block or Post-Block ACL/VACL, do the following:

1. Disable blocking on the sensor.
   
   Because you are making a temporary change, you can disable and then reenable blocking by using the IPS Device Manager (IDM) on the device. Alternatively, you can deselect the Enable Blocking option on the General tab of the Blocking policy in Security Manager, then deploy the configuration to the IPS sensor. To reenable blocking, select the Enable Blocking option again and deploy the configuration to the IPS sensor.

2. Make the changes to the configuration of the device. For example, if you manage the blocking device in Security Manager, deploy the updated configuration and wait for the device to reload.

3. Reenable blocking on the sensor.

**Understanding the Master Blocking Sensor**

Multiple sensors (blocking forwarding sensors) can forward blocking requests to a specified master blocking sensor, which controls one or more devices. The master blocking sensor is the ARC running on a sensor that controls blocking on one or more devices on behalf of one or more other sensors. When a signature fires that has blocking or rate limit requests configured as event actions, the sensor forwards the block or rate limit request to the master blocking sensor, which then performs the block or rate limit.

When you add a master blocking sensor, you reduce the number of blocking devices per sensor. For example, if you want to block on 10 firewalls and 10 routers with one blocking interface/direction each, you can assign 10 to the sensor and assign the other 10 to a master blocking sensor.

You configure master blocking sensors on the Master Blocking Sensors tab of the Blocking policy, as described in Blocking Page, page 41-8.

When configuring master blocking sensors, keep the following tips in mind:

- Two sensors cannot control blocking or rate limiting on the same device. If this situation is needed, configure one sensor as the master blocking sensor to manage the devices and the other sensors can forward their requests to the master blocking sensor.

- On the blocking forwarding sensor, identify which remote host serves as the master blocking sensor; on the master blocking sensor you must add the blocking forwarding sensors to its access list using the Allowed Hosts policy. See Identifying Allowed Hosts, page 34-7.

- If the master blocking sensor requires TLS for web connections, you must configure the ARC of the blocking forwarding sensor to accept the X.509 certificate of the master blocking sensor remote host. Sensors by default have TLS enabled, but you can change this option. For more information, see Master Blocking Sensor Dialog Box, page 41-13.

- Typically the master blocking sensor is configured to manage the network devices. Blocking forwarding sensors are not normally configured to manage other network devices, although doing so is permissible.

- Only one sensor should control all blocking interfaces on a device.
Configuring IPS Blocking and Rate Limiting

If you use the Request Block Host, Request Block Connection, or Request Rate Limit actions on any signatures, or add them to events using the event action override policy, you must configure blocking devices. If you do not use these actions, there is no need to configure blocking devices.

Before you configure blocking, read the following topics:

- Understanding IPS Blocking, page 41-1
- Strategies for Applying Blocks, page 41-3
- Understanding Rate Limiting, page 41-4
- Understanding Router and Switch Blocking Devices, page 41-4
- Understanding the Master Blocking Sensor, page 41-6

---

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Security > Blocking** from the Policy selector.
- (Policy view) Select **IPS > Platform > Security > Blocking**, then select an existing policy or create a new one.

For an overview of the blocking policy, see **Blocking Page, page 41-8**.

**Step 2**

On the General tab, change any settings where you want non-default values. However, the default values are appropriate for most networks. For detailed information about the settings, see **General Tab, IPS Blocking Policy, page 41-10**.

**Step 3**

Click the **User Profiles** tab and create the user profiles that are required to log into the blocking devices.

- To add a profile, click the **Add Row** button and fill in the Add User Profile dialog box (see **User Profile Dialog Box, page 41-12**).
- To edit a profile, select it and click the **Edit Row** button.
- To delete a profile, select it and click the **Delete Row** button. Before you delete a profile, ensure that it is not currently being used by a blocking device.

**Step 4**

If you need to use a master blocking sensor, as described in **Understanding the Master Blocking Sensor, page 41-6**, click the **Master Blocking Sensors** tab and do the following:

- To add a master blocking sensor, click the **Add Row** button and fill in the Add Master Blocking Sensor dialog box (see **Master Blocking Sensor Dialog Box, page 41-13**).
- To edit a master blocking sensor, select it and click the **Edit Row** button.
- To delete a master blocking sensor, select it and click the **Delete Row** button.

**Step 5**

Identify the blocking devices (unless you will use master blocking sensors only). You must add the devices to the correct tab:

- **Routers** tab—For all Cisco IOS Software devices, including Catalyst 6500 switches that are running IOS Software.
- **Firewalls** tab—For ASA, PIX, and FWSM.
- **Catalyst 6K** tab—For Catalyst 6500/7600 devices that are running the Catalyst operating system.

On each tab, the configuration steps are the same:

- To add a device, click the **Add Row** button and fill in the Add Router, Firewall, or Cat6K Device dialog box (see **Router, Firewall, Cat6K Device Dialog Box, page 41-13**).
Step 6

Click the **Never Block Hosts and Networks** tab and identify the hosts and networks that should never be blocked. These lists affect blocking actions, but they do not affect limiting actions. Identify your trusted networks and hosts:

- To add a host or network, click the **Add Row** button beneath the appropriate table and fill in the Add Never Block Host or Network dialog box (see *Never Block Host or Network Dialog Boxes*, page 41-17).
- To edit a host or network, select it and click the **Edit Row** button.
- To delete a host or network, select it and click the **Delete Row** button.

## Blocking Page

Use the Blocking page to configure IPS sensor blocking properties. Configure the blocking policy only if you use the Request Block Connection, Request Block Host, or Request Rate Limit event actions in your signatures or event actions policies. Blocking hosts are used only for events to which these actions are assigned.

**Tip**

The list of hosts and networks to never block applies only to the Request Block Connection and Request Block Host event actions. The list does not affect rate limiting, nor does it affect any of the Deny actions such as Deny Packet Inline. To exempt hosts and networks from Deny or rate limiting actions, use event action filter rules, specify the hosts and networks as Attackers, and remove the actions from events. For more information, see *Configuring Event Action Filters*, page 38-5.

### Navigation Path

- (Device view) Select **Platform > Security > Blocking** from the Policy selector.
- (Policy view) Select **IPS > Platform > Security > Blocking**, then select an existing policy or create a new one.

General Tab, IPS Blocking Policy

Use the General tab of the Blocking policy to configure the basic settings required to enable blocking and rate limiting.

Navigation Path

- (Device view) Select Platform > Security > Blocking from the Policy selector. If necessary, select the General tab.
- (Policy view) Select IPS > Platform > Security > Blocking, then select an existing policy or create a new one. If necessary, select the General tab.

## Field Reference

### Table 41-2  General Tab, IPS Blocking Policy

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log All Block Events and Errors</td>
<td>Whether to log events that follow blocks from start to finish and any error messages that occur. When a block is added to or removed from a device, an event is logged. You may not want all these events and errors to be logged. Disabling this option suppresses new events and errors. The default is enabled.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  Log all block events and errors also applies to rate limiting.</td>
</tr>
<tr>
<td>Enable NVRAM Write</td>
<td>Whether to have the router write to non-volatile RAM (NVRAM) when Attack Response Controller (ARC) first connects. If enabled, NVRAM is written each time the ACLs are updated. The default is disabled. Enabling NVRAM writing ensures that all changes for blocking and rate limiting are written to NVRAM. If the router is rebooted, the correct blocks and rate limits will still be active. If NVRAM writing is disabled, a short time without blocking or rate limiting occurs after a router reboot. Not enabling NVRAM writing increases the life of the NVRAM and decreases the time for new blocks and rate limits to be configured.</td>
</tr>
<tr>
<td>Enable ACL Logging</td>
<td>Whether to have ARC append the log parameter to block entries in the access control list (ACL) or VLAN ACL (VACL). This causes the device to generate syslog events when packets are filtered. This option applies to routers and switches only. The default is disabled.</td>
</tr>
<tr>
<td>Allow Sensor IP address to be Blocked</td>
<td>Whether the sensor IP address can be blocked. The default is disabled.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip</strong>  If you allow the sensor address to be blocked, the IPS does not add an explicit permit entry to the interface ACL to allow the IPS address. You must ensure that the IPS address is permitted by the device ACL or the IPS cannot implement blocking on the device.</td>
</tr>
<tr>
<td>Enable Blocking</td>
<td>Whether to enable the blocking and rate limiting of hosts. The default is enabled.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  When you enable blocking, you also enable rate limiting. When you disable blocking, you also disable rate limiting. This means that ARC cannot add new or remove existing blocks or rate limits.</td>
</tr>
<tr>
<td>Max Blocks</td>
<td>The maximum number of entries to block. The range is 1 to 65535. The default is 250.</td>
</tr>
</tbody>
</table>
Chapter 41  Configuring Attack Response Controller for Blocking and Rate Limiting

User Profile Dialog Box

Use the Add or Modify User Profile dialog box to add or modify a user profile for an IPS blocking device. The profile defines a username and passwords that the IPS device can use to log into and configure the router, switch, or firewall that will implement IPS blocking.

Although you can save a profile that has a profile name only, the requirements for username, password, and enable password are determined by the device. You must specify the items required by the device to enter configuration mode, or the IPS cannot configure blocking on the device.

**Navigation Path**

From the IPS Blocking policy, select the User Profiles tab and click the **Add Row** button or select an existing sensor and click the **Edit Row** button. For information on opening the Blocking policy, see **Blocking Page, page 41-8**.

**Field Reference**

**Table 41-3  User Profile Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile Name</td>
<td>The name of the profile, up to 64 alphanumeric characters.</td>
</tr>
<tr>
<td>Username</td>
<td>The username to use when logging into the blocking device.</td>
</tr>
<tr>
<td>Password</td>
<td>The login password for the username, if required.</td>
</tr>
<tr>
<td>Enable Password</td>
<td>The enable password for entering Privileged EXEC Mode (enable mode), if required.</td>
</tr>
</tbody>
</table>
Master Blocking Sensor Dialog Box

Use the Add or Modify Master Blocking Sensor dialog box to configure a master blocking sensor. For more information about master blocking sensors, see Understanding the Master Blocking Sensor, page 41-6.

Navigation Path
From the IPS Blocking policy, select the Master Blocking Sensors tab and click the Add Row button or select an existing sensor and click the Edit Row button. For information on opening the Blocking policy, see Blocking Page, page 41-8.

Field Reference

Table 41-4  Master Blocking Sensor Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Address</td>
<td>The IP address of the master blocking sensor. Enter the IP address or the name of a network/host policy object that contains a single host address, or click Select to select an object from a list or to create a new one.</td>
</tr>
<tr>
<td>Username</td>
<td>The username to use to log in to the master blocking sensor. The user account must be an active account configured on the master blocking sensor.</td>
</tr>
<tr>
<td>Password</td>
<td>The login password for the username.</td>
</tr>
<tr>
<td>Port</td>
<td>The port on which to connect on the master blocking sensor. The default is 443.</td>
</tr>
<tr>
<td>TLS</td>
<td>Whether to use TLS. If you select the TLS option, you must configure the ARC of the blocking forwarding sensor to accept the TLS/SSL X.509 certificate of the master blocking sensor remote host. (The blocking forwarding sensor is any device to which you are assigning this blocking policy.) The easiest way to configure the blocking forwarding sensor to accept the X.509 certificate is to use the IPS Device Manager (IDM) to log into the sensor, choose Configuration &gt; Sensor Management &gt; Certificates &gt; Trusted Hosts &gt; Add Trusted Host, and add the master blocking sensor as a trusted host. Alternatively, you can log into the sensor CLI, enter configuration mode, and use the tls trusted-host ip-address command.</td>
</tr>
</tbody>
</table>

Router, Firewall, Cat6K Device Dialog Box

Use the Add or Modify Router, Firewall, or Cat6K Device dialog box to configure a device as a blocking device for an IPS sensor. The name of the dialog box indicates the type of device you are adding:

- Router—IOS Software routers and Catalyst 6500/7600 devices. These devices can do rate limiting as well as blocking. See Understanding Router and Switch Blocking Devices, page 41-4.
- Firewall—ASA and PIX appliances.
- Cat6K—Catalyst 6500/7600 devices that are running Catalyst OS software.

Tip
If the Catalyst 6500/7600 runs Cisco IOS Software, add the device as a router on the Router tab. Do not add the device to the Cat6K tab.
Navigation Path

From the IPS Blocking policy, select the Router, Firewall, or Catalyst 6K tab and click the **Add Row** button or select an existing row and click the **Edit Row** button. For information on opening the Blocking policy, see **Blocking Page**, page 41-8.

Field Reference

Table 41-5  **Router, Firewall, Cat6K Device Dialog Boxes**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Address</td>
<td>The IP address of the device. Enter the IP address or the name of a network/host policy object that contains a single host address, or click <strong>Select</strong> to select an object from a list or to create a new one.</td>
</tr>
<tr>
<td>Communication Type</td>
<td>The communication mechanism used to log in to the blocking device (SSH 3DES, SSH DES, Telnet). The default is SSH 3DES. If you choose SSH 3DES or SSH DES, you must add the device to the known hosts list. The easiest way to add the device to the known hosts list is to use the IPS Device Manager (IDM) to log into the sensor, choose <strong>Configuration &gt; Sensor Management &gt; SSH &gt; Known Host Keys &gt; Add Known Host Key</strong>, and add the device address. Alternatively, you can log into the sensor CLI, enter configuration mode, and use the <strong>ssh host-key</strong> command.</td>
</tr>
<tr>
<td>NAT Address</td>
<td>The NAT address of the sensor, if any is used between the sensor and the blocking device. Enter the NAT address or the name of a network/host policy object that contains a single host address, or click <strong>Select</strong> to select an object from a list or to create a new one. Leave the default 0.0.0.0 if NAT is not used.</td>
</tr>
<tr>
<td>Profile Name</td>
<td>The login profile used to log in to the blocking device. You must create this profile on the User Profiles tab of the blocking policy or the IPS cannot successfully use this blocking device.</td>
</tr>
<tr>
<td>Interfaces and directions where blocks will be applied (table) (Routers only.)</td>
<td>The interfaces on the device that should be used for blocking or rate limiting. The table shows the interface name, direction, and the names of existing ACLs that the IPS device should incorporate into the blocking ACL. If the interface already has an ACL configured for the specified direction, you must specify that ACL name as a pre- or post-ACL or the IPS removes the ACL. These ACLs are used for blocking only, not for rate limiting.</td>
</tr>
<tr>
<td></td>
<td>- To add an interface, click the <strong>Add Row</strong> button and fill in the Add Router Block Interface dialog box (see <strong>Router Block Interface Dialog Box</strong>, page 41-15).</td>
</tr>
<tr>
<td></td>
<td>- To edit an interface, select it and click the <strong>Edit Row</strong> button.</td>
</tr>
<tr>
<td></td>
<td>- To delete an interface, select it and click the <strong>Delete Row</strong> button.</td>
</tr>
</tbody>
</table>
**Table 41-5  Router, Firewall, Cat6K Device Dialog Boxes (Continued)**

<tbody>
<tr>
<td>Response Capabilities (Routers only.)</td>
<td>The actions that this router can implement. Use Ctrl+click to select multiple actions (highlighted actions are selected). Options are:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Block</strong>—The router can implement blocks in response to Request Block Connection and Request Block Host actions.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Rate Limit</strong>—The router can implement rate limits in response to Request Rate Limit actions.</td>
</tr>
<tr>
<td>VLANs where blocks will be applied (table)</td>
<td>The VLANs on the device that should be used for blocking. The table shows the VLAN name and the names of existing VLAN ACLs (VACL) that the IPS device should incorporate into the blocking VACL.</td>
</tr>
<tr>
<td>(Catalyst 6500/7600 devices running the Catalyst operating system only.)</td>
<td>If the VLAN already has a VACL configured, you must specify that VACL name as a pre- or post-VACL or the IPS removes the VACL.</td>
</tr>
<tr>
<td></td>
<td>• To add a VLAN, click the <strong>Add Row</strong> button and fill in the Add Cat6K Block VLAN dialog box (see <strong>Cat6k Block VLAN Dialog Box</strong>, page 41-16).</td>
</tr>
<tr>
<td></td>
<td>• To edit a VLAN, select it and click the <strong>Edit Row</strong> button.</td>
</tr>
<tr>
<td></td>
<td>• To delete a VLAN, select it and click the <strong>Delete Row</strong> button.</td>
</tr>
</tbody>
</table>

**Router Block Interface Dialog Box**

Use the Add or Modify Router Block Interface dialog box to configure a blocking interface on a router or IOS Software Catalyst 6500/7600 device that is configured as an IPS blocking device. The IPS sensor uses the interface for blocking actions.

**Navigation Path**

From the Add or Modify Router Device dialog box, click the **Add Row** button beneath the interfaces table, or select a row in the table and click the **Edit Row** button. For information on opening the Router Device dialog box, see **Router, Firewall, Cat6K Device Dialog Box**, page 41-13.

**Field Reference**

**Table 41-6  Router Block Interface Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Name</td>
<td>The name of the interface on the router that the IPS should use for blocking. Enter the name exactly as it is configured on the router (for example, GigabitEthernet0/1).</td>
</tr>
<tr>
<td>Direction</td>
<td>The direction to apply the blocking ACL, In or Out.</td>
</tr>
</tbody>
</table>
Use the Add or Modify Cat6k Block VLAN dialog box to configure a blocking VLAN on a Catalyst 6500/7600 device that runs the Catalyst operating system and that is configured as an IPS blocking device. The IPS sensor uses the VLAN for blocking actions.

**Tip** If the Catalyst 6500/7600 runs Cisco IOS Software, add the device as a router, not a Cat6K.

**Navigation Path**

From the Add or Modify Cat6K Device dialog box, click the **Add Row** button beneath the VLANs table, or select a row in the table and click the **Edit Row** button. For information on opening the Cat6K Device dialog box, see **Router, Firewall, Cat6K Device Dialog Box**, page 41-13.

**Field Reference**

**Table 41-7  Cat6k Block VLAN Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN</td>
<td>The number of the VLAN on the Catalyst 6500/7600 device that the IPS should use for blocking. The number can be 1 to 4094 and must be defined on the device.</td>
</tr>
</tbody>
</table>
Never Block Host or Network Dialog Boxes

Use the Add or Modify Never Block Host or Network dialog boxes to specify a host or network that should never be subject to blocking. The name of the dialog box indicates whether you are adding a host or network address.

Enter the IP address or the name of a network/host policy object that specifies the address. You can also click Select to select an object from a list or to create a new object. When selecting objects, the object can contain a single entry of the appropriate type. Host addresses do not have subnet masks (for example, 10.100.10.1), whereas network addresses have masks (for example, 10.100.10.0/24).

Navigation Path
From the IPS Blocking policy, select the Never Block Hosts or Networks tab and click the Add Row button or select an existing row and click the Edit Row button. Hosts and networks are listed in separate tables, so ensure that you click the buttons associated with the desired table. For information on opening the Blocking policy, see Blocking Page, page 41-8.

Table 41-7 Cat6k Block VLAN Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre VACL Name</td>
<td>The VLAN ACLs to combine with the blocking entries that the IPS creates to implement blocking actions. The Pre VACL is added before the blocking VACL, and the Post VACL is added after the blocking VACL. For more information, see Understanding Router and Switch Blocking Devices, page 41-4.</td>
</tr>
<tr>
<td>Post VACL Name</td>
<td>Tip If you have configured a VACL on the VLAN, you must specify the name of the VACL in the Pre or Post VACL Name field or the VACL will be removed from the VLAN. When you identify a VLAN as a blocking interface, the IPS takes control of the VACL on that VLAN. Typically, you would specify the VACL name as the post-VACL.</td>
</tr>
</tbody>
</table>

Tip
If you have configured a VACL on the VLAN, you must specify the name of the VACL in the Pre or Post VACL Name field or the VACL will be removed from the VLAN. When you identify a VLAN as a blocking interface, the IPS takes control of the VACL on that VLAN. Typically, you would specify the VACL name as the post-VACL.
Managing IPS Sensors

To perform day-to-day sensor management, you typically need to use a device manager such as the IPS Device Manager (IDM). Security Manager is focused on policy and event management. However, the following topics describe some management activities that you can perform using Security Manager:

- Managing IPS Licenses, page 42-1
- Managing IPS Updates, page 42-4
- Managing IPS Certificates, page 42-10
- Rebooting IPS Sensors, page 42-12

Managing IPS Licenses

The following topics explain how to manage licenses for IPS devices:

- Updating IPS License Files, page 42-1
- Redeploying IPS License Files, page 42-2
- Automating IPS License File Updates, page 42-3

Updating IPS License Files

You can use Security Manager to update the licenses for IPS devices. This procedure explains how to update the licenses manually by retrieving them from Cisco.com or from a license file on the Security Manager server. For information about setting up automatic license updates, see Automating IPS License File Updates, page 42-3.

Before You Begin

If you use Cisco.com, you must first configure the IPS Update server to be Cisco.com, so that you can specify the username and password. You must use Cisco.com for licensing if you are using a device that requires it; for example, an IPS 4270 or an AIP SSM-40 in an ASA device requires a Cisco.com account. For information on configuring Cisco.com as the IPS Update server, see Configuring the IPS Update Server, page 42-4.

If you use local licenses, you must download them directly to the Security Manager server file system. You cannot do this through Security Manager; you must log into Windows on the server to download the licenses.
Managing IPS Licenses

Related Topics
- Redeploying IPS License Files, page 42-2

Step 1
Select Tools > Security Manager Administration and select Licensing from the table of contents.

Step 2
Click the IPS tab (see IPS Tab, Licensing Page, page 11-35).

The table lists all IPS devices in the device inventory and displays the status of their licenses. The status can be valid, invalid, expired, no license, or trial license. The expiration date for the license is also shown. Click Refresh License to update the table with the latest license information from the devices (you can select one or more devices to limit the scope of the refresh).

To update licenses, do one of the following:

- To update devices with licenses obtained directly from Cisco.com—Select the devices you want to update and click Update Selected via CCO. A dialog box opens that lists the devices that can be updated from Cisco.com, which might not be all of the devices you selected. Review the list and click OK. The status of the update task is shown in the License Update Status Details dialog box (see License Update Status Details Dialog Box, page 11-38).

  To successfully update the license using this method, you must have a Cisco.com support contract that includes the serial numbers of the selected devices.

  Tip
  The Cisco software license server (SWIFT) that contains the licenses might block requests from the same server for more than 9 licenses within a three minute period. Thus, you should select fewer than 9 devices at a time when performing manual license updates.

- To update devices with licenses that you have copied to the Security Manager server—Click Update from License File. A dialog box opens where you can select the license files. Click Browse to select them from the Security Manager local file system. You can select more than one license file. When you have selected the desired files, click OK to have them applied to the devices.

Redeploying IPS License Files

If an attempt to apply an IPS license update to a device fails, you can redeploy the update. Redeployment works only if you have already attempted to apply an update and a license file is associated with the IPS device.

Related Topics
- Updating IPS License Files, page 42-1
- Automating IPS License File Updates, page 42-3

Step 1
Select Tools > Security Manager Administration and select Licensing from the table of contents.

Step 2
Click the IPS tab (see IPS Tab, Licensing Page, page 11-35).

Step 3
Select the devices to which you want to redeploy licenses and click Redeploy Selected Licenses. A dialog box opens listing devices whose licenses you are redeploying. Click OK to perform the update.
The status of the update task is shown in the License Update Status Details dialog box (see License Update Status Details Dialog Box, page 11-38).

### Automating IPS License File Updates

Security Manager can automatically apply IPS license updates to your IPS devices on a regular schedule. To successfully configure automatic updates, you must have a Cisco.com support contract that includes the serial numbers of your IPS devices.

**Tip**

Security Manager applies new licenses only if the downloaded license has an expiration date further into the future than the one replaced or if the license information is different.

**Before You Begin**

You must first configure the IPS Update server to be Cisco.com, so that you can specify the Cisco.com username and password. For information on configuring Cisco.com as the IPS Update server, see Configuring the IPS Update Server, page 42-4.

**Related Topics**

- Updating IPS License Files, page 42-1
- Redeploying IPS License Files, page 42-2

### Step-by-Step Instructions

**Step 1**

Select *Tools > Security Manager Administration* and select **Licensing** from the table of contents.

**Step 2**

Click the **IPS** tab (see IPS Tab, Licensing Page, page 11-35).

**Step 3**

Select **Download and apply licenses** and configure the following settings:

- **Days before the expiration date**—Select the number of days before a license expires that Security Manager should download an updated license. The default is 1 day.

- **Discover devices daily at**—Select the time of day when Security Manager should download licenses. At this time, Security Manager will check the license status on the devices, and contact Cisco.com for new licenses for devices that have no license, have expired licenses, or that have licenses that will expire within the number of days you selected.

- **Email License Update Results**—Select whether Security Manager should send e-mail notification of license update results. E-mails are sent with license expiration status and for license update job results. If you select this option, enter one or more e-mail addresses in the Email Notification field. Separate multiple addresses with commas.

For the e-mails to be sent, you must configure an SMTP server as described in Configuring an SMTP Server and Default Addresses for E-Mail Notifications, page 1-23.

**Step 4**

Click **Save** to save your changes.
Managing IPS Updates

You can use Security Manager to apply sensor and signature updates to your IPS devices and shared policies. Through Security Manager, you can download updates and either set up automatic updates or apply them manually.

Signature updates are available only for IPS 5.1(4) and higher.

Tip
If you have problems applying patches, service packs, or signature updates, check the time on your IPS sensor. If the time on the sensor is ahead of the time on the associated certificate, the certificate is rejected and the update may fail. Use the Network Time Protocol (NTP) to maintain accurate time on an IPS sensor. For information on configuring NTP on the sensor, see Identifying an NTP Server, page 34-21.

The IPS packages included with Security Manager do not include the package files that are required for updating IPS devices. You must download IPS packages from Cisco.com or your local update server before you can apply any updates. The downloaded versions include all required package files and replace the partial files that are included in the Security Manager initial installation.

The following topics describe how to use Security Manager to manage IPS updates:

- Configuring the IPS Update Server, page 42-4
- Checking for IPS Updates and Downloading Them, page 42-5
- Automating IPS Updates, page 42-6
- Manually Applying IPS Updates, page 42-7

Configuring the IPS Update Server

To apply IPS sensor and signature updates, Security Manager must download the updates to the Security Manager server from an identified IPS Update server.

You can use Cisco.com as the IPS Update server. Using Cisco.com ensures that the latest updates are available to you at their earliest availability. However, if you cannot use Cisco.com for some reason, you can set up your own local IPS Update web server, manually download updates to it, and configure Security Manager to obtain the updates from your local server.

Tip
If you are using a device that requires a Cisco.com login for updating licenses, such as an IPS 4270 or an AIP SSM-40 in an ASA device, you must configure the IPS Update server as Cisco.com. You cannot use a local server.

Related Topics
- Automating IPS Updates, page 42-6
- Manually Applying IPS Updates, page 42-7

Step 1
Select Tools > Security Manager Administration and select IPS Updates from the table of contents to open the IPS Updates page (see IPS Updates Page, page 11-28).

Step 2
In the Update Server area, click Edit Settings to open the Edit Update Server Settings dialog box (see Edit Update Server Settings Dialog Box, page 11-31).
Step 3  Enter the identifying information for your server. Based on the server type selected in the Update From field:

- **Cisco.com**—Enter a Cisco.com username and password. The user account you specify must have applied for eligibility to download strong encryption software. To verify the account has the appropriate permissions, go to Cisco.com and try to download an IPS update package. You will be prompted to accept the appropriate agreements if the account is not already qualified.

- **Local server**—Enter the IP address or DNS host name of your server, a username and password if you require a log in before allowing access, and the path to the folder that contains the files. For the path, do not enter the entire URL; enter only the path portion of the URL (for example, the path in http://servername/IPSpath is IPSpath). Also add IIS configuration settings:
  
  - Home Directory should have listing enabled.
  - Documents should have Default Content Page disabled.

If your network requires a proxy server to get from the Security Manager server to the IPS Update server, select **Enable Proxy Server** and enter the information for the proxy server.

Click **OK** to save your changes.

**Step 4**  Click **Save** on the IPS Updates page. Your changes are not completely saved unless you click **Save**.

**Step 5**  Test the connectivity to the IPS Update server by clicking **Download Latest Updates**. A dialog box opens. Click **Start** to have Security Manager log into the update server, check for new updates, and download them. The dialog box displays the results of the operation.

If you are using Cisco.com and experience a download failure, double-check the user account to ensure it has the required permissions for downloading strong encryption software.

---

**Checking for IPS Updates and Downloading Them**

You can use Security Manager to check for IPS sensor and signature updates and download them to the Security Manager server, where you can apply them to your IPS devices and policies.

You can manually download IPS updates, automate IPS update downloads, or download them when you try to manually apply them to a device. The following procedure explains how to manually check for updates and download them. For information on configuring automatic downloads, see **Automating IPS Updates, page 42-6**. For information on downloading updates while manually applying them to devices or policies, see **Manually Applying IPS Updates, page 42-7**.

**Before You Begin**

You must configure the IPS Update server as described in **Configuring the IPS Update Server, page 42-4**.

**Related Topics**

- **Automating IPS Updates, page 42-6**
- **Manually Applying IPS Updates, page 42-7**

**Step 1**  Select **Tools > Security Manager Administration** and select **IPS Updates** from the table of contents to open the IPS Updates page (see **IPS Updates Page, page 11-28**).

**Step 2**  Review the status information in the Update Status group, and do any of the following:

- Click **Check for Updates**. A dialog box opens to display the results of the operation. Click **Start** to have Security Manager log into the IPS Update server and check for updates.
• Click Download Latest Updates. A dialog box opens to display the results of the operation. Click Start to have Security Manager log into the IPS Update server, check for updates, and download them to the Security Manager server.

**Tip**  If a Cisco.com download fails, ensure that the account you are using has applied for eligibility to download strong encryption software. For details, see the description of User Name in Edit Update Server Settings Dialog Box, page 11-31.

### Automating IPS Updates

You can automatically apply sensor image and signature updates to compatible IPS devices to ensure that they are up to date. If desired, you can partially automate the updates to maintain the desired level of control over the process.

**Tip**  If you later decide that you did not want to apply a signature update, you can revert to the previous update level by selecting the Signatures policy on the device, clicking the View Update Level button, and clicking Revert.

**Tip**  If you do not manage IPS devices, consider taking the following performance tuning step. In \$NMSROOT\MDC\ips\etc\sensorupdate.properties, change the value of packageMonitorInterval from its initial default value of 30,000 milliseconds to a less-frequent value of 600,000 milliseconds. Taking this step will improve performance somewhat. [\$NMSROOT is the full pathname of the Common Services installation directory (the default is C:\Program Files\CSCOpx).]

**Before You Begin**

You must configure the IPS Updates server as described in Configuring the IPS Update Server, page 42-4.

**Related Topics**

- Checking for IPS Updates and Downloading Them, page 42-5
- Manually Applying IPS Updates, page 42-7
- Understanding IPS Network Sensing, page 34-1
- Deploying Configurations in Non-Workflow Mode, page 8-27
- Deploying Configurations in Workflow Mode, page 8-32

**Step 1**  Select Tools > Security Manager Administration and select IPS Updates from the table of contents to open the IPS Updates page (see IPS Updates Page, page 11-28).

**Step 2**  In the Auto Update Settings group in the lower portion of the page, select an auto update mode to establish the extent of automation. Choices include:

- Download, Apply, and Deploy Updates—Security Manager checks for updates according to your schedule, downloads them to the Security Manager server, applies them to the selected devices and policies, and starts a deployment job to update the affected devices. This choice ensures that your devices are running the latest updates with minimal effort for your operations staff.
• Disable Auto Update—Security Manager does not perform any automatic actions for IPS updates.
• Check for Updates—Security Manager checks for updates according to your schedule and updates the information in the Update Status group. No devices or policies are updated.
• Download Updates—Security Manager checks for updates according to your schedule and downloads any new updates to the Security Manager server.
• Download and Apply Updates—Security Manager checks for updates according to your schedule, downloads them, and applies them to the selected devices and policies. You must separately create a deployment job to deploy the changes to the affected devices.

Step 3 Click Edit Update Schedule to open a dialog box where you can specify the schedule for the operation. Select the starting date, enter the starting time in 24-hour format (hh:mm), and select whether the schedule should be by the hour, day, week, month, or a one-time event. Click OK to save the schedule.

Step 4 (Optional) Enter an e-mail address in the Notify Email field. Security Manager will notify this user when a package is available for download or has been downloaded, applied, or deployed. You can enter more than one address by separating the addresses with commas.

Step 5 Select the devices and shared policies you want to automatically update in the Apply Update To selector. Use the Type field to toggle between local policies (for devices) and shared policies.

To select a device or policy, click it in the selector and click the Edit Row button (the pencil icon below the selector). This action opens the Edit Auto Update Settings dialog box. Select the types of updates you want to apply: minor sensor updates and service packs or service packs only, and the signature update level. Click OK to save your changes. The devices to which the policy apply are added to the Devices to be Auto Updated list. A message will indicate if you need to submit your changes for the change to take effect.

Step 6 Click Save.

Manually Applying IPS Updates

You can manually apply image and signature updates to compatible IPS devices using the Apply IPS Update wizard. Use this procedure with policies and devices that you did not configure for automatic updates (as described in Automating IPS Updates, page 42-6).

When applying signature updates, the wizard displays those signatures in the update that are not configured on the target IPS devices. You can configure the new signatures before they are applied.

When applying image and signature updates, only those devices to which the updates can be applied are available for selection. Inapplicable devices are grayed out. A device can be grayed out even if a signature update applies to it if the required engine upgrade or generic packages are not available.

Tip If you later decide that you did not want to apply a signature update, you can revert to the previous update level by selecting the Signatures policy on the device, clicking the View Update Level button, and clicking Revert.

Before You Begin
Configure the IPS Update server as described in Configuring the IPS Update Server, page 42-4.

• Selecting a Signature Category for Cisco IOS IPS, page 43-6
Managing IPS Updates

Step 1
Select **Tools > Apply IPS Update** to open the Apply IPS Update wizard.

Step 2
On the first page of the wizard, select the update that you want to apply. This page lists the sensor and signature updates that are available. Do the following on this page:

- To update the list of packages, click **Download Latest Updates**. Security Manager logs into the IPS Update server and downloads the updates that have become available since the last download. This works only if you have configured an update server as described in Configuring the IPS Update Server, page 42-4. You can also update the list of packages by doing the following:
  - Configure automatic downloads on the IPS Updates page (select **Tools > Security Manager Administration > IPS Updates**). For more information, see **IPS Updates Page**, page 11-28.
  - Manually download the updates to the CSCOpx\MDC\ips\updates folder in the product installation folder (typically Program Files) on the Security Manager server.

You can also check for updates without downloading them by clicking **Check for Updates**. The Update Status information is the same as described in **IPS Updates Page**, page 11-28.

- Select the signature or sensor update you want to apply to your IPS devices in the Updates Downloaded table. Use the **Type** field to toggle between the types of updates (you can select only one update to apply):
  - **Sensor Updates**—Displays the filename, the major, minor, service pack, and patch versions, as well as the supported engine release. You must apply all major sensor updates, however, minor updates are cumulative.
  - **Signature Updates**—Displays the filename, the signature number, and the supported engine release. Signature updates are cumulative; however, applying them as separate packages allows you to separate your work into more manageable units if you intend to tune the updates to match the specific needs of your network.

Note

The engine package is not listed on the update page, but Security Manager implicitly pushes the engine package automatically in the case of a signature update that requires a higher engine version. (This occurs only when updating a device with the particular version that the engine package requires.)

Click **Next** to continue.

Step 3
On the second page of the wizard, select the local signature policies (representing devices not assigned to any shared signature policy) and shared signature policies you want to update from the Apply Updates To list. Use the **Type** field to toggle between the types of policies. You can select any combination of local and shared policies. When you select a policy, the devices that use the policy are selected for update.

To select all applicable devices or shared policies, click **Select All**. To erase your selection and start over, click **Deselect All**. These buttons apply only to the displayed list.
IPS devices to which the update does not apply are grayed out in the Apply Updates To list, and you cannot select them. When you select a device that can be updated, it is listed in the Devices Assigned to Selected Policies list; these are the only devices that will be updated. If you select a shared policy, all devices that are using the policy appear in the selected policies list, but the devices to which the update does not apply are grayed out.

**Tip**

The engine release controls which devices you can select for sensor updates; you can apply the update only to devices that use the same engine version, regardless of the release version. For example, if your device is running 6.0(5) E3, you can update to 6.1(1) E3 but not to 6.1(1) E2. You also cannot apply a 6.1(1) E3 update to a device running 6.1(1) E2. If you want to update the engine version, select a signature update with the higher engine version, and Security Manager will update the engine level automatically while updating the signatures. For example, if the device has the 6.1(1) E2 version and needs to have the E3 engine package applied, choose the signature package that requires the E3 engine and apply it to the device; doing so applies the engine package automatically to the device while updating the signatures. Thus, if the device you want to update is grayed out, click **Back** and change your update selection.

If you are applying a signature update, and you want to edit the signatures before applying them, click **Next** to continue. Otherwise, click **Finish** to apply your update to the policies.

### Step 4

(Optional) On the third page of the wizard, modify the signatures as desired.

The signatures list displays the new and modified signatures between the signature level of the selected update and the lowest signature level among the selected devices. If the selected devices include both IPS sensors and Cisco IOS IPS devices, the signatures for these devices appear on separate tabs.

Click the link in the ID number to read the description for the signature on Cisco.com. The Status column indicates whether the signature is new or modified (see the visual description of the icons on the wizard page).

To edit a signature, select it in the table and click the Edit button below the table (the pencil icon). For help in understanding the signature, click **Help** in the dialog box that the Edit button opens.

For details on available signature information, see **Signatures Page, page 37-4**. In the Signature Summary Table, you can also add custom signatures and delete signatures, but you cannot do that on this page of the Apply IPS Update Wizard.

Click **Finish** to apply your update to the policies and to save your edits.

### Step 5

Submit your changes and deploy them to the devices. For information on creating deployment jobs, see these topics:

- **Deploying Configurations in Non-Workflow Mode, page 8-27**
- **Deploying Configurations in Workflow Mode, page 8-32**
Managing IPS Certificates

When you configure Security Manager to use SSL (HTTPS) to communicate with your IPS devices, the certificate configured on the device must match the certificate stored in Security Manager’s certificate store. Mismatched certificates will result in communication failures during policy discovery or deployment.

IPS devices use self-signed certificates that have a fixed validity period of about 2 years. When the certificate expires, you need to regenerate the certificate and update the certificate store with the new certificate.

Security Manager includes a utility that you can use to synchronize the certificate store with the certificate defined on the device, to regenerate expired certificates, and to view the status of certificates (including expiration dates) on the IPS devices that you manage.

Tip

If you are using HTTP for communication with the IPS devices, certificates are not used and you cannot manage them. IPS device communication settings are configured in the Security Manager Administration Device Communication page (see Device Communication Page, page 11-15).

The following procedure explains how to manage your IPS certificates with Security Manager.

Related Topics

- Table Columns and Column Heading Features, page 1-44
- Filtering Tables, page 1-44
- Manually Adding SSL Certificates for Devices that Use HTTPS Communications, page 9-4
- Invalid Certificate Error During Device Discovery, page 9-6

Step 1

Select Manage > IPS > IPS Certificates to open the IPS Certificates dialog box.

Tip

The list shown in this dialog box is not automatically refreshed. Click Refresh whenever you open the dialog box to ensure that you are looking at the most current certificate expiration information.

The dialog box lists all IPS sensors that are in the inventory according to their Security Manager display name. Not all columns are displayed (right-click any cell heading to select additional columns). The main columns of interest are the following:

- **Certificate Mismatch?**—Whether the certificate defined on the device is the same as that in Security Manager. This field is blank if the certificate is unavailable or non-retrievable; otherwise, it can have these values:
  - **No**—The device and Security Manager have the same certificate. No action is required.
  - **Yes**—The device and Security Manager have different certificates. If the certificate has not expired, select the device and click Sync Certificates to replace the certificate in the Security Manager certificate store with the certificate from the device.

- **Valid Until on Device, Valid From on Device**—These two separate columns show the date range within which the certificate is valid. The certificate expires after the Valid Until date is reached. Consider regenerating the certificate as this date approaches.
- **Certificate Status on Device**—Shows the current status of the certificate as it exists on the device:
  - **Valid Certificate**—The certificate is good and within the validity date range.
  - **Expired Certificate**—The certificate has passed its Valid Until date and is now expired. Select the device and click **Regenerate Certificate** to create a new valid certificate on the device and to have the certificate loaded into the Security Manager certificate store.
  - **Certificate Not Yet Valid**—The certificate has not yet reached its Valid From date and cannot be used yet. This might indicate a mismatch between the time settings on the device and on the Security Manager server. Ensure that the time settings are the same (consider using an NTP server). Consider regenerating the certificate.
  - **Unavailable – Refresh to get Cert Info**—The certificate is not currently in the Security Manager certificate store. Click **Refresh** to have Security Manager retrieve the certificate from the device and load it into the certificate store.
  - **Nonretrievable – Cert Info not available**—Security Manager was not able to log into the device and retrieve the certificate, or you are using HTTP for communications. Select the device and click **Refresh**.

  If refresh does not resolve the problem, ensure that the device is operating normally (that it is not down), and then check the device properties to ensure that correct credentials are configured for access (see Viewing or Changing Device Properties, page 3-37). If credentials are not the problem, also check the Allowed Hosts policy configured on the device and ensure that the Security Manager server is included as an allowed host (see Identifying Allowed Hosts, page 34-7). You can also log into Windows on the Security Manager server and use ping to see if there is a route between the server and the IPS device.

- **Thumbprint on CSM, Thumbprint on Device**—These separate columns show the thumbprint for the certificate in the certificate store and on the device.

**Step 2**

Use any of the following buttons to perform the indicated actions. Except where indicated, if you do not select one or more devices before clicking the button, the action is performed on all listed devices, which can be time-consuming if there are a lot of IPS devices. You are warned before an operation is performed on all devices and given the option to stop it.

- **Sync Certificate**—Synchronize the certificate information in the Security Manager certificate store with the certificate on the device. The device certificate replaces the one in the certificate store.
- **Regenerate Certificate**—Generate a new certificate on the device and then load the new certificate into the certificate store.
- **Refresh**—Refresh the status information by having Security Manager contact the devices and retrieve certificate information, such as validity dates, and compare the certificate with the one in the certificate store. This action updates the Certificate Status on Device column and also determines whether there is a certificate mismatch.
- **Export**—Exports the entire certificates table to a comma-separated values (CSV) file. You cannot export less than the entire table. You are prompted for a file name and folder on the Security Manager server.
Rebooting IPS Sensors

You can reboot an IPS sensor from Security Manager.

To reboot the sensor, select it in Device view, right-click and select **Reboot Device**. You are asked to confirm that you want to reboot.

Security Manager does not provide status information on the reboot process.
Configuring IOS IPS Routers

Some Cisco IOS routers, such as integrated services routers (ISRs), include native IPS capabilities based on IPS 5.1 software. You can configure some basic IPS inspection on these devices to supplement IPS sensor inspection or to support small networks.

This chapter contains the following topics:

- Understanding Cisco IOS IPS, page 43-1
- Overview of Cisco IOS IPS Configuration, page 43-3

Understanding Cisco IOS IPS

You can use Cisco Security Manager with the Cisco IOS Intrusion Prevention System (IPS) to manage intrusion prevention on Cisco routers that use supported Cisco IOS Software releases 12.4(11)T2 and higher.

The Cisco IOS IPS acts as an in-line intrusion prevention sensor, watching packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When it detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE).

You can configure Cisco IOS IPS to choose the appropriate response to various threats. The Signature Event Action Processor (SEAP) can dynamically control actions that are to be taken by a signature event on the basis of parameters such as fidelity, severity, or target value rating. You can configure these actions in Security Manager through the Signatures and Event Actions policies.

When packets in a session match a signature, Cisco IOS IPS can take any of the following actions, as appropriate:

- Send an alarm to a syslog server or a centralized management interface.
- Drop the packet.
- Reset the connection.
- Deny traffic from the source IP address of the attacker for a specified amount of time.
- Deny traffic on the connection for which the signature was seen for a specified amount of time.

Cisco developed its Cisco IOS software-based intrusion-prevention capabilities and Cisco IOS Firewall with flexibility in mind, so that individual signatures could be disabled in case of false positives. Generally, it is preferable to enable both the firewall and Cisco IOS IPS to support network security policies. However, each of these features can be enabled independently and on different router interfaces.
For an overall understanding of the Cisco IOS IPS configuration process, see Overview of Cisco IOS IPS Configuration, page 43-3.

This section contains the following topics:

- Understanding IPS Subsystems and Support of IOS IPS Revisions, page 43-2
- Cisco IOS IPS Signature Scanning with Lightweight Signatures, page 43-2
- Router Configuration Files and Signature Event Action Processor (SEAP), page 43-3
- Cisco IOS IPS Limitations and Restrictions, page 43-3

Understanding IPS Subsystems and Support of IOS IPS Revisions

Cisco Security Manager automatically supports minor revisions of IOS IPS. To identify minor revisions that are supported, the IPS subsystem version is needed.

The IPS subsystem version is a version number used to keep track of Cisco IOS IPS feature changes. The subsystem number is show in the device properties (right-click the device and select Device Properties). You can also use the command show subsys name ips at a command line on the router that is running Cisco IOS IPS to show the detailed Cisco IOS IPS subsystem version. The 3.x subsystems are equivalent to IPS 5.x. For a list of the supported subsystems by Cisco IOS Software release, see the Supported Devices and Software Versions for Cisco Security Manager on Cisco.com for this release of Security Manager.

An IPS subsystem version is minor if the version difference is limited at postfix. For example, a revision from 3.0.1 to 3.0.2 is considered minor. For another example, 3.0.1 to 3.1.1 is also considered a minor version change. However, minor revisions that include new features are not automatically supported by Cisco Security Manager.

Cisco IOS IPS Signature Scanning with Lightweight Signatures

The addition of Cisco IOS IPS signature scanning with lightweight signatures in Cisco IOS Release 15.0(1)M is an enhancement to Cisco IOS IPS that allows loading of larger signatures sets, without consuming significant additional memory or reducing the memory consumed by an existing signature set, by loading equivalent lighter-weight signatures. These signatures are referred to as lightweight signatures.

Security Manager can discover and tune custom signatures with LWEs on ISRs and modular access routers. Security Manager supports the following features for signatures with LWEs on ISRs and modular access routers:

- New signature types
- Signature categories
- New default signature category recognition
- New engine update levels
- Licensing status—bypassed, expired, or not installed
Router Configuration Files and Signature Event Action Processor (SEAP)

As of Cisco IOS Release 12.4(11)T, signature definition files (SDFs) are no longer used by Cisco IOS IPS. Thus, you cannot use the deprecated built-in signature sets, 128.sdf, 256.sdf, and attack-drop.sdf, with Security Manager.

Instead, routers access signature definition information through a directory that contains three configuration files—the default configuration, the delta configuration, and the SEAP configuration. You configure the location using the IPS > General Settings policy.

SEAP is the control unit responsible for coordinating the data flow of a signature event. It allows for advanced filtering and signature overrides on the basis of the Event Risk Rating (ERR) feedback. ERR is used to control the level in which a user chooses to take actions in an effort to minimize false positives.

Signatures once stored in NVRAM are now stored in the delta configuration file.

Cisco IOS IPS Limitations and Restrictions

Cisco IOS IPS routers do not support all the features that are supported by dedicated IPS sensor appliances and service modules. In addition, routers that support IOS IPS might not allocate as much memory to IPS functionality as an IPS sensor does. The following limitations and restrictions are important:

- When configuring an IOS IPS device, select only the signatures that you need. If you select all signatures that are available in Security Manager, you might exceed the memory available on the IOS IPS router and deployment can fail, the device might fail to load all of the signatures, or performance might be significantly degraded. If you encounter deployment failures, select a reduced set of signatures and then redeploy the configuration to the device.

- Virtual sensors are not supported by IOS IPS.

- When using event action filters with an IOS IPS router, only a subset of IPS actions are available for removal from an event that meets the criteria of the event action filter. For more information on available event actions, see Filter Item Dialog Box, page 38-9 and Understanding IPS Event Actions, page 38-2.

- IOS IPS is based on IPS Software 5.1. Therefore, features introduced in later versions of IPS Software are typically not available in IOS IPS. For example, you cannot configure the following features:
  - Global correlation.
  - Anomaly detection.
  - OS identification in the event action network identification policy.

Overview of Cisco IOS IPS Configuration

There are a wide variety of devices on which you can configure the Intrusion Prevention System. From a configuration point-of-view, you can separate the devices into two groups: dedicated appliances and service modules (for routers, switches, and ASA devices) that run the full IPS software; and IPS-enabled routers running Cisco IOS Software 12.4(11)T and later (Cisco IOS IPS).

The following procedure is an overview of IPS configuration on a Cisco IOS IPS router. For dedicated IPS devices, including IPS service modules installed in a router, see Overview of IPS Configuration, page 34-5.
Cisco IOS IPS is a more limited feature meant for branch offices and small to medium sized networks, or to distribute IPS throughout a network. You typically cannot employ as many signatures in a Cisco IOS IPS router compared to a dedicated appliance. You also cannot configure advanced features such as global correlation, because Cisco IOS IPS is based on IPS Software version 5.1. When configuring Cisco IOS IPS devices, you are mostly configuring standard router policies, because the device is a router that is running a few IPS features. In comparison, the platform policies for IPS appliances and service modules are specific to IPS software.

**Tip** Before configuring Cisco IOS IPS, read *Cisco IOS Intrusion Prevention System Deployment Guide* on Cisco.com.

---

**Step 1** Install and connect the device to your network. Install the device software and perform basic device configuration. Install the licenses required for all of the services running on the device. The amount of initial configuration that you perform influences what you will need to configure in Security Manager. For information about required basic settings, see:

- Setting Up SSL on Cisco IOS Routers, page 2-4
- Setting Up SSH, page 2-5
- Configuring Licenses on Cisco IOS Devices, page 2-12
- Initial Preparation of a Cisco IOS IPS Router, page 43-5
- Selecting a Signature Category for Cisco IOS IPS, page 43-6

**Step 2** Add the device to the Security Manager device inventory (see Adding Devices to the Device Inventory, page 3-7). When you add the device be sure to make the following selections:

- When adding from Network or Export File, ensure that you select **IPS Policies** for policy discovery.
- When adding from Configuration File or by Manual Definition, ensure that you select **IPS** from the **Options** list, or the device will not be IPS-capable from Security Manager’s point of view.

**Step 3** Configure the IPS general settings to specify the location of the IPS files on the router. For more information, see Configuring General Settings for Cisco IOS IPS, page 43-7.

**Step 4** Configure the IPS interface rules to enable IPS and to identify the interfaces on which traffic will be subject to IPS inspection. For more information, see Configuring IOS IPS Interface Rules, page 43-8.

**Step 5** Configure IPS signatures and event actions. Event action policies are easier to configure than creating custom signatures, so try to use event action filters and overrides to modify signature behavior before trying to edit specific signatures. For more information, see the following topics:

- Chapter 38, “Configuring Event Action Rules”
- Configuring Signatures, page 37-4

**Step 6** Maintain the device:

- Update and redeploy configurations as necessary.
- Apply updated signature and engine packages. For information about checking for updates, applying them, and setting up regular automated updates, see Managing IPS Updates, page 42-4.
Initial Preparation of a Cisco IOS IPS Router

Before you add a Cisco IOS IPS router to the Security Manager inventory, you need to perform some preparatory steps. The white paper Getting Started with Cisco IOS IPS with 5.x Format Signatures on Cisco.com provides a step-by-step explanation of a basic configuration. Although you could do some of the steps after adding the router to Security Manager, such as configuring interface rules, you should do at least the basic steps.

The following procedure explains the steps you are required to complete in the CLI. These steps are required because Security Manager either cannot complete them, or it is simply easier to do it in the CLI (as a one-time configuration). The white paper includes additional steps that you can complete in the CLI, and Security Manager can discover your configuration when you add the device to the inventory. The more you do in CLI, the less you will have to configure in Security Manager.

Tip
You also must complete the basic router configuration steps as explained in Setting Up SSL on Cisco IOS Routers, page 2-4, Setting Up SSH, page 2-5, and Configuring Licenses on Cisco IOS Devices, page 2-12. The following steps apply to the IPS configuration only.

Step 1
Create a directory for IPS files on flash. For example, the following command creates a directory named ips:

```
router# mkdir ips
```

At this point, you can optionally configure the router to use this directory for IPS, or you can do it later in Security Manager (in the IPS > General Settings policy). Use the following commands to configure it in CLI:

```
router# configure terminal
router(config)# ip ips config location flash:ips
```

Step 2
Configure the Cisco IOS IPS crypto key. The crypto key is used to verify the digital signature for the master signature file (sigdef-default.xml) whose contents are signed by a Cisco private key to guarantee its authenticity and integrity at every release.

You can obtain the CLI required for the key from http://download-sj.cisco.com/cisco/ciscosecure/ids/sigup/5.0/ios/realm-cisco.pub.key.txt (login to Cisco.com is required). Configuring the key through the CLI is probably the easiest way to do it. Alternatively, you can configure it in Security Manager by assigning the IOS_IPS_PUBLIC_KEY pre-defined FlexConfig object to the router’s FlexConfig policy. For more information about FlexConfigs, see Chapter 7, “Managing FlexConfigs”.

Tip
Configuring the key through the CLI is probably the easiest way to do it. Alternatively, you can configure it in Security Manager by assigning the IOS_IPS_PUBLIC_KEY pre-defined FlexConfig object to the router’s FlexConfig policy. For more information about FlexConfigs, see Chapter 7, “Managing FlexConfigs”.

- Open the text file and copy its contents to the clipboard (select all text then press Ctrl+C).
- If necessary, enter configure terminal at the router CLI prompt.
- Paste the copied text file at the router prompt.
- Exit configuration mode.
- Enter the show run command to confirm that the key was correctly configured.
Step 3  Syslog is configured for IPS notifications by default. If you want to use SDEE for notifications, enable SDEE:

```
router# configure terminal
router(config)# ip ips notify sdee
```

Step 4  Select a signature category to compile. For detailed information, see Selecting a Signature Category for Cisco IOS IPS, page 43-6.

Selecting a Signature Category for Cisco IOS IPS

Cisco IPS appliances and Cisco IOS IPS with IPS 5.x format signatures operate with signature categories. All signatures are grouped into categories; the categories are hierarchical. An individual signature can belong to more than one category. Top-level categories help to define general types of signatures. Subcategories exist beneath each top-level signature category. (For a list of supported top-level categories, use your router CLI help (?) with the category command.)

Router memory and resource constraints prevent a router from loading all Cisco IOS IPS signatures. Thus, it is recommended that you load only a selected set of signatures that are defined by the categories. Because the categories are applied in a “top-down” order, you should first retire all signatures, followed by “unretiring” specific categories. Retiring signatures enables the router to load information for all signatures, but the router does not build the parallel scanning data structure.

Retired signatures are not scanned by Cisco IOS IPS, so they do not fire alarms. If a signature is irrelevant to your network or if you want to save router memory, you should retire signatures, as appropriate.

Security Manager does not manage the signature category command. You cannot configure it directly with a policy. However, you can configure the FlexConfig policy to include a FlexConfig object that configures the command. There is a pre-defined object, IOS_IPS_SIGNATURE_CATEGORY, that you can use. If you want to configure a different category than basic, make a copy of the object and edit it. For information on how to use FlexConfigs, see Chapter 7, “Managing FlexConfigs”.

Tip  If you do not use the category command to select a subset of IPS signatures that the device will attempt to compile, Security Manager will configure the category command to enable the IOS IPS Basic category to prevent the device resources from being overloaded. You can change the category manually on the device to select another set of signatures to compile. We recommend that you configure the category before adding the device to Security Manager; however, this is not possible if you add the device through manual definition.

The following example shows how to first retire all signatures, then to configure the basic category and unretire the basic signatures:

```
Router> enable
Router# configure terminal
Router(config)# ip ips signature-category
Router(config-ips-category)# category all
Router(config-ips-category-action)# retired true
Router(config-ips-category-action)# exit
Router(config-ips-category)# category ios_ips basic
Router(config-ips-category-action)# retired false
Router(config-ips-category-action)# exit
```
Configuring General Settings for Cisco IOS IPS

Use the General Settings page to specify the global settings used for Cisco IOS IPS properties defined for a particular router. The default settings are appropriate for most situations; however, you must specify an IPS configuration file location. If storing the configuration file on the router, you must first create the directory as described in Initial Preparation of a Cisco IOS IPS Router, page 43-5.

Navigation Path

- (Device view) Select IPS > General Settings from the Policy selector.
- (Policy view) Select IPS (Router) > General Settings, then select an existing policy or create a new one.

Related Topics

- Overview of Cisco IOS IPS Configuration, page 43-3
- Understanding Cisco IOS IPS, page 43-1

Field Reference

Table 43-1 General Settings Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Traffic when IPS engine is unavailable</td>
<td>Whether to block all inspected traffic if the IPS engine is not available, for example, when the signature engine is being built or if it fails to build. If you select this option, any traffic specified for inspection is dropped if IPS cannot process it (also known as fail-closed mode). Otherwise, traffic is allowed to pass in accordance with the other rules in place on the router (the default).</td>
</tr>
</tbody>
</table>
| Apply Deny Action On | Where to apply ACL entries to drop traffic for Deny Attacker Inline or Deny Flow Inline events. Select one of the following values:  
  - Ingress Interface (the default)—Enforce the deny action on the interface attached to the network from which the traffic originated.  
  - IPS enabled interfaces—Enforce the deny action on the interface on which the triggered IPS rule is applied.  
  Enabling this option causes IOS IPS to apply the ACLs directly to the IPS interfaces, and not to the interfaces that originally received the attack traffic. If the router is not performing load balancing, do not enable this setting. If the router is performing load balancing, we recommend that you enable this setting. |

SDEE Properties

| Maximum Subscriptions | The maximum number of concurrent SDEE subscriptions allowed, in the range of 1-3. An SDEE subscription is a live feed of SDEE events. The default is 1. |
| Maximum Alerts | The maximum number of SDEE alerts that you want the router to store, in the range of 10-2000. Storing more alerts uses more router memory. The default is 200. |
Overview of Cisco IOS IPS Configuration

Configuring IOS IPS Interface Rules

Use the IPS Interface Rules policy to enable IPS inspection on Cisco IOS IPS routers and to specify the interfaces that will be subject to IPS inspection. You can identify a subset of the traffic on the interface that is subject to inspection by configuring an ACL and by specifying the traffic direction relative to the interface.

Related Topics
- Overview of Cisco IOS IPS Configuration, page 43-3
- Understanding Cisco IOS IPS, page 43-1
Step 1
Do one of the following to open the Interface Rules policy you want to modify:

- (Device view) Select **IPS > Interface Rules** from the Policy selector.
- (Policy view) Select **IPS (Router) > Interface Rules** from the Policy selector. Select an existing policy or create a new one.

The policy shows any existing interface rules, including the rule name, the name of the ACL that defines which traffic is inspected (if any), and the interface and traffic direction that is inspected. If no ACL is specified, all traffic on the interface in the specified direction is inspected.

Although the rules are numbered, the sequence of rules has no effect on IPS processing.

Step 2
Select **Enable IPS** to enable the deployment of IOS IPS configuration to the device.

If Enable IPS is unchecked, IPS rules are removed from all the router interfaces, which disables IPS. Also, no signature or event action policy will be deployed.

Step 3
Configure the interface rules. The rules identify the interfaces, and traffic direction on the interface, that will be inspected by IPS. The rules can optionally include an ACL to identify a subset of traffic for inspection.

- To add a rule, click the **Add Row (+)** button and fill in the Add IPS Rule dialog box. For detailed information, see **IPS Rule Dialog Box**, page 43-9.
- To edit a rule, select it and click the **Edit Row (pencil)** button.
- To delete a rule, select it and click the **Delete Row (trash can)** button.

### IPS Rule Dialog Box

Use the Add or Edit IPS Rule dialog box to identify the traffic flows to be inspected using the active signature policy.

**Navigation Path**

From the Interface Rules policy, click the **Add Row** button to add a new rule, or select a rule and click the **Edit Row** button. For information on opening the Interface Rules policy, see **Configuring IOS IPS Interface Rules**, page 43-8.

**Field Reference**

**Table 43-2 Add or Edit IPS Rule Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Name</td>
<td>The unique name for this IPS rule. IPS rule names are not case sensitive. You cannot use a rule name that contains the same characters as another one previously defined but using a different case. For example MYRULE and MyRule are the same.</td>
</tr>
</tbody>
</table>
Overview of Cisco IOS IPS Configuration

Chapter 43 Configuring IOS IPS Routers

Table 43-2  Add or Edit IPS Rule Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| ACL Name      | The name of the ACL policy object that defines which traffic should be subject to IPS inspection. If you do not specify an ACL, all traffic on the interface/direction pairs listed in the Interface Pairs table is subject to inspection.  
**Tip** If you create an ACL, permit entries identify traffic that is subject to inspection, whereas deny entries identify traffic that is exempt from inspection. Remember that there is an implicit deny any any rule at the end of the ACL, so if your intention is simply to identify exempt traffic, be sure to add a permit any any rule at the end of the ACL.  
Enter the name of the ACL policy object, or click Select to select it from a list or to create a new object. |
| Interface Pairs table | The interfaces and traffic direction pairs that are subject to IPS inspection.  
- To add a pair, click the Add Row (+) button and fill in the Adding Pair dialog box. See Pair Dialog Box, page 43-10.  
- To edit a pair, select it and click the Edit Row (pencil) button.  
- To delete a pair, select it and click the Delete Row (trash can) button. |

Pair Dialog Box

Use the Adding or Editing Pair dialog box to identify the interface and traffic direction pair to add to a Cisco IOS IPS interface rule. For information on configuring interface rules, see Configuring IOS IPS Interface Rules, page 43-8.

Navigation Path

From the Add or Edit IPS Rule dialog box, click the Add Row button to add a new pair, or select a pair and click the Edit Row button. For information on opening the Add or Edit IPS Rule dialog box, see IPS Rule Dialog Box, page 43-9.

Field Reference

Table 43-3 Adding or Editing Pair Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Direction | The traffic direction, with respect to the interface, on which IPS inspection should be performed. Select one of the following:  
- **In** (default)—The IPS rule should be applied to inbound traffic.  
- **Out**—The IPS rule should be applied to outbound traffic.  
- **Both**—The IPS rule should be applied to both inbound and outbound traffic. |
## Table 43-3 Adding or Editing Pair Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Interfaces | The interface on which to apply this IPS rule. Enter the name of an interface or interface role object, or click **Select** to select the interface or interface role from a list or to create a new interface role.  
If you use interface roles, the rule is applied to all interfaces on the device that are defined by the role. The interfaces that match the role cannot conflict with an existing rule. You cannot specify the same interface for more than one interface rule. |
PART 5

PIX/ASA/FWSM Device Configuration
Managing Firewall Devices

The following topics describe configuration and management of security services and policies on Cisco security devices: Adaptive Security Appliances (ASAs), PIX Firewalls, and the Catalyst 6500 series switch Services Modules—that is, Firewall Services Modules (FWSMs) and ASA-SMs.

This chapter contains the following topics:

- Firewall Device Types, page 44-1
- Default Firewall Configurations, page 44-2
- Configuring Firewall Device Interfaces, page 44-2

Firewall Device Types

Security Manager can discover and manage a variety of Cisco security appliances or firewall devices, most notably the following:

- PIX 500 Series firewall devices
- ASA 5500 Series security appliances
- Security-specific Catalyst Services Modules

PIX 500 Series

The Private Internet eXchange (PIX) 500 Series firewall appliances are no longer sold, however they are still supported and a great many are still in use world-wide.

ASA 5500 Series

The Adaptive Security Appliance (ASA) 5500 Series devices provide comprehensive security services, including context-aware firewall capabilities and real-time threat defense. The ASA 5500 has replaced the PIX 500 as Cisco’s primary security appliance. Visit the Cisco ASA 5500 Series Adaptive Security Appliance page on cisco.com for more information.

Catalyst Services Modules

A variety of Services Modules (SMs) are available for the Catalyst 6500 switch, including two that provide firewall and security services. These are blade-type modules that are installed directly into the switch chassis.

The Firewall Services module (FWSM) allows any port on the switch to operate as a firewall port, integrating firewall security inside the network structure. See Cisco Catalyst 6500 Series Firewall Services Module for more information.
Chapter 44      Managing Firewall Devices

Default Firewall Configurations

Firewall devices are shipped with certain settings already configured. When you manually add a newly installed firewall device to Cisco Security Manager, you should discover (import) the pre-set or default policies for that device. Importing these policies into Security Manager prevents them being unintentionally removed the first time you deploy a configuration to that device. For more information about importing policies, see Discovering Policies, page 5-12.

Cisco Security Manager provides a set of configuration files that contain default policies for a number of device types and versions. These configuration files are located in the directory: 

\<install_dir>\CSCOpx\MDC\fwtools\pixplatform\ (for example, C:\Program Files\CSCOpx\MDC\fwtools\pixplatform\).

The file name indicates device type, operating system version, context support, and operation type. For example, “FactoryDefault_FWSM2_2_MR.cfg” is the configuration file for an FWSM, version 2.2, with support for Multiple contexts, operating in Routed mode. Similarly, “FactoryDefault_ASA7_0_1_ST.cfg” is the configuration file for an ASA, version 7.0.1, in Single-context, Transparent mode.

Refer to Interfaces in Single and Multiple Contexts, page 44-5 for more about security contexts, and Interfaces in Routed and Transparent Modes, page 44-4 for more about routed and transparent operation.

See Adding Devices from Configuration Files, page 3-18 for information about adding new devices from the supplied configuration files.

Configuring Firewall Device Interfaces

The Interfaces page displays configured physical interfaces, logical interfaces, and redundant interfaces, as well as hardware ports and bridge groups, for the selected device. From this page, you can add, edit and delete interfaces; enable communication between interfaces on the same security level; and manage VPDN groups and PPPoE users.

The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: Hardware Ports and Interfaces. Similarly, the Interfaces page displayed for the Catalyst 6500 services modules (ASA-SMs and FWSMs) operating in transparent mode also presents two tabbed panels: Interfaces and Bridge Groups.

Navigation Path
To access the Interfaces page, select a security device in Device View and then select Interfaces from the Device Policy selector.
This section contains the following topics:
- Understanding Device Interfaces, page 44-3
- Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14
- Advanced Interface Settings (PIX/ASA/FWSM), page 44-42

Understanding Device Interfaces

An interface is a point of connection between a security device and some other network device. Interfaces are initially disabled; thus, as an essential part of firewall configuration, interfaces must be enabled and configured to allow appropriate packet inspection and forwarding.

There are two types of interface: physical and logical, where a physical interface is the actual slot on the device into which a network cable is plugged, and a logical interface is a virtual port assigned to a specific physical port. Generally, physical ports are referred to as interfaces, while logical ports are referred to as subinterfaces, virtual interfaces, VLANs, or EtherChannels, depending on their function. The number and type of interfaces you can define varies with appliance model and type of license purchased.

Note

On devices running version 6.3 of the PIX operating system, the labels “physical” and “logical” are used, rather than “interface” and “subinterface.” Also, transparent mode and multiple contexts are not supported on these devices.

Subinterfaces let you divide a physical interface into multiple logical interfaces that are tagged with different VLAN IDs. Because VLANs keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or security appliances. This feature is particularly useful in multiple-context mode, allowing you to assign unique interfaces to each context.

As a general rule, interfaces attach to router-based networks, and subinterfaces attach to switch-based networks. All subinterfaces must be associated with a physical interface that is responsible for routing allowed traffic correctly.

If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. The physical interface must be enabled for the subinterface to pass traffic, but do not name the physical interface to ensure it does not pass traffic. However, if you do want to let the physical interface pass untagged packets, you can name the interface as usual. See Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14 for information about naming an interface.

The Catalyst 6500 services modules (ASA-SMs and FWSMs) do not include any external physical interfaces—instead, they use internal VLAN interfaces. For example, assume you assign VLAN 201 to an FWSM inside interface, and VLAN 200 to the outside interface. You assign these VLANs to physical switch ports, and hosts connect to those ports. When communication occurs between VLANs 201 and 200, the FWSM is the only available path between the VLANs, forcing traffic to be statefully inspected.

Note

The ASA 5505, combining switch and security appliance features, is a special case in that you configure both physical switch ports and logical VLAN interfaces. See Understanding ASA 5505 Ports and Interfaces, page 44-6 for more information.
See the following sections for additional information about device interfaces:

- Interfaces in Routed and Transparent Modes, page 44-4
- Interfaces in Single and Multiple Contexts, page 44-5
- Understanding ASA 5505 Ports and Interfaces, page 44-6
- Configuring Subinterfaces (PIX/ASA), page 44-7
- Configuring Redundant Interfaces, page 44-8
- Configuring EtherChannels, page 44-9

Security Appliance Configurations

Firewall devices allow a variety of configurations, and the configuration determines how to define the interfaces associated with a specific device. The following table outlines the various configurations.

<table>
<thead>
<tr>
<th>Device Type</th>
<th>Operational Mode (Router or Transparent)</th>
<th>Context Support (Single or Multiple)</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIX 6.3.x</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>

<td>Multiple (see Checklist for Configuring Multiple Security Contexts, page 56-2)</td>
</tr>
<tr>
<td>FWSM, or security context of unmanaged switch (multiple mode)</td>
<td>Router or Transparent</td>
<td>Single or Multiple</td>
</tr>
</tbody>
</table>

Interfaces in Routed and Transparent Modes

Beginning with ASA/PIX 7.0 and FWSM 2.2.1, you can configure a security device to operate in one of two modes: routed or transparent. (The PIX 6.3 operates only in routed mode.)

In routed mode, the security appliance acts as a gateway or router for connected networks: it maintains IP addresses for its interfaces, and inspects and filters traffic traversing these interfaces based on IP address (Layer 3) information. In this mode, each device interface is connected to a different IP subnet, and has its own IP address on that subnet. Routed mode supports up to 256 interfaces in single mode or per context, with a maximum of 1000 interfaces divided between all contexts.

In transparent mode, the security appliance operates as a Layer 2 (data link) device, or transparent bridge, and is often referred to as a “bump in the wire,” or a “stealth firewall.” In this mode, you can define only two interfaces: inside and outside. The interfaces do not require IP addresses; they use VLAN IDs to forward inspected traffic. However, if the device includes a dedicated management interface, you can use it—either the physical interface or a subinterface—as a third interface for device-management traffic.

Note

Cisco Security Manager does not populate the interface information for FWSM 2.x devices during discovery.
**Bridge Groups**

Beginning with the ASA 8.4.1 and FWSM 3.1, in transparent mode, you can increase the number of interfaces available to a device or context through use of bridge groups. You can configure up to eight bridge groups; on an FWSM each group can contain two interfaces; on an ASA each group can contain four interfaces. See Add/Edit Bridge Group Dialog Box, page 44-41 for more information.

**Related Topics**
- Chapter 45, “Configuring Bridging Policies on Firewall Devices”

**Interfaces in Single and Multiple Contexts**

Security “contexts” allow a single physical device to operate as multiple, independent firewalls. In multiple-context mode, each context defines a single virtual firewall, complete with its own configuration. Each context acts as a unique virtual firewall that inspects and filters traffic traversing the interfaces allocated to that context. Each context is “unaware” of other contexts defined on the same security appliance.

As with a single-context, routed-mode device, interfaces on a multiple-context device connect to router-based networks, subinterfaces connect to switch-based networks, and each subinterface must be associated with an interface that routes allowed traffic correctly.

However, you cannot define IP addresses, the routed-mode portion of the configuration, or identify the management interface until you have defined and deployed the contexts. But you cannot define a security context until you have defined the necessary interfaces and subinterfaces.

In other words, you must enable and configure the interfaces and subinterfaces on a device that will provide multiple security contexts (in either routed or transparent mode) before you can define and configure the security contexts themselves.

Refer to Chapter 56, “Configuring Security Contexts on Firewall Devices” for more information.

**About Asymmetric Routing Groups**

In some situations, return traffic for a session may be routed through a different interface than the one from which it originated. Similarly, in failover configurations, return traffic for a connection that originated on one unit may return through the peer unit. This most commonly occurs when two interfaces on a single FWSM, or two FWSMs in a failover pair, are connected to different service providers and the outbound connection does not use a NAT address. By default, the FWSM drops the return traffic because there is no connection information for that traffic.

You can prevent return traffic being dropped by assigning the VLAN interfaces on which this is likely to occur to an asymmetric routing (ASR) group. When a member interface receives a packet for which it has no session information, it checks the session information for other interfaces that are members of the same group.

If a match is not found, the packet is dropped. If a match is found, one of the following actions occurs:

- If the incoming traffic originated on a different interface on the same FWSM, some or all of the Layer 2 header is rewritten and the packet is re-injected into the stream.
- If the incoming traffic originated on a peer unit in a failover configuration, some or all of the Layer 2 header is rewritten and the packet is redirected to the other unit. This redirection continues as long as the session is active.
In failover configurations, you must enable Stateful Failover for session information to be passed from the standby unit or failover group to the active unit or failover group.

To assign an FWSM virtual interface to an asymmetric routing group, simply specify an ASR Group ID in the Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+), page 44-27. If the group does not exist, it is created and the interface assigned to it.

You must repeat the assignment for each interface that will participate in this ASR group. You can create up to 32 ASR groups and assign a maximum of eight interfaces to each group.

The upstream and downstream routers must use one MAC address per VLAN, and have different MAC addresses for different VLANs, to allow the redirection of packets from a standby unit to an active unit in failover configurations.

Understanding ASA 5505 Ports and Interfaces

The ASA 5505 is unique in that it includes a built-in switch, and there are two kinds of ports and interfaces that you need to configure:

- Physical switch ports – The ASA 5505 has eight Fast Ethernet switch ports that forward traffic at Layer 2, using the switching function in hardware. Two of these ports are power-over-Ethernet (PoE) ports. You can connect these ports directly to user equipment such as PCs, IP phones, or DSL modems. Or you can connect to another switch.

- Logical VLAN interfaces – In routed mode, these interfaces forward traffic between VLAN networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces forward traffic between the VLANs on the same network at Layer 2, using the configured security policy to apply firewall services.

To segregate the switch ports into separate VLANs, you assign each switch port to a VLAN interface. Switch ports on the same VLAN can communicate with each other using hardware switching. But when a switch port on one VLAN attempts to communicate with a switch port on another VLAN, the ASA 5505 applies the security policy to the traffic, and routes or bridges between the two VLANs.

Subinterfaces and redundant interfaces are not available on the ASA 5505.

Navigation Path

The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: Hardware Ports and Interfaces. To access these panels, select an ASA 5505 in Device View and then select Interfaces from the Device Policy selector.

Configuring ASA 5505 Switch Ports and Interfaces

Refer to Configuring Hardware Ports on an ASA 5505, page 44-39 for information about configuring the switch ports.

Refer to Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19 for information about configuring the interfaces.

Related Topics

- Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14
Configuring Subinterfaces (PIX/ASA)

Subinterfaces let you divide a physical interface into multiple logical interfaces that are tagged with different VLAN IDs. Because VLANs keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or security appliances. This feature is particularly useful in multiple-context mode, letting you assign unique interfaces to each context.

Note
If you use subinterfaces, you typically do not also want the physical interface to pass traffic, as the physical interface passes untagged packets. Because the physical interface must be enabled for the subinterface to pass traffic, do not name the physical interface to ensure it does not pass traffic. However, if you do want to let the physical interface pass untagged packets, you can name the interface as usual.

Note
This option is available only on PIX 7.0+ and non-5505 ASA devices.

Defining Subinterfaces

Follow these steps to configure a subinterface in the Add/Edit Interface (ASA/PIX 7.0+) dialog box, which is accessed from the device Interfaces page (see Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14).

1. Choose Subinterface as the interface Type in the Add/Edit Interface dialog box.
   The VLAN ID and Subinterface ID fields appear below the Hardware Port, Name and Security Level fields.

2. Choose the desired Hardware Port from the list of previously defined interface ports. If you do not see a desired interface ID, be sure that Interface is defined and enabled.

3. VLAN ID – Provide a VLAN ID for this subinterface: enter a value between 1 and 4094. The specified VLAN ID must not be in use on any connected device.
   Some VLAN IDs might be reserved on connected switches; see the switch documentation for more information. In multiple-context mode, you can only set the VLAN ID in the system configuration.

4. Subinterface ID – Provide an integer between 1 and 4294967293 as the Subinterface ID. The number of subinterfaces allowed depends on your platform.
   For subinterface port identification, this ID is appended to the chosen Hardware Port. For example, GigabitEthernet0.4 represents the subinterface assigned an ID of 4, operating on the port GigabitEthernet0.

   Note
   You cannot change the Subinterface ID after you set it.

5. Continue configuring this interface, as described in Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19.
Configuring Redundant Interfaces

Beginning with Security Manager 3.2.2, you can define logical “redundant” interfaces to increase security appliance reliability. A redundant interface is a specific pair of physical interfaces, with one designated as active (or primary) and the other as standby (or secondary). If the active interface fails, the standby interface becomes active and starts passing traffic. This feature is separate from device-level failover, but you can configure redundant interfaces as well as failover, if desired. You can configure up to eight redundant interface pairs.

A redundant interface functions as a single interface (inside, outside, etc.), with only one of the member pair active at any one time. This redundant interface is configured normally, with a unique interface name, security level and IP address. Note that each member interface must be of the same type (e.g., GigabitEthernet), and cannot have a name, security level, or IP address assigned. In fact, do not configure any options other than Duplex and Speed on the member interfaces.

The redundant interface uses the MAC address of the first physical interface that you specify. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. Alternatively, you can explicitly assign a MAC address to the redundant interface; this address is then used regardless of the member interface MAC addresses. In either case, when the active interface fails over to the standby, the same MAC address is maintained so that traffic is not disrupted.

Note
This option is available only on PIX 8.0+ and non-5505 ASA devices.

Defining Redundant Interfaces

Follow these steps to configure two physical interfaces as a single logical “redundant interface” in the Add/Edit Interface (ASA/PIX 7.0+) dialog box, which is accessed from the device Interfaces page (see Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14).

1. Choose Redundant as the interface Type in the Add/Edit Interface dialog box.
   The Redundant ID, Primary Interface and Secondary Interface options appear.
2. Provide an identifier for this redundant interface in the Redundant ID field; valid IDs are the integers from 1 to 8.
3. Primary Interface – Choose the primary member of the redundant interface pair from this list of available interfaces. Available interfaces are presented by Hardware Port IDs, as named interfaces cannot be used for a redundant interface pair.
4. Secondary Interface – Choose the secondary member of the redundant interface pair from this list of available interfaces. Available interfaces are presented by Hardware Port IDs, as named interfaces cannot be used for a redundant interface pair.

Note  Member interfaces must be enabled and of the same type (e.g., GigabitEthernet), and cannot have a Name, IP Address, or Security Level assigned. In fact, do not configure any options other than Duplex and Speed on the member interfaces.

5. Continue configuring this interface, as described in Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19.
Configuring EtherChannels

Beginning with ASA 8.4.1, you can define logical EtherChannel interfaces. An EtherChannel, also called a port-channel interface, is a logical interface consisting of a bundle of individual Ethernet links (a channel group). This provides increased bandwidth and fault tolerance compared to the individual links.

An EtherChannel interface is configured and used in the same manner as a single physical interface. You can configure up to 48 EtherChannels, each of which consists of between one and eight active Fast Ethernet, Gigabit Ethernet, or Ten-Gigabit Ethernet ports.

Note

You cannot use a redundant interface as part of an EtherChannel, nor can you use an EtherChannel as part of a redundant interface. You cannot use the same physical interfaces in a redundant interface and an EtherChannel interface. You can, however, configure both types on the ASA if they do not use the same physical interfaces.

EtherChannel MAC Addressing

All interfaces that are part of a channel group share the same MAC address. This makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. By default, the EtherChannel uses the MAC address of the lowest-numbered member interface as its MAC address.

Alternatively, you can manually configure a MAC address for the port-channel interface. We recommend doing so in case the channel interface membership changes. For example, if you remove the interface that provides the port-channel MAC address, the port-channel is assigned the MAC address of the next lowest numbered interface, causing traffic disruption. Manually assigning a unique MAC address to the EtherChannel interface prevents this disruption. (Note that in multiple-context mode, you can assign unique MAC addresses to interfaces assigned to an individual context, including EtherChannel interfaces.)

About Management Only EtherChannel Interfaces

You can specify an EtherChannel group as a management-only interface, but note the following caveats:

- Routed mode – You must explicitly configure the EtherChannel to be Management Only in the Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19. Any non-management interface added to the management-only port-channel is treated as a management port. If you add an interface already defined as management-only to the management-only group, that attribute is ignored on the physical interface. Similarly, you cannot designate an interface as management-only if it is already a member of a management-only port-channel.

- Transparent mode – In this mode, members of a management-only EtherChannel can themselves only be management-only ports. Thus, when a management-only member is added to a transparent-mode EtherChannel, the channel inherits the management-only designation, while the designation is removed from the member interface. Conversely, when such an interface is removed from the EtherChannel, the designation is restored on the individual interface.

Using an EtherChannel Interface as a Failover Link

If an EtherChannel interface is specified as a failover link, all state-sync traffic for that link will travel over a single physical interface. Should that physical interface fail, the state-sync traffic will then traverse another physical interface that is part of the EtherChannel aggregated link. If there are no remaining available physical interfaces in the EtherChannel link specified for failover, the ASA falls back to the redundant interface, if one is specified.
While an EtherChannel interface is being used as an active failover link, changes to that EtherChannel configuration are not allowed. You can change the EtherChannel configuration of that link only by disabling either the link or failover, as follows:

- Disable the EtherChannel link while the configuration changes are being made, and then reactivate it (failover will not occur while the link is disabled).
- Disable failover while the configuration changes are being made, and then re-enable it (failover will not occur in the interim).

**Note**

As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named. Further, none of the EtherChannel’s member interfaces can be named.

### Defining EtherChannels on an ASA

Follow these steps to configure multiple physical interfaces as a single logical EtherChannel interface in the ASA Add Interface or Edit Interface dialog boxes, which are accessed from the device Interfaces page (see Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14).

**Step 1** Choose *EtherChannel* as the interface Type.

The Port-channel ID and interface-selection options appear on the General panel of the dialog box; the Load Balancing and the Active Physical Interfaces: Minimum and Maximum fields appear on the Advanced panel.

**Step 2** Provide an identifier for this EtherChannel in the Port-channel ID field; valid IDs are the integers from 1 to 48. This number is appended to “Port-channel” to identify the EtherChannel in the Interface column of the table on the device’s Interfaces page.

**Step 3** Available Interfaces – Specify the members of this port-channel group by select one or more interfaces in this list of available interfaces, and then click the >> button to add them to the member list on the right.

**Note**

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

You can assign up to 16 interfaces to a channel group. In a standard EtherChannel, up to eight of these interfaces can be active, while the remaining interfaces act as stand-by links in case of individual interface failure. Alternatively, you can create a static EtherChannel by setting LACP Mode to On (on the Advanced panel, as described below), which means all interfaces in the group can pass traffic.

**Note**

After assigning interfaces to this EtherChannel group, you can edit the LACP Port parameters for each member interface, as described in Editing LACP Parameters for an Interface Assigned to an EtherChannel, page 44-11.

**Step 4** Click the Advanced tab to display that panel.

**Step 5** Choose a Load Balancing option in the EtherChannel section. See About EtherChannel Load Balancing, page 44-13, for more information about this option.
Step 6  Select the desired **LACP Mode**; the default is Active, which means up to eight interfaces are active, while up to eight are in stand-by mode, as determined by the Minimum and Maximum values under Active Physical Interfaces.

If you select On, a static port-channel is created in which all member interfaces are all “on,” meaning you can have up to 16 ports passing traffic, with no stand-by ports. When you select this option, the Mode for all interfaces assigned to this EtherChannel group is switched to On (if the Mode for each is not already On). See **Editing LACP Parameters for an Interface Assigned to an EtherChannel**, page 44-11, for more information about this mode.

Step 7  Specify the Minimum and Maximum number of Active Physical Interfaces for this EtherChannel.

As mentioned, an EtherChannel can consist of between one and eight active links, with up to 16 assigned to the group (on the General panel). Use these fields to indicate the minimum and maximum number of interfaces that can be active in this channel group at any given time.

Step 8  Continue configuring this interface, as described in **Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM)**, page 44-19.

---

**Note**  The EtherChannel **LACP System Priority** for this device is specified in the **Advanced Interface Settings (PIX/ASA/FWSM)**, page 44-42 dialog box.

---

### Editing LACP Parameters for an Interface Assigned to an EtherChannel

After assigning interfaces to an EtherChannel (port-channel) group, you can edit the LACP Port parameters for each member interface, as described here.

**Note**  This feature is available only on ASA 8.4.1+ devices.

The Link Aggregation Control Protocol (LACP) directs aggregation of physical Fast Ethernet, Gigabit Ethernet, or Ten-Gigabit Ethernet interfaces into an EtherChannel group, and updating the remote partner device with current information after it finds a compatible set of ports and assigns a unique value called an “operational key” to the group. Note that operational key assignment is automatic; you cannot configure it.

**Caution**  These LCAP parameters are not available when the EtherChannel is assigned as a failover link.

### LACP System Priority

Every LACP-enabled device has a unique system ID that is formed by combining a System Priority identifier and the system’s MAC address. In certain situations, two EtherChannel-linked systems may need to change the operational key assigned to a set of ports to allow optimal aggregation. In such a situation, the system with higher priority is allowed to dynamically modify the operational key value assigned to the ports to achieve better aggregation. The system with the lower priority is not allowed to change the operational keys. The System Priority identifier is user-configurable, as described in **Advanced Interface Settings (PIX/ASA/FWSM)**, page 44-42.
LACP Port Parameters

Port identification is provided by a unique number assigned to every group interface; this identifier is formed by combining a configurable Port Priority number and the port number assigned to the interface.

The port identifier provides port aggregation priority. Ports are considered for active use in an aggregation starting with the port that has highest aggregation priority in the system, and working down through an ordered list of port identifiers. The use of this port aggregation priority makes aggregation predictable and reproducible by selecting the links for aggregation in the same manner when all links are running LACP concurrently.

In addition, you can configure the priority of each port to administratively control the set of stand-by ports. For example, the port with the lowest priority will be considered last for group aggregation and will be become a stand-by port (assuming enough members are assigned to the group to allow stand-by ports).

Related Topics

- Configuring EtherChannels, page 44-9

Editing LACP Port Parameters for an Existing Channel Interface

Follow these steps to edit an existing EtherChannel-assigned interface:

**Step 1**
In the table on the device’s Interfaces page, select an interface that is a Member of a Port-channel group. (See Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14 for information about accessing and using this table.)

**Step 2**
Click **Edit Row** to open the Edit Interface dialog box for that interface.

Only the Enable Interface check box, the LACP Port parameters, and the Description field can be altered.

**Step 3**
Edit the **LACP Port** parameters as necessary:

- **Priority** – This number is combined with the port number assigned to the interface to produce a unique port identification number. This value can be 1 to 65535, with higher numbers signifying lower priorities. The default is 32768. This parameter applies only when the port is in Active or Passive mode.

- **Mode** – Choose one of these LACP modes:
  - **Active** – In Active mode, a port initiates LACP exchanges with the partner device and periodically sends updates to the partner. Active LACP reflects the port’s preference to participate in the protocol regardless of the partner’s control mode.
  - **Passive** – A Passive-mode port does not initiate LACP exchanges, but upon receiving a request from the partner, the port will start exchanging LACP information with the partner. Passive mode is useful when it is not clear if the remote port supports LACP.

Some devices may show undesired behavior when they do not have LACP enabled and they receive periodic LACP updates. However, for channeling to operate correctly, at least one port must be configured in Active mode.

- **On** – Use this mode to configure a static port-channel in which all member interfaces are “on,” meaning up to 16 ports are passing traffic, with no stand-by ports. No negotiation takes place and most restrictions associated with the other two modes do not apply; for example, the speed and duplex settings do not have to be the same for all member ports, and all member ports (up to 16) remain Active. Note that the remote ports also must be On.

**Step 4**
Continue editing this interface, as described in Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19.
About EtherChannel Load Balancing

Traffic in an EtherChannel is distributed across the individual bundled links in a deterministic fashion; however, the load is not necessarily balanced equally across all the links. Instead, frames are forwarded on a specific link as a result of a hashing algorithm. This algorithm uses a specific field or combination of fields in the packet header to produce a fixed Result Bundle Hash (RBH) value that indicates which link to use.

The algorithm can use one or a combination of the following packet-header fields to determine link assignment: source IP address, destination IP address, source MAC address, destination MAC address, TCP/UDP port numbers, or VLAN IDs. The field combination used by the algorithm is chosen from the Load Balancing list (on the Advanced tab of the ASA's Add Interface and Edit Interface dialog boxes); these options are described in the following section. For additional information, see Configuring EtherChannels, page 44-9.

For example, suppose source MAC address (src-mac) is the chosen field: when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source MAC address of each incoming packet. Therefore, to provide load balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel (and the MAC addresses learned by the device do not change).

Similarly, with destination MAC address forwarding, when packets are forwarded to an EtherChannel, each packet is distributed across the ports in the channel based on the packet's destination host MAC address. Thus, packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

Therefore, when choosing a load-balancing option, use the option that provides the greatest variety in your configuration. For example, if most of the traffic on a channel is going only to a single MAC address, choosing the destination MAC address results in most of the traffic always using the same link in the channel. Alternatively, using source addresses or IP addresses might result in better load balancing, while a method that uses the source and destination addresses along with UDP or TCP port numbers can distribute traffic much differently.

Note

This option is available only on ASA 8.4.1+ devices.

Load Balancing Options

When defining a single logical EtherChannel interface in the ASA Add/Edit Interface dialog box, choose one of the following Load Balancing options (on the Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+), page 44-27) to specify the basis of load distribution:

- **dst-ip** – Load distribution is based on the destination-host IP address only; the source of the packets is not considered. Each packet with the same destination IP address is forwarded over the same link.
- **dst-ip-port** – Load distribution is based on the destination-host IP address and TCP/UDP port. This option offers more granularity and a little more complexity than destination IP address alone.
- **dst-mac** – Load distribution is based on the destination host MAC address of incoming packets.
- **dst-port** – Distribution is based on the destination port; that is, a TCP or UDP port and not a physical interface.
- **src-dst-ip** – Distribution is based on source and destination IP addresses—source and destination IP addresses are paired for hash calculations. This method provides more granularity than destination IP address, for example: packets to the same destination can be forwarded over different links in a port-channel if they are coming from a different IP source.
• **src-dst-ip-port** – Distribution calculation considers source and destination IP addresses, and TCP/UDP ports. Provides even greater granularity and distribution.

• **src-dst-mac** – Calculation is based on source and destination MAC address pairing.

• **src-dst-port** – Load distribution is based on source and destination TCP/UDP port.

• **src-ip** – Based on source host IP address only.

• **src-ip-port** – Source IP address and TCP/UDP port.

• **src-mac** – Source MAC address only.

• **src-port** – Source TCP/UDP port only.

• **vlan-dst-ip** – Destination IP address and VLAN ID pairing.

• **vlan-dst-ip-port** – Combination of destination IP address, TCP/UDP port, and VLAN ID.

• **vlan-only** – VLAN ID only.

• **vlan-src-dst-ip** – Source and destination IP address, and VLAN ID.

• **vlan-src-dst-ip-port** – Source and destination IP address, TCP/UDP port, and VLAN ID.

• **vlan-src-ip** – Source IP address and VLAN ID.

• **vlan-src-ip-port** – Source IP address, TCP/UDP port, and VLAN ID.

**Managing Device Interfaces, Hardware Ports, and Bridge Groups**

The Interfaces page displays the interfaces, subinterfaces, redundant interfaces, virtual interfaces (VLANs), and EtherChannel interfaces, as well as the hardware ports and bridge groups, configured on the selected device, and lets you add, edit and delete them.

The types of interface available depend on device type, operating system version, and mode (routed or transparent). For example, EtherChannel interfaces are available only on ASA 8.4.1 and later devices, in both routed and transparent mode. See Understanding Device Interfaces, page 44-3 for more information.

**Note**

The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: Interfaces and Hardware Ports. Similarly, the Interfaces page displayed for both Firewall Services Modules (FWSMs), version 3.1 and later, and ASAs version 8.4.1 and later, operating in transparent mode also present two tabbed panels: Interfaces and Bridge Groups. Links to configuration information for these features are included in the following procedure.

Each security device must be configured, and each active interface must be enabled. Inactive interfaces can be disabled. When disabled, the interface does not transmit or receive data, but its configuration information is retained.

If you bootstrapped a new security device, the set-up feature configures only the addresses and names associated with the inside interface. You must define the remaining interfaces on that device before you can specify access and translation rules for traffic traversing that security device.

Transparent firewall mode allows only two interfaces to pass traffic; however, if your platform includes a dedicated management interface, you can use it (either the physical interface or a subinterface) as a third interface for management traffic.

Follow these general steps to manage security-device interfaces and related options. You can add, edit and delete configured interfaces, subinterfaces, redundant interfaces, virtual interfaces (VLANs), EtherChannel interfaces, hardware ports, and bridge groups, according to the type of device selected.
Step 1  Ensure Device View is your present application view; if necessary, click the Device View button on the toolbar.

Note  For more information on using the Device View to configure device policies, see Managing Policies in Device View and the Site-to-Site VPN Manager, page 5-28.

Step 2  Select the security device you want to configure.

Step 3  Select Interfaces in the Device Policy selector.

The Interfaces page is displayed. The information displayed, and the page itself, varies based on the selected device type and version, the operational mode (routed versus transparent), and whether the device hosts single or multiple contexts.

Note that the Interfaces page for ASA 5505 devices presents two tabbed panels: Hardware Ports and Interfaces. Similarly, the Interfaces page displayed for both FWSMs (version 3.1 and later) and ASAs (version 8.4.1 and later), operating in transparent mode also presents two tabbed panels: Interfaces and Bridge Groups.

Step 4  Add, edit and delete interfaces and related options, as necessary.

The Interfaces pages/panels and the Bridge Groups and Hardware Ports panels present standard Security Manager tables, with Add Row, Edit Row and Delete Row buttons, which are described in Using Tables, page 1-43.

The actual dialog box presented when you click the Add Row or Edit Row button depends on the type of device (and panel) you have selected. Refer to the following topics for device-specific dialog box information:

- Add/Edit Interface Dialog Box (PIX 6.3), page 44-16
- Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19
- Configuring Hardware Ports on an ASA 5505, page 44-39
- Add/Edit Bridge Group Dialog Box, page 44-41

Step 5  To manage Advanced Interface settings, including enabling communication between interfaces with the same security level, click the Advanced button at the bottom of the Interfaces page to open the Advanced Interface Settings dialog box. See Advanced Interface Settings (PIX/ASA/FWSM), page 44-42 for more information.

Step 6  When you are finished adding, editing and deleting interfaces, click Save at the bottom of the window to save your interface definitions to the Cisco Security Manager server.
Add/Edit Interface Dialog Box (PIX 6.3)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>

</table>
| Enable Interface | Enables this interface to pass traffic. In addition to this setting, you must specify an IP Type and a Name before traffic can pass according to your security policy.  
You must enable a physical interface before traffic can pass through any enabled subinterfaces. |
| Type             | Choose the type of interface:                                                                                                              |
|                  | • Physical – VLAN is on the same network as its underlying hardware interface.  
• Logical – VLAN is associated with a logical interface.                                    |
| Name             | Provide an interface name up to 48 characters in length. The Name should be a memorable name for the interface that relates to its use. Supported interface names are:  
• Inside—Connects to your internal network. Must be most secure interface.  
• DMZ—Demilitarized zone (Intermediate interface). Also known as a perimeter network.  
• Outside—Connects to an external network or the Internet. Must be least secure interface. |
| Hardware Port    | When defining a physical network interface, this value represents the name identifies the interface type and its slot or port in the device.  
When you add a logical network interface, you can choose any enabled physical interface to which you want to add a logical interface. If you do not see the desired hardware port, verify that the interface is enabled.  
Valid values are:  
• ethernet0 to ethernetn.  
• gb-etherntn.  
where n represents the number of network interfaces in the device. |
| IP Type          | The IP Type defines the type of IP addressing used for the interface; choose Static IP or Use DHCP, as described in Device Interface: IP Type (PIX 6.3), page 44-18. (The PPoE option is not applicable to PIX 6.3 devices.) |

Note: You can configure DHCP only on the outside interface of a security appliance.

</table>
Device Interface: IP Type (PIX 6.3)

A PIX 6.3 security device requires IP addressing for its interfaces; however, firewall interfaces do not have IP addresses until you assign them.

The Add/Edit Interface dialog box presented for a PIX 6.3 security device includes the section IP Type, where you specify the type of IP addressing for the interface and provide related parameters, as described here. See Add/Edit Interface Dialog Box (PIX 6.3), page 44-16 for information about the other sections of the dialog box.

Note

The IP Type options presented for other security appliances are described in Device Interface: IP Type (PIX/ASA 7.0+), page 44-36.

Step 1

In the Add/Edit Interface dialog box, choose a method for address assignment from the IP Type list, and then provide related parameters, as follows:

- **Static IP** – Provide a static IP Address and Subnet Mask that represents the security device on this interface’s connected network. The IP address must be unique for each interface.

  The Subnet mask can be expressed in dotted decimal format (for example, 255.255.255.0), or by entering the number of bits in the network mask (for example, 24). Do not use 255.255.255.254 or 255.255.255.255 for an interface connected to the network because this will stop traffic on that interface. If you omit the Subnet Mask value, a “classful” network is assumed, as follows:

  - The Class A netmask (255.0.0.0) is assumed if the first octet of the IP Address is 1 through 126 (i.e., addresses 1.0.0.0 through 126.255.255.255).

  - The Class B netmask (255.255.0.0) is assumed if the first octet of the IP Address is 128 through 191 (i.e., addresses 128.0.0.0 through 191.255.255.255).
The Class C netmask (255.255.255.0) is assumed if the first octet of the IP Address is 192 through 223 (i.e., addresses 192.0.0.0 through 223.255.255.255).

**Note**  Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry.

- **Use DHCP** – Enables Dynamic Host Configuration Protocol (DHCP) for automatic assignment of an IP address from a DHCP server on the connected network. The following options become available:
  - **Obtain Default Route using DHCP** – Check this box to obtain a default route from the DHCP server so that you do not need to configure a default static route.
  - **Retry Count** – The number of times the PIX will resend the DHCP request. Valid values are 4 to 16; the default is 2

- **PPPoE (PIX and ASA 7.2+)** – This option does not apply to PIX 6.3 devices.

**Note**  You can configure DHCP only on the outside interface of a firewall device.

### Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM)

These Add Interface and Edit Interface dialog boxes are used to define and configure interfaces, subinterfaces, redundant, and EtherChannel interfaces on PIX 7.0+, ASA, and FWSM devices. You can access the Add/Edit Interface dialog boxes from the Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14 for more information.

**Note**  The ASA 5505, combining switch and security appliance features, is a special case in that you configure both physical switch ports and logical VLAN interfaces. Thus, the Interfaces page displayed for ASA 5505 devices presents two tabbed panels: Hardware Ports and Interfaces. See Understanding ASA 5505 Ports and Interfaces, page 44-6 for more information.

ASA 8.4.1+ and FWSM 3.1+ devices operating in transparent mode also present two tabbed panels: Interfaces and Bridge Groups. See Add/Edit Bridge Group Dialog Box, page 44-41 for information about configuring bridge groups.

Many of the parameters presented in these dialog boxes vary according to device type and version, operational mode (routed versus transparent), and whether the device hosts a single or multiple contexts.

**Note**  If you intend to use an interface for failover, you can define that interface in the Add Interface dialog box but do not configure it; instead, use the Failover page (see Chapter 48, “Configuring Failover”). In particular, do not specify an interface Name, as this parameter disqualifies the interface from being used as the failover link.
Chapter 44      Managing Firewall Devices

Configuring Firewall Device Interfaces

Using the Add Interface and Edit Interface Dialog Boxes

The following steps outline the general use of these dialog boxes:

1. An interface Type drop-down list appears at the top of the Add Interface and Edit Interface dialog boxes.

   Note Catalyst 6500 services modules (ASA-SMs and FWSMs) and the ASA 5505 do not present the Type list.

Depending on device type, operating-system version and operating mode (router or transparent), the Type options presented will be two, three or all of the following:

   - **Interface** – Choose this option to configure a physical interface on the device.
   
   - **Subinterface** – Choose this option to configure a logical interface (or VLAN connection) associated with a previously defined physical interface. Refer to Configuring Subinterfaces (PIX/ASA), page 44-7 for more information.
   
   - **Redundant** – Choose this option to configure two physical interfaces as a single logical “redundant interface.” Refer to Configuring Redundant Interfaces, page 44-8 for more information.
   
   - **EtherChannel** – Choose this option to configure a logical interface consisting of a bundle of up to eight individual Ethernet links; this bundle is known as an EtherChannel, or a port-channel interface. (This option is available only on ASA 8.4+ devices.) Refer to Configuring EtherChannels, page 44-9, for more information.

2. Below the Type option, the dialog boxes present up to three tabbed panels. Again, this depends on device type, operating-system version and operating mode.

   - **Configure the General options,** as appropriate. This panel is described in Add/Edit Interface Dialog Box: General Tab (PIX 7.0+/ASA/FWSM), page 44-20.
   
   - **Configure the Advanced-panel options,** as appropriate. This panel is described in Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+), page 44-27.
   
   - **Configure the IPv6 options,** as appropriate. This panel is described in Configuring IPv6 Interfaces (ASA/FWSM), page 44-29.

3. When you have finished configuring this interface, click OK to close the dialog box and return to the device Interfaces page.

**Add/Edit Interface Dialog Box: General Tab (PIX 7.0+/ASA/FWSM)**

The Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19, is used to define and configure interfaces, subinterfaces, VLAN interfaces, and redundant, and EtherChannel interfaces on firewall devices. You can access the Add/Edit Interface dialog box from the Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14 for more information.

   Note In the following descriptions, the term “interface” may be used generically to refer to any of these types of interface.
The General panel of this dialog box is used to configure general interface settings, including Name, Security Level and IP Type parameters. Note that many of the parameters presented in this panel vary according to device type and version, operational mode (routed versus transparent), and whether the device hosts a single or multiple contexts. Thus, some of the options in the following table may not appear for the device you are configuring.

**Related Topics**
- Configuring Subinterfaces (PIX/ASA), page 44-7
- Configuring Redundant Interfaces, page 44-8
- Configuring EtherChannels, page 44-9
- Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+), page 44-27

**Table 44-3 General tab: Add/Edit Interface Dialog Box**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Interface</td>
<td>Enables this interface to pass traffic. By default, all physical interfaces are shut down. Traffic cannot traverse an interface of any type if the interface is not enabled. If you are defining a logical interface such as a subinterface, enable the physical interface it will be associated with before defining the subinterface. If you are defining a redundant interface or an EtherChannel interface, enable the member interfaces before defining the group interface. When you check this option, you must also specify a Name and, in routed mode, an IP Type (or IP Address and Subnet Mask on an FWSM or ASA-SM) before traffic can pass according to your security policy. In multiple-context mode, if you allocate a physical or logical interface to a context, the interface is enabled by default in the context. However, before traffic can pass through the context interface, you must also enable the interface in the system configuration. If you shut down an interface in the system execution space, that interface is shut down in all contexts in which it shared.</td>
</tr>
<tr>
<td>Management Only</td>
<td>Reserves this interface for device administration. Only traffic for management of this device is accepted; pass-through traffic for other interfaces and devices is rejected. You cannot set a Primary or Secondary ISP interface to be Management Only. Defining a management-only EtherChannel interface has certain member-interface restrictions. See Configuring EtherChannels, page 44-9, for more information.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Not available on devices in transparent mode.</td>
</tr>
</tbody>
</table>
Hardware Port

On the ASA 5505, the Hardware Port is specified on the Hardware Ports panel (see Configuring Hardware Ports on an ASA 5505, page 44-39). Also, this option is not part of Catalyst 6500 services module (ASA-SM and FWSM) configuration.

For a physical interface, provide the specific hardware port assigned to the interface: enter a physical port ID, which includes network type, slot and port number, in the form: type[slot]/port. This is also the name by which subinterfaces can be associated with the interface.

The network type specified for the physical interface can be either Ethernet or GigabitEthernet; on the ASA 5580, TenGigabitEthernet is also available. This field provides automatic pattern matching: if you begin typing with the letter e, “Ethernet” is inserted into the field. Similarly, typing the letter g produces “GigabitEthernet.” Therefore, valid values are:

- Ethernet0 to Ethernetn
- GigabitEthernet0 to GigabitEthernetn
- GigabitEthernets/n
- TenGigabitEthernets/n (ASA 5580 only)

where s represents a slot number, and n represents a port number, up to the maximum number of network ports in the slot or device.

For an ASA 5500 series appliance, enter the type and a slot/port pair; for example, gigabitethernet0/1. Ports that are built into the chassis are assigned to slot 0, while ports on the 4-Port Gigabit Ethernet Security Services Module (4GE SSM) are assigned to slot 1. When you enter a slot/port pair, the Media Type options are enabled.

The ASA 5500 series appliances also include a management interface type. The management interface is a Fast Ethernet interface designed for device-management traffic only, and is specified as management0/0. You can, however, use this physical interface for through traffic if desired (be sure the Management Only option is not selected). Thus, in transparent firewall mode, you can use the management interface in addition to the two interfaces allowed for through traffic. You can also add subinterfaces to the management interface to provide management in each security context in multiple-context mode.

If you are defining a subinterface, you can simply choose the desired Hardware Port from a list of previously defined ports (you must also supply a VLAN ID). If you do not see a desired interface ID, be sure that Interface is defined and enabled.
### Table 44-3  General tab: Add/Edit Interface Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Name          | Provide an identifier for this interface of up to 48 characters in length. The name should be a memorable name for the interface that relates to its use. However, if you are using failover, do not name interfaces that you are reserving for failover communications; this includes an EtherChannel intended for failover, as well as its member interfaces. Also, do not name interfaces intended for use as a member of a redundant-interface pair. Certain names are reserved for specific interfaces, in accordance with the interface naming conventions of the security appliance. As such, these reserved names enforce default, reserved security levels, as follows:  
  - Inside – Connects to your internal network. Must be the most secure interface.  
  - DMZ – “Demilitarized zone” attached to an intermediate interface. DMZ is also known as a perimeter network. You can name a DMZ interface any name you choose. Typically, DMZ interfaces are prefixed with “DMZ” to identify the interface type.  
  - Outside – Connects to an external network or the Internet. Must be the least secure interface.  
  Similarly, a subinterface name typically identifies its associated interface, in addition to its own unique identifier. For example, `DMZoobmgmt` could represent an out-of-band management network attached to the DMZ interface.  
  **Note** Again, **do not name the interface if you intend to use it for failover, or as a member of a redundant interface.** See Chapter 48, “Configuring Failover” and Configuring Redundant Interfaces, page 44-8 for more information. |
| Security Level| Specify the security level of the interface: enter a value between 0 (least secure) and 100 (most secure). The security appliance lets traffic flow freely from an inside network to an outside network (lower security level). Many other security features are affected by the relative security level of two interfaces.  
  - The outside interface is always 0.  
  - The inside interface is always 100.  
  - DMZ interfaces are between 1 and 99. |
### Configuring Firewall Device Interfaces

#### Media Type
When Interface is the chosen Type and you enter a hardware port ID with slot/port numbers in the Hardware Port field, these options are enabled. (These options apply to ASA slot/port interfaces only.)

For all ASA 5500 series appliances, except the 5505, ports that are built into the chassis are assigned to slot 0, while ports on the 4GE SSM are assigned to slot 1. By default, all connectors used on an ASA are RJ-45 connectors. However, the ports on the 4GE SSM can include fiber SFP connectors. As part of the interface configuration for one of these fiber-based connections, you must change the Media Type setting from the default (RJ45) to the fiber-connector setting (SFP).

Fiber-based interfaces do not support duplexing and have a fixed speed, so the Duplex option is disabled, and the Speed options are limited to auto and nonegotiate.

Select the connector type used by this slot-1 interface:
- **RJ45** – The port uses RJ-45 (copper) connectors.
- **SFP** – The port uses fiber SFP connectors. Required for 10-Gigabit Ethernet cards.

#### VLAN ID
When Subinterface is the chosen interface Type, or when you are defining a logical interface on a device operating in transparent mode, on an ASA 5505, or on a Catalyst 6500 services module (ASA-SM or FWSM), provide a VLAN ID for this interface.

For PIX/ASA devices running operating system 7.2(2)18 or earlier, valid VLAN IDs are 1 to 1001; with version 7.2(2)19 or later, valid IDs are 1 to 4090. For Catalyst 6500 services modules, valid IDs are 1 to 4096. The specified VLAN ID must not be in use on any connected device.

Some VLAN IDs might be reserved on connected switches; see the switch documentation for more information. In multiple-context mode, you can only set the VLAN ID in the system configuration.

See Configuring Subinterfaces (PIX/ASA), page 44-7 for more information.

#### Subinterface ID
When Subinterface is the chosen interface Type, or when defining an interface on a device operating in transparent mode, provide an integer between 1 and 4294967293 as the Subinterface ID.

For subinterface port identification, this ID is appended to the chosen Hardware Port. For example, `GigabitEthernet0.4` represents the subinterface assigned an ID of 4, operating on the port `GigabitEthernet0`.

**Note** You cannot change the Subinterface ID after you set it.

#### IP Type
**PIX 7.0+ and ASA (except the 5505 in transparent mode) only.**

The IP Type defines the type of IP addressing used for the interface; choose **Static IP**, **Use DHCP**, or **PPPoE** (as described in Device Interface: IP Type (PIX/ASA 7.0+), page 44-36).

**Note** You can configure DHCP and PPPoE only on the outside interface of a security appliance.

| IP Address  | Catalyst 6500 services modules (ASA-SMs and FWSMs) in routed mode only. Use these two fields to assign an IP address and subnet mask to the VLAN interface. The IP address must be unique for each interface. The Subnet Mask can be expressed in dotted decimal format (for example, 255.255.255.0), or by entering the number of bits in the network mask (for example, 24). Do not use 255.255.255.254 or 255.255.255.255 for an interface connected to the network because this will stop traffic on that interface. If you omit the Subnet Mask value, a “classful” network is assumed, as follows:  
- The Class A netmask (255.0.0.0) is assumed if the first octet of the IP Address is 1 through 126 (that is, addresses 1.0.0.0 through 126.255.255.255).  
- Subnet Mask  
  The Class B netmask (255.255.0.0) is assumed if the first octet of the IP Address is 128 through 191 (that is, addresses 128.0.0.0 through 191.255.255.255).  
- The Class C netmask (255.255.255.0) is assumed if the first octet of the IP Address is 192 through 223 (that is, addresses 192.0.0.0 through 223.255.255.255).  
Note Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry. |
| Subnet Mask | You can enter an optional description of up to 240 characters on a single line, without carriage returns. In multiple-context mode, the system description is independent of the context description. For a failover or state link, the description is fixed as “LAN Failover Interface,” “STATE Failover Interface,” or “LAN/STATE Failover Interface,” for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link. |
| Description | Redundant Interface; these options not available on ASA 5505 devices or Catalyst 6500 services modules (ASA-SMs and FWSMs).  
Redundant ID | When Redundant Interface is the chosen interface Type, provide an identifier for this redundant interface; valid IDs are the integers from 1 to 8. See Configuring Redundant Interfaces, page 44-8 for more information. |
### Configuring Firewall Device Interfaces

#### Chapter 44  Managing Firewall Devices

## Configuring Firewall Device Interfaces

### Primary Interface
- When Redundant Interface is the chosen interface Type, choose the primary member of the redundant interface pair from the Primary Interface list of available interfaces. Available interfaces are presented by Hardware Port IDs, as named interfaces cannot be used for a redundant interface pair.

### Secondary Interface
- Similarly, choose the secondary member of the redundant interface pair from the Secondary Interface list of available interfaces.

**Note**  Member interfaces must be enabled and of the same type (e.g., GigabitEthernet), and cannot have a Name, IP Address, or Security Level assigned. In fact, do not configure any options other than Duplex and Speed on the member interfaces.

### Block Traffic To
- Restricts this VLAN interface from initiating contact with the VLAN chosen here.

### Backup Interface
- Choose a VLAN interface as a backup interface, for example, to an ISP. The backup interface does not pass traffic unless the default route through the primary interface fails. To ensure that traffic can pass over the backup interface, be sure to configure default routes on both the primary and backup interfaces so that the backup interface can be used when the primary fails.

### Active MAC Address
- Use the Active MAC Address field to manually assign a private MAC address to the interface; the Standby MAC Address field can be used to set a standby MAC address for use with device-level failover.

**Note**  Refer to Device Interface: MAC Address, page 44-38 for more information about these fields.

### EtherChannel Interface options; available on ASA 8.4.1+ devices only.

#### Port-channel ID
- When EtherChannel is the chosen interface Type, enter an identifier for this EtherChannel (also referred to as a “port-channel”). Valid values are 1 to 48—you can define up to 48 port-channel groups. See Configuring EtherChannels, page 44-9, for more information.

#### Available Interfaces/Members in Group
- When EtherChannel is the chosen interface Type, you can assign interfaces to this EtherChannel group by selecting them in the Available Interfaces list and then clicking the >> button to add them to the members list to the right.

**Note**  All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the type and speed for the group.

See Configuring EtherChannels, page 44-9, for more information.
Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+)

The Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19, is used to define and configure interfaces, subinterfaces, redundant, and EtherChannel interfaces on ASA and PIX 7.0+ devices. You can access the Add/Edit Interface dialog box from the Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14 for more information.

The Advanced panel of this dialog box is used to configure basic interface settings, including Duplex, Speed, and maximum transmission unit (MTU) parameters, as described in the following table.

### Related Topics

<td>- nonegotiate</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This option is not available when Subinterface or Redundant is the chosen Interface type.</td>
</tr>
<tr>
<td>MTU</td>
<td>Specify the maximum packet size in bytes; that is, the maximum transmission unit (MTU). The value depends on the type of network connected to the interface. Valid values are 300 to 65535 bytes. Default is 1500 for all types except PPPoE, for which the default is 1492. In multiple-context mode, set the MTU in the context configuration.</td>
</tr>
<tr>
<td>Active MAC Address</td>
<td>Available only on PIX 7.2+ and ASA 7.2+ devices.</td>
</tr>
<tr>
<td>Standby MAC Address</td>
<td>Use the Active MAC Address field to manually assign a private MAC address to the interface; the Standby MAC Address field can be used to set a standby MAC address for use with device-level failover. Refer to Device Interface: MAC Address, page 44-38 for more information about these fields.</td>
</tr>
</tbody>
</table>
### Configuring Firewall Device Interfaces

#### Roles
All interface roles assigned to this interface are listed in this field. Role assignments are based on pattern matching between the Name given to this interface and all currently defined Interface Role objects in Security Manager. Interface role objects are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces.

For more information on roles and how to define and use them, see Understanding Interface Role Objects, page 6-62.

#### EtherChannel Interface options; available on ASA 8.4.1+ devices only.

- **Load Balancing**
  When EtherChannel is the chosen interface Type (on the General panel), choose a load-balancing method for the channel links. See About EtherChannel Load Balancing, page 44-13, for more information about this option.

- **Active Physical Interfaces**
  When EtherChannel is the chosen interface Type (on the General panel), specify the minimum and maximum number of interfaces that can be active for this EtherChannel group:
  - **Minimum** – Specify the minimum number of interfaces that can be active for this group; enter a value from 1 to 8. Interfaces available to the channel are selected on the General tab of this dialog box (Add/Edit Interface Dialog Box: General Tab (PIX 7.0+/ASA/FWSM), page 44-20).
  - **Maximum** – Specify the maximum number of interfaces that can be active; enter a value from 1 to 8. Interfaces available to the channel are selected on the General tab of this dialog box.

  Specifying 3, 5, 6, or 7 active ports in an EtherChannel bundle provides poor load balancing, because some ports get up to twice the load of others. We recommend specifying 2, 4, or 8 active ports per EtherChannel to achieve effective load balancing. (A value of 1 provides no load balancing at all.)

#### Advanced tab options specific to ASA 5505 devices (routed mode only)

- **Block Traffic To**
  Restricts this VLAN interface from initiating contact with the VLAN chosen here.

- **Backup Interface**
  Choose a VLAN interface as a backup interface, for example, to an ISP. The backup interface does not pass traffic unless the default route through the primary interface fails. To ensure that traffic can pass over the backup interface, be sure to configure default routes on both the primary and backup interfaces so that the backup interface can be used when the primary fails.

#### Advanced tab options specific to FWSM 3.1+ devices

- **Bridge Group**
  For an FWSM 3.1+ operating in transparent mode, this read-only field indicates the Bridge group to which this interface is assigned. See Add/Edit Bridge Group Dialog Box, page 44-41 for more information.

- **ASR Group**
  To add this interface to an asymmetric routing group, enter the ASR group number in this field. Stateful failover must be enabled for asymmetric routing support to function properly between units in failover configurations. Valid values for ASR group range from 1 to 32. See About Asymmetric Routing Groups, page 44-5 for more information.

Configuring IPv6 Interfaces (ASA/FWSM)

When Interface, Subinterface, Redundant, or EtherChannel is the chosen Type in the Add Interface or Edit Interface dialog box, the dialog box presents three tabbed panels of options: General, Advanced and IPv6. The options provided by the IPv6 panel are described in this section.

Note

These options are available only on ASA 7.0+ devices in routed mode; ASA 8.2+ devices in transparent mode; and FWSM 3.1+ devices in routed mode.

Navigation Path

You can access the IPv6 panel in the Add Interface and Edit Interface dialog boxes, which are accessed from the ASA or FWSM Interfaces page, as described in Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14.

Related Topics

Field Reference

Table 44-5  IPv6 tab: Add/Edit Interface Dialog Box (ASA/FWSM)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable IPv6</td>
<td>Check this box to enable IPv6 and configure IPv6 addresses on this interface. You can deselect this option to disable IPv6 on the interface, but retain the configuration information.</td>
</tr>
<tr>
<td>Enforce EUI-64</td>
<td>When selected, use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link is enforced.</td>
</tr>
</tbody>
</table>

When this option is enabled on an interface, the source addresses of IPv6 packets received on the interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the interface identifier in an IPv6 packet is not in the Modified EUI-64 format, the packet is dropped and the following system log message is generated:

```
%PIX|ASA-3-325003: EUI-64 source address check failed.
```

Address format verification is performed only when a flow is created. Packets from an existing flow are not checked. Additionally, address verification can be performed only for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address.

The Modified EUI-64 format interface identifier is derived from the 48-bit link-layer (MAC) address by inserting the hex number FFEE between the upper three bytes (OUI field) and the lower 3 bytes (serial number) of the link-layer address. To ensure the chosen address is from a unique Ethernet MAC address, the next-to-lowest order bit in the high-order byte is inverted (universal/local bit) to indicate the uniqueness of the 48-bit address. For example, an interface with a MAC address of 00E0.B601.3B7A would have a 64-bit interface ID of 02E0:B6FF:FE01:3B7A.
Configuring Firewall Device Interfaces

DAD Attempts

To specify the number of consecutive neighbor solicitation messages that are sent on an interface during duplicate address detection (DAD), enter a number from 0 to 600 in this field. Entering 0 disables duplicate address detection on the interface. Entering 1 configures a single transmission without follow-up transmissions; this is the default.

Duplicate address detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection uses neighbor solicitation messages to verify the uniqueness of unicast IPv6 addresses.

When duplicate address detection identifies a duplicate address, the state of the address is set to DUPLICATE and the address is not used. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface and an error message similar to the following is issued:

%PIX-4-DUPLICATE: Duplicate address FE80::1 on outside

If the duplicate address is a global address of the interface, the address is not used and an error message is issued, similar to that shown previously for a duplicate link-local address.

All configuration commands associated with the duplicate address remain as-configured while the state of the address is set to DUPLICATE. If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address, and all other IPv6 addresses associated with the interface are regenerated (that is, duplicate address detection is performed only on the new link-local address).

NS Interval

The interval between IPv6 neighbor solicitation retransmissions, in milliseconds. Valid values range from 1000 to 3600000 milliseconds; the default value is 1000 milliseconds.

Note This value is included in all IPv6 router advertisements sent out on this interface.

Reachable Time

The amount of time, in milliseconds, within which a remote IPv6 node is considered still reachable, after initial reachability was confirmed. Valid values range from 0 to 3600000 milliseconds, the default value is 0. When 0 is used for the value, the reachable time is set as undetermined—it is up to the receiving devices to set and track reachable time.

A configured time enables detection of unavailable neighbors. A shorter time allows detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.
Enable RA

When checked, IPv6 router advertisement transmissions are enabled on the interface. The following options are enabled:

- **RA Lifetime** – The “router lifetime” value specifies how long nodes on the local link should consider the security appliance as the default router on the link. Valid values range from 0 to 9000 seconds; the default is 1800 seconds. Entering 0 indicates that the security appliance should not be considered a default router on the selected interface.
  
  Any non-zero value should not be less than the following RA Interval value.

  **Note** 
  This value is included in all IPv6 router advertisements sent out on this interface.

- **RA Interval** – The interval between IPv6 router advertisement transmissions on this interface. Valid values range from 3 to 1800 seconds, (or from 500 to 1800000 milliseconds if the following RA Interval in Milliseconds option is checked); the default is 200 seconds.
  
  The interval between transmissions should be less than or equal to the RA Lifetime value if it is non-zero. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the desired value.

- **RA Interval in Milliseconds** – Checking this option indicates that the provided RA Interval value is in milliseconds, rather than seconds.
IPv6 Address for Interface Dialog Box

This dialog box is used to add or edit an IPv6 address assigned to an ASA or FWSM interface. Multiple IPv6 addresses can be assigned to the interface in the IPv6 panel of the Add Interface or Edit Interface dialog box.

Note

This dialog box is available only on ASA 7.0+ devices in routed mode; ASA 8.2+ devices in transparent mode; and FWSM 3.1+ devices in routed mode.
Navigation Path
You can access the IPv6 Address for Interface dialog box:

- From the IPv6 panel of the ASA or FWSM Add Interface and Edit Interface dialog boxes.
- From the Management IPv6 page of an ASA 5505 in transparent firewall mode (version 8.2 and 8.3 devices only).

Click the Add Row or Edit Row buttons beneath the table in the Interfaces IPv6 Addresses section to open the dialog box.

Field Reference

<table>
<thead>
<tr>
<th>Table 44-6 IPv6 Address for Interface Dialog Box</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element</strong></td>
</tr>
<tr>
<td>Address/Prefix Length</td>
</tr>
<tr>
<td>EUI-64</td>
</tr>
</tbody>
</table>

IPv6 Prefix Editor Dialog Box
This dialog box is used to add or edit an IPv6 prefix (that is, the network portion of an IPv6 address), providing control over individual parameters, including whether the prefix should be included in IPv6 router advertisements. Multiple prefixes can be configured in the IPv6 panel of the ASA or FWSM Add Interface or Edit Interface dialog box.
Note

This dialog box is available only on ASA 7.0+ devices in routed mode; ASA 8.2+ devices in transparent mode; and FWSM 3.1+ devices in routed mode.

By default, prefixes configured as addresses on an interface are advertised in router advertisements. If you configure specific prefixes for advertisement, then only those prefixes are advertised. The valid and preferred lifetimes are counted down in real time. Alternately, a date can be set to specify the expiration of a prefix. When the expiration is reached, the prefix is no longer advertised.

Navigation Path

You can access the IPv6 Prefix Editor dialog box from the IPv6 panel of the Add Interface and Edit Interface dialog boxes: click the Add Row or Edit Row buttons beneath the table in the Interfaces IPv6 Prefixes section in either of those dialog boxes.

Related Topics

- IPv6 Address for Interface Dialog Box, page 44-33

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address/Prefix Length</td>
<td>Enter an IPv6 network address, with its Prefix Length appended, where the Prefix Length integer indicates how many of the high-order, contiguous bits of the address represent the network portion of the address. A slash (/) must precede the Prefix Length. For example, 3FFE:C00:0:1::/64.</td>
</tr>
<tr>
<td>Default</td>
<td>If this box is checked, the settings in this dialog box will apply to all prefixes, rather than a single address. (When checked, the Address/Prefix Length field is disabled.)</td>
</tr>
<tr>
<td>No Advertisements</td>
<td>When checked, hosts on the local link cannot use the specified prefix in advertisements.</td>
</tr>
</tbody>
</table>
| Off Link                     | When checked, the specified prefix is “off-link”; that is, not locally reachable on the link.  
When on-link (the default), the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. |
| No Auto-Configuration        | When checked, hosts on the local link cannot use the specified prefix for IPv6 autoconfiguration.  
When auto-configuration is on (the default), hosts on the local link can use the specified prefix for IPv6 autoconfiguration. |
Chapter 44      Managing Firewall Devices

Configuring Firewall Device Interfaces

A security device operating in single-context, routed mode requires IP addressing for its interfaces; however, firewall interfaces do not have IP addresses until you assign them. Note that in transparent mode, the device acts as an access-control bridge (a “bump in the wire”)—you assign different VLANs to each interface, but IP addressing is not necessary.

The Add/Edit Interface dialog box presented for an independent ASA or PIX 7.0+ device in single-context, routed mode includes the section **IP Type**, where you specify the type of IP addressing for the interface and provide related parameters, as described here. (The IP Type section of the Add/Edit Interface dialog box for PIX 6.3 devices is described in **Device Interface: IP Type (PIX 6.3)**, page 44-18.)

In multiple-context mode, interface IP addresses are set in the context configuration.

<tr>
<td></td>
<td>• <strong>Lifetime Duration</strong> – Select this option to define prefix expiration as a length of time; the following options are enabled:</td>
</tr>
<tr>
<td></td>
<td>– <strong>Valid Lifetime</strong> – The amount of time (in seconds) that the specified IPv6 prefix is advertised as being valid. Enter a value from 0 to 4294967295 seconds. The maximum value represents infinity (that is, the lifetime does not expire), which can also be specified by checking the <strong>Infinite</strong> box. The default is 292000 (30 days).</td>
</tr>
<tr>
<td></td>
<td>– <strong>Preferred Lifetime</strong> – The amount of time (in seconds) that the specified IPv6 prefix is advertised as being preferred. Enter a value from 0 to 4294967295 seconds. The maximum value represents infinity (that is, the lifetime does not expire), which can also be specified by checking the <strong>Infinite</strong> box. The default is 604800 (7 days). The Preferred Lifetime must be less than or equal to the Valid Lifetime.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Lifetime Expiration Date</strong> – Select this option to define prefix expiration as a specific date. Note that acceptable values for this date can range from today’s date to one year from today’s date. The following options are enabled:</td>
</tr>
<tr>
<td></td>
<td>– <strong>Valid</strong> – The prefix is advertised as being valid until this date and time are reached. Enter a date in the format Mmm dd yyyy (that is, three-letter month abbreviation, two-digit date, and four-digit year), or click the calendar icon to select a date from a scrolling calendar. Also, enter the time of expiration on the specified date, in the form hh:mm, based on a 24-hour clock.</td>
</tr>
<tr>
<td></td>
<td>– <strong>Preferred</strong> – The prefix is advertised as being preferred until this date and time are reached. Enter a date in the format Mmm dd yyyy (that is, three-letter month abbreviation, two-digit date, and four-digit year), or click the calendar icon to select a date from a scrolling calendar. Also, enter the time of expiration on the specified date, in the format hh:mm, based on a 24-hour clock. The Preferred date and time must be earlier than or equal to the Valid date and time.</td>
</tr>
</tbody>
</table>
Chapter 44      Managing Firewall Devices

Configuring Firewall Device Interfaces

**Note**

Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry.

Also, do not specify IP Type information for an interface you intend to use as a redundant interface.

---

**Step 1**

In the Add/Edit Interface dialog box, choose a method for address assignment (Static IP, Use DHCP, or PPPoE (PIX and ASA 7.2+)) from the IP Type list, and then provide related parameters, as follows:

- **Static IP** – Provide a static IP Address and Subnet Mask that represents the security device on this interface’s connected network. The IP address must be unique for each interface.

  The Subnet mask can be expressed in dotted decimal format (for example, 255.255.255.0), or by entering the number of bits in the network mask (for example, 24). Do not use 255.255.255.254 or 255.255.255.255 for an interface connected to the network because this will stop traffic on that interface. If you omit the Subnet Mask value, a “classful” network is assumed, as follows:

  - The Class A netmask (255.0.0.0) is assumed if the first octet of the IP Address is 1 through 126 (i.e., addresses 1.0.0.0 through 126.255.255.255).
  - The Class B netmask (255.255.0.0) is assumed if the first octet of the IP Address is 128 through 191 (i.e., addresses 128.0.0.0 through 191.255.255.255).
  - The Class C netmask (255.255.255.0) is assumed if the first octet of the IP Address is 192 through 223 (i.e., addresses 192.0.0.0 through 223.255.255.255).

**Note**

Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry.

- **Use DHCP** – Enables Dynamic Host Configuration Protocol (DHCP) for automatic assignment of an IP address from a DHCP server on the connected network. The following options become available:

  - **DHCP Learned Route Metric** (required) – Assign an administrative distance to the learned route. Valid values are 1 to 255. The administrative distance for learned routes defaults to 1. All routes have a value or “metric” that represents its priority of use. (This metric is also referred to as “administrative distance.”) When two or more routes to the same destination are available, devices use administrative distance to decide which route to use.
  - **Obtain Default Route using DHCP** – Select this option to obtain a default route from the DHCP server so that you do not need to configure a default static route. See also Configuring Static Routes, page 53-31.
  - **Enable Tracking for DHCP Learned Route** – If Obtain Default Route using DHCP is selected, you can select this option to enable route tracking via a specific Service Level Agreement (SLA) monitor. The following option becomes available:

    - **Tracked SLA Monitor** – Required if Enable Tracking for DHCP Learned Route is selected. Enter or Select the name of the SLA monitor object that defines the route tracking (connectivity monitoring) to be applied to this interface. See Monitoring Service Level Agreements (SLAs) To Maintain Connectivity, page 49-7 for more information.

- **PPPoE (PIX and ASA 7.2+)** – Enables Point-to-Point Protocol over Ethernet (PPPoE) for automatic assignment of an IP address from a PPPoE server on the connected network; this option is not supported with failover. The following options become available:
Chapter 44      Managing Firewall Devices

Configuring Firewall Device Interfaces

- **VPDN Group Name** (required) – Choose the Virtual Private Dialup Network (VPDN) group that contains the authentication method and user name/password to use for network connection, negotiation and authentication. See Managing VPDN Groups, page 44-45 for more information.

- **IP Address** – If provided, this static IP address is used for connection and authentication, instead of a negotiated address.

- **Subnet Mask** – The subnet mask to be used in conjunction with the provided IP Address.

- **PPPoE Learned Route Metric** (required) – Assign an administrative distance to the learned route. Valid values are 1 to 255; defaults to 1.

  All routes have a value or “metric” that represents its priority of use. (This metric is also referred to as “administrative distance.”) When two or more routes to the same destination are available, devices use administrative distance to decide which route to use.

- **Obtain Default Route using PPPoE** – Select this option to obtain a default route from the PPPoE server; sets the default routes when the PPPoE client has not yet established a connection. When using this option, you cannot have a statically defined route in the configuration.

- **Enable Tracking for PPPoE Learned Route** – If Obtain Default Route using PPPoE is selected, you can select this option to enable route tracking for PPPoE-learned routes. The following options become available:

  - **Dual ISP Interface** – If you are defining interfaces for dual ISP support, choose Primary or Secondary to indicate which connection you are configuring.

  - **Tracked SLA Monitor** – Required if Enable Tracking for PPPoE Learned Route is selected. Enter or Select the name of the SLA monitor object that defines the route tracking (connectivity monitoring) to be applied to this interface. See Monitoring Service Level Agreements (SLAs) To Maintain Connectivity, page 49-7 for more information.

---

**Note**

You can configure DHCP and PPPoE only on the outside interface of a firewall device. If you have already configured PPPoE on the outside interface, it is no longer available as an option.

**Step 2**  
Continue configuring the device interface in the Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19.

---

**Device Interface: MAC Address**

By default, a physical interface uses its “burned-in” MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

A redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then its MAC address changes to match the MAC address of the interface that is now listed first. If you manually assign a MAC address to the redundant interface, that is used regardless of the physical-interface MAC addresses.

Similarly, all interfaces assigned to an EtherChannel group share the same MAC address. By default, the EtherChannel uses the MAC address of the lowest-numbered member interface. However, you can manually configure a MAC address for the EtherChannel to prevent traffic disruption should the low-numbered interface be removed from the group.

You also might want to assign unique MAC addresses to subinterfaces. For example, your service provider might control access based on MAC addresses.

Further, if you use failover, you can provide a standby MAC address. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.
Note
The following options appear only on the Advanced tab of the Add Interface and Edit Interface dialog boxes presented by PIX 7.2+ and ASA 7.2+ devices.

(Optional) To manually assign a private MAC address to the current interface:

Step 1
In the Add/Edit Interface dialog box, provide the desired MAC address in the **Active MAC Address** field.

MAC addresses are provided in **H.H.H** format, where **H** is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE.

R Note
In some cases, you may have to press the Tab key after entering the Active MAC Address to activate the Standby MAC Address field.

Step 2
If desired, provide a **Standby MAC Address** for use with device-level failover.

If the active unit fails over and the standby unit becomes active, the new active unit begins using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Step 3
Continue configuring the device interface in the Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19.

Configuring Hardware Ports on an ASA 5505

The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: **Hardware Ports** and **Interfaces**. The table on the Hardware Ports panel displays currently configured switch ports for the selected ASA 5505.

Use the Configure Hardware Ports dialog box to configure the switch ports on an ASA 5505, including setting the mode, assigning a switch port to a VLAN, and setting the Protected option. (The following dialog-box parameter descriptions also describe the fields in the Hardware Ports table.)

Caution
The ASA 5505 does not support Spanning Tree Protocol for loop detection in the network. Therefore, you must ensure that any connection with the appliance does not end up in a network loop.

Navigation Path
You can access the Configure Hardware Ports dialog box by clicking Add Row or Edit Row on the Hardware Ports panel of the ASA 5505 Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14 for more information.

Related Topics

<td>- <strong>Access Port</strong> – Sets the port to access mode. Each access port can be assigned to one VLAN.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Trunk Port</strong> – Sets the port to trunk mode using 802.1Q tagging. Trunk ports can carry multiple VLANs using 802.1Q tagging.</td>
</tr>
<tr>
<td></td>
<td>Trunk mode is available only with the Security Plus license. Trunk ports do not support untagged packets, there is no native VLAN support, and the appliance drops all packets that do not contain a tag.</td>
</tr>
<tr>
<td>VLAN ID</td>
<td>Enter VLAN ID(s) for this port, according to the chosen Mode:</td>
</tr>
<tr>
<td></td>
<td>- For Access Port mode, enter the ID of the VLAN to which this switch port is to be assigned.</td>
</tr>
<tr>
<td></td>
<td>- For Trunk Port mode, you can enter multiple VLAN IDs, and multiple ID ranges (such as 4-8), separated by commas.</td>
</tr>
</tbody>
</table>

**Note** For devices running operating system 7.2(2)18 or earlier, valid VLAN IDs are 1 to 1001; with version 7.2(2)19 or later, valid IDs are 1 to 4090.
Add/Edit Bridge Group Dialog Box

A transparent firewall connects the same network on its inside and outside interfaces, and supports only the two interfaces per context. However, you can increase the number of interfaces available to a context through use of bridge groups. You can configure up to eight bridge groups; on an FWSM each group can contain two interfaces; on an ASA each group can contain four interfaces.

Each bridge group connects to a separate network. Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the security appliance—traffic must exit the security appliance to be routed by an external router back to another bridge group in the security appliance.

You might want to use more than one bridge group if you do not want the overhead of security contexts, or want to maximize your use of security contexts. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration. For complete security policy separation, use security contexts with one bridge group in each context.

For FWSM 3.1+ and ASA 8.4.1+ devices in transparent mode, the Interfaces page displays two tabbed panels: Interfaces and Bridge Groups. The following information applies to the Bridge Groups panel and the Add/Edit Bridge Group dialog box; refer to Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FWSM), page 44-19 for information about the Interfaces panel.

Navigation Path
You can access the Add/Edit Bridge Group dialog box from the Bridge Groups panel of the Interfaces page.

<td></td>
</tr>
<tr>
<td>IP Address</td>
<td>Enter or Select a management IP address for the bridge group. A transparent firewall does not participate in IP routing. Thus, the only IP configuration required for a bridge group is this management IP address. This address is the source address for traffic originating on the security appliance, such as system messages or communications with AAA servers. You can also use this address for remote management access. IPv6 addresses are not supported for bridge groups.</td>
</tr>
<tr>
<td>Netmask</td>
<td>Network mask for the specified IP address. You can express the value in dotted decimal format (for example, 255.255.255.0) or by entering the number of bits in the network mask (for example, 24). Do not use 255.255.255.254 or 255.255.255.255 for an interface connected to the network because this will stop traffic on that interface.</td>
</tr>
<tr>
<td>Description</td>
<td>You can enter an optional description for this bridge group.</td>
</tr>
</tbody>
</table>

Advanced Interface Settings (PIX/ASA/FWSM)

Advanced configuration options are available for interfaces on FWSMs and ASA/PIX 7.0+ devices operating in single-context mode.

These are general device-related settings; that is, they are not applied to individual interfaces.

Note  The information in this section does not apply to PIX 6.3 devices, nor to security devices in multiple-context mode.

The Advanced Interface Settings dialog box includes the following elements:

- **Traffic between interfaces with same security levels** – This parameter controls communication between interfaces and subinterfaces on the same security level. If you enable same security interface communication, you can still configure interfaces at different security levels as usual. Refer to Enabling Traffic between Interfaces with the Same Security Level, page 44-43 for more information.
• **PPPoE Users button** – Click this button to open the PPPoE Users dialog box, where you can add, edit and delete PPPoE users, as described in Managing the PPPoE Users List, page 44-44. This option is available only for ASA and PIX 7.0+ devices.

• **VPDN Groups (PIX and ASA 7.2+)** – This table lists currently defined VPDN Groups. The buttons below the table are used to add, edit and delete VPDN group entries, as described in Managing VPDN Groups, page 44-45.

• **LACP System Priority (ASA 8.4.1+)** – All systems participating in EtherChannel link aggregation require a Link Aggregation Control Protocol (LACP) System Priority. The value can be 1 to 65535, with the higher number signifying lower priority. The default is 32768.

This value is combined with the system MAC address to form the system’s LACP identifier, and thus is applicable only for EtherChannel interfaces. See Configuring EtherChannels, page 44-9, for more information.

> **Note** Additional LACP parameters are available in the Edit Interface dialog box for individual interfaces assigned to an EtherChannel; see Editing LACP Parameters for an Interface Assigned to an EtherChannel, page 44-11, for more information.

**Navigation Path**

You can open the Advanced Interface Settings dialog box by clicking the Advanced button at the bottom of the Interfaces page (for non-5505 ASAs, PIX 7.0+ devices, and FWSMs), or at the bottom of the Interfaces tab on the ASA 5505 Ports and Interfaces page.

**Related Topics**

• Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14

**Enabling Traffic between Interfaces with the Same Security Level**

The Advanced Interface Settings (PIX/ASA/FWSM), page 44-42 dialog box presented for a single-context security device includes the “Traffic between interfaces with the same security level” drop-down list, as described in this section.

By default, interfaces or subinterfaces on the same security level cannot communicate with each other. Allowing communication between same-security interfaces provides the following benefits:

• You can configure more than 101 communicating interfaces.

  If you use different levels for each interface and do not assign any interfaces to the same security level, you can configure only one interface per level (0 to 100).

• You can allow traffic to flow freely between all same-security interfaces without access lists.

> **Note** If you enable NAT control, you do not need to configure NAT between same-security-level interfaces.

**Step 1** In the Advanced Interface Settings dialog box, choose the option that identifies how you want this device to handle Traffic between interfaces with the same security levels:

• **Disabled**—Communication between interfaces on the same security level is not allowed.

• **Inter-interface**—Enables traffic flows between interfaces with the same security level setting. When this option is enabled, you are not required to define translation rules to enable traffic flow between interfaces in the firewall device.
• **Intra-interface**—Enables traffic flows between subinterfaces with the same security level setting. When this option is enabled, you are not required to define translation rules to enable traffic flow between subinterfaces assigned to an interface.

• **Both**—Allows both intra- and inter-interface communications among interfaces and subinterfaces with the same security level.

**Step 2** Continue with *Advanced Interface Settings (PIX/ASA/FWSM), page 44-42* configuration, or click OK to close the Advanced Interface Settings dialog box.

### Managing the PPPoE Users List

Point-to-Point Protocol over Ethernet (PPPoE) allows standard PPP communication between a security device and an external ISP, via an Ethernet interface on the device. To establish a communication link, the device must provide authentication credentials and obtain network parameters. This is accomplished using a Virtual Private Dialup Network (VPDN) group, which basically consists of established PPPoE user credentials (i.e., a user name and password) and an authentication protocol. See *Managing VPDN Groups, page 44-45* for more information about VPDN groups.

The PPPoE user credentials available for use with VPDN groups are maintained in the PPPoE dialog box, which you can access from the *Advanced Interface Settings (PIX/ASA/FWSM), page 44-42* dialog box, and from the Add/Edit VPND Group dialog boxes.

#### Adding and Editing PPPoE Users

The PPPoE Users dialog box presents a table of currently defined PPPoE users, along with standard Add Row, Edit Row, and Delete Row buttons. The Add Row button opens the Add PPPoE User dialog box; the Edit Row button opens the virtually identical Edit PPPoE User dialog box.

Enter or edit the following PPPoE user parameters, and then click OK to close the Add (Edit) PPPoE User dialog box and return to the Advanced Interface Settings dialog box.

**Note**

PPPoE user options are not available on Firewall Service Modules (FWSMs).

</tr>
</tbody>
</table>
Managing VPDN Groups

A Virtual Private Dialup Network (VPDN) group—basically an established PPPoE user and an authentication protocol—is used by a security device to contact an external ISP and authenticate itself, in order to establish a PPPoE communications link and obtain network parameters. (See Managing the PPPoE Users List, page 44-44 for information about establishing PPPoE users.)

Available VPDN groups are maintained in the Advanced Interface Settings dialog box, which opens when you click the Advanced button at the bottom of the Interfaces page, as described in Advanced Interface Settings (PIX/ASA/FWSM), page 44-42.

Adding and Editing VPDN Groups

The Advanced Interface Settings dialog box includes a table of currently defined VPDN groups, and standard Add Row, Edit Row, and Delete Row buttons. The Add Row button opens the Add VPDN Group dialog box; the Edit Row button opens the virtually identical Edit VPDN Group dialog box.

Enter or edit the following VPDN group parameters, and then click OK to close the Add (Edit) VPDN Group dialog box and return to the Advanced Interface Settings dialog box.

Note

VPDN group options are not available on Firewall Service Modules (FWSMs).

- Management IPv6 Page (ASA 5505), page 45-11

About Bridging on Firewall Devices

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 device that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. The security appliance connects the same network on its inside and outside ports, acting as an access-control bridge; you assign different VLANs to each interface, and IP addressing is not used.

Thus, you can easily introduce a transparent firewall into an existing network—IP re-addressing is unnecessary—and maintenance is facilitated because there are no complicated routing patterns to troubleshoot and no NAT configuration.

Although the transparent-mode device acts as a bridge, Layer 3 traffic, such as IP traffic, cannot pass through the security appliance unless you explicitly permit it with specific access rules. The only traffic allowed through a firewall without an access list is ARP traffic, which you can control using ARP inspection, and IPv6 neighbor discovery.

When the security appliance runs in transparent mode, the outgoing interface of a packet is determined by performing a MAC address lookup instead of a route lookup. Route statements can still be configured, but they apply only to security appliance-originated traffic. For example, if your syslog server is located on a remote network, you must use a static route so the security appliance can reach that subnet.
Chapter 45  Configuring Bridging Policies on Firewall Devices

About Bridging on Firewall Devices

To configure a transparent firewall, use the following policies. When configuring an ASA/PIX/FWSM device in multiple-context mode, configure these policies on each transparent security context.

- **Firewall > Access Rules**—Access rules control layer 3 and higher traffic using extended access control lists. In routed mode, some types of traffic cannot pass through the security appliance even if you allow it in an access list. For example, you can establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on access rules. Likewise, protocols like HSRP or VRRP can pass through the security appliance. However, the transparent-mode security appliance does not pass CDP packets.

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can provide those functions. For example, by using access rules, you can allow DHCP traffic to pass (instead of the unsupported DHCP relay feature), or multicast traffic such as that created by IP/TV.

For more information, see Understanding Access Rules, page 15-2 and Configuring Access Rules (IPv4 or IPv6), page 15-7.

- **Firewall > Transparent Rules**—Transparent rules control non-IP layer 2 traffic using Ethertype access control lists. For example, you can configure rules to allow AppleTalk, IPX, BPDUs, and MPLS to pass through the device. For more information, see Configuring Transparent Firewall Rules, page 21-1.

- **Platform > Bridging > ARP Table, ARP Inspection and IPv6 Neighbor Cache**—Use these policies to control the types of ARP and IPv6 traffic allowed through the bridge. If desired, you can configure static ARP and IPv6 neighbor cache entries and drop any traffic not defined by those static rules. Enable ARP inspection so that if a mismatch between the MAC address, the IP address, or the interface occurs, the security appliance drops the packet. This helps prevent ARP spoofing. For more information, see ARP Table Page, page 45-3 and ARP Inspection Page, page 45-5.

> **Note** The ARP Table and IPv6 Neighbor Cache are the only bridging policies available for non-transparent ASA/PIX/FWSM devices.

- **Platform > Bridging > MAC Address Table and MAC Learning**—Use these policies to configure static MAC-IP address mappings and to enable or disable MAC learning. MAC learning is enabled by default, which allows the appliance to add MAC-IP address mappings as traffic passes through the interface. If you want to prevent all traffic except from static entries, you can disable MAC learning. For more information, see MAC Address Table Page, page 45-7 and MAC Learning Page, page 45-9.

- **Platform > Bridging > Management IP and Platform > Bridging > Management IPv6**—Use these policies to configure a management IP address that Security Manager can use to communicate with the device.

> **Note** The Management IP and Management IPv6 pages are not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

If you change the management IP address, you also need to update the device properties for the device or security context. Follow these steps:

- Change the management IP address, save and submit your changes.
- Deploy your changes to the device.
In Device view, select the device or security context, then select **Tools > Device Properties**. On the General page, enter the new management IP address in the IP Address field. On the Credentials tab, update the username and password fields with account credentials that can log into the management interface. Security Manager will now use this address and user account for subsequent deployments and device communication.

For more information, see **Management IP Page, page 45-10**.

- **Interfaces in Routed and Transparent Modes, page 44-4**
- **Transparent Rules Page, page 21-3**

**Bridging Support for FWSM 3.1**

Although FWSM 3.1 can support multiple L2 interface pairs, Security Manager lets you specify no more than two L2 interfaces (a single interface pair), and one associated management IP address. That means only one bridge group with two named interfaces associated is provisioned with a management IP address. If the device configuration contains a maximum of one bridge group and two named interfaces, it is valid for discovery. All other scenarios result in an error message and the commands are ignored during discovery. Furthermore, discovery will not show any bridge-group information in Security Manager, although the bridge-group commands will be generated during deployment. Bridge group 1 will be deployed and used in transparent rule policies if no bridge group exists in the device configuration.
