Managing the IPv6 Neighbor Cache

Use the IPv6 Neighbor Cache page to manage static IPv6 neighbor entries that map a MAC address to an IPv6 address, and identify the interface through which the neighbor host is reached, to provide address-resolution functions for IPv6. This is available on ASA 7.0+ devices only.

The IPv6 Neighbor Cache entries are the IPv6 equivalent of the static ARP entries, managed on the ARP Table Page, page 45-3.

If an entry for a specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry. Static entries in the IPv6 neighbor discovery cache are not modified by the neighbor discovery process.

The IPv6 Neighbor Cache page is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons. (These are standard buttons, as described in Using Tables, page 1-43.) The Add Row button opens the Add IPv6 Neighbor Cache Configuration dialog box, and Edit Row opens the Edit IPv6 Neighbor Cache Configuration dialog box. Other than the titles, the two dialog boxes are identical.

Ensure that IPv6 is enabled on at least one interface before trying to add a neighbor.

MAC Address Table Page

Use the MAC Address Table page to add static MAC address entries to the MAC Address table. The table associates the MAC address with the source interface so that the security appliance knows to send any packets addressed to the device out the correct interface.

**Navigation Path**

- (Device view) Select **Platform > Bridging > MAC Address Table** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > MAC Address Table** from the Policy Type selector. Right-click **MAC Address Table** to create a policy, or select an existing policy from the Shared Policy selector.

</tbody>
</table>
MAC Learning Page

Use the MAC Learning page to enable or disable MAC address learning on an interface. By default, each interface learns the MAC addresses of entering traffic, and the security appliance adds corresponding entries to the MAC address table. You can disable MAC address learning if desired; however, unless you statically add MAC addresses to the table, no traffic can pass through the security appliance.

**Navigation Path**

- (Device view) Select **Platform > Bridging > MAC Learning** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > MAC Learning** from the Policy Type selector. Right-click **MAC Learning** to create a policy, or select an existing policy from the Shared Policy selector.

Management IP Page

A transparent firewall does not participate in IP routing. The only IP configuration required for the
device is specification of a management IP address, which is used as the source address for traffic
originating on the device, such as system messages or communications with AAA servers. You can also
use this address for remote-management access.

For IPv4 traffic, the management IP address is required to pass any traffic.

Note

In addition to the management IP address for the device, you can configure an IP address for the
Management 0/0 or 0/1 management-only interface. This IP address can be on a separate subnet from
the main management IP address.

Use the Management IP page to set the management IP address for a security device, or for a context in
transparent firewall mode.

Navigation Path

- (Device view) Select Platform > Bridging > Management IP from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Bridging > Management IP from the Policy
  Type selector. Right-click Management IP to create a policy, or select an existing policy from the
  Shared Policy selector.

Management IPv6 Page (ASA 5505)

A transparent firewall does not participate in IP routing. The only IP configuration required for the device is specification of a management IP address, which is used as the source address for traffic originating on the device, such as system messages or communications with AAA servers. You can also use this address for remote-management access.

For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations. If you configure the global address, a link-local address is automatically configured on each interface, so you do not also need to specifically configure a link-local address. However, if you do not configure a global management address, you need to configure interface link-local addresses, as described in Configuring IPv6 Interfaces (ASA/FWSM), page 44-29. Note that you can configure both IPv6 and IPv4 management addresses on a device.

On an ASA 5505 in transparent mode, use the Management IPv6 page to enable IPv6, configure neighbor solicitation, and manage IPv6 interface addresses.

---

**Note**

This page is available only on ASA 5505 version 8.2 and 8.3 devices in transparent mode.

**Navigation Path**

- (Device view) Select Platform > Bridging > Management IPv6 from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Bridging > Management IPv6 from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

</tr>
</tbody>
</table>
| DAD Attempts  | To specify the number of consecutive neighbor solicitation messages that are sent on an interface during duplicate address detection (DAD), enter a number from 0 to 600 in this field. Entering 0 disables duplicate address detection. Entering 1 configures a single transmission without follow-up transmissions; this is the default. Duplicate address detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection uses neighbor solicitation messages to verify the uniqueness of unicast IPv6 addresses. When duplicate address detection identifies a duplicate address, the state of the address is set to DUPLICATE and the address is not used. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface and an error message similar to the following is issued:

%PIX-4-DUPLICATE: Duplicate address FE80::1 on outside

If the duplicate address is a global address of the interface, the address is not used and an error message is issued, similar to that shown previously for a duplicate link-local address. All configuration commands associated with the duplicate address remain as-configured while the state of the address is set to DUPLICATE. If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address, and all other IPv6 address associated with the interface are regenerated (that is, duplicate address detection is performed only on the new link-local address). |
| NS Interval   | The interval between IPv6 neighbor solicitation retransmissions, in milliseconds. Valid values range from 1000 to 3600000 milliseconds; the default value is 1000 milliseconds. |
### Table 45-11  Management IPv6 Page (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reachable Time</td>
<td>The amount of time, in milliseconds, within which a remote IPv6 node is considered still reachable, after initial reachability was confirmed. Valid values range from 0 to 3600000 milliseconds, the default value is 0. When 0 is used for the value, the reachable time is set as undetermined—it is up to the receiving devices to set and track reachable time. A configured time enables detection of unavailable neighbors. A shorter time allows detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.</td>
</tr>
<tr>
<td>Interface IPv6 Addresses</td>
<td>The IPv6 address(es) assigned to the management interface are listed in this table. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables, page 1-43.) Add Row and Edit Row open the IPv6 Address for Interface Dialog Box, page 44-33.</td>
</tr>

</table>
Configuring Device Administration Policies on Firewall Devices

The Device Admin section contains pages for configuring device administration policies for firewall devices. This chapter contains the following topics:

- About AAA on Security Devices, page 46-1
- Configuring Banners, page 46-7
- Configuring Boot Image/Configuration Settings, page 46-8
- Setting the Device Clock, page 46-10
- Configuring Device Credentials, page 46-12

About AAA on Security Devices

Authentication-Authorization-Accounting (AAA) enables the security appliance to determine who a user is (authentication), what the user can do (authorization), and what the user did (accounting). You can use authentication alone, or with authorization and accounting. Authorization always requires a user to be authenticated first. You also can use accounting alone, or with authentication and authorization.

Authentication-Authorization-Accounting provides an extra level of protection and control for user access beyond access lists alone. For example, you can create an ACL that allows all outside users to access Telnet on a server on the DMZ network. If you want to limit user access to the server when you may not always know the IP addresses of these users, you can enable AAA to allow only authenticated and/or authorized users to make it through the security appliance. (The Telnet server enforces authentication, too; the security appliance prevents unauthorized users from attempting to access the server.)

- **Authentication**—Authentication grants access based on user identity. Authentication establishes user identity by requiring valid user credentials, which are typically a user name and password. You can configure the security appliance to authenticate the following items:
  - Administrative connections to the security appliance using Telnet, SSH, HTTPS/ASDM, or serial console,
  - The `enable` command.

- **Authorization**—Authorization controls user capabilities after users are authenticated. Authorization controls the services and commands available to each authenticated user. If you do not enable authorization, authentication alone would provide the same access to services for all authenticated users.

  If you need the control that authorization provides, you can configure a broad authentication rule, and then have a detailed authorization configuration. For example, you might authenticate inside users who attempt to access any server on the outside network, and then use authorization to limit the outside servers that a particular user can access.
The security appliance caches the first 16 authorization requests per user, so if the user accesses the same services during the current authentication session, the security appliance does not resend the request to the authorization server.

- **Accounting**—Accounting tracks traffic that passes through the security appliance, providing a record of user activity. If you enable authentication for that traffic, you can account for traffic per user. If you do not authenticate the traffic, you can account for traffic per IP address. Accounting information includes when sessions start and stop, user name, the number of bytes that pass through the security appliance for the session, the service used, and the duration of each session.

### Preparing for AAA

AAA services depend upon the use of the Local database or at least one AAA server. You can also use the Local database as a fallback for most services provided by an AAA server. Before you implement AAA, you should configure the Local database and configure AAA server groups and servers.

Configuration of the Local database and AAA servers depends upon the AAA services you want the security appliance to support. Regardless of whether you use AAA servers, you should configure the Local database with user accounts that support administrative access, to prevent accidental lock-outs and, if so desired, to provide a fallback method when AAA servers are unreachable. For more information, see Configuring User Accounts, page 49-6.

The following table provides a summary of AAA service support by each AAA server type and by the Local database. You manage the Local database by configuring user accounts on the Platform > Device Admin > User Accounts page (see Configuring User Accounts, page 49-6). You establish AAA server groups and add individual AAA servers to the server groups using the Platform > Device Admin > AAA page.

</tbody>
</table>

1 HTTP Form protocol supports single sign-on authentication for WebVPN users only.

2 For firewall sessions, RADIUS authorization is supported with user-specific ACLs only, which are received or specified in a RADIUS authentication response.

3 Local command authorization is supported by privilege level only.
Local Database

The security appliance maintains a Local database that you can populate with user accounts, which contain, at a minimum, a user name. Typically, you assign a password and a privilege level to each user name, although passwords are optional. You can manage Local user accounts on the Platform > Device Admin > User Accounts page (see Configuring User Accounts, page 49-6).

If you enable command authorization using the Local database, the security appliance refers to the assigned user privilege level to determine what commands are available. By default, all commands are assigned either privilege level 0 or level 15.

If you add users to the Local database with access to the CLI and whom you do not want to enter privileged mode, you should enable command authorization. Without command authorization, users can access privileged mode (and all commands) at the CLI using their own password if their privilege level is 2 or greater (2 is the default). Alternatively, you can use RADIUS or TACACS+ authentication for console access so the user will not be able to use the login command, or you can set all local users to level 1 so you can control who can use the system enable password to access privileged mode.

You cannot use the local database for network access authorization.

The user accounts in the Local database can provide fallback support for console and enable-password authentication, for command authorization, and for VPN authentication and authorization. This behavior is designed to help you prevent accidental lock-out from the security appliance.

For users who need fallback support, we recommend that their user names and passwords in the Local database match their user names and passwords on the AAA servers. This provides transparent fallback support. Because the user cannot determine whether a AAA server or the local database is providing the service, using user names and passwords on AAA servers that are different than the user names and passwords in the Local database means that the user cannot be certain which user name and password should be given.

For multiple-context mode, you can configure user names in the system execution space to provide individual logins at the CLI using the login command; however, you cannot configure any aaa commands that use the local database in the system execution space.

Note

VPN functions are not supported in multiple mode.

AAA for Device Administration

You can authenticate all administrative connections to the security appliance, including:

- Telnet
- SSH
- Serial console
- ASDM
- VPN management access

You can also authenticate administrators who attempt to enter enable mode. You can authorize administrative commands. You can have accounting data for administrative sessions and for commands issued during a session sent to an accounting server.

You can configure AAA for device administration using the Platform > Device Admin > AAA page (see About AAA on Security Devices, page 46-1).
AAA for Network Access

You can configure rules for authenticating, authorizing, and accounting for traffic passing through the firewall by using the Firewall > AAA Rules page (see Chapter 14, “Managing Firewall AAA Rules”). The rules you create are similar to access rules, except that they specify whether to authenticate, authorize, or perform accounting for the traffic defined; and which AAA server group the security appliance is to use to process the AAA service request.

AAA for VPN Access

AAA services for VPN access include the following:

- User account settings for assigning users to VPN groups, configured on the Platform > Device Admin > User Accounts page (see Configuring User Accounts, page 49-6).
- VPN group policies that can be referenced by many user accounts or tunnel groups, configured on the Remote Access VPN > RA VPN Policies > User Group Policy or Site to Site VPN > User Group Policy page.
- Tunnel group policies, configured on the Remote Access VPN > RA VPN Policies > PIX7.0/ASA Tunnel Group Policy or Site to Site VPN > PIX7.0/ASA Tunnel Group Policy page.

Configuring AAA - Authentication Tab

The AAA page presents three tabbed panels; the Authentication panel is presented when you navigate to the AAA page. Use these options to control privileged access to the device console, to restrict access by connection type, and to define access messages.

Use the Authorization Tab, page 46-6 to control the services and commands available to authenticated users. Use the Accounting Tab, page 46-6 to activate tracking of console traffic, providing a record of user activity.

Navigation Path

- (Device view) Select Platform > Device Admin > AAA from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > AAA from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- About AAA on Security Devices, page 46-1
- Configuring User Accounts, page 49-6

Using the Authentication Tab

Use the Authentication tab to enable authentication for administrator access to the security appliance. The Authentication tab also lets you configure the prompts and messages a user sees when authenticated by an AAA server.

The device will prompt for a user name and password before you can enter commands. If the authentication server is offline, wait until the console login request times out. You can then access the console with the firewall username and the enable password.
Field Reference

Table 46-2 Authentication Tab

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Require AAA Authentication to allow use of privileged commands</td>
<td></td>
</tr>
<tr>
<td>Enable</td>
<td>Requires authentication from an AAA server to allow a user to access EXEC mode on the firewall. This option allows up to three attempts to access the firewall console. If this number is exceeded, an “access denied” message is displayed. When checked, the Server Group field is enabled.</td>
</tr>
<tr>
<td>Server Group</td>
<td>Enter or Select the name of an AAA server to contact for user authentication.</td>
</tr>
<tr>
<td>Use LOCAL when server group fails</td>
<td>Check this box to use the LOCAL database as back-up if the selected server fails. (This option is not enabled until you provide a Server Group.)</td>
</tr>
</tbody>
</table>

Require AAA Authorization for the following types of connections

Select the connections that require authorization. For each type, users are allowed up to three attempts to access the firewall console. If this number is exceeded, an “access denied” message is displayed.

Select each connection option individually:

- **HTTP** – Require AAA authentication when a user initiates an HTTPS connection to the firewall console.
- **Serial** – Require AAA authentication when a user initiates a connection to the firewall console via the serial console cable.
- **SSH** – Require AAA authentication when a user initiates a Secure Shell (SSH) connection to the console.
- **Telnet** – Require AAA authentication when a user initiates a Telnet connection to the firewall console.

For each selected connection, provide a Server Group and indicate whether the LOCAL database is used as a back-up:

- **Server Group** – Enter or Select the name of an AAA server to contact for user authentication.
- **Use LOCAL when server group fails** – Check this box to use the LOCAL database as back-up if the selected server fails. (This option is not enabled until you provide a Server Group.)

Authentication Prompts

| Login Prompt | Enter the prompt a user will see when logging in to the security appliance. |
| Accepted Message | Enter the message displayed when successfully authenticated. |
| Rejected Message | Enter the message displayed when authentication fails for any reason. |
| Rejected Message for Invalid Credentials | Enter the message displayed when authentication fails following entry of unknown or invalid credentials. Available only on FWSM 3.2+ devices. |
About AAA on Security Devices

Authorization Tab

The Authorization tab allows you to configure authorization for accessing firewall commands.

Navigation Path
You can access the Authorization tab from the AAA page; see Configuring AAA - Authentication Tab, page 46-4.

**Configuring Banners**

You can use the Banner page to specify Session (exec), Login, and Message-of-the-Day (motd) banners for a security appliance or shared policy.

---

**Note**

If you use the token $(hostname) or $(domain) in a banner, it is replaced with the host name or domain name of the security appliance. When you enter the $(system) token in a context configuration, the context uses the banner configured in the system configuration.
Spaces in banner text are preserved; however, tabs cannot be entered. Multiple lines in a banner are created by entering a separate line of text for each line you wish to add. Each line is then appended to the end of the existing banner. If the line is empty, a carriage return (CR) is added to the banner.

There is no limit on the length of a banner other than RAM and flash-memory limits. You can only use ASCII characters, including new-line (press the Enter key), which counts as two characters. When accessing the security appliance through Telnet or SSH, the session closes if there is not enough system memory available to process the banner messages, or if a TCP write error occurs when attempting to display the banner messages.

Related Topics
- Chapter 50, “Configuring Server Access Settings on Firewall Devices”

---

**Step 1**
To configure banners, access the Banner page:
- (Device view) Select **Platform > Device Admin > Banner** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Banner** from the Policy Types selector. Select an existing policy from the Policies selector, or create a new one.

**Step 2**
In the **Session (exec) Banner** field, enter the text you want the system to display as a banner before displaying the enable prompt.

**Step 3**
In the **Login Banner** field, enter the text you want the system to display as a banner before the password login prompt when accessing the security appliance using Telnet.

**Step 4**
In the **Message-of-the-Day (motd) Banner** field, enter the text you want the system to display as a message-of-the-day banner.

**Step 5**
To replace a banner, change the contents of the appropriate box.

**Step 6**
To remove a banner, clear the contents of the appropriate box.

---

**Configuring Boot Image/Configuration Settings**

Use the Boot Image/Configuration page to specify which configuration file the security appliance will use at start-up. You can also specify the path to an Adaptive Security Device Manager (ASDM) configuration file.

If you do not specify a boot-image location, the first valid image on internal flash memory will be chosen to launch the system.

**Note**

This page is available only on ASA and PIX 7.0+ devices

**Navigation Path**

- (Device view) Select **Platform > Device Admin > Boot Image/Configuration** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Boot Image/Configuration** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.
### Table 46-5  Boot Image/Configuration Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boot Config Location     | Enter the path to and name of the configuration file to be used when the system is loaded. On an ASA, you can use any of the following syntactical constructs:  
  - `disk0:/path/filename`  
    The value “disk0” represents the internal flash card. You can also use “flash” instead of “disk0,” as they are aliased:  
    - `flash:/path/filename`  
    - `disk1:/path/filename`  
    The value “disk1” represents the external flash card.  
  On a PIX device, you can use only the “flash” syntax; that is:  
  - `flash:/path/filename`                                                                                                                                 |
| ASDM Image Location      | The location and name of the ASDM software image to be used when ASDM sessions are initiated. (You can use ASDM to monitor both ASA and PIX devices.)  
  On a PIX device, as with the Boot Config Location, you are restricted to only the “flash” syntax.  
  On an ASA, as with the Boot Config Location, you can use the “disk0,” “flash,” or “disk1” constructs. In addition, you can specify an image file on a TFTP server, as follows  
  - `tftp://[user[:password]@[server[:port]]]/path/filename`                                                                                             |
| Boot Images Table        | This table lists any alternate configuration files you have defined; you can specify up to four. The first available image in this list is used if you did not specify a primary file in the Boot Config Location field, or if that file is unavailable.  
  This is a standard Security Manager table; use the up-arrow, down-arrow, Add Row, Edit Row, and Delete Row buttons below the table to manage these entries, as described in Using Tables, page 1-43.  
  The Add Row and Edit Row open the Images Dialog Box, page 46-10, used to add and edit the paths to alternate configuration files.  
  **Note** On an ASA, the first (and only the first) entry in this table can refer to an ASDM configuration file on a TFTP server. If the device cannot reach the TFTP server, it will attempt to load the next image file in the list. |
Images Dialog Box

Use the Images dialog box to add or edit a configuration file entry in the Boot Images table on the Boot Image/Configuration page.

Navigation Path
You can access the Images dialog box from the Boot Image/Configuration page. For more information, see Configuring Boot Image/Configuration Settings, page 46-8.

Field Reference
The Images dialog box contains one field, used to define the path to a boot image or configuration file, as follows:

<table>
<thead>
<tr>
<th>Table 46-6 Images Dialog Box</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

Setting the Device Clock

Use the Clock page to set the date and time on the selected device.

**Note**
This page is not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

To dynamically set the time using an NTP server, see NTP Page, page 50-18; time derived from an NTP server overrides any time set manually on the Clock page.
In multiple-context mode, set the time in the system context only.

**Navigation Path**
- (Device view) Select **Platform > Device Admin > Clock** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Clock** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

**Field Reference**

<td>Choose the month in which daylight savings time begins or ends.</td>
</tr>
</tbody>
</table>
Configuring Device Credentials

Use the Credentials page to specify the user credentials Security Manager will use when contacting this device. You can also change the Enable password and the Telnet/SSH password on the device.

This user name-password combination lets you log into the device (in EXEC mode) if you connect to the security appliance using an HTTP, HTTPS, Telnet, or SSH session. You also can specify a separate password specifically for Telnet and SSH sessions. (Further, you can define separate credentials for HTTP/HTTPS connections on the Device Credentials Page, page 3-41 in the Device Properties window.)

The Enable password lets you access privileged EXEC mode after you log in.

Tip

The Username, Password, and Enable Password on this page are linked to the Credentials settings in the Device Properties window. When you update these parameters and then deploy the changes to the device, Security Manager uses the existing credentials defined in the Device Properties to log into the device and deploy changes. After successful deployment, the Device Properties credentials are updated to match these settings. For more information about Credentials in Device Properties, see Device Credentials Page, page 3-41.

Navigation Path

- (Device view) Select Platform > Device Admin > Credentials from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Credentials from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Warning

Since several user accounts may exist on each device, applying a shared Credentials policy to multiple devices will update only the Enable Password on each device; the Username and Password provided in the shared policy are not applied (nor is the Telnet/SSH password). The Enable Password is sufficient for subsequent access to PIX/ASA/FWSM devices, unless external authentication such as AAA or TACACS+ is configured, in which case the Enable Password alone is not sufficient. In this situation, you must manually update the Username, Password and Enable Password on each device that uses external authentication.

# Chapter 46: Configuring Device Administration Policies on Firewall Devices

## Configuring Device Credentials

### Related Topics
- Configuring User Accounts, page 49-6

### Field Reference

#### Table 46-8: Credentials Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username</td>
<td>Enter a user name for logging into the device. The name must be at least four characters; the maximum is 64 characters. Entries are case-sensitive.</td>
</tr>
<tr>
<td>Password</td>
<td>Provide a password for logging into the device (EXEC mode) with the specified Username. This password must be at least three characters; the maximum is 32 characters. Entries are case-sensitive. Re-enter the user password in the Confirm field.</td>
</tr>
<tr>
<td>Privilege Level</td>
<td>Choose a privilege level for this user; available values are 1 through 15. Level 1 allows EXEC-mode access only, the default level for log-in; level 15 allows Privileged EXEC-mode access; that is, access to the Enable mode. Other levels must be explicitly defined on the device.</td>
</tr>
<tr>
<td>Enable Password</td>
<td>You can specify an Enable password that lets this user access Privileged EXEC mode after logging in. This password must be at least three characters; the maximum is 32 characters. Entries are case-sensitive. Re-enter the Enable password in the Confirm field.</td>
</tr>
<tr>
<td>Telnet/SSH Password</td>
<td>You can specify a password that provides access to EXEC mode when connecting to the device via a Telnet or SSH session. This password must be at least three characters; the maximum is 32 characters. Entries are case-sensitive. Re-enter the Telnet/SSH password in the Confirm field.</td>
</tr>
</tbody>
</table>

**Note**
- We recommend a password length of at least 8 characters.
- If you configure user authentication for Enable access, each user has their own password and this password is not used. See Configuring AAA - Authentication Tab, page 46-4 for more information.
- If you configure user authentication for Telnet or SSH access, each user has their own password and this password is not used. See Configuring AAA - Authentication Tab, page 46-4 for more information.
Configuring Device Access Settings on Firewall Devices

The Device Access section, located under the Device Admin folder in the Policy selector, contains pages for defining access to firewall devices.

This chapter contains the following topics:
- Configuring Console Timeout, page 47-1
- HTTP Page, page 47-2
- Configuring ICMP, page 47-3
- Configuring Management Access, page 47-5
- Configuring Secure Shell Access, page 47-5
- Configuring SNMP, page 47-7
- Telnet Page, page 47-13

Configuring Console Timeout

Use the Console page to specify a timeout value for inactive console sessions. When the time limit you specify is reached, the console session is closed.

In the Console Timeout field, enter the number of minutes a console session can remain idle before the device closes it. Valid values are 0 to 60 minutes. To prevent a console session from timing out, enter 0.

Navigation Path
- (Device view) Select Platform > Device Admin > Device Access > Console from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Device Access > Console from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics
- Chapter 47, “Configuring Device Access Settings on Firewall Devices”
HTTP Page

Use the table on the HTTP page to manage the interfaces configured to access the HTTP server on a device, as well as HTTP redirect to HTTPS on those interfaces. You also can enable or disable the HTTP server on the device from this page. Administrative access by the specific device manager requires HTTPS access.

Note

To redirect HTTP, the interface requires an access list that permits HTTP. Otherwise, the interface cannot listen to port 80, or to any other port that you configure for HTTP.

Navigation Path

- (Device view) Select Platform > Device Admin > Device Access > HTTP from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Device Access > HTTP from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 47-1 HTTP Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP Interface table</td>
<td>Use the Add Row, Edit Row, and Delete Row buttons below this table to manage device interfaces on which HTTP-to-HTTPS redirect is configured. Add Row and Edit Row open the HTTP Configuration Dialog Box, page 47-2.</td>
</tr>
<tr>
<td>Enable HTTP Server</td>
<td>Enables or disables the HTTP server on the device. When enabled, you can specify a communications Port for the server. The Port range is 1 to 65535; the default is 443.</td>
</tr>
</tbody>
</table>

HTTP Configuration Dialog Box

Use the HTTP Configuration dialog box to add or edit a host or network that will be allowed to access the HTTP server on the device via a specific interface; you also can enable and disable HTTP redirect.

Navigation Path

You can access the HTTP Configuration dialog box from the HTTP Page, page 47-2.
Field Reference

Table 47-2 HTTP Configuration Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Name</td>
<td>Enter or Select the interface on which access to the HTTP server on the device is allowed.</td>
</tr>
<tr>
<td>IP Address/Netmask</td>
<td>Enter the IP address and netmask, separated by a forward slash (“/”) of the host or network that is permitted to establish an HTTP connection with the device. Alternately, you can click Select to select a Networks/Hosts object.</td>
</tr>
<tr>
<td>Enable Authentication Certificate</td>
<td>Select this option to require user certificate authentication in order to establish an HTTP connection. On ASA and PIX 8.0(2)+ devices, you can specify the authentication Port.</td>
</tr>
<tr>
<td>Redirect port</td>
<td>The port on which the security appliance listens for HTTP requests, which it then redirects to HTTPS. To disable HTTP redirect, ensure that this field is blank.</td>
</tr>
</tbody>
</table>

Configuring ICMP

Use the table on the ICMP page to manage Internet Control Message Protocol (ICMP) rules, which specify the addresses of all hosts or networks that are allowed or denied ICMP access to specific interfaces on the security device.

The ICMP rules control ICMP traffic that terminates on any device interface. If no ICMP control list is configured, the device accepts all ICMP traffic that terminates at any interface, including the outside interface. However, by default, the device does not respond to ICMP echo requests directed to a broadcast address.

It is recommended that permission is always granted for the ICMP Unreachable message (type 3). Denying ICMP Unreachable messages disables ICMP Path MTU discovery, which can halt IPsec and PPTP traffic. See RFC 1195 and RFC 1435 for details about Path MTU Discovery.

If an ICMP control list is configured, the device uses a first match to the ICMP traffic, followed by an implicit deny all. That is, if the first matched entry is a permit entry, the processing of the ICMP packet continues. If the first matched entry is a deny entry, or an entry is not matched, the device discards the ICMP packet and generates a syslog message. If an ICMP control list is not configured, a permit rule is assumed in all cases.

Navigation Path

- (Device view) Select Platform > Device Admin > Device Access > ICMP from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Device Access > ICMP from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.
Field Reference

Table 47-3 ICMP Page

<table>

<td>Use the Add Row, Edit Row, and Delete Row buttons below this table to manage ICMP rules. Add Row opens the Add ICMP dialog box, while Edit Row opens the Edit ICMP dialog box. See Add and Edit ICMP Dialog Boxes, page 47-4 for information about these dialog boxes.</td>
</tr>
</tbody>
</table>

ICMP Unreachable Parameters

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rate Limit</td>
<td>For ICMP traffic that terminates at an interface on this device, the maximum number of ICMP Unreachable messages the device can transmit per second. This value can be between 1 and 100 messages per second; the default is 1 message per second.</td>
</tr>
</tbody>
</table>
| Burst Size | The burst size for ICMP Unreachable messages; this can be a value between 1 and 10.  
**Note** This parameter is not currently used by the system, so you can choose any value. |

Add and Edit ICMP Dialog Boxes

Use the Add ICMP dialog box to add an ICMP rule, which specifies a host/network that is allowed or denied the specified ICMP access on the specified device interface.

**Note** The Edit ICMP dialog box is virtually identical to the Add ICMP dialog box, and is used to modify existing ICMP rules. The following descriptions apply to both dialog boxes.

Navigation Path

You can access the Add or Edit ICMP dialog boxes from the Configuring ICMP, page 47-3.

Field Reference

Table 47-4 Add and ICMP Dialog Boxes

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Action       | Whether this rule permits or denies the selected ICMP Service message from the specified Network on the specified Interface. Choose:  
- **Permit** – ICMP messages from the specified networks/hosts are allowed to the specified interface.  
- **Deny** – ICMP messages from the specified networks/hosts to the specified interface are dropped. |
| ICMP Service  | Enter or Select the specific ICMP service message to which the rule applies. |
Configuring Management Access

Use the Management Access page to enable or disable access on a high-security interface so you can perform management functions on the device. You can enable this feature on an internal interface to allow management functions to be performed on the interface over an IPsec VPN tunnel. You can enable the Management Access feature on only one interface at a time.

**Navigation Path**
- (Device view) Select Platform > Device Admin > Device Access > Management Access from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Device Access > Management Access from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

**Enabling and Disabling Management Access**

In the Management Access Interface field, enter the name of the device interface that is to permit management access connections. You can click Select to select the interface from a list of interface objects.

You can enable the Management Access feature on only one interface at a time.

Clear the Management Access Interface field to disable management access.

Configuring Secure Shell Access

Use the Secure Shell page to configure rules that permit administrative access to a security device using the SSH protocol. The rules restrict SSH access to a specific IP address and netmask. Any SSH connection attempts that comply with these rules must then be authenticated by an AAA server or Telnet password.

**Navigation Path**

- (Device view) Select Platform > Device Admin > Device Access > Secure Shell from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Device Access > Secure Shell from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.
Field Reference

**Table 47-5  Secure Shell Page**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSH Version</td>
<td>Specify the SSH version(s) accepted by the device: choose 1, 2, or 1 and 2. By default, SSH Version 1 and SSH Version 2 connections are accepted.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Enter the number of minutes, 1 to 60, the Secure Shell session can remain idle before the device closes it. The default value is 5 minutes.</td>
</tr>
<tr>
<td>Allowed Hosts</td>
<td>Use the Add Row, Edit Row, and Delete Row buttons below this table to manage the hosts allowed to connect to the security device via SSH. Add Row opens the Add Host dialog box, while Edit Row opens the Edit Host dialog box. See Add and Edit SSH Host Dialog Boxes, page 47-6 for information about these dialog boxes.</td>
</tr>
</tbody>
</table>
| Enable Secure Copy | Check this box to enable the secure copy (SCP) server on the security appliance. This allows the appliance to function as an SCP server for transferring files from/to the device. Only clients that are allowed to access the security appliance using SSH can establish a secure copy connection. This implementation of the secure copy server has the following limitations:  
  * The server can accept and terminate connections for secure copy, but cannot initiate them.  
  * The server does not have directory support. The lack of directory support limits remote client access to the security appliance internal files.  
  * The server does not support banners.  
  * The server does not support wildcards.  
  * The security appliance license must have the VPN-3DES-AES feature to support SSH version 2 connections. |

---

Add and Edit SSH Host Dialog Boxes

Use the Add Host dialog box to add an SSH access rule.

**Note**  
The Edit Host dialog box is virtually identical to the Add Host dialog box, and is used to modify existing SSH access rules. The following descriptions apply to both dialog boxes.

**Navigation Path**

You can access the Add and Edit Host dialog boxes from the Configuring Secure Shell Access, page 47-5.
Field Reference

Table 47-6 Add and Edit Host Dialog Boxes

<td>Enter the name or IP address for each host or network that is permitted to establish an SSH connection with the security device on the specified interface; use commas to separate multiple entries. You also can click Select to select Networks/Hosts objects from a list.</td>
</tr>
</tbody>
</table>

**Configuring SNMP**

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

The Simple Network Management Protocol (SNMP) enables monitoring of network devices from a central location. Cisco security appliances support network monitoring using SNMP versions 1 and 2c, as well as traps and SNMP read access; SNMP write access is not supported.

You can configure a security appliance to send “traps” (event notifications) to a network management station (NMS), or you can use the NMS to browse the management information bases (MIBs) on the security appliance. Use CiscoWorks for Windows or any other SNMP MIB-II-compliant browser to receive SNMP traps and browse a MIB.

The security appliance has an SNMP agent that notifies designated management stations if specified events occur, for example, when a link in the network goes up or down. The notification includes an SNMP system object ID (OID), identifying the device to the management stations. The security appliance SNMP agent also replies when a management station asks for information.

**SNMP MIBs and OIDs**

An SNMP trap reports significant events occurring on a network device, most often errors or failures. SNMP traps are defined in Management Information Bases (MIBs), which can be either standard or enterprise-specific.

Standard traps and MIBs are created by the Internet Engineering Task Force (IETF) and documented in various RFCs. Standard traps are compiled into the security appliance software. If needed, you can also download RFCs, standard MIBs, and standard traps from the IETF website: [http://www.ietf.org/](http://www.ietf.org/).

This section contains the following topics:

- **SNMP Terminology, page 47-8**
- **SNMP Page, page 47-8**
SNMP Terminology

Here are definitions for some common SNMP terms:

- **Agent** – The SNMP server running on the security appliance. The agent responds to requests for information and action from the management station. The agent also controls access to its management information base (MIB), the collection of data objects that can be viewed or changed by the SNMP manager.

- **Management stations** – The PCs or workstations set up to monitor SNMP events and manage devices such as the security appliance. Management stations can also receive messages about events which require attention, such as hardware failures.

- **MIBs** – The agent maintains standardized data structures called Management Information Bases (MIBs), used to collect information, such as packet, connection and error counters, and buffer usage and failover status. A number of MIBs are defined for specific products, and for the common protocols and hardware standards used by most network devices. SNMP management stations can browse MIBs, or request only specific fields. In some applications, MIB data can be modified for administrative purposes.

- **OID** – The SNMP standard assigns a system object ID (OID) so that a management station can uniquely identify network devices with SNMP agents, and indicate to users the source of information monitored and displayed.

- **Traps** – Specified events that generate a message from the SNMP agent to the management station. Events include alarm conditions such as linkup, linkdown, coldstart, authentication, or syslog events.

SNMP Page

Use the SNMP page to configure the security appliance for monitoring by Simple Network Management Protocol (SNMP) management stations.

**Navigation Path**

- (Device view) Select **Platform > Device Admin > Device Access > SNMP** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > SNMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, as described in <strong>Using Tables, page 1-43.</strong> The Add Row and Edit Row buttons open the <strong>Add SNMP Host Access Entry Dialog Box, page 47-12,</strong> used to add and edit management station host entries.</td>
</tr>
</tbody>
</table>

**SNMP Trap Configuration Dialog Box**

Use the SNMP Trap Configuration dialog box to configure SNMP traps (event notifications) for the selected security device.

Traps are different than browsing; they are unsolicited “comments” from the managed device to the management station for certain events, such as *linkup, linkdown,* and *syslog event generated.*

An SNMP object ID (OID) for the device appears in SNMP event traps sent from the device. The SNMP service running on a security device performs two functions:

- Replies to SNMP requests from management stations.
- Sends traps to management stations or other devices that are registered to receive them from the security appliance.

Cisco security devices support three types of traps:

- firewall
- generic
- syslog
In the SNMP Trap Configuration dialog box, available traps are presented on four tabbed panels: Standard, Entity MIB, Resource, and Other.

**Navigation Path**
You can access the SNMP Trap Configuration dialog box from the [SNMP Page, page 47-8](#).

</tbody>
</table>
| Server Poll/Trap Specification | Specify the type(s) of communication with this management station: poll only, trap only, or both trap and poll. Check either or both:  
  • Poll – The security device waits for periodic requests from the management station.  
  • Trap – The device sends trap events when they occur. |

Telnet Page

Use the Telnet page to configure rules that permit only specific hosts or networks to connect to the firewall device using the Telnet protocol.

The rules restrict administrative Telnet access through a firewall device interface to a specific IP address and netmask. Connection attempts that comply with the rules must then be authenticated by a preconfigured AAA server or the Telnet password. You can monitor Telnet sessions using Monitoring > Telnet Sessions.

Note

Only five Telnet sessions can be active at the same time in single-context mode. In multiple-context mode on ASAs, there can be only five Telnet sessions active per context, 100 Telnet sessions active per blade. With resource class, the administrator can further tune this parameter.

Note  To limit access to a single IP address, use 255.255.255.255 or 32 as the netmask. Do not use the subnetwork mask of the internal network.
Configuring Failover

The Failover page provides access to failover settings for the selected security appliance. The available settings and the overall appearance of the Failover page may change slightly, depending upon the type of device selected, its mode of operation (routed or transparent), and its context mode (single or multiple).

In other words, how you configure failover depends upon both the operating mode and the security context of the security appliance.

Please note the following caveats when assigning an interface as a failover link:

- You can define the interface in the Add/Edit Interface dialog box, but do not configure it. In particular, do not specify an interface Name, as this parameter disqualifies the interface from being used as the failover link. See Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14 for more information.
- IPv6 addresses are not supported for failover links.
- On an ASA 5505, an interface assigned as the backup for another interface cannot be used as a failover link (although no checking is performed to prevent this).
- Do not assign a PPPoE-enabled interface as a failover link. PPPoE and Failover should not be configured on the same device interface (although no checking is performed to prevent this).
- A failover interface cannot use the same IP address as another interface, especially the Management IP address (although no checking is performed to prevent this).

Note also that after you assign an interface as a failover link, the interface is listed on the Interfaces page, but you cannot edit or delete the interface from that page. The only exception is if you set a physical interface to be the stateful failover link—you can configure its speed and duplex.

This chapter contains the following topics:

- Understanding Failover, page 48-2
- Basic Failover Configuration, page 48-5
- Additional Steps for an Active/Standby Failover Configuration, page 48-8
- Failover Policies, page 48-9
Understanding Failover

Failover lets you configure two identical security appliances such that one will take over firewall operations if the other fails. Using a pair of security appliances, you can provide high system availability without operator intervention.

The linked security appliances communicate failover information over a dedicated link. This failover link can be either a LAN-based connection or, on PIX security appliances, a dedicated serial failover cable. The following information is communicated over the failover link:

- Current failover state (active or standby)
- “Hello” messages (also called “keep-alives”)
- Network link status
- MAC address exchange
- Configuration replication
- Per-connection state information, in the case of Stateful failover

Caution

All information sent over the failover link is sent in clear text unless you secure the communication with a failover key. If the security appliance is used to terminate VPN tunnels, this information includes any user names, passwords, and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing failover communications with a failover key, particularly if you are using the security appliance to terminate VPN tunnels.

Cisco security appliances support two types of failover:

- **Active/Standby** – The active security appliance inspects all network traffic, while the standby security appliance remains idle until a failure occurs on the active appliance. Changes to the configuration of the active security appliance are transmitted over the failover link to the standby security appliance.

  When failover occurs, the standby security appliance becomes the active unit, and it assumes the IP and MAC addresses of the previously active unit. Because other devices on the network do not see any changes in the IP or MAC addresses, ARP entries do not change or time-out anywhere on the network.

  Active/Standby failover is available to security appliances operating in single- or multiple-context mode. In single-context mode, only Active/Standby failover is available, and all failover configuration is by means of the Failover page.

Note

When using Active/Standby failover, you must make all configuration changes on the active unit. The active unit automatically replicates the changes to the standby unit. The standby unit should not be imported or added to the Security Manager device list.

Also, you must manually copy the authentication certificate from the active device to the standby device. See Additional Steps for an Active/Standby Failover Configuration, page 48-8 for additional information.
Chapter 48  Configuring Failover

Understanding Failover

- **Active/Active** – Both security appliances inspect network traffic by alternating their roles—such that one is active and one is standby—on a per context basis. This means Active/Active failover is available only on security appliances operating in multiple-context mode. However, Active/Active failover is not required in multiple-context mode. That is, on a device operating in multiple-context mode, you can configure Active/Standby or Active/Active failover. In either case, you provide system-level failover settings in the system context, and context-level failover settings in the individual security contexts.

  See Active/Active Failover, page 48-3 for additional information about this topic.

In addition, failover can be stateless or stateful:

- **Stateless** – Also referred to as “regular” failover. With stateless failover, all active connections are dropped when failover occurs. Clients need to re-establish connections when the new active unit takes over.

- **Stateful** – The active unit in the failover pair continually passes per-connection state information to the standby unit. When failover occurs, the same connection information is available on the new active unit. Supported end-user applications are not required to reconnect to maintain the current communication session.

  See Stateful Failover, page 48-4 for more information.

**Related Topics**

- Chapter 48, “Configuring Failover”
- Basic Failover Configuration, page 48-5
- Failover Policies, page 48-9

**Active/Active Failover**

Active/Active failover is available only on security appliances operating in multiple-context mode. In an Active/Active failover configuration, both security appliances inspect network traffic, on a per-context basis. That is, for each context, one of the appliances is the active device, while the other is the standby device.

The active and standby roles are assigned over the complete set of security contexts, more or less arbitrarily.

To enable Active/Active failover on the security appliance, you must assign the security contexts to one of two failover groups. A failover group is a simply a logical group of one or more security contexts. You should specify failover group assignments on the unit that will have failover group 1 in the active state. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default.

As in Active/Standby failover, each unit in an Active/Active failover pair is given a primary or secondary designation. Unlike Active/Standby failover, this designation does not indicate which unit is active when both units start simultaneously. Each failover group in the configuration is given a primary or secondary role preference. This preference determines the unit on which the contexts in the failover group appear in the active state when both units start simultaneously. You can have both failover groups be in the active state on a single unit in the pair, with the other unit containing the failover groups in the standby state. However, a more typical configuration is to assign each failover group a different role preference to make each one active on a different unit, balancing the traffic across the devices.
Understanding Failover

To reliably manage security contexts in Active/Active failover mode, Cisco Security Manager requires an IP address for the management interface of each context so that it can communicate directly with the active security context of a failover pair.

Initial configuration synchronization occurs when one or both units start. This synchronization occurs as follows:

- When both units start simultaneously, the configuration is synchronized from the primary unit to the secondary unit.
- When one unit starts while the other unit is already active, the unit that is starting up receives the configuration from the already active unit.

After both units are running, commands are replicated from one unit to the other as follows:

- Commands entered within a security context are replicated from the unit on which the security context is in the active state to the peer unit.

Note: A context is considered in the active state on a unit if the failover group to which it belongs is in the active state on that unit.

- Commands entered in the system execution space are replicated from the unit on which failover group 1 is in the active state to the unit on which failover group 1 is in the standby state.
- Commands entered in the admin context are replicated from the unit on which failover group 1 is in the active state to the unit on which failover group 1 is in the standby state.

Failure to enter the commands on the appropriate unit for command replication to occur will cause the configurations to be out of synchronization. Those changes may be lost the next time the initial configuration synchronization occurs.

Note: When bootstrapping the peer devices in an Active/Active Failover configuration, the bootstrap configurations are only applied to the system contexts of the respective failover peer devices.

In an Active/Active failover configuration, failover occurs on a failover group basis, not a system basis. For example, if you designate both failover groups as active on the primary unit, and failover group 1 fails, failover group 2 remains active on the primary unit, while failover group 1 becomes active on the secondary unit.

Note: When configuring Active/Active failover, make sure that the combined traffic for both units is within the capacity of each unit.

Stateful Failover

Note: Stateful failover is not supported on the ASA 5505 appliance.

When stateful failover is enabled, the active unit in the failover pair continually updates the current connection-state information on the standby unit. When failover occurs, supported end-user applications are not required to reconnect to maintain the current communication session.
The IP and MAC addresses for the state and LAN failover links do not change at failover.

To employ stateful failover, you must configure a link to pass all state information to the standby unit. If you are using a LAN failover connection rather than the serial failover interface (which is available only on the PIX platform), you can use the same interface for the state link and the failover link. However, we recommend that you use a dedicated interface for passing state information to the standby unit.

The following information is passed to the standby unit when stateful failover is enabled:

- NAT translation table
- TCP connection table (except for HTTP), including the timeout connection
- HTTP connection states (if HTTP replication is enabled)
- H.323, SIP and MGCP UDP media connections
- The system clock
- The ISAKMP and IPsec SA table

The following information is not copied to the standby unit when stateful failover is enabled:

- HTTP connection table (unless HTTP replication is enabled)
- The user authentication (UAUTH) table
- The ARP table
- Routing tables

Basic Failover Configuration

The following steps describe basic failover configuration. Please note the following caveats when assigning an interface as a failover link:

- You can define the interface in the Add/Edit Interface dialog box, but do not configure it. In particular, do not specify an interface Name, as this parameter disqualifies the interface from being used as the failover link.
- On an ASA 5505, an interface assigned as the backup for another interface cannot be used as a failover link (although no checking is performed to prevent this).
- Do not assign a PPPoE-enabled interface as a failover link. PPPoE and Failover should not be configured on the same device interface (although no checking is performed to prevent this).
- A Failover interface cannot use the same IP address as another interface, especially the Management IP address (although no checking is performed to prevent this).

When you save a failover configuration, it is applied to both the security appliance and the failover peer.

Before You Begin

Licenses installed on the device must allow failover configurations. On ASA 5505 and 5510 devices, this failover license is an optional license. You must install the failover license outside of Security Manager, using ASDM or the device CLI, and ensure that the License Supports Failover option is selected in the General page of the device properties (right-click the device and select Device Properties). If the license is installed when you add the device to the inventory, or you install the license and then rediscover device policies, Security Manager can identify the license and set this option appropriately.
Basic Failover Configuration

If the option is selected and the license is not in fact installed, you will see deployment failures. If the option is not selected, Security Manager will not deploy the failover policy to the device even if you configure the policy.

Related Topics
- Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14
- Understanding Failover, page 48-2
- Additional Steps for an Active/Standby Failover Configuration, page 48-8
- Failover Policies, page 48-9

Step 1
Ensure Device View is your present application view; if necessary, click the Device View button on the toolbar.

Note
For more information on using the Device View to configure device policies, see Managing Policies in Device View and the Site-to-Site VPN Manager, page 5-28.

Step 2
Select the appliance you want to configure.

Step 3
Expand the Platform entry in the Device Policy selector, then expand Device Admin and select Failover. The Failover page is displayed.

Step 4
(PIX only) Choose the Failover Method: Serial Cable or LAN Based. If you choose Serial Cable, the LAN Failover settings are disabled; be sure the cable connecting the two devices is in place.

Step 5
Select Enable Failover to enable failover on this appliance.

Step 6
(Optional) Click the Settings button to open the Settings dialog box for the selected device. The contents of the Settings dialog box depend on the type of device, and whether it is operating in single or multiple mode—some options may not be available. Refer to the following sections:
- Settings Dialog Box, page 48-19 (ASA/PIX 7+)
- Advanced Settings Dialog Box, page 48-14 (FWSM)

Step 7
Click the Bootstrap button to open the Bootstrap configuration for LAN failover dialog box, which provides bootstrap configurations that can be applied to the primary and secondary devices in a LAN failover configuration. See Bootstrap Configuration for LAN Failover Dialog Box, page 48-25 for more information.

Step 8
(Multiple-context devices only) In the Configuration section, select the failover mode: Active/Active or Active/Standby.

Step 9
(Optional) Follow these steps to configure an interface for LAN Failover communications between the two devices:

a. Assign a device Interface for LAN-based communications, and then press the Tab key on your keyboard to update the page.

   On PIX and ASA devices, this drop-down list displays the interfaces defined on the device. You can type in a port ID (e.g., gigabitethernet1), or you can choose the port if you have already defined the interface.

   On an FWSM, the Interface list is not populated with VLAN IDs; you must enter the numeric ID of the VLAN you wish to use.
**Note** In both cases, this cannot be a Named interface, nor can the interface be configured for PPPoE.

b. Provide a **Logical Name** for this failover interface.

c. Enter the **Active IP** address for failover communications.

d. Enter a **Standby IP** address for failover communications. The Standby IP address is used on the security appliance that is currently the standby unit.

e. Enter the **Subnet Mask** for both IP addresses. Both must be on the same subnet.

**Step 10** (Optional) Follow these steps to enable and configure an interface for **Stateful Failover** communications between the two devices:

a. Assign a device **Interface** for update communications, and then press the Tab key on your keyboard to update the page.

You can type in a port ID (e.g., `gigabitethernet1`), or you can choose the port if you have already defined the interface; note that this cannot be a Named interface.

**Note** On an FWSM, this is a **VLAN** interface.

b. Provide a **Logical Name** for this interface.

c. Enter the **Active IP** address for connection updates.

d. Enter a **Standby IP** address for update communications.

e. Enter the **Subnet Mask** for both IP addresses. Both must be on the same subnet.

f. Select **Enable HTTP Replication** to preserve HTTP connection information.

Connection information is communicated to the standby unit for all TCP protocols except HTTP, because HTTP connections are generally short-lived. Select this option to maintain HTTP connections during failover.

**Step 11** Provide a communications-encryption key: enter a **Shared Key** and then repeat it in the **Confirm** field. Be sure to enter the same key on both devices. (Not available on FWSM versions prior to 3.1)

The Shared Key can be any arbitrary string of up to 63 alphanumeric characters. If **HEX** is checked, the Shared Key is an arbitrary string of exactly 32 hexadecimal characters. (The HEX option is available only on PIX/ASA version 7.0.5 and later, and FWSM versions 3.1.3 and later.)

**Note** This step is optional, but we strongly recommend encrypting failover communications.

**Step 12** To specify a failover reconnect timeout value for asymmetrically routed sessions, enter a length of time in the **Timeout** field, in the form hh:mm:ss (the minutes and seconds values are optional). If the field is blank (the default), or contains a zero, reconnections are prevented. Setting this value to -1 disables the timeout, allowing connections to reconnect after any amount of time.

**Step 13** (FWSM only) – Configured interfaces are listed in the Interface Configuration table. To edit the failover configuration for a listed interface, select it and click the Edit Row button to open the **Edit Failover Interface Configuration Dialog Box**, page 48-22.
Additional Steps for an Active/Standby Failover Configuration

Cisco Security Manager lets you authenticate a PIX/ASA/FWSM device by validating the certificate installed on the device. When configuring firewalls in an active/standby failover configuration, you must manually copy the certificate from the active device to the standby device so that Security Manager can communicate with the standby device after a failover occurs.

The following procedures describe how to export or display the identity certificate, CA certificate, and keys for a security appliances in your network using ASDM, and then import that information onto a standby device using ASDM.

- Exporting the Certificate to a File or PKCS12 data, page 48-8
- Importing the Certificate onto the Standby Device, page 48-8

Exporting the Certificate to a File or PKCS12 data

To export a trustpoint configuration, follow these steps using ASDM:

**Step 1**  
Go to Configuration > Features > Device Administration > Certificate > Trustpoint > Export.

**Step 2**  
Fill in the Trustpoint Name, Encryption Passphrase, and Confirm Passphrase fields. For information on these fields, click Help.

**Step 3**  
Select a method for exporting the trustpoint configuration.
- Export to a File—Type the filename or browse for the file.
- Display the trustpoint configuration in PKCS12 format—Display the entire trustpoint configuration in a text box and then copy it for importing. For more information, click Help.

**Step 4**  
Click Export.

Importing the Certificate onto the Standby Device

To import a trustpoint configuration, follow these steps using ASDM:

**Step 1**  
Go to Configuration > Features > Device Administration > Certificate > Trustpoint > Import.

**Step 2**  
Fill in the Trustpoint Name, Decryption Passphrase, and Confirm Passphrase fields. For information on these fields, click Help. The decryption passphrase is the same as the encryption passphrase used when the trustpoint configuration was exported.

**Step 3**  
Select a method for importing the trustpoint configuration.
- Import from a File—Type the filename or browse for the file.
- Enter the trustpoint configuration in PKCS12 format—Paste the entire trustpoint configuration from the exported source into a text box. For more information, click Help.
Failover Policies

This section lists the pages that describe configuring failover on various types of security appliances; the pages are organized by device type.

**PIX 6.x Firewalls**
- Failover Page (PIX 6.3), page 48-9
  - Edit Failover Interface Configuration Dialog Box (PIX 6.3), page 48-11
  - Bootstrap Configuration for LAN Failover Dialog Box, page 48-25

**Firewall Services Modules**
- Failover Page (FWSM), page 48-12
  - Advanced Settings Dialog Box, page 48-14
  - Add/Edit Interface MAC Address Dialog Box, page 48-21
  - Edit Failover Interface Configuration Dialog Box, page 48-22
  - Bootstrap Configuration for LAN Failover Dialog Box, page 48-25

**Adaptive Security Appliances and PIX 7.0 Firewalls**
- Failover Page (ASA/PIX 7.0+), page 48-16
  - Settings Dialog Box, page 48-19
  - Edit Failover Group Dialog Box, page 48-23
  - Edit Failover Interface Configuration Dialog Box, page 48-22
  - Add/Edit Interface MAC Address Dialog Box, page 48-21
  - Bootstrap Configuration for LAN Failover Dialog Box, page 48-25

**Failover Page (PIX 6.3)**

Use the Failover page to configure failover settings for a PIX 6.3.x Firewall.

**Navigation Path**
Select a PIX 6.3.x device in Device View and then select **Platform > Device Admin > Failover** from the Device Policy selector.

**Related Topics**
- Understanding Failover, page 48-2
- Failover Policies, page 48-9
## Field Reference

### Table 48-1  Failover Page (PIX 6.3)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failover Method</td>
<td>Choose the type of failover link: <strong>Serial Cable</strong> or <strong>LAN Based</strong>. If you choose Serial Cable, ensure the physical cable is connected to both devices.</td>
</tr>
<tr>
<td>Enable Failover</td>
<td>Check this box to enable failover on this device. Ensure that both devices have the same software version, activation key type, flash memory, and RAM. On PIX devices with LAN Based chosen as the Failover Method, you must next configure the logical LAN Failover interface and, optionally, the stateful failover interface.</td>
</tr>
<tr>
<td>Bootstrap button</td>
<td>Click to display the Bootstrap Configuration for LAN Failover dialog box. See <strong>Bootstrap Configuration for LAN Failover Dialog Box</strong>, page 48-25 for more information.</td>
</tr>
<tr>
<td>Failover Poll Time</td>
<td>Specify the amount of time between hello messages among units. Values can range from 3 to 15 seconds; default is 15.</td>
</tr>
</tbody>
</table>

### LAN-Based Failover

These fields are available when LAN Based is the chosen Failover Method.

<table>
<thead>
<tr>
<th>Interface</th>
<th>Choose the interface to be used for LAN-based failover. If “Not Selected” is chosen, LAN-based failover is disabled.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shared Key Confirm</td>
<td>Used to encrypt communications between the primary and standby devices. Value can be any alphanumeric string. Re-enter the Shared Key in the Confirm field.</td>
</tr>
</tbody>
</table>

### Stateful Failover

(Optional) To configure **Stateful Failover**, page 48-4, provide the following parameters.

<table>
<thead>
<tr>
<th>Interface</th>
<th>Choose the interface to be used for Stateful Failover. If “Not Selected” is chosen, Stateful Failover is disabled.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable HTTP Replication</td>
<td>When selected, active HTTP sessions are copied to the standby firewall. Otherwise, HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link.</td>
</tr>
</tbody>
</table>

### Interface Configuration

The table lists all available named interfaces. To define a Standby IP address and Active and Standby MAC addresses for an interface, select it in the list and click the Edit Row button to open the **Edit Failover Interface Configuration Dialog Box (PIX 6.3)**, page 48-11.
Edit Failover Interface Configuration Dialog Box (PIX 6.3)

Use the Edit Failover Interface Configuration dialog box to configure failover interfaces for the selected PIX 6.3.x device.

**Note**
The failover interface cannot be configured for PPPoE.

**Navigation Path**
You can access the Edit Failover Interface Configuration dialog box from the Interface Configuration table on the Failover Page (PIX 6.3), page 48-9.

**Related Topics**
- Failover Policies, page 48-9

**Field Reference**

<table>
<thead>
<tr>
<th>Table 48-2</th>
<th>Edit Failover Interface Configuration Dialog Box (PIX 6.3)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Interface</td>
<td>The name of the interface; read-only.</td>
</tr>
<tr>
<td>Active IP Address</td>
<td>Displays the IP address of the active interface. This address is used by the standby device to communicate with the active device. The address must be on the same network as the system IP address. The active IP address of this interface; read-only. This address is used by the standby device to communicate with the active device. This field is blank if an IP address has not been assigned to the interface.</td>
</tr>
<tr>
<td>Netmask</td>
<td>The subnet mask for the active IP address; read-only. This field is blank if an IP address has not been assigned to the interface.</td>
</tr>
<tr>
<td>Standby IP Address</td>
<td>Specify the IP address of the corresponding interface on the standby failover unit. This address is used by the active device to communicate with the standby device. The address must be on the same network as the system IP address. This field does not appear if an IP address has not been assigned to the interface.</td>
</tr>
<tr>
<td>Active MAC Address</td>
<td>Specify a MAC address for the active interface in hexadecimal format (for example, 0123.4567.89ab).</td>
</tr>
<tr>
<td>Standby MAC Address</td>
<td>Specify a MAC address for the standby interface in hexadecimal format (for example, 0123.4567.89ab).</td>
</tr>
</tbody>
</table>

**Failover MAC Addresses**
These parameters let you define virtual MAC addresses for a physical interface that is configured for failover; these addresses are optional.
Failover Page (FWSM)

Use the Failover page to configure basic failover settings for the selected Firewall Services Module (FWSM).

Navigation Path
To access this feature, select a FWSM in Device View and then select Platform > Device Admin > Failover from the Device Policy selector.

Configuration
This section is presented only for FWSM 3.1.1+ devices operating in multiple-context mode.

Active/Active
In an Active/Active failover configuration, both security appliances inspect network traffic, on a per-context basis. That is, for each context, one of the appliances is the active device, while the other is the standby device.

To enable Active/Active failover on the device, you must assign the security contexts to one of two failover groups. A failover group is a simply a logical group of one or more security contexts. You should specify failover group assignments on the unit that will have failover group 1 in the active state. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default. See Add/Edit Security Context Dialog Box (FWSM), page 56-5 for information about assigning a context to a failover group.

Active/Standby
In an Active/Standby configuration, the active security appliance handles all network traffic passing through the failover pair. The standby security appliance does not handle network traffic until a failure occurs on the active security appliance. Whenever the configuration of the active security appliance changes, it sends configuration information over the failover link to the standby security appliance.

When a failover occurs, the standby security appliance becomes the active unit. It assumes the IP and MAC addresses of the previously active unit. Because the other devices on the network do not see any changes in the IP or MAC addresses, ARP entries do not change or time out.

Failover Policies

Chapter 48  Configuring Failover

The Advanced Settings dialog box lets you configure additional failover settings for the selected FWSM.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shared Key</td>
<td>(FWSM 3.1.1+ only) The options in this section let you encrypt the communications between the active and standby devices by providing a shared encryption key.</td>
</tr>
<tr>
<td>Caution</td>
<td>All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If this device is used to terminate VPN tunnels, this information includes any user names, passwords and shared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communications with a shared key.</td>
</tr>
<tr>
<td>Shared Key Confirm</td>
<td>Enter any string of characters up to 63 numbers, letters and punctuation characters. This string is used to generate the encryption key. Re-enter this string in the Confirm field. If you select HEX, the entry in the Shared Key and Confirm fields must be exactly 32 hexadecimal characters (0-9, a-f).</td>
</tr>
</tbody>
</table>

Interface Configuration

This table is presented on the Failover page for devices operating in single-context mode, or for individual security contexts only.

The table lists all available named interfaces. To enable or disable monitoring of an interface, select it in the list and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box, page 48-22. Select or deselect Monitor this interface for failure.

**Advanced Settings Dialog Box**

The Advanced Settings dialog box lets you configure additional failover settings for the selected FWSM.

The following reference table describes all fields that can be presented in the Advanced Settings dialog box. The fields actually presented depend on operating mode (routed or transparent) and whether the device is hosting single or multiple contexts.

**Navigation Path**

You can access the Advanced Settings dialog box by clicking the Settings button on the Failover Page (FWSM), page 48-12.

**Related Topics**

- Failover Policies, page 48-9
Field Reference

Table 48-4  Advanced Settings Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Policy</td>
<td>Select a failed-interfaces option and provide an appropriate value.</td>
</tr>
<tr>
<td>Number of failed interfaces</td>
<td>When the number of failed monitored interfaces exceeds this value, the security appliance fails over. Valid values range from 1 to 250.</td>
</tr>
<tr>
<td>Percentage of failed interfaces</td>
<td>When the number of failed monitored interfaces exceeds this percentage, the security appliance fails over.</td>
</tr>
</tbody>
</table>

Failover Poll Time

These fields define how often hello messages are sent on the failover link, and how long to wait before testing the peer for failure if no hello messages are received.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unit Failover</td>
<td>The amount of time between hello messages between failover units. Enter a value between 1 and 15 seconds, or if msec is checked, between 500 and 999 milliseconds.</td>
</tr>
<tr>
<td>Unit Hold Time</td>
<td>The amount of time to wait for a hello message on the failover link, after which the unit begins testing for peer failure. Enter a value between 3 and 45 seconds. This value must be at least three times the Unit Failover value.</td>
</tr>
<tr>
<td>Monitored Interface</td>
<td>The amount of time between polls among interfaces. Enter a value between 3 and 15 seconds.</td>
</tr>
</tbody>
</table>

MAC Address Mapping

In Active/Standby mode, this table lists interface-virtual MAC address mappings. This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, which are described in Using Tables, page 1-43.

To add or edit interface mappings, click the Add Row or Edit Row button to open the Add/Edit Interface MAC Address Dialog Box, page 48-21.

Failover Groups

In Active/Active mode, this table lists both failover groups. To edit failover parameters for either group, select it in the list and click the Edit Row button to open the Edit Failover Group Dialog Box, page 48-23.

Bridge Group Configuration

In single-context transparent mode, this table lists all currently defined bridge groups (see Managing Device Interfaces, Hardware Ports, and Bridge Groups, page 44-14). To add a standby IP address to a bridge group, select it in the list and click the Edit Row button to open the Edit Failover Bridge Group Configuration Dialog Box, page 48-16.
Edit Failover Bridge Group Configuration Dialog Box

Use this dialog box to add a standby IP address to a failover bridge group.

Navigation Path

You can access the Edit Failover Bridge Group Configuration dialog box as follows:

- On the Failover page presented for an individual security context in transparent mode on an ASA.
- From the Bridge Group Configuration table in the Advanced Settings Dialog Box, page 48-14 presented by an FWSM in transparent mode.

Related Topics

<td>Identifies the IP address assigned to the bridge group; not editable.</td>
</tr>
<tr>
<td>Network Mask</td>
<td>Identifies the subnet mask for the IP Address; not editable.</td>
</tr>
<tr>
<td>Standby Address</td>
<td>Enter the IP address of the standby bridge group; this address must be on the same subnet as the primary address.</td>
</tr>
</tbody>
</table>

Failover Page (ASA/PIX 7.0+)

Use the Failover page to configure basic failover settings for ASA and PIX 7.0+ security devices.

Note

The features and options presented on the Failover page vary according to type of device selected, operating system version, firewall mode (routed or transparent), and security contexts (single or multiple). Thus, some of the elements described in the following table may not appear on the Failover page for your currently selected device.

Navigation Path

Select an ASA or PIX 7.0+ in Device View and then select Platform > Device Admin > Failover from the Device Policy selector.

<tr>
<td>Timeout</td>
<td>The failover Timeout specifies the amount of time after a system boots or becomes active that “nailed” sessions are accepted; used in conjunction with static translation rules (see <em>Static Rules Tab, page 22-26</em> for more information).</td>
</tr>
<tr>
<td></td>
<td>Enter a value in this field to specify the failover reconnect timeout value for asymmetrically routed sessions. The value is in the form hh:mm:ss (hours:minutes:seconds); both minutes and seconds are optional.</td>
</tr>
<tr>
<td></td>
<td>Valid values for the number of hours are -1 to 1193; the default value is 0, which means connections cannot be re-established. Setting this value to -1 disables the timeout, allowing reconnections after any amount of time.</td>
</tr>
</tbody>
</table>

### Configuration

This section is presented only for devices operating in multiple-context mode.

| Active/Active            | In an Active/Active failover configuration, both security appliances inspect network traffic, on a per-context basis. That is, for each context, one of the appliances is the active device, while the other is the standby device. |
|                         | To enable Active/Active failover on the security appliance, you must assign the security contexts to one of two failover groups. A failover group is a simply a logical group of one or more security contexts. You should specify failover group assignments on the unit that will have failover group 1 in the active state. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default. See *Add/Edit Security Context Dialog Box (PIX/ASA), page 56-7* for information about assigning a context to a failover group. |
Failover Policies

Chapter 48 Configuring Failover

Failover Policies

Active/Standby In an Active/Standby configuration, the active security appliance handles all network traffic passing through the failover pair. The standby security appliance does not handle network traffic until a failure occurs on the active security appliance. Whenever the configuration of the active security appliance changes, it sends configuration information over the failover link to the standby security appliance.

When a failover occurs, the standby security appliance becomes the active unit. It assumes the IP and MAC addresses of the previously active unit. Because the other devices on the network do not see any changes in the IP or MAC addresses, ARP entries do not change or time out.

LAN Failover

Interface Choose the interface to use as the failover link; all interfaces available on the device are listed.

When configured for failover, the interface is directly connected to the standby device.

Note You can choose an EtherChannel interface as the failover link. As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named, and none of the EtherChannel’s member interfaces can be named. Further, while being used as an active failover link, changes to the interface configuration are not allowed. Refer to Configuring EtherChannels, page 44-9 for more information.

Logical Name Enter a logical name for the failover interface.

Active IP Address Specify the active IP address for this interface.

Standby IP Address Specify a standby IP address for this interface.

To receive packets from both units in a failover pair, standby IP addresses need to be configured on all interfaces. The Standby IP address is used on the security appliance that is currently the standby unit, and it must be in the same subnet as the active IP address.

Subnet Mask Enter the Subnet Netmask for the active and standby IP addresses.

Stateful Failover

(Optional) To configure Stateful Failover, page 48-4, provide the following parameters.

Interface Choose the interface to use for the stateful failover link; all interfaces available on the device are listed.

Note You can choose an EtherChannel interface as the stateful failover link. As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named, and none of the EtherChannel’s member interfaces can be named. Further, while being used as an active failover link, changes to the interface configuration are not allowed. Refer to Configuring EtherChannels, page 44-9 for more information.

Logical Name Enter the logical name of the interface on the active firewall device to communicate with standby device for failover. When configured for stateful failover, the interface is directly connected to the standby device.

Table 48-6 Failover Page (ASA/PIX 7.0+) (Continued)

</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>You can choose an EtherChannel interface as the failover link. As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named, and none of the EtherChannel’s member interfaces can be named. Further, while being used as an active failover link, changes to the interface configuration are not allowed. Refer to Configuring EtherChannels, page 44-9 for more information.</td>
</tr>
</tbody>
</table>

Logical Name Enter a logical name for the failover interface.

Active IP Address Specify the active IP address for this interface.

Standby IP Address Specify a standby IP address for this interface. To receive packets from both units in a failover pair, standby IP addresses need to be configured on all interfaces. The Standby IP address is used on the security appliance that is currently the standby unit, and it must be in the same subnet as the active IP address.

Subnet Mask Enter the Subnet Netmask for the active and standby IP addresses.

Stateful Failover

(Optional) To configure Stateful Failover, page 48-4, provide the following parameters.

Interface Choose the interface to use for the stateful failover link; all interfaces available on the device are listed. Note You can choose an EtherChannel interface as the stateful failover link. As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named, and none of the EtherChannel’s member interfaces can be named. Further, while being used as an active failover link, changes to the interface configuration are not allowed. Refer to Configuring EtherChannels, page 44-9 for more information.

Logical Name Enter the logical name of the interface on the active firewall device to communicate with standby device for failover. When configured for stateful failover, the interface is directly connected to the standby device.
**Settings Dialog Box**

The Settings dialog box lets you define criteria for when failover should occur on the selected ASA or PIX 7.x appliance.

**Navigation Path**

You can access the Settings dialog box by clicking the Settings button on the Failover Page (ASA/PIX 7.0+), page 48-16.

---

<td>Subnet Mask</td>
<td>Enter the Subnet Netmask for the active and standby IP addresses.</td>
</tr>
<tr>
<td>Enable HTTP Replication</td>
<td>When selected, active HTTP sessions are copied to the standby firewall. Otherwise, HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link.</td>
</tr>
</tbody>
</table>

---

**Key**

The options in this section let you encrypt the communications between the active and standby devices. Select the type and provide a string of characters to produce the shared encryption key.

**Caution**

All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If this device is used to terminate VPN tunnels, this information includes any user names, passwords and shared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communications with a shared key.

- **Any string**
  - If you select Any string, the entry in the Shared Key field can be any combination of up to 63 numbers, letters and punctuation characters. This string is used to generate the encryption key.

- **HEX**
  - If you select HEX, the entry in the Shared Key and Confirm fields must be exactly 32 hexadecimal characters (0-9, a-f). This string is used as the encryption key.

**Interface Configuration**

(in some instances, labeled Monitor Interface Configuration)

This table is presented on the Failover page for ASA 8.4.1+ devices operating in single-context, transparent mode, and for individual contexts on PIX/ASA devices. Otherwise, it appears in the Settings Dialog Box, page 48-19.

The table lists all available named interfaces. To enable or disable monitoring of an interface, select it in the list and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box, page 48-22. Select or deselect Monitor this interface for failure.
The following reference table presents all fields that can be presented in the Settings dialog box. The fields actually presented depend on operating mode (routed or transparent) and whether the device is hosting single or multiple contexts.

</table>

Failover Groups

In Active/Active mode, this table lists both failover groups. To edit failover parameters for either group, select it in the list and click the Edit Row button to open the Edit Failover Group Dialog Box, page 48-23.

MAC Address Mapping

In Active/Standby mode, this table lists interface-virtual MAC address mappings. This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, which are described in Using Tables, page 1-43.

To add or edit interface mappings, click the Add Row or Edit Row button to open the Add/Edit Interface MAC Address Dialog Box, page 48-21.
Chapter 48 Configuring Failover

**Monitor Interface Configuration**

In single-context mode, this table lists all available named interfaces. To define a Standby IP address for, and enable or disable monitoring of an interface, select it in the list and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box, page 48-22.

**Management IP Address**

In single-context transparent mode, this section presents the management IP address and netmask defined for the device (on the Management IP Page, page 45-10); you cannot change these values.

| Standby       | Enter the management IP address of the standby unit; this address must be on the same subnet as the primary address. |

Add/Edit Interface MAC Address Dialog Box

The Add/Edit Interface MAC Address dialog box lets you define virtual MAC addresses for a physical interface on ASA, FWSM 3.x and PIX 7.x security appliances that are configured for failover (not available on ASA 5505 devices).

In Active/Standby failover, the MAC addresses for the primary unit are always associated with the active IP addresses. If the secondary unit boots first and becomes active, it uses the burned-in MAC address for its interfaces. When the primary unit comes online, the secondary unit obtains the MAC addresses from the primary unit. This change can disrupt network traffic. You can configure virtual MAC addresses for each interface to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not specify virtual MAC addresses, the failover pair uses the burned-in MAC addresses.

**Note**

You cannot configure a virtual MAC address for the failover or Stateful Failover links. The MAC and IP addresses for those links do not change during failover.

**Navigation Path**

You can open the Add/Edit Interface MAC Address dialog box from the Settings Dialog Box, page 48-19.

Table 48-9  Edit Failover Interface Configuration Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Monitor this interface for failure | Specifies whether this interface is monitored for failure: check this box to enable monitoring. The number of interfaces that can be monitored for the security appliance is 250.

Hello messages are exchanged between the security appliance failover pair during every interface poll time period. The failover interface poll time is 3 to 15 seconds. For example, if the poll time is set to 5 seconds, testing begins on an interface if 5 consecutive hellos are not heard on that interface (25 seconds). Monitored failover interfaces can have the following status:

- Unknown—Initial status. This status can also mean the status cannot be determined.
- Normal—The interface is receiving traffic.
- Testing—Hello messages are not heard on the interface for five poll times.
- Link Down—The interface is administratively down.
- No Link—The physical link for the interface is down.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

| ASR Group Number                   | If this interface is part of an asymmetric routing group, provide its ASR group number. Valid values for ASR group numbers are 1 through 32. Stateful failover must be enabled for asymmetric routing support to function properly between units in failover configurations. |

MAC Address Mapping
This table displays interfaces to which active and standby MAC addresses are mapped.

Failover Page (Security Context)

The Failover page for individual ASA and PIX 7.0+ security contexts presents the Interface Configuration table, which lists all available named interfaces.

You can select an interface in the table and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box, page 48-22, where you can specify a standby IP address and an ASR group number, and enable or disable monitoring of the interface.

For individual transparent-mode contexts on ASA 8.4.1+ devices, the Failover page also presents the Bridge Group Configuration table, which lists all currently defined failover bridge groups.
You can select an entry in the table and click the Edit Row button to open the Edit Failover Bridge Group Configuration Dialog Box, page 48-16, where you can specify a standby IP address for the selected bridge group.

Navigation Path
Select a security context in Device View and then select Platform > Device Admin > Failover from the Device Policy selector.

Field Reference

Table 48-11 Bootstrap Configuration for LAN Failover Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
<td>Contains the bootstrap configuration for the primary device. Open a console connection to the primary device and then paste this configuration to activate failover on the device.</td>
</tr>
<tr>
<td>Secondary</td>
<td>Contains the bootstrap configuration for the secondary device. After the primary device becomes active, open a console connection to the secondary device and then paste this configuration to activate failover on the device.</td>
</tr>
</tbody>
</table>

Note
For Active/Active Failover, the bootstrap configurations are only applied to the system contexts of the respective failover peer devices.
Configuring Hostname, Resources, User Accounts, and SLAs

The following topics describe configuring the host name on a security appliance, defining and managing Resource classes on Firewall Services Modules (FWSMs) in multiple-context mode, managing user accounts in the Local user database, and monitoring service level agreements (SLAs) to perform route tracking.

This chapter contains the following topics:

- Hostname Page, page 49-1
- Resource Management on Multi-context FWSMs, page 49-2
- Configuring User Accounts, page 49-6
- Monitoring Service Level Agreements (SLAs) To Maintain Connectivity, page 49-7

Hostname Page

You can use the Hostname page to specify a host name for your security device, and to specify a default domain. After the configuration file is deployed, the device uses this domain name when you do not enter a fully qualified domain name in other commands. It also uses this domain name in RSA key generation.

The device appends this domain name to unqualified names. For example, if you set the domain name to “example.com,” and specify a syslog server by the unqualified name “jupiter,” the security appliance completes the name to “jupiter.example.com.”

When you set a host name for the security appliance, that name appears in the command line prompt. If you establish sessions to multiple devices, the host name helps you keep track of where you enter commands. The default host name depends on your platform.

In multiple-context mode, you can specify a domain name for each context, as well as the system execution space. The host name you specify in the system execution space appears in the command line prompt for all contexts. The host name that you optionally set within a context does not appear in the command line, but can be used by the banner command $(hostname) token.

Navigation Path

In Device View, select a security device and then select Platform > Device Admin > Hostname from the Device Policy selector.
Resource Management on Multi-context FWSMs

By default, all security contexts on a multiple-context Firewall Services Module (FWSM) have unlimited access to the resources of the FWSM, except where maximum limits per context are enforced. However, if you find that one or more contexts use too many resources, and they cause other contexts to be denied connections, for example, then you can configure resource management to limit the use of resources per context.

The FWSM does not limit the bandwidth per context; however, the switch containing the FWSM can limit bandwidth per VLAN. See the switch documentation for more information.

The FWSM manages resources by assigning contexts to resource classes. Each context uses the resource limits set by its class. When you create a class, the FWSM does not set aside a portion of the resources for each context assigned to the class; rather, the FWSM sets the maximum limit for a context. If you oversubscribe resources, or allow some resources to be unlimited, a few contexts can “use up” those resources, potentially affecting service to other contexts.

You can set the limit for all resources together as a percentage of the total available for the device. Also, you can set the limit for individual resources as a percentage or an absolute value.

You can oversubscribe the FWSM by assigning more than 100 percent of the resources across all contexts. For example, you can set up a class to limit connections to 20 percent per context, and then assign 10 contexts to the class for a total of 200 percent. If contexts concurrently use more than the system limit, then each context gets less than the 20 percent you intended.

The FWSM also lets you assign unlimited access to one or more resources in a class, instead of a percentage or absolute number. When a resource is unlimited, contexts can use as much of the resource as the system has available. For example, contexts A, B, and C are assigned to class “Onepercent,” which limits each class member to one percent of the system inspections per second, for a total of three percent; but the three contexts are currently using more than two percent combined. On the other hand, class “Nolimit” has unlimited access to inspections. The contexts in Nolimit can use more than the 97 percent of “unassigned” inspections; they can also use the one percent of inspections not currently in use by contexts A, B, and C, even if that means that contexts A, B, and C are unable to reach their three percent combined limit. Setting unlimited access is similar to oversubscribing the FWSM, except that you have less control over how much you oversubscribe the system.
Default Class

All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to the default class.

If a context belongs to a class other than the default class, those class settings always override the default class settings. However, if the other class has any settings that are not defined, then the member context uses the default class for those limits. For example, if you create a class with a two percent limit for all concurrent connections, but no other limits, then all other limits are inherited from the default class. Conversely, if you create a class with a two percent limit for all resources, the class uses no settings from the default class.

As initially configured, the default class provides unlimited access to resources for all contexts, except for the following limits, which are by default set to the maximum allowed per context:

- Telnet sessions – 5 sessions
- SSH sessions – 5 sessions
- IPSec sessions – 5 sessions
- MAC addresses – 65,535 entries

Note that you can edit the default class.

Related Topics

- Add/Edit Security Context Dialog Box (FWSM), page 56-5

Resources Page

Use the Resources page to configure and manage resource-management classes.

The table on this page lists all currently defined resource classes. Use the buttons below the table to manage this list:

- Add Row – Opens the Add Resource dialog box, where you can define a new class, and assign it to security contexts. See Add and Edit Resource Dialog Boxes, page 49-3 for more information.
- Edit Row – For the currently selected row, opens the Edit Resource dialog box, so you can edit that class and its context assignments. See Add and Edit Resource Dialog Boxes, page 49-3 for more information.
- Delete Row – Deletes the currently selected row(s); confirmation may be required.

Navigation Path

In Device View, select the system context of an FWSM in multiple-context mode, and then select Platform > Device Admin > Resources from the Device Policy selector.

Related Topics
- Resource Management on Multi-context FWSMs, page 49-2

Add and Edit Resource Dialog Boxes

Use the Add Resource and Edit Resource dialog boxes to add or edit resource classes and assignments for FWSM security contexts.

Except for their titles, both dialog boxes are identical; the following descriptions apply to both.
Navigation Path
You can access the Add Resource and Edit Resource dialog boxes from the Resources Page, page 49-3.

Related Topics
- Resource Management on Multi-context FWSMs, page 49-2

</tr>
</tbody>
</table>

Limits Tab

| Note                  | For the following Limits, if you do not specify a value for a particular limit, the limit is inherited from the default class. If the default class does not set that limit, the limit inherits the system limit. |
|                       | Also, any value you enter is considered to be that rate *per second*, unless you also check the related *percent* box, in which case the value is that percentage of the total resource. |

<table>
<thead>
<tr>
<th>TCP or UDP Connections</th>
<th>Sets a Rate Limit for TCP or UDP connections between any two hosts, including connections between one host and multiple other hosts. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 102400, or you can assign more than 100 percent if you want to oversubscribe the device.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inspections (Fixups)</td>
<td>Sets a Rate Limit for application inspections. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 10000 per second, or you can assign more than 100 percent if you want to oversubscribe the device.</td>
</tr>
<tr>
<td>Syslog Messages</td>
<td>Sets a Rate Limit for system log messages. You can set the limit as an absolute value, or you can assign more than 100 percent if you want to oversubscribe the device. The FWSM can support 30,000 messages per second for messages sent to the FWSM terminal or buffer. If you send messages to a syslog server, the FWSM supports 25,000 per second.</td>
</tr>
</tbody>
</table>
Connections: Sets the Absolute Limit for concurrent TCP or UDP connections. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 999990, or you can assign more than 100 percent if you want to oversubscribe the device.

**Note:** For concurrent connections, the FWSM allocates half of the limit to each of two network processors (NPs) that accept connections. Typically, the connections are divided evenly between the NPs. However, in some circumstances, the connections are not evenly divided, and the maximum connection limit could be reached on one NP before reaching the maximum on the other. In this case, the maximum connections allowed is less than the limit you set. The NP distribution is controlled by the switch, based on a distribution algorithm. You can adjust this algorithm on the switch (see Customizing the FWSM Internal Interface on cisco.com), or you can adjust the connection limit upward to account for the inequity.

Hosts: Sets the limit for concurrent hosts that can connect through the FWSM. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 262144, or you can assign more than 100 percent if you want to oversubscribe the device.

IPsec Sessions: Sets the limit for IPsec sessions. You can set the limit as an absolute value by entering an integer between 1 and 5, or you can assign more than 100 percent if you want to oversubscribe the device. The system allows a maximum of 10 concurrent sessions divided between all contexts.

SSH Sessions: Sets the limit for SSH sessions. You can set the limit as an absolute value by entering an integer between 1 and 5, or you can assign more than 100 percent if you want to oversubscribe the device. The system allows a maximum of 100 concurrent sessions divided between all contexts.

Telnet Sessions: Sets the limit for concurrent Telnet sessions. You can set the limit as an absolute value by entering an integer between 1 and 5, or you can assign more than 100 percent if you want to oversubscribe the device. The system allows a maximum of 100 concurrent sessions divided between all contexts.

NAT Translations: Sets the limit for concurrent address translations. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 266144, or you can assign more than 100 percent if you want to oversubscribe the device.

MAC Address: (Transparent mode only) Sets the limit for concurrent MAC address entries allowed in the MAC address table. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 65535, or you can assign more than 100 percent if you want to oversubscribe the device.

Configuring User Accounts

The User Accounts page lets you manage the Local user database. User accounts in the Local database can be used in conjunction with the Authentication, Authorization, Accounting (AAA) functions to determine “who is allowed to do what” on a device. Refer to About AAA on Security Devices, page 46-1 for more information.

The table on this page lists all currently defined Local user accounts, showing for each, the name of the user and the assigned privilege level. For a detailed explanation of these fields, see Add/Edit User Account Dialog Boxes, page 49-7.

- To add a user account, click the Add Row button.
- To edit the settings for an account, select it and click the Edit Row button.
- To delete a user account, select it and click the Delete Row button.

Navigation Path
- (Device view) Select Platform > Device Admin > User Accounts from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > User Accounts from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics
- Local Database, page 46-3
- Preparing for AAA, page 46-2
Add/Edit User Account Dialog Boxes

Use the Add and Edit User Account dialog boxes to add a local user account or to modify an existing user account.

Navigation Path

You can access the Add and Edit User Account dialog boxes from the User Accounts page, as described in Configuring User Accounts, page 49-6.

Monitoring Service Level Agreements (SLAs) To Maintain Connectivity

You can configure ASA or PIX devices that run version 7.2 or higher to perform route tracking by monitoring service level agreements. By monitoring the connectivity to a device on another network, you can track the availability of a primary route and install a backup route if the primary route fails. For example, you can define a default route to an Internet service provider (ISP) gateway and a backup default route to a secondary ISP in case the primary ISP becomes unavailable. This technique, called Dual ISP, provides security appliances with a form of high availability, which is a vital part of providing customers with the services to which they are entitled.

Without route tracking, there is no inherent mechanism for determining if the route is up or down. A static route remains in the routing table even if the next hop gateway becomes unavailable, and is removed only if the associated interface on the security appliance goes down.

The security appliance performs route tracking by associating a route with a monitoring target that you define in an SLA monitor policy object. It monitors the target using ICMP echo requests, according to the parameters configured in the object. If an echo reply is not received within a specified time period, the SLA monitor is considered down and the associated route is removed from the routing table. A previously configured backup route is used in place of the removed route.

SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration (that is, they do not age out).
Creating Service Level Agreements

The following procedure explains how to configure SLA monitor objects and associate them with routes and interfaces in an ASA or PIX configuration.

**Related Topics**
- Monitoring Service Level Agreements (SLAs) To Maintain Connectivity, page 49-7
- Configuring Static Routes, page 53-31
- Configuring Firewall Device Interfaces, page 44-2
- Creating Policy Objects, page 6-8

This section contains the following topics:
- Creating Service Level Agreements, page 49-8

**Step 1** Create the SLA monitor policy object:

a. Select **Manage > Policy Objects** to open the Policy Object Manager (see Policy Object Manager Window, page 6-4) and select **SLA Monitors** from the table of contents.

   **Tip** You can also create SLA monitor objects when defining policies that use this object type. For more information, see Selecting Objects for Policies, page 6-2.

b. Right-click in the work area and select **New Object** to open the Add SLA Monitor dialog box. For more information, see Configuring SLA Monitor Objects, page 49-9.

c. The monitoring options are appropriate for most connections, so you need only configure the following:
   - Name—The name of the object.
   - SLA Monitor ID—An identifying number for the monitoring process. The number must be unique within a device configuration.
   - Monitored Address—The address that you are monitoring. When you select a monitoring target, make sure that it can respond to ICMP echo requests (pings). The target can be any network address that you choose, but consider the use of:
     - The ISP gateway address.
     - The next hop gateway address (if you are concerned about the availability of the ISP gateway).
     - A server on the target network, such as an AAA server, with which the security appliance needs to communicate.
     - A persistent network device on the destination network. (A desktop or notebook computer that gets shut down at night is not a good choice.)
     - Interface—The interface name, or interface role that identifies an interface, that will be the source of the ICMP messages. The device pings the monitored address from this interface’s IP address.
   
d. Click **OK** to save the object.
Step 2 Configure ASA/PIX policies to use the object to monitor routes. You can configure the following policies to monitor SLAs:

- **Platform > Routing > Static Route**—When you define a static route, you can select an SLA monitor object to do route tracking for the route. For more information, see Configuring Static Routes, page 53-31 and Add/Edit Static Route Dialog Box, page 53-32.

- **Interfaces**—When you define an interface that uses DHCP or PPPoE, you can configure the DHCP or PPPoE learned default routes to be tracked. For more information, see Device Interface: IP Type (PIX/ASA 7.0+), page 44-36.

### Configuring SLA Monitor Objects

Use the Add or Edit SLA (Service Level Agreement) Monitor dialog box to create, edit, and copy SLA monitor objects. Each SLA monitor defines a connectivity policy to a monitored address and tracks the availability of a route to the address. The route is periodically checked for availability by sending ICMP echo requests and waiting for the response. If the requests time out, the route is removed from the routing table and replaced with a backup route.

You can configure SLA monitors only for security appliances running PIX/ASA version 7.2 or higher. SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration (that is, they do not age out).

For more information about configuring and using SLA monitor objects, see Monitoring Service Level Agreements (SLAs) To Maintain Connectivity, page 49-7.

#### Navigation Path

Select **Manage > Policy Objects**, then select **SLA Monitors** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Table 49-4  SLA Monitor Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
<td>The source interface for all ICMP echo requests sent to the monitored address to test its availability. Enter the name of an interface or interface role, or click Select to select an it from a list or to create a new interface role.</td>
</tr>
<tr>
<td>Frequency</td>
<td>The frequency of ICMP echo request transmissions, in seconds. Values range from 1 to 604800 seconds (7 days). The default is 60 seconds. Note: The frequency cannot be less than the timeout value; you must convert frequency to milliseconds to compare the values.</td>
</tr>
<tr>
<td>Threshold</td>
<td>The amount of time that must pass after an ICMP echo request before a rising threshold is declared, in milliseconds. Values range from 0 to 2147483647 milliseconds. The default is 5000 milliseconds. The threshold value is used only to indicate events that exceed the defined value. You can use these events to evaluate the proper timeout value. It is not a direct indicator of the reachability of the monitored address. Note: The threshold value should not exceed the timeout value.</td>
</tr>
<tr>
<td>Time out</td>
<td>The amount of time that the SLA operation waits for a response to the ICMP echo requests, in milliseconds. Values range from 0 to 604800000 milliseconds (7 days). The default is 5000 milliseconds. If a response is not received from the monitored address within the amount of time defined in this field, the static route is removed from the routing table and replaced by the backup route. Note: The timeout value cannot exceed the frequency value (adjust the frequency value to milliseconds to compare the numbers).</td>
</tr>
<tr>
<td>Request Data Size</td>
<td>The size of the ICMP request packet payload, in bytes. Values range from 0 to 16384 bytes. The default is 28 bytes, which creates a total ICMP packet of 64 bytes. Do not set this value higher than the maximum allowed by the protocol or the Path Maximum Transmission Unit (PMTU). For purposes of reachability, you might need to increase the default data size to detect PMTU changes between the source and the target. A low PMTU can affect session performance and, if detected, might indicate that the secondary path should be used.</td>
</tr>
<tr>
<td>ToS</td>
<td>The type of service (ToS) defined in the IP header of the ICMP request packet. Values range from 0 to 255. The default is 0. This field contains information such as delay, precedence, reliability, and so on. It can be used by other devices on the network for policy routing and features such as committed access rate.</td>
</tr>
<tr>
<td>Number of Packets</td>
<td>The number of packets that are sent. Values range from 1 to 100. The default is 1 packet. Tip: Increase the default number of packets if you are concerned that packet loss might falsely cause the security appliance to believe that the monitored address cannot be reached.</td>
</tr>
<tr>
<td>Category</td>
<td>The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects, page 6-11.</td>
</tr>

Configuring Server Access Settings on Firewall Devices

The Server Access section contains pages for configuring server access on firewall devices; Server Access is under Device Admin in the Device or Policy selector.

This chapter contains the following topics:

- AUS Page, page 50-1
- DHCP Relay Page, page 50-5
- Configuring DHCP Servers, page 50-7
- DNS Page, page 50-11
- Configuring DDNS, page 50-15
- NTP Page, page 50-18
- SMTP Server Page, page 50-19
- TFTP Server Page, page 50-20

AUS Page

The AUS page lets you configure remote updating of a security appliance from a server that supports the Auto Update specification. Auto Update applies configuration changes and software updates to the appliance automatically from the remote server.

Note

The server you identify on this page must be the same server you identify in the Auto Update section of the Device Properties (from the Tools menu, choose Device Properties). The Device Properties information identifies the AUS server to which Security Manager sends configuration updates, whereas the information on this page defines for the server the device will contact for updates. Also, the Device Identity you provide in the Device Properties must match the Device ID on this page.

If you change AUS servers, note that the device will continue to use the AUS server defined in its current configuration until it receives a new configuration. Thus, you should change the AUS policy but deploy the configuration using the previous AUS server. After deployment is successful, change the Device Properties to point to the new server. For more information on deploying to AUS, see Deploying Configurations Using an Auto Update Server or CNS Configuration Engine, page 8-39.
Navigation Path

- (Device view) Select Platform > Device Admin > Server Access > AUS from the Device Policy selector.

- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Server Access > AUS from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

Table 50-1 AUS Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Update Servers table</td>
<td>This table lists currently configured Auto Update servers. Use the buttons below the table to manage these entries. The entries are listed in order of precedence for contacting AUS servers. Use the Up and Down arrow buttons to change the ordering of the list by moving the selected entry up or down. Use the Add Row, Edit Row, and Delete Row buttons to add, edit or delete entries. Add Row opens the Add Auto Update Server dialog box, while Edit Row opens the Edit Auto Update Server dialog box for the selected row. See Add and Edit Auto Update Server Dialog Boxes, page 50-3 for information about these dialog boxes. Note The URL for contacting this AUS server is produced by concatenating the Protocol://Username:Password@IP IP Address:(Port)/Path provided in the Add/Edit Auto Update Server dialog boxes. The Port is included only if you entered a port number other than the default 443.</td>
</tr>
<tr>
<td>Device ID Type</td>
<td>Choose the method used for identifying this device to the AUS server:</td>
</tr>
<tr>
<td></td>
<td>• Host Name – The host name of this device, as provided in the Device Properties window (Tools &gt; Device Properties).</td>
</tr>
<tr>
<td></td>
<td>• Serial Number – The serial number of this device.</td>
</tr>
<tr>
<td></td>
<td>• IP Address – The IP address of the specified interface. When you choose this option, an Interface field appears; enter or Select the desired device interface.</td>
</tr>
<tr>
<td></td>
<td>• MAC Address – The MAC address of the specified interface. When you choose this option, an Interface field appears; enter or Select the desired device interface.</td>
</tr>
<tr>
<td></td>
<td>• User Defined – A unique user-specified ID is used. When you choose this option, a User Defined field appears; enter any alphanumeric string. Note that this string must also appear in the Device Identity field in the Device Properties window (Tools &gt; Device Properties).</td>
</tr>
</tbody>
</table>
Use the Add Auto Update Server dialog box to configure a new AUS server definition. The security appliance will automatically poll this server for image and configuration updates.

The Auto Update specification allows the Auto Update server to either push configuration information and send requests for information to the security appliance, or to pull configuration information by causing the security appliance to periodically poll the Auto Update server. The Auto Update server can
also send a command to the security appliance to send an immediate polling request at any time.
Communication between the Auto Update server and the security appliance requires a communications
path and local CLI configuration on each security appliance.

The URL for contacting this AUS server is produced by concatenating the
Protocol://Username:Password@IP IP Address:(Port)/Path provided in these dialog boxes. The Port is
included only if you entered a port number other than the default 443.

With the exception of the title, the Edit Auto Update Server dialog box is identical to the Add Auto
Update Server dialog box. The following descriptions apply to both.

Navigation Path
You can access the Add and Edit Auto Update Server dialog boxes from the AUS Page, page 50-1.

DHCP Relay Page

Use the DHCP Relay page to configure DHCP relay services for security devices. Dynamic Host Configuration Protocol (DHCP) relay passes DHCP requests received on one interface to an external DHCP server located behind a different interface. To configure DHCP relay, you need to specify at least one DHCP relay server and then enable a DHCP relay agent on the interface receiving DHCP requests.

**Note**

You cannot enable a DHCP relay agent on an interface where a DHCP relay server is configured. The DHCP relay agent works only with external DHCP servers; it will not forward DHCP requests to a security appliance interface configured as a DHCP server.

**Navigation Path**

- (Device view) Select **Platform > Device Admin > Server Access > DHCP Relay** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > DHCP Relay** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

**Field Reference**

Configuring DHCP Servers

A Dynamic Host Configuration Protocol (DHCP) server provides network configuration parameters, such as IP addresses, to DHCP clients. The security appliance can provide DHCP server or DHCP relay services to DHCP clients attached to the security appliance interfaces. The DHCP server provides network configuration parameters directly to DHCP clients: DHCP relay passes DHCP requests received on one interface to an external DHCP server located behind a different interface. For more information about DHCP relay, see DHCP Relay Page, page 50-5.

Note

The security appliance DHCP server does not support BOOTP requests.

In multiple-context mode, you cannot enable a DHCP server or DHCP relay on an interface that is used by more than one context.

You can configure a DHCP server on each interface of the security appliance, and each interface can have its own pool of addresses to draw from. However, the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.

You cannot configure a DHCP client or DHCP relay services on an interface on which the DHCP server is enabled. Additionally, DHCP clients must be directly connected to the interface on which the server is enabled.

If your firewall is also acting as a DHCP client on the outside interface, you can enable auto-negotiated IP configuration. This allows the firewall to pass the DNS, WINS and domain name parameters it gets from the outside interface (as a DHCP client) to hosts on its inside network. Alternatively, you can manually specify the DNS, WINS and domain name parameters. If you specify those parameters manually and auto-configuration is on, your values take precedence over auto-configuration.

Use the DHCP Server Page, page 50-8 to manage DHCP server definitions.
DHCP Server Page

Use the DHCP Server page to configure global DHCP server and dynamic DNS (DDNS) update options, to set up a DHCP server on one or more device interfaces, and to configure advanced server options.

Navigation Path

- (Device view) Select Platform > Device Admin > Server Access > DHCP Server from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Server Access > DHCP Server from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

DNS Page

Use the DNS page to configure DNS server groups. The firewall device uses these DNS servers to resolve fully-qualified domain names (host names) to IP addresses for SSL VPN, certificates, and FQDN network/host objects used in identity-aware firewall policies. Other features that define server names (such as AAA) do not support DNS resolution—you must enter the IP address or manually resolve the name to an IP address.

Tip

The DefaultDNS server group is predefined on the ASA and is used for FQDN network/host object resolution. If you use FQDN objects, ensure that you configure DNS servers for this group; otherwise, the names cannot be resolved. To enhance security, ensure that you specify DNS servers that are trusted and that are preferably inside your network. For more information, see Requirements for Identity-Aware Firewall Policies, page 13-3.
Navigation Path

- (Device view) Select Platform > Device Admin > Server Access > DNS from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Server Access > DNS from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

<td>Check this box to enable DNS Guard for the selected device or shared policy. DNS Guard tears down the DNS session associated with a DNS query as soon as the DNS reply is forwarded by the security appliance. DNS Guard also monitors the message exchange to ensure that the ID of the DNS reply matches the ID of the DNS query. This command is effective only on interfaces for which DNS inspection is disabled. When DNS inspection is enabled, the DNS Guard function is always performed. Note In releases prior to 7.0(5), the DNS Guard functions are always enabled regardless of the configuration of DNS inspection.</td>
</tr>
</tbody>
</table>
Add DNS Server Group Dialog Box

Use the Add DNS Server Group dialog box to define the DNS servers and settings for a DNS server group, used by security devices to resolve server names to IP addresses in policies that support name resolution.

Note

With the exception of its title, the Edit DNS Server Group dialog box is identical to this one, and the following descriptions apply to both.

Navigation Path

You can access the Add DNS Server Group and Edit DNS Server Group dialog boxes from the DNS Page, page 50-11.

---

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultDNS Server Group (ASA 8.4(2)+)</td>
<td>Additional settings that apply to the DefaultDNS server group only. These settings are used when resolving FQDN network/host objects to IP addresses.</td>
</tr>
</tbody>
</table>

- **Poll Timer**—The time, in minutes, of the polling cycle used to resolve FQDN network/host objects to IP addresses. FQDN objects are resolved only if they are used in a firewall policy. The timer determines the maximum time between resolutions; the DNS entry’s time-to-live (TTL) value is also used to determine when to update to IP address resolution, so individual FQDNs might be resolved more frequently than the polling cycle.
  
  The default is 240 (four hours). The range is 1 to 65535 minutes.

- **Expire Entry Timer**—The number of minutes after a DNS entry expires (that is, the TTL has passed) that the entry is removed from the DNS lookup table. Removing an entry requires that the table be recompiled, so frequent removals can increase the processing load on the device. Because some DNS entries can have very short TTL (as short as three seconds), you can use this setting to virtually extend the TTL.
  
  The default is 1 minute (that is, the entry is removed one minute after the TTL has passed). The range is 1 to 65535 minutes.

Table 50-11  Add/Edit DNS Server Group Dialog Boxes

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a name for the group of DNS servers.</td>
</tr>
<tr>
<td><strong>Tip</strong></td>
<td>The name DefaultDNS is predefined on the ASA and includes the servers used for policies that do not allow the selection of a specific group, such as for FQDN network/host object resolution.</td>
</tr>
</tbody>
</table>
| DNS Servers      | Lists the DNS servers in this group. You can specify up to six servers to which DNS requests can be forwarded. The security appliance tries each DNS server in top-to-bottom order until it receives a response. **Note** You also must specify at least one interface on which DNS is enabled in the DNS Lookup section of the DNS Page, page 50-11. Use the buttons next to this list to manage the entries; from the top down, they are:  
  - Add a DNS server to the list; opens the Add DNS Server Dialog Box, page 50-14.  
  - Delete the currently selected DNS server entry from the list.  
  - Move the currently selected entry up one row.  
  - Move the currently selected entry down one row. |
| Timeout          | Specify the number of seconds, from 1 to 30, to wait before trying the next DNS server; the default is 2 seconds. Each time the security device retries the list of servers, this timeout doubles. |
| Retries          | Specify the number of times, from 0 to 10, to retry the list of DNS servers when the security device does not receive a response.                  |
| Domain Name      | Optionally, specify a valid DNS domain name for the server; for example, dnsexample.com.                                                          |

Add DNS Server Dialog Box

Use the Add DNS Server dialog box to add a DNS server to the DNS servers list in the Add DNS Server Group or Edit DNS Server Group dialog boxes.

Navigation Path

You can access the Add DNS Server dialog box from the Add DNS Server Group or Edit DNS Server Group dialog boxes. For more information about these dialog boxes, see Add DNS Server Group Dialog Box, page 50-13.

Configuring DDNS

Dynamic DNS (DDNS) provides IP-address and domain-name mapping updates so hosts can find each other even though their DHCP-assigned IP addresses may change frequently. Also, beginning with the version 7.2(3), Cisco security appliances can generate DDNS updates. The DDNS page is where you configure this feature.

The DDNS mappings are maintained on the DHCP server in two types of resource records (RRs): the address or A records contain the name-to-IP-address mappings, while the pointer or PTR records map addresses to host names.

By automatically recording the association between assigned addresses and host names at defined intervals, DDNS allows frequently changing address-host name associations to be updated frequently. Mobile hosts, for example, can then move freely on a network without user or administrator intervention.

Navigation Path

- (Device view) Select Platform > Device Admin > Server Access > DDNS from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Server Access > DDNS from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

</table>
NTP Page

Network Time Protocol (NTP) is used to implement a hierarchical system of servers that provide precisely synchronized timing for network systems. This kind of accuracy is required for time-sensitive operations, such as validating Certificate Revocation Lists (CRLs), which include a precise time stamp. You can configure multiple NTP servers. The security device chooses the server with the lowest stratum—a measure of how reliable the data is.

Note

This page is not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

Use the NTP page to enable NTP and manage the NTP servers used to dynamically set the time on a security device.

Note

Time derived from an NTP server overrides any time set manually on the Clock page.

Navigation Path

- (Device view) Select Platform > Device Admin > Server Access > NTP from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Server Access > NTP from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

TFTP Server Page

The Trivial File Transfer Protocol (TFTP) is a simple client/server file transfer protocol described in RFC783 and RFC1350 Rev. 2. You can use the TFTP Server page to configure the security appliance as a TFTP client so it can transfer a copy of its running configuration file to a TFTP server. In this way, you can back up and propagate configuration files to multiple security appliances. Only one server is supported.

Navigation Path

- (Device view) Select Platform > Device Admin > Server Access > TFTP Server from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Device Admin > Server Access > TFTP Server from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

</tbody>
</table>
Configuring Logging Policies
on Firewall Devices

The Logging feature lets you enable and manage NetFlow “collectors,” and enable system logging, set up logging parameters, configure event lists (syslog filters), apply the filters to a destination, set up syslog messages, configure syslog servers, and specify e-mail notification parameters.

After you enable logging and set up the logging parameters using the Logging Setup page, the Event Lists page lets you configure filters (for a set of syslogs) which can be sent to a logging destination. The Logging Filters page lets you specify a logging destination for the syslogs to be sent. Finally, the Syslog and E-Mail pages configure syslog and e-mail setup.

This chapter contains the following topics:
- NetFlow Page, page 51-1
- E-Mail Setup Page, page 51-2
- Event Lists Page, page 51-3
- Logging Filters Page, page 51-7
- Configuring Logging Setup, page 51-9
- Configuring Rate Limit Levels, page 51-11
- Configuring Syslog Server Setup, page 51-14
- Defining Syslog Servers, page 51-18

NetFlow Page

A device configured for NetFlow data export captures flow-based traffic statistics on the device. This information is periodically transmitted from the device to a NetFlow collection server, in the form of User Datagram Protocol (UDP) datagrams.

The NetFlow page lets you enable NetFlow export on the selected device, and define and manage NetFlow “collectors” to which collected flow information is transmitted.

Navigation Path
- (Device view) Select Platform > Logging > NetFlow from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Logging > NetFlow from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

<tr>
<td>Enable Flow Export</td>
<td>If checked, NetFlow data export is enabled.</td>
</tr>
<tr>
<td>Template Export Interval</td>
<td>Interval (in minutes) between transmissions of flow information to the collectors. The value can be from one to 3600 minutes; the default is 30.</td>
</tr>
<tr>
<td>Collectors table</td>
<td>Lists the currently defined NetFlow collectors. Use the Add Row, Edit Row and Delete Row buttons below the table to manage these entries. The Add Row and Edit Row buttons open the Add and Edit Collector Dialog Boxes (NetFlow), page 51-2.</td>
</tr>
</tbody>
</table>

**Add and Edit Collector Dialog_boxes (NetFlow)**

Use the Add Collector and Edit Collector dialog boxes to define and edit NetFlow “collectors.” Except for the title, the two dialog boxes are identical; the following information applies to both.

**Navigation Path**

You can open the Add and Edit Collector dialog boxes from the NetFlow Page, page 51-1.

**Field Reference**

**Table 51-2 Add and Edit Collector Dialog Boxes**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
<td>Enter or Select the name of the device interface through which the collector is contacted.</td>
</tr>
<tr>
<td>Collector</td>
<td>Enter the IP address or the network name of the server to which NetFlow packets will be sent. You also can Select a Networks/Hosts object.</td>
</tr>
<tr>
<td>UDP Port</td>
<td>Specify the UDP port on the specified Collector to which NetFlow packets will be sent. Values can range from 1 to 65535; the default is 2055.</td>
</tr>
</tbody>
</table>

**E-Mail Setup Page**

The E-Mail Setup page (PIX 7.0/ASA Only) lets you set up a source e-mail address, as well as a list of recipients for specified syslog messages to be sent as e-mails. You can filter the syslog messages sent to a destination e-mail address by severity. The table shows which entries have been set up.

The syslog severity filter used for the destination e-mail address will be the higher of the severity selected in this section and the global filter set for all e-mail recipients in the Logging Filters page.
Navigation Path

- (Device view) Select **Platform > Logging > Syslog > E-Mail Setup** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > E-Mail Setup** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

</table>
Add/Edit Event List Dialog Box

The Add/Edit Event List dialog box lets you create or edit an event list, and specify which syslog messages to include in the event list filter.

You can use the following criteria to define an event list:

- Class and Severity
- Message ID

Class represents specific types of related syslog messages. For example, the class auth represents all syslog messages related to user authentication.

Severity classifies syslogs based on the relative importance of the event in the normal functioning of the network. The highest severity is Emergency, which means the resource is no longer available. The lowest severity is Debugging, which provides detailed information about every network event.

The message ID is a numeric value that uniquely identifies each individual message. You can specify a single message ID, or a range of IDs, in an event list.

Navigation Path

You can access the Add/Edit Event List dialog box from the Event Lists Page, page 51-3.

</tr>
</tbody>
</table>

Add/Edit Syslog Message ID Filter Dialog Box

The Add/Edit Syslog Message ID Filter dialog box lets you specify the a syslog message ID, or a range of IDs, as an the event list filter.

Navigation Path
You can access the Add/Edit Syslog Message ID Filter dialog box from the Add/Edit Event List Dialog Box, page 51-5.

Related Topics
- Add/Edit Syslog Class Dialog Box, page 51-5
- Event Lists Page, page 51-3

Field Reference

**Message IDs** – Enter a syslog message ID, or a range of IDs. Use a hyphen to specify a range; for example, 100001-101010. Message IDs must be between 100000 and 999999.

Message IDs and their corresponding messages are listed in the System Log Message guides for the appropriate product. You can access these guides from cisco.com:

- **PIX Firewall**

- **ASA**

- **FWSM**
Logging Filters Page

The Logging Filters page lets you configure a logging destination for event lists (syslog filters) that have been configured using the Event Lists page, or for only the syslog messages that you specify using the Edit Logging Filters page. Syslog messages from specific or all event classes can be selected using the Edit Logging Filters page.

Navigation Path

- (Device view) Select Platform > Logging > Syslog > Logging Filters from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Logging > Syslog > Logging Filters from the Policy Type selector. Right-click Logging Filters to create a policy, or select an existing policy from the Shared Policy selector.

Configuring Logging Setup

The Logging Setup page lets you enable system logging on the security appliance and configure other logging options. These options include enabling logging on the security appliance and failover unit, specifying the base log format and detail, and logging to longer-term storage devices, FTP server or Flash, before purging the internal buffer.

**Related Topics**
- Logging Setup Page, page 51-10

**Table 51-9 Edit Logging Filters Dialog Box (Continued)**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syslog from Specific Event Classes (PIX7.0)</td>
<td>Specifies the event class and severity. Event classes include one or all available items. Event classes are described in Table 51-5 on page 51-4.</td>
</tr>
<tr>
<td>Severity</td>
<td>Specifies the level of logging messages. Severity levels are described in Table 51-15 on page 51-17.</td>
</tr>
</tbody>
</table>

**Step 1**
Select **Platform > Logging > Syslog > Logging Setup** to display the Logging Setup page.

**Step 2**
Check **Enable Logging**.
This option enables logging on the security appliance.

**Step 3**
To enable logging on the failover unit paired with this security appliance, select the **Enable logging on the standby failover unit** check box.

**Step 4**
To enable EMBLEM format, or to send debug messages as part of the syslog messages, select the corresponding check boxes.

If you enable EMBLEM, you must use the UDP protocol to publish syslog messages. It is not compatible with TCP.

**Step 5**
To write the internal buffer data to an FTP server for future processing prior to clearing the buffer, do the following:

a. Check **FTP Server Buffer wrap**.

b. Enter the IP address of the FTP server in the **IP Address** field.

c. Enter the user name of the account used to log into the FTP server in the **User Name** field.

d. Enter the path in the **Path** field, relative to the FTP root, where the file should be stored.

e. Enter and confirm the password used to authenticate the user name.

**Step 6**
To write the internal buffer data to Flash for future processing prior to clearing the buffer, do the following:

a. Check **Flash**.

b. Specify the maximum amount of memory to allocate to the storage of internal buffer data.

c. Specify the minimum memory that should remain free on the Flash drive. If this minimum value cannot be retained while writing out the data from the internal buffer, the messages will be pruned to meet the space requirements.

**Step 7**
To specify the maximum queue size maintained on the appliance for viewing by an ASDM client, enter that value in the **Message Queue Size (Messages)** field.
Logging Setup Page

The Logging Setup page lets you enable system logging on the security appliance and configure other logging options.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog > Logging Setup** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Logging Setup** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

<td>Turns on logging for the standby security appliance, if available.</td>
</tr>
<tr>
<td>Send syslogs in EMBLEM format (PIX7.x+, ASA, FWSM 3.x+)</td>
<td>Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages; EMBLEM is not compatible with TCP. <strong>Note</strong> This setting is not compatible with CS-MARS.</td>
</tr>
<tr>
<td>Send debug messages as syslogs (PIX7.x+, ASA, FWSM 3.x+)</td>
<td>Redirects all the debug trace output to the syslog. The syslog message does not appear in the console if this option is enabled. Therefore, to see debug messages, you must enable logging at the console and configure it as the destination for the debug syslog message number and logging level. The syslog message number used is 711011. Default logging level for this syslog is debug.</td>
</tr>
<tr>
<td>Memory Size of Internal Buffer (bytes)</td>
<td>Specify the size of the internal buffer to which syslogs is saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 1048576.</td>
</tr>
</tbody>
</table>

**Specify FTP Server Information (PIX7.x+, ASA, FWSM 3.x+)**

| FTP Server Buffer Wrap | To save the buffer contents to the FTP server before it is overwritten, check this box and enter the necessary destination information in the following fields. To remove the FTP configuration, deselect this option. |
| IP Address | Enter the IP address of the FTP server. |
| User Name | Enter the user name to use when connecting to the FTP server. |
| Path | Enter the path, relative to the FTP root, where the buffer contents should be saved. |
| Password/Confirm | Enter and confirm the password used to authenticate the user name to the FTP server. |
Configuring Rate Limit Levels

The Rate Limit page lets you specify the maximum number of log messages of specific types (e.g., “alert” or “critical”), and messages with specific Syslog IDs, that can be generated within given periods of time. You can specify individual limits for each logging level, and each Syslog message ID. If the settings conflict, the Syslog message ID limits take precedence.

The Add/Edit Rate Limited Syslog Message Dialog Box, page 51-13 is used to specify the maximum number of messages that can be generated for a particular Syslog message ID within a given period of time.

The Add/Edit Rate Limit for Syslog Logging Levels Dialog Box, page 51-13 is used to specify the maximum number of messages that can be generated for a particular Syslog logging level within a given period of time.

Related Topics
- Rate Limit Page, page 51-12

Follow these steps to manage rate limits for message logging:

Step 1 Access the Rate Limit page by doing one of the following:
- (Device view) Select Platform > Logging > Syslog > Rate Limit from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Logging > Syslog > Rate Limit from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new policy.

Step 2 Add, edit and delete rate limits for Syslog logging levels:
- To specify the maximum number of messages that can be generated within a given period of time for particular logging level, click the Add Row button under the Rate Limits for Syslog Logging Levels table to open the Add/Edit Rate Limit for Syslog Logging Levels Dialog Box, page 51-13. Choose a logging level and define a rate limit.
- To edit the rate limit for a particular logging level, select the appropriate entry in the Rate Limits for Syslog Logging Levels table, and then click the Edit Row button under the table to open the Add/Edit Rate Limit for Syslog Logging Levels Dialog Box, page 51-13. Alter the rate limit as necessary.
To delete a rate limit entry from the Rate Limits for Syslog Logging Levels table, select it and then click the **Delete Row** button under the table. A confirmation dialog box may be displayed; click OK to delete the entry.

**Step 3**
Add, edit and delete limits for log messages according to message IDs:

- To specify the maximum number of messages that can be generated within a given period of time for particular message ID, click the **Add Row** button under the Individually Rate Limited Syslog Messages table to open the Add/Edit Rate Limited Syslog Message Dialog Box. Choose a Syslog message ID and define a rate limit.

- To edit the rate limit for a particular Syslog message ID, select the appropriate entry in the Individually Rate Limited Syslog Messages table, and then click the **Edit Row** button under the table to open the Add/Edit Rate Limited Syslog Message Dialog Box. Alter the rate limit as necessary.

- To delete a message limit entry from the Individually Rate Limited Syslog Messages table, select it and then click the **Delete Row** button under the table. A confirmation dialog box may be displayed; click OK to delete the entry.

---

**Rate Limit Page**

The Rate Limit page allows you to specify the maximum number of log messages of a particular type (for example, alert or critical) that should be generated within a given period of time. You can specify a limit for each logging level and Syslog message ID. If the settings differ, Syslog message ID limits take precedence.

**Navigation Path**

- (Device view) Select **Platform > Logging > Syslog > Rate Limit** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Rate Limit** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new policy.

Add/Edit Rate Limit for Syslog Logging Levels Dialog Box

Using the Add/Edit Rate Limit for Syslog Logging Levels dialog box, you can specify the maximum number of log messages for particular log level that should be generated within a given period of time. You can specify a limit for each logging level or syslog message ID (see Add/Edit Rate Limited Syslog Message Dialog Box, page 51-13). If the settings differ, the rate limited syslog message-level settings override rate limit logging level settings.

Navigation Path
You can access the Add/Edit Rate Limit for Syslog Logging Levels dialog box from the Rate Limit page. For more information, see Rate Limit Page, page 51-12.

</tr>
<tr>
<td>Interval (Seconds)</td>
<td>Number of seconds before the rate limit counter resets.</td>
</tr>
</tbody>
</table>

Add/Edit Rate Limited Syslog Message Dialog Box

Using the Add/Edit Rate Limited Syslog Message dialog box you can specify the maximum number of log messages of a particular Syslog ID that can be generated within a given period of time. You can specify a limit for each syslog message ID or logging level (see Add/Edit Rate Limit for Syslog Logging Levels Dialog Box, page 51-13). If the settings differ, the rate limited syslog message-level settings override rate limit logging level settings.

Navigation Path
You can access the Add/Edit Rate Limited Syslog Message dialog box from the Rate Limit page. For more information, see Rate Limit Page, page 51-12.
Configuring Syslog Server Setup

You can configure general syslog server settings to set the facility code to be included in syslog messages that are sent to syslog servers, specify whether a timestamp is included in each message, specify the device ID to include in messages, view and modify the severity levels for messages, and disable the generation of specific messages.

Related Topics
- Defining Syslog Servers, page 51-18

Step 1
Do one of the following:

- (Policy view) Select PIX/ASA/FWSM Platform > Logging > Syslog > Server Setup from the Policy Type selector. Select an existing policy or create a new one.

Step 2
Change the basic message configuration as required:

- If your syslog server expects a different facility than the default, select the required facility in the Facility list.
- If you want to include the date and time a message was generated in the message, select Enable Timestamp on Each Syslog Message.
- If you want to add a device identifier to syslog messages (which is placed at the beginning of the message), select Enable Syslog Device ID and then select the type of ID:
  - Interface—To use the IP address of the specified interface, regardless of the interface through which the appliance sends the message. Click Select to select the interface or the interface role that identifies the interface. Interface roles must map to a single interface.
  - User Defined ID—To use a text string (up to 16 characters) of your choosing.
  - Host Name—To use the hostname of the device.

<table>
<thead>
<tr>
<th>Table 51-13 Add/Edit Rate Limited Syslog Message Dialog Box</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element</strong></td>
</tr>
<tr>
<td>Syslog ID</td>
</tr>
<tr>
<td>Number of Messages</td>
</tr>
<tr>
<td>Interval (Seconds)</td>
</tr>
</tbody>
</table>
**Step 3** Use the Syslog Message table to alter the default settings for specific syslog messages. You need to configure rules in this table only if you want to change the default settings. You can change the severity assigned to a message, or you can suppress (disable) the generation of a message.

- To add a rule, click the **Add Row** button and fill in the **Add/Edit Syslog Message Dialog Box**, page 51-17.

  You select the message number whose configuration you want to change, and then select the new severity level, or select **Suppressed** to disable the generation of the message. Typically, you would not change the severity level and disable the message, but you can make changes to both fields if desired. Click **OK** to add the rule to the table.

  For a description of message severity levels, see **Logging Levels**, page 51-17.

- To edit a rule, select it and click the **Edit Row** button, make the desired changes, and click **OK**.

- To delete a rule, select it and click the **Delete Row** button.

- If you are using NetFlow, you can easily disable the generation of syslog messages that have NetFlow equivalents by clicking the **Disable NetFlow Equivalent Syslogs** button. This adds the messages to the table as suppressed messages. Note that if any of these syslog equivalents are already in the table, your existing rules are not overwritten.

---

**Server Setup Page**

The Server Setup page allows you to set the facility code to be included in syslog messages that are sent to syslog servers, specify whether a timestamp is included in each message, specify the device ID to include in messages, view and modify the severity levels for messages, and disable the generation of specific messages.

**Navigation Path**

- (Device view) Select **Platform > Logging > Syslog > Server Setup** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Server Setup** from the Policy Type selector. Select an existing policy or create a new one.

### Field Reference

#### Table 51-14  Server Setup Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Facility</td>
<td>The syslog facility code that the appliance includes in messages destined for syslog servers. The default is LOCAL4(20), which is what most UNIX systems expect. You can select a facility between LOCAL0(16) and LOCAL7(23). Syslog facility is useful when you have a central syslog monitoring system that needs to distinguish among the various network devices that generate syslog data streams. Because your network devices share the eight available facilities, you might need to change this value.</td>
</tr>
<tr>
<td>Enable Timestamp on Each Syslog Message</td>
<td>Whether to include the date and time a message was generated in syslog messages. The default is to not include time stamps.</td>
</tr>
</tbody>
</table>
| Enable Syslog Device ID | Whether to configure a device ID in non-EMBLEM-format syslog messages. If you select this option, select one of the following to use as the device ID, which is place at the start of all syslog messages:
- Interface—The IP address of the selected interface. Enter the name of the interface or click Select to select it from a list (or to select an interface role that specifies the interface). Messages include the IP address of the interface specified, regardless of which interface the adaptive security appliance uses to send the log data to the external server.
  If you select an interface role, that role must map to a single interface on the device.
- User Defined ID—A text string you define as the device ID. This string can be up to 16 characters, but cannot contain any of the following special characters: & ' " < > ?
- Host Name—The hostname of the security appliance. |
| Syslog Message table | Use this table to enable or disable the generation of specific syslog messages, or to change the severity level of a message. If you do not want to constrict which message types are generated, or change any message severity levels, you do not need to configure anything in this table. The table shows the messages you have configured with the message level and whether generation is suppressed (“true” in the table).
  - To add a rule, click the Add Row button and fill in the Add/Edit Syslog Message Dialog Box, page 51-17.
  - To edit a rule, select it and click the Edit Row button.
  - To delete a rule, select it and click the Delete Row button. |

<td>No logging.</td>
</tr>
</tbody>
</table>

Add/Edit Syslog Message Dialog Box

The Add/Edit Syslog Message dialog box lets you modify the logging level or suppression setting for a syslog message.

Navigation Path

You can access the Add/Edit Syslog Message dialog box from the Server Setup Page, page 51-15.
Defining Syslog Servers

The Syslog Servers page lets you specify the syslog servers to which the security appliance will send syslog messages. To make use of the syslog servers you define, you must enable logging using the Logging Setup page and set up the appropriate filters for destinations using the Logging Filters page.

Table 51-16 Add/Edit Syslog Message Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syslog ID list</td>
<td>The message log ID of the message whose severity level or suppression setting you want to alter. These values and their corresponding messages are identified in the System Log Message guides for the appropriate product:</td>
</tr>
<tr>
<td>Logging Level list</td>
<td>The logging level that you want to assign to the message. For logging levels and descriptions, see Logging Levels, page 51-17. Select (default) to use the default level assigned to the message.</td>
</tr>
<tr>
<td>Suppressed</td>
<td>Whether to suppress the generation of the syslog message. Suppressing a message disables its generation, so you will not see it in syslogs.</td>
</tr>
</tbody>
</table>

Defining Syslog Servers

If you want to view events from an ASA device using Security Manager Event Viewer, ensure that you define the Security Manager server as a syslog server. Also, if you use CS-MARS or other applications to manage syslog events, include those servers in this policy.

By directing syslog records generated by a security appliance to a syslog server, you can process and study the records.

Related Topics

- Syslog Servers Page, page 51-19
- Add/Edit Syslog Server Dialog Box, page 51-20
Step 1 Select **Platform > Logging > Syslog > Syslog Servers** to display the Syslog Servers page.

Step 2 Do one of the following:
- To add a new syslog target, click the **Add Row** button.
- To edit an existing syslog target, select the check box for the row, then click the **Edit Row** button.

Step 3 Enter or select the interface name in the **Interface** field.
The list displays all interfaces defined at the current scope.

Step 4 Enter or select the IP address of the syslog server in the **IP Address** field.

Step 5 Determine whether to use UDP or TCP, then click the appropriate radio button under **Protocol**.

Step 6 Enter the port from which the security appliance sends either UDP or TCP syslog messages. The port must be the same port on which the syslog server listens.
- TCP—1470 (Default). TCP ports work only with a security appliance syslog server.
- UDP—514 (Default).

Step 7 To generate syslog messages using the EMBLEM format, select the **Log messages in Cisco EMBLEM format** check box.
To enable this option, you must select UDP protocol to publish messages to this syslog server.

Step 8 Click **OK**.
The definition appears in the Syslog Servers table.

---

**Syslog Servers Page**

The Syslog Servers page lets you specify the syslog servers to which the security appliance sends syslog messages. To make use of the syslog servers you define, you must enable logging using the Logging Setup page and set up the appropriate filters for destinations using the Logging Filters page.

**Tip**
If you want to view events from an ASA device using Security Manager Event Viewer, ensure that you define the Security Manager server as a syslog server. Also, if you use CS-MARS or other applications to manage syslog events, include those servers in this policy.

**Navigation Path**
- (Device view) Select **Platform > Logging > Syslog > Syslog Servers** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Syslog Servers** from the Policy Type selector. Select an existing policy or create a new one.

Configuring Multicast Policies on Firewall Devices

The Multicast section contains pages for defining IP multicast routing on security devices. Multicast routing is supported in single-context, routed mode only.

Enabling multicast routing enables IGMP and PIM on all interfaces by default. Internet Group Management Protocol (IGMP) is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. Protocol Independent Multicast (PIM) is used to maintain forwarding tables for multicast datagrams.

**Note**

Only the UDP transport layer is supported for multicast routing.

This chapter contains the following topics:

- Enabling PIM and IGMP, page 52-1
- Configuring IGMP, page 52-2
- Configuring Multicast Routes, page 52-8
- Configuring Multicast Boundary Filters, page 52-9
- Configuring PIM, page 52-10

### Enabling PIM and IGMP

The Enable PIM and IGMP page lets you enable or disable Internet Group Management Protocol (IGMP) and Protocol Independent Multicast (PIM) on all interfaces on the security appliance. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

When **Enable PIM and IGMP** is checked on this page, PIM and IGMP are enabled on all interfaces on the security appliance. Deselect the option to disable PIM and IGMP on all interfaces.

**Note**

You can disable PIM and IGMP on a per-interface basis; see IGMP Page - Protocol Tab, page 52-3 and PIM Page - Protocol Tab, page 52-11 for more information.
Navigation Path

- (Device view) Select **Platform > Multicast > Enable PIM and IGMP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Multicast > Enable PIM and IGMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Configuring IGMP

Internet Protocol hosts use IGMP to report their group memberships to directly connected multicast routers. Internet Group Management Protocol (IGMP) uses group-address (Class D) IP addresses. Host group addresses can be in the range 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

The IGMP page provides four tabbed panels, used to configure and manage IGMP in Security Manager:

- **IGMP Page - Protocol Tab, page 52-3** – This panel displays interface-specific IGMP parameters; you can disable IGMP and change IGMP parameters.
- **IGMP Page - Access Group Tab, page 52-5** – Lets you manage access groups that restrict the multicast sources allowed on an interface.
- **IGMP Page - Static Group Tab, page 52-6** – Sometimes, hosts on a network may have a configuration that prevents them from answering IGMP queries; however, you still want multicast traffic to be forwarded to that network segment. There are two methods to pull multicast traffic down to a network segment:
  - Use the Join Group tab to configure the interface as a member of the multicast group. With this method, the security appliance accepts the multicast packets in addition to forwarding them to the specified interface.
  - Use the StaticGroup tab to configure the security appliance to be a statically connected member of a group. With this method, the security appliance does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but itself is not a member of the multicast group.

Use this tab to statically assign a multicast group to an interface, or change existing static group assignments.

- **IGMP Page - Join Group Tab, page 52-7** – Use this tab to manage the multicast groups to which the security appliance belongs.

Note

If you simply want to forward multicast packets for a specific group to an interface without the security appliance accepting those packets as part of the group, see **IGMP Page - Static Group Tab, page 52-6**.
Navigation Path

- (Device view) Select **Platform > Multicast > IGMP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Multicast > IGMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

**IGMP Page - Protocol Tab**

Use the Protocol tab to configure IGMP parameters for an interface on the security appliance.

**Navigation Path**

You can access the Protocol tab from the IGMP page. For more information about the IGMP page, see **Configuring IGMP, page 52-2**.

**PIX 7.x and ASA Only**

| **Element** | **Description** |
| Enable IGMP | When selected, IGMP is enabled on the specified interface. |
| Group Limit | The maximum number of hosts that can join on an interface. Valid values range from 1 to 500. The default value is 500. |
| Query Timeout | The period of time, in seconds, before the security appliance takes over querying the interface, after the previous appliance has stopped doing so. Valid values range from 60 to 300 seconds. The default value is 255 seconds. |
**IGMP Page - Access Group Tab**

Use the Access Group tab to control the multicast groups that are allowed on an interface.

The table on this page lists all currently defined multicast access groups, showing for each, the name of the interface or interface role for which the group is defined, the group network(s), and whether this group is permitted or denied. For a detailed explanation of these fields, see Configure IGMP Access Group Parameters Dialog Box, page 52-5.

- To add a multicast access group to the table, click the Add Row button.
- To edit the settings for a group, select it and click the Edit Row button.
- To delete a group, select it and click the Delete Row button.

**Navigation Path**

You can access the Access Group tab from the Configuring IGMP, page 52-2.

</tr>
</tbody>
</table>
Configuring Multicast Routes

Static multicast routes let you separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them, sending the multicast packets over the tunnel.

Static multicast routes are local to the security appliance and are not advertised or redistributed.

Use the Multicast Routes page to manage static multicast routes—currently defined routes are listed, and you can add, edit and delete static multicast routes.

See Add/Edit MRoute Configuration Dialog Box, page 52-8 for more information about the fields displayed in the table on this page.

Navigation Path

- (Device view) Select Platform > Multicast > Multicast Routes from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Multicast > Multicast Routes from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

</tr>
<tr>
<td>Output Interface/Dense</td>
<td>(Optional) Enter or Select the outgoing interface for the multicast route. If you specify the destination interface, the route is forwarded through the selected interface. If you do not specify a destination interface, then RPF is used to forward the route. You can specify the interface, or the RPF neighbor, but not both at the same time.</td>
</tr>
</tbody>
</table>
Configuring Multicast Boundary Filters

On an ASA running version 7.2(1) or later, you can use the Multicast Boundary Filter page to configure the appliance to act as a boundary between multicast domains. The ASA compares multicast group addresses to an access list, blocking all multicast traffic except that specifically permitted by the list.

The Multicast Boundary Filter page lists all currently defined per-interface boundary filter lists; you can add, edit and delete filter lists from this page.

Refer to Add/Edit MBoundary Configuration Dialog Box, page 52-9 for a description of the fields on this page.

Navigation Path

- (Device view) Select Platform > Multicast > Multicast Boundary Filter from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Multicast > Multicast Boundary Filter from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

You also can Select a named network/host object.</td>
</tr>
</tbody>
</table>

Configuring PIM

Protocol independent multicast (PIM) provides a scalable method for determining the best paths in a network for distributing a specific multicast transmission to each host that has registered using IGMP to receive the transmission. Routers and security devices use PIM to maintain tables for forwarding multicast datagrams.

With PIM sparse mode (PIM SM), which is the default for Cisco routers, when the source of a multicast transmission begins broadcasting, the traffic is forwarded from one multicast router to the next until the packets reach every registered host. If a more direct path to the traffic source exists, the last-hop router sends a join message to the source that causes the traffic to be rerouted along the better path.
PIM is not supported with PAT—the PIM protocol does not use ports and PAT only works with protocols that use ports.

When you enable multicast routing on a security appliance, PIM and IGMP are enabled on all interfaces by default. You can disable PIM on a per-interface basis.

The PIM page provides up to six tabbed panels:

- **PIM Page - Protocol Tab, page 52-11** – Lets you manage interface-specific PIM properties.
- **PIM Page - Neighbor Filter Tab, page 52-12** – Lets you manage neighbor filters for individual interfaces; available only on ASA 7.2(1)+ devices.
- **PIM Page - Bidirectional Neighbor Filter Tab, page 52-13** – Lets you manage bidirectional neighbor filters for individual interfaces; available only on ASA 7.2(1)+ devices.
- **PIM Page - Rendezvous Points Tab, page 52-15** – When you configure PIM, you must choose one or more devices to operate as the rendezvous point (RP). An RP is a single, common root of a shared distribution tree and is statically configured on each device. First-hop routers use the RP to send registration packets on behalf of the source multicast hosts.
- **PIM Page - Route Tree Tab, page 52-17** – By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This reduces delay, but requires more memory than shared tree. You can configure whether the security appliance should join shortest-path tree, or use a shared tree, either for all multicast groups or only for specific multicast addresses.
- **PIM Page - Request Filter Tab, page 52-18** – When the security appliance is acting as an RP, you can restrict specific multicast sources from registering. This prevents unauthorized sources from registering with the RP. The Request Filter panel lets you define the multicast sources from which the security appliance will accept PIM registration messages.

**PIM Page - Protocol Tab**

Use the Protocol tab to configure PIM properties for the interfaces on a security appliance (not available on PIX 6.3 devices). All currently configured interfaces are listed; you can add, edit and delete entries on this panel.

Refer to **Add/Edit PIM Protocol Dialog Box, page 52-12** for a description of the fields on this panel.

**Navigation Path**

You access the Protocol tab from the PIM page. For more information, see **Configuring PIM, page 52-10**.

**Related Topics**

Add/Edit PIM Protocol Dialog Box

Use the Add/Edit PIM Protocol dialog box to configure PIM properties for an interface on a security appliance running PIX 7.x or later.

About the Designated Router

The DR is responsible for sending PIM register, join, and prune messages to the Rendezvous Point (RP). When there is more than one multicast routing device on a network segment, there is an election process to select the Designated Router based on DR priority. If multiple devices have the same DR priority, then the device with the highest IP address becomes the DR. By default, security appliances have a DR priority of 1.

Navigation Path

You can access the Add/Edit PIM Protocol dialog box from the PIM Page - Protocol Tab, page 52-11.

Field Reference

Table 52-11  Add/Edit PIM Protocol Dialog Box

<table>

<td>The frequency, in seconds, at which the interface sends PIM join and prune advertisements. Valid values range from 10 to 600 seconds; the default value is 60 seconds.</td>
</tr>
</tbody>
</table>

PIM Page - Neighbor Filter Tab

A PIM neighbor filter is an access control list (ACL) that defines the neighbor devices that can participate in PIM. If a neighbor filter is not configured for an interface, then there are no restrictions. If a PIM neighbor filter is configured, only those neighbors permitted by the filter list can participate in PIM with the security appliance.

On an ASA running version 7.2(1) or later, you can use the Neighbor Filter tab to control the devices that can become PIM neighbors. This panel is used to define and manage the per-interface neighbor filter list. Refer to Add/Edit PIM Neighbor Filter Dialog Box, page 52-13 for a description of the fields on this panel.

Navigation Path

You access the Protocol tab from the PIM page. For more information, see Configuring PIM, page 52-10.

You also can Select a named network/host object.</td>
</tr>
<tr>
<td>Action</td>
<td>Choose <strong>permit</strong> to allow the specified neighbors to participate in PIM, or <strong>deny</strong> to prevent the specified neighbors from participating in PIM.</td>
</tr>
</tbody>
</table>

PIM Page - Bidirectional Neighbor Filter Tab

A PIM bidirectional neighbor filter is an access control list (ACL) that defines the neighbor devices that can participate in the bidirectional trees and designated forwarder (DF) election. If a PIM bidirectional neighbor filter is not configured for an interface, then there are no restrictions. If a PIM bidirectional neighbor filter is configured, only those neighbors permitted by the ACL can participate in DF election process.

The PIM bidirectional neighbor filters enable the transition from a sparse-mode-only network to a “bidir” network by letting you specify the devices that should participate in DF election, while still allowing all devices to participate in the sparse-mode domain. The bidir-enabled devices can elect a DF from among themselves, even when there are non-bidir devices on the segment. Multicast boundaries on the non-bidir devices prevent PIM messages and data from the bidir groups from leaking in or out of the bidir subset cloud.

Bidirectional PIM allows multicast devices to maintain reduced state information. All of the multicast devices in a segment must be bidirectionally enabled for bidir to elect a DF.
When a PIM bidirectional neighbor filter is enabled, the routers and other devices that are permitted by the ACL are considered to be bidir-capable. Therefore:

- If a permitted neighbor does not support bidir, the DF election does not occur.
- If a denied neighbor supports bidir, then DF election does not occur.
- If a denied neighbor does not support bidir, the DF election can occur.

**Managing the Bidirectional Neighbor Filter List**

On an ASA running version 7.2(1) or later, you can use this panel to define and manage the per-interface bidirectional neighbor filter list, permitting or denying multicast source addresses for specific interfaces. Refer to Add/Edit PIM Bidirectional Neighbor Filter Dialog Box, page 52-14 for a description of the fields on this panel.

**Navigation Path**

You access the Bidirectional Neighbor Filter tab from the PIM page. For more information, see Configuring PIM, page 52-10.

PIM Page - Rendezvous Points Tab

When you configure PIM, you must choose one or more routers or routing devices to operate as the RP. An RP is a single, common root of a shared distribution tree and is statically configured on each device. First hop routers use the RP to send register packets on behalf of the source multicast hosts.

You can configure a single RP to serve more than one group. If a specific group is not specified, the RP for the group is applied to the entire IP multicast group range (224.0.0.0/4).

Use the Rendezvous Points panel to define rendezvous points. You can configure more than one RP, but you cannot have more than one entry with the same RP.

Navigation Path
You access the Rendezvous Points tab from the PIM page. For more information, see Configuring PIM, page 52-10.

Configuring Routing Policies on Firewall Devices

This chapter contains the following topics:

- Configuring No Proxy ARP, page 53-1
- Configuring OSPF, page 53-2
- Configuring RIP, page 53-22
- Configuring Static Routes, page 53-31

Configuring No Proxy ARP

When a host sends IP traffic to another device on the same Ethernet network, the host needs to know the MAC address of the device. Address Resolution Protocol (ARP) is a Layer 2 protocol that resolves an IP address to a MAC address: a host sends an ARP request asking “Who is this IP address?” The device owning the IP address replies, “I own that IP address; here is my MAC address.”

With Proxy ARP, a device responds to an ARP request with its own MAC address, even though the device does not own the IP address. Serving as an ARP Proxy for another host effectively directs network traffic to the proxy, in this case your security appliance. Traffic that passes through the appliance is then routed to the appropriate destination.

For example, the security appliance uses proxy ARP when you configure NAT and specify a global address that is on the same network as the appliance interface. The only way traffic can reach the destination hosts is if the appliance claims and subsequently routes traffic to the destination global addresses.

By default, proxy ARP is enabled for all interfaces. Use the No Proxy ARP page to disable proxy ARP for global addresses:

- To disable proxy ARP for one or more interfaces, enter their names in the Interfaces field. Separate multiple interfaces with commas. You can click Select to choose the interfaces from a list of interfaces defined on the device, and interface roles defined in Security Manager.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

On ASA 8.4.2 and later devices operating in routed mode, you can disable Proxy ARP on the egress interface for a Manual NAT rule. See **Do not proxy ARP on Destination Interface** in Add and Edit NAT Rule Dialog Boxes, page 22-35 for more information.
Navigation Path

- (Device view) Select **Platform > Routing > No Proxy ARP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > No Proxy ARP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

- Configuring OSPF, page 53-2

Configuring OSPF

The OSPF page provides nine tabbed panels for configuring OSPF (Open Shortest Path First) routing on a firewall device. The following topics provide detailed information about enabling and configuring OSPF:

- About OSPF, page 53-2
- General Tab, page 53-3
- Area Tab, page 53-6
- Range Tab, page 53-8
- Neighbors Tab, page 53-10
- Redistribution Tab, page 53-11
- Virtual Link Tab, page 53-13
- Filtering Tab, page 53-16
- Summary Address Tab, page 53-17
- Interface Tab, page 53-19

Navigation Path

- (Device view) Select **Platform > Routing > OSPF** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > OSPF** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

About OSPF

Open Shortest Path First (OSPF) is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. OSPF propagates link-state advertisements (LSAs) rather than routing table updates. Because only LSAs are exchanged, rather than entire routing tables, OSPF networks converge more quickly than RIP networks.

OSPF supports MD5 and clear-text neighbor authentication. Authentication should be used with all routing protocols whenever possible, because route redistribution between OSPF and other protocols (like RIP) can potentially be used by attackers to subvert routing information.

If NAT is used when OSPF is operating on public and private areas, and if address filtering is required, you need to run two OSPF processes—one process for the public areas and one for the private areas.
Chapter 53      Configuring Routing Policies on Firewall Devices

Configuring OSPF

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR type 3 LSA filtering, you can have separate private and public areas with the security appliance acting as an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other. This lets you use NAT and OSPF together without advertising private networks.

Note

Only type 3 LSAs can be filtered. If you configure the security appliance as an ASBR in a private network, it will send type 5 LSAs describing private networks, which will be broadcast to the entire autonomous system (AS) including public areas.

If NAT is employed but OSPF is only running in public areas, routes to public networks can be redistributed inside the private network, either as default or type 5 AS External LSAs. However, you need to configure static routes for the private networks protected by the security appliance. Also, you should not mix public and private networks on the same security appliance interface.

Related Topics

- Configuring OSPF, page 53-2

General Tab

Use the General panel on the OSPF page to enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks.

Note

You cannot enable OSPF if you have RIP enabled.

Navigation Path

You can access the General panel from the OSPF Page; see Configuring OSPF, page 53-2 for more information.

<td>To use a fixed router ID, enter a router ID in IP address format in the Router ID field. If you leave this value blank, the highest-level IP address on the security appliance is used as the router ID.</td>
</tr>
<tr>
<td>Ignore LSA MOSPF</td>
<td>Select this option to suppress transmission of syslog messages when the security appliance receives Type 6 (MOSPF) LSA packets.</td>
</tr>
<tr>
<td>RFC 1583 Compatible</td>
<td>Select this option to calculate summary route costs per RFC 1583. Deselect this option to calculate summary route costs per RFC 2328. To minimize the chance of routing loops, all OSPF devices in an OSPF routing domain should have RFC compatibility set identically. This option is selected by default.</td>
</tr>
</tbody>
</table>
Configuring OSPF

Adjacency Changes These options specify the syslog messages sent when adjacency changes occur.
- Log Adjacency Changes – When selected, the security appliance sends a syslog message whenever an OSPF neighbor goes up or down. This option is selected by default.
- Log Adjacency Changes Detail – When selected, the security appliance sends a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This option is not selected by default.

Administrative Route Distances Settings for the administrative route distances, according to the route type.
- Inter Area – The administrative distance for all routes from one area to another. Valid values range from 1 to 255; the default value is 110.
- Intra Area – The administrative distance for all routes within an area. Valid values range from 1 to 255; the default value is 110.
- External – The administrative distance for all routes from other routing domains that are learned through redistribution. Valid values range from 1 to 255; the default value is 110.

Timers (in seconds) Settings used to configure LSA pacing and SPF calculation timers.
- SPF Delay – The time between receipt of a topology change and the start of shortest path first (SPF) calculations. Valid values range from 0 to 65535; the default value is 5 seconds.
- SPF Hold – The hold time between consecutive SPF calculations. Valid values range from 1 to 65534; the default value is 10 seconds.
- LSA Group Pacing – The interval at which LSAs are collected into a group and refreshed, checksummed, or aged. Valid values range from 10 to 1800; the default value is 240 seconds.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSPF Process</td>
<td>Select the OSPF process associated with the route redistribution entry.</td>
</tr>
</tbody>
</table>
| Route Type     | Select the source protocol from which the routes are being redistributed. You can choose one of the following options:  
- Static—The route is a static route.  
- Connected—The route was established automatically by virtue of having IP enabled on the interface.  
- OSPF—The route is an OSPF route from another process. |
| Match          | The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions:  
- Internal—The route is internal to a specific AS.  
- External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 external routes.  
- External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 external routes.  
- NSSA External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes.  
- NSSA External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes. |
| Metric Value   | The metric value for the routes being redistributed. Valid values range from 1 to 16777214. When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified. |
| Metric Type    | Select “1” if the metric is a Type 1 external route, “2” if the metric is a Type 2 external route.     |
| Tag Value      | The tag value is a 32-bit decimal value attached to each external route. This is not used by OSPF itself. It may be used to communicate information between ASBRs. Valid values range from 0 to 4294967295. |
| Use Subnets    | When selected, redistribution of subnetted routes is enabled. Deselect this check box to cause only routes that are not subnetted to be redistributed. |
| Route Map      | The name of the route map to apply to the redistribution entry. |
Virtual Link Tab

Use the Virtual Link tab to create virtual links. If you add an area to an OSPF network, and it is not possible to connect the area directly to the backbone area, you need to create a virtual link. A virtual link connects two OSPF devices that have a common area, called the transit area. One of the OSPF devices must be connected to the backbone area.

Navigation Path
You can access the Virtual Link tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF, page 53-2.

## Table 53-12   Add/Edit OSPF Virtual Link Configuration Dialog Box

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSPF Process</td>
<td>Select the OSPF process associated with the virtual link.</td>
</tr>
<tr>
<td>Area ID</td>
<td>Select the area shared by the neighbor OSPF devices. The selected area cannot be an NSSA or a stub area.</td>
</tr>
<tr>
<td>Peer Router</td>
<td>Enter the IP address of the virtual link neighbor.</td>
</tr>
<tr>
<td>Hello Interval</td>
<td>The interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected but the more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. Valid values range from 1 to 65535 seconds. The default value is 10 seconds.</td>
</tr>
<tr>
<td>Retransmit Interval</td>
<td>The time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgement message. If the router receives no acknowledgement, it will resend the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 65535 seconds. The default value is 5 seconds.</td>
</tr>
<tr>
<td>Transmit Delay</td>
<td>The estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 65535 seconds. The default value is 1 second.</td>
</tr>
<tr>
<td>Dead Interval</td>
<td>The interval, in seconds, in which no hello packets are received, causing neighbors to declare a router down. Valid values range from 1 to 65535. The default value of this field is four times the interval set by the Hello Interval field.</td>
</tr>
<tr>
<td>Authentication</td>
<td>Contains the OSPF authentication options.</td>
</tr>
<tr>
<td></td>
<td>• None—Choose this option to disable OSPF authentication.</td>
</tr>
<tr>
<td></td>
<td>• Password—Choose this option to use clear text password authentication. This is not recommended where security is a concern.</td>
</tr>
<tr>
<td></td>
<td>• MD5—Choose this option to use MD5 authentication (recommended).</td>
</tr>
</tbody>
</table>
Add/Edit OSPF Virtual Link Configuration Dialog Box

Use the Add/Edit OSPF Virtual Link Configuration dialog box to define MD5 keys for authentication of virtual links.

Navigation Path
You can access the Add/Edit OSPF Virtual Link MD5 Configuration dialog box from the Add/Edit OSPF Virtual Link Configuration Dialog Box, page 53-13.

| Authentication Password | Contains the settings for entering the password when password authentication is enabled.  
  - Password—Enter a text string of up to 8 characters.  
  - Confirm—Re-enter the password. |
| MD5 IDs and Keys | Contains the settings for entering the MD5 keys and parameters when MD5 authentication is enabled. All devices on the interface using OSPF authentication must use the same MD5 key and ID.  
  - MD5 Key ID and MD5 Key Table  
    - MD5 Key ID—A numerical key identifier. Valid values range from 1 to 255.  
    - MD5 Key—An alphanumeric character string of up to 16 bytes. |
Filtering Tab

Use the Filtering tab to configure the ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restricts all other prefixes. This type of area filtering can be applied out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF areas at the same time.

Benefits
OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

Restrictions
Only type-3 LSAs that originate from an ABR are filtered.

Navigation Path
You can access the Filtering tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF, page 53-2.

<td>Enter a sequence number for the filter. Valid values range from 1 to 4294967294. When multiple filters apply to an LSA, the filter with the lowest sequence number is used.</td>
</tr>
<tr>
<td>Action</td>
<td>Select “Permit” to allow the LSA traffic or “Deny” to block the LSA traffic.</td>
</tr>
<tr>
<td>Lower Range</td>
<td>Specify the minimum prefix length to be matched. The value of this setting must be greater than the length of the network mask entered in the Filtered Network field and less than or equal to the value, if present, entered in the Upper Range field.</td>
</tr>
<tr>
<td>Upper Range</td>
<td>Enter the maximum prefix length to be matched. The value of this setting must be greater than or equal to the value, if present, entered in the Lower Range field, or, if the Lower Range field is left blank, greater than the length of the network mask length entered in the Filtered Network field.</td>
</tr>
</tbody>
</table>

Summary Address Tab

Use the Summary Address tab to configure summary addresses for each OSPF routing process. Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

Navigation Path

You can access the Summary Address tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF, page 53-2.

</tr>
</tbody>
</table>
Routing Information Protocol (RIP) is a dynamic routing protocol, or more precisely, an interior gateway protocol that is based on distance vectors. RIP uses hop count as the metric for path selection. When RIP is enabled on an interface, the interface exchanges RIP broadcast packets with neighboring devices to dynamically learn about and advertise routes. These RIP packets contain information about the destination networks that the gateways can reach, and the number of gateways that a packet must travel through to reach those destinations.

Cisco Security Manager supports both RIP version 1 and RIP version 2. Version 1 does not send the subnet mask with the routing update; RIP version 2 sends the subnet mask with the routing update, and supports variable-length subnet masks. Additionally, RIP version 2 supports neighbor authentication when routing updates are exchanged. This authentication ensures that the security appliance receives reliable routing information from a trusted source.

**Limitations**

RIP has the following limitations:

- Cisco Security Manager cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.

You cannot enable RIP if you have OSPF processes running.
RIP Version 2 Notes
The following information applies to RIP Version 2 only:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP version 2 updates to the interface.
- With RIP version 2, the security appliance transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP version 2 configuration is removed from an interface, that multicast address is unregistered.

Using Security Manager to Configure RIP on Security Appliances
Use the RIP page to enable the Routing Information Protocol on an interface. The settings and features available when configuring RIP depend on the type of device and OS version that you are configuring:

- To configure RIP on a PIX Firewall or ASA running an OS version earlier than 7.2, or on any FWSM, see RIP Page for PIX/ASA 6.3–7.1 and FWSM, page 53-23.
- To configure RIP on a PIX Firewall or ASA running OS version 7.2 or later, see RIP Page for PIX/ASA 7.2 and Later, page 53-25.

RIP Page for PIX/ASA 6.3–7.1 and FWSM
Use this RIP page to enable the Routing Information Protocol (RIP) on an interface in any FWSM, or in a PIX/ASA running a pre-7.2 version operating system.

The RIP table on this page lists all interfaces on which RIP is currently defined. Use the Add RIP Configuration and Edit RIP Configuration dialog boxes to create and maintain these entries. See RIP Page for PIX/ASA 6.3–7.1 and FWSM, page 53-23 for more information.

Navigation Path
- (Device view) Select Platform > Routing > RIP from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Routing > RIP from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

When creating a shared RIP policy, you must choose a Version in the Create a Policy dialog box, as follows:
- PIX/ASA 6.3-7.1 and FWSM
- PIX/ASA 7.2 and Later

When assigning a shared RIP policy, be sure to assign the appropriate RIP policy for the device. For example, you cannot assign a PIX/ASA 7.2+ RIP policy to an FWSM.

**RIP Page for PIX/ASA 7.2 and Later**

Use this RIP page to enable and configure the Routing Information Protocol (RIP) on PIX and ASA devices running operating system 7.2 or later. The RIP page consists of these tabbed panels:

- RIP - Setup Tab, page 53-26
- RIP - Redistribution Tab, page 53-27
- RIP - Filtering Tab, page 53-29
- RIP - Interface Tab, page 53-30

**Navigation Path**

- (Device view) Select **Platform > Routing > RIP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > RIP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

When creating a shared RIP policy, you must choose a Version in the Create a Policy dialog box, as follows:

- **PIX/ASA 6.3-7.1 and FWSM**
- **PIX/ASA 7.2 and Later**

When assigning a shared RIP policy, be sure to assign the appropriate RIP policy for the device. For example, you cannot assign a PIX/ASA 7.2+ RIP policy to an FWSM.

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Networks</td>
<td>Define one or more networks for RIP routing. Enter IP address(es), or enter or Select the desired Network/Host objects (see Understanding Network/Host Objects (IPv4 and IPv6), page 6-69); IP addresses must not contain any subnet information. There is no limit to the number of networks you can add to the security appliance configuration. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.</td>
</tr>
</tbody>
</table>
| Passive Interface | Use this option to specify passive interfaces on the security appliance, and by extension the active interfaces. The device listens for RIP routing broadcasts on passive interfaces, using that information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive, receive and send updates. Choose one of these options:  
  1. **None** – No interfaces are designated as passive.  
  2. **All Interfaces** – All interfaces on the device are designated as passive, except those entered the Excluded Interfaces field below.  
  3. **Specified Interfaces** – Only those interfaces explicitly specified in the Interfaces field below are designated as passive. |
Table 53-21  Setup Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Interfaces/Excluded Interfaces | Use this field to specify the interfaces excluded from the passive list, or those explicitly designated as passive, depending on your choice from the Passive Interface list above:  
  • If you chose All Interfaces, this field is labeled **Excluded Interfaces**: enter or Select only those interfaces to be excluded (that is, those that are to be active not passive).  
  • If you chose Specified Interfaces in the Passive Interface list, enter or Select those interfaces that are to be designated as passive.  
  **Note** You cannot specify two different RIP configurations for the same interface.                              |
| RIP Version                 | Choose the RIP versions for sending and receiving RIP updates:  
  • Receive Version 1 and 2, Send Version 1  
  • Send and Receive Version 1  
  • Send and Receive Version 2                                                                                                                                   |
| Generate Default Route      | When selected, a default route is generated for distribution, based on the Route Map you specify.                                                                                                                                                                                                                                     |
| Route Map                   | Specify the route map to use for generating default routes.  
  **Note** This field contains only the Route Map name. The Route Map is created and contained within a FlexConfig; see Chapter 7, “Managing FlexConfigs” for more information.                                                                                                                                                             |
| Enable Auto-Summary         | When Send and Receive Version 2 is the chosen RIP Version, this option is available. When checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.  
  **Note** RIP Version 1 always uses automatic summarization—you cannot disable it.                                                                               |

**RIP - Redistribution Tab**

Use the Redistribution panel to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process. See Add/Edit Redistribution Dialog Box, page 53-28 for more information.

**Navigation Path**

You can access the Redistribution tab from the RIP Page for PIX/ASA 7.2 and Later, page 53-25.

Configuring Static Routes

A static route is a specific path to a particular destination network that is manually defined on the current device. Static routes are used in a variety of situations, and can be a quick and effective way to route data from one network to another when there is no dynamic route to the destination, or when use of a dynamic routing protocol is not feasible.

All routes have a value or “metric” that represents its priority of use. (This metric is also referred to as “administrative distance.”) When two or more routes to the same destination are available, devices use administrative distance to decide which route to use.

For static routes, the default metric value is one, which gives them precedence over routes from dynamic routing protocols. If you increase the metric to a value greater than that of a dynamic route, the static route operates as a back-up in the event that dynamic routing fails. For example, Open Shortest Path First (OSPF)-derived routes have a default administrative distance of 100. To configure a back-up static route that is overridden by an OSPF route, specify a metric value for the static route that is greater than 100. This is referred to as a “floating” static route.

There is a special kind of static route known as a default route, or a “zero-zero” route because all zeroes are used for both the destination address and subnet mask. The default static route serves as a catch-all gateway: if there are no matches for a particular destination in the device’s routing table, the default route is used. The default route generally includes a next-hop IP address or local exit interface.

Use the Static Route page to maintain manually defined static routes. The Static Route table on this page lists all currently defined static routes, showing for each, the name of the interface or interface role for which the route is defined, the destination network(s), the next hop gateway, the route metric, whether the route is tunneled, and whether there is service-level agreement tracking for the route. For a detailed explanation of these fields, see Add/Edit Static Route Dialog Box, page 53-32 or Add/Edit IPv6 Static Route Dialog Box, page 53-33.
Configuring Static Routes

Navigation Path

- (Device view) Select **Platform > Routing > Static Route** or **Platform > Routing > IPv6 Static Route** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > Static Route** or **PIX/ASA/FWSM Platform > Routing > IPv6 Static Route** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

</tr>
<tr>
<td>Network</td>
<td>Enter or Select the destination network(s). You can provide one or more IP address/netmask entries, one or more Networks/Hosts objects, or a combination of both; separate the entries with commas. Enter “0.0.0.0/0” or “any” to specify a default route.</td>
</tr>
<tr>
<td>Gateway</td>
<td>Enter or Select the gateway router which is the next hop for this route. You can provide an IP address, or a Networks/Hosts object. <strong>Note</strong> If an IP address from one of the security appliance’s interfaces is used as the Gateway IP address, the security appliance will resolve the designated IP address in the packet instead of resolving the Gateway IP address.</td>
</tr>
</tbody>
</table>
Configuring Static Routes

Add/Edit IPv6 Static Route Dialog Box

The Add/Edit IPv6 Static Route dialog box lets you add or edit an IPv6 static route. IPv6 static routes are only supported on the following devices:

- ASA 7.0 and later (Routed mode)
- ASA 8.2 and later (Transparent mode)
- FWSM 3.1 and later (Routed mode)

**Navigation Path**

You can access the Add/Edit IPv6 Static Route dialog box from the IPv6 Static Route page. Click the **Add Row** button to add a new static route; select an existing static route and click the **Edit Row** button to edit that route.

**Related Topics**

- Configuring Static Routes, page 53-31
- Chapter 53, “Configuring Routing Policies on Firewall Devices”
Field Reference

<table>
<thead>

<td>Enter or Select the interface to which this static route applies.</td>
</tr>
<tr>
<td>IPv6 Network</td>
<td>Enter or Select the destination network(s). You can provide one or more IP address entries, one or more Networks/Hosts objects, or a combination of both; separate the entries with commas. Enter two colons (::) to specify a default route.</td>
</tr>
</tbody>
</table>
| IPv6 Gateway | Enter or Select the gateway router which is the next hop for this route. You can provide an IP address, or a Networks/Hosts object.  
**Note** If an IP address from one of the security appliance’s interfaces is used as the Gateway IP address, the security appliance will resolve the designated IP address in the packet instead of resolving the Gateway IP address. |
| Metric       | The Metric is a measurement of the “expense” of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. Because the hop count includes the destination network, all directly connected networks have a metric of 1. Enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1. The maximum number of equal-cost (equal-metric) routes that can be defined per interface is three. You cannot add a route with the same metric on different interfaces that are on the same network. |
| Tunneled     | Select this option to specify the route as the default tunnel gateway for VPN traffic. You can configure only one default tunneled gateway per device. Available only on ASA 7.0+ devices in routed mode. |
CHAPTER 54

Configuring Security Policies on Firewall Devices

You can configure general security settings for the device using the General page and the Timeouts page under Platform > Security. You can enable anti-spoofing on interfaces, configure IP fragment settings, and configure a variety of timeout values for the device.

This chapter contains the following topics:

- General Page, page 54-1
- Configuring Timeouts, page 54-4

General Page

Use the General page to configure security settings that help protect against malformed packets, spoofed packets, fragmented packets, and denial of service attacks. See Configuring Floodguard, Anti-Spoofing and Fragment Settings, page 54-2 for more information about the settings on this page.

Navigation Path

- (Device view) Select Platform > Security > General from the Device Policy selector.
- (Policy view) Select PIX/ASA/FWSM Platform > Security > General from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Chapter 54, “Configuring Security Policies on Firewall Devices”

<td>Check this box to disable Floodguard on the firewall device. This option is available only on PIX 6.3 and FWSM 2.x devices. See Configuring Floodguard, Anti-Spoofing and Fragment Settings, page 54-2 for more information about the Floodguard feature.</td>
</tr>
</tbody>
</table>

Global Fragment Settings

Use these options to configure global fragment settings for the device. You can override these settings for individual interfaces; see Add/Edit General Security Configuration Dialog Box, page 54-3 for more information.

<table>
<thead>
<tr>
<th>Enable Default Settings</th>
<th>Check this box to enable the default fragment settings fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size</td>
<td>Specify the maximum number of fragments that can be in the IP re-assembly database waiting for re-assembly. The default is 200.</td>
</tr>
<tr>
<td>Chain</td>
<td>Specify the maximum number of fragments into which a full IP packet can be fragmented. The default is 24 packets.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Specify the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.</td>
</tr>
</tbody>
</table>

Interface Configuration Table

This table lists all interfaces on which individual anti-spoofing and fragment settings have been defined. Refer to Configuring Floodguard, Anti-Spoofing and Fragment Settings, page 54-2 for more information about these settings. Refer to Add/Edit General Security Configuration Dialog Box, page 54-3 for more information about configuring these settings on individual interfaces.

Configuring Floodguard, Anti-Spoofing and Fragment Settings

Use the General page under Platform > Security to enable or disable Floodguard (on a PIX 6.3 or FWSM 2.x device), to enable Unicast Reverse Path Forwarding (anti-spoofing) on individual interfaces, and to configure IP fragment settings for the device, and for each interface of the device.

Floodguard

Floodguard lets you reclaim firewall resources if the user authentication subsystem runs out of resources. If an inbound or outbound uauth connection is being attacked or overused, the firewall will actively reclaim TCP user resources.

If the user authentication subsystem is depleted, TCP user resources in different states are reclaimed in the following order, depending on urgency:

1. Timewait
2. LastAck
3. FinWait
4. Embryonic
5. Idle

Floodguard is enabled by default. This option applies only to PIX 6.3 or FWSM 2.x devices.
Anti-spoofing

Unicast Reverse Path Forwarding (RPF) guards against IP spoofing—a packet using an incorrect source IP address to obscure its true source—by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the security appliance looks only at the destination address when determining where to forward the packet. Unicast RPF instructs the security appliance to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the security appliance, the security appliance routing table must include a route back to the source address. See RFC 2267 for more information.

With outside traffic, for example, the security appliance can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the security appliance uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, the security appliance drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the security appliance drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:
- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route look-up. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

Fragment Settings

Fragment settings provide management of packet fragmentation and improve compatibility with the Network File System (NFS). By default, the security appliance allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to allow fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the security appliance, as fragmented packets are often used as DoS attacks.

Related Topics
- General Page, page 54-1
- Add/Edit General Security Configuration Dialog Box, page 54-3

Add/Edit General Security Configuration Dialog Box

Use the Add/Edit General Security Configuration dialog box to enable or disable anti-spoofing, and to configure override fragment settings, for an interface.

Navigation Path

You can access the Add/Edit General Security Configuration dialog box from the Anti-Spoofing and Fragment Interface Configuration table on the Platform > Security > General Page, page 54-1.

Related Topics
- Chapter 54, “Configuring Security Policies on Firewall Devices”
- Configuring Floodguard, Anti-Spoofing and Fragment Settings, page 54-2
### Configuring Timeouts

The Timeouts page lets you set a variety of timeout values on the security appliance. All times are in the format `hh:mm:ss`.

These values represent idle timeouts for the connection and translation slots for various protocols. If a slot has not been used for the idle time specified, the resource is returned to the free pool. TCP connection slots are freed approximately 60 seconds after a normal connection close sequence.

**Warning**

We recommend that you do not change these values unless advised to do so by Customer Support.

#### Navigation Path

- (Device view) Select **Platform > Security > Timeouts** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Security > Timeouts** from the Policy Types selector. Select an existing policy from the Policies selector, or create a new one.

Configuring Service Policy Rules on Firewall Devices

This section describes configuring service policy rules. Service policies provide a consistent and flexible way to configure certain security appliance features, including priority queuing, application inspection, and QoS (quality of service). For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications.

Note

Detailed information regarding the range and implementation of particular service policies can be found on cisco.com. For example, the following references may be helpful:

- Using Modular Policy Framework
- QoS Configuration and Monitoring

This chapter contains the following topics:

- About Service Policy Rules, page 55-1
- About TCP State Bypass, page 55-3
- Priority Queues Page, page 55-4
- IPS, QoS, and Connection Rules Page, page 55-5
- Configuring Traffic Flow Objects, page 55-15
- Configuring TCP Maps, page 55-19

About Service Policy Rules

Service policy rules encompass these features:

- TCP and general connection settings (including TCP State Bypass; see About TCP State Bypass, page 55-3)
- Content security control (CSC)
- Application inspection
- Intrusion Prevention Services
- QoS queuing and policing
- CXSC redirection (see About CXSC, page 55-14)
- User statistics for identity-based firewall policies
About Service Policy Rules

The configuration options for these features are presented on two pages in Security Manager—Priority Queues and IPS, QoS and Connection Rules—accessed by navigating to Platform > Service Policy Rules.

Priority Queuing

Priority queuing establishes two queues on an interface, a Low Latency Queuing (LLQ) priority queue and a “best effort” queue. This lets you prioritize latency-sensitive traffic like voice and video, so it is transmitted ahead of other traffic. Packets in the priority queue are always transmitted before packets in the best effort queue.

Because queues are not of infinite size, they can fill and overflow. When a queue is full, additional packets cannot get into the queue and are dropped. This is called “tail drop.” To minimize tail drop, you can increase the queue buffer size. You can also fine-tune the maximum number of packets allowed into the transmit queue. These options let you control the latency and robustness of priority queuing.

Priority queuing is a Quality of Service (QoS) feature. In Security Manager, priority queue size and transmit queue size are managed on the Priority Queues Page, page 55-4, while establishment of priority queuing for a traffic class is an option on the QoS tab of the Service Policy (MPC) Rule Wizard, which is accessed from the IPS, QoS, and Connection Rules Page, page 55-5.

Application Inspection and QoS

Some applications require special handling by the security appliance, and specific application inspection engines are provided for this purpose. Specifically, applications that embed IP addressing information in the user data packet, or open secondary channels on dynamically assigned ports require special inspection.

Application inspection is enabled by default for many protocols, while it is disabled for others. In many cases, you can change the port which the application inspection engine monitors for traffic.

Application inspection engines work with network address translation (NAT) to help identify the location of embedded addressing information. This allows NAT to translate these embedded addresses, and to update any checksum or other fields that are affected by the translation.

Service policy rules define how specific types of application inspection are applied to different types of traffic processed by the security appliance. You can apply rules to specific interfaces, or globally to every interface.

These rules provide a means to configure security appliance features in a manner similar to the Cisco IOS software quality-of-service (QoS) CLI. For example, with service policy rules you can include IP Precedence as one of the criteria to identify traffic for rate-limiting. You can also create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications.

Traffic match criteria are used to define the types of traffic to which you want to apply application inspection. For example, TCP traffic on port 23 might be classified as the Telnet traffic class. You then might use the traffic class to apply connection limits.

Multiple traffic match criteria can be assigned to a single interface, but a packet will only match the first criteria within a specific service policy rule.
About TCP State Bypass

By default, all traffic that enters an ASA or FWSM is inspected using the Adaptive Security Algorithm, and is either allowed through or dropped based on the security policy. The device maximizes its firewall performance by checking the state of each packet—to determine whether this a new connection, or an established connection—and assigning it to the session management path (if it is a new connection SYN packet), the fast path (if it is an established connection), or the control-plane path (for advanced inspection).

Note

TCP State Bypass is available on FWSM 3.2+ and ASA 8.2+ devices only.

TCP packets that match existing connections in the fast path can pass through the appliance without every aspect of the security policy being rechecked. This feature maximizes performance. However, the method of establishing the session in the fast path using the SYN packet, and the checks that occur in the fast path (such as TCP sequence number), require that both outbound and inbound flows for a connection pass through the same device, which is not the case in asymmetric routing environments.

For example, assume a new connection is assigned to security device 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through device 1, then the packets match the entry in the fast path, and are passed through. But if subsequent packets go to device 2, where a SYN packet did not go through the session management path, there is no entry in the fast path for the connection, and the packets are dropped.

Thus, if you have asymmetric routing configured on upstream routers, and traffic alternates between two security devices, enable TCP state bypass for those specific traffic flows. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. TCP traffic is then treated much as a UDP connection is treated: when a non-SYN packet matching the specified networks enters the security device, and there is not a fast path entry, then the packet goes through the session management path to establish a connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.

Unsupported Features

The following features are not supported when you enable TCP state bypass:

- Application inspection – Application inspection requires both inbound and outbound traffic to go through the same security device, so application inspection is not supported with TCP state bypass.
- AAA authenticated sessions – When a user authenticates with one security device, traffic returning via the other security device will be denied because the user did not authenticate with that device.
- TCP Intercept, Maximum Embryonic Connections limit, TCP sequence number randomization – If TCP state bypass is enabled, the device does not keep track of the state of the connection, so these features are not applicable.
- Cisco CSC SSM (Content Security and Control Security Services Module) – SSM and SSC functionality cannot be used with TCP state bypass.

Compatibility with NAT

Because the translation session is established separately for each security device, be sure to configure static NAT on both devices for TCP state bypass traffic; if you use dynamic NAT, the address chosen for the session on device 1 will differ from the address chosen for the session on device 2.

- About Service Policy Rules, page 55-1
Priority Queues Page

Priority queues let you define how traffic is prioritized in the network. You can define a series of filters based on packet characteristics to cause traffic to be placed in a higher or lower priority queue. The queue with the highest priority is serviced first until it is empty, then the lower queues are serviced in sequence.

In Security Manager, priority queue size and transmit queue size are managed on this page, while establishment of priority queuing for a traffic class is an option on the QoS tab of the Service Policy (MPC) Rule Wizard, which is accessed from the IPS, QoS, and Connection Rules Page, page 55-5.

The Priority Queue Configuration dialog box is used to add and edit these queues. Refer to Priority Queue Configuration Dialog Box, page 55-4 for descriptions of the fields displayed in the Priority Queues table on this page.

**Note**
Priority queuing is not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

**Navigation Path**
- (Device view) Select **Platform > Service Policy Rules > Priority Queues** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Service Policy Rules > Priority Queues** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

IPS, QoS, and Connection Rules Page

Use the IPS, QoS, and Connection Rules page to define new service policy rules, and to edit or delete existing service policy rules.

Configuring IPS, QoS and Connection Rules consists of three tasks:

1. **Configure a service policy.** Create a service policy and determine the interfaces to which the service policy applies. For more information, see Step 1. Configure a Service Policy, page 55-6.

2. **Configure the traffic class.** Specify the criteria you want to use to identify the traffic to which the service policy applies. For more information, see Step 2. Configure the traffic class, page 55-7.

3. **Configure the actions.** Specify the actions that should be taken to protect information or resources, or to perform QoS functions for the traffic specified in this service policy. For more information, see Step 3. Configure the MPC actions, page 55-8.

The three tasks are performed using the Insert/Edit Service Policy (MPC) Rule Wizard, page 55-6. Refer to the individual task topics for descriptions of the fields displayed in the IPS, QoS and Connection Rules table on this page.

Navigation Path

- (Policy view) Select PIX/ASA/FWSM Platform > Service Policy Rules > IPS, QoS, and Connection Rules from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

CXSC Auth Proxy Configuration

The CXSC Auth Proxy button below the IPS, QoS, and Connection Rules table opens the Add/Edit CXSC Auth Proxy Configuration dialog box, which is described in CXSC Auth Proxy Configuration, page 55-15.

**Note**

The CXSC Auth Proxy button is available below the IPS, QoS, and Connection Rules table only in Device view; it is not visible in Policy view.
Insert/Edit Service Policy (MPC) Rule Wizard

Use the Insert/Edit Service Policy (MPC) Rule wizard to add and edit service policy rules on the IPS, QoS, and Connection Rules page. The Insert/Edit Service Policy (MPC) Rule wizard presents the following steps:

- Step 1. Configure a Service Policy, page 55-6
- Step 2. Configure the traffic class, page 55-7
- Step 3. Configure the MPC actions, page 55-8

Note

“MPC” refers to what is now called the Modular Policy Framework. Refer to Using Modular Policy Framework for additional information.

Navigation Path

Open the Insert/Edit Service Policy (MPC) Rule wizard by clicking the Add Row or Edit Row button on the IPS, QoS, and Connection Rules Page, page 55-5.

Step 1. Configure a Service Policy

The first step in using the Insert/Edit Service Policy (MPC) Rule Wizard to configure an IPS, QoS and Connection Rule involves enabling the rule and specifying the interface(s) to which it is applied.

Navigation Path

Open the Insert/Edit Service Policy (MPC) Rule wizard by clicking the Add Row or Edit Row button on the IPS, QoS, and Connection Rules Page, page 55-5.

Related Topics

- Step 2. Configure the traffic class, page 55-7
- Step 3. Configure the MPC actions, page 55-8
Step 2. Configure the traffic class

The second step in using the Insert/Edit Service Policy (MPC) Rule Wizard to configure an IPS, QoS and Connection Rule involves specifying the traffic class to which the rule is applied.

Specify the class to use to match traffic for this rule:

- **Use class-default As The Traffic Class**—Select this option to use the traffic class `class-default` for this service policy. The class-default traffic class matches all traffic.

- **Traffic Class**—Select this option to apply this rule to a specific traffic class. Enter the name of the previously defined traffic class, or click **Select** to select it from the Traffic Flows Selector.

You also can define or edit a traffic flow “on the fly” by clicking the either Create or Edit buttons in the Traffic Flows Selector. (Traffic flows are also created and edited on the Traffic Flows page of the Policy Object Manager.) See **Configuring Traffic Flow Objects**, page 55-15 for more information.

**Related Topics**

- **Step 1. Configure a Service Policy**, page 55-6
- **Step 3. Configure the MPC actions**, page 55-8
Step 3. Configure the MPC actions

The third step in the Insert/Edit Service Policy (MPC) Rule Wizard involves specifying IPS, CXSC, Connection Setting, QoS, CSC, and User Statistics parameters for the rule; each set of parameters is presented on a separate tabbed panel.

Related Topics

- Step 1. Configure a Service Policy, page 55-6
- Step 2. Configure the traffic class, page 55-7

<tr>
<td>Enable IPS for This Traffic</td>
<td>Enables or disables intrusion prevention for this traffic flow. When this box is checked, the other parameters on this panel are available. Note: These parameters are applicable only on ASA 7.0+ devices that have an IPS module installed. See About IPS Modules on ASA Devices, page 55-12 for more information.</td>
</tr>
<tr>
<td>IPS Mode</td>
<td>Select the operating mode for intrusion prevention:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Inline</strong>—This mode places the IPS module directly in the traffic flow. No traffic that you identified for IPS inspection can continue through the ASA without first passing through, and being inspected by, the IPS module. This mode is the most secure because every packet identified for inspection is analyzed before being allowed through. Also, the IPS module can implement a blocking policy on a packet-by-packet basis. However, this mode can affect throughput.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Promiscuous</strong>—This mode sends a duplicate stream of traffic to the IPS module. This is less secure than Inline mode, but has little impact on traffic throughput. Unlike Inline mode, in Promiscuous mode the IPS module cannot drop the original packets, it can only block traffic by instructing the ASA to shun the traffic, or by resetting the connection on the appliance. Also, while the IPS module is analyzing the traffic, a small amount of traffic may pass through the ASA before the IPS module can shun it.</td>
</tr>
<tr>
<td>On IPS Card Failure</td>
<td>Specify the action to be taken if the IPS module becomes inoperable. Select either:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Open</strong>—Permits traffic if the module or card fails.</td>
</tr>
<tr>

<td>- <strong>Close</strong>—Blocks traffic if the module or card fails.</td>
</tr>
<tr>
<td><strong>CXSC tab</strong></td>
<td></td>
</tr>
<tr>
<td>Enable CXSC For This Traffic</td>
<td>Check this box to enable redirection of this traffic flow to a Context Security Card (CXSC) installed in the ASA. When this box is checked, the other parameters on this panel are available. Note: These parameters are applicable only on ASA 5585 devices running version 8.4.(4)+ that have a Context Security Card installed.</td>
</tr>
</tbody>
</table>
Table 55-3 Insert/Edit Service Policy (MPC) Rule Wizard—Step 3. Configure the actions.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On Context Security Card Failure</td>
<td>Specify the action to be taken if the CXSC card becomes inoperable. Select either:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Open</strong> – If the CXSC fails for any reason, the ASA will continue to pass traffic that would otherwise be redirected to the CXSC.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Close</strong> – If the CXSC, the ASA will drop any traffic that would otherwise be redirected to the CXSC.</td>
</tr>
<tr>
<td>Enable Auth Proxy</td>
<td>Check this box to enable the authentication proxy, which is required if you want to use active authentication in the identity policies on the CXSC. If not checked, only passive authentication is performed.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> You can change the port used for authentication proxy; see CXSC Auth Proxy Configuration, page 55-15 for more information.</td>
</tr>
<tr>
<td>Connection Settings tab</td>
<td>Enables or disables connection settings for this traffic flow. When this box is checked, the other parameters on this panel become active. From the Connection Settings tab you can configure maximum connections, embryonic connections, timeouts, and TCP parameters.</td>
</tr>
<tr>
<td>Maximum Connections</td>
<td>You can specify the maximum number of TCP and UDP connections, and the maximum number of embryonic connections for this traffic flow:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Maximum TCP &amp; UDP Connections</strong> – Specify the maximum number of simultaneous TCP and UDP connections for the entire subnet, up to 65,536. The default is zero for both protocols, which means the maximum possible connections are allowed.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Maximum TCP &amp; UDP Connections Per Client</strong> – For ASA/PIX 7.1+ only; specify the maximum number of simultaneous TCP and UDP connections on a per client basis.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Maximum Embryonic Connections</strong> – For ASA/PIX 7.0+ only; specify the maximum number of embryonic connections per host, up to 65,536. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. This limit enables the TCP Intercept feature. The default is zero, which means the maximum embryonic connections. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server. This feature is not applicable if TCP State Bypass is enabled.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Maximum Embryonic Connections Per Client</strong> – For ASA/PIX 7.1+ only; specify the maximum number of embryonic connections on a per client basis. This feature is not applicable if TCP State Bypass is enabled.</td>
</tr>
</tbody>
</table>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Timeouts</td>
<td>You can specify the following connection timeout settings for this traffic flow:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Embryonic Connection Timeout</strong> – Specify the idle time until an embryonic connection slot is freed. Enter 0:0:0 to disable timeout for the connection. The default is 20 seconds for FWSMs, and 30 seconds for ASA/PIX devices.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Half Closed Connection Timeout</strong> – Specify the idle time until a half-closed connection slot is freed. Enter 0:0:0 to disable timeout for the connection.</td>
</tr>
<tr>
<td></td>
<td>For FWSMs, the default value is 20 seconds; the maximum value is 255 seconds (four minutes, 15 seconds). For ASA/PIX devices, this duration must be at least 5 minutes; the default is 10 minutes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>TCP Connection Timeout</strong> – Specify the idle time until a connection slot is freed. Enter 0:0:0 to disable timeout for the connection. This duration must be at least 5 minutes. The default is 1 hour.</td>
</tr>
<tr>
<td>Reset Connection Upon Timeout</td>
<td>If selected, connections are reset after a timeout occurs. Available for ASA/PIX 7.0(4)+ only.</td>
</tr>
<tr>
<td>Detect Dead Connections</td>
<td>Enables the Dead Connection Detection feature; available for ASA/PIX 7.2+ devices. Selecting this option enables these two fields:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Dead Connection Detection Timeout</strong> – Specify the period of time between retries when a dead connection is detected. The default is 15 seconds.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Dead Connection Detection Retries</strong> – Specify the number of retries to be performed after a dead connection is detected. The default is five.</td>
</tr>
<tr>
<td>Traffic Flow Idle Timeout</td>
<td>Specify the period of time between a traffic flow becoming idle and the flow's disconnection. Applicable to FWSM 3.2+ only. The default is 1 hour.</td>
</tr>
<tr>
<td>Enable TCP Normalization</td>
<td>Enables TCP normalization, and activates the TCP Map selection option. Applies to ASA/PIX 7.0+ only; not applicable if TCP State Bypass is enabled.</td>
</tr>
<tr>
<td>TCP map</td>
<td>Specify the TCP map to use for TCP normalization: enter or Select the name of a TCP map. For more information, see Configuring TCP Maps, page 55-19.</td>
</tr>
<tr>
<td>Randomize TCP Sequence Number</td>
<td>Enables the Randomize Sequence Number feature. Disable this feature only if another inline security appliance is also randomizing sequence numbers and the result is scrambling the data. Each TCP connection has two Initial Sequence Numbers: one generated by the client and one generated by the server. The security appliance randomizes the ISN that is generated by the host/server on the higher security interface. At least one ISN must be randomly generated so that attackers cannot predict the next ISN and potentially hijack the session. Not applicable if TCP State Bypass is enabled.</td>
</tr>
</tbody>
</table>
### Table 55-3  Insert/Edit Service Policy (MPC) Rule Wizard—Step 3. Configure the actions.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable TCP State Bypass</td>
<td>Enables TCP state bypass for this traffic flow. This is allows specific traffic flows in asymmetric routing environments when both the outbound and inbound flow for a connection do not pass through the same device. Applicable to FWSM 3.2+ and ASA 8.2+ only. See About TCP State Bypass, page 55-3 for more information.</td>
</tr>
<tr>
<td>Enable Decrement TTL</td>
<td>Select this option to turn on decrementing of the time-to-live (TTL) value in packets passed by the security appliance. Applicable to PIX/ASA 7.2.2+ only.</td>
</tr>
<tr>
<td>QoS tab</td>
<td></td>
</tr>
<tr>
<td>Enable QoS For This Traffic</td>
<td>Enables Quality of Service (QoS) options for this traffic flow. When selected, the Enable Priority For This Flow and the Traffic Policing options become active. Note The options on this tab are applicable to PIX/ASA 7.0+ devices only.</td>
</tr>
<tr>
<td>Enable Priority For This Flow</td>
<td>Enables strict scheduling priority for this flow. The priority queues must be defined on the Priority Queues Page, page 55-4.</td>
</tr>
<tr>
<td>Traffic Policing</td>
<td>Enables output and input traffic policing. Traffic policing lets you control the maximum rate of traffic transmitted or received on an interface.</td>
</tr>
<tr>
<td>Output (Traffic Policing)</td>
<td>Enables policing of traffic flowing out of the device. If you enable policing, you can specify the following values:</td>
</tr>
<tr>
<td></td>
<td><strong>Committed Rate</strong> – The rate limit for this traffic flow; this is a value in the range 8,000 to 2,000,000,000, specifying the maximum speed (bits per second) allowed.</td>
</tr>
<tr>
<td></td>
<td><strong>Burst Rate</strong> – A value in the range 1,000 to 512,000,000 that specifies the maximum number of instantaneous bytes allowed in a sustained burst before throttling to the conforming rate value.</td>
</tr>
<tr>
<td></td>
<td><strong>Conform Action</strong> – The action to take when the rate is less than the conform-burst value. Choices are Transmit or Drop.</td>
</tr>
<tr>
<td></td>
<td><strong>Exceed Action</strong> – Take this action when the rate is between the conform-rate value and the conform-burst value. Choices are Transmit or Drop.</td>
</tr>
</tbody>
</table>
You can install a variety of IPS modules, such as the Advanced Inspection and Prevention Security Services Module (AIP-SSM), in some ASA device models. The IPS modules supported by each ASA model differ. The IPS modules run advanced IPS software that provides proactive, full-featured intrusion prevention services to stop malicious traffic, including worms and network viruses, before they can affect your network.

The ASA IPS module runs separately from the adaptive security appliance, and you need to add it to the device inventory as a separate device. It is, however, integrated into the ASA traffic flow.
When you configure the ASA IPS module, you need to configure the service policy rules on the host ASA as well as the IPS policies on the IPS module. The service policy rules determine which traffic is inspected by the IPS module. For an overview of IPS policy configuration, see Overview of IPS Configuration, page 34-5.

When you identify traffic for IPS inspection, the traffic flows through the ASA and the IPS module as follows:

1. Traffic enters the ASA.
2. Firewall policies, such as interface access rules, are applied.
3. Traffic is sent to the IPS module over the backplane when you operate in inline mode. If you configure the system to use promiscuous mode, a copy of the traffic is sent to the IPS module. See IPS Mode in the Intrusion Prevention section of the Insert/Edit Service Policy (MPC) Rule wizard (Step 3. Configure the MPC actions, page 55-8) for more information about Inline and Promiscuous modes.
4. The IPS module applies its security policy to the traffic and takes appropriate actions.
5. Allowed traffic is sent back to the adaptive security appliance over the backplane. In Inline mode, the IPS module may block some traffic according to its security policy; in other words, that traffic is not passed back.
6. VPN policies are applied (if configured).
7. Traffic exits the ASA.

The following illustration depicts traffic flow when running the IPS module in Inline mode. In this example, the IPS module automatically blocks traffic that it identifies as an attack. All other traffic is returned to the ASA.

The next illustration depicts traffic flow when the IPS module is running in Promiscuous mode. In this example, the IPS module sends a shun message to the ASA for traffic it has identified as a threat.
About CXSC

The CXSC is a ConteXi-aware Security Card that can be installed in the Cisco ASA-5585-X Series Adaptive Security Appliance. You configure the parent ASA to redirect traffic to the CXSC, which then applies its security policies and either drops the traffic, or returns it to the ASA for further processing and routing to the next destination.

Note

The CXSC can be installed on ASA 5585 version 8.4.(4)+ devices only.

There are two basic policies that may need adjustment in the ASA when you add a CXSC: access rules and inspection rules:

- Access rules, whether global rules or those applied to specific interfaces, are always applied before traffic is redirected to the CXSC. Thus, the security card sees only the traffic already permitted, and does not process traffic that was dropped at entry to the ASA. Consider adjusting the rules to ensure that all traffic that you want the CXSC to process is permitted.

- Inspection rules determine which traffic is inspected. The CXSC does not inspect traffic that has already been inspected by the ASA. Therefore, you must ensure that you do not inspect traffic that you intend for the CXSC to inspect. Specifically, do not inspect HTTP traffic, because HTTP inspection is one of the core functions of the CXSC. The default inspection rules on the ASA do not include HTTP inspection, so you must alter your inspection rules only if you added HTTP rules.

Determine if you need to create access rules for an interface, or global access rules that apply to all interfaces. Use the ASA access rules to pre-filter traffic before it is redirected to the CXSC. If you know there are classes of traffic that you never want to pass, it is more efficient to drop them immediately upon entry to the ASA.

If you have already established access rules, there is no requirement to change them. However, you should evaluate whether they might need to be relaxed in order to have the CXSC process certain types of traffic that you are now dropping by means of access rules.
Enabling traffic redirection to an installed CXSC is described in Step 3, Configure the MPC actions, page 55-8 of the Insert/Edit Service Policy (MPC) Rule Wizard, page 55-6.

## CXSC Auth Proxy Configuration

If you enabled Context Security Card (CXSC) authentication proxy—on the CXSC tab during Step 3 of the Insert/Edit Service Policy (MPC) Rule Wizard; see Step 3, Configure the MPC actions, page 55-8—and you want to use a non-default port for active authentication, use the Add/Edit CXSC Auth Proxy Configuration dialog box to change the CXSC Auth Proxy Port number.

If users must be prompted for authentication credentials, the prompting is done through this port.

**Navigation Path**

Open the Add/Edit CXSC Auth Proxy Configuration dialog box by clicking the CXSC Auth Proxy button below the rules table on the IPS, QoS, and Connection Rules Page, page 55-5.

**Note**
The CXSC Auth Proxy button is available below the IPS, QoS, and Connection Rules table only in Device view; it is not visible in Policy view.

Related Topics
- IPS, QoS, and Connection Rules Page, page 55-5

## Configuring Traffic Flow Objects

Use the Add and Edit Traffic Flow dialog boxes to configure traffic-match definitions. These traffic-flow definitions correspond to class maps (the `class map` command) in the IPS, QoS and Connection Rules service policy for devices running the PIX 7.0+, ASA 7.0+, and FWSM 3.2+ operating systems. For more information on configuring these rules, see Chapter 55, “Configuring Service Policy Rules on Firewall Devices”.

**Navigation Path**

Select Manage > Policy Objects, then select Traffic Flows from the Object Type selector. Right-click inside the work area and choose New Object, or right-click a row and choose Edit Object.

These dialog boxes also can be opened by clicking the Create or Edit buttons in the Traffic Flows Selector while defining a Service Policy rule. See for Step 2, Configure the traffic class, page 55-7 more information about selecting a Traffic Flow class.

<td>• Default Inspection Traffic – Matches default inspection traffic. For a list of default settings, see Default Inspection Traffic, page 55-17.</td>
</tr>
<tr>
<td></td>
<td>• Default Inspection Traffic with access list – Matches default inspection traffic limited by the access control list that you specify.</td>
</tr>
<tr>
<td></td>
<td>• TCP or UDP Destination Port – Matches traffic to the TCP or UDP destination port or port range that you specify. Valid port numbers here are 0 to 65535.</td>
</tr>
<tr>
<td></td>
<td>• RTP Range – Matches traffic to the range of UDP destination ports that you specify. Valid port numbers here are 2000 to 65535.</td>
</tr>
<tr>
<td></td>
<td>• Tunnel Group – Matches the destination address based on flows in VPN tunnels belonging to a specified tunnel group.</td>
</tr>
<tr>
<td></td>
<td>• IP Precedence Bits – Matches precedence values assigned to the traffic packets. You can select a maximum of four values.</td>
</tr>
<tr>
<td></td>
<td>• IP DiffServ Code Points (DSCP) Values – Matches DSCP values associated with the traffic packets. You can select a maximum of eight values.</td>
</tr>
</tbody>
</table>

### Variable Fields

The following fields may appear in the Add and Edit Traffic Flow dialog boxes, depending on your choice in the Traffic Match Type field. This list is the complete set of possible fields.

| Available ACLs | A list of the access control list (ACL) objects that you can select for the map. Select the ACL that defines the target traffic, or click the Create button to add a new object. You can also select an object and click Edit to change its definition. If the list of objects is large, use the Filter field to limit the display (see Filtering Items in Selectors, page 1-41). |

</tbody>
</table>
Configuring TCP Maps

Use the Add and Edit TCP Map dialog boxes to define TCP normalization maps for use with IPS, QoS, and Connection Rules service policies. The TCP normalization feature lets you specify criteria that identify abnormal packets, which the security appliance drops when they are detected. The map is used for TCP traffic that passes through the device or that is going to the device.

These TCP maps can be applied to TCP flows on PIX 7.x+ and ASA devices. For more information on configuring IPS, QoS, and Connection Rules, see Chapter 55, “Configuring Service Policy Rules on Firewall Devices”.

Navigation Path
Select Manage > Policy Objects, then select Maps > TCP Maps from the Object Type selector. Right-click inside the work area and choose New Object, or right-click a row and choose Edit Object.

These dialog boxes also can be opened by clicking the Create or Edit buttons in the TCP Maps Selector while defining a Service Policy rule. See the “Connection Settings” section of Step 3. Configure the MPC actions, page 55-8 for more information about enabling TCP normalization and selecting a TCP map.

Table 55-7  Add and Edit TCP Map Dialog Boxes

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the TCP normalization map. A maximum of 128 characters is allowed.</td>
</tr>
<tr>
<td>Description</td>
<td>A description of the map object. A maximum of 1024 characters is allowed.</td>
</tr>
</tbody>
</table>
| Queue Limit (ASA devices only) | The maximum number of out-of-order packets that can be buffered and put in order for a TCP connection; enter a value between 1 and 250. Enter 0 to disable this setting and use the default system queue limit, which depends on the type of traffic:  
  - Connections for application inspection, IPS, and TCP check-retransmission have a queue limit of 3 packets. If the security appliance receives a TCP packet with a different window size, then the queue limit is dynamically changed to match the advertised setting.  
  - For other TCP connections, out-of-order packets are passed through untouched.  
However, if you set the Queue Limit to 1 or higher, the number of out-of-order packets allowed for all TCP traffic matches the specified value. For application inspection, IPS, and TCP check-retransmission traffic, any advertised settings are ignored. For other TCP traffic, out-of-order packets are now buffered and put in order instead of passed through untouched. |
| Time Out (ASA 7.2(4)+ devices only) | The maximum amount of time that out-of-order packets can remain in the buffer before they are dropped; enter a value between 1 and 20 seconds. The default is 4 seconds. This setting is ignored if you entered 0 for the Queue Limit. |
### Table 55-7 Add and Edit TCP Map Dialog Boxes (Continued)

<table>
<thead>
<tr>

<td>If checked, TCP SYN packets that include data are dropped.</td>
</tr>
<tr>
<td>Drop Connection on Window Variation</td>
<td>If checked, connections that change window size unexpectedly are dropped.</td>
</tr>
<tr>
<td>Drop Packets that Exceed Maximum Segment Size</td>
<td>If checked, packets that exceed the maximum segment size (MSS) set by a peer are dropped.</td>
</tr>
<tr>
<td>Check if Transmitted Data is the Same as Original</td>
<td>If checked, retransmit data checking is enabled.</td>
</tr>
<tr>
<td>Clear Urgent Flag</td>
<td>If checked, the URG (urgent) flag is cleared through the security appliance. The URG flag is used to indicate that the packet contains information that is of higher priority than other data within the stream. The TCP RFC is vague about the exact interpretation of the URG flag; therefore end systems handle urgent offsets in different ways, which may make the end system vulnerable.</td>
</tr>
<tr>
<td>Clear Selective Ack</td>
<td>Whether the selective acknowledgment mechanism (SACK) option is cleared or allowed.</td>
</tr>
<tr>
<td>Clear TCP Timestamp</td>
<td>Whether the timestamp option, which disables PAWS and RTT, is cleared or allowed.</td>
</tr>
<tr>
<td>Clear Window Scale</td>
<td>Whether the window scale timestamp option is cleared or allowed.</td>
</tr>
<tr>
<td>Enable TTL Evasion Protection</td>
<td>Enables the TTL evasion protection offered by the security appliance. Do not enable this option if you want to prevent attacks that attempt to evade security policy. For example, an attacker can send a packet that passes policy with a very short TTL. When the TTL goes to zero, a router between the security appliance and the endpoint drops the packet. It is at this point that the attacker can send a malicious packet with a long TTL that appears to the security appliance to be a retransmission and is passed. To the endpoint host, however, it is the first packet that has been received. In this case, an attacker is able to succeed without security preventing the attack.</td>
</tr>
<tr>
<td>Reserved Bits</td>
<td>Specify how to handle TCP packets with the reserved bits set in the TCP header. The six reserved bits in the TCP header are for future use and usually have a value of 0.</td>
</tr>
<tr>
<td></td>
<td>- Clear and Allow—Clears the reserved bits in the TCP header and allows the packet.</td>
</tr>
<tr>
<td></td>
<td>- Allow only—Permits packets with the reserved bits set in the TCP header.</td>
</tr>
<tr>
<td></td>
<td>- Drop—Drops packets with the reserved bits set in the TCP header.</td>
</tr>
</tbody>
</table>
Add and Edit TCP Option Range Dialog Boxes

Use the Add and Edit TCP Option Range dialog boxes to define or edit a range of TCP options for use with a TCP normalization map; these are TCP options not explicitly supported on the device. This feature lets you allow or discard packets with the specified TCP options set. The typical range numbers are 6-7 and 9-255.

Navigation Path
In the Add and Edit TCP Map dialog boxes, right-click inside the TCP Range Options table and choose Add Row, or right-click an existing row and choose Edit Row. See Configuring TCP Maps, page 55-19.

Field Reference

Table 55-8  Add and Edit TCP Option Range Dialog Boxes

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Lower     | The lower bound of the range; enter either 6 or 7, or an integer from 9 to 255.  
  **Note** The Lower bound must be less than or equal to the Upper bound.  |
| Upper     | The upper bound of the range; enter either 6 or 7, or an integer from 9 to 255.  |
| Action    | Choose the action to take for packets with the specified options set:  
  • Allow – Allows any packet with a specified option set.  
  • Clear – Clears the specified option from any packet that has it set and allows the packet.  
  • Drop – Discards any packet with a specified option set.  |
Chapter 55 Configuring Service Policy Rules on Firewall Devices

Configuring TCP Maps
Configuring Security Contexts on Firewall Devices

You can define multiple security “contexts” on a single security appliance. Each context operates as an independent virtual device, with its own security policy, interfaces and administrators. Multiple contexts are similar to having multiple stand-alone devices. Many features are supported in multiple-context mode, including routing tables, firewall features, IPS, and management. Some features are not supported; for example, VPN, multicast, and dynamic routing protocols; security contexts support only static routes; and you cannot enable OSPF or RIP in multiple-context mode. Also, some features are not directly managed by Cisco Security Manager, such as the IPS feature set for ASA and PIX devices.

In multiple-context mode, the security appliance includes a configuration for each context that identifies the security policy, interfaces, and most of the options you can configure on a stand-alone device. The system administrator adds and manages contexts by configuring them in the system configuration, which, like a single-mode configuration, is the start-up configuration. The system configuration identifies basic settings for the security appliance, but it does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses the context that is designated as the Admin context. The system configuration is used to add, delete and edit basic context settings, including allocating network interfaces to the various contexts.

The Admin context is just like any other context, except that when a user logs in to the Admin context, that user has system administrator rights and can access the system configuration and all other contexts.

This chapter contains the following topics:

- Enabling and Disabling Multiple-Context Mode, page 56-1
- Checklist for Configuring Multiple Security Contexts, page 56-2
- Managing Security Contexts, page 56-4

Enabling and Disabling Multiple-Context Mode

Cisco Security Manager does not support switching to multiple-context mode on an existing device. To perform this task, you must delete the device from Security Manager, enable multiple-context mode using a device manager or CLI input, and then add the device again to Security Manager. After the device is added in multiple-context mode, you can add, edit and delete security contexts.

Note

When manually defining a multiple-context device, choose Multi from the Contexts list in the Operating System section of the New Device - Device Information dialog box.
Similarly, Cisco Security Manager does not support restoring an existing device to single-context mode. To perform this task, you must delete the device and any of its child contexts from Security Manager, restore single-context operation using a device manager or CLI input, and then add the device again to Security Manager.

**Note**

When manually defining a single-context device, choose Single from the Contexts list in the Operating System section of the New Device - Device Information dialog box.

## Checklist for Configuring Multiple Security Contexts

Security contexts allow a single physical device to act as multiple independent firewalls. Each security context defines a single virtual firewall, complete with its own configuration—and just as with physical devices, each security context must be correctly configured, or overall security can be compromised. Thus, defining and configuring multiple firewalls on the same physical appliance requires special care.

The following checklist outlines the basic steps necessary to configure a firewall device with multiple security contexts. Each of these steps may involve multiple substeps; all steps should be performed in the order presented. For example, you must define interfaces before configuring the various contexts.
<table>
<thead>
<tr>
<th>Step</th>
<th>Task</th>
</tr>
</thead>
</table>
| **Step 1** | Define interfaces and subinterfaces, or VLANs, on the physical appliance.  
In this task, you define the interfaces and subinterfaces, or VLANs on FWSMs, that will be allocated to the various security contexts when you create them later. Provide physical interface parameters, such as connection type (Ethernet, GigabitEthernet, etc.), hardware Port ID, speed, and duplex mode, as well as VLAN ID if defining a subinterface.  
**Result:** All interfaces and subinterfaces are defined.  
For more information, see Configuring Firewall Device Interfaces, page 44-2. |
| **Step 2** | Define an Admin context for administering the base security appliance.  
This task is called out separately to ensure you define a context and IP address specifically for administration of the security appliance. The process is the same as defining a security context; however, during the process, be sure to check **Admin Context** to designate this as the administration context.  
In addition to being used to administer the appliance, the Admin context is used to publish syslog and SNMP messages to monitoring devices, such as the Cisco Security Monitoring, Analysis and Response System (CS-MARS), for further processing.  
Until you associate a specific management IP address with the Admin context, the IP address used to manage the security appliance is the one you specified when defining the device. When you specify a Management IP Address with the Admin context, it takes precedence over the one on the Device Properties page.  
**Result:** The Admin context is defined and associated with a physical interface.  
For more information, see:  
- Add/Edit Security Context Dialog Box (PIX/ASA), page 56-7  
- Add/Edit Security Context Dialog Box (FWSM), page 56-5 |
| **Step 3** | Define each security context, or virtual firewall, on the base appliance.  
In this task, you define individual security contexts, naming each, assigning a location for its configuration files, and allocating interfaces. Each security context represents a virtual firewall, and its definition includes the interfaces and range of associated VLAN IDs that are under its control.  
**Note** While the Admin context can operate as a firewall device, it is typically used as such only in single-context mode. Therefore, security contexts are treated as separate entities in this checklist.  
You cannot add new interfaces or modify the hardware Port value when defining a security context—you simply select previously defined interfaces for allocation to the context.  
**Result:** Each security context is defined and associated with a physical interface; the VLANs on which the security context will inspect traffic are also specified.  
For more information, see:  
- Add/Edit Security Context Dialog Box (PIX/ASA), page 56-7  
- Add/Edit Security Context Dialog Box (FWSM), page 56-5 |
Managing Security Contexts

The Security Contexts page lists security contexts configured for the selected device. You can add, edit and delete security contexts for an ASA, PIX 7.0+, or FWSM device running in multiple-context mode from this page.

Deleting a security context from an FWSM device removes the security context from the running configuration of the device, but it does not delete the associated configuration file. This can cause problems if you later add another security context with the same name as the one previously deleted. This is a known issue for FWSM and is not connected to the behavior of Security Manager. A work-around is to use the CLI to delete the configuration file from the device.

Remember, the security appliance must be in multiple-context mode in order for you to configure contexts using Security Manager. See Enabling and Disabling Multiple-Context Mode, page 56-1 for more information.

### Tip
Deleting a security context from an FWSM device removes the security context from the running configuration of the device, but it does not delete the associated configuration file. This can cause problems if you later add another security context with the same name as the one previously deleted. This is a known issue for FWSM and is not connected to the behavior of Security Manager. A work-around is to use the CLI to delete the configuration file from the device.

### Step 4
Submit/deploy to generate the virtual firewalls as children of the base appliance.

You must create the desired contexts on the security appliance before you can begin defining the individual settings of each context. To create contexts on the appliance, you must define them, and then either submit changes in Workflow mode, or deploy the changes to the security appliance in non-Workflow mode.

When you create a security context, a “virtual firewall device” appears beneath the original security appliance in the Device View. Each virtual device is indicated by a related device icon with a dotted outline, and its name is the base security appliance name, underscore (_), context name. For example, the virtual device `asaMultiRouted_admin` would represent the Admin context (named “admin”) on the security appliance named “asaMultiRouted.” Similarly, `asaMultiRouted_security1` would represent the security context “security1” on the same base appliance.

**Result:** Your changes are submitted or deployed (depending on the Workflow mode), which in turn creates the Admin and security contexts as children of the base security appliance.

For more information, see:
- Workflow and Activities Overview, page 1-17
- Submitting an Activity for Approval (Workflow Mode with Activity Approver), page 4-19
- Working with Deployment and the Configuration Archive, page 8-24

### Step 5
Define additional settings for each security context.

You can now complete the definition of each security context by selecting a virtual firewall device in the Device Selector and editing available policies, such as access rules, translation options and so on.

**Result:** Each security context is fully defined, ready to operate as a virtual firewall.
Follow these steps to manage security contexts:

**Step 1** Ensure Device View is your present application view; if necessary, click the **Device View** button on the toolbar.

For more information on using the Device View to configure device policies, see **Managing Policies in Device View and the Site-to-Site VPN Manager**, page 5-28).

**Step 2** Select the appliance you want to configure.

**Step 3** Select **Security Contexts** in the Device Policy selector to display the Security Contexts page.

*Note* The child contexts of a multiple-mode device are represented using a different icon than firewall devices in single mode.

**Step 4** Add, edit and delete contexts, as necessary:

- To define a new context, click the **Add Row** button at the bottom of the page to open the Add Security Context box.

- To edit an existing context, select the desired entry in the Security Contexts list and then click the **Edit Row** button at the bottom of the page to open the Edit Security Context dialog box.

- To delete an existing context, select the desired entry in the list and then click the **Delete Row** button.

*Note* Deleting a security context here will also cause the security context device to be removed from device inventory.

Confirm the deletion of the security context and corresponding security context device.

*Note* Except for the titles, the Add Security Context dialog box and the Edit Security Context dialog box are identical. For PIX/ASA devices, see **Add/Edit Security Context Dialog Box (PIX/ASA)**, page 56-7 for more information; for FWSMs, see **Add/Edit Security Context Dialog Box (FWSM)**, page 56-5 for more information.

**Add/Edit Security Context Dialog Box (FWSM)**

The Add Security Context and Edit Security Context dialog boxes let you define and maintain contexts for the currently selected Firewall Service Module. (Except for their titles, the two dialog boxes are identical.)

Note that at least one security context must be designated as the Admin context.

*Caution* Security Manager does not support mapped (that is, “named” or “aliased”) interfaces for FWSMs. If you discover an FWSM with named interfaces and then change the related configuration, redeployment will fail. Replace any interface aliases with the appropriate VLAN IDs.
Navigation Path

You can access the Add Security Context and Edit Security Context dialog boxes from the Security Contexts page, as described in Managing Security Contexts, page 56-4.

<td>Suffix Range From/To</td>
<td>If you specified a range of subinterfaces, these fields are available to let you specify numeric suffixes for their aliased name. The aliased name for each subinterface consists of its sequence number from this range appended to the Alias Name you provided in the previous field. These values default to the beginning and ending subinterface ID numbers, but you can enter any valid range of numbers.</td>
</tr>
<tr>
<td>Show hardware properties in context</td>
<td>Select this option to allow the <strong>show interface</strong> CLI command to display of physical interface properties for the context even if you defined an alias. If not selected, the show interface output includes the aliased name.</td>
</tr>
</tbody>
</table>
PART 6

Router and Switch Device Configuration
Managing Routers

Cisco Security Manager supports the management and configuration of security features and other platform-specific features on Cisco IOS access security routers. You configure these features in the form of policies, each of which defines a different aspect of the configuration of the router. For a detailed explanation of the policy paradigm used by Security Manager, see Chapter 5, “Managing Policies”.

You can discover the configurations that are already defined on Cisco IOS routers. The discovery process imports the device configuration into Security Manager as policies and policy objects that you can then manage as required. For more information, see Discovering Router Policies, page 57-3.

Note

Security Manager supports Cisco IOS Software Releases 12.3 and higher. However, a limited number of policies are supported for routers running Cisco IOS Software Release 12.1 or 12.2. See Configuring Routers Running IOS Software Releases 12.1 and 12.2, page 57-2.

By right-clicking a policy type in one of the policy selectors, you can assign a policy to a single router, share the policy among multiple routers, or unassign the policy from the device.

The following topics describe how to configure platform policies and interface policies on Cisco IOS routers:

- Interface polices:
  - Basic Interface Settings on Cisco IOS Routers, page 58-1
  - Advanced Interface Settings on Cisco IOS Routers, page 58-13
  - IPS Module Interface Settings on Cisco IOS Routers, page 58-22
  - CEF Interface Settings on Cisco IOS Routers, page 58-24
  - Dialer Interfaces on Cisco IOS Routers, page 58-27
  - ADSL on Cisco IOS Routers, page 58-33
  - SHDSL on Cisco IOS Routers, page 58-40
  - PVCs on Cisco IOS Routers, page 58-46
  - PPP on Cisco IOS Routers, page 58-70

- Device administration policies:
  - AAA on Cisco IOS Routers, page 59-2
  - User Accounts and Device Credentials on Cisco IOS Routers, page 59-13
  - Bridging on Cisco IOS Routers, page 59-18
  - Time Zone Settings on Cisco IOS Routers, page 59-22
Configuring Routers Running IOS Software Releases 12.1 and 12.2

Security Manager provides limited support for routers running Cisco IOS Software Releases 12.1 and 12.2 (with the exception of the ASR 1000 Series, which supports more features). You can configure the following policies on these routers:

- Interfaces. See Basic Interface Settings on Cisco IOS Routers, page 58-1.
Discovering Router Policies

You can discover the configurations of your Cisco IOS routers and import these configurations as policies into Security Manager. This makes it possible to add existing devices and manage them with Security Manager without having to manually configure each device policy by policy. For more information, see Adding Devices to the Device Inventory, page 3-7.

You can discover all Cisco IOS commands that can be configured with Security Manager. Discovery ignores unsupported commands, which means that they are left intact on the device even after subsequent deployments. Additionally, in cases where Security Manager can discover the command, but not all the subcommands and keywords related to that command, the unsupported elements are ignored and left intact on the device.

You can also rediscover the configurations of devices that you are already managing with Security Manager at any time. Be aware, however, that performing rediscovery overwrites the policies that you have defined in Security Manager, and is therefore not generally recommended. For more information, see Discovering Policies on Devices Already in Security Manager, page 5-15.

Note

We recommend that you perform deployment immediately after you discover the policies on a Cisco IOS router, before you make any changes to policies or unassign policies from the device. Otherwise, the changes that you configure in Security Manager might not be deployed to the device.

Note

If a policy that is not configured in Security Manager was configured on the device using an out-of-band method (such as the CLI) between the time of the first discovery and rediscovery, we recommend that you perform deployment immediately after rediscovery.

- PPP/MLP Policy Page, page 58-75

Basic Interface Settings on Cisco IOS Routers

You typically add interfaces to Security Manager by performing discovery, as described in Discovering Policies, page 5-12. After you have discovered the interfaces, you can modify the properties of each interface.

You can also use Security Manager to configure physical and virtual interfaces manually. This is useful when you modify interface configurations of existing devices, and makes it possible for you to configure all the interfaces of a device before you physically add the device to the network.
Available Interface Types

Table 58-1 on page 58-2 describes the types of interfaces that can be configured on Cisco IOS routers.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>

</tbody>
</table>
Defining Basic Router Interface Settings

When you define an interface or subinterface for a Cisco IOS router, you name it, specify how it is assigned an IP address, and optionally define other properties, such as the speed, maximum transmission unit (MTU), and the encapsulation type.

Table 58-1 Router Interface Types (Continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Loopback</td>
<td>A logical interface that emulates an interface that is always up. For example, having a loopback interface on the router prevents a loss of adjacency with neighboring OSPF routers if the physical interfaces on the router go down. The name of a loopback interface must end with a number ranging from 0-2147483647.</td>
</tr>
<tr>
<td>Multilink</td>
<td>Multilink interface. A logical interface used for multilink PPP (MLP).</td>
</tr>
<tr>
<td>Port channel</td>
<td>Port channel interface. This interface type enables you to bundle multiple point-to-point Fast Ethernet links into one logical link. It provides bidirectional bandwidth of up to 800 Mbps.</td>
</tr>
<tr>
<td>POS</td>
<td>Packet OC-3 interface on the Packet-over-SONET (POS) interface processor.</td>
</tr>
<tr>
<td>PRI</td>
<td>ISDN PRI interface. Includes 23/30 B-channels and one D-channel.</td>
</tr>
<tr>

<td>Tunnel</td>
<td>Tunnel interface.</td>
</tr>
<tr>
<td>VG-AnyLAN</td>
<td>100VG-AnyLAN port adapter.</td>
</tr>
<tr>
<td>VLAN</td>
<td>Virtual LAN subinterface.</td>
</tr>
<tr>
<td>Virtual Template</td>
<td>Virtual template interface. When a user dials in, a predefined configuration template is used to configure a virtual access interface; when the user is done, the virtual access interface goes down and the resources are freed for other dial-in uses.</td>
</tr>
</tbody>
</table>

Related Topics
- Defining Basic Router Interface Settings, page 58-3
- Deleting a Cisco IOS Router Interface, page 58-6
- Basic Interface Settings on Cisco IOS Routers, page 58-1
Basic interface settings are always local to the device on which they are configured. You cannot share this policy with other devices. You can, however, share advanced interface settings. For more information, see Advanced Interface Settings on Cisco IOS Routers, page 58-13.

Related Topics
- Deleting a Cisco IOS Router Interface, page 58-6

Step 1
In Device view, select Interfaces > Interfaces from the Policy selector.

The Router Interfaces Page, page 58-7 is displayed.

Step 2
To add a new interface or subinterface, click the Add Row button to open the Create Router Interface dialog box.

To edit an existing interface or subinterface, select it in the Interfaces table, and then click the Edit Row button to open the Edit Router Interface dialog box. Refer to Create Router Interface Dialog Box, page 58-8 for descriptions of the fields in these dialog boxes.

Step 3
Select Enabled to have Security Manager actively manage this interface or subinterface. If this option is deselected, the interface/subinterface definition is retained, but the interface/subinterface itself is disabled (or “shutdown”).

Step 4
Choose Interface or Subinterface from the Type list.

Step 5
If you are creating an interface, enter a name for the interface. You can click Select to open a dialog box that will help you generate a standard name based on interface type and details about the interface’s location, such as card, slot, and subinterface. For more information on using the dialog box to generate an interface name, see Interface Auto Name Generator Dialog Box, page 58-12.

Note
When naming a BVI interface, use the bridge group number as the card number. Deployment will fail if you configure a BVI interface without configuring a corresponding bridge group.

Step 6
If you are creating a subinterface, provide the following:

a. Parent—Choose the parent interface for this subinterface.
b. Subinterface ID—Enter a number to identify the subinterface.

Note
Security Manager configures serial subinterfaces as point-to-point, not multipoint.

Step 7
To specify a Layer Type, choose a Level 2 (data link) or Level 3 (network) option from this list.

Step 8
Choose a method of IP address assignment for this interface/subinterface, then provide additional information, as required:

- Static IP—Provide an IP Address and Subnet Mask.
- DHCP—No additional information is required.
- PPPoE—No additional information is required.
- Unnumbered—Provide the name of the interface from which an IP address is to be “borrowed.”

Note
Layer 2 interfaces do not support IP addresses.

Step 9  Define additional properties of the interface/subinterface:

- Use the **Negotiation** check box to enable and disable auto-negotiation for the interface.

  Auto-negotiation detects the capabilities of remote devices and negotiates the best possible performance between the two devices. When Negotiation is enabled, the Fast Ethernet Duplex and Speed options are disabled.

  **Note**  Auto-negotiation is available only for Fast Ethernet and Gigabit Ethernet interfaces on ASR devices.

- Choose a transmission mode from the **Duplex** list. If you choose Auto, be sure the network device to which this interface is connected is set to automatically detect the transmission mode. (Auto is not available on ASRs; use auto-negotiation instead.)

  **Note**  You must configure a fixed speed to define the duplex value. Tunnel and loopback interfaces do not support this setting.

- Choose a transmission speed from the **Speed** list. If you choose Auto, be sure the network device to which this interface is connected is set to automatically detect the transmission speed. (Auto is not available on ASRs; use auto-negotiation instead.)

- Enter the maximum transmission unit (MTU), which defines the largest packet size, in bytes, that this interface can support.

  **Note**  Certain interface properties are set automatically, or are unavailable, depending on the interface type and the underlying port type. For example, the Speed options are available for Fast Ethernet and Gigabit Ethernet interfaces only.

Step 10  Choose an encapsulation method from the **Encapsulation** list:

- **None**—No encapsulation; no additional parameters are required.

- (Ethernet subinterfaces only) **DOT1Q**—VLAN encapsulation, as defined by the IEEE 802.1Q standard. Provide the following VLAN parameters for this subinterface:
  - Enter a VLAN ID to associate with this subinterface.

    **Note**  All VLAN IDs must be unique among all subinterfaces configured on the same physical interface.

  - If you are defining the 802.1Q trunk interface, select Native VLAN.

  **Tip**  To configure DOT1Q encapsulation on an Ethernet interface without associating a VLAN with the subinterface, enter the `vlan-id dot1q` command using CLI commands or FlexConfigs. See Understanding FlexConfig Policies and Policy Objects, page 7-2. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the router.

- (Serial interfaces only) **Frame Relay**—IETF Frame Relay encapsulation. Provide a data-link connection identifier (DLCI) for the subinterface.
Note: Frame relay must be configured on the parent interface.

Note: IETF Frame Relay encapsulation provides interoperability between a Cisco IOS router and equipment from other vendors. To configure Cisco Frame Relay encapsulation, use CLI commands or FlexConfigs.

Step 11 (Optional) Enter a description of up to 1024 characters for the interface.

Step 12 Click OK to save the interface/subinterface definition and close the dialog box. The new interface is displayed on the Router Interfaces page. Subinterfaces are displayed beneath the parent interface.

Deleting a Cisco IOS Router Interface

Although you can delete the definition of a virtual interface at any time, use this option with great care. If the interface is included in any policy definitions that exist for this router, deleting the interface causes these policy definitions to fail when they are deployed to the device.

Note: Deleting the basic interface definition does not delete any advanced settings that are configured under Interface > Settings > Advanced Settings. You must delete these advanced settings separately. If you fail to do so, deployment fails.

Note: Deleting the definition of a physical interface from the Router Interfaces page does not remove the interface from the device. If you perform this operation by mistake, you can perform rediscovery to restore the definition to Security Manager. For more information, see Discovering Policies on Devices Already in Security Manager, page 5-15.

Related Topics
- Defining Basic Router Interface Settings, page 58-3
- Basic Interface Settings on Cisco IOS Routers, page 58-1

Step 1 Click the Device View button on the toolbar.

Step 2 Select a router from the Device selector.

Step 3 Select Interfaces > Interfaces from the Policy selector. The Router Interfaces page is displayed. See Table 58-2 on page 58-7 for an explanation of the fields on this page.

Step 4 Select an interface from the table, then click the Delete button. The interface is deleted.
Router Interfaces Page

Use the Router Interfaces page to view, create, edit, and delete interface definitions (physical and virtual) on a selected Cisco IOS router. The Router Interfaces page displays interfaces that were discovered by Security Manager as well as interfaces added manually after you added the device to the system.

Note

Unlike other router policies, the Interfaces policy cannot be shared among multiple devices. The Advanced Settings policy, however, may be shared. See Local Policies vs. Shared Policies, page 5-3.

For more information, see Basic Interface Settings on Cisco IOS Routers, page 58-1.

Navigation Path

Select a Cisco IOS router from the Device selector, then select Interfaces > Interfaces from the Policy selector.

<tr>
<td>Negotiation</td>
<td>Available on ASRs; applies to Fast Ethernet and Gigabit Ethernet interfaces only.</td>
</tr>
<tr>
<td></td>
<td>Auto-negotiation detects the capabilities of remote devices and negotiates the best possible performance between the two devices. When Negotiation is enabled, the Duplex and Speed options are disabled.</td>
</tr>
</tbody>
</table>
### Table 58-3  Create Router Interface Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Duplex | The interface transmission mode:  
- None—The transmission mode is returned to its device-specific default setting.  
- Full—The interface transmits and receives at the same time (full duplex).  
- Half—The interface can transmit or receive, but not at the same time (half duplex). This is the default.  
- Auto—The router automatically detects and sets the appropriate transmission mode, either full or half duplex. Not available on ASRs; use auto-negotiation instead.  
**Note** When using Auto mode, be sure that the port on the active network device to which you connect this interface is also set to automatically negotiate the transmission mode. Otherwise, select the appropriate fixed mode.  
**Note** You can configure a duplex value only if you set the Speed to a fixed speed, not Auto.  
**Note** This setting does not apply to serial, HSSI, ATM, PRI, DSL, tunnel, or loopback interfaces. |
| Speed | The speed of the interface:  
- None—The setting is not configurable on the device.  
- 10—10 megabits per second (10Base-T networks).  
- 100—100 megabits per second (100Base-T networks). This is the default for Fast Ethernet interfaces.  
- 1000—1000 megabits per second (Gigabit Ethernet networks). This is the default for Gigabit Ethernet interfaces.  
- Auto—The router automatically detects and sets appropriate interface speed. Not available on ASRs; use auto-negotiation.  
**Note** When using Auto mode, be sure that the port on the active network device to which you connect this interface is also set to automatically negotiate the transmission speed. Otherwise, select the appropriate fixed speed.  
| MTU | The maximum transmission unit, which refers to the maximum packet size, in bytes, that this interface can handle.  
Valid values for serial, Ethernet, and Fast Ethernet interfaces range from 64 to 17940 bytes.  
Valid values for Gigabit Ethernet interfaces range from 1500 to 9216 bytes. |
### Table 58-3  Create Router Interface Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encapsulation</td>
<td>The type of encapsulation performed by the interface: &lt;ul&gt;• None—No encapsulation.&lt;li&gt;• DOT1Q—VLAN encapsulation, as defined by the IEEE 802.1Q standard. Applies only to Ethernet subinterfaces.&lt;li&gt;• Frame Relay—IETF Frame Relay encapsulation. Applies only to serial interfaces (not serial subinterfaces).&lt;li&gt;Note: IETF Frame Relay encapsulation provides interoperability between a Cisco IOS router and equipment from other vendors. To configure Cisco Frame Relay encapsulation, use CLI commands or FlexConfigs.</td>
</tr>
<tr>
<td>VLAN ID</td>
<td>Applies only to subinterfaces with encapsulation type DOT1Q. The VLAN ID associated with this subinterface. The VLAN ID specifies where 802.1Q tagged packets are sent and received on this subinterface; without a VLAN ID, the subinterface cannot send or receive traffic. Valid values range from 1 to 4094. &lt;li&gt;Note: All VLAN IDs must be unique among all subinterfaces configured on the same physical interface. &lt;li&gt;Tip: To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the <code>vlan-id dot1q</code> command using CLI commands or FlexConfigs. See Understanding FlexConfig Policies and Policy Objects, page 7-2. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the router.</td>
</tr>
<tr>
<td>Native VLAN</td>
<td>Applies only when the encapsulation type is DOT1Q and you are configuring a physical interface that is meant to serve as an 802.1Q trunk interface. Trunking is a way to carry traffic from several VLANs over a point-to-point link between two devices. When selected, the Native VLAN is associated with this interface, using the ID specified in the VLAN ID field. (If no VLAN ID is specified for the Native VLAN, the default is 1.) The native VLAN is the VLAN to which all untagged VLAN packets are logically assigned by default. This includes the management traffic associated with the VLAN. If no VLAN ID is defined, the default is 1. For example, if the VLAN ID of this interface is 1, all incoming untagged packets and packets with VLAN ID 1 are received on the main interface and not on a subinterface. Packets sent from the main interface are transmitted without an 802.1Q tag. When deselected, the Native VLAN is not associated with this interface. &lt;li&gt;Note: The Native VLAN cannot be configured on a subinterface of the trunk interface. Be sure to configure the same Native VLAN value at both ends of the link; otherwise, traffic may be lost or sent to the wrong VLAN.</td>
</tr>
</tbody>
</table>

Advanced Interface Settings on Cisco IOS Routers

In addition to the basic interface definitions that you can define on the Interfaces page, Security Manager provides a method for defining selected advanced settings on interfaces that support those settings. Unlike the basic interface settings defined on the Interface page, you can share an advanced settings policy with multiple devices. This provides a convenient method for configuring multiple devices with identical settings. See Working with Shared Policies in Device View or the Site-to-Site VPN Manager, page 5-34.

You can define a variety of advanced settings on a selected interface, subinterface, or interface role, including:

- Cisco Discovery Protocol (CDP) settings.
- Internet Control Message Protocol (ICMP) settings.
- Directed broadcast settings.
- Load interval for determining the average load.
- Throughput delay for use by routing protocols.
- Configuring TCP maximum segment size.
- Helper addresses for forwarding UDP broadcasts. For more information on helper addresses, see Understanding Helper Addresses, page 58-14.
- Enabling Maintenance Operation Protocol (MOP).
- Enabling virtual fragmentation reassembly (VFR).
- Enabling proxy ARP.
- Enabling NBAR protocol discovery.
- Enabling and configuring unicast reverse path forwarding (RFP).

Tip
You can define these settings for multiple interfaces on a device at once by choosing an interface role instead of a specific interface. For example, if you have defined an All-Ethernets interface role, you can define identical advanced settings for every Ethernet interface on the device with a single definition. See Understanding Interface Role Objects, page 6-62.

Before You Begin
- Define basic interface settings. See Basic Interface Settings on Cisco IOS Routers, page 58-1.

Step 1 Do one of the following:
- (Device view) Select Interfaces > Settings > Advanced Settings from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > Advanced Settings from the Policy Type selector. Select an existing policy or create a new one.

The Advanced Interface Settings page is displayed (see Advanced Interface Settings Page, page 58-15).

Step 2 Do one of the following:
- Click the Add button to add an interface or interface role to the table. In the Advanced Interface Settings dialog box, enter the name of the interface or interface role, or click Select to select an existing role or to create a new role.
- Select an existing entry in the table and click the Edit button to change its settings.
Step 3 Configure the advanced settings required for the selected interface. For details about each setting, see Advanced Interface Settings Dialog Box, page 58-16.

Step 4 Click OK to save your definitions. Your definitions are displayed in the Advanced Interface Settings table.

Understanding Helper Addresses

Network hosts occasionally use User Datagram Protocol (UDP) broadcasts to determine address, configuration, and name information. This presents a problem if the host is on a network segment that does not include the required server, as by default, routers do not forward UDP broadcasts beyond their subnet. You can remedy this situation by configuring the interface to forward certain classes of broadcasts to a helper address.

One common use of helper addresses is when the router acts as a relay agent for DHCP clients who need to contact a DHCP server located on a different subnet. The helper address can either represent a specific DHCP server or a network address for a segment containing multiple DHCP servers. You can also configure a helper address for each DHCP server.

In Figure 58-1, hosts located on network 192.168.1.0 can use 10.44.23.7 as a helper address to forward UDP broadcasts to the other network, while hosts located on network 10.44.0.0 can use 192.168.1.19 as their helper address.

Table 58-5 on page 58-14 lists the default UDP services that can be forwarded to helper addresses.

<table>
<thead>
<tr>
<th>Service</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOTP/DHCP Client</td>
<td>68</td>
</tr>
<tr>
<td>BOOTP/DHCP Server</td>
<td>67</td>
</tr>
</tbody>
</table>
To forward additional UDP services, use the CLI or FlexConfigs to configure the ip forward-protocol command. Use the no form of this command to prevent the forwarding of any of the default services listed in Table 58-5 on page 58-14.

All of the following conditions must be met in order for a UDP or IP packet to use helper addresses:

- The MAC address of the received frame must be an all-ones broadcast address (ffff.ffff.ffff).
- The IP destination address must be one of the following: all-ones broadcast (255.255.255.255), subnet broadcast for the receiving interface, or major-net broadcast for the receiving interface if the no ip classless command is also configured.
- The IP time-to-live (TTL) value must be at least 2.
- The IP protocol must be UDP (17).

### Related Topics

- Advanced Interface Settings on Cisco IOS Routers, page 58-13
- Basic Interface Settings on Cisco IOS Routers, page 58-1

### Advanced Interface Settings Page

Use the Advanced Interface Settings page to configure advanced interface definitions (physical and virtual) on a router. Examples of advanced settings include Cisco Discovery Protocol (CDP) settings, ICMP message settings, and virtual fragment reassembly settings. You can configure settings for specific interfaces or for interface roles. The columns in the table summarize the advanced settings for an entry and are explained in Advanced Interface Settings Dialog Box, page 58-16.

To configure advanced settings:

- Click the Add button to add an interface or interface role to the table, and fill in the Advanced Interface Settings dialog box.
- Select an entry and click the Edit button to edit an existing entry.
- Select an entry and click the Delete button to delete it.

For more information, see Advanced Interface Settings on Cisco IOS Routers, page 58-13.

### Navigation Path

- (Device view) Select Interfaces > Settings > Advanced Settings from the Policy selector.
• (Policy view) Select **Router Interfaces > Settings > Advanced Settings** from the Policy Type selector. Right-click **Advanced Settings** to create a policy, or select an existing policy from the Shared Policy selector.

<tbody>
<tr>
<td><strong>Element</strong></td>
</tr>
<tr>
<td>Interface</td>
</tr>
<tr>
<td>Max Bandwidth</td>
</tr>
</tbody>
</table>
### Table 58-6 Advanced Interface Settings Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load Interval</td>
<td>The length of time, in seconds, used to calculate the average load on the interface. Valid values range from 30 to 600 seconds, in multiples of 30 seconds. The default is 300 seconds (5 minutes). Load interval is not supported on subinterfaces. Modify the default to shorten the length of time over which load averages are computed. You can do this if you want load computations to be more reactive to short bursts of traffic. Load data is gathered every 5 seconds. This data is used to compute load statistics, including input/output rate in bits and packets per second, load, and reliability. Load data is computed using a weighted-average calculation in which recent load data has more weight in the computation than older load data. <strong>Tip</strong> You can use this option to increase or decrease the likelihood of activating a backup interface; for example, a backup dial interface may be triggered by a sudden spike in the load on an active interface.</td>
</tr>
<tr>
<td>TCP Maximum Segment Size</td>
<td>The maximum segment size (MSS) of TCP SYN packets that pass through this interface. Valid values range from 500 to 1460 bytes. If you do not specify a value, the MSS is determined by the originating host. This option helps prevent TCP sessions from being dropped as they pass through the router. Use this option when the ICMP messages that perform auto-negotiation of TCP frame size are blocked (for example, by a firewall). We highly recommend using this option on the tunnel interfaces of DMVPN networks. For more information, see <em>TCP MSS Adjustment</em> at this URL: <a href="http://www.cisco.com/en/US/docs/ios/12_2t/12_2t4/feature/guide/ft_admss.html">http://www.cisco.com/en/US/docs/ios/12_2t/12_2t4/feature/guide/ft_admss.html</a> <strong>Note</strong> Typically, the optimum MSS is 1452 bytes. This value plus the 20-byte IP header, the 20-byte TCP header, and the 8-byte PPPoE header add up to a 1500-byte packet that matches the MTU size for the Ethernet link.</td>
</tr>
<tr>
<td>Helper Addresses</td>
<td>The helper addresses that are used to forward User Datagram Protocol (UDP) broadcasts that are received on this interface. Enter one or more addresses or the names of the network/host objects, or click <strong>Select</strong> to select an object from a list or to create a new object. By default, routers do not forward broadcasts outside of their subnet. Helper addresses provide a solution by enabling the router to forward certain types of UDP broadcasts as a unicast to an address on the destination subnet. For more information, see <em>Understanding Helper Addresses, page 58-14</em>.</td>
</tr>
</tbody>
</table>
### Table 58-6  Advanced Interface Settings Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Throughput Delay</td>
<td>The expected delay for the interface in tens of microseconds (for example, 3000 translates to 30,000 microseconds). You can enter a value between 1 and 16777215, and the default varies by the type of interface. Higher-level protocols might use delay information to make operating decisions. For example, IGRP can use delay information to differentiate between a satellite link and a land link. This setting is for informational purposes only and does not affect the actual delay on the interface.</td>
</tr>
</tbody>
</table>
| Cisco Discovery Protocol settings | Settings related to the Cisco Discovery Protocol (CDP). CDP is a media- and protocol-independent device-discovery protocol that runs on all Cisco-manufactured equipment including routers, access servers, bridges, and switches. It is primarily used to obtain protocol addresses of neighboring devices and to discover the platform of those devices. The options are:  
- Enable CDP—Whether to enable the Cisco Discovery Protocol (CDP) on this interface. You cannot enable CDP on ATM interfaces.  
- Log CDP Messages—On Ethernet interfaces, whether to log duplex mismatches for this interface. |
| ICMP Messages Settings |  
- Enable Redirect Messages—Whether to enable the sending of Internet Control Message Protocol (ICMP) redirect messages if the device is forced to resend a packet through the same interface on which it was received to another device on the same subnet. Redirect messages are sent when the device wants to instruct the originator of the packet to remove it from the route and substitute a different device that offers a more direct path to the destination.  
- Enable Unreachable Messages—Whether to enable the sending of ICMP unreachable messages. Unreachable messages are sent in two circumstances:  
  - If the interface receives a nonbroadcast packet destined for itself that uses an unknown protocol, the interface sends an ICMP unreachable message to the source.  
  - If the device receives a packet that it cannot deliver to its ultimate destination because it knows of no route to the destination address, it sends an ICMP host unreachable message to the originator of the packet. |
| Enable Mask Reply Messages | Whether to enable the sending of ICMP mask reply messages. Mask reply messages are sent in response to mask request messages, which are sent when a device needs to know the subnet mask for a particular subnetwork. |
| Note | This is the only advanced setting supported by the null0 interface. |
### Table 58-6  Advanced Interface Settings Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Maintenance Operation Protocol (MOP)</td>
<td>Whether to enable MOP on the interface. You can use MOP for utility services such as uploading and downloading system software, remote testing, and problem diagnosis.</td>
</tr>
<tr>
<td>Enable Virtual Fragment Reassembly (VFR)</td>
<td>Whether to enable virtual fragmentation reassembly (VFR) on this interface. VFR is a feature that enables the Cisco IOS Firewall to create dynamic ACLs that can protect the network from various fragmentation attacks. For more information, see Virtual Fragmentation Reassembly at this URL: <a href="http://www.cisco.com/en/US/docs/ios/sec_data_plane/configuration/guide/sec_virt_frag_reassm_ps6441_TSD_Products_Configuration_Guide_Chapter.html">http://www.cisco.com/en/US/docs/ios/sec_data_plane/configuration/guide/sec_virt_frag_reassm_ps6441_TSD_Products_Configuration_Guide_Chapter.html</a></td>
</tr>
<tr>
<td>Enable Proxy ARP</td>
<td>Whether to enable proxy Address Resolution Protocol (ARP) on the interface. Proxy ARP, defined in RFC 1027, is the technique in which one host, usually a router, answers ARP requests intended for another machine, thereby accepting responsibility for routing packets to the real destination. Proxy ARP can help machines on a subnet reach remote subnets without configuring routing or a default gateway.</td>
</tr>
<tr>
<td>Enable NBAR Protocol Discovery</td>
<td>Whether to enable network-based application recognition (NBAR) on this interface to discover traffic and keep traffic statistics for all protocols known to NBAR. Protocol discovery provides a method to discover application protocols traversing an interface so that QoS policies can be developed and applied to them. For more information, go to: <a href="http://www.cisco.com/en/US/products/ps6616/products_qanda_item09186a00800a3ded.shtml">http://www.cisco.com/en/US/products/ps6616/products_qanda_item09186a00800a3ded.shtml</a></td>
</tr>
</tbody>
</table>
**Enable Directed Broadcasts**

Whether to have directed broadcast packets “exploded” as a link-layer broadcast when this interface is directly connected to the destination subnet. When deselected, directed broadcast packets that are intended for the subnet to which this interface is directly connected are dropped rather than being broadcast. This is the default.

An IP directed broadcast is an IP packet whose destination address is a valid broadcast address on a different subnet from the node on which it originated. In such cases, the packet is forwarded as if it was a unicast packet until it reaches its destination subnet.

This option affects only the final transmission of the directed broadcast on its destination subnet; it does not affect the transit unicast routing of IP directed broadcasts.

If you enable directed broadcasts, you can apply an ACL to determine which directed broadcasts are permitted to be broadcast on the destination subnet. All other directed broadcasts destined for the subnet to which this interface is directly connected are dropped. Enter the name of a standard or extended ACL object, or click **Select** to select an object from a list or to create a new object.

**Tip**

Because directed broadcasts, and particularly ICMP directed broadcasts, have been abused by malicious persons, we recommend deselecting this option on interfaces where directed broadcasts are not needed. When you enable directed broadcasts, apply an ACL to restrict their use.

---

**Unicast Reverse Path Forwarding (RFP) Settings**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Unicast RFP</td>
<td>Whether to enable unicast reverse path forwarding (RFP) on the interface. When you enable Unicast RPF on an interface, the router examines all packets that are received on that interface. The router checks to make sure that the source address appears in the FIB, and takes action based on your unicast RPF settings. Use unicast RPF to mitigate problems caused by malformed or forged (spoofed) IP source addresses that pass through a router. Malformed or forged source addresses can indicate DoS attacks based on source IP address spoofing. For more information on unicast RFP, see the description of the <strong>ip verify unicast source reachable-via</strong> command in the <em>Cisco IOS Interface and Hardware Component Command Reference</em>. To enable unicast RFP, you must also globally enable Cisco Express Forwarding (CEF). For more information on CEF, see CEF Interface Settings on Cisco IOS Routers, page 58-24.</td>
</tr>
</tbody>
</table>
Chapter 58  Configuring Router Interfaces

### Table 58-6  Advanced Interface Settings Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mode</td>
<td>How strict to make unicast RFP:</td>
</tr>
</tbody>
</table>
|                                 | - Loose Mode—The default. Examines incoming packets to determine whether the source address is in the Forwarding Information Base (FIB) and permits the packet if the source is reachable through any interface on the router.  
  Use loose mode on interfaces where asymmetric paths allow packets from valid source networks (networks contained in the FIB). For example, routers that are in the core of an ISP network have no guarantee that the best forwarding path out of the router will be the path selected for packets returning to the router.  
  Use strict mode on interfaces where only one path allows packets from valid source networks (networks contained in the FIB). Also, use strict mode when a router has multiple paths to a given network as long as the valid networks are switched through the incoming interfaces. Packets for invalid networks are dropped. For example, routers at the edge of the network of an ISP are likely to have symmetrical reverse paths. Strict mode is also applicable in certain multihomed situations, provided that optional Border Gateway Protocol (BGP) attributes, such as weight and local preference, are used to achieve symmetric routing. |

| Allow Use Of Default Route for RFP Verification | Whether to permit Unicast RPF to successfully match on prefixes that are known through the default route when determining whether to pass packets. Normally, sources found in the FIB but only by way of the default route are dropped.                                                                                           |

<table>
<thead>
<tr>
<th>Allow Self Ping</th>
<th>Whether to allow the router to ping its own interfaces. By default, when you enable Unicast RPF, packets that are generated by the router and destined to the router are dropped, thereby making certain troubleshooting and management tasks difficult to accomplish.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Caution</strong></td>
<td>Allowing self-ping opens a potential denial of service (DoS) hole.</td>
</tr>
</tbody>
</table>

| ACL (For Unicast RFP) | If you enable unicast RFP, you can apply an ACL to refine how packets are handled when a reverse path is not found. If you specify an ACL, when (and only when) a packet fails the Unicast RPF check, the ACL is checked to determine whether the packet should be dropped (using a deny statement in the ACL) or forwarded (using a permit statement in the ACL). Enter the name of a standard or extended ACL object, or click **Select** to select an object from a list or to create a new object. |
IPS Module Interface Settings on Cisco IOS Routers

On some routers, you can install IPS modules such as the Cisco Intrusion Prevention System Advanced Integration Module or Network Module. When installed and active, you must configure the IPS Module interface settings policy to define the following:

- The name of the interface between the module and the router.
- The failure mode of the module. If the module fails, you can configure it to allow all traffic or to deny all traffic.
- The router interfaces to monitor. You can name specific interfaces or use interface roles to cover more than one interface at a time. For example, if you have defined an All-Ethernets interface role, you can define identical monitoring settings for every Ethernet interface on the device with a single definition. See Understanding Interface Role Objects, page 6-62.

Tip

After you have defined an IPS Module interface settings policy, you can share the policy and assign it to other devices. This provides a convenient method for configuring multiple devices with identical settings. See Working with Shared Policies in Device View or the Site-to-Site VPN Manager, page 5-34.

Before You Begin

Define basic interface settings. See Basic Interface Settings on Cisco IOS Routers, page 58-1.

Step 1

Do one of the following:

- (Device view) Select Interfaces > Settings > IPS Module from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > IPS Module from the Policy Type selector.
  
  Select an existing policy or create a new one.

The IPS Module Interface Settings page is displayed. See IPS Module Interface Settings Page, page 58-22 for an explanation of the fields on this page.

Step 2

In the IPS Module Interface Settings fields, enter the name of the IPS interface (such as IDS-Sensor1/0) or click Select to select it from a list. Also determine whether you want to allow all traffic if the module fails (fail open) or to deny all traffic (fail closed).

Step 3

Identify the router interfaces that the module should monitor. Click the Add button below the IPS Module Service Module Monitoring Settings table to add interfaces to the list, or select an interface and click the Edit button to change the settings for an existing interface. Use the IPS Monitoring Information dialog box to define the interface name or role, monitoring mode, and access list (if any). For more information, see IPS Monitoring Information Dialog Box, page 58-23.

IPS Module Interface Settings Page

Use the IPS Module Interface Settings page to define the settings on the Cisco Intrusion Prevention System Advanced Integration Module or Network Module. The module must be running IPS 6.0 or later. You can define the fail mode for the IPS interface, and the interfaces that the module should monitor. Configure this policy only if the router hosts an IPS module.
Caution
Cisco IOS IPS and the Cisco IPS module cannot be used together. Cisco IOS IPS must be disabled when the IPS module is installed.

Navigation Path
- (Device view) Select Interfaces > Settings > IPS Module from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > IPS Module from the Policy Type selector. Create a new policy or select an existing policy from the Shared Policy selector.

**CEF Interface Settings on Cisco IOS Routers**

Cisco Express Forwarding (CEF) is an advanced Layer 3 IP switching technology that optimizes network performance and scalability for all kinds of networks, from those that carry small amounts of traffic to those that carry large amounts of traffic in complex patterns, such as the Internet and networks characterized by intensive web-based applications or interactive sessions. CEF is enabled by default on most Cisco IOS routers.

Typically, you do not need to configure a CEF policy unless you want to enable CEF accounting so that you can view statistics with the `show ip cef` command on the router. You would also configure the policy if you want to disable CEF, or to configure non-default CEF behavior on specific interfaces, for example, to have CEF load balance based on packets rather than source-destination packet streams.

When configuring alternate CEF settings for interfaces, you can name specific interfaces or use interface roles to cover more than one interface at a time. For example, if you have defined an All-Ethernets interface role, you can define identical CEF settings for every Ethernet interface on the device with a single definition. See Understanding Interface Role Objects, page 6-62.
Tip

After you have defined a CEF interface settings policy, you can share the policy and assign it to other devices. This provides a convenient method for configuring multiple devices with identical settings. See Working with Shared Policies in Device View or the Site-to-Site VPN Manager, page 5-34.

Before You Begin

Define basic interface settings. See Basic Interface Settings on Cisco IOS Routers, page 58-1.

Step 1

Do one of the following:

- (Device view) Select Interfaces > Settings > CEF from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > CEF from the Policy Type selector. Select an existing policy or create a new one.

The CEF Interface Settings page is displayed. See CEF Interface Settings Page, page 58-25 for an explanation of the fields on this page.

Step 2

If you are enabling CEF, select the accounting options you desire.

Step 3

If you want to configure non-default behavior for certain interfaces, add them to the CEF Interface Settings table. Click the Add button below the table to add interfaces to the list, or select an interface and click the Edit button to change the settings for an existing interface. For more information about the options, see CEF Interface Settings Dialog Box, page 58-26.

CEF Interface Settings Page

Use the CEF Interface Settings page to define the settings for Cisco Express Forwarding. CEF is an advanced Layer 3 IP switching technology that optimizes network performance and scalability for all kinds of networks, from those that carry small amounts of traffic to those that carry large amounts of traffic in complex patterns, such as the Internet and networks characterized by intensive web-based applications or interactive sessions. CEF is enabled by default on most Cisco IOS routers.

Navigation Path

- (Device view) Select Interfaces > Settings > CEF from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > CEF from the Policy Type selector. Create a new policy or select an existing policy from the Shared Policy selector.

Table 58-9 CEF Interface Settings Page

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Cisco Express Forwarding</td>
<td>Whether to enable CEF globally on the device. The option is greyed out if you cannot disable CEF on the device. You can configure other settings on the page only if you enable CEF globally.</td>
</tr>
</tbody>
</table>
| CEF Network Accounting          | These options are for configuring CEF accounting globally. If you collect accounting statistics, you can view them using the `show ip cef` command on the router. You can select the following options to enable different types of accounting:  
  - Enable Accounting for Traffic Through Non-Recursive Prefixes—For network prefixes with directly connected next hops, non-recursive accounting enables express forwarding of the collection of packets through a prefix.  
  - Enable Per-Prefix Accounting—Accounting statistics based on the packet's network prefix.  
  - Enable Prefix Length Accounting—Accounting statistics based on the network prefix length.  
  - Enable Load Balance Hash Accounting—When you use per-destination load balancing (the default), CEF uses a series of 16 hash buckets to distribute the available paths based on the source and destination addresses. Enabling load balance hash accounting provides per-hash-bucket counters. |

CEF Interface Settings table  
The interfaces on the router for which you are defining special CEF configurations. When you enable CEF globally, by default, all interfaces on the router enable CEF and use per-destination load balancing. Add interfaces to this table only if you want to configure different behavior for the interfaces.  
The table shows the name of the interface or interface role, whether CEF is enabled or disabled, and whether the interface is load balancing based on destination or on a per-packet basis. For a detailed explanation of the fields, see CEF Interface Settings Dialog Box, page 58-26.  
- To add an interface to the table, click the Add button.  
- To edit the settings for an interface, select it and click the Edit button.  
- To delete an interface, select it and click the Delete button.

CEF Interface Settings Dialog Box

Use the CEF Interface Settings dialog box to add or edit the CEF properties of interfaces when you want to configure something different than the global default.

Navigation Path  
Go to the CEF Interface Settings Page, page 58-25, then click the Add or Edit button beneath the CEF Interface Settings table.
Dialer Interfaces on Cisco IOS Routers

Before you can configure a dial backup policy for a site-to-site VPN (see Configuring Dial Backup, page 23-38), you must configure a dialer interface policy on the appropriate Cisco IOS router. The dialer interface policy uses dialer pools to associate the dialer interface used by dial backup with a physical BRI interface on the router. Each dialer interface is associated with a single dialer pool, which can contain one or more physical interfaces. Multiple dialer interfaces can reference the same dialer pool.

The following topics describe how to create dialer interfaces policies on Cisco IOS routers:

- Defining Dialer Profiles, page 58-27
- Defining BRI Interface Properties, page 58-29

Defining Dialer Profiles

When you configure a dialer profile, you must select the interface or interface role representing the dialer interface and specify the number to be dialed. You must also assign a pool ID, which you use to reference this dialer interface when configuring the physical dialer interface. Additionally, you can modify the default timeout settings for the line.

Note

IP is the only protocol supported for dialer profiles by Security Manager.

Note

Authentication parameters for the dialer profile are defined in the PPP policy.
Before You Begin
Define the virtual and physical dialer interfaces on the router. See Basic Interface Settings on Cisco IOS Routers, page 58-1.

Note
In addition, you can optionally define interface roles for the virtual and physical dialer interfaces. See Defining Dialer Profiles, page 58-27.

Related Topics
- Defining BRI Interface Properties, page 58-29
- Dialer Interfaces on Cisco IOS Routers, page 58-27

Step 1
Do one of the following:
- (Device view) Select Interfaces > Settings > Dialer from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > Dialer from the Policy Type selector. Select an existing policy or create a new one.

The Dialer page is displayed. See Table 58-11 on page 58-30 for a description of the fields on this page.

Step 2
Select a dialer profile from the upper table on the Dialer Interfaces page, then click Edit, or click Add to create a profile. The Dialer Profile dialog box appears. See Table 58-12 on page 58-31 for a description of the fields in this dialog box.

Step 3
Enter the name of the interface or interface role that represents the virtual dialer interface, or click Select to select an interface role object or to create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 4
Enter a name for the dialer profile. Having a name makes it easier for you to assign the correct dialer pool to the physical interface. See Defining BRI Interface Properties, page 58-29.

Tip
We recommend that you define a name that is logically associated with the site to which the dialer interface serves as a backup. For example, if the dialer interface is serving as a backup connection to the London site, define the name London for the dialer profile.

Step 5
Enter an ID number for the dialer pool to associate with this dialer interface. Each dialer interface is associated with a single pool. Multiple interfaces may, however, be associated with the same dialer pool.

Step 6
Enter the number of the dialer group to assign to the dialer interface.

Step 7
(Optional) In the Interesting Traffic ACL field, enter the name of the extended ACL object that defines which packets are permitted to initiate calls using this dialer profile, or click Select to select the object from a list or to create a new one. Use this option to limit the IP traffic that can make use of the dialer.

Step 8
Enter the dialer string, which is the phone number of the remote side of the dialer interface connection.

Step 9
(Optional) Modify the default timeout values (Idle Timeout and Fast Idle Timeout), if required.

Step 10
Click OK to save your definitions locally on the client and close the dialog box. The dialer profile appears in the Dialer Profile table on the Dialer page.
Defining BRI Interface Properties

You configure the properties of the physical BRI interfaces used for dialer interface policies by selecting the appropriate interface or interface role, defining the dialer pools to which the interface belongs, and defining the ISDN switch type. It is the dialer pool that connects the physical interface with the virtual dialer interface.

Note
To define other types of physical dialer interfaces, such as ATM and Ethernet, use FlexConfigs. For more information, see Understanding FlexConfig Policies and Policy Objects, page 7-2.

Before You Begin
Define the virtual and physical dialer interfaces on the router. See Basic Interface Settings on Cisco IOS Routers, page 58-1.

Note
In addition, you can optionally define interface roles for the virtual and physical dialer interfaces. See Creating Interface Role Objects, page 6-63.

Related Topics
- Defining Dialer Profiles, page 58-27
- Dialer Interfaces on Cisco IOS Routers, page 58-27

Step 1
Do one of the following:
- (Device view) Select Interfaces > Settings > Dialer from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > Dialer from the Policy Type selector. Select an existing policy or create a new one.

The Dialer Interfaces page is displayed. See Table 58-11 on page 58-30 for a description of the fields on this page.

Step 2
Select a physical BRI interface from the Dialer Physical Interfaces table, then click Edit, or click Add to add an interface. The Dialer Physical Interface dialog box appears. See Table 58-13 on page 58-32 for a description of the fields in this dialog box.

Step 3
Enter the name of the interface or interface role that represents the physical dialer interface, or click Select to select an interface role object from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 4
Enter the names of the dialer pools to associate with the physical interface, or click Select to display a selector. Separate multiple entries with commas.

Step 5
Select the ISDN switch type used by the physical interface. Table 58-13 on page 58-32 describes the available switch types.

Step 6
(Optional) If you selected the Basic-DMS-100, Basic-NI, or Basic-5ess switch type, enter up to two service provider identifiers (SPIIDs).

Note
We recommend that you do not enter SPIIDs for the Basic-5ess switch type, even though SPIIDs are supported.
Step 7  Click OK to save your definitions locally on the client and close the dialog box. The interface definition appears in the Dialer Physical Interfaces table on the Dialer Interface page.

Dialer Policy Page

Use the Dialer page to define the relationship between physical Basic Rate Interface (BRI) and virtual dialer interfaces. You use these dialer interfaces when you configure the dial backup feature for site-to-site VPNs.

For more information, see Dialer Interfaces on Cisco IOS Routers, page 58-27.

Navigation Path

- (Device view) Select Interfaces > Settings > Dialer from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > Dialer from the Policy Type selector.
  Right-click Dialer to create a policy, or select an existing policy from the Shared Policy selector.

ADSL on Cisco IOS Routers

Digital Subscriber Line (DSL) is a family of technologies that transports data over existing twisted-pair copper wire. DSL uses frequencies that are beyond the upper list used by POTS (plain old telephone service) to deliver broadband applications, such as multimedia and video, over the local loop (or last mile) that connects the telephone company’s central office to customer sites.

<tr>
<td>SPID1</td>
<td>Applies only when you select Basic-DMS-100, Basic-NI, or Basic-5ess as the switch type. The service provider identifier (SPID) for the ISDN service to which the interface subscribes. Some service providers in North America assign SPIDs to ISDN devices when you first subscribe to an ISDN service. If you are using a service provider that requires SPIDs, your ISDN device cannot place or receive calls until it sends a valid assigned SPID to the service provider when accessing the switch to initialize the connection. Valid SPIDs can contain up to 20 characters, including spaces and special characters.</td>
</tr>
<tr>
<td></td>
<td>Note We recommend that you do not enter a SPID for interfaces using the AT&amp;T 5ESS switch type, even though they are supported.</td>
</tr>
<tr>
<td>SPID2</td>
<td>Applies only when you select DMS-100 or NI as the switch type. The service provider identifier (SPID) for a second ISDN service to which the interface subscribes. Valid SPIDs can contain up to 20 alphanumeric characters (no spaces are permitted).</td>
</tr>
</tbody>
</table>
Asymmetric Digital Subscriber Line (ADSL) is a form of DSL where the data flow downstream to customer sites is much greater than the data flow upstream to the central office (CO). This asymmetric setup is well-suited for applications where users typically download far more information than they send, such as web surfing, video-on-demand, and remote LAN access. With ADSL, the connection speed is related to the distance between the customer site and the digital subscriber line-access multiplexer (DSLAM) that aggregates the connections from multiple customer sites onto a high-speed line.

ADSL downstream rates range from 1.5 to 9 Mbps, whereas upstream bandwidth ranges from 16 to 640 kbps. ADSL transmissions work at distances up to 18,000 feet (5,488 meters) over a single copper twisted pair. Newer versions of ADSL technology, such as ADSL2 and ADSL2+, offer even higher data rates for short distances, as well as power management and realtime performance monitoring.

ATM is used in many ADSL implementations due to its small, fixed-length cell size, which makes it suitable for carrying time-critical traffic, such as voice and video, in conjunction with other traffic. You can use Security Manager to configure ATM over DSL on a Cisco IOS router. For more information about configuring ADSL policies in Security Manager, see Defining ADSL Settings, page 58-35.

To configure ADSL in Security Manager, you must do the following:

2. Configure ADSL settings on the ATM interface or subinterface. See Defining ADSL Settings, page 58-35.
3. Configure PVCs on the ATM interface or subinterface. See Defining ATM PVCs, page 58-50.

If you perform discovery on the device, Security Manager populates the Interfaces policy with the ATM interface and subinterface and the ADSL policy with the ADSL settings for that interface. Any discovered PVCs are added to the PVC policy.

- ADSL on Cisco IOS Routers, page 58-33

**Defining ADSL Settings**

When you configure an ADSL definition in Security Manager, you must select the ATM interface on which ADSL is being defined. In addition, we highly recommend that you specify the router type or the type of WIC (WAN interface card) installed in the router. The validity of DSL policy definitions is highly dependent on the hardware. By specifying the hardware used by this policy, you enable Security Manager to properly validate the values you define and avoid deployment failures.

You can optionally specify the following parameters:
- The DSL operating mode.
- Whether to enable dynamic VC bandwidth adjustments when using Inverse Multiplexing over ATM (IMA).
- Whether certain interface cards should use a particular set of carrier tones.

Modular Cisco IOS routers may contain multiple interface cards, each of which contains a single ATM interface. You may define only one ADSL definition per interface.

**Before You Begin**
- Make sure that the device contains an ADSL ATM interface. See Basic Interface Settings on Cisco IOS Routers, page 58-1.

**Related Topics**
- Supported ADSL Operating Modes, page 58-34
- ADSL on Cisco IOS Routers, page 58-33
- PVCs on Cisco IOS Routers, page 58-46

**Step 1**

Do one of the following:
- (Device view) Select Interfaces > Settings > DSL > ADSL from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > DSL > ADSL from the Policy Type selector. Select an existing policy or create a new one.
ADSL Policy Page

The ADSL page is displayed. See Table 58-16 on page 58-37 for a description of the fields on this page.

Step 2 Click the Add button beneath the table to display the ADSL Settings dialog box. See Table 58-17 on page 58-38 for a description of the fields in this dialog box.

Step 3 In the ATM Interface field, enter the name of the ATM interface or interface role on which you want to define ADSL settings, or click Select to select an interface role or create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Note The interface that you select must be physically present on the device; otherwise, deployment fails.

Step 4 (Optional) Select the interface card type installed on the router.

Note When discovering from a live device, the correct interface card type is already displayed. If you did not perform discovery on a live device, or if Security Manager cannot detect the type of interface card installed on the device, this field displays “Unknown”.

Step 5 (Optional) When using IMA groups, select the Allow bandwidth change on ATM PVCs check box to enable dynamic adjustments to VC bandwidth in response to changes in group bandwidth. If this check box is left deselected, you must make these adjustments manually.

Step 6 (Optional) Specify the DSL operating mode for this ATM interface. See Table 58-14 on page 58-34 for a list of the operating modes supported for each card type.

Step 7 (Optional) Select the Use low tone set check box to have the interface card use carrier tones 29 through 48.

Step 8 Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the ADSL table.

Note To edit an ADSL definition, select it from the table, then click Edit. To remove an ADSL definition, select it, then click Delete.

Step 9 Repeat Step 2 through Step 8 to define ADSL settings on additional ATM interfaces. Only one ADSL definition may be defined on an interface.

ADSL Policy Page

Use the ADSL page to create, edit, and delete ADSL definitions on the ATM interfaces of the router. For more information, see Defining ADSL Settings, page 58-35.

Navigation Path
  • (Device view) Select Interfaces > Settings > DSL > ADSL from the Policy selector.
  • (Policy view) Select Router Interfaces > Settings > DSL > ADSL from the Policy Type selector. Right-click ADSL to create a policy, or select an existing policy from the Shared Policy selector.

ADSL Settings Dialog Box

Use the ADSL Settings dialog box to configure ADSL settings on a selected ATM interface.

Note

When you configure ADSL settings, we highly recommend that you select the type of device or interface card on which the ATM interface is defined. ADSL settings are highly dependent on the hardware. Defining the hardware type in Security Manager enables proper validation of your configuration for a successful deployment to your devices.

Navigation Path

Go to the ADSL Policy Page, page 58-36, then click the Add or Edit button beneath the table.

SHDSL on Cisco IOS Routers

Digital Subscriber Line (DSL) is a family of technologies that transports data over existing twisted-pair copper wire. DSL uses frequencies that are beyond the upper list used by POTS (plain old telephone service) to deliver broadband applications, such as multimedia and video, over the local loop (or last mile) that connects the telephone company’s central office to customer sites.

Based on the International Telecommunications Union (ITU) G.991.2 global industry standard, symmetric high-speed digital subscriber line (SHDSL) delivers symmetrical data rates from 192 up to 2.3 Mbps on a single wire pair. It transports many types of signals, such as T1, E1, ISDN, ATM, and IP. In addition, the G.SHDSL signal has a greater distance reach from the central office than ADSL and proprietary SDSL connections.

To configure SHDSL in Security Manager, do the following:

2. Deploy the SHDSL policy. If ATM mode is activated, the router creates an ATM interface that corresponds to the controller upon deployment. See Working with Deployment and the Configuration Archive, page 8-24.

4. (Optional) Create one or more subinterfaces on the ATM interface. See Defining Basic Router Interface Settings, page 58-3.

5. Configure PVCs on the ATM interface or subinterface. See Defining ATM PVCs, page 58-50.

Note

If you perform discovery on the device, Security Manager populates the SHDSL policy with the definition of the controller and the Interfaces policy with the ATM interface and subinterface. Any discovered PVCs are added to the PVC policy.

- PVCs on Cisco IOS Routers, page 58-46

Defining SHDSL Controllers

When you configure an SHDSL controller in Security Manager, you must enter the name of the controller that is installed in the Cisco IOS router. The following settings are then applied automatically:

- ATM mode is enabled.
- The line termination is set to CPE (customer premises equipment).
- The line mode is set to Auto.

You can optionally change the line termination to CO and specify the DSL mode and line mode. In addition, you can define signal-to-noise ratio margins to improve line stability.

A Cisco IOS router may contain multiple SHDSL controllers. You may define only one SHDSL definition per controller.
Chapter 58  Configuring Router Interfaces

Note
When you deploy an SHDSL policy with ATM mode enabled, an ATM interface is created automatically on the router. Perform rediscovery to add the interface into Security Manager. You can then define PVCs on the ATM interface as required. See Defining ATM PVCs, page 58-50.

Before You Begin
- Make sure that an SHDSL controller is installed on the device.

Related Topics
- SHDSL on Cisco IOS Routers, page 58-40
- PVCs on Cisco IOS Routers, page 58-46

---

Step 1
Do one of the following:
- (Device view) Select Interfaces > Settings > DSL > SHDSL from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > DSL > SHDSL from the Policy Type selector. Select an existing policy or create a new one.

The SHDSL page is displayed. See Table 58-18 on page 58-42 for a description of the fields on this page.

Step 2
Click the Add button beneath the table to display the SHDSL dialog box.

Step 3
Enter the name of the controller, or click Select to display the utility for generating the name. See Controller Auto Name Generator Dialog Box, page 58-45.

Note
The controller that you select must be physically present on the device; otherwise, deployment fails.

Step 4
Define the SHDSL controller as required. For more information, see Table 58-19 on page 58-43.

Step 5
Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the SHDSL table.

Note
To edit an SHDSL controller, select it from the table, then click Edit. To remove an SHDSL controller, select it, then click Delete.

Step 6
Repeat Step 2 through Step 5 to define additional SHDSL controllers. Only one definition may be defined per controller.

---

SHDSL Policy Page

Use the SHDSL page to create, edit, and delete DSL controller definitions on the router. For more information, see Defining SHDSL Controllers, page 58-40.

Navigation Path
- (Device view) Select Interfaces > Settings > DSL > SHDSL from the Policy selector.
SHDSL Policy Page

- (Policy view) Select Router Interfaces > Settings > DSL > SHDSL from the Policy Type selector. Right-click SHDSL to create a policy, or select an existing policy from the Shared Policy selector.

PVCs on Cisco IOS Routers

Asynchronous Transfer Mode (ATM) is an International Telecommunication Union (ITU-T) standard designed for the high-speed transfer of voice, video, and data through public and private networks using cell relay technology. A cell switching and multiplexing technology, ATM combines the benefits of circuit switching (constant transmission delay, guaranteed capacity) with those of packet switching (flexibility, efficiency for intermittent traffic). An ATM network is made up of one or more ATM switches and ATM endpoints, such as a Cisco IOS router.

There are three general types of ATM services, permanent virtual connections (PVCs), switched virtual connections (SVCs), and connectionless service. PVCs allow direct and permanent connections between sites to provide a service that is similar to a leased line. Advantages of PVCs are the guaranteed availability of a connection and that no call setup procedures are required between switches. Each piece of equipment between the source and destination must be manually provisioned for the PVC.

For more information about ATM PVCs, see:

- Understanding Virtual Paths and Virtual Channels, page 58-46
- Understanding ATM Service Classes, page 58-47
- Understanding ATM Management Protocols, page 58-48

For more information about defining PVCs in Security Manager, see:

- Defining ATM PVCs, page 58-50
- Defining OAM Management on ATM PVCs, page 58-53

Related Topics

- ADSL on Cisco IOS Routers, page 58-33
- SHDSL on Cisco IOS Routers, page 58-40

Understanding Virtual Paths and Virtual Channels

ATM networks are fundamentally connection oriented. This means that a virtual connection needs to be established across the ATM network before any data transfer. Two types of ATM connections exist:

- Virtual path connections (VPCs), identified by a virtual path identifier (VPI).
- Virtual channel connections (VCCs), identified by the combination of a VPI and a VCI (virtual channel identifier). PVCs are a type of VCC where a permanent connection is defined between two sites.
As shown in Figure 58-2, a virtual path is a bundle of virtual channels, all of which are switched transparently across the ATM network on the basis of the common VPI. A VPC can be thought of as a bundle of VCCs with the same VPI value.

Figure 58-2  ATM Virtual Path and Virtual Channel Connections

Every cell header contains a VPI field and a VCI field, which explicitly associate a cell with a given virtual channel on a physical link. It is important to remember the following attributes of VPIs and VCIs:

- VPIs and VCIs are not addresses, such as MAC addresses used in LAN switching.
- VPIs and VCIs are explicitly assigned at each segment of a connection and, as such, have only local significance across a particular link. They are remapped, as appropriate, at each switching point.

Using the VPI/VCI identifier, the ATM layer can multiplex (interleave), demultiplex, and switch cells from multiple connections. Certain VPI/VCI identifiers are reserved for particular uses, such as the Integrated Local Management Interface (ILMI).

Understanding ATM Service Classes

Version 4.0 of the Traffic Management Specification published by the ATM Forum defines five service classes that describe the user traffic transmitted on a network and the quality of service that a network needs to provide for that traffic. Security Manager supports the following ATM service classes:

- **Available Bit Rate (ABR)** This is a service class where ATM switches make no guarantee of cell delivery, but do guarantee a minimum bit rate and that cell loss is kept as low as possible with the use of a feedback mechanism. The ABR service category is designed for VCs that carry file transfers and other bursty, non-real-time traffic that requires a minimum amount of bandwidth. This bandwidth is specified via a minimum cell rate that must be available while the VC is configured and active. For more details, see [Understanding the Available Bit Rate (ABR) Service Category for ATM VCs](http://www.cisco.com/en/US/tech/tk39/tk51/technologies_tech_note09186a00800fbc76.shtml).

- **Constant Bit Rate (CBR)** This is a service class where cells are transmitted in a continuous bitstream to meet voice and video QoS needs. The CBR service class is designed for ATM virtual circuits (VCs) that need a static amount of bandwidth that is continuously available for the duration of the active connection. An ATM VC configured as CBR can send cells at peak cell rate (PCR) at any time and for any duration. It also can send cells at a rate less than the PCR or even emit no cells. The
configuration on CBR may vary with different platforms. For more details, see Understanding the CBR Service Category for ATM VCs at:

- **Unspecified Bit Rate (UBR)** This is a service class where the network management makes no Quality of Service (QoS) commitment. It models the best-effort service that the Internet normally provides and is suitable for applications tolerant to delay that do not require real-time responses. Examples include email, fax transmission, file transfers, Telnet, LAN and remote office interconnections. For more details, see Understanding the UBR Service Category for ATM Virtual Circuits at:

- **Unspecified Bit Rate (UBR+)** Cisco provides a variant of the UBR service class called UBR+. The main advantage of the UBR+ service class is that it allows an ATM end-system to signal a minimum cell rate to an ATM switch in a connection request, and the ATM network attempts to maintain this minimum as an end-to-end guarantee. For more details, see Understanding the UBR+ Service Category for ATM VCs at:

- **Variable Bit Rate - Non-Real Time (VBR-nrt)** This service class is used to transmit non-real-time applications that are bursty in nature. The traffic characteristics are defined in terms of the Peak Cell Rate (PCR), Sustained Cell Rate (SCR), and Minimum Burst Size (MBS). For more details, see Understanding the VBR-nrt Service Category and Traffic Shaping for ATM VCs at:

- **Variable Bit Rate - Real Time (VBR-rt)** This service class is used to transmit real-time data that is sensitive to time delays, like compressed voice over IP and video conferencing. As with VBR-nrt, VBR-rt traffic is defined in terms of a PCR, SCR, and MBS. For more details, see Understanding the Variable Bit Rate Real Time (VBR-rt) Service Category for ATM VCs at:

You can use these service classes to define ATM quality of service (QoS) guarantees, such as traffic shaping. Traffic shaping is the use of queues to constrain data bursts, limit peak data rate, and smooth jitter so that traffic fits within the envelope defined by the traffic contract. ATM devices use traffic shaping to adhere to the terms of the traffic contract.

**Understanding ATM Management Protocols**

ATM uses two different types of signaling for tracking the status of PVCs:

- **Integrated Local Management Interface (ILMI).** For more information, see Understanding ILMI, page 58-49.
- **Flow 4 (F4) and Flow 5 (F5) Operation, Administration, and Maintenance (OAM) cells.** For more information, see Understanding OAM, page 58-50.

Security Manager can be used to enable and disable ILMI on specific PVCs and to configure F5 OAM functionality.
Understanding ILMI

The Integrated Local Management Interface (ILMI) is a protocol defined by the ATM Forum for setting and capturing physical layer, ATM layer, virtual path, and virtual circuit parameters on ATM interfaces. ILMI facilitates network-wide autoconfiguration by enabling devices to determine the status of components at the other end of a physical link and to negotiate a common set of operational parameters to ensure interoperability. The ATM routing protocols, PNNI (Private Network to Network Interface) and IIISP (Interim-Interswitch Signaling Protocol), use this information to discover and bring up a network of interconnected ATM switch routers.

When two ATM interfaces run the ILMI protocol, they exchange ILMI packets across the physical connection. These packets consist of SNMP messages as large as 484 octets. ATM interfaces encapsulate these messages in an ATM adaptation layer 5 (AAL5) trailer, segment the packet into cells, and schedule the cells for transmission. ATM interfaces use the SNMP object IDs in network functions such as permanent virtual circuit (PVC) autodiscovery, which is particularly useful in digital subscriber line (DSL) applications.

ILMI organizes managed objects into multiple information bases (MIBs), including one for link management. This MIB contains the following object groups for all ATM interfaces:

- **Physical layer**—ILMI 4.0 discontinues or “deprecates” earlier physical-layer ILMI values and specifies the use of the standard Interface MIB (RFC 1213).
- **ATM layer**—Indicates the number of available bits for VPI and VCI values in the ATM cell header, maximum number of virtual path connections (VPCs) and virtual channel connections (VCCs) allowed, number of configured PVCs, and so on.
- **Virtual path connection**—Indicates the up or down status of a VPC and its Quality of Service (QoS) parameters.
- **Virtual channel connection**—Indicates the up or down status of the VCC and its QoS parameters.

Administrators may enable or disable ILMI at will, but we highly recommend you enable it. Without ILMI, you must manually configure many of the parameters otherwise managed by ILMI for the ATM devices to operate correctly. ILMI operates over a reserved PVC of VPI=X, VCI=16.

Understanding OAM

The Operation, Administration, and Maintenance (OAM) feature provides fault management and performance management for ATM and is based on the standard defined in ITU recommendation I.610. OAM detects network connectivity failures on a PVC and reacts by bringing down the PVC. Without OAM, a PVC would remain up after network connectivity is lost. In such a situation, routing table entries would continue to point to the PVC, resulting in lost packets.

Security Manager enables the use of F5 OAM, which operates at the virtual circuit (VC) level. To detect a failure along the PVC path on an end-device, such as a Cisco IOS router, OAM uses the following cells:

- Loopback cells—At regular intervals, routers configured for OAM send loopback cells which must be looped in the network. This looping point can be the machine at the end of the PVC (end-to-end loopback cells) or a device on the path (segment loopback cells). A failure occurs when the loopback cell fails to return to its point of origin.
- Continuity Check (CC) cells—CC cells are sent regularly by routers configured for OAM to check the integrity of the link. CC cells can be sent either end-to-end or confined to a particular segment of the PVC. Activation and deactivation cells are used to initiate and suspend continuity checking. Any connectivity failures are reported in special SNMP notifications.
- Alarm Indication Signal (AIS) cells—In the event of a failure at the physical layer, AIS cells are sent to downstream devices to report a virtual connection failure at the ATM layer. The PVC moves to the down state after a defined number of AIS cells are received and does not come up again until a defined interval passes without additional AIS cells.
- Remote Detection Indication (RDI) cells—When AIS cells are sent to warn downstream devices of a connectivity failure, RDI cells are sent upstream in response as a control and feedback mechanism for the network.

AIS/RDI cells are sent using the same VPI/VCI as the user cells on the affected PVC until the failure is resolved.

- Defining OAM Management on ATM PVCs, page 58-53

Defining ATM PVCs

You define an ATM permanent virtual circuit (PVC) by selecting an ATM interface and then defining the following settings:

- The PVC ID.
- The type of encapsulation to use.
- Whether ILMI management is enabled on this PVC.
- Whether Inverse ARP (InARP) is used to learn the IP addresses of the destination devices.
- Options related to PPP over Ethernet (PPPoE) and PPP over ATM (PPPoA).
- Quality-of-service settings, such as traffic shaping.
- Static IP address mappings in place of InARP.
For information about defining F5 Operation, Administration, and Maintenance (OAM) management, such as loopbacks and continuity checks, on PVCs, see Defining OAM Management on ATM PVCs, page 58-53.

**Before You Begin**

- When configuring ATM over DSL, make sure that you have configured either an ADSL policy (see ADSL on Cisco IOS Routers, page 58-33) or an SHDSL policy (SHDSL on Cisco IOS Routers, page 58-40).
- Make sure that the device contains an ATM interface and subinterface. (PVCs are typically configured on ATM subinterfaces.) See Basic Interface Settings on Cisco IOS Routers, page 58-1.

*Note*  
When configuring ATM for SHDSL, the ATM interface is created when you define the SHDSL controller and enable ATM mode. You must then rediscover the device to add the ATM interface to Security Manager. See Defining SHDSL Controllers, page 58-40.

**Related Topics**

- Defining OAM Management on ATM PVCs, page 58-53
- Understanding Policing and Shaping Parameters, page 62-6
- PVCs on Cisco IOS Routers, page 58-46

**Step 1**  
Do one of the following:

- (Device view) Select Interfaces > Settings > PVC from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > PVC from the Policy Type selector. Select an existing policy or create a new one.

The PVC page is displayed. See Table 58-21 on page 58-55 for a description of the fields on this page.

**Step 2**  
Click the Add button beneath the table to display the PVC dialog box. See Table 58-22 on page 58-56 for a description of the fields in this dialog box.

**Step 3**  
In the Interface field, enter the name of the ATM interface, ATM subinterface, or interface role on which you want to define the PVC, or click Select to select an interface role or to create a new one.

**Step 4**  
Select the type of device or DSL WAN interface card that contains the ATM interface.

*Note*  
We highly recommend that you define this setting to ensure the proper validation of your PVC policy, as the settings in this policy are highly hardware-dependent.

**Step 5**  
On the Settings tab of the PVC dialog box, define the basic settings of the PVC:

a. Enter the VPI/VCI identifier and an optional text handle. If you are defining the management PVC, select the Management PVC (ILMI) check box.

*Note*  
An error occurs if two users attempt to define PVCs with the same identifiers at the same time.

b. Select the type of ATM encapsulation to use. If you select aal5autoppp or aal5ciscoppp, you must define the virtual template to use for PPPoA, or click Select to display a selector. If you select aal5mux as the encapsulation type, you must select the protocol that is carried by the PVC.
Note: Do not select an encapsulation type when defining the management PVC.

Note: If you modify the virtual template settings on an existing PVC, you must enter the `shutdown` command followed by the `no shutdown` command on the ATM subinterface to restart the interface. This causes the newly configured parameters to take effect.

c. Select the Enable ILMI check box to enable the ILMI to manage this PVC. For more information, see Understanding ILMI, page 58-49.

Note: You cannot configure the management PVC on a subinterface.

d. Select the Inverse ARP check box to enable the PVC to dynamically learn the Layer 3 addresses that are required to forward traffic to those devices.

Note: Alternatively, you can create static address mappings, as described in Step 7.

e. In the PPPoE Max Sessions field, define the maximum number of PPPoE sessions allowed on the PVC.

f. In the VPN Service Name field, define the static domain name to use for PPPoA sessions on the PVC.

See Table 58-23 on page 58-57 for a description of the fields on the Settings tab.

Step 6  (Optional) On the QoS tab of the PVC dialog box, define the type of ATM traffic shaping to perform on the traffic carried by this PVC. Traffic shaping regulates the flow of traffic carried by the PVC by queuing traffic that exceeds the defined bit rates. See Table 58-24 on page 58-61 for a description of the fields on the QoS tab.

Step 7  (Optional) On the Protocol tab of the PVC dialog box, create static mappings for the IP addresses at the other end of the PVC:

a. Click Add to display the Define Mapping dialog box. See Table 58-26 on page 58-65 for a description of the fields in this dialog box.

b. Select IP Address, then enter the address or network/host object that you want to map, or click Select to select a network/host object from a list or to create a new one.

c. Click OK. The static mapping is displayed on the Protocol tab.

d. Repeat a. through c. to define additional static mappings.

Note: You can also use the Protocol tab to change the type of InARP to use, broadcast or non-broadcast.

Step 8  Click Advanced to configure OAM management on the PVC. See Defining OAM Management on ATM PVCs, page 58-53.

Step 9  Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the PVC table.
Defining OAM Management on ATM PVCs

Security Manager enables you to configure the following F5 (VC level) Operation, Administration, and Maintenance (OAM) cells for detecting PVC failures in a Cisco IOS router:

- Loopback cells
- Continuity Check (CC) cells
- Alarm Indication Signal (AIS) cells
- Remote Detection Indication (RDI) cells

You can enable and disable each of these cell types and define settings that determine how each cell type affects the PVC when a failure is detected.

Before You Begin

- Select the ATM interface on which the PVC is defined.
- Define the general settings and the QoS settings of the PVC. See Defining ATM PVCs, page 58-50.

Related Topics

- Defining ATM PVCs, page 58-50
- PVCs on Cisco IOS Routers, page 58-46

Step 1

In the PVC dialog box, click Advanced to display the PVC Advanced Settings dialog box. See Table 58-27 on page 58-65 for a description of the fields in this dialog box.

Step 2

Enable OAM loopback cells on the selected PVC:

a. Click the OAM-PVC tab. See Table 58-29 on page 58-68 for a description of the fields on this tab.

b. Select the Enable OAM Management check box.

c. Define the frequency of loopback cell transmissions.

Step 3

(Optional) Enable segment CC cells on the PVC:

a. Under Segment Continuity Check, select Configure Continuity Check.

b. Choose whether the router should act as the sink, source, or both. This determines the direction in which CC cells are sent.

c. Choose whether the PVC should remain up after segment or end-to-end failures are detected.

Note

Select Deny Activation Requests to have the router reject CC activation requests received from peers.
Step 4 (Optional) Enable end-to-end CC cells on the PVC, using the procedure described in Step 3 for segment CC cells.

Step 5 (Optional) Configure additional loopback cell parameters:
   a. Click the OAM tab.
   b. Select the Enable OAM Retry check box, then define the down count, up count, and retry frequency. See Table 58-28 on page 58-66 for a description of the available options.

Step 6 (Optional) Configure additional CC cell parameters:
   a. Select the Enable check box for segment CC cells, then define the activation count, deactivation count, and retry frequency. These fields determine how many activation and deactivation requests are sent to peers and how often the router waits between each attempt. See Table 58-28 on page 58-66 for a description of the available options.
   b. Repeat a. for end-to-end CC cells.

Step 7 (Optional) Configure AIS/RDI cells on the PVC:
   a. On the OAM tab, select the Enable AIS-RDI Detection check box.
   b. Define how many AIS/RDI cells are required to move the PVC to the down state.
   c. Define how many seconds must elapse without receiving AIS/RDI cells before moving the PVC to the up state.

Step 8 Click OK to close the dialog box and return to PVC dialog box.

---

PVC Policy Page

Use the PVC page to create, edit, and delete permanent virtual connections (PVCs) on the router. PVCs allow direct and permanent connections between sites to provide a service that is similar to a leased line. These PVCs can be used in ADSL, SHDSL, or pure ATM environments. For more information, see Defining ATM PVCs, page 58-50.

Navigation Path
- (Device view) Select Interfaces > Settings > PVC from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > PVC from the Policy Type selector.
  Right-click PVC to create a policy, or select an existing policy from the Shared Policy selector.

PVC Dialog Box

Use the PVC dialog box to configure ATM permanent virtual circuits (PVCs).

You can configure the following types of interface cards:

- **Unknown**—The interface card type is not defined.
- **WIC-1ADSL**—A 1-port ADSL WAN interface card that provides ADSL over POTS (ordinary telephone lines).
- **WIC-1ADSL-I-DG**—A 1-port ADSL WAN interface card that provides ADSL over ISDN with Dying Gasp support. (With Dying Gasp, the router warns the DSLAM of imminent line drops when the router is about to lose power.)
- **WIC-1ADSL-DG**—A 1-port ADSL WAN interface card that provides ADSL over POTS with Dying Gasp support.
- **HWIC-1ADSL**—A 1-port high-speed ADSL WAN interface card that provides ADSL over POTS.
- **HWIC-1ADSLI**—A 1-port high-speed ADSL WAN interface card that provides ADSL over ISDN.
- **HWIC-ADSL-B/ST**—A 2-port high-speed ADSL WAN interface card that provides ADSL over POTS with an ISDN BRI port for backup.
- **HWIC-ADSLI-B/ST**—A 2-port high-speed ADSL WAN interface card that provides ADSL over ISDN with an ISDN BRI port for backup.
- **WIC-1-SHDSL-V2**—A 1-port multiline G.SHDSL WAN interface card with support for 2-wire mode and enhanced 4-wire mode.
• WIC-1-SHDSL-V3—A 1-port multiline G.SHDSL WAN interface card with support for 2-wire mode and 4-wire mode (standard & enhanced).
• NM-1A-T3—A 1-port ATM network module with a T3 link.
• NM-1A-OC3-POM—A 1-port ATM network module with an optical carrier level 3 (OC-3) link and three operating modes (multimode, single-mode intermediate reach (SMIR), and single-mode long-reach (SMLR)).
• NM-1A-E3—A 1-port ATM network module with an E3 link.
• 857 ADSL—Cisco 857 Integrated Service Router with an ADSL interface.
• 876 ADSL—Cisco 876 Integrated Services Router with an ADSL interface.
• 877 ADSL—Cisco 877 Integrated Services Router with an ADSL interface.
• 878 888 G.SHDSL—Cisco 878 Integrated Services Router with a G.SHDSL interface.
• 1801 ADSLoPOTS—Cisco 1801 Integrated Services Router that provides ADSL over POTS.
• 1802 ADSLoISDN—Cisco 1802 Integrated Services Router that provides ADSL over ISDN.
• 1803 G.SHDSL—Cisco 1803 Integrated Services Router that provides 4-wire G.SHDSL.

Navigation Path

</tr>
</tbody>
</table>
Use the QoS tab of the PVC dialog box to configure the ATM traffic shaping and other quality-of-service settings of the PVC, including:

- The limit on packets placed on transmission rings.
- The QoS service.
- Whether random detection is enabled.

These settings regulate the flow of traffic over the PVC by queuing traffic that exceeds the defined allowable bit rates.
QoS values are highly hardware dependent. Please refer to your router documentation for additional details about the settings that can be configured on your device.

**Navigation Path**

Go to the PVC Dialog Box, page 58-55, then click the QoS tab.

### PVC Dialog Box—QoS Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| **ABR** | The following fields are displayed when ABR is selected as the Bit Rate:  
  - PCR—The peak cell rate in kilobits per second (kbps). It specifies the maximum value of the ABR.  
  - MCR—The minimum cell rate in kilobits per second (kbps). It specifies the minimum value of the ABR.  
  
  The ABR varies between the MCR and the PCR. It is dynamically controlled using congestion control mechanisms. |
| **CBR** | The following field is displayed when CBR is selected as the Bit Rate:  
  - Rate—The constant bit rate (also known as the average cell rate) for the PVC in kilobits per second (kbps). An ATM VC configured for CBR can send cells at this rate for as long as required. |
| **UBR** | The following field is displayed when UBR is selected as the Bit Rate:  
  - PCR—The peak cell rate for output in kilobits per second (kbps). Cells in excess of the PCR may be discarded. |
| **UBR+** | The following fields are displayed when UBR+ is selected as the Bit Rate:  
  - PCR—The peak cell rate for output in kilobits per second (kbps). Cells in excess of the PCR may be discarded.  
  - MCR—The minimum guaranteed cell rate for output in kilobits per second (kbps). Traffic is always allowed to be sent at this rate.  
  
  **Note**  
  UBR+ requires Cisco IOS Software Release 12.4(2)XA or later, or version 12.4(6)T or later. |
| **VBR-NRT** | The following fields are displayed when VBR-NRT is selected as the Bit Rate:  
  - PCR—The peak cell rate for output in kilobits per second (kbps). Cells in excess of the PCR may be discarded.  
  - SCR—The sustained cell rate for output in kilobits per second (kbps). This value, which must be lower than or equal to the PCR, represents the maximum rate at which cells can be transmitted without incurring data loss.  
  - MBS—The maximum burst cell size for output. This value represents the number of cells that can be transmitted above the SCR but below the PCR without penalty. |
User Guide for Cisco Security Manager 4.3

Chapter 58  Configuring Router Interfaces

PVC Policy Page

Table 58-24  PVC Dialog Box—QoS Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| VBR-RT    | The following fields are displayed when VBR-RT is selected as the Bit Rate:  
|           | • Peak Rate—The peak information rate for realtime traffic in kilobits per second (kbps).  
|           | • Average Rate—The average information rate for realtime traffic in kilobits per second (kbps). This value must be lower than or equal to the peak rate.  
|           | • Burst—The burst size for realtime traffic, in number of cells. Configure this value if the PVC carries bursty traffic.  
|           | These values configure traffic shaping between realtime traffic (such as voice and video) and data traffic to ensure that the carrier does not discard realtime traffic, for example, voice calls. |
| IP QoS settings | |
| Random Detect | When selected, enables Weighted Random Early Detection (WRED) or VIP-distributed WRED (DWRED) on the PVC.  
|           | When deselected, WRED and DWRED are disabled. This is the default. WRED is a queue management method that selectively drops packets as the interface becomes congested. See Tail Drop vs. WRED, page 62-4. |

PVC Dialog Box—Protocol Tab

Use the Protocol tab of the PVC dialog box to add, edit, or delete the protocol mappings configured for the PVC. You may configured static mappings or Inverse ARP (broadcast or nonbroadcast) for each PVC, but not both.

Note  
IP is the only protocol supported by Security Manager for protocol mapping on ATM networks. You cannot define protocol mappings on the Management PVC (ILMI).

Navigation Path
Go to the PVC Dialog Box, page 58-55, then click the Protocol tab.

<td>Opens the Define Mapping Dialog Box, page 58-64. From here you can edit the selected mapping.</td>
</tr>
<tr>
<td>Delete button</td>
<td>Deletes the selected mapping from the table.</td>
</tr>
</tbody>
</table>

Define Mapping Dialog Box

Use the Define Mapping dialog box to configure the IP protocol mappings to use on the ATM PVC. Mappings are required by the PVC to discover which IP address is reachable at the other end of a connection. Mappings can either be learned dynamically using Inverse ARP (InARP) or defined statically. Static mappings are best suited for simple networks that contain only a few nodes.

- **Note**
  Inverse ARP is only supported for the aal5snap encapsulation type. See PVC Dialog Box—Settings Tab, page 58-57.

- **Tip**
  Use the CLI or FlexConfigs to configure mappings for protocols other than IP.

Navigation Path

Go to the PVC Dialog Box—Protocol Tab, page 58-63, then click Add or Edit.

### PVC Policy Page

**Table 58-28 PVC Advanced Settings Dialog Box—OAM Tab (Continued)**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Enable AIS-RDI Detection       | When selected, alarm indication signal (AIS) cells and remote defect indication (RDI) cells are used to report connectivity failures at the ATM layer of the PVC.  
When deselected, AIS/RDI cells are disabled.  
AIS cells notify downstream devices of the connectivity failure. The last ATM switch then generates RDI cells in the upstream direction towards the device that sent the original failure notification. |
| Down Count                     | The number of consecutive AIS/RDI cells that cause the PVC to go down. Valid values range from 1 to 60. The default is 1.                          |
| Up Count                       | The number of seconds after which a PVC is brought up if no AIS/RDI cells are received. Valid values range from 3 to 60 seconds. The default is 3.   |
| Segment Continuity Check       | When selected, OAM F5 continuity check (CC) activation and deactivation requests are sent to a device at the other end of a segment.  
When deselected, segment CC activation and deactivation requests are disabled.  
**Note** If Configure Continuity Check is deselected in the OAM-PVC tab, these settings are saved in the device configuration but are not applied. |
| Activation Count               | The maximum number of times that the activation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3. |
| Deactivation Count             | The maximum number of times that the deactivation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3. |
| Retry Frequency                | The interval between activation/deactivation retries, in seconds. The default is 30 seconds.                                                 |
| Enable End-to-End Continuity Check | When selected, OAM F5 continuity check (CC) activation and deactivation requests are sent to a device at the other end of the PVC.  
When deselected, segment CC activation and deactivation requests are disabled.  
**Note** If Configure Continuity Check is deselected in the OAM-PVC tab, these settings are saved in the device configuration but are not applied. |
| Activation Count               | The maximum number of times that the activation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3. |
| Deactivation Count             | The maximum number of times that the deactivation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3. |

  • sink—CC cells are transmitted toward the router that initiated the CC activation request.  
  • source—CC cells are transmitted away from the router that initiated the CC activation request. |
| **Keep VC up after segment failure** | When selected, the PVC is kept in the up state when CC cells detect connectivity failure.  
  When deselected, the PVC is brought down when CC cells detect connectivity failure. |
| **Keep VC up after end-to-end failure** | When selected, specifies that if AIS/RDI cells are received, the PVC is not brought down because of end CC failure or loopback failure.  
  When deselected, the PVC is brought down because of end CC failure or loopback failure. |
| **End-to-End Continuity Check** | The current configuration of OAM F5 end-to-end continuity checks on the PVC:  
  • None—End-to-end continuity checks (CC) are disabled.  
  • Deny Activation Requests—The PVC rejects activation requests from peer devices, which prevents OAM F5 CC management from being activated on the PVC.  
  • Configure Continuity Check—End-to-end CCs are enabled on the PVC. The router on which CC management is configured sends a CC activation request to the router at the other end of the connection, directing it to act as either a source or a sink.  
  End-to-end CC monitoring is performed on the entire PVC between two ATM end stations. |
| **Direction**               | Applies only when CC management is enabled. The direction in which CC cells are transmitted:  
  • both—CC cells are transmitted in both directions.  
  • sink—CC cells are transmitted toward the router that initiated the CC activation request.  
  • source—CC cells are transmitted away from the router that initiated the CC activation request. |
| **Keep VC up after end-to-end failure** | When selected, the PVC is kept in the up state when CC cells detect connectivity failure.  
  When deselected, the PVC is brought down when CC cells detect connectivity failure. |
PPP on Cisco IOS Routers

The Point-to-Point Protocol (PPP), as defined in RFC 1661, provides a method for transporting packets between two devices or hosts using physical or logical links. PPP is a Layer 2 data-link protocol that can work with multiple Layer 3 network-layer protocols, including IP, IPX, and AppleTalk.

PPP is used in many common scenarios, such as:

- Connecting remote users to a central network over dial-in connections.
- Connecting the gateway of an enterprise network to an ISP for internet access.
- Connecting two LANs (for example, a central office and a branch office) to exchange data between them.

PPP connectivity is established in stages:

1. First, a Link Control Protocol (LCP) establishes, configures, and tests the data-link connection.
2. (Optional) Authentication verifies the identity of the two parties.
3. A family of Network Control Protocols (NCPs) establishes and configures the necessary network-layer protocols.

The PPP policy in Security Manager provides a method for configuring selected parameters that are negotiated between the two nodes during the LCP stage, including authentication (typically CHAP or PAP) and Multilink PPP (MLP). For more information about MLP, see Defining Multilink PPP Bundles, page 58-74.

The following topics describe the tasks you perform to create PPP policies on Cisco IOS routers:

- Defining PPP Connections, page 58-71
- Defining Multilink PPP Bundles, page 58-74

Understanding Multilink PPP (MLP)

MLP, as defined in RFC 1990, is a method for splitting, recombining, and sequencing datagrams across multiple logical data links. MLP was originally designed to exploit multiple bearer channels in ISDN, but it can be used whenever multiple PPP links connect two systems, including asynchronous links.

MLP spreads inbound and outbound traffic across multiple physical WAN links (known collectively as a bundle) while providing the following benefits:

- Packet fragmentation and reassembly
- Proper sequencing
- Multivendor interoperability
- Load balancing
As shown in Figure 58-3, traffic routed across an MLP link is fragmented, with the fragments being sent across the different physical links. At the remote end of the link, the fragments are reassembled and forwarded to the next hop toward their ultimate destination. By using multiple physical links, MLP provides a way to temporarily use the additional bandwidth afforded by these links.

**Figure 58-3  Multilink PPP**

Every MLP bundle is controlled by a single interface, the bundle master, which is a virtual-access interface. This interface is created in the background when the bundle is first created. The physical interface becomes part of the bundle that is managed by the bundle master. Bundles are also used when you create a multilink group consisting of a multilink interface and its associated serial interfaces, which is a setup that is often found in static, leased-line environments.

MLP uses an endpoint discriminator to identify the system transmitting a packet. By default, this discriminator is based on the hostname of the router, but it can also be based on other criteria, such as the IP address or MAC address of the interface, a telephone number, or a user-defined string. If the endpoint discriminator matches the discriminator of an existing link, the new link is added to the matching bundle. If no match exists, a new bundle is created. When authentication is used, a new bundle is established whenever there is a mismatch in either the discriminator or the authentication information exchanged between the two nodes.

Related Topics

- PPP on Cisco IOS Routers, page 58-70

### Defining PPP Connections

When you define a PPP connection, the first step is to select the interface on which PPP should be enabled. You must select one of the following interface types:

- Async
- Group-Async
- Serial
- High-Speed Serial Interface (HSSI)
- Dialer
- BRI, PRI (ISDN)
- Virtual template
• Multilink

You cannot define PPP connections on:
• Subinterfaces.
• Serial interfaces with Frame Relay encapsulation.
• Virtual template interfaces defined as Ethernet or tunnel types (serial is supported).

Note: You cannot configure PPP on serial interfaces that are configured for Frame Relay encapsulation. See Defining Basic Router Interface Settings, page 58-3.

Note: Deployment might fail if you define PPP on a virtual template that is also used in an 802.1x policy. See Defining 802.1x Policies, page 60-4.

You can select one or more authentication protocols and define when authentication should be performed.

In addition, you can configure the authentication and authorization methods to use when performing AAA on a remote security server. You can either define a default method list to use for all PPP connections on the device or define a customized method list that applies to a specific connection.

Before You Begin
• Make sure that the device contains an interface on which PPP can be configured. See Basic Interface Settings on Cisco IOS Routers, page 58-1.

Related Topics
• Defining Multilink PPP Bundles, page 58-74
• PPP on Cisco IOS Routers, page 58-70

Step 1
Do one of the following:
• (Device view) Select Interfaces > Settings > PPP/MLP from the Policy selector.
• (Policy view) Select Router Interfaces > Settings > PPP/MLP from the Policy Type selector.

Select an existing policy or create a new one.

The PPP/MLP page is displayed. See Table 58-30 on page 58-75 for a description of the fields on this page.

Step 2
Click the Add button beneath the table to display the PPP dialog box.

Step 3
In the Interface field, enter the name of the interface or interface role on which you want to define the PPP connection, or click Select to select an interface role from a list or to create a new one.

Step 4
(Optional) On the PPP tab, define authentication for the PPP connection:

a. Select one or more authentication protocols.

b. Select one or more authentication options. These options determine when to perform authentication (callin, callout, and callback), whether to use one-time passwords, and whether to allow a mobile station in a PDSN configuration to receive Simple IP and Mobile IP services without using CHAP or PAP.
Chapter 58 Configuring Router Interfaces

PPP on Cisco IOS Routers

Note
The Call Back option only enables authentication during callback. Use the CLI or FlexConfigs to configure the callback feature on the device.

c.  See PPP Dialog Box—PPP Tab, page 58-77 for a description of the fields on this tab.

Step 5
(Optional) When using a remote AAA server to perform authentication, select Default List or Custom Method List in the Authenticate Using field, then define the methods to use in the Prioritized Method List field.

Note
If you modify the default list, your changes affect all PPP connections on the devices that use this list. If you leave this field blank, authentication is performed using the local database on the device.

Step 6
(Optional) When using a remote AAA server to perform authorization, select AAA Policy Default List or Custom Method List, then define the methods to use in the Prioritized Method List field.

Note
If you choose AAA Policy Default List, the device uses the default authorization methods defined in the AAA policy. See Defining AAA Services, page 59-4.

Step 7
(Optional) Define the username and password to send in response to PAP authentication requests.

Note
If you entered the encrypted version of the password, select the Encrypted check box.

Step 8
(Optional) Define a different hostname to send in all CHAP challenges and responses in place of the router's own hostname.

Note
If you entered the encrypted version of the password, select the Encrypted check box.

Step 9
(Optional) To enable Multilink PPP on this connection, click the MLP tab. See Defining Multilink PPP Bundles, page 58-74.

Step 10
Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the PPP table.

Note
To edit a PPP connection, select it from the table, then click Edit. To remove a PPP connection, select it, then click Delete.

Step 11
Repeat Step 2 to Step 10 to define PPP connections on additional interfaces. Only one PPP connection may be defined on an interface.
Defining Multilink PPP Bundles

You enable Multilink PPP (MLP) on the selected interface by selecting the check box at the top of the Multilink tab in the PPP dialog box. You can optionally enable Multiclass Multilink PPP (MCMP), which prevents delay-sensitive traffic from fragmentation, and interleaving, which enables packets to be interspersed among the fragments of larger packets. If you want to restrict a serial interface to a specific bundle, you can select the multilink interface that represents that bundle.

In addition, you can optionally modify the following default settings:

- The maximum fragment delay.
- The endpoint discriminator that identifies the router when negotiating the use of MLP.
- The maximum receive reconstructed unit (MRRU) permitted by the router and its peers.
- The maximum queue depth for first-in, first-out (FIFO) and non-FIFO queues.

Before You Begin

- Select the interface on which the PPP connection should be enabled.

Related Topics

- Defining PPP Connections, page 58-71
- PPP on Cisco IOS Routers, page 58-70

Step 1

In the PPP dialog box, click the MLP tab. See PPP Dialog Box—MLP Tab, page 58-79 for a description of the fields on this tab.

Step 2

Select the Enable Multilink Protocol (MLP) check box.

Step 3

(Optional) Configure one or more of the following options:

a. Whether to enable the multiclass feature that prevents delay-sensitive traffic from being fragmented. This is achieved by placing delay-sensitive traffic in a separate class from regular traffic.

b. Whether to enable the interleaving of packets among the fragments of larger packets on the MLP bundle.

c. Whether to restrict the physical link to joining only a designated multilink-group (defined by selecting a multilink interface). If a peer at the other end of the link tries to join a different bundle, the connected is severed.

d. Whether to modify the default amount of time required to transmit a fragment on the MLP bundle. The default is 30 milliseconds.

Note

If you enable interleaving without defining a fragment delay, the default delay of 30 seconds is configured. This value does not appear in Security Manager or in the device configuration.

Step 4

(Optional) Under Endpoint, modify the default endpoint discriminator used on the MLP bundle.

The endpoint discriminator is used to identify the router on the MLP bundle. The default endpoint discriminator is either the globally configured hostname, or the PAP username or CHAP hostname (depending on the authentication protocol being used), if you configured those values on the PPP tab. See Defining PPP Connections, page 58-71.

Step 5

(Optional) In the MRRU fields, modify the default maximum packet size that the router (local) or the peer (remote) is capable of receiving.
Step 6  (Optional) Modify the default maximum size of link transmit queues when using FIFO and non-FIFO (QoS) queuing.

Step 7  Click OK to close the dialog box. Your definitions are displayed on the PPP page.

PPP/MLP Policy Page

Use the PPP/MLP page to create, edit, and delete PPP connections on the router. For more information, see Defining PPP Connections, page 58-71.

Navigation Path

- (Device view) Select Interfaces > Settings > PPP/MLP from the Policy selector.
- (Policy view) Select Router Interfaces > Settings > PPP/MLP from the Policy Type selector. Right-click PPP/MLP to create a policy, or select an existing policy from the Shared Policies selector.

</tbody>
</table>
| PPP Encapsulation | The authentication protocols to use:  
  - PAP—Password Authentication Protocol.  
  - MS-CHAP—Version 1 of the Microsoft version of CHAP (RFC 2433).  
  - MS-CHAP-2—Version 2 of the Microsoft version of CHAP (RFC 2759).  
  - EAP—Extensible Authentication Protocol.  
You may select one or more authentication protocols, as required. |
### Options

The authentication options to use:

- **Call In**—When selected, authentication is performed on incoming calls.
- **Call Out**—When selected, authentication is performed on outgoing calls.
- **Call Back**—When selected, authentication is performed on callback.
- **One Time**—When selected, one-time passwords are used for authentication. One-time passwords are considered highly secure since each one is used only once. When deselected, one-time passwords are not used.

**Note**

AAA authentication must be enabled in order to use one-time passwords. See AAA Policy Page, page 59-6. One-time passwords cannot be used with CHAP.

- **Optional**—When selected, allows a mobile station in a Packet Data Serving Node (PDSN) configuration to receive Simple IP and Mobile IP services without using CHAP or PAP.

When deselected, mobile stations must use CHAP or PAP to receive Simple IP and Mobile IP services.

### Authenticate Using

AAA authentication settings for the PPP connection:

- **PPP Default List**—Defines a default list of methods to be queried when authenticating a user for PPP. Enter the names of one or more AAA server group objects (up to four) in the Prioritized Method List field, or click **Select** to select it. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it.

  The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.

**Tip**

After you create the default list for one PPP connection, you can use it for other PPP connections on this device.

- **Prioritized Method List**—Defines a sequential list of methods to be queried when authenticating a user for this PPP connection only.

**Note**

Leave this field blank to perform authentication using the local database on the router.

### PAP Authentication settings

**Username**

The username to send in PAP authentication requests. The username is case sensitive.

<td>Enable Multilink PPP (MLP)</td>
<td>When selected, MLP is enabled on this PPP connection. When deselected, MLP is disabled.</td>
</tr>
<tr>
<td>Allow Multiple Data Classes</td>
<td>When selected, enables multiple data classes on the MLP bundle. Delay-sensitive traffic is placed into Class 1, where it can be interleaved but never fragmented. Normal data traffic is placed into Class 0, which is subject to fragmentation just as regular multilink packets are. When deselected, all traffic is subject to fragmentation.</td>
</tr>
<tr>
<td>Enable Interleaving of Packets Among Fragments of Larger Packets</td>
<td>When selected, enables the interleaving of packets among the fragments of larger packets on the MLP bundle.</td>
</tr>
<tr>
<td>Note</td>
<td>If you enable interleaving without defining a fragment delay, the default delay of 30 seconds is configured. This value does not appear in Security Manager or in the device configuration.</td>
</tr>
<tr>
<td></td>
<td>When deselected, interleaving is disabled.</td>
</tr>
<tr>
<td>Note</td>
<td>Serial interfaces do not support interleaving.</td>
</tr>
<tr>
<td>Multilink Group</td>
<td>Applies only to serial, Group-Async, and multilink interfaces. Restricts the physical link to the selected multilink-group interface. Enter the name of a multilink interface or interface role, or click Select to select it. If the object that you want is not listed, click the Create button to create it.</td>
</tr>
<tr>
<td></td>
<td>This option is typically used in static leased-line environments, where the remote systems to which the device’s serial lines are connected are known in advance.</td>
</tr>
<tr>
<td></td>
<td>In effect, this option dedicates a specific interfaces to a particular user, even when that user is not connected. If a peer at the other end of the link tries to join a different bundle, the connected is severed.</td>
</tr>
<tr>
<td>Maximum Fragment Delay</td>
<td>The maximum amount of time that should be required to transmit a fragment on the MLP bundle. Valid values range from 1 to 1000 milliseconds. Fragment size is determined by the defined fragment delay and the bandwidth of the links.</td>
</tr>
<tr>
<td>Note</td>
<td>Serial interfaces do not support this feature.</td>
</tr>
</tbody>
</table>
### Endpoint Type
The identifier used by the router when transmitting packets on the MLP bundle:

- **[null]**—Negotiation is conducted without using an endpoint discriminator. (No CLI command is generated.)
- **Hostname**—The hostname of the router. This option is useful when multiple routers are using the same username to authenticate but have different hostnames.
- **IP**—A defined IP address. Enter the address or the name of a network/host object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.
- **MAC**—The MAC address of a specific interface. Enter the name of the interface or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.
- **None**—Negotiation is conducted without using an endpoint discriminator. (The relevant CLI command is generated, but no endpoint discriminator is provided.) This option is useful when the router is connected to a malfunctioning peer that does not handle the endpoint discriminator properly.
- **Phone**—An E.164-compliant telephone number. Enter the number in the field displayed.
- **String**—A character string. Enter the string in the field displayed.

The default endpoint discriminator is either the globally configured hostname, or the PAP username or CHAP hostname (depending on the authentication protocol being used), if you have configured those values on the PPP tab.

### MRRU Local Peer
The maximum receive reconstructed unit (MRRU) value of the local peer. This value represents the maximum size packet that the local router is capable of receiving.

Valid values range from 128 to 16384 bytes. The default is the maximum transmission unit (MTU) of the multilink group interface and 1524 bytes for all other interfaces.

### MRRU Remote Peer
The maximum receive reconstructed unit (MRRU) value of the remote peer. This value represents the maximum size packet that the remote peer is capable of receiving.

Valid values range from 128 to 16384 bytes. The default is 1524 bytes.

### Maximum FIFO Queue Size
The maximum queue depth when the bundle uses first-in, first-out (FIFO) queuing. Valid values range from 2 to 255 packets. The default is 8.

### Maximum QoS Queue Size
The maximum queue depth when the bundle uses non-FIFO queuing. Valid values range from 2 to 255 packets. The default is 2.

---

AAA on Cisco IOS Routers

Authentication, authorization, and accounting (AAA) network security services provide the primary framework through which you set up access control on your Cisco IOS router. Use the AAA policy in Security Manager to enable AAA functionality on Cisco IOS routers and to configure default AAA settings. The default settings that you define in this policy can be used in other policies, such as HTTP and line access (console and VTY) policies. Enabling AAA functionality is a prerequisite for any device policy that makes use of AAA, including NAC, SDP, and 802.1x.

For more information about AAA, see:
- Supported Authorization Types, page 59-2
- Supported Accounting Types, page 59-3
- Understanding Method Lists, page 59-3

To configure a AAA policy, see:
- Defining AAA Services, page 59-4

Related Topics
- Understanding AAA Server and Server Group Objects, page 6-23
- Line Access on Cisco IOS Routers, page 59-35

Supported Authorization Types

AAA authorization enables you to limit the services available to an authenticated user. Security Manager supports the following types of authorization:
- Network—Authorizes various types of network connections, such as PPP, SLIP, and ARAP.
- EXEC—Authorizes the launching of EXEC (CLI) sessions.
- Command—Authorizes the use of all EXEC mode commands that are associated with specific privilege levels.

When authorization is enabled, the router uses information retrieved from the user’s profile to configure the user session. The profiles are located either in the local user database or on a security server. Users are granted access to a requested service only if the profile allows it.

Related Topics
- Supported Accounting Types, page 59-3
- Understanding Method Lists, page 59-3
- Defining AAA Services, page 59-4
- AAA on Cisco IOS Routers, page 59-2
Supported Accounting Types

AAA accounting enables you to track the services the users are accessing and the amount of network resources that they are consuming. Security Manager supports the following accounting types:

- **Connection**—Records information about all outbound connections made from this device, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin connections.

  For example, a RADIUS connection accounting record for an outbound Telnet connection includes such information as the port and IP address of the network access server (NAS), the start and end times of the connection, the identity of the user, and the number of packets that were transmitted during the session.

- **EXEC**—Records information about user EXEC (CLI) sessions on the devices, including the username, date, start and stop times, and the IP address of the NAS. For dial-in users, the record includes the telephone number from which the call originated.

- **Command**—Records information about the EXEC commands executed on the device by users with specific privilege levels. Each command accounting record includes a list of the commands executed for that privilege level, the date and time each command was executed, and the name of the user who executed it.

For each accounting type, you can choose whether you want to generate an accounting record at the start and end of each user session or only at the end.

When AAA accounting is enabled, the router sends accounting records of user activity to the TACACS+ or RADIUS security server. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can later be analyzed for network management, client billing, and auditing purposes.

**Related Topics**

- Supported Accounting Types, page 59-3
- Understanding Method Lists, page 59-3
- Defining AAA Services, page 59-4
- AAA on Cisco IOS Routers, page 59-2

Understanding Method Lists

A method list is a sequential list describing the methods to use to perform a particular AAA function. In Security Manager, you define method lists by selecting AAA server groups, which are reusable objects that typically contain one or more AAA servers running the same protocol, such as RADIUS or TACACS+. Method lists enable you to designate one or more security protocols to be used for each AAA function, thus ensuring a backup system if the initial method fails.

**Note**

Security Manager also contains predefined AAA server group objects for using the enable password or a local database. See Predefined AAA Authentication Server Groups, page 6-26.

For each AAA function, the device initially uses the first method defined in the list. If that method fails to respond, the device selects the next method in the list. This process continues until there is successful communication with a listed method, or all methods defined in the method list are exhausted.
Defining AAA Services

To define AAA services on a Cisco IOS router, you must first enable AAA functionality on the router. After you do this, you can define the kind of functionality (authentication, authorization, and accounting) that you want the device to implement. You must define a method list for each function, including lists for each type of authorization and accounting that you enable.

For example, if you want to configure EXEC authorization and command authorization, you must define one method list for EXEC authorization and other method lists for each privilege level on which command authorization is performed.

Note If you use RADIUS for authentication, you must use the same RADIUS server group for authorization as well.

Step 1 Do one of the following:

- (Device view) Select Platform > Device Admin > AAA from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > AAA from the Policy Type selector.

Select an existing policy or create a new one.

The AAA page is displayed. See AAA Policy Page, page 59-6 for a description of the fields on this page.

Step 2 Define which login authentication methods to use on users who access the device:

a. On the Authentication tab (see AAA Page—Authentication Tab, page 59-6), select the Enable Device Login Authentication check box.

b. Enter the names of one or more AAA server group objects (up to four) in the Prioritized Method List field, or click Select select the object from a list or to create a new one. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used.
Note: If you select None as a method, it must appear as the last method in the list.

**Step 3**  (Optional) In the Maximum Number of Attempts field, define the maximum number of unsuccessful authentication attempts to allow before a user is locked out.

**Step 4**  (Optional) Define which authorization methods to use on users who have been successfully authenticated:

a. Click the **Authorization** tab on the AAA page. See Table 59-3 on page 59-8 for a description of the fields on this tab.

b. Define method lists for one or more of the following types of authorization:

   • Network
   • EXEC
   • Command—Click the **Add** button to display the Command Authorization dialog box (see Command Authorization Dialog Box, page 59-9). From here, you can select a privilege level and the method list to apply to it.

For more information about these authorization types, see Supported Authorization Types, page 59-2.

**Note**  RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

**Step 5**  (Optional) Define which accounting methods to use on the activities performed by users:

a. Click the **Accounting** tab on the AAA page. See Table 59-5 on page 59-11 for a description of the fields on this tab.

b. Define method lists for one or more of the following types of accounting:

   • Connection
   • EXEC
   • Command—Click the **Add** button to display the Command Accounting dialog box (see Command Accounting Dialog Box, page 59-12). From here, you can select a privilege level and the method list to apply to it.

For more information about these accounting types, see Supported Accounting Types, page 59-3.

c. For each accounting type defined above, select a value from the Accounting Process Notices list. This defines when to create an accounting record, at the beginning and end of the user process or only at the end.

d. For each accounting type defined above, select the **Enable broadcast to multiple servers** check box if you want accounting information sent simultaneously to the first server in each AAA server group defined in the method list.
AAA Policy Page

Use the AAA page to define the default authentication, authorization, and accounting methods to use on the router. You do this by configuring method lists, which define which methods to use and the sequence in which to use them.

Note

You can use the method lists defined in this policy as default settings when you configure AAA on the router’s console port and VTY lines. See Console Policy Page, page 59-42 and VTY Policy Page, page 59-50.

Navigation Path

- (Device view) Select Platform > Device Admin > AAA from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > AAA from the Policy Type selector.

Right-click AAA to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 59-2  AAA Page—Authentication Tab

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Enable Device Login Authentication | When selected, enables the authentication of all users when they log in to the device, using the methods defined in the method list.  
When deselected, authentication is not performed. |
| Prioritized Method List         | Defines a sequential list of methods to be queried when authenticating a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.  
The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.  
Supported methods include Line, Local, Kerberos, LDAP, RADIUS, TACACS+, and None.  
**Note** If you select None as a method, it must appear as the last method in the list. |
| Maximum Number of Attempts      | The maximum number of unsuccessful authentication attempts before a user is locked out. This feature is disabled by default. Valid values range from 1 to 65535.  
**Note** From the standpoint of the user, there is no distinction between a normal authentication failure and an authentication failure due to being locked out. The system administrator has to explicitly clear the status of a locked-out user using clear commands. |

AAA Page—Authorization Tab

Use the Authorization tab of the AAA page to define the type of authorization services to enable on the device and the methods to use for each type. Security Manager supports the following types of authorization:
- Network—Authorizes various types of network connections, such as PPP.
- EXEC—Authorizes the launching of EXEC sessions.
• Command—Authorizes the use of all EXEC mode commands that are associated with specific privilege levels.

**Note** You can use the method lists defined in this policy on the console and VTY lines that are used to communicate with the device. See Console Policy Page, page 59-42 and VTY Line Dialog Box—Authentication Tab, page 59-55.

**Navigation Path**
Go to the AAA Policy Page, page 59-6, then click the **Authorization** tab.

**Related Topics**

EXEC Authorization settings
Use the Command Authorization dialog box to define which methods to use when authorizing the EXEC commands that are associated with a given privilege level. This enables you to authorize all commands associated with a specific privilege level, from 0 to 15.

**Navigation Path**
From the **AAA Page—Authorization Tab**, page 59-7, click the **Add** button beneath the Command Authorization table.

**Related Topics**
- Defining AAA Services, page 59-4
- Supported Authorization Types, page 59-2
- Understanding Method Lists, page 59-3
AAA Page—Accounting Tab

Use the Accounting tab of the AAA page to define the type of accounting services to enable on the device and the methods to use for each type. Security Manager supports the following types of accounting:

- **Connection**—Records information about all outbound connections made from this device.
- **EXEC**—Records information about user EXEC sessions on the devices, including the username, date, start and stop times, and the IP address.
- **Command**—Records information about the EXEC commands executed on the device by users with specific privilege levels.

In addition, you use the Accounting page to determine when accounting records should be generated and whether they should be broadcast to more than one AAA server.

**Note**
You can use the method lists defined in this policy on the console and VTY lines that are used to communicate with the device. See Console Policy Page, page 59-42 and VTY Line Dialog Box—Authentication Tab, page 59-55.

**Navigation Path**
Go to the AAA Policy Page, page 59-6, then click the Accounting tab.

**Related Topics**
- Defining AAA Services, page 59-4
- Supported Accounting Types, page 59-3
- Understanding Method Lists, page 59-3

Field Reference

Table 59-5 AAA Page—Accounting Tab

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Connection Accounting settings</strong></td>
<td></td>
</tr>
</tbody>
</table>
| Enable Connection Accounting  | When selected, enables the recording of information about outbound connections (such as Telnet) made over this device, using the methods defined in the method list.  
When deselected, connection accounting is not performed.                                                                                                                                   |
| Generate Accounting Records for | Defines when the device sends an accounting notice to the accounting server:  
- Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the “start” accounting record.  
- Stop Only—Generates an accounting record at the end of the user process only.  
- None—Disables this type of accounting.                                                                                                                                 |
| Prioritized Method List        | Defines a sequential list of methods to be queried when creating connection accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it. Supported methods include LDAP, RADIUS, and TACACS+. |
| Enable Broadcast to Multiple Servers | When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group.  
When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.                                                                 |
| **EXEC Accounting Settings**   |                                                                                                                                                                                                                                                                                                                                                   |
| Enable CLI/EXEC Operations Accounting | When selected, enables the recording of basic information about user EXEC sessions, using the methods defined in the method list.  
When deselected, EXEC accounting is not performed.                                                                                                                                                                                                                                        |
| Generate Accounting Records for | See description Table 41-7 on page 41-16.                                                                                                                                                                                                                                                                                                           |
| Prioritized Method List        | Defines a sequential list of methods to be queried when creating connection accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it. |
Use the Command Accounting dialog box to define which methods to use when recording information about the EXEC commands that are executed for a given privilege level. Each accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the name of the user who executed it.

**Navigation Path**

From the AAA Page—Accounting Tab, page 59-10, click the Add button beneath the Command Accounting table.

</tbody>
</table>
User Accounts and Device Credentials on Cisco IOS Routers

Accounts and credential policies define the contact information for accessing the router, including the privilege level provided to each user account. You can configure as many user accounts as required. However, the user account that Security Manager uses to connect to the router is always the one configured in the Device Properties page.

Additionally, you use device access policies to define the enable or enable secret password required to access privileged EXEC mode. This is the mode required to make any configuration changes on the router.

Table 59-6 Command Accounting Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Generate Accounting Records for | Defines when the device sends an accounting notice to the accounting server:  
  - Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the “start” accounting record.  
  - Stop Only—Generates an accounting record at the end of the user process only.  
  - None—No accounting records are generated. |
| Prioritized Method List | Defines a sequential list of methods to be used when creating accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.  
  The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.  
  TACACS+ is the only supported method, but you can select multiple AAA server groups configured with TACACS+.  
  **Note** If you select None as a method, it must appear as the last method in the list. |
| Enable Broadcast to Multiple Servers | When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group.  
  When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list. |
If you use this policy to define a password, be careful later not to unassign this policy without assigning a replacement policy before your next deployment. If you deploy a device access policy that removes this password and the device contains a different type of password not known to Security Manager, such as a line console password, you will not be able to configure this device in the future. This is because the device reverts to this unknown password if Security Manager removes the enable password that it had previously configured.

**Related Topics**

---

### Defining Accounts and Credential Policies

This procedure describes how to define a device access policy on a Cisco IOS router. If the username that you configured on the Device Properties page to connect to the router (see Viewing or Changing Device Properties, page 3-37) matches one of the user accounts you defined in this policy, Security Manager updates the device credentials according to your policy definition.

If you change the password for the user defined in the device properties, which Security Manager uses to deploy configurations to the device, or change the enable password, Security Manager uses the existing credentials defined in the device properties to log into the device and deploy changes. After successful deployment, the device properties are then changed to use your new settings. For more information on credentials in device properties, see Device Credentials Page, page 3-41.

**Note**
You can discover encrypted passwords, but any password you enter must be in clear text. If you discover an encrypted password and then modify it, the password is saved as clear text.

**Related Topics**
- User Accounts and Device Credentials on Cisco IOS Routers, page 59-13

---

#### Step 1
Do one of the following:
- (Device view) Select **Platform > Device Admin > Accounts and Credentials** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Accounts and Credentials** from the Policy Type selector. Select an existing policy or create a new one.

The Accounts and Credentials page is displayed. See Table 59-7 on page 59-16 for a description of the fields on this page.

#### Step 2
Enter the password for switching to privileged EXEC mode on the router:

- **Enable Password** or **Enable Secret Password**. The Enable Secret Password option offers better security than the Enable Password option by storing the password using MD5 encryption. This option is useful in environments in which the password crosses the network or is stored on a TFTP server.

**Note**
After you set an enable secret password, you can switch to an enable password only if the enable secret is disabled or an older version of Cisco IOS software is being used, such as when running an older rxboot image.
b. Enter a password, then enter it again in the Confirm field. The password that you enter must be in clear text. If you are configuring the enable secret password, the password is encrypted on deployment.

**Step 3**

(Optional) Select the **Enable Password Encryption Service** check box to encrypt all passwords on the device. This includes, for example, the enable password, username passwords, authentication key passwords, console and VTY line access passwords, and BGP neighbor passwords.

We recommend using this feature to help prevent unauthorized individuals from viewing the passwords in your configuration file.

---

Note
This option does not provide a high level of security and should not be used as a substitute for additional network security measures.

---

**Step 4**

To define new user accounts for the router:

a. Click the **Add** button under the table to display the User Accounts dialog box.

b. Enter the details for the new user. See Table 59-8 on page 59-17 for a description of the available fields.

c. Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the User Accounts table.

---

Note
To edit a user account, select it from the User Accounts table, then click **Edit**. To remove a user account, select it, then click **Delete**.

---

**Accounts and Credentials Policy Page**

Use the Accounts and Credentials page to define the enable password or enable secret password assigned to the router. In addition, you can define a list of usernames that can be used to access the router.

For more information, see Defining Accounts and Credential Policies, page 59-14.

**Navigation Path**

- (Device view) Select **Platform > Device Admin > Accounts and Credentials** from the Policy selector.

- (Policy view) Select **Router Platform > Device Admin > Accounts and Credentials** from the Policy Type selector. Right-click **Accounts and Credentials** to create a policy, or select an existing policy from the Shared Policy selector.

</tr>
<tr>
<td>Delete button</td>
<td>Deletes the selected user accounts from the table.</td>
</tr>
</tbody>
</table>
User Account Dialog Box

Employ the User Account dialog box to define a username and password combination that can be used by Security Manager to access the router. You can also define the privilege level of the user account, which determines whether you can configure all commands on this router or only a subset of them.

**Note**
Remember—there may be additional user accounts defined on the router using other methods, such as the CLI.

**Navigation Path**
Go to the Accounts and Credentials Policy Page, page 59-15, then click the Add or Edit button beneath the table.

<td></td>
<td><strong>Note</strong> Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig.</td>
</tr>
</tbody>
</table>
Bridging on Cisco IOS Routers

Bridging policies enable you to perform transparent bridging (as specified in RFC 1286) on selected interfaces that you have configured to function as a bridge group. Security Manager supports integrated routing and bridging, which makes it possible to route a specific protocol between routed interfaces and bridge groups, or route a specific protocol between bridge groups. Local or unroutable traffic can be bridged among the bridged interfaces in the same bridge group, while routable traffic can be routed to other routed interfaces or bridge groups, as shown in Figure 59-1.

Using integrated routing and bridging, you can:

- Switch packets from a bridged interface to a routed interface.
- Switch packets from a routed interface to a bridged interface.
- Switch packets within the same bridge group.

**Figure 59-1  Transparent Bridging**

![Transparent Bridging Diagram](image)

**Related Topics**

- Defining Bridge Groups, page 59-19
- Bridge-Group Virtual Interfaces, page 59-18

**Bridge-Group Virtual Interfaces**

Because bridging takes places at the data link layer and routing takes place at the network layer, they have different protocol configuration models. With IP, for example, bridge group interfaces belong to the same network and have a collective IP network address. In contrast, each routed interface represents a distinct network and has its own IP network address. Integrated routing and bridging uses the concept of a bridge-group virtual interface (BVI) to enable these interfaces to exchange packets for a given protocol. As shown in Figure 59-2, the interface number assigned to the BVI corresponds to the bridge group that the BVI represents. This number serves as the link between the virtual interface and the bridge group.
When you enable routing for a given protocol on the BVI, packets coming from a routed interface that are destined for a host in a bridged domain are routed to the BVI and then forwarded to the corresponding bridged interface. All traffic routed to the BVI is forwarded to the corresponding bridge group as bridged traffic. All routable traffic received on a bridged interface is routed to other routed interfaces as if it is coming directly from the BVI.

**Note**
BVI interfaces are configured using the Interfaces policy. See Defining Basic Router Interface Settings, page 58-3. The BVI interface must have a corresponding bridge group with the same number; otherwise, deployment will fail.

**Note**
When the bridge group contains more than two interfaces, add a BVI interface to the group to help prevent unicast flooding, which is a potential security issue.

**Related Topics**
- Defining Bridge Groups, page 59-19
- Bridging on Cisco IOS Routers, page 59-18

### Defining Bridge Groups

You define a bridge group by selecting the L3 interfaces that are part of the bridge group and assigning the group a number. All bridge groups in Security Manager perform integrated routing and bridging on IP traffic only and use the standard Spanning Tree Protocol (IEEE 802.1D).

**Note**
Use CLI commands or FlexConfigs to bridge other protocols, such as AppleTalk or IPX, and to use other spanning tree protocols, such as VLAN-Bridge. Concurrent routing and bridging is not supported.

**Related Topics**
- Bridging on Cisco IOS Routers, page 59-18
- Bridge-Group Virtual Interfaces, page 59-18

#### Step 1
Do one of the following:
- (Device view) Select **Platform > Device Admin > Bridging** from the Policy selector.
Bridging Policy Page

Use the Bridging page to define bridge groups that can perform integrated routing and bridging on the router. For more information, see Defining Bridge Groups, page 59-19.

Navigation Path

- (Device view) Select Platform > Device Admin > Bridging from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Bridging from the Policy Type selector.

Right-click Bridging to create a policy, or select an existing policy from the Shared Policy selector.

Time Zone Settings on Cisco IOS Routers

The local time on a Cisco IOS router is typically set using the clock set command in the CLI command or by dynamically deriving the time from an NTP server. You can adjust these time settings by defining the time zone in which the router resides and the start and end dates of Daylight Saving Time (DST) in that time zone.

Related Topics
- Defining Time Zone and DST Settings, page 59-22
- NTP on Cisco IOS Routers, page 59-96

Defining Time Zone and DST Settings

Security Manager enables you to define the time zone in which a Cisco IOS router is located. You can also define the start and end dates for Daylight Saving Time (DST).

Related Topics
- Defining NTP Servers, page 59-97
- Time Zone Settings on Cisco IOS Routers, page 59-22

Step 1
Do one of the following:
- (Device view) Select Platform > Device Admin > Clock from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Clock from the Policy Type selector. Select an existing policy or create a new one.

The Clock page is displayed. See Table 59-11 on page 59-24 for a description of the fields on this page.
Step 2  Select the time zone in which the router is located. Time zones are listed according the number of hours behind or ahead of Greenwich Mean Time (GMT).

Step 3  (Optional) Select the method for determining the start and end dates for DST:
- Set by Date—Select this option when DST starts and ends on fixed dates. Continue with Step 4.
- Set by Day—Select this option when DST starts and ends on days whose specific dates vary from year to year. Continue with Step 5.
- None—Select this option when DST is not used.

Step 4  (When Set by Date is selected) Define the fixed dates when DST starts and ends:
- a. Under Start, click the calendar icon, then click the appropriate date.
- b. Select the hour and minute from the displayed lists.
- c. Repeat steps a and b to configure the end date and time.

Step 5  (When Set by Day is selected) Select the Specify Recurring Time check box if you want to define a DST period other than the default, which is the period used throughout most of the United States.

Step 6  (When Specify Recurring Time is selected) Define the start and end of DST:
- a. Under Start, select the month when DST begins.
- b. Select the week of the month (1, 2, 3, 4, first, or last).
- c. Select the day of the week.
- d. Select the hour and minute from the displayed lists. For example, if DST begins at 1:00 a.m. on the last Sunday of each March, select March, last, Sunday, 1, and 00.
- e. Repeat Steps a through d to configure the end date and time.

Clock Policy Page

Use the Clock page to configure the time zone in which the router is located and the settings for Daylight Saving Time (DST). For more information, see Time Zone Settings on Cisco IOS Routers, page 59-22.

Tip  You can configure the local time on the router by defining an NTP policy or by configuring the clock set command using the CLI.

Navigation Path
- (Device view) Select Platform > Device Admin > Clock from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Clock from the Policy Type selector. Right-click Clock to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics
- NTP Policy Page, page 59-98

<tr>
<td>(Summer Time)</td>
<td>- Set by Date—Enables you to define the exact date and time when DST begins and ends.</td>
</tr>
<tr>
<td></td>
<td>- Set by Day—Enables you to define the relative recurring date and time when DST begins and ends. For example, you can use this option when DST begins the last Sunday of March and ends the last Sunday of October.</td>
</tr>
<tr>
<td></td>
<td>None—Daylight savings time is not used.</td>
</tr>
</tbody>
</table>

**Additional Set by Date fields**

**Start**

- The date and time when DST begins:
  - Date—Click the calendar icon to select the start date.
  - Hour—Select the start hour.
  - Minute—Select the start minute.

**End**

- The date and time when DST ends:
  - Date—Click the calendar icon to select the end date.
  - Hour—Select the end hour.
  - Minute—Select the end minute.

**Note**

Cisco IOS Software supports dates up to and including December 31st, 2035.

**Additional Set by Day fields**

**Specify Recurring Time**

When selected, the router implements DST according to the dates and times specified in this policy.

When deselected, the router implements DST according to the schedule used throughout most of the United States.

**Start**

- The relative date and time when daylight savings time begins:
  - Month—Select the month.
  - Week—Select the week of the month (1, 2, 3, 4, first, or last).
  - Weekday—Select the day of the week.
  - Hour—Select the hour.
  - Minute—Select the minute.

For example, if DST begins at 1:00 a.m. on the last Sunday of each March, select March, last, Sunday, 1, and 00.
CPU Utilization Settings on Cisco IOS Routers

The CPU policy configures settings relating to CPU utilization. This policy provides you with methods for monitoring CPU resources and tracking processes that exceed a predetermined level of utilization.

Note

The CPU policy is supported on routers running Cisco IOS Software Release 12.3(14)T or later.

Related Topics
- Defining CPU Utilization Settings, page 59-25

Defining CPU Utilization Settings

You can use Security Manager to modify the following default CPU utilization settings:
- The size of the CPU history table.
- The size of the extended CPU load history table.
- Whether to enable the automatic CPU Hog profiling.

In addition, you can optionally define:
- The CPU utilization level that causes a process to be included in the history table.
- The types of CPU utilization thresholds to enable. For each type of threshold, you can determine the threshold values that trigger notifications.

HTTP and HTTPS on Cisco IOS Routers

Security Manager enables you to configure HTTP and HTTP over Secure Socket Layer (known as HTTP over SSL or HTTPS) server functionality on Cisco IOS routers. This feature provides SSL version 3.0 support for the HTTP 1.1 server.

A secure HTTP connection means that data sent to and received from an HTTP server are encrypted before being sent out over the internet. HTTP with SSL encryption provides a secure connection to allow such functions as configuring a router from a web browser.

In addition to providing access to the device via the Cisco web browser user interface, HTTP and HTTPS are used by device management applications, such as the Cisco Router and Security Device Manager (SDM), to communicate with the device.

Related Topics
- Defining HTTP Policies, page 59-29
Defining HTTP Policies

When you define an HTTP policy, you can:

- Enable and disable HTTP and SSL functionality on the router.
- Specify the ports used by each protocol.
- Optionally define a standard, numbered ACL that restricts access to the device using these protocols.

In addition, you can define the methods of AAA authentication and authorization methods to perform on users.

You must use caution when defining an HTTP policy, as your settings may affect communication between Security Manager (as well as other management applications that use these protocols) and the device.

Note

As a general rule, Cisco IOS routers that have been discovered by Security Manager already have HTTPS enabled because Security Manager uses SSL as the default protocol for communicating with them. See Setting Up SSL on Cisco IOS Routers, page 2-4.

Before You Begin

- Enable AAA services on the router. See Defining AAA Services, page 59-4.

Related Topics

- HTTP and HTTPS on Cisco IOS Routers, page 59-28

Step 1

Do one of the following:

- (Device view) Select Platform > Device Admin > Device Access > HTTP from the Policy selector, then click the Setup tab in the work area.
- (Policy view) Select Router Platform > Device Admin > Device Access > HTTP from the Policy Type selector. Select an existing policy or create a new one.

The HTTP Setup tab is displayed. See Table 59-13 on page 59-32 for a description of the fields on this tab.

Step 2

Select the check boxes to enable HTTP and SSL (HTTPS) server functionality on the router.

Note

If SSL is disabled (or if the HTTP policy as a whole is unassigned), Security Manager cannot communicate with the device after deployment unless you change the transport protocol for this device to SSH. This setting can be found in Device Properties. See Managing Device Communication Settings and Certificates, page 9-3.

Tip

We recommend that you disable HTTP when SSL is enabled. This is required to ensure only secure connections to the server.

Step 3

(Optional) Modify the default ports used by HTTP (80) and HTTPS (443).
Step 4  (Optional) In the Allow Connection From field, enter the name of the standard, numbered ACL object that specifies which addresses can use HTTP and HTTPS on this device, or click Select to select the ACL object from a list or to create a new one. Use this option to restrict access to these protocols. For more information about creating standard ACL objects, see Creating Standard Access Control List Objects, page 6-50

Note  Make sure that the ACL you select permits the Security Manager server; otherwise, communication with the device is lost.

Step 5  (Optional) On the AAA tab, modify the default type of authentication to perform on users who attempt to access the device using HTTP or HTTPS. Options include AAA, Enable Password (default), Local Database, and TACACS.

If you select AAA, continue with Step 6; otherwise, continue with Step 8.

Note  The TACACS option applies only to devices using an IOS software version prior to 12.3(8).

See Table 59-14 on page 59-33 for a description of the fields on the AAA tab.

Step 6  Select the authentication method to perform on users:

- If you want to use the default AAA login authentication methods defined in the device’s AAA policy (see Defining AAA Services, page 59-4), do not select the Enable Device Login Authentication check box. Continue with Step 7.
- If you want to define a method list especially for this policy, do the following:
  a. Select the Enable Device Login Authentication check box.
  b. Under Prioritized Method List, enter the names of the AAA server groups to use for authentication, or click Select to select the AAA server groups from a list or to create new ones. Use the up and down arrows in the selector to define the order in which you want to apply these authentication methods.

Note  Make sure that Security Manager users are defined on the AAA servers; otherwise communication with the device is lost.

Step 7  Select the authorization method to perform on users who use HTTP or HTTPS to begin an EXEC session:

- If you want to use the default AAA authorization methods defined in the device’s AAA policy, do not select the Enable CLI/EXEC Operations Authorization check box. Continue with Step 8.
- If you want to define a method list especially for this policy, select the Enable CLI/EXEC Operations Authorization check box, then define the method list.

Note  If you leave this option deselected, make sure that EXEC authorization is enabled in the router’s AAA policy. Otherwise, you will be unable to connect to the device via HTTP or HTTPS (SSL). This applies to Security Manager as well as other applications, such as SDM. See Defining AAA Services, page 59-4.
Step 8  (Optional) Create command authorization definitions for specific privilege levels:

a. Click the Add button under the Command Authorization Override table. The Command Authorization Override dialog box is displayed. See Table 59-15 on page 59-34 for a description of the fields in this dialog box.

b. Configure the command authorization definition as required.

c. Click OK. The dialog box closes and the authorization method is displayed in the Command Authorization Override table.

d. Repeat a. through c. to create additional command authorization definitions.

HTTP Policy Page

Use the HTTP page to configure HTTP and HTTPS access on the router. You can configure HTTP policies on a Cisco IOS router from the following tabs on the HTTP policy page:

- HTTP Page—Setup Tab, page 59-31
- HTTP Page—AAA Tab, page 59-32

For more information, see HTTP and HTTPS on Cisco IOS Routers, page 59-28.

Navigation Path

- (Device view) Select Platform > Device Admin > Device Access > HTTP from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Device Access > HTTP from the Policy Type selector. Right-click HTTP to create a policy, or select an existing policy from the Shared Policy selector.

HTTP Page—Setup Tab

Use the Setup tab of the HTTP page to enable HTTP and HTTP over Secure Socket Layer (HTTP over SSL or HTTPS) on the router. You can optionally limit access to these protocols to the addresses defined in an access control list.

Note

As a general rule, Cisco IOS routers that have been discovered by Security Manager already have HTTPS enabled because Security Manager uses SSL as the default protocol for communicating with them. See Setting Up SSL on Cisco IOS Routers, page 2-4.

Navigation Path

Go to the HTTP Policy Page, page 59-31, then click the Setup tab.

Related Topics

</tbody>
</table>
Security Manager enables you to configure command line access (also called EXEC access) to a router using the following methods:

- **Console port**—Physical connection via a standard RS232 cable for local access. For more information, see:
  - Defining Console Port Setup Parameters, page 59-35
  - Defining Console Port AAA Settings, page 59-37
- **VTY lines**—Virtual terminal lines for remote access, typically using protocols such as Telnet, SSH, or rlogin. For more information, see:
  - Defining VTY Line Setup Parameters, page 59-38
  - Defining VTY Line AAA Settings, page 59-40

After you configure and deploy these policies, you can use these lines to communicate with individual devices directly when you want to configure or diagnose them using the CLI.

### Defining Console Port Setup Parameters

The console port on a router is generally used for local system access by an administrator with physical access to the device. By default, the console port is set up as follows:

- All permitted users have privileged access to the router, including all configuration commands (privilege level 15).
- The line is disconnected after 10 minutes without user input.
- Incoming connections are not permitted.
- Outgoing connections support Telnet only.

In addition to modifying any of the default settings, you can optionally define the following settings:

- The password for accessing the console.
- Whether to disable all EXEC sessions on the console.

<table>
<thead>
<tr>

**Line Access on Cisco IOS Routers**

Defining Console Port Setup Parameters
Chapter 59  Router Device Administration

Line Access on Cisco IOS Routers

• Incoming and outgoing ACLs that restrict the connections that are permitted on the console.
• Whether VRF connections are permitted on the console.

Related Topics
• Line Access on Cisco IOS Routers, page 59-35

Step 1  Do one of the following:
• (Device view) Select Platform > Device Admin > Device Access > Line Access > Console from the Policy selector, then click the Setup tab in the work area.
• (Policy view) Select Router Platform > Device Admin > Device Access > Line Access > Console from the Policy Type selector. Select an existing policy or create a new one, and then click the Setup tab.

The Console Setup tab is displayed. See Table 59-16 on page 59-42 for a description of the fields on this tab.

Step 2  (Optional) Enter the password for accessing the console port, then enter it again in the Confirm field.

Step 4  (Optional) Select the Disable all the EXEC sessions to the router via this line check box to prevent any incoming connections via the console.

Note  Selecting this option blocks all access to the device via the console port.

Step 5  (Optional) Modify the default timeout after which the line is disconnected if no user input is detected.

Note  Setting this value to 0 disables the timeout. Disabling the timeout could compromise the security of your network.

Step 6  (Optional) Specify which protocols can be used for outbound connections on the console port:
• All—All supported protocols are permitted.
• None—No protocols are permitted.
• Protocol—Enables one or more of the following protocols: SSH, Telnet, and rlogin.

Note  You must configure AAA authentication on devices where the console port permits the SSH and rlogin protocols. See Defining Console Port AAA Settings, page 59-37.

Step 7  (Optional) Enter the names of ACLs that restrict incoming and outgoing connections between the device and the addresses in these lists, or click Select to select the ACL object or to create a new one. At the top of the selector, in the Type field, select the ACL type as either Standard or Extended.

Step 8  (Optional) Click the AAA tab to define authentication, authorization, and accounting settings for the console port. See Defining Console Port AAA Settings, page 59-37.
Defining Console Port AAA Settings

By default, authentication, authorization, and accounting are not performed on the console port. When you configure one or more of these access control options, you can either make use of the default method lists defined in the device’s AAA policy or define a custom method list containing one or more AAA methods.

Related Topics
- Defining Console Port Setup Parameters, page 59-35
- Line Access on Cisco IOS Routers, page 59-35

Step 1
Do one of the following:
- (Device view) Select Platform > Device Admin > Device Access > Line Access > Console from the Policy selector, then click the Authentication tab in the work area.
- (Policy view) Select Router Platform > Device Admin > Device Access > Line Access > Console from the Policy Type selector. Select an existing policy or create a new one, and then click the Authentication tab.

The Console Authentication tab is displayed.

Step 2
(Optional) Select the authentication method to perform on users who attempt to access the console line.

See Table 59-17 on page 59-45 for a description of the fields on the Authentication tab.

Note
If you select local authentication, preview the full configuration before deployment to make sure that the `aaa new-model` command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.

Step 3
(Optional) On the Authorization tab, select the authorization method to perform on users who access the console line and begin an EXEC session.

See Table 59-18 on page 59-46 for a description of the fields on the Authorization tab.

Note
RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

Step 4
(Optional) Create command authorization definitions for specific privilege levels:

a. Click the Add button under the Commands Authorization table. The Command Authorization dialog box is displayed. See Table 59-26 on page 59-61 for details.

b. Configure the command authorization definition as required.

c. Click OK. The dialog box closes and the authorization method is displayed in the Commands Authorization table.

d. Repeat a. through c. to create additional command authorization definitions.

Step 5
(Optional) On the Accounting tab, select the EXEC and connection accounting methods to perform on users who access the console line.

See Table 59-19 on page 59-47 for a description of the fields on this tab.
Step 6  (Optional) Create command accounting definitions for specific privilege levels:
   a. Click the Add button under the Commands Accounting table. The Command Accounting Dialog Box—Line Access, page 59-61 is displayed.
   b. Configure the command accounting definition as required.
   c. Click OK. The dialog box closes and the accounting method is displayed in the Commands Accounting table.
   d. Repeat a. through c. to create additional command accounting definitions.

Defining VTY Line Setup Parameters

All Cisco IOS routers are configured by default with five VTY lines (labeled 0-4) that have the following settings:
- All permitted users have privileged access to the router, including all configuration commands (privilege level 15).
- VTY lines are disconnected after 10 minutes without user input.
- Incoming connections are not permitted.
- Outgoing connections support Telnet only.

You can use Security Manager to modify the default settings on these five VTY lines or to configure additional lines (up to a maximum of 16). In addition, you can optionally configure the following settings on each line:
- The password for accessing the line.
- Whether to disable all EXEC sessions on the line.
- Incoming and outgoing ACLs that restrict the connections that are permitted on the line.
- Whether VRF connections are permitted on the line.

Defining Groups of VTY Lines

You can configure multiple VTY lines as a contiguous group, which enables you to define identical settings for all the lines in the group with one procedure. All the lines within the group must fall within one of two ranges, 0-4 or 6-15. The group cannot overlap these two ranges.

The rules for configuring VTY line 5 are as follows. Line 5 can be part of the same definition as lines 0-4 only when there are no lines configured above line 5. If there are lines configured above line 5, you cannot include line 5 in the definition for lines 0-4, even if their configurations are the same. Line 5 can be included in the definition of the lines above line 5 if their configurations are the same.

For example, if lines 0-5 all share one configuration and lines 6-9 have a different configuration, you need to create three definitions—one definition for lines 0-4, a second definition for line 5, and a third definition for lines 6-9.

Note
When you configure VTY lines, bear in mind that users are assigned a line at random when they connect to the device.
You can create only one definition per VTY line. An error is displayed if you create a VTY line definition that overlaps an existing definition.

If you use Security Manager to configure the default VTY lines (0-4), your definition overrides the default settings on the device. If you later delete this definition from Security Manager, the input protocol settings are retained and the other default settings are restored. This ensures that you always have VTY lines available for remote access to the device.

You can use the CLI or FlexConfigs to configure additional VTY lines on devices that support more than 16 lines.

**Related Topics**
- Line Access on Cisco IOS Routers, page 59-35

**Step 1**
Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > VTY** from the Policy selector.

- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > VTY** from the Policy Type selector. Select an existing policy or create a new one.

The VTY page is displayed. See Table 59-20 on page 59-50 for a description of the fields on this page.

**Step 2**
Click the **Add** button beneath the Lines table, or select a line definition and then click the **Edit** button. The Setup tab of the VTY Lines dialog box is displayed. See Table 59-21 on page 59-51 for a description of the fields on this tab.

**Step 3**
Enter the relative line number of the VTY line. If you are configuring a group of VTY lines, enter the first and last numbers of the group in the fields provided.

**Step 4**
(Optional) Enter the password for accessing the console line, then enter it again in the Confirm field.

**Step 5**
(Optional) Modify the default Privilege (15) granted to users of this VTY line (or group of lines).

**Step 6**
(Optional) Select the **Disable all the EXEC sessions to the router via this line** check box to prevent any incoming connections over this VTY line (or group of lines).

**Step 7**
(Optional) Modify the default timeout after which the line is disconnected if no user input is detected.

**Note**
Setting this value to 0 to disables the timeout. Disabling the timeout could cause abandoned sessions to block available VTY lines. It can also compromise the security of your network.

**Step 8**
(Optional) Specify which protocols can be used for inbound and outbound connections on this VTY line (or group of lines):

- **All**—All supported protocols are permitted.
- **None**—No protocols are permitted.
- **Protocol**—Enables one or more of the following protocols: SSH, Telnet, and rlogin.
Caution
Setting the inbound connections setting to None might prevent Security Manager from connecting to the device after deployment.

Note
You must configure AAA authentication when the VTY line permits the SSH and rlogin protocols. See Defining VTY Line AAA Settings, page 59-40.

Step 9
(Optional) Enter the names of ACLs that restrict incoming and outgoing connections between the device and the addresses in these lists, or click Select to select an ACL object from a list or to create a new one. You can choose from standard or extended ACLs.

Tip
Defining an inbound ACL is a good way to reserve a VTY line for administrative access only.

Step 10
(Optional) Click the AAA tab to define authentication, authorization, and accounting settings for this VTY line (or group of lines). See Defining VTY Line AAA Settings, page 59-40.

Step 11
Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Lines table.

Note
To remove a VTY line definition, select it, then click Delete. If you delete a VTY line from an IOS device, any subsequent lines are also deleted. For example, if the device contains lines 0-9 and you delete line 5, lines 6-9 are deleted as well. If you delete the definition for lines 0-4 from Security Manager, the router retains the inbound protocol definition and restores the other default settings for these lines on the device. This ensures that five VTY lines are always available.

Defining VTY Line AAA Settings

By default, authentication, authorization, and accounting are not performed on VTY lines. When you configure one or more of these access control options, you can either make use of the default method lists defined in the device’s AAA policy or define a custom method list containing one or more AAA methods.

Before You Begin
- Define the basic parameters of the VTY line or group of VTY lines. See Defining VTY Line Setup Parameters, page 59-38.

Related Topics
- Defining VTY Line Setup Parameters, page 59-38
- Line Access on Cisco IOS Routers, page 59-35

Step 1
Do one of the following:
- (Device view) Select Platform > Device Admin > Device Access > Line Access > VTY from the Policy selector.
Step 2  Select a VTY line definition in the Lines tables, click the Edit button to display the VTY Line dialog box, then click the Authentication tab.

Step 3  (Optional) Select the authentication method to perform on users who attempt to access the VTY line. See Table 59-23 on page 59-55 for a description of the fields on this tab.

Note If you select local authentication, preview the full configuration before deployment to make sure that the aaa new-model command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.

Step 4  (Optional) On the Authorization tab, select the authorization method to perform on users who access the VTY line and begin an EXEC session. See Table 59-24 on page 59-56 for a description of the fields on the Authorization tab.

Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

Step 5  (Optional) Create command authorization definitions for specific privilege levels:
   a. Click the Add button under the Commands Authorization table. The Command Authorization Dialog Box—Line Access, page 59-60 is displayed.
   b. Configure the command authorization definition as required.
   c. Click OK. The dialog box closes and the authorization method is displayed in the Commands Authorization table.
   d. Repeat a. through c. to create additional command authorization definitions.

Step 6  (Optional) On the Accounting tab, select the EXEC and connection accounting methods to perform on users who attempt to access the VTY line. See Table 59-25 on page 59-58 for a description of the fields on the Accounting tab.

Step 7  (Optional) Create command accounting definitions for specific privilege levels:
   a. Click the Add button under the Commands Accounting table. The Command Accounting Dialog Box—Line Access, page 59-61 is displayed.
   b. Configure the command accounting definition as required.
   c. Click OK. The dialog box closes and the accounting method is displayed in the Commands Accounting table.
   d. Repeat a. through c. to create additional command accounting definitions.
Console Policy Page

Use the Console page to configure access to the router over the console port. You can configure console policies on a Cisco IOS router from the following tabs on the Console policy page:

- Console Page—Setup Tab, page 59-42
- Console Page—Authentication Tab, page 59-44
- Console Page—Authorization Tab, page 59-45
- Console Page—Accounting Tab, page 59-47

For more information, see Line Access on Cisco IOS Routers, page 59-35.

Navigation Path
- (Device view) Select Platform > Device Admin > Device Access > Line Access > Console from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Device Access > Line Access > Console from the Policy Type selector. Right-click Console to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics
- VTY Policy Page, page 59-50

Console Page—Setup Tab

Use the Setup tab of the Console page to define the basic parameters of the console port. This includes the password for accessing the port, the privilege level assigned to users, the protocols that are permitted, and the ACLs that limit access.

Navigation Path
Go to the Console Policy Page, page 59-42, then click the Setup tab.

Related Topics
- Console Page—Authentication Tab, page 59-44

### Chapter 59  Router Device Administration

**Console Policy Page**

### Table 59-16  Console Page—Setup Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Privilege Level | The privilege level assigned to users connected to the console port. Valid values range from 0 to 15:  
  - 0—Grants access to these commands only: disable, enable, exit, help, and logout.  
  - 1—Enables nonprivileged access to the router (normal EXEC-mode use privileges).  
  - 15—Enables privileged access to the router (traditional enable privileges).  
  
  **Note**  
  Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig.  
  
  **Note**  
  If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration. |
| Disable all the EXEC sessions to the router via this line | When selected, disables EXEC sessions over this line. Select this option when you want to allow only an outgoing connection on the console. This option is useful for keeping the console port free from unsolicited incoming data that can tie up the line.  
  When deselected, EXEC sessions are enabled on the console port. This is the default.  
  
  **Note**  
  Selecting this option blocks all access to the device via the console port. |
| Exec Timeout | The amount of time (in seconds) that the EXEC command interpreter waits to detect user input on the console port. If no input is detected, the line is disconnected. Valid values range from 0 to 2147483. The default is 600 (10 minutes). Setting the value to 0 disables the timeout.  
  
  **Note**  
  Although the timeout is defined in seconds, it appears in the CLI in the format [mm:ss]. |
Use the Authentication tab of the Console page to define the AAA authentication methods to perform on users who attempt to access the console port.

**Navigation Path**
Go to the **Console Policy Page**, page 59-42, then click the **Authentication** tab.

<td></td>
<td>Note: SSH and rlogin require that you configure AAA authentication. See VTY Line Dialog Box—Authentication Tab, page 59-55.</td>
</tr>
<tr>
<td>Output Protocols</td>
<td>The protocols that you can use for outgoing connections on this line:</td>
</tr>
<tr>
<td></td>
<td>• All—All supported protocols are permitted. Supported protocols include LAT, MOP, NASI, PAD, rlogin, SSH, Telnet, and V.120.</td>
</tr>
<tr>
<td></td>
<td>• None—No protocols are permitted. This makes the port unusable by outgoing connections.</td>
</tr>
<tr>
<td></td>
<td>• Protocol—Enables one or more of the following protocols:</td>
</tr>
<tr>
<td></td>
<td>– SSH—Secure Shell protocol.</td>
</tr>
<tr>
<td></td>
<td>– Telnet—Standard TCP/IP terminal emulation protocol.</td>
</tr>
<tr>
<td></td>
<td>– rlogin—UNIX rlogin protocol.</td>
</tr>
<tr>
<td></td>
<td>Note: SSH and rlogin require that you configure AAA authentication. See VTY Line Dialog Box—Authentication Tab, page 59-55.</td>
</tr>
<tr>
<td></td>
<td>Note: Not all IOS Software Versions support rlogin as an output protocol.</td>
</tr>
<tr>
<td>Inbound Access List</td>
<td>The name of the ACL object that restricts incoming connections on this line. Enter the name of the ACL object, or click Select to select it. If the object that you want is not listed, click the Create button to create it.</td>

</tr>
<tr>
<td></td>
<td>- Stop Only—Generates an accounting record at the end of the user process only.</td>
</tr>
<tr>
<td></td>
<td>- None—No accounting records are generated.</td>
</tr>
</tbody>
</table>
Prioritized Method List

Applies only when Custom Method List is selected as the EXEC method.

Defines a sequential list of methods to be queried when creating accounting methods for a user. Enter the names of one or more AAA server group objects (up to four), or click Select to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the Create button to create it.

The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.

Note: If you select None as a method, it must appear as the last method in the list.

Enable Broadcast to Multiple Servers

Applies only when Method List is selected as the EXEC method.

When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group.

When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.

Connection Accounting settings

Perform Connection Accounting Using

The accounting method to use for recording information about outbound connections made over the VTY line:

- None—Accounting is not performed. This is the default.
- AAA Policy Default List—Uses the default connection accounting method list that is defined in the device’s AAA policy. See AAA Page—Accounting Tab, page 59-10.
- Custom Method List—Uses the accounting methods specified in the Prioritized Method List field.

Connection accounting records details about outgoing connections over the line, such as Telnet and rlogin connections.

Generate Accounting Records for

Applies only when Custom Method List is selected as the connection method.

Defines when the device sends an accounting notice to the accounting server:

- Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the “start” accounting record. This is the default.
- Stop Only—Generates an accounting record at the end of the user process only.
- None—No accounting records are generated.
### Command Authorization Dialog Box—Line Access

Use the Command Authorization dialog box to define which methods to use when authorizing the EXEC commands that are associated with a given privilege. This enables you to authorize all commands associated with a specific privilege level, from 0 to 15.

Optional SSH Settings on Cisco IOS Routers

Secure Shell (SSH) is an application and a protocol that uses encryption to provide secure communication between a client and server. You can use SSH to connect remotely to a Cisco IOS router over a VTY line and establish an EXEC session. SSH is the recommended replacement for other protocols, such as Telnet and rlogin, in environments where security is a concern.

All Cisco IOS routers are required to have SSH configured before they can be added to Security Manager. This is because Security Manager uses SSH (in addition to SSL) to communicate with them. The SSH policy provides a way to modify selected default settings and configure selected optional settings.

Related Topics
- Defining Optional SSH Settings, page 59-63
- Chapter 2, “Preparing Devices for Management”
- Setting Up SSH, page 2-5

Defining Optional SSH Settings

SSH is configured by default with the following settings:
- Both SSH version 1 and SSH version 2 are supported.
- The negotiation phase is terminated if not completed successfully after 120 seconds.
- The router tries 3 times to authenticate SSH clients before disconnecting.

You can use Security Manager to modify these default settings and optionally configure the following settings:
- The source interface for SSH packets.
- The name of the RSA key pair to use.
- Whether to regenerate the key during the next deployment.

Before You Begin
- Make sure that SSH is enabled on the router. See Chapter 2, “Preparing Devices for Management”.
- Make sure that the VTY lines on the router allow inbound SSH traffic. See Defining VTY Line Setup Parameters, page 59-38.
- Make sure that a hostname and domain name are configured on the router (unless you plan to use a different RSA key pair). You can use the CLI or the Hostname policy in Security Manager for this purpose. See Hostnames and Domain Names on Cisco IOS Routers, page 59-77.

Related Topics
- Optional SSH Settings on Cisco IOS Routers, page 59-63
- Setting Up SSH, page 2-5

Step 1
Do one of the following:
- (Device view) Select Platform > Device Admin > Device Access > Secure Shell from the Policy selector.
Secure Shell Policy Page

Use the Secure Shell page to change the default SSH settings on the router and to define additional optional settings, if required.

For more information, see Optional SSH Settings on Cisco IOS Routers, page 59-63.
You must configure SSH on the device using CLI commands before adding the device to Security Manager. This is because Security Manager uses SSH (as well as SSL) to communicate with Cisco IOS routers. For more information, see Setting Up SSH, page 2-5.

### Navigation Path
- (Device view) Select Platform > Device Admin > Device Access > Secure Shell from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Device Access > Secure Shell from the Policy Type selector. Right-click Secure Shell to create a policy, or select an existing policy from the Shared Policy selector.

**Note** You must configure SSH on the device using CLI commands before adding the device to Security Manager. This is because Security Manager uses SSH (as well as SSL) to communicate with Cisco IOS routers. For more information, see Setting Up SSH, page 2-5.
SNMP on Cisco IOS Routers

Simple Network Management Protocol (SNMP) defines a standard way for network management stations or workstations to monitor the health and status of many types of devices, including switches, routers, and firewall devices. It comprises a protocol, a database-structure specification, and a set of management data objects. Each SNMP device or member is part of a **community**, which determines the access that each device has (read-only or read-write).

SNMP obtains information from the managed device through a Management Information Base (MIB). The MIB is a database of code blocks called MIB objects, each of which controls one specific function. The MIB object comprises MIB variables, which define the MIB object name, description, default value, and so forth. MIB objects are structured hierarchically in a MIB tree.

SNMP policies enable you to configure the behavior of the SNMP agent running on the router. The agent sends unsolicited information back to the SNMP host as events occur. These unsolicited messages, which are generated in response to significant, predetermined events on the router, are called traps.

The following topics describe the tasks you perform to create SNMP policies on Cisco IOS routers:

- **Defining SNMP Agent Properties, page 59-67**

---

**Table 59-28 Secure Shell Page (Continued)**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSA Key Pair</td>
<td>The name of the RSA key pair to use for SSH connections.</td>
</tr>
<tr>
<td></td>
<td>If you do not enter a value, the router uses the RSA key pair generated from its hostname and domain name. This is the default.</td>
</tr>
<tr>
<td><strong>Tip</strong></td>
<td>Use the CLI command <code>show crypto key mypubkey rsa</code> to display the names and values of each key pair configured on the device. These are the valid names that can be entered in this field.</td>
</tr>
<tr>
<td>Regenerate Key During Deployment</td>
<td>When selected, regenerates the RSA key pair on the router during the next deployment. This option is useful if you are concerned that the secrecy of the keys might be compromised.</td>
</tr>
<tr>
<td></td>
<td>When deselected, a new key pair is not generated.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This check box is <strong>not</strong> deselected automatically after deployment. If you do not return to this policy to deselect the check box, the key is regenerated each time you deploy.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This option requires interaction with the device during deployment. Therefore, you should use it only when deploying to live devices, not when deploying to a file.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>A key pair must already exist on the device before you select this option; otherwise, deployment will fail. (This will typically be the case, since IOS routers must have SSH enabled in order to be added to Security Manager.)</td>
</tr>
<tr>
<td>Modulus Size</td>
<td>Applies only when the Regenerate Key check box is selected.</td>
</tr>
<tr>
<td></td>
<td>The size of the modulus used to generate a new key pair. A larger modulus is more secure but takes longer to generate. Valid values range from 360 to 2048 bits. The default is 1024 bits.</td>
</tr>
</tbody>
</table>
Defining SNMP Agent Properties

When you define the properties of the SNMP agent, you must define the community string and community string type, as well as the address and properties of the SNMP host that receives the traps. SNMP community strings are embedded passwords to MIBs, which store data about the router's operation and are meant to be available to authenticated remote users. Two types of community strings exist: “public” community strings, which provide read-only access to all objects in the MIB (except community strings themselves), and “private” community strings, which provide read-write access to all objects in the MIB (except community strings).

SNMP hosts receive the traps generated by the router. You must define the address, password, and port number for accessing the SNMP host, as well as the SNMP version being used. Security Manager supports SNMP version 1, version 2c (also called “community-based SNMP”) and version 3, which offers authentication and encryption.

Related Topics
- SNMP on Cisco IOS Routers, page 59-66

Step 1
Do one of the following:
- (Device view) Select Platform > Device Admin > Device Access > SNMP from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Device Access > SNMP from the Policy Type selector. Select an existing policy or create a new one.

The SNMP page is displayed. See Table 59-29 on page 59-69 for a description of the fields on this page.

Step 2
Define the community string needed to access the MIB:
- a. Under Permissions, click Add to display the Permission dialog box.
- b. Define the string. See Table 59-30 on page 59-70 for a description of the available fields.
- c. Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Permissions table.

Note
A warning is displayed if you attempt to edit or delete a community string that is in use by an SNMP host. If you continue with the operation, the device creates a private, read-only string that matches the definition for the host in the Trap Receiver table.

Step 3
Define the SNMP host that receives the traps generated by the SNMP agent:
- a. Under Trap Receiver, click Add to display the Trap Receiver dialog box.
- b. Define the host. See Table 59-31 on page 59-71 for a description of the available fields.
- c. Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Trap Receiver table.

Step 4
Under SNMP Server Properties, enter the location and contact information for the administrator responsible for routers configured with this SNMP policy.

This definition, which is text-only and does not affect the operation of the router, provides useful information to the manager of the SNMP host when the manager investigates a particular trap.
Step 5  Click **Configure Traps** to display the SNMP Traps dialog box, which is used to select which traps to enable on the router. For more information, see Enabling SNMP Traps, page 59-68.

---

**Enabling SNMP Traps**

The router immediately sends notifications, also called SNMP traps, to the designated SNMP host (management station) when a defined condition occurs, such as a link up, link down, or a syslog event.

To enable SNMP traps, select the check box next to each relevant trap. Certain check boxes activate multiple, related traps.

**Note** Each trap that you enable consumes system resources. To lessen the impact on system performance, select only those traps that you need for network monitoring.

**Related Topics**

- SNMP on Cisco IOS Routers, page 59-66

---

**Step 1**  Open the SNMP page for defining SNMP server policies on Cisco IOS routers, as described in Defining SNMP Agent Properties, page 59-67.

**Step 2**  On the SNMP page, click **Configure Traps**. The SNMP Traps dialog box is displayed.

**Step 3**  Select the check box next to each type of trap to enable. The traps are divided into the following four categories:

- Standard SNMP traps (for example, Authentication, Cold Start, and Warm Start).
- ISAKMP traps (related to Phase 1 of the IPsec process).
- IPsec traps (related to Phase 2 of the IPsec process).
- Other traps (includes syslog messages, protocol-related notifications, and CPU usage warnings).

See Table 59-32 on page 59-73 for a description of the available traps.

**Note**  You must add command-line interface (CLI) commands to fully implement the IP multicast and CPU traps. One method available for entering these commands is by using FlexConfigs. See Chapter 7, “Managing FlexConfigs”.

---

**Tip**  Click **Select All** to enable all traps displayed in the dialog box or **Deselect All** to disable all the traps.

**Step 4**  Click **OK** to save your definitions locally on the client and close the dialog box.

**Tip**  To configure SNMP traps not included in this dialog box, define a FlexConfig. See Chapter 7, “Managing FlexConfigs” for more information.
SNMP Policy Page

Use the SNMP page to configure the parameters necessary to send traps from the router to a designated SNMP host. These traps are unsolicited messages that notify the SNMP host of important events occurring on the router.

For more information, see Defining SNMP Agent Properties, page 59-67.

Navigation Path

- (Device view) Select Platform > Device Admin > Device Access > SNMP from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Device Access > SNMP from the Policy Type selector. Right-click SNMP to create a policy, or select an existing policy from the Shared Policy selector.

**DNS on Cisco IOS Routers**

The Domain Name System (DNS) is a distributed database in which you can map hostnames to IP addresses through the DNS protocol from a DNS server. Each unique IP address can have an associated hostname. DNS is what makes it possible to connect to hosts without having to know the 32-bit IP address of that host. The DNS server takes the provided hostname and translates it into the appropriate IP address.

In addition to the translation provided by remote DNS servers, you can configure Cisco IOS routers with a local host table containing static mappings of hosts to IP addresses. When commands such as connect, telnet, and ping are used, the router checks this host table before querying the DNS servers, which speeds the translation process.

By default, the DNS feature is enabled on all Cisco IOS routers.

**Related Topics**
- Defining DNS Policies, page 59-75
Defining DNS Policies

When you define a DNS policy in Security Manager, you can specify the remote DNS servers used by the router for hostname-to-address translations. In addition, you can define a static host table that contains local translations used exclusively by this device. Having selected addresses in this type of cache can speed the translation process by eliminating the need to query the DNS servers.

Related Topics
- DNS on Cisco IOS Routers, page 59-74

Step 1
Do one of the following:
- (Device view) Select Platform > Device Admin > DNS from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > DNS from the Policy Type selector. Select an existing policy or create a new one.

The DNS page is displayed. See Table 59-33 on page 59-76 for a description of the fields on this page.

Step 2
In the Servers field, enter the addresses of the DNS servers (up to 6) that can perform hostname-to-address translations for the router. You can use a combination of addresses and network/host objects, or click Select to display a selector. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

Tip
If the network you want is not listed in the selector, click the Create button or the Edit button in the selector to display the Add or Edit Network/Host Dialog Box (IPv4 or IPv6), page 6-73. From here you can create a network/host object to use in the policy.

Step 3
(Optional) In the Hosts field, enter the static host mappings that you want to define in the router’s host table:
- Click Add to display the IP Host Dialog Box, page 59-76.
- Enter the hostname to translate.
- Enter up to three addresses or network/host objects, or click Select to display a selector. These are the addresses to which the router translates the hostname.
- Click OK. The mapping is displayed in the Hosts field on the DNS page.
- Repeat a. through d. to add more hosts to the host table.

Note
To edit a host mapping, select the definition from the Hosts field, then click Edit. To remove a host mapping, select it, then click Delete.

Step 4
(Optional) Deselect the Domain Lookup check box to disable DNS functionality on the router.
DNS Policy Page

Use the DNS policy page to define the local IP host table and the Domain Name System (DNS) servers that the router should use for translating hostnames to IP addresses. You can also prevent the router from performing DNS lookups by disabling the DNS feature.

**Navigation Path**

- (Device view) Select **Platform > Device Admin > DNS** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > DNS** from the Policy Type selector.

Right-click DNS to create a policy, or select an existing policy from the Shared Policy selector.

**Related Topics**

- DNS on Cisco IOS Routers, page 59-74

### Field Reference

**Table 59-33  DNS Page**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Servers</td>
<td>The DNS servers used by the router to perform DNS lookups. Enter one or more addresses or network/host objects, or click Select to select an object from a list or to create a new one. You can define a maximum of six DNS servers.</td>
</tr>
<tr>
<td>Hosts</td>
<td>The local host table configured on the router. When a user types in a hostname, the router checks this table first before querying the DNS servers defined in the Servers field. Click Add to display the IP Host Dialog Box, page 59-76. From here you can define a hostname and the IP addresses to associate with that hostname. <strong>Note</strong> To edit an entry in the host table, select it, then click Edit. To remove an entry, select it, then click Delete.</td>
</tr>
<tr>
<td>Domain Lookup</td>
<td>When selected, the router performs lookups on the defined DNS servers. This is the default. When deselected, lookups on remote DNS servers are disabled.</td>
</tr>
</tbody>
</table>

**IP Host Dialog Box**

Use the IP Host dialog box to configure the host table on the router. This is the table of static, local mappings that the router uses to translate hostnames to IP addresses. If the router does not find the required entry in the host table, it queries the DNS servers that are defined on the DNS page.

**Navigation Path**

Go to the **DNS Policy Page, page 59-76**, then click Add under Hosts.

**Related Topics**

</tr>
</tbody>
</table>

Hostnames and Domain Names on Cisco IOS Routers

The Hostname policy configures the hostname and domain name of the selected router. After you deploy this policy, any changes that you made to the hostname and domain name are reflected in the Device Properties page (see Viewing or Changing Device Properties, page 3-37).

Related Topics
- Defining Hostname Policies, page 59-77

Defining Hostname Policies

When you define a hostname policy, Security Manager updates the hostname and domain name fields in the Device Properties dialog box after deployment. See Viewing or Changing Device Properties, page 3-37.

Related Topics
- Hostnames and Domain Names on Cisco IOS Routers, page 59-77

Step 1
Do one of the following:
- (Device view) Select Platform > Device Admin > Hostname from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Hostname from the Policy Type selector. Select an existing policy or create a new one.

The Hostname page is displayed. See Table 59-35 on page 59-78 for a description of the fields on this page.

Step 2
Enter the hostname for the router. Names must start with a letter, end with a letter or digit, and include only letters, digits, and hyphens. The maximum length is 63 characters.

Step 3
Enter the domain name for the router. The router uses this domain name for RSA key generation and in policies when you do not enter the fully-qualified domain name.
Hostname Policy Page

Use the Hostname page to define the hostname and domain name assigned to the router. For more information, see Defining Hostname Policies, page 59-77.

Navigation Path

- (Device view) Select Platform > Device Admin > Hostname from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Hostname from the Policy Type selector. Right-click Hostname to create a policy, or select an existing policy from the Shared Policy selector.

Memory Settings on Cisco IOS Routers

The Memory policy configures settings relating to router memory. This policy provides you with methods for monitoring memory consumption, including the ability to generate notification messages when available memory drops below predefined thresholds.

Note

The Memory policy is supported on routers running Cisco IOS Software Release 12.3(14)T or later.

Related Topics

- Defining Router Memory Settings, page 59-78

Defining Router Memory Settings

You can use Security Manager to modify the following default memory settings:

- The number of hours that the router maintains the log of memory consumption.
- Whether to enable the Memory Allocation Lite feature.
- The amount of memory to reserve for critical system log messages.
In addition, you can define:

- The lower thresholds for processor and I/O memory. Log messages are sent when available memory drops below these thresholds.
- The types of sanity checks to perform.

**Related Topics**

- Memory Settings on Cisco IOS Routers, page 59-78
- Logging on Cisco IOS Routers, page 61-1

---

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Device Admin > Memory** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Memory** from the Policy Type selector.
  
  Select an existing policy or create a new one.

The Memory page is displayed.

**Step 2**

(Optional) Define the memory settings of the router, as required. See Table 59-36 on page 59-80 for a description of the available fields.

---

**Memory Policy Page**

Use the Memory page to define settings related to router memory, including:

- The amount of time to retain the memory log.
- The thresholds for available processor and I/O memory.
- The amount of memory reserved for critical log messages.
- Whether to perform sanity checks on buffers and queues.
- Whether to enable the “memory-allocation lite” feature.

For more information, see Defining Router Memory Settings, page 59-78.

**Navigation Path**

- (Device view) Select **Platform > Device Admin > Memory** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Memory** from the Policy Type selector.
  
  Right-click Memory to create a policy, or select an existing policy from the Shared Policy selector.

Secure Device Provisioning on Cisco IOS Routers

Secure Device Provisioning (SDP) offers an integrated solution for streamlining VPN and network security deployment. SDP (previously called Easy Secure Device Deployment, or EzSDD) enables remote-site users to securely bootstrap their VPN device through an easy-to-use web interface, thereby easing the deployment burden, lowering costs, and shortening the network development cycle. For example, a telecommuter or small branch office user can remove a new device from its shipping package, plug it in, open a simple web management interface, and establish VPN connectivity, all within a period of just a few minutes.

For more information about SDP, see Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI, which can be found in Cisco IOS Security Configuration Guide, Release 12.4T.

Note

SDP requires Cisco IOS Software Release 12.3(8)T or later. Attempting to deploy this policy to a router running an earlier version could result in deployment failure. You also cannot configure the policy on NO-VPN router models (those that do not allow VPN configurations, such as the 3845 NOVPN).

Trusted Transitive Introduction (TTI) is the protocol that acts as the primary mechanism for implementing SDP. As shown in Figure 59-3, TTI comprises the following three entities:

- **Introducer**—A mutually trusted device that introduces the petitioner to the registrar. Introducers can be end users who use SDP to deploy VPN devices associated with themselves to the PKI network, or an administrator/management system that uses SDP to deploy many VPN devices to the PKI network. This latter type is known as an administrative introducer. For more information, see Configuring a AAA Server Group for Administrative Introducers, page 59-84.

- **Petitioner**—A remote-site device that is joined to the secure domain. The petitioner serves web pages to the introducer and receives the bootstrap configuration from the introducer’s web browser. The petitioner component is enabled by default on all Cisco IOS devices.

- **Registrar**—A server that authorizes the petitioner by communicating directly with an authentication, authorization, and accounting (AAA) server to verify user credentials, permit or deny enrollment, and retrieve user-specific configuration information.

Use the SDP policy in Security Manager to configure the router as a registrar.

Figure 59-3  Secure Device Provisioning

For more information about Secure Device Provisioning, see:

- Contents of Bootstrap Configuration, page 59-82
- Secure Device Provisioning Workflow, page 59-82
Secure Device Provisioning Workflow

The following illustrates the steps required to use SDP to register a remote-site device in a secure network:

1. Unpack the router and connect the power, LAN, and WAN cables.
2. Turn on a computer (introducer) that is assigned an IP address from the DHCP server on the router, open a web browser, and go to the petitioner URL (http://device/ezsdd/welcome) on the router. The router responds with a registration page (also called the local login dialog box).
3. Enter the username and password, then click OK. On the welcome page, enter the URL for the registrar. The following actions occur:
   a. The browser opens an HTTPS-secured session to the central-site registrar, which verifies the username with the AAA server and returns the appropriate bootstrap configuration to the browser.
   b. The browser feeds the bootstrap configuration to the remote-site router, configuring PKI trustpoint enrollment and IPsec VPN connectivity, and provisioning system attributes and other information.
   c. You are notified that bootstrap configuration is complete.

Defining Secure Device Provisioning Policies

The petitioner component is automatically enabled on all Cisco IOS routers. The SDP policy in Security Manager enables the registrar. To define an SDP policy you must define:

- The AAA server group containing the AAA server that the registrar uses to authenticate and authorize the introducer.
- The CA server to which the petitioner enrolls during the bootstrap process.
- The location of the introduction page that is displayed after authorization was performed.
- The location of the bootstrap configuration to be provided to the petitioner.

Related Topics

- Secure Device Provisioning Workflow, page 59-82
- Configuring a AAA Server Group for Administrative Introducers, page 59-84
- Secure Device Provisioning on Cisco IOS Routers, page 59-81

Step 1

Do one of the following:

- (Device view) Select Platform > Device Admin > Secure Device Provisioning from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Secure Device Provisioning from the Policy Type selector. Select an existing policy or create a new one.

The Secure Device Provisioning page is displayed. See Table 59-37 on page 59-85 for a description of the fields on this page.

Step 2

Under Introducer Authentication, enter the name of the AAA server group containing the relevant AAA server, or click Select to select it from a list or to create a new object.

The selected AAA server determines whether the username and password supplied by the introducer represent an authorized user. The AAA server must use TACACS+, RADIUS, or be local.

| Note | Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails. If you want to configure a different AAA server group for authenticating and authorizing administrative introducers, see Configuring a AAA Server Group for Administrative Introducers, page 59-84. |

Step 3

Under Petitioner Authentication, define the CA server that authenticates the identity of the petitioner by doing one of the following:

- Select Local CA Server, then enter the local CA name in the field provided. If you have already configured the CA server locally on the registrar, a trustpoint is generated automatically.

| Note | If you have not configured the router as the CA server, enter the command `Crypto pki server [name]` using the CLI or FlexConfigs. This command is mandatory when you deploy an SDP policy configured with a local CA server. |

- Select Remote CA Server, then enter the name of a PKI enrollment object, or click Select to select it from a list or to create a new object.

The PKI enrollment object defines the external CA server used in the SDP policy.
Step 4  Select the source of the introduction page that is displayed after you log in to the registrar. The introduction page indicates whether authorization was successfully completed and contains a button for completing the process of obtaining the bootstrap configuration.

If you do not select the default welcome page, you must enter the URL required to access a different welcome page that you prepared elsewhere.

Step 5  Select the source of the bootstrap configuration provided to the petitioner to implement its first-time configuration:

- If the source of the bootstrap configuration is a non-Security Manager URL, enter the URL and also the username and password for accessing the URL, if required.
- If the source of the configuration file is a Security Manager URL:
  - Enter the name of a FlexConfig, or click Select to select it from a list or to create a new object. The FlexConfig contains the device commands required to retrieve the appropriate bootstrap configuration. For more information, see Add or Edit FlexConfig Dialog Box, page 7-29.
  - Enter the device name formula required by the FlexConfig to derive the device name of the petitioner from the username submitted by the introducer. (The two names typically have a fixed relationship.) The default formula is $n, which uses the introducer name to determine the device name.

The device name determines which bootstrap configuration the petitioner should receive. The resulting URL contains the name of the FlexConfig you selected, as well as the parameters and formula you defined.

- Enter a username and password for accessing the Security Manager server containing the FlexConfig. The password can contain alphanumeric characters, but cannot consist of a single digit.

Configuring a AAA Server Group for Administrative Introducers

Administrative introducers are administrators or management systems that introduce many devices to the PKI network. You can configure a AAA server group for authenticating and authorizing administrative introducers by appending the following FlexConfig to the configuration of the router:

```
aaa new-model
radius-server host 1.2.3.4 auth-port 1645 acct-port 1646 key key
aaa group server radius default-radius-group2
server 1.2.3.4 auth-port 1645 acct-port 1646
exit
aaa authentication login CSM_SDP2 group default-radius-group2
crypto provisioning registrar
administrator authentication list CSM_SDP2
administrator authorization list CSM_SDP2
exit
```

This FlexConfig serves two functions—it configures the AAA server group to use and it associates this server group with the SDP crypto.

For more information about administrative introducers, see Administrative Secure Device Provisioning Introducer on Cisco.com at this URL: http://www.cisco.com/en/US/docs/ios/12_3t/12_3t14/feature/guide/gtadintr.html
Secure Device Provisioning Policy Page

Secure Device Provisioning (SDP) policies (formerly known as Easy Secure Device Deployment or EzSDD) enable you to configure a Cisco IOS router as a registrar. This is the SDP component that retrieves bootstrap configurations for petitioners, which are remote-site devices that are enrolling in the network security infrastructure. These devices use the bootstrap configuration for first-time configuration purposes. The registrar also verifies the identity of the introducer, which is the user who introduces the petitioner to the registrar.

For more information, see Defining Secure Device Provisioning Policies, page 59-83.

Navigation Path

- (Device view) Select Platform > Device Admin > Secure Device Provisioning from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Secure Device Provisioning from the Policy Type selector. Create a new policy or select an existing one.

DHCP on Cisco IOS Routers

In Security Manager, certain security features, such as Easy VPN and 802.1x, require Dynamic Host Configuration Protocol (DHCP) client/server configuration. DHCP is widely used in LAN environments to dynamically assign host IP addresses from a centralized server, which significantly reduces the overhead of administering IP addresses.

DHCP servers assign and manage IP addresses from specified address pools within a router to DHCP clients. If the DHCP server cannot satisfy a DHCP request from its own database, it can forward the request to one or more secondary DHCP servers defined by the network administrator.

Security Manager enables you to configure a Cisco IOS device as a DHCP server for clients (hosts) that are connected to the device’s inside interface. When you configure a DHCP server, you use IP pools (a range of IP addresses reserved for a DHCP server). The IP pools you select determine the range of IP

</tbody>
</table>
addresses the server can use. These addresses are provided to client devices for a defined period of time called a lease. When this lease expires, the address is returned to the address pool, enabling the DHCP server to assign it to a different device.

For more information about DHCP, see:

- Understanding DHCP Database Agents, page 59-88
- Understanding DHCP Relay Agents, page 59-88
- Understanding DHCP Option 82, page 59-89
- Understanding Secured ARP, page 59-89

To configure a DHCP policy, see:

- Defining DHCP Policies, page 59-90
- Defining DHCP Address Pools, page 59-91

**Understanding DHCP Database Agents**

A DHCP database agent is any external host—for example, an FTP, TFTP, or RCP server—that stores the DHCP bindings database. You can include one or more DHCP database agents in each DHCP policy, as well as configure the interval between database updates to the agent.

If you configure an external DHCP database agent, it is not necessary to define IP address pools, but you may do so. For more information about IP address pools, see Defining DHCP Address Pools, page 59-91.

- Understanding DHCP Option 82, page 59-89
- Understanding Secured ARP, page 59-89
- Defining DHCP Policies, page 59-90
- DHCP on Cisco IOS Routers, page 59-87

**Understanding DHCP Relay Agents**

A DHCP relay agent is any host that forwards DHCP packets between clients and servers when they do not reside on the same physical subnet. Relay agents receive DHCP messages and then generate a new DHCP message to send on another interface. You can configure a reforwarding policy that determines what the DHCP relay agent should do if a forwarded message already contains relay information.

DHCP relay options in Security Manager include:

- Drop—The relay agent discards messages with existing relay information if Option 82 information is also present.
- Keep—The relay agent retains existing relay information.
- Replace—The relay agent overwrites existing information with its own relay information.
For example, you can have the DHCP relay agent replace the forwarded message with a new relay message. Additionally, you can choose whether to have the relay agent check the validity of relay information contained within forwarded BOOTREPLY messages.

Understanding DHCP Option 82

DHCP option 82 enables the DHCP relay agent to include information about itself and its attached client when it forwards requests from a DHCP client to a DHCP server. The DHCP server can use this information to assign IP addresses, perform access control, and set quality of service (QoS) and security policies for each of its subscribers. When the DHCP option 82 feature is enabled, a subscriber is identified by the switch port through which it connects to the networks, instead of by its MAC address. Multiple hosts on the subscriber LAN can be connected to the same port on the access switch and are uniquely identified. Option 82 also enhances security on access switches by providing the ability to use a user’s IP address to locate the port on which a user is attached.

- DHCP on Cisco IOS Routers, page 59-87

Understanding Secured ARP

The DHCP Secure IP Address Assignment feature (also called DHCP Authorized ARP) enables you to secure Address Resolution Protocol (ARP) table entries to DHCP leases in the DHCP database. This feature secures and synchronizes the client’s MAC address to the DHCP binding, preventing unauthorized clients or hackers from spoofing the DHCP server and taking over a DHCP lease of an authorized client.

When you enable this feature and the DHCP server assigns an IP address to the DHCP client, the DHCP server adds a secure ARP entry to the ARP table with the assigned IP address and the MAC address of the client. These ARP entries cannot be updated by any other dynamic ARP packets, and they exist in the ARP table for as long as the lease is active.

Secure ARP entries can be deleted only by an explicit termination message from the DHCP client or by the DHCP server when the binding expires. To detect when a client has logged out, Secured ARP sends periodic ARP messages to which only authorized users can respond. Unauthorized responses are blocked at the DHCP server, providing an additional level of security.
Secured ARP disables dynamic ARP learning on an interface.

- DHCP on Cisco IOS Routers, page 59-87

## Defining DHCP Policies

When you configure a DHCP policy, you must define the IP address pools for the server to use to provide addresses to DHCP clients. In addition, you can optionally define the following:

- External DHCP database agent.
- IP ranges to exclude from DHCP.
- DHCP relay parameters.

**Note**
When configuring DHCP on a Cisco IOS router, make sure that the router does not contain an access rule denying Bootstrap Protocol (BootP) traffic. Having such a rule blocks DHCP traffic from being transmitted.

**Related Topics**
- DHCP on Cisco IOS Routers, page 59-87

### Step 1

Do one of the following:

- (Device view) Select **Platform** > **Device Admin** > **Server Access** > **DHCP** from the Policy selector.
- (Policy view) Select **Router Platform** > **Device Admin** > **Server Access** > **DHCP** from the Policy Type selector. Select an existing policy or create a new one.

The DHCP Policy page is displayed. See Table 59-38 on page 59-92 for a description of the fields on this page.

### Step 2

(Optional) Under Databases, click the **Add** button to display the **DHCP Database Dialog Box**, page 59-94. From here you can define external DHCP database agents. For more information, see Understanding DHCP Database Agents, page 59-88.

### Step 3

(Optional) Under Excluded IPs, enter the IP addresses or address ranges within a DHCP address pool that should not be made available to DHCP clients. You can use a combination of addresses and network/host objects, or click **Select** to display a selector. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

**Tip**
If the network you want is not listed in the selector, click the **Create** button to display the Add or Edit Network/Host Dialog Box (IPv4 or IPv6), page 6-73. From here you can create a network/host object.
Step 4 Under IP Pools, click the **Add** button to display the IP Pool Dialog Box, page 59-94. From here you can define the address pools to be used by the DHCP server. For more information, see Defining DHCP Address Pools, page 59-91.

Step 5 (Optional) When you use a relay agent to manage requests from DHCP clients located on a different subnet from the DHCP server, define the following DHCP relay options:

a. Select the **relay** agent information reforwarding policy (Drop, Keep, or Replace). DHCP relay agents implement this policy when they receive messages already containing relay information.

b. Select the **Option** check box to enable the insertion of Option 82 data in requests that the relay agent forwards to the DHCP server.

c. Select the **Check** check box to validate DHCP Option 82 reply packets sent by the DHCP server.

When you enable this option, invalid messages are dropped. Valid messages are stripped of the option-82 field before they are forwarded to the DHCP client. When you disable this option, the option-82 field is removed from the packet without being checked first for validity.

See Understanding DHCP Relay Agents, page 59-88 for more information.

---

**Defining DHCP Address Pools**

When you configure a DHCP policy that does not include an external database agent, you must define at least one IP address pool. This pool contains the addresses that the DHCP server can dynamically assign to DHCP clients. Additionally, you can define the following IP pool-specific options:

- The default routers, DNS servers, WINS servers, and domain used by DHCP clients.
- Whether to use the Secured ARP feature.
- Whether to import information regarding IP pool options from a centralized DHCP server.
- The length of the lease.
- The location of the TFTP server that IP telephony devices require to use addresses from this pool.

**Related Topics**

- Defining DHCP Policies, page 59-90
- DHCP on Cisco IOS Routers, page 59-87

---

**Step 1**

On the DHCP page, click the **Create** button under IP Pools. The IP Pool dialog box is displayed.

**Step 2**

Define the address pool. See Table 59-40 on page 59-95 for a description of the available fields.

**Step 3**

Click **OK** to save your definitions locally on the client and close the dialog box. The IP pool appears in the table displayed under IP Pools on the DHCP page.

**Step 4**

Repeat **Step 1** through **Step 3** to define additional address pools, if required.

**Note**

To edit an IP pool, select it from the table, then click the **Edit** button. To delete an IP pool, select it from the table, then click the **Delete** button. You cannot delete a pool whose addresses have been assigned to DHCP clients.
DHCP Policy Page

Use the DHCP policy page to define a DHCP server policy on the selected router. This includes specifying the address pools used by the DHCP server when assigning addresses to requesting clients. For more information, see Defining DHCP Policies, page 59-90.

Navigation Path
- (Device view) Select Platform > Device Admin > Server Access > DHCP from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Server Access > DHCP from the Policy Type selector. Right-click DHCP to create a policy, or select an existing policy from the Shared Policy selector.

<tr>
<td>Secured ARP</td>
<td>When selected, enables the DHCP Authorized ARP feature, which limits the leasing of IP addresses to authorized mobile users. This feature helps prevent IP spoofing by unauthorized users. See Understanding Secured ARP, page 59-89. When deselected, the DHCP Authorized ARP feature is disabled. <strong>Note</strong> This feature also disables dynamic ARP learning on an interface.</td>
</tr>
</tbody>
</table>
The Network Time Protocol (NTP) is the standard for time synchronization between network devices. Synchronized time enables you to correlate syslog and other debug output to specific events, which is essential for troubleshooting, fault analysis, and security incident tracking. Time comparisons are not possible without precise time synchronization between the logging, management, and AAA functions occurring in your network.

NTP uses the concept of a stratum to describe how far removed a machine is from an authoritative time source. For example, a stratum 1 time server is directly attached to a radio or atomic clock. NTP then distributes the time from this authoritative time source across the network. A stratum 2 time server synchronizes with a stratum 1 time server; a stratum 3 time server synchronizes with a stratum 2 time server and so on. One NTP transaction per minute is sufficient to synchronize two machines to within a millisecond.

NTP runs over the User Datagram Protocol (UDP) using port 123. Security Manager supports NTP version 3, as defined in RFC 1305.

Related Topics
- Defining NTP Servers, page 59-97
Defining NTP Servers

This procedure describes how to define the NTP servers that the routers users to synchronize time. After the NTP policy is deployed, the router uses an algorithm (based on factors such as delay, dispersion, and jitter) to determine which NTP server is the most accurate and synchronizes to that one.

At the global level, you can enable MD5 authentication and specify a source address to use on all NTP packets sent from the router.

To add an NTP server to the policy, all you need to do is enter its IP address. In addition, you can optionally define authentication parameters and determine whether a particular server should be preferred over other NTP servers of similar accuracy.

Related Topics

- NTP on Cisco IOS Routers, page 59-96

---

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Device Admin > Server Access > NTP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Server Access > NTP** from the Policy Type selector. Select an existing policy or create a new one.

The NTP page is displayed. See Table 59-41 on page 59-98 for a description of the fields on this page.

**Step 2**

(Conditional) In the Source Interface field, enter the name of the interface or interface role whose address should be used as the source interface for all NTP packets sent from the router, or click **Select** to select an interface role from a list or to create a new one. The source interface must have an IP address.

This option is useful when the NTP server cannot reach the address from which the connection originated (for example, due to a firewall). If you do not enter a value in this field, the address of the outgoing interface is used.

**Note**

You can override this global setting for individual NTP servers, as described in **Step 5**.

**Step 3**

(Conditional) Select the **Enable NTP Authentication** check box to authenticate all associations between this router and the NTP servers defined in this policy.

**Step 4**

Click the **Add** button under the Servers table to display the NTP Server dialog box. From here you can define an NTP server.

**Step 5**

Define an NTP server. See Table 59-42 on page 59-100 for a description of the available fields.

**Step 6**

(Conditional) Define authentication parameters for this NTP server.

**Note**

If you modify the value of a previously defined authentication key, the change affects all NTP servers that share this key.

**Note**

When you define an authentication key in Security Manager, the value 0 is automatically appended to the end of the CLI command. This value, which represents the default authentication key encryption type, can be modified using the CLI.

**Step 7**

Repeat **Step 5** and **Step 6** to define additional NTP servers.
Step 8

Click OK to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Servers table.

Note

To edit an NTP server, select it from the Servers table, then click Edit. To remove an NTP server, select it, then click Delete. If the key defined on the server you delete is not defined on a different NTP server, the key is also deleted.

NTP Policy Page

Use the NTP page to define one or more NTP servers that the router can use for time synchronization. This includes enabling authentication, if required, and defining a global source interface for all traffic sent to these servers.

For more information, see Defining NTP Servers, page 59-97.

Navigation Path

- (Device view) Select Platform > Device Admin > Server Access > NTP from the Policy selector.
- (Policy view) Select Router Platform > Device Admin > Server Access > NTP from the Policy Type selector. Right-click NTP to create a policy, or select an existing policy from the Shared Policy selector.

<td><strong>IP Address</strong></td>
<td>The IP address of the NTP server. Enter an address or the name of a network/host object, or click <strong>Select</strong> to select the object from a list or to create a new one.</td>
</tr>
<tr>
<td><strong>Source Interface</strong></td>
<td>The source address for all packets sent to this NTP server. This setting might be necessary when the NTP server cannot respond to the address from which the packet originated (for example, due to a firewall). The source interface must have an IP address. If you do not define a value in this field and there is no global setting, the address of the outgoing interface is used. <strong>Note</strong> This setting overrides the global setting you defined on the NTP Policy Page, page 59-98. Enter the name of an interface or interface role, or click <strong>Select</strong> to select the object from a list or to create a new one.</td>
</tr>
<tr>
<td><strong>Preferred</strong></td>
<td>When selected, this NTP server is preferred over other NTP servers of similar accuracy. If this server is used for synchronization, the time offset used to correct the local clock is calculated from this server only. <strong>Note</strong> If a different NTP server is significantly more accurate than the preferred server (for example, stratum 2 versus stratum 3), the router synchronizes to the more accurate server. When deselected, this NTP server is not given preference over other NTP servers of similar accuracy. The time offset used to correct the local clock is calculated by taking the combined offset of all NTP servers. We recommend that you configure an NTP server as preferred only when multiple servers have the same stratum and you can rely on the accuracy of the preferred server.</td>
</tr>
</tbody>
</table>
| **Authentication Key** | The MD5 key that is used to authenticate associations with the NTP server.  
  - Key Number—The ID number of the authentication key. Enter the key number or select a previously defined number from the list.  
  - Key Value—An arbitrary string of up to 32 characters that defines the authentication key. Enter the string again in the Confirm field.  
  - Trusted—When selected, this key authenticates the identity of systems attempting to synchronize with this server. When deselected, this key is not used for authentication. If you select a key number from the list and then change the key value, you are warned that saving this change affects any other NTP servers using the same authentication key. **Note** To use authentication, you must enable it from the NTP Policy Page, page 59-98. |
CHAPTER 60

Configuring Identity Policies

This chapter contains the following topics:

- 802.1x on Cisco IOS Routers, page 60-1
- 802.1x Policy Page, page 60-5
- Network Admission Control on Cisco IOS Routers, page 60-8
- Network Admission Control Policy Page, page 60-14

802.1x on Cisco IOS Routers

The IEEE 802.1x standard defines 802.1x port-based authentication as a client-server based access control and authentication protocol that restricts unauthorized clients from connecting to a LAN through public ports. The authentication server validates each client connected to an interface before making available any services offered by the router or the LAN.

Until the client is authenticated, 802.1x access control allows only Extensible Authentication Protocol over LAN (EAPOL) traffic through the interface to which the client is connected. If authentication is successful, normal traffic can pass through the interface.

802.1x authentication provides VPN access control, enabling unauthenticated traffic to access the Internet while preventing it from accessing the VPN tunnel. This solution is especially useful for enterprises whose workers access the corporate VPN through a home access router that other family members use to access the Internet. When you use 802.1x, you create a virtual interface to carry unauthenticated traffic while authenticated traffic continues to pass through the physical interface.

802.1x requires that you use DHCP to provide IP addresses to the clients that request authentication. We recommend that you use two IP address pools, one for authenticated traffic and the other for unauthenticated traffic. If you use two pools, the DNS server in the corporate DHCP pool should point to the corporate DNS server. The DNS server for the noncorporate DHCP pool should use the DNS server provided by the ISP on the public interface. You configure DHCP by selecting a DHCP policy. See DHCP on Cisco IOS Routers, page 59-87 for more information.

Note

802.1x is supported on the following platforms—Cisco 800, 1700, 1800, 1900, 2600, 2800, 2900, 3600, 3700, 3800, 3900 Series Routers.

For more information about 802.1x, see:

- Understanding 802.1x Device Roles, page 60-2
- 802.1x Interface Authorization States, page 60-2
Understanding 802.1x Device Roles

802.1x port-based authentication uses the following device roles:

- **Client**—The workstation requesting access to the VPN. It must be running 802.1x-compliant client software, such as that offered with the Microsoft Windows XP operating system.
- **Authentication server**—Authenticates clients. The authentication server validates the client’s identity and notifies the router whether the client is authorized to access the network. The Remote Authentication Dial-In User Service (RADIUS) security system with EAP extensions is the only supported authentication server. In Security Manager, a AAA (authentication, authorization, and accounting) server, as defined in a AAA server object, is the authentication server for 802.1x policies.
- **Router** (edge router or wireless access point) — Controls physical access to the network based on the authentication status of the client. The router is an intermediary (proxy) between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client. In Security Manager, the router on which you configure an 802.1x policy acts as the switch.

802.1x Interface Authorization States

When you use 802.1x, the interface state determines whether to grant the client network access. By default, the interface starts in the unauthorized state. While in this state, the interface disallows all traffic in both directions, except for EAPOL packets. After a client is authenticated, the interface transitions to the authorized state, enabling all client traffic to flow normally.

If a client that does not support 802.1x is connected to an unauthorized 802.1x interface, the router requests the client’s identity. In this situation, the client does not respond to the request, the interface remains in the unauthorized state, and the client is not granted access to the network. In contrast, when an 802.1x-enabled client connects to an interface that is not running the 802.1x protocol, the client initiates the authentication process by sending the EAPOL-Start frame. If no response is received, the client sends the request a fixed number of times. Because no response is received, the client begins sending frames as if the interface were in the authorized state.

You can control the interface authorization state by selecting one of the following options:

- **Auto**—Enables 802.1x authentication, which causes the interface to start in the unauthorized state. Only EAPOL frames are sent and received through the interface. Authentication begins when the link state of the interface transitions from down to up or when an EAPOL-Start frame is received. The router requests the client’s identity and begins relaying authentication messages between the client and the authentication server. The router uses the MAC address of each client trying to access the network as unique client identifiers.
• Force authorized—Disables 802.1x authentication, which causes the interface to move to the authorized state without authenticating the client.

After a client is successfully authenticated, the interface state changes to authorized, which enables all frames from the client to enter the network. If authentication fails, the interface remains in the unauthorized state, but authentication can be retried. If the authentication server cannot be reached, the router can retransmit the request. If the authentication server does not respond after the defined number of attempts, authentication fails and network access is denied to the client.

When a client logs off, it sends an EAPOL-Logoff message, which causes the interface to return to the unauthorized state.

**Related Topics**

- Understanding 802.1x Device Roles, page 60-2
- Topologies Supported by 802.1x, page 60-3
- Defining 802.1x Policies, page 60-4
- 802.1x on Cisco IOS Routers, page 60-1

**Topologies Supported by 802.1x**

802.1x port-based authentication supports two topologies:

- Point-to-point
- Wireless LAN

In a point-to-point configuration, only one client can be connected to the 802.1x-enabled interface. The router detects the client when the interface state changes from down to up. If a client leaves the network or is replaced by another client, the interface state changes from up to down, which returns the interface to the unauthorized state.

**Figure 60-1  802.1x Topology**

![802.1x Topology Diagram](image)

In a wireless LAN configuration, the 802.1x interface is configured in multihost mode, which is authorized as soon as one client is authenticated. After the interface is authorized, all other clients indirectly attached to the interface are granted access to the network. If the port becomes unauthorized (either because reauthentication fails or an EAPOL-Logoff message is received), the router denies access to the network to all attached clients. In this topology, the wireless access point is a client to the router and is responsible for authenticating the clients attached to it.
Defining 802.1x Policies

You configure an 802.1x policy by defining:

- The AAA server group containing the AAA server that authenticates hosts that are trying to connect to the network.
- The virtual interface that carries unauthenticated traffic and the physical interface that carries authenticated traffic.
- (Optional) Properties of the physical interface, including the control type, automatic reauthentication, and several timeout values.

If the router on which you are defining the 802.1x policy is not part of a VPN (for example, if it is directly connected to the corporate network to which you want to restrict access), you must manually define an access list. You can do this by defining an access rules policy (see Chapter 15, “Managing Firewall Access Rules”).

Before You Begin

- Configure the selected router with a DHCP policy that contains two IP address pools, one for authenticated clients and one for unauthenticated clients. See Defining DHCP Policies, page 59-90.
- Make sure the router can route packets to the configured AAA (RADIUS) server. You can verify this by pinging the server from the router.

Related Topics

- Understanding 802.1x Device Roles, page 60-2
- 802.1x Interface Authorization States, page 60-2
- Defining 802.1x Policies, page 60-4
- 802.1x on Cisco IOS Routers, page 60-1

Step 1

Do one of the following:

- (Device view) Select Platform > Identity > 802.1x from the Policy selector.
- (Policy view) Select Router Platform > Identity > 802.1x from the Policy Type selector. Select an existing policy or create a new one.

The 802.1x page is displayed. See Table 60-1 on page 60-6 for a description of the fields on this page.

Step 2

Enter the name of the AAA server group containing the AAA server to use for authenticating clients using 802.1x, or click Select to select a server group from a list or to create a new one. The selected AAA server must use RADIUS with EAP extensions.

Note: Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails.
Step 3 In the Virtual Template field, enter the name of the interface or interface role that serves as the untrusted, virtual interface for carrying unauthenticated traffic, or click Select to select an interface role from a list or to create a new role. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Note Integrated Services Routers (ISRs), such as the Cisco 800, 1800, 1900, 2800, 2900, 3800, and 3900 Series, automatically use VLANs to carry unauthenticated traffic. If you define a virtual template, however, it is used in place of the VLAN.

Note Deployment might fail if PPP is defined on the virtual template defined here. See Defining PPP Connections, page 58-71.

Step 4 Enter the name of the interface or interface role that serves as the trusted, physical interface for carrying authenticated traffic, or click Select to select a role from a list.

The interface role you select should represent the internal protected interface that was configured as part of the VPN topology and no other physical interface on the selected router. For more information, see Defining the Endpoints and Protected Networks, page 23-33.

Step 5 (Optional) Modify the defaults of the physical interface used for 802.1x authentication. See Table 60-1 on page 60-6 for details.

802.1x Policy Page

Use the 802.1x policy page to create policies that limit VPN access to authorized users. Authenticated traffic is allowed to pass through a designated physical interface on the router. Unauthenticated traffic is allowed to pass through a virtual interface to the Internet but is not allowed to access the VPN.

For more information, see Defining 802.1x Policies, page 60-4.

Note 802.1x policies require DHCP address pools in order to assign IP addresses to clients. You define these pools by defining a DHCP policy on the same router. See DHCP Policy Page, page 59-92.

Navigation Path
- (Device view) Select Platform > Identity > 802.1x from the Policy selector.
- (Policy view) Select Router Platform > Identity > 802.1x from the Policy Type selector. Right-click 802.1x to create a policy, or select an existing policy from the Shared Policy selector.

Network Admission Control on Cisco IOS Routers

Network Admission Control (NAC), an industry initiative sponsored by Cisco Systems, uses the network infrastructure to enforce security-policy compliance on all devices seeking to access network computing resources, thereby limiting damage from viruses and worms. By using NAC, organizations can provide network access to endpoint devices such as PCs, PDAs, and servers that are verified to be fully compliant with established security policy. NAC can also identify noncompliant devices and deny them access, place them in a quarantined area, or give them restricted access to computing resources.

Network access decisions are made through a process of posture validation, which evaluates the posture credentials presented by the endpoint device. These credentials can include such information as the endpoint’s antivirus state, operating system version, operating system patch level, or Cisco Security Agent version and settings.

You can use NAC to enforce security policy compliance in many types of deployments, including branch offices, remote access, and dial-in access.

NAC policies in Security Manager enable a Cisco IOS router to act as a Network Access Device (NAD) for enforcing policy compliance on devices seeking to access the network. The following topics describe additional details about NAC:

- Understanding NAC Components, page 60-9
- Understanding NAC System Flow, page 60-9

The following topics describe the tasks you perform to create NAC policies on Cisco IOS routers:

- Defining NAC Setup Parameters, page 60-10
- Defining NAC Interface Parameters, page 60-11
- Defining NAC Identity Parameters, page 60-13

Router Platforms Supporting NAC

To configure NAC policies on a router, the router must be running Cisco IOS Software Release 12.3(8)T images and higher (with the Advanced Security feature set). However, the following routers do not support NAC:

- Cisco 7600 Series (7603, 7604, 7606, 7609, 7613)
- Cisco 7300 Series (7301, 7304)
- Cisco 7100 Series VPN Routers (7120, 7140, 7160)
- Cisco 3600 Series Multiservice Platforms (3620, 3631, 3661, 3662)

---

**Table 60-1 802.1x Page (Continued)**

</table>
Chapter 60 Configuring Identity Policies

Network Admission Control on Cisco IOS Routers

- Cisco 1700 Series Modular Access Routers (1710, 1720, 1750)
- Cisco 1600 Series (1601, 1602, 1603, 1604, 1605)
- Cisco ASR 1000 Series Aggregation Services Routers (all models)
- Cisco 800 Series (801, 803, 805, 811, 813, 828, 851, 857, 871, 876, 877, 878)
- Cisco SOHO 90 Series Secure Broadband Routers (91, 96, 97)
- Cisco SOHO 77 Series (71, 76, 77 ADSL, 77 H ADSL, 78)

Understanding NAC Components

NAC contains the following components:

- Cisco Trust Agent (CTA)—The CTA acts as the NAC client. It provides posture credentials for the endpoint device on which it is installed, including the type of operating system and the version of antivirus software installed.
- Network access device (NAD)—The NAD initiates posture validation with the CTA when its Intercept ACL is triggered. It relays posture credentials received from the CTA to a AAA server. In return, the NAD receives configuration information from the AAA server, which it enforces on the selected interface. The NAD also:
  - Periodically polls the CTA to confirm that it is communicating with the same client at this IP address.
  - Revalidates all current sessions.
  - Sends username and password information from devices lacking a CTA (clientless hosts) to the AAA server for authentication.
  - Supports an exception list of predefined actions applied to specific devices, based on the device IP address or MAC address.

When you configure NAC policies in Security Manager, you are configuring the behavior of the Cisco IOS router acting as the NAD.

- AAA server—The AAA server obtains and validates posture credentials received from the CTA and returns the access policy to be enforced on the NAD. The AAA server must be a Cisco Secure Access Control Server (ACS), running the RADIUS protocol. Existing ACS authorization support can be used to provide access to clientless hosts. Posture validation rules and the access policies resulting from those rules are configured on the ACS.

Related Topics

- Understanding NAC System Flow, page 60-9
- Network Admission Control on Cisco IOS Routers, page 60-8

Understanding NAC System Flow

As shown in Figure 60-2, the system flow for NAC is:

1. An IP packet from a connecting device triggers the Intercept ACL configured on the NAD.
2. The NAD triggers posture validation with the CTA configured on the device using the Extensible Authentication Protocol over User Datagram Protocol, otherwise known as EAP over UDP, or simply EoU.
3. The CTA sends its posture credentials to the NAD using EAP over UDP.
4. The NAD sends these posture credentials to the ACS using RADIUS.
5. The ACS performs posture validation, which determines whether to allow the device to access the network. (If necessary, the ACS requests additional posture validation from a third-party server. For example, if the CTA forwards credentials that are specific to a particular antivirus application, the ACS forwards this information via the HCAP protocol to a vendor server for validation.) If the device is a clientless host, the ACS checks the username and password it receives against its locally stored list.
6. The ACS directs the NAD to enforce the appropriate access policy on the requesting device. Access may be granted, denied, redirected, or restricted.

**Related Topics**
- Understanding NAC Components, page 60-9
- Network Admission Control on Cisco IOS Routers, page 60-8

**Defining NAC Setup Parameters**

You configure NAC setup parameters by selecting the AAA server groups that obtain and validate the posture credentials received from devices trying to connect to the network. You can configure an option that allows devices lacking the Cisco Trust Agent (CTA) to be authenticated by a predefined username and password stored on a Cisco Secure Access Control Server (ACS). Additionally, you can modify default settings for EAP over UDP. This is the protocol used for posture validation communications between the Cisco IOS router serving as the network access device (NAD) and the device trying to access your network.

**Related Topics**
- Defining NAC Interface Parameters, page 60-11
- Defining NAC Identity Parameters, page 60-13
- Network Admission Control on Cisco IOS Routers, page 60-8

**Step 1**

Do one of the following:
- (Device view) Select **Platform > Identity > Network Admission Control** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Identity > Network Admission Control** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The NAC Setup tab is displayed. See **Table 60-2 on page 60-15** for a description of the fields on this tab.
Step 2  Enter the name of the AAA server group containing the AAA server that performs posture validation, or click Select to select the server group from a list or to create a new one. The selected AAA server group must contain ACS devices running RADIUS.

Note  Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails.

Step 3  (Optional) Select up to two AAA server groups as backups to the main server group. If all the servers in the main server group go down, the servers in the backup server group perform NAC. Both backup server groups must consist of ACS devices running RADIUS.

Step 4  (Optional) Under EAP over UDP, select one or both of the following Allow parameters:

a. Select the Allow IP Station ID check box to include IP addresses in the RADIUS requests sent to the ACS.

b. Select the Allow Clientless check box to provide access to devices that do not have the CTA installed. In such cases, the ACS authenticates these devices by checking the username and password against a predefined list.

If you do not select this check box, devices without CTA are prevented from accessing the network if their traffic matches the Intercept ACL. This is because without CTA, posture validation cannot be performed.

Note  This feature is not supported on routers running Cisco IOS Software Release 12.4(6)T or later.

Step 5  (Optional) Under EAP over UDP, modify the default settings related to the EAP over UDP (EoU) protocol, if required. See Table 60-2 on page 60-15 for details.

Defining NAC Interface Parameters

You configure NAC interface parameters by selecting the interfaces on which NAC is performed. You must also define the Intercept ACL, which determines which traffic on these interfaces is subject to posture validation. Additionally, you can optionally override the device-level setting for initiating EAP over UDP sessions and subject all sessions to periodic revalidation (see Defining NAC Setup Parameters, page 60-10).

A NAC policy must include at least one interface definition to function.

Before You Begin

- Select the AAA server group containing the ACS device performing posture validation. See Defining NAC Setup Parameters, page 60-10.
- Define an ACL object that defines the traffic to subject to posture validation in NAC policies. See Creating Access Control List Objects, page 6-48.
- Define an ACL object that defines the default access on the selected interface (default ACL). See Creating Access Control List Objects, page 6-48.
Chapter 60  Configuring Identity Policies

Related Topics

- Defining NAC Setup Parameters, page 60-10
- Defining NAC Identity Parameters, page 60-13
- Network Admission Control on Cisco IOS Routers, page 60-8

Step 1
Do one of the following:

- (Device view) Select **Platform > Identity > Network Admission Control** from the Policy selector, then click the **Interfaces** tab in the work area.
- (Policy view) Select **Router Platform > Identity > Network Admission Control** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Interfaces** tab.

The NAC Interfaces tab is displayed. See Table 60-3 on page 60-16 for a description of the fields on this tab.

Step 2
On the NAC Interfaces tab, select an interface definition from the table, then click **Edit**, or click **Add** to create a definition. The NAC Interface Configuration dialog box appears. See Table 60-4 on page 60-17 for a description of the fields in this dialog box.

Step 3
Enter the name of the interface or interface role on which NAC is performed, or click **Select** to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 4
(Optional) Enter the name of the ACL object that acts as the intercept ACL, or click **Select** to select it from a list or to create a new object.

The intercept ACL determines which traffic on the selected interfaces is subject to posture validation before being granted access to the network. If you do not select an ACL, all traffic on the selected interfaces is subject to posture validation.

**Note**
If you defined an authentication proxy on the same interface as a NAC interface, you must use the same intercept ACL in both policies. Otherwise, deployment might fail. For more information about authentication proxies, see Configuring AAA Rules for IOS Devices, page 14-7.

Step 5
(Optional) To override the device-level value defined for maximum attempts to initiate an EAP over UDP session, enter a new value in the EAP over UDP Max Retries field.

Step 6
(Optional) Deselect the **Enable EOU Session Revalidation** check box if you do not want the NAD to periodically revalidate all EAP over UDP sessions.

**Note**
Subinterfaces support default values only for the options described in Step 5 and Step 6.

Step 7
Click **OK** to save your definitions locally on the client and close the dialog box. Your interface definitions appear in the table on the NAC Interfaces tab.
Defining NAC Identity Parameters

By default, any traffic over the selected interfaces that match the intercept ACL is subjected to posture validation before it is permitted to enter the network. However, you can create an exception list of predefined actions to apply to specific devices. You use identity profiles to create this exception list. Each profile contains two elements:

- A profile definition, identifies the device to which the profile applies. Devices can be identified by their IP addresses, MAC addresses, or types (for Cisco IP phones).
- An action, which defines the result when this device tries to access the network. Each action can include an ACL, a redirect URL, or both. If you do not specify an action, the default ACL is applied.

When you configure NAC identity parameters, you first define one or more identity actions and then create the identity profiles to which these actions apply. You can apply each action to multiple profiles.

Related Topics

- Defining NAC Setup Parameters, page 60-10

- Network Admission Control on Cisco IOS Routers, page 60-8

---

Step 1

Do one of the following:

- (Device view) Select Platform > Identity > Network Admission Control from the Policy selector, then click the Identities tab in the work area.
- (Policy view) Select Router Platform > Identity > Network Admission Control from the Policy Type selector. Select an existing policy or create a new one, and then click the Identities tab.

The NAC Identities tab is displayed. See Table 60-5 on page 60-18 for a description of the fields on this tab.

Step 2

Define one or more identity actions:

a. On the NAC Identities tab, select an identity action from the lower table, then click Add. The NAC Identity Action dialog box appears.

b. Define an identity action. See Table 60-7 on page 60-20 for a description of the available fields.

c. Click OK to save your definitions and close the dialog box. The action appears in the Identity Actions table in the NAC Identities tab.

d. (Optional) Repeat a through c to define additional identity actions, as required.

Step 3

Define identity profiles:

a. Select an identity profile from the upper table on the NAC Identities tab, then click Add. The NAC Identity Profile dialog box appears. See Table 60-6 on page 60-19 for a description of the fields in this dialog box.

b. Enter the name of an identity action (as defined in Step 2) or click Select to display a selector.

c. Select and define a profile definition, which identifies the device to which the profile should apply.

d. Click OK to save your definitions and close the dialog box. The profile appears in the Identity Profiles table in the NAC Identities tab.

e. (Optional) Repeat a through d to define additional identity profiles, as required.
Network Admission Control Policy Page

Network Admission Control (NAC) policies enable Cisco IOS routers acting as network access devices (NADs) to enforce access privileges when an endpoint tries to connect to a network. Access decisions are made on the basis of information provided by the endpoint device, such as its current antivirus state, thus keeping insecure nodes from infecting the network.

You can configure NAC policies on a Cisco IOS router from the following tabs on the Network Admission Control policy page:

- **Network Admission Control Page—Setup Tab, page 60-14**
- **Network Admission Control Page—Interfaces Tab, page 60-16**
- **Network Admission Control Page—Identities Tab, page 60-18**

For more information, see *Network Admission Control on Cisco IOS Routers, page 60-8*.

**Navigation Path**

- (Device view) Select **Platform > Identity > Network Admission Control** from the Policy selector.
- (Policy view) Select **Router Platform > Identity > Network Admission Control** from the Policy Type selector. Right-click **Network Admission Control** to create a policy, or select an existing policy from the Shared Policy selector.

### Network Admission Control Page—Setup Tab

Use the Network Admission Control Setup tab to select the Cisco Secure Access Control Servers used for authentication during the NAC process, as well as to define the EAP over UDP settings for communications between the NAD and the client seeking access to the network.

**Navigation Path**

Go to the *Network Admission Control Policy Page, page 60-14*, then click the **Setup** tab.

Configuring Logging Policies

This chapter contains the following topics:

- Logging on Cisco IOS Routers, page 61-1
- Syslog Logging Setup Policy Page, page 61-7
- Syslog Servers Policy Page, page 61-10
- NetFlow Policy Page, page 61-12

Logging on Cisco IOS Routers

Security Manager provides the following policies for configuring logging on a Cisco IOS router:

- Syslog Logging Setup—Enable the syslog-logging feature, and define basic logging parameters. For more information, see Defining Syslog Logging Setup Parameters, page 61-1.
- Syslog Servers—Define the remote servers to which syslog messages are sent. For more information, see Defining Syslog Servers, page 61-3.

Note

We strongly recommend configuring a Network Time Protocol (NTP) policy on all routers on which logging is enabled. NTP synchronization provides accurate timestamps for syslog messages, which is essential for comparing logs on multiple devices.

Defining Syslog Logging Setup Parameters

This procedure describes enabling syslog logging on the router, and defining which messages are sent to a syslog server. In addition, you can optionally define:

- The source interface for all syslog messages sent from this device.
- The messages that are saved to a local buffer.
- An origin identifier added to each message.
- A rate limit on the number of messages that can be sent.
To send syslog messages from the router to a syslog server, you must also define the IP address of the syslog server. For more information, see Defining Syslog Servers, page 61-3.

Related Topics
- Defining Syslog Servers, page 61-3
- Understanding Log Message Severity Levels, page 61-4
- Logging on Cisco IOS Routers, page 61-1

Step 1
Do one of the following to access the router’s Syslog Logging Setup page:
- (Device view) Select Platform > Logging > Syslog Logging Setup from the Policy selector.
- (Policy view) Select Router Platform > Logging > Syslog Logging Setup from the Policy Type selector. Select an existing policy or create a new one.

The Syslog Logging Setup page is displayed. See Table 61-2 on page 61-8 for a description of the fields on this page.

Step 2
Select Enable Logging to turn on the syslog logging feature. If this option is not selected, no log messages are created.

Tip
To use the device’s default logging settings, or to restore the default settings, simply select Enable Logging, ensure all other fields are blank, then click Save. The default settings vary by device. See your router documentation for more details.

Step 3
(Optional) In the Source Interface field, enter the name of the interface or interface role whose address should be used as the source interface for all log messages sent to a syslog server; or click Select to select an interface role from a list or to create a new one. The source interface must have an IP address.

This option is useful when the syslog server cannot reach the address from which the connection originated (for example, due to a firewall). If you do not enter a value in this field, the address of the outgoing interface is used.

Step 4
(Optional) To send log messages to a syslog server:
- a. Select Enable Trap. This option is selected by default.
- b. Select a value from the Trap Level list. All messages of this severity or greater (that is, having the same or a lower severity-level number) are sent to the syslog server; messages of a lesser severity are ignored. For more information about severity levels, see Table 61-1 on page 61-4.

Step 5
(Optional) To save log messages locally to a buffer on the router:
- a. Select Enable Buffer. This option is selected by default.
- b. Enter the Buffer Size in bytes.
- c. Select the lowest severity level for messages to be saved to the buffer. All messages of that severity level or greater are saved to the buffer.
- d. Select Use XML Format to save messages in XML format. (You can configure both the regular buffer and the XML buffer in the same policy.) If you select this option, enter the size of the XML buffer in bytes.
Step 6  (Optional) Define a rate limit to prevent a flood of output messages:

a. Select **Enable Rate Limit**. This option is selected by default.

b. Enter the maximum number of messages that can be sent per second.

c. Select the severity levels to *exclude* from the rate limit. For example, if you select 2 (critical), all syslog messages of severity levels 0-2 are sent to the syslog server regardless of the defined rate limit.

d. Select **All Messages** to apply the rate limit to all syslog messages *except* console messages (and excepting those severity levels specifically excluded above).

e. Select **Console Messages** to apply the rate limit to console messages only.

**Note**  If you enable rate limiting without specifying any options, the default settings (10 messages per second, applied to console messages only) are applied.

Step 7  (Optional) To add an origin identifier to the beginning of each syslog message:

a. Select the type of origin ID to send—the IP address of the router, its host name, or a text string that you provide.

b. If you select String, enter the desired text in the field provided. Spaces are permitted.

The origin identifier is useful for identifying the source of syslog messages in cases where you send output from multiple devices to a single syslog server.

**Note**  The origin identifier is not added to messages sent to local destinations, such as the buffer, the console, and the monitor.

---

**Defining Syslog Servers**

This procedure describes how to define the servers to which the router should send syslog messages. When you define a syslog server, you can choose whether the logging messages it receives should be forwarded as plain text or in XML format.

If you define multiple syslog servers, logging messages are sent to all of them.

**Before You Begin**

- Enable syslog logging and define basic logging parameters on the Syslog Logging Setup page. For more information, see Defining Syslog Logging Setup Parameters, page 61-1.

**Related Topics**

- Defining Syslog Logging Setup Parameters, page 61-1
- Understanding Log Message Severity Levels, page 61-4
- Logging on Cisco IOS Routers, page 61-1
Step 1  Do one of the following to access the router’s Syslog Servers page:
   • (Device view) Select Platform > Logging > Syslog Servers from the Policy selector.
   • (Policy view) Select Router Platform > Logging > Syslog Servers from the Policy Type selector. Select an existing policy or create a new one.

The Syslog Servers page is displayed. See Table 61-3 on page 61-11 for a description of the fields on this page.

Step 2  To define a server to receive syslog messages from this router, click the Add button below the table to open the Syslog Server dialog box. See Table 61-4 on page 61-12 for more about this dialog box.

Step 3  In the IP Address field, enter the address of the desired syslog server, or click Select to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

Step 4  (Optional) Select Forward Messages in XML Format to forward received syslog messages in XML format instead of plain text.

Step 5  Click OK to save your definition and close the dialog box. The syslog server you defined is displayed in the table.

Note  To edit a syslog server, select it from the table, then click Edit. To remove a syslog server, select it, then click Delete.

Understanding Log Message Severity Levels

Syslog messages on Cisco IOS routers are classified into eight severity levels. Each severity level is identified by a number and a corresponding name. The lower the number, the greater the severity, as shown in the following table.

Table 61-1  Syslog Message Severity Levels

<table>
<thead>
<tr>
<th>Level Number</th>

NetFlow on Cisco IOS Routers

The ability to characterize IP traffic and understand how and where it flows is critical for network availability, performance, and troubleshooting. Monitoring IP traffic flows facilitates accurate capacity planning, and ensures that network resources are used appropriately in support of organizational goals.

NetFlow is a logging feature available on IOS devices for recording, caching, and transmitting IP traffic-flow information on a per-interface basis. The basic output of NetFlow is a flow record, where a “flow” is defined as a unidirectional stream of packets between a given source and destination—both defined by a network-layer IP address and transport-layer source and destination port numbers.

On the IOS device, NetFlow consists of two key components—a NetFlow cache which stores IP flow data, and the NetFlow export mechanism that transmits the NetFlow records to a collection server for data reporting. Thus, when enabled, NetFlow records and caches statistics for incoming and outgoing traffic flows, periodically transmitting these records from the device to a NetFlow collector, in the form of User Datagram Protocol (UDP) datagrams.

Several different formats for the export packet, or flow record, have evolved as NetFlow has matured, and these formats are commonly referred to as the NetFlow version. These versions are well documented, and include versions 1, 5, 7, and 9. The most commonly used format is NetFlow version 5, but version 9 is the latest format and has some advantages for extensibility, security, traffic analysis, and multicasting.

Security Manager currently supports Traditional NetFlow on IOS devices. Traditional NetFlow provides a fixed flow record, even for version 9, meaning the device will use certain flags and predefined record combinations in generating the flow. The device configuration settings define export destinations, export interface, and certain version-specific transmission options.

More About Traffic Flows and NetFlow

Each packet that passes into or out of a router or switch is examined for a set of IP packet attributes. These attributes are the IP packet identity or “fingerprint,” and they define whether the packet is unique, or related to other packets.

All packets with the same source/destination IP address, source/destination ports, protocol interface, and class of service are grouped into a flow and the packets and bytes are tallied. This method of flow determination (or “fingerprinting”) is scalable because a large amount of network information can be condensed into a database of NetFlow information called the NetFlow cache.

In general, the NetFlow cache is constantly filling with flows, and software in the router or switch is searching the cache for flows that have terminated or expired, and these flows are exported to the NetFlow collector. (Unlike SNMP polling, NetFlow export periodically transmits information to the NetFlow collector.) The NetFlow collector has the job of assembling and organizing the exported flows to produce the real-time or historical reports used for traffic and security analysis.

NetFlow Summary

To summarize, the following steps outline NetFlow:

- NetFlow is configured on the router or switch to capture IP traffic flows
- Flow records are stored in the local NetFlow cache
- Periodically, approximately 30 to 50 flow records are bundled together and exported to a NetFlow collector server
- The collector software creates reports from the NetFlow data

Defining NetFlow Parameters

This procedure describes enabling NetFlow logging on the router.

Related Topics
- NetFlow on Cisco IOS Routers, page 61-5
- NetFlow Policy Page, page 61-12
- Logging on Cisco IOS Routers, page 61-1

Step 1 To access the router’s NetFlow page, do one of the following:
- (Device view) Select Platform > Logging > NetFlow from the Policy selector.
- (Policy view) Select Router Platform > Logging > NetFlow from the Policy Type selector. Select an existing policy or create a new one.

The router’s NetFlow page is displayed. See NetFlow Policy Page, page 61-12 for complete descriptions of the fields on this page.

Step 2 On the Setup tab of the NetFlow page, specify global NetFlow parameters for the router:
- **Primary Destination** – Choose IP Address or Hostname from this list to enable NetFlow collection and to specify how the primary NetFlow collector will be defined. You can choose the blank entry to disable this option.
  - **IP Address** – Enter the IP address of the device hosting the primary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)
  - **Hostname** – Enter the fully qualified domain name of the device hosting the primary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)
- **Redundant Destination** – Choose IP Address or Hostname from this list to specify how the back-up NetFlow collector will be defined. You can choose the blank entry to disable this option.
  - **IP Address** – Enter the IP address of the device hosting the secondary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)
  - **Hostname** – Enter the fully qualified domain name of the device hosting the secondary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)

Note If you define a Primary and a Redundant Destination, flow data is transmitted to both.

- **Source Interface** – Specify the router interface through which flow data will be transmitted to the collector destination(s).
Chapter 61      Configuring Logging Policies

Version – Define the record format to be used for flow data by choosing the appropriate NetFlow version number from this drop-down list. You can choose the blank entry to disable this option.

- **1** – The original record format. No additional parameters are required.
- **5** – The most widely adopted format; includes Border Gateway Protocol (BGP) autonomous system (AS) information and flow sequence numbers.

If BGP is configured on your network, you can include either origin or peer AS information in the NetFlow records. Choose *origin-as* or *peer-as* from the AS Type drop-down list. You can choose the blank entry to disable this option.

Check **Enable BGP Nexthop** to include BGP next hop information in the flow caches. (Note that with version 5, this information is visible in the caches, but it is not exported.)

- **9** – The most-recent, template-based version; not yet fully supported.

If BGP is configured on your network, you can include either origin or peer AS information in the NetFlow records. Choose *origin-as* or *peer-as* from the AS Type drop-down list. You can choose the blank entry to disable this option.

Check **Enable BGP Nexthop** to include BGP next hop information in the flow records.

Note

AS information collection is resource intensive, especially for *origin-as*. If you are not interested in monitoring peering arrangements, disabling AS collection may improve performance.

Step 3

On the **Interfaces** tab, define the interfaces for which traffic flows are to be reported.

- To add an interface, click the Add Row button to open the Add NetFlow Interface Settings dialog box. This dialog box is described in *Adding and Editing NetFlow Interface Settings*, page 61-15.
- To edit an existing interface, select the appropriate entry in the Interfaces table and then click the Edit Row button to open the Edit NetFlow Interface Settings dialog box (described in *Adding and Editing NetFlow Interface Settings*, page 61-15).
- To delete an existing interface, select that entry in the Interfaces table and then click the Delete Row button, and then confirm the deletion.

Note

You can disable NetFlow data collection on an interface without deleting it. Refer to *Adding and Editing NetFlow Interface Settings*, page 61-15 for more information.

Syslog Logging Setup Policy Page

Use the Syslog Logging Setup page to enable syslog logging and define basic logging parameters on the selected Cisco IOS router.

For more information, see *Defining Syslog Logging Setup Parameters*, page 61-1.

Note

We strongly recommend that you define an NTP policy on all routers on which logging is enabled in order to create accurate timestamps for each log message. For more information, see *NTP Policy Page*, page 59-98.
Note

If you unassign a logging setup policy, the default logging configuration is restored on the device upon deployment.

Navigation Path

- (Device view) Select Platform > Logging > Syslog Logging Setup from the Policy selector.
- (Policy view) Select Router Platform > Logging > Syslog Logging Setup from the Policy Type selector. Right-click Syslog Logging Setup to create a policy, or select an existing policy from the Shared Policy selector.

NetFlow Policy Page

Use the NetFlow page to enable NetFlow recording and define its parameters on the selected Cisco IOS router.

The NetFlow page consists of two tabbed panels: Setup and Interfaces. The Setup tab provides global configuration parameters for NetFlow collection on the router. The Interfaces tab lists router interfaces for which NetFlow data collection is configured, and allows enabling and disabling ingress and egress accounting on a per-interface basis.

**Note**

We strongly recommend that you define an NTP policy on all routers on which logging is enabled in order to create accurate timestamps for each log message. For more information, see NTP Policy Page, page 59-98.

**Navigation Path**

- (Device view) Select Platform > Logging > NetFlow from the Policy selector.
- (Policy view) Select Router Platform > Logging > NetFlow from the Policy Type selector. Select an existing policy from the Shared Policy selector, or right-click NetFlow to create a new policy.

Configuring Quality of Service

This chapter contains the following topics:

- Quality of Service on Cisco IOS Routers, page 62-1
- Quality of Service Policy Page, page 62-19

Quality of Service on Cisco IOS Routers

Quality of service (QoS) refers to the ability of a network to provide priority service to selected network traffic over various underlying technologies, including Frame Relay, ATM, Ethernet and 802.1 networks, SONET, and IP-routed networks. QoS features enhance the predictability of network service by:

- Supporting dedicated bandwidth.
- Improving loss characteristics.
- Avoiding and managing network congestion.
- Shaping network traffic.
- Setting traffic priorities across the network.

QoS is generally used at entry points to service providers, as well as at consolidation points where multiple lines converge. QoS is also useful where speed mismatches occur (for example, at the boundary between a WAN and a LAN), as these places are often traffic congestion points.

QoS policies in Security Manager are based on the Cisco Systems Modular QoS CLI (MQC). MQC standardizes the CLI and semantics for QoS features across all platforms supported by Cisco IOS software, which provides a modular and highly extensible framework for deploying QoS. Security Manager provides an easy-to-use interface for MQC that concentrates key QoS features inside a single dialog box, streamlining the creation of QoS policies for selected traffic entering and leaving the router.

Related Topics

- Quality of Service and CEF, page 62-2
- Understanding Marking Parameters, page 62-3
- Understanding Queuing Parameters, page 62-4
- Understanding Policing and Shaping Parameters, page 62-6
Quality of Service and CEF

Cisco Express Forwarding (CEF) is an advanced Layer 3 IP switching technology that optimizes network performance and scalability for all kinds of networks. It defines the fastest method by which a Cisco IOS router forwards packets from ingress to egress interfaces.

Certain QoS features configurable in Security Manager, such as Class-Based Policing and Class-Based Weighted Random Early Detection, are supported only on routers that run CEF. All routers from the Cisco 800 Series to the Cisco 7200 Series require CEF for these QoS features; the Cisco 7500 Series requires distributed CEF (dCEF).

Note

For a complete list, see When is CEF Required for Quality of Service on Cisco.com at this URL:

By default, CEF is enabled as part of the router’s initial configuration. To verify whether CEF is enabled on your router, use the `show ip cef` command. You can configure CEF using the CEF interface settings policy (see CEF Interface Settings on Cisco IOS Routers, page 58-24). Be aware, however, that if your router does not have CEF enabled, activating CEF could have a significant impact on your router’s packet streaming. Consult your router documentation before enabling CEF.

Related Topics

- Quality of Service on Cisco IOS Routers, page 62-1

Understanding Matching Parameters

You define matching parameters by identifying the traffic on which QoS is performed, that is, classifying the interesting packets. Various classification tools are available, including protocol type, IP precedence (IPP) value, Differentiated Service Code Point (DSCP) value, and ACLs.

Traffic classes consist of a series of match criteria and a means of evaluating these criteria. For example, you might define a class with matching criteria based on several specified protocols and a DSCP value. You can then specify that a packet must match only one of these defined criteria to be considered part of this class. Your other option is to specify that packets must match all defined criteria considered part of the traffic class.

Packets that are members of a defined traffic class are forwarded according to the QoS specifications that you defined in the policy map. Packets that fail to meet any of the matching criteria are classified as members of the default traffic class.

For information about defining matching parameters in a QoS policy, see Defining QoS Class Matching Parameters, page 62-13.

Related Topics

- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1
Understanding Marking Parameters

Marking parameters enable you to classify packets, which entails using a traffic descriptor to categorize a packet within a specific group. This defines the packet and makes it accessible for QoS handling on the network. Both traffic policers and traffic shapers use the packet classification to ensure adherence to the contracted level of service agreed upon between the source and your network. Additionally, marking parameters enable you to take packets that might have arrived at the device with one QoS classification and reclassify them. Downstream devices use this new classification to identify the packets and apply the appropriate QoS functions to them.

Security Manager uses two types of marking for IPv4 packets—one based on IPP classes and one based on DSCP values. IPP is based on the three most significant bits in the Type of Service (ToS) byte of each packet, which means you can partition traffic into eight classes. For historical reasons, each precedence value corresponds with a name, as defined in RFC 791. Table 62-1 on page 62-3 lists the numbers and their corresponding names, from least to most important.

Table 62-1 IP Precedence Classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>routine</td>
</tr>
<tr>
<td>1</td>
<td>priority</td>
</tr>
<tr>

</tr>
<tr>
<td>5</td>
<td>critical</td>
</tr>
<tr>
<td>6</td>
<td>internet</td>
</tr>
<tr>
<td>7</td>
<td>network</td>
</tr>
</tbody>
</table>

Note

Classes 6 and 7 are generally reserved for network control information, such as routing updates.

DSCP is based on the six most significant bits in the ToS byte (the remaining two bits are used for flow control), with values ranging from 0 to 63. The DSCP bits contains the IPP bits, which makes DSCP backward-compatible with IPP.

Marking is generally used on devices that are close to the network edge or administrative domain so that subsequent devices can provide service based on the classification mark.

For information about defining marking parameters in a QoS policy, see Defining QoS Class Marking Parameters, page 62-15.

Related Topics

- Understanding Queuing Parameters, page 62-4
- Understanding Policing and Shaping Parameters, page 62-6
- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1
Understanding Queuing Parameters

Queuing manages congestion on traffic leaving a Cisco IOS router by determining the order in which to send packets out over an interface, based on priorities you assign to those packets. Queuing makes it possible to prioritize traffic to satisfy time-critical applications, such as desktop video conferencing, while still addressing the needs of less time-dependent applications, such as file transfer.

During periods of light traffic, that is, when no congestion exists, packets are sent out as soon as they arrive at an interface. However, during periods of transmission congestion at the outgoing interface, packets arrive faster than the interface can send them. By using congestion management features such as queuing, packets accumulating at the interface are queued until the interface is free to send them. They are then scheduled for transmission according to their assigned priority and the queuing mechanism configured for the interface. The router determines the order of packet transmission by controlling which packets are placed in which queue and how queues are serviced with respect to one another.

Security Manager uses a form of queuing called Class-Based Weighted Fair Queuing (CBWFQ). With CBWFQ, you define traffic classes based on match criteria. Packets matching the criteria constitute the traffic for this class. A queue is reserved for each class, containing the traffic belonging to that class. You assign characteristics to queues, such as the bandwidth (fixed or minimum) assigned to it and the queue limit, which is the maximum number of packets allowed to accumulate in the queue.

When you use CBWFQ, the sum of all bandwidth allocation on an interface cannot exceed 75 percent of the total available interface bandwidth. The remaining 25 percent is used for other overhead, including Layer 2 overhead, routing traffic, and best-effort traffic. Bandwidth for the CBWFQ default class, for instance, is taken from the remaining 25 percent.

For more information about queuing, see:
- Tail Drop vs. WRED, page 62-4
- Low-Latency Queuing, page 62-5
- Default Class Queuing, page 62-6

For information about defining queuing parameters in a QoS policy, see Defining QoS Class Queuing Parameters, page 62-16.

Related Topics
- Understanding Marking Parameters, page 62-3
- Understanding Policing and Shaping Parameters, page 62-6
- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1

Tail Drop vs. WRED

After a queue reaches its configured queue limit, the arrival of additional packets causes tail drop or packet drop to take effect, depending on how you configured the QoS policy. Tail drop, which is the default response, treats all traffic equally and does not differentiate between different classes of service. When tail drop is in effect, packets are dropped from full queues until the congestion is eliminated and the queue is no longer full. This often leads to global synchronization, in which a period of congestion is followed by a period of underutilization, as multiple TCP hosts reduce their transmission rates simultaneously.

A more sophisticated approach to managing queue congestion is offered by Cisco’s implementation of Random Early Detection, called Weighted Random Early Detection, or WRED. As shown in Figure 62-1, WRED reduces the chances of tail drop by selectively dropping packets when the output
interface begins to show signs of congestion. By dropping some packets early instead of waiting until the queue is full, WRED avoids dropping large numbers of packets at once and allows the transmission line to be used fully at all times.

**Figure 62-1 Weighted Random Early Detection**

WRED is useful only when the bulk of the traffic is TCP/IP traffic, because TCP hosts reduce their transmission rate in response to congestion. With other protocols, packet sources might not respond, or might resend dropped packets at the same rate. As a result, dropping packets does not decrease congestion.

**Note**

WRED treats non-IP traffic as precedence 0, the lowest precedence value. Therefore, non-IP traffic is more likely to be dropped than IP traffic.

**Related Topics**

- Low-Latency Queuing, page 62-5
- Default Class Queuing, page 62-6
- Understanding Queuing Parameters, page 62-4

**Low-Latency Queuing**

The low-latency queuing (LLQ) feature brings strict priority queuing to CBWFQ. Strict priority queuing gives delay-sensitive data, such as voice traffic, preference over other traffic.

**Note**

Although it is possible to assign various types of real-time traffic to the strict priority queue, we strongly recommend that you direct only voice traffic to it.
LLQ defines the maximum bandwidth that you can allocate to priority traffic during times of congestion. Setting a maximum ensures that nonpriority traffic does not starve (meaning that this traffic is also provided with bandwidth). When the device is not congested, the priority class traffic is allowed to exceed its allocated bandwidth. Policing drops packets from the priority queue; therefore, neither WRED nor tail drop (as configured in the Queue Limit field) is used.

When LLQ is not used, CBWFQ provides weighted fair queuing based on defined classes, with no strict priority queue available for real-time traffic.

**Related Topics**
- Tail Drop vs. WRED, page 62-4
- Default Class Queuing, page 62-6
- Understanding Queuing Parameters, page 62-4

### Default Class Queuing

You use the Fair Queue field to define the number of dynamic queues that should be reserved for the default class to use. This is the class to which traffic that does not satisfy the match criteria of other classes is directed. By default, the number of queues that are created is based on the interface bandwidth.

Table 62-2 on page 62-6 lists the default number of dynamic queues that CBWFQ uses when it is enabled on an interface:

**Table 62-2**  Default Number of Queues for Default Class

<table>
<thead>
<tr>
<th>Bandwidth Range</th>
<th>Number of Dynamic Queues</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than or equal to 64 kbps</td>
<td>16</td>
</tr>
<tr>
<td>More than 64 kbps and less than or equal to 128 kbps</td>
<td>32</td>
</tr>
<tr>
<td>More than 128 kbps and less than or equal to 256 kbps</td>
<td>64</td>
</tr>
<tr>
<td>More than 256 kbps and less than or equal to 512 kbps</td>
<td>128</td>
</tr>
<tr>
<td>More than 512 kbps</td>
<td>256</td>
</tr>
</tbody>
</table>

### Understanding Policing and Shaping Parameters

Security Manager offers two kinds of traffic regulation mechanisms:
- The rate-limiting feature of Class-Based Policing for policing traffic. Policing limits traffic flow to a configured rate. Policing can be performed on a selected interface or on the control plane. See Understanding Control Plane Policing, page 62-9.
- Distributed Traffic Shaping (DTS) for shaping traffic. Traffic shaping enables you to control the traffic leaving an interface (output traffic) in order to match its flow to the speed of the remote target interface and to ensure that the traffic conforms to the policies defined for it. By shaping traffic to meet downstream requirements, you can eliminate bottlenecks in topologies with data-rate mismatches. Shaping can either be performed on selected QoS classes or at the interface level (hierarchical shaping).

Both policing and shaping mechanisms use the traffic descriptor for a packet—indicated by the classification of the packet (see Understanding Marking Parameters, page 62-3)—to ensure adherence to the agreed upon level of service. Although policers and shapers usually identify traffic descriptor violations in the same way, they differ in the way they respond to violations, as shown in Figure 62-2:

- A policer typically drops excess traffic. In other cases, it transmits the traffic with a different (usually lower) priority.
- A shaper typically delays excess traffic using a buffer, or queuing mechanism, to hold packets and shape the flow when the data rate of the source is higher than expected.

**Figure 62-2  Traffic Policing vs. Traffic Shaping**

- Quality of Service on Cisco IOS Routers, page 62-1
Understanding the Token-Bucket Mechanism

Both policing and shaping use a token-bucket mechanism to regulate data flow. A token bucket is a formal definition of a rate of transfer. It has three components: a burst size, a mean rate, and a time interval (Tc). Any two values may be derived from the third using this formula:

\[
\text{mean rate} = \frac{\text{burst size}}{\text{time interval}}
\]

These terms are defined as follows:

- **Mean rate**—Also called the committed information rate (CIR), it specifies how much data can be sent or forwarded per unit time on average. The CIR is defined either as an absolute value or as a percentage of the available bandwidth on the interface. When defined as a percentage, the equivalent value in bits per second (bps) is calculated after deployment based on the interface bandwidth and the percent value defined in the policy.

  *Note* If the interface bandwidth changes (for example, more bandwidth is added), the bps value of the CIR is recalculated based on the revised amount of bandwidth.

- **Burst size**—Also called the committed burst (Bc) size, it specifies for each burst how much data can be sent within a given time without creating scheduling concerns. When you use percentages to calculate the CIR, burst size is measured in milliseconds.

- **Time interval**—Also called the measurement interval, it specifies the amount of time in seconds per burst. Over any integral multiple of this interval, the bit rate of the interface does not exceed the mean rate. The bit rate, however, might be arbitrarily fast within the interval.

In the token-bucket metaphor, tokens are put into the bucket at a certain rate. These tokens represent permission for the source to send a certain number of bits into the network. To send a packet, the regulator (policer or shaper) must remove a number of tokens from the bucket that equals the packet size.

Security Manager uses a two-bucket algorithm, as shown in Figure 62-3. The first bucket is the conform bucket and the second bucket is the exceed bucket. The full size of the conform bucket is the number of bytes specified as the normal burst size. The full size of the exceed bucket is the number of bytes specified in the maximum burst size. Both buckets are initially full, and they are updated based on the token arrival rate, which is determined by the CIR. If the number of bytes in the arriving packet is less than the number of bytes in the conform bucket, the packet conforms. The required number of tokens are removed from the conform bucket and the defined conform action is taken (for example, the packet is transmitted). The exceed bucket is unaffected.

If the conform bucket does not contain sufficient tokens, the excess token bucket is checked against the number of bytes in the packet. If enough tokens are present in the two buckets combined, the exceed action is taken on the packet and the required number of bytes are removed from each bucket. If the exceed bucket contains an insufficient number of bytes, the packet is in violation of the burst limits and the violate action is taken on the packet.
When you use traffic policing, the token-bucket algorithm provides three actions for each packet: a conform action, an exceed action, and an optional violate action. For instance, packets that conform can be configured to be transmitted, packets that exceed can be configured to be sent with a decreased priority, and packets that violate can be configured to be dropped.

Traffic policing is often configured on interfaces at the edge of a network to limit the rate of traffic entering or leaving the network. In the most common traffic policing configurations, traffic that conforms is transmitted and traffic that exceeds is sent with a decreased priority or is dropped. You can change these configuration options to suit your network needs.

When you use traffic shaping, the token-bucket mechanism includes a data buffer for holding packets that cannot be sent immediately. (Policers do not have such a buffer.) The token buckets permit packets to be sent in bursts, but places bounds on this capability so that the flow is never faster than the capacity of the buckets plus the time interval multiplied by the refill rate. The buffer also guarantees that the long-term transmission rate does not exceed the CIR.

Understanding Control Plane Policing

The Control Plane Policing feature enables you to manage input traffic entering the control plane (CP) of the router. The CP is a collection of processes that run at the process level on the route processor. These processes collectively provide high-level control for most Cisco IOS functions. Control plane policing protects the CP of Cisco IOS routers and switches against reconnaissance and denial-of-service (DoS) attacks, enabling the CP to maintain packet forwarding and protocol states despite an attack or heavy traffic load on the router or switch.

The Control Plane Policing feature treats the CP as a separate entity with its own ingress (input) and egress (output) ports, enabling you to use Security Manager to configure QoS policies on input. These policies are applied when a packet enters the CP. You can configure a QoS policy to prevent unwanted
packets from progressing after a specified rate limit is reached. For example, a system administrator can limit all TCP/SYN packets that are destined for the CP to a maximum rate of 1 megabit per second. Additional packets beyond this limit are silently discarded.

The following types of Layer 3 packets are forwarded to the CP and processed by aggregate control plane policing:

- Routing protocol control packets
- Packets destined for the local IP address of the router
- Packets from management protocols, such as SNMP, Telnet, and secure shell (SSH).

**Note** Support for output policing is available only in Cisco IOS Release 12.3(4)T and later T-train releases.

For information about how to define Control Plane Policing, see *Defining QoS on the Control Plane*, page 62-12. For more information about this feature, refer to the document, *Control Plane Policing* on Cisco.com at this URL:

**Related Topics**

### Defining QoS Policies

When you define QoS policies, you must first decide whether to configure the policy on specific interfaces or on the control plane. This initial choice determines how you configure the rest of the policy, as described in the following topics:

- Defining QoS on Interfaces, page 62-10
- Defining QoS on the Control Plane, page 62-12

**Note** If you define a QoS policy on both the interfaces and the control plane of the same device, only the control plane configuration is deployed.

**Related Topics**

- Quality of Service on Cisco IOS Routers, page 62-1

### Defining QoS on Interfaces

You can create multiple QoS interface definitions, each of which applies to either input traffic (entering the router) or output traffic (exiting the router).

When you create a QoS interface definition on output traffic, you have the option of configuring hierarchical shaping on the interface as a whole instead of configuring shaping on individual QoS classes.
Quality of Service on Cisco IOS Routers

After you create your interface definitions, you must define one or more QoS classes on each interface. QoS classes contain the matching criteria that determine which packets are included in the class and the QoS functions (marking, queuing, policing, and shaping) to apply to that traffic. You can configure each interface (or interface role) with up to 16 QoS classes, each containing its own set of matching criteria and a defined set of QoS functions to apply to the traffic in that class.

For each interface, we recommend that for each interface you define at least one QoS class and a default class. If you do not configure a default class, packets that do not match the criteria of the other defined classes are treated as members of a default class that has no configured QoS functionality. Packets assigned to this class are placed in a simple first-in first-out (FIFO) queue, and are forwarded at a rate determined by the available underlying link bandwidth. This FIFO queue is managed by tail drop, which avoids congestion by dropping packets from the queue until it is no longer full.

**Note**

QoS is applied to packets on a first-match basis. The router examines the table of QoS classes starting from the top and applies the properties of the first class whose matching criteria matches the packet. Therefore, it is important that you define and order your classes carefully. The default class should be placed last to prevent traffic that matches a specific class from being treated as unmatched traffic.

**Before You Begin**

Ensure that Cisco Express Forwarding (CEF) is enabled on the router. For more information, see CEF Interface Settings on Cisco IOS Routers, page 58-24.

**Related Topics**

- Defining QoS Policies, page 62-10
- Defining QoS on the Control Plane, page 62-12
- Quality of Service on Cisco IOS Routers, page 62-1

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Quality of Service** from the Policy selector.
- (Policy view) Select **Router Platform > Quality of Service** from the Policy Type selector. Select an existing policy or create a new one.

The Quality of Service page is displayed. See Table 62-3 on page 62-20 for a description of the fields on this page.

**Step 2**

In the Applied to field, select **Interfaces** to define QoS parameters for specific interfaces on the selected router.

**Step 3**

Click the **Add** button under the upper table to display the QoS Policy dialog box. See Table 62-4 on page 62-21 for a description of the fields in this dialog box.

**Step 4**

In the Interface field, enter the name of an interface or interface role, or click **Select** to display a selector.

**Tip**

If the interface role you want is not listed in the selector, click the **Create** button or the **Edit** button to open the Interface Role Dialog Box, page 6-64. From here you can define an interface role to use in the policy.

**Step 5**

Select the traffic direction on which you want to apply the QoS definition, Output (traffic exiting the interface) or Input (traffic entering the interface). Queuing and shaping can be applied only to output traffic.
Step 6  (Optional) Define interface-level (hierarchical) shaping parameters. See Table 62-4 on page 62-21 for details.

Note When you enable hierarchical shaping on an interface, you cannot define shaping parameters for specific QoS classes. Shaping can be used only on output traffic. See Understanding Policing and Shaping Parameters, page 62-6 for more information about shaping.

Step 7  Click OK. The QoS interface definition is displayed in the upper table of the Quality of Service page.

Note To edit a QoS interface definition, select an interface from the upper table, then click the Edit button. To remove an interface definition, select it from the table, then click the Delete button. You cannot delete an interface that has defined classes.

Step 8  With the interface selected in the upper table, click the Add button beneath the QoS Classes table. The QoS Class dialog box is displayed. See Table 62-5 on page 62-23 for a description of the fields in this dialog box.

The QoS Class dialog box enables you to determine which traffic over the selected interface is included in the QoS class and how to handle that traffic.

Step 9  (Optional) Select the Default class check box if you are defining the properties of the default QoS class for this interface. The default class is assigned to all traffic that does not match the criteria of the other defined classes.

Step 10  Define the QoS class using one or more tabs in the QoS Class dialog box, as described in:

- Defining QoS Class Matching Parameters, page 62-13
- Defining QoS Class Marking Parameters, page 62-15
- Defining QoS Class Queuing Parameters, page 62-16
- Defining QoS Class Policing Parameters, page 62-17
- Defining QoS Class Shaping Parameters, page 62-18

Step 11  Repeat Step 8 through Step 10 to add QoS classes to the interface defined in Step 3. If required, use the Up Row and Down Row buttons to reorder the classes.

Note To edit a QoS class, select the relevant interface from the upper table to display its defined classes in the QoS Class table. Select the class to edit, then click the Edit button. To remove a class, select it from the table, then click the Delete button.

Step 12  Repeat Step 3 through Step 11 to define QoS classes for a different interface on the selected router.

---

**Defining QoS on the Control Plane**

When you configure QoS on input traffic entering the control plane, you can define multiple QoS classes, including a default class for traffic that does not match the criteria you define for the other classes. After defining the matching criteria for a particular class, you can configure a policing definition for that class. (Marking, queuing, and shaping are not available.) For more information, see Understanding Control Plane Policing, page 62-9.
QoS policies defined on the control plane override any QoS parameters defined on an interface of the same device.

---

**Note**

QoS is applied to packets on a first-match basis. The router examines the table of QoS classes starting from the top and applies the properties of the first class whose matching criteria matches the packet. Therefore, it is important that you define and order your classes carefully. The default class should be placed last to prevent traffic that matches a specific class from being treated as unmatched traffic.

---

**Before You Begin**

Ensure that Cisco Express Forwarding (CEF) is enabled on the router. For more information, see CEF Interface Settings on Cisco IOS Routers, page 58-24.

**Related Topics**

- Defining QoS Policies, page 62-10
- Defining QoS on Interfaces, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1

---

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Quality of Service** from the Policy selector.
- (Policy view) Select **Router Platform > Quality of Service** from the Policy Type selector. Select an existing policy or create a new one.

The Quality of Service page is displayed. See Table 62-3 on page 62-20 for a description of the fields on this page.

**Step 2**

In the **Applied to** field, select **Control Plane** to define QoS policing on input traffic entering the control plane.

**Step 3**

Click the **Add** button beneath the Control Plane QoS Classes table. The QoS Class dialog box is displayed. See Table 62-5 on page 62-23 for a description of the fields in this dialog box.

The QoS Class dialog box enables you to determine which traffic over the selected interface is included in the QoS class and how to handle that traffic.

**Step 4**

(Optional) Select the **Default class** check box if you are defining the properties of the default QoS class for the control plane. The default class is assigned to all traffic that does not match the criteria of the other defined classes.

**Step 5**

Define the QoS class using the tabs in the QoS Class dialog box, as described in the following sections:

- Defining QoS Class Matching Parameters, page 62-13
- Defining QoS Class Policing Parameters, page 62-17

**Step 6**

Repeat **Step 3** through **Step 5** to add QoS classes to the control plane. If required, use the **Up Row** and **Down Row** buttons to reorder the classes.

---

### Defining QoS Class Matching Parameters

When you define matching parameters, you must define matching criteria and specify whether packets must meet one or all of the criteria to be considered part of the class. See **Understanding Matching Parameters**, page 62-2 for more information.
You do not define matching parameters when configuring the default class.

**Related Topics**
- Defining QoS Class Marking Parameters, page 62-15
- Defining QoS Class Queuing Parameters, page 62-16
- Defining QoS Class Policing Parameters, page 62-17
- Defining QoS Class Shaping Parameters, page 62-18
- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1

**Step 1**
On the Quality of Service page, click the **Add** button beneath the QoS Classes table, or select a class and then click the **Edit** button. The QoS Class dialog box is displayed.

**Step 2**
Click the **Matching** tab. See Table 62-6 on page 62-24 for a description of the fields on this tab.

**Step 3**
Select a matching method:
- **Any**—Traffic matching any of the defined parameters is included in this class.
- **All**—Only traffic matching all of the defined parameters is included in this class.

**Step 4**
(Optional) Under Protocol, click **Add** to display a selector for choosing the protocols to include in this class. Select one or more items from the Available Protocols list, then click **>>** to add them to the Selected Protocols list.

**Note**
When configuring QoS on the control plane, only the ARP protocol can be selected.

When you finish, click **OK** to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the Protocol field.

**Step 5**
(Optional) Under Precedence, click **Add** to display a selector for choosing which IP precedence values (from 0 to 7) to include in this class. Select one or more items from the Available Precedences list, then click **>>** to add them to the Selected Precedences list. Traffic that arrives marked with one of these values matches this criterion.

**Note**
For more information about IP precedence values, see Table 62-1 on page 62-3.

When you finish, click **OK** to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the Precedences field.

**Step 6**
(Optional) Under DSCP, click **Add** to display a selector for choosing which DSCP values (from 0 to 63) to include in this class. Select one or more items (up to eight) from the Available DSCPs list, then click **>>** to add them to the Selected DSCPs list. Traffic that arrives marked with one of these values matches this criterion.

When you finish, click **OK** to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the DSCP field.

**Step 7**
(Optional) Under ACL, define ACLs as part of the matching criteria for this class:

a. Click **Edit** to display the Edit ACLs dialog box. Use this dialog box to define which ACLs to include in this class.
b. Enter one or more ACLs, or click Select to select an ACL object from a list or to create a new one. Traffic that matches these ACL definitions matches this criterion.

c. When you finish, click OK twice to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the ACL field.

Tip: Use the up and down arrows to order the ACLs. We recommend placing more frequently used ACLs at the top of the list to optimize the matching process.

Step 8 Go to another tab or click OK to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 9 Do one of the following:
- When defining QoS on interfaces, continue as described in Defining QoS on Interfaces, page 62-10.
- When defining control plane policing, continue as described in Defining QoS on the Control Plane, page 62-12.

Defining QoS Class Marking Parameters

When you define marking parameters, you can mark the packets in this QoS class with either a precedence value or a DSCP value. See Understanding Marking Parameters, page 62-3 for more information.

Note: Marking is not available when you configure QoS on the control plane.

Related Topics
- Defining QoS Class Matching Parameters, page 62-13
- Defining QoS Class Queuing Parameters, page 62-16
- Defining QoS Class Policing Parameters, page 62-17
- Defining QoS Class Shaping Parameters, page 62-18
- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1

Step 1 On the Quality of Service page, click the Add button beneath the QoS Classes table, or select a class and then click the Edit button. The QoS Class dialog box is displayed.

Step 2 Click the Marking tab. See Table 62-7 on page 62-26 for a description of the fields on this tab.

Step 3 Select the Enable Marking check box.

Step 4 Select one of the following marking options:
- Precedence—Select an IP precedence value (0 to 7) from the displayed list. For more information about these values, see Table 62-1 on page 62-3.
- DSCP—Select a DSCP value (0 to 63) from the displayed list.

Step 5 Go to another tab or click OK to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.
Step 6  Continue as described in Defining QoS Policies, page 62-10.

Defining QoS Class Queuing Parameters

When you define queuing parameters, you can specify the amount of available bandwidth to provide to the traffic in this QoS class. You can also define a fixed amount of bandwidth that must be provided to high-priority traffic; you can define the priority parameter on only one class per interface. In addition, you must specify the type of queue management to perform on this class. See Understanding Queuing Parameters, page 62-4 for more information.

Note  Queuing is not available when you configure QoS on the control plane.

Related Topics

- Defining QoS Class Matching Parameters, page 62-13
- Defining QoS Class Marking Parameters, page 62-15
- Defining QoS Class Policing Parameters, page 62-17
- Defining QoS Class Shaping Parameters, page 62-18
- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1

Step 1  On the Quality of Service page, click the **Add** button beneath the QoS Classes table, or select a class and then click the **Edit** button. The QoS Class dialog box is displayed.

Step 2  Click the **Queuing and Congestion Avoidance** tab. See Table 62-8 on page 62-27 for a description of the fields on this tab.

Step 3  Click the **Enable Queuing and Congestion Avoidance** check box.

Queuing options depend on whether you are defining the default class or a different class:

- When you define any class other than the default class, select one of the following queuing options:
  - **Priority**—Define the amount of bandwidth to make available to high-priority traffic. **Low-Latency Queuing**, page 62-5 (LLQ) ensures that this traffic receives this fixed amount of bandwidth at all times. This is particularly useful for voice traffic, which requires low latency. You can define this amount by percentage or by an absolute value of kilobits per second.

  Note  You can define this option for only one class per interface.

  - **Bandwidth**—Enter the amount of bandwidth to allocate to this class. You can define this amount by percentage or by an absolute value of kilobits per second.

  Note  The sum of all class bandwidth allocations on an interface cannot exceed 100 percent of the total available bandwidth.

- When you define the default class, select one of the following queuing options:
– Fair queue—Enter the number of queues to reserve for the default class. Values range in powers of 2 from 16 to 4096. By default, the number of queues is based on the available bandwidth of the selected interface. For more information, see Table 62-2 on page 62-6.
– Bandwidth—Enter the amount of bandwidth to allocate to this class. You can define this amount by percentage or by an absolute value of kilobits per second.

**Step 4**  
(Optional) Define one of the following queue length management options:

- Queue Limit—(Default) Specify the maximum number of packets allowed. If you select this option, tail drop drops excess packets when the queue reaches its capacity.
- WRED Weight for Mean Queue Depth—WRED proactively drops packets until the transmitting protocol (usually TCP) responds by dropping its transmission rate, thereby alleviating congestion. Configure WRED by entering an exponential weight factor that is used to calculate the average queue size.

For more information, see Tail Drop vs. WRED, page 62-4.

---

**Note**  
You should change the default only if you are certain that your applications will benefit from a different value.

---

**Note**  
Do not use WRED with protocols that are not sufficiently robust to reduce their transmission rates in response to packet loss, such as IPX or AppleTalk. WRED cannot be configured when you select the Priority percent option.

**Step 5**  
Go to another tab or click OK to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

**Step 6**  
Continue as described in Defining QoS Policies, page 62-10.

---

### Defining QoS Class Policing Parameters

When you define policing parameters, you must specify the average data rate, which determines the amount of traffic that can be transmitted. In addition, you must specify the action to take on traffic bursts that exceed this data rate.

You can configure policing for all QoS classes, including the default class. For more information about policing, see Understanding Policing and Shaping Parameters, page 62-6.

You can also configure policing on the control plane. For more information, see Understanding Control Plane Policing, page 62-9.

**Related Topics**

- Defining QoS Class Matching Parameters, page 62-13
- Defining QoS Class Marking Parameters, page 62-15
- Defining QoS Class Queuing Parameters, page 62-16
- Defining QoS Class Shaping Parameters, page 62-18
- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1
Step 1 On the Quality of Service page, click the Add button beneath the QoS Classes table, or select a class and then click the Edit button. The QoS Class dialog box is displayed.

Step 2 Click the Policing tab. See Table 62-9 on page 62-29 for a description of the fields on this tab.

Step 3 Select the Enable Policing check box.

Step 4 Define CIR, confirm burst, and excess burst values. You can define the CIR by percentage or by an absolute value of bits per second. The option you choose determines how you define the burst values.

Step 5 Select the action to perform on packets that conform to the rate limit:
   - transmit—Transmit the packet.
   - set-prec-transmit—Set the IP precedence to a defined value, then send the packet. This option is not available when configuring QoS on the control plane.
   - set-dscp-transmit—Set the DSCP to a defined value, then send the packet. This option is not available when configuring QoS on the control plane.
   - drop—Drop the packet.

Step 6 Select the action to perform on exceed packets. The list of available actions depends on the selected conform action.

   For example, if transmit is performed on conforming packets, you can select any of the actions listed in Step 5 for exceeding packets. However, if you selected one of the set actions for conforming packets, you can select only a set action or the drop action for exceeding packets. If you selected drop as the conform action, you must select drop as the exceed action.

Step 7 Select the action to perform on violate packets. The list of available actions depends on the selected exceed action.

   For example, if transmit is performed on exceeding packets, you can select any of the actions listed in Step 5 for violating packets. However, if you selected one of the set actions for exceeding packets, you can select only a set action or the drop action for violating packets. If you selected drop as the exceed action, you must select drop as the violate action.

Step 8 Go to another tab, or click OK to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 9 Do one of the following:
   - When defining QoS on interfaces, continue as described in Defining QoS Policies, page 62-10.
   - When defining control plane policing, continue as described in Defining QoS on the Control Plane, page 62-12.

---

**Defining QoS Class Shaping Parameters**

When you define shaping parameters, you must specify whether to base traffic shaping on the average data rate or on the average data rate plus the excess burst rate that occurs during traffic peaks. In both cases, traffic that exceeds these definitions is buffered until the rate lowers, allowing the packets to be sent.

The following conditions pertain:
   - Shaping can be used only on output traffic.
   - Shaping can be configured for all QoS classes, including the default class.
   - Shaping is not available when you configure the QoS class for priority traffic.
Shaping is not available when you configure QoS on the control plane.

For more information about shaping, see Understanding Policing and Shaping Parameters, page 62-6.

Tip
To configure shaping on all the QoS classes defined for the interface (hierarchical shaping), see Defining QoS on Interfaces, page 62-10.

Related Topics
- Defining QoS Class Matching Parameters, page 62-13
- Defining QoS Class Marking Parameters, page 62-15
- Defining QoS Class Queuing Parameters, page 62-16
- Defining QoS Class Policing Parameters, page 62-17
- Defining QoS Policies, page 62-10
- Quality of Service on Cisco IOS Routers, page 62-1

Step 1
On the Quality of Service page, click the Add button beneath the QoS Classes table, or select a class and then click the Edit button. The QoS Class dialog box is displayed.

Step 2
Click the Shaping tab. See Table 62-10 on page 62-31 for a description of the fields on this tab.

Step 3
Select the Enable Shaping check box.

Step 4
Select the shaping type (Average or Peak).

Step 5
Define CIR, sustained burst, and excess burst values. You can define the CIR by percentage or by an absolute value of bits per second. The option you choose determines how you define the burst values.

Step 6
Proceed to another tab or click OK to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 7
Continue as described in Defining QoS Policies, page 62-10.

Quality of Service Policy Page

Use the Quality of Service page to view, create, and edit QoS classes on specific interfaces of the selected device or on the control plane. QoS policies enable you to define techniques for managing the delay, delay variation (jitter), bandwidth, and packet loss parameters on a network. In addition, you can use the Quality of Service page to configure hierarchical shaping on an interface as an alternative to configuring shaping parameters for individual QoS classes.

For more information, see Quality of Service on Cisco IOS Routers, page 62-1.

Navigation Path
- (Device view) Select Platform > Quality of Service from the Policy selector.
- (Policy view) Select Router Platform > Quality of Service from the Policy Type selector. Create a new policy or select an existing policy from the Shared Policy selector.

Related Topics
- Defining QoS Policies, page 62-10

</tr>
<tr>
<td></td>
<td>• Interfaces—Configures QoS classes on specific interfaces.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> If you configure QoS on both the interfaces and the control plane of the same device, only the control plane configuration is deployed.</td>
</tr>
</tbody>
</table>

Interface Table

If you are defining classes on interfaces, the upper table lists the interfaces on which you are defining QoS classes. The direction column indicates the direction of traffic through the interface to which the classes apply (Output or Input). The classes you can define vary based on the direction.

The other fields indicate whether you defined shaping on the interface, and if shaping is defined, the type of hierarchical shaping (average or peak), the committed information rate (CIR), and the sustained and excess burst size. For detailed information about the attributes, see QoS Policy Dialog Box, page 62-21.

- To add an interface to the table, click the Add button.
- To edit the settings for an interface, select it and click the Edit button.
- To delete an interface, select it and click the Delete button.

QoS Classes Table

The classes defined for the interface selected in the upper table, or for the control plane. Each row represents a separate class. The No. column indicates the order of the classes, and is very important: QoS is applied to packets on a first-match basis, based on class order.

The Default Class column indicates whether this class is the default for all packets on the interface that do not match the criteria of the other defined classes. Make this the last class in the list.

The remaining columns indicate the match criteria for the class, and the packet marking, queuing and congestion avoidance, policing, and shaping defined for the class, if any. For detailed information about the attributes, see QoS Class Dialog Box, page 62-23.

- To add class to the table, click the Add button.
- To edit the settings for a class, select it and click the Edit button.
- To delete a class, select it and click the Delete button.
- To change the order of a class, select it and click the Up and Down arrow buttons to reposition it.
QoS Policy Dialog Box

Use the QoS Policy dialog box to select an interface on which you want to define QoS parameters. In addition, you can use this dialog box to configure a single set of shaping parameters for all the traffic on the selected interface (known as hierarchical shaping). Using hierarchical shaping eliminates the need to configure shaping parameters for each QoS class defined on the interface.

Note
This dialog box is not applicable when defining a QoS policy on the control plane. For more information, see Defining QoS on the Control Plane, page 62-12.

After you create your QoS interface definitions, you can define one or more QoS classes for each interface. For more information, see QoS Class Dialog Box, page 62-23.

Navigation Path
Go to the Quality of Service Policy Page, page 62-19, then click the Add or Edit button beneath the upper table to define a QoS interface definition.

</tbody>
</table>
QoS Class Dialog Box

Use the QoS Class dialog box to create or edit a QoS class on a selected interface or control plane of a Cisco IOS router. You can define up to 16 classes on a single interface and 256 classes for the device as a whole.

Note QoS is applied to packets on a first-match basis. The router examines the table of QoS classes starting from the top and applies the properties of the first class whose matching criteria matches the packet. Therefore, it is important that you define and order your classes carefully. The default class should be placed last to prevent traffic that matches a specific class from being treated as unmatched traffic.

Navigation Path
Go to the Quality of Service Policy Page, page 62-19. Complete the options at the top of the page, then do one of the following:

- To create a QoS class, select an interface from the upper table, then click the Add button beneath the QoS Class table. When creating a QoS class for the control plane, just click the Add button beneath the table.
- To edit a QoS class:
  - Select the interface whose class you want to edit from the upper table (Not required when selecting the control plane.).
  - Select the relevant class defined for that interface in the QoS Classes table. (Not required when selecting the control plane.)
  - Click the Edit button under the QoS Class table.

Related Topics

<td>Protocol</td>
<td>One or more protocols included in this class map. Click Add to display a selector. Select one or more items from the Available Protocols list, then click &gt;&gt; to add them to the Selected Protocols list. The only protocol available for the control plane is ARP; ARP and CDP are not available for input classes configured on an interface. When you finish, click OK to return to the QoS Class dialog box. Your selections are displayed in the Protocol field. Note To remove a protocol from the QoS class, select it from the Protocol field, then click Delete.</td>
</tr>
<tr>
<td>Precedence</td>
<td>One or more IP Precedence (IPP) values included in this class map. Click Add to display a selector. Select one or more items from the Available Precedences list, then click &gt;&gt; to add them to the Selected Precedences list. For more information about IP precedence values, see Table 62-1 on page 62-3. When you finish, click OK to return to the QoS Class dialog box. Your selections are displayed in the Precedence field. Note To remove an IPP value from the QoS class, select it from the Precedence field, then click Delete.</td>
</tr>
<tr>
<td>DSCP</td>
<td>One or more Differentiated Services Code Point (DSCP) values included in this class map. Click Add to display a selector. Select one or more items (up to eight) from the Available DSCPs list, then click &gt;&gt; to add them to the Selected DSCPs list. When you finish, click OK to return to the QoS Class dialog box. Your selections are displayed in the DSCP field. Note To remove a DSCP value from the QoS class, select it from the DSCP field, then click Delete.</td>
</tr>
<tr>
<td>ACL</td>
<td>The ACLs that are used for defining which traffic requires QoS. Click Edit to add or remove ACL objects. Use the up and down arrows to order the ACLs in the list. We recommend that you place frequently used ACLs at the top of the list to optimize the matching process.</td>
</tr>
</tbody>
</table>

Edit ACLs Dialog Box—QoS Classes

When configuring a QoS policy on a Cisco IOS router, use the Edit ACLs dialog box to specify which ACLs should be included in the matching criteria for the selected QoS class. Traffic matching this criteria is included as part of the class.

Enter the names of the extended ACLs or click Select to select an ACL object from a list or to create a new one. Separate multiple ACL objects with commas and place them in priority order.

For more information, see Creating Extended Access Control List Objects, page 6-49.

Navigation Path
Go to the QoS Class Dialog Box—Matching Tab, page 62-24, then click Edit in the ACL field.
QoS Class Dialog Box—Marking Tab

Use the Marking tab of the QoS Class dialog box to classify packets. Traffic policers and shapers use these classifications to ensure adherence to the contracted level of service. Downstream devices use this classification to identify the packets and apply the appropriate QoS features to them.

Note

The Marking tab is unavailable when you define a QoS policy on the control plane.

Navigation Path

Go to the QoS Class Dialog Box, page 62-23, then click the Marking tab.

Related Topics

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Marking</td>
<td>When selected, enables you to mark the traffic in this QoS class with a specific precedence or DSCP value (regardless of any value the traffic might have had when it first entered the device). This mark enables downstream devices to identify the traffic and apply the appropriate QoS features to it. When deselected, disables all marking options for the selected QoS class. The traffic in this QoS class maintains its original precedence or DSCP value, if any.</td>
</tr>
</tbody>
</table>
QoS Class Dialog Box—Queuing and Congestion Avoidance Tab

Use the Queuing and Congestion Avoidance tab of the QoS Class dialog box to perform Class-Based Weighted Fair Queuing (CBWFQ) on the output traffic in the selected QoS class. Queuing prioritizes traffic and manages congestion on your network by determining the order in which packets are sent out over an interface. Queuing and congestion avoidance applies only to interface classes for output traffic.

The fields displayed in the Queuing tab depend on whether you are defining a specific QoS class or the default class (by selecting Set as Default Class), and also by the type of router and the Cisco IOS software version.

The fields displayed in the Queuing tab depend on whether you are defining a specific QoS class or the default class (by selecting Set as Default Class), and also by the type of router and the Cisco IOS software version.

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Queuing and Congestion Avoidance</td>
<td>Whether to configure queuing and congestion avoidance properties in the QoS class.</td>
</tr>
</tbody>
</table>
### Priority (Non-default classes only.)

Configure low-latency queuing (LLQ) in this class to ensure that priority traffic, such as voice traffic, receives the defined bandwidth (see Low-Latency Queuing, page 62-5). Specify the amount of bandwidth allocated to high-priority traffic on this interface by:

- **Percentage**—Valid values range from 1 to 100%.
- **Kbit/sec**—Valid values range from 8-2000000 kilobits per second.

**Note**
You can define this option for one class only per interface. If you select this option, the Shaping tab is disabled.

### Fair Queue Number of Dynamic Queues (Default class only.)

Configure class-based weighted fair queuing in this class. If the device is running an IOS software version lower than 12.4(20)T, you must specify the number of dynamic queues to reserve for this class. You should base your number on the available bandwidth of the interface. You can specify a number between 16 and 4096 that is a power to 2. For information on the default number of queues the device uses, see Default Class Queuing, page 62-6. Available bandwidth is evenly distributed among the queues unless you configure a queue limit.

**Tip**
Failure to provide a sufficient number of queues for the default class (a condition known as starvation) could result in the traffic not being sent.

### Bandwidth

Configure the minimum bandwidth to guarantee to this class. You can define this amount by:

- **Percentage**—Valid values range from 1 to 100% of the total available bandwidth.
- **Kbit/sec**—Valid values range from 8-2000000 kilobits per second.

### Enable Fair Queue (Non-default class only.)

When you configure bandwidth for a non-default class, whether to also enable class-based weighted fair queuing (CBWFQ). The device calculates the number of queues to configure based on the available bandwidth, and distributes the bandwidth evenly among the queues unless you configure a queue limit.

This option is available only for Aggregation Services Routers (ASR) and for routers running 12.4(20)T and higher.

### Queue Limit

The maximum number of packets that can be queued for the class. Any additional packets are dropped using tail drop until the congestion is gone.

This is the default option for limiting queue size unless Weighted Random Early Detection (WRED) is configured.

### Table 62-8 QoS Class Dialog Box—Queuing and Congestion Avoidance Tab (Continued)

Chapter 62 Configuring Quality of Service

Table 62-8 QoS Class Dialog Box—Queuing and Congestion Avoidance Tab (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WRED Weight for Mean Queue Depth</td>
<td>The exponential weight factor to use to calculate the average queue size. Use this option when defining WRED instead of tail drop (queue limit) for this class. When the queue size exceeds the value determined by this weight factor, WRED randomly discards packets until the transmitting protocol decreases its transmission rate to ease congestion. Exponent values range from 1 to 16. The default is 9. This option is best suited for protocols like TCP, which respond to dropped packets by decreasing the transmission rate. We recommend that you do not change the default unless you determine that your applications would benefit from the change.</td>
</tr>
</tbody>
</table>

QoS Class Dialog Box—Policing Tab

Use the Policing tab of the QoS Class dialog box to configure rate limits on the traffic in a selected QoS class. Excess traffic is either dropped or transmitted with a different (typically lower) priority.

Navigation Path
Go to the QoS Class Dialog Box, page 62-23, then click the Policing tab.

Related Topics
- Defining QoS Class Policing Parameters, page 62-17

<tr>
<td>Enable Policing</td>
<td>When selected, enables you to configure Class-Based Policing to control the maximum rate of traffic for this class. Security Manager uses a two-token bucket algorithm, which includes a defined violate action that is performed when neither bucket can accommodate the incoming packet. When deselected, disables all policing options for the selected QoS class.</td>
</tr>
</tbody>
</table>
The average data rate (also known as the committed information rate or CIR). You can define this amount by:

- Percentage—Valid values range from 0 to 100% of the overall available bandwidth.
- Bit/sec—Valid values range from 8000 to 2000000000 bits per second.

In the token bucket algorithm, this rate represents the token arrival rate for filling both token buckets. Traffic that falls under this rate always conforms.

**Note** When you configure Understanding Control Plane Policing, page 62-9, you must define the CIR in bits per second.

The normal burst size, which determines how large traffic bursts can be before some traffic exceeds the rate limit. In the token bucket algorithm, it represents the full size of the first (conform) token bucket.

The range of valid values is determined by the CIR:

- When the CIR is defined by percentage—Valid values range from 1 to 2000 milliseconds.
- When the CIR is defined by an absolute value—Valid values range from 1000-512000000 bytes.

The excess burst size, which determines how large traffic bursts can be before all traffic exceeds the rate limit. In the token bucket algorithm, it represents the full size of the second (exceed) token bucket.

The range of valid values is determined by the CIR:

- When the CIR is defined by percentage—Valid values range from 1 to 2000 milliseconds.
- When the CIR is defined by an absolute value—Valid values range from 1000-512000000 bytes.

The action to take on packets that conform to the rate limit:

- transmit—Transmits the packet.
- set-prec-transmit—Sets the IP precedence to a value you specify (0 to 7) and then sends the packet. Not available on the control plane.
- set-dscp-transmit—Sets the DSCP to a value you specify (0 to 63) and then sends the packet. Not available on the control plane.
- drop—Drops the packet.

The action to take on packets that exceed the rate limit, but can be handled using the second (exceed) token bucket.

The actions available for selection depend on the defined conform action. For example, if you select one of the set options as the conform action, you cannot select transmit as the exceed action. If you select drop as the conform action, then you must also select drop as the exceed action.

<tr>
<td></td>
<td>The actions available for selection depend on the defined conform action. For example, if you select one of the set options as the</td>
</tr>
<tr>
<td></td>
<td>conform action, you cannot select transmit as the exceed action. If you select drop as the conform action, then you must also select</td>
</tr>
<tr>
<td></td>
<td>drop as the exceed action.</td>
</tr>
</tbody>
</table>
Use the Shaping tab of the QoS Class dialog box to control the rate of output traffic for the selected QoS class. Shaping typically delays excess traffic by using a buffer, or queuing mechanism, to hold packets and shape the flow when the data rate of the source is higher than expected.

Note

The Shaping tab is unavailable when you define a QoS policy on the control plane, use hierarchical shaping on the interface, define a QoS class for input traffic, or perform queuing on priority traffic.

Navigation Path

Go to the QoS Class Dialog Box, page 62-23, then click the **Shaping** tab.

**User Guide for Cisco Security Manager 4.3**  
**Chapter 62       Configuring Quality of Service**  
**OL-26838-01**
BGP Routing on Cisco IOS Routers

BGP is an Exterior Gateway Protocol (EGP) that guarantees the loop-free exchange of routing information between autonomous systems (ASs). The primary function of a BGP system is to exchange information with other BGP systems about the networks it can reach, including AS path information. This information can be used to construct a graph of AS connectivity from which routing loops can be pruned and with which AS-level policy decisions can be enforced.

BGP is the routing protocol used on the Internet and is commonly used between Internet service providers. To achieve scalability at this level, BGP uses several route parameters (attributes) to define routing policies and maintain a stable routing environment. Additionally, BGP uses classless interdomain routing (CIDR) to greatly reduce the size of Internet routing tables.

A BGP route consists of a network number, a list of ASs through which information has passed (called the autonomous system path), and the defined path attributes.

A BGP router exchanges routing information only with those routers that you define as its neighbors. BGP neighbors exchange complete routing information when the TCP connection between them is established. Updates are sent to neighbors only when changes to the routing table are detected. BGP routers do not send regular, periodic updates.

The following topics describe the tasks you perform to create a BGP routing policy:
Defining BGP Routes

As with all EGP, when you configure a BGP routing policy, you must define the relationship the router has with its neighbors. BGP supports two kinds of neighbors: internal (located in the same AS) and external (located in a different AS). Typically, external neighbors are adjacent to each other and share a subnet; internal neighbors can be anywhere in the same AS.

In addition, you can select whether to enable the following optional features:

- Auto-summarization
- Synchronization
- Neighbor logging

If enabled, auto-summarization injects only the network route when a subnet is redistributed from an Interior Gateway Protocol (IGP) such as OSPF or EIGRP into BGP. Synchronization is useful if your AS acts as an intermediary, passing traffic from one AS to another AS, because it ensures that your AS is consistent about the routes it advertises. For example, if BGP were to advertise a route before all routers in your network had learned about the route through your IGP, your AS might receive traffic that some routers cannot yet route. Neighbor logging enables the router to keep track of messages issued by BGP neighbors when they reset, become unreachable, or restore their connection to the network.

This procedure describes how to define a BGP route. You can define only one BGP route on each router.

### Related Topics
- Static Routing on Cisco IOS Routers, page 63-50
- RIP Routing on Cisco IOS Routers, page 63-42
- OSPF Routing on Cisco IOS Routers, page 63-19
- EIGRP Routing on Cisco IOS Routers, page 63-8

---

Step 1
Do one of the following:

- (Device view) Select Platform > Routing > BGP from the Policy selector, then click the Setup tab in the work area.
- (Policy view) Select Router Platform > Routing > BGP from the Policy Type selector. Select an existing policy or create a new one, and then click the Setup tab.

The BGP Setup is displayed. See Table 63-1 on page 63-5 for a description of the fields on this tab.

Step 2
On the BGP Setup tab, enter the AS number to which the router belongs.
Step 3  (Optional) Enter the addresses of the networks that are local to this AS. You can use a combination of addresses and network/host objects, or click Select to select an object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

Step 4  Define external and internal BGP neighbors for the routers:

a. Click Add under Neighbors to display the BGP Neighbors dialog box. See Table 63-2 on page 63-6 for a description of the fields in this dialog box.

b. Enter an AS number and then click Select to select the hosts that are neighbors within the defined AS. Internal neighbors are located in the same AS as the router; external neighbors are located in a different AS.

c. Click OK to save your definitions and return to the BGP Neighbors dialog box.

d.  (Optional) Repeat b. and c. to define neighbors in additional ASs.

Note   When you define BGP neighbors, the IP addresses cannot belong to an interface on the selected router. In addition, you cannot define the same IP address in more than one AS.

When you finish, click OK in the BGP Neighbors dialog box to return to the BGP Setup tab. Your selections are displayed in the Neighbors field.

Step 5  (Optional) Select the Auto-Summary check box to enable automatic summarization. If automatic summarization is enabled, only the network route is injected into the BGP table when a subnet is redistributed from an IGP (such as OSPF or EIGRP) into BGP.

Step 6  (Optional) Select the Synchronization check box to synchronize BGP with the IGP. Enabling this feature causes BGP to wait until the IGP propagates routing information across the AS.

You do not need synchronization if your AS does not pass traffic it receives from one AS to another AS, or if all the routers in your AS run BGP. Disabling synchronization enables BGP to converge more quickly.

Step 7  (Optional) Select the Log-Neighbor check box to enable the logging of messages generated when a BGP neighbors resets, comes up, or goes down.

Redistributing Routes into BGP

Redistribution refers to using a routing protocol, such as BGP, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you can redistribute routes from the OSPF routing protocol into your BGP autonomous system (AS). Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

Before You Begin

- Define a BGP AS. See Defining BGP Routes, page 63-2.

Related Topics

- Defining BGP Routes, page 63-2
- BGP Routing on Cisco IOS Routers, page 63-1

Step 1  Do one of the following:
(Device view) Select **Platform > Routing > BGP** from the Policy selector, then click the **Redistribution** tab in the work area.

(Policy view) Select **Router Platform > Routing > BGP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The BGP Redistribution tab is displayed. See Table 63-3 on page 63-7 for a description of the fields on this tab.

**Step 2** On the BGP Redistribution tab, select a row from the BGP Redistribution Mappings table, then click **Edit**, or click **Add** to create a mapping. The BGP Redistribution Mapping dialog box appears. See Table 63-4 on page 63-8 for a description of the fields in this dialog box.

**Step 3** Select the protocol whose routes you want to redistribute into BGP.

**Note** You can create a single mapping for each static route, RIP route, EIGRP AS, and OSPF process.

**Step 4** (Optional) Modify the default metric (cost) of the redistributed routes. The metric determines the priority of the routes.

**Step 5** Click **OK** to save your definitions locally on the client and close the dialog box. The redistribution mapping appears in the Redistribution Mapping table in the BGP Redistribution tab.

---

### BGP Routing Policy Page

Border Gateway Protocol (BGP) is an exterior gateway protocol (EGP) that performs routing between multiple autonomous systems or domains and exchanges routing and reachability information with other BGP systems. BGP is used to exchange routing information on the Internet and is the protocol used between Internet service providers.

You can configure BGP routing policies from the following tabs on the BGP Routing page:

- **BGP Page—Setup Tab, page 63-4**
- **BGP Page—Redistribution Tab, page 63-6**

For more information, see **BGP Routing on Cisco IOS Routers, page 63-1**.

**Navigation Path**

- (Device view) Select **Platform > Routing > BGP** from the Policy selector.
- (Policy view) Select **Router Platform > Routing > BGP** from the Policy Type selector. Right-click **BGP** to create a policy, or select an existing policy from the Shared Policy selector.

### BGP Page—Setup Tab

Use the BGP Setup tab to define the number of the autonomous system (AS) in which the selected router is located. You must then define which networks are included in the AS and which networks are the internal and external neighbors of the router. Additionally, you can enable or disable options that govern the interaction between BGP and Interior Gateway Protocols (IGPs), such as OSPF and EIGRP. Use a third option to enable the logging of messages from BGP neighbors.
Navigating Path

Go to the BGP Routing Policy Page, page 63-4, then click the **Setup** tab.

Related Topics

**Table 63-1  BGP Setup Tab**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AS Number</td>
<td>The number of the autonomous system in which the router is located. Valid values range from 1 to 65535. This number enables a BGP routing process. If BGP is already configured on the device, you cannot successfully change and deploy this number. If you need to change the AS number, first unassign the BGP policy, deploy your change (thus removing the BGP configuration from the device), then configure the BGP policy with the new number and redeploy the configuration.</td>
</tr>
<tr>
<td>Networks</td>
<td>The networks associated with the BGP route. Enter one or more network addresses or network/host objects, or click <em>Select</em> to select the object from a list or to create a new one. <strong>Note</strong> To remove a network from the route, select it from the Network field, then click <em>Delete</em>.</td>
</tr>
<tr>
<td>Neighbors</td>
<td>The <em>internal</em> neighbors (those located in the same AS as the router) and <em>external</em> neighbors (located in different ASs) of the router. See Neighbors Dialog Box, page 63-6.</td>
</tr>
<tr>
<td>Auto-Summary</td>
<td>When selected, automatic summarization is enabled. When a subnet is redistributed from an IGP (such as RIP, OSPF or EIGRP) into BGP, this BGP version 3 feature injects only the network route into the BGP table. Automatic summarization reduces the size and complexity of the routing table that the router must maintain. When deselected, automatic summarization is disabled. This is the default.</td>
</tr>
<tr>
<td>Synchronization</td>
<td>When selected, synchronization is enabled. Use this feature to ensure that all routers in your network are consistent about the routes they advertise. Synchronization forces BGP to wait until the IGP propagates routing information across the AS. When deselected, synchronization is disabled. You can disable synchronization if this router does not pass traffic from a different AS to a third AS, or if all the routers in the AS are running BGP. Disabling this feature has the benefit of reducing the number of routes the IGP must carry, which improves convergence times. This is the default.</td>
</tr>
</tbody>
</table>

EIGRP Routing on Cisco IOS Routers

Enhanced Interior Gateway Routing Protocol (EIGRP) is an enhanced distance vector protocol developed by Cisco Systems that integrates the capabilities of link-state protocols. EIGRP is suited for many different topologies and media. Key capabilities that distinguish EIGRP from other routing protocols are fast convergence, support for variable-length subnet masks, partial updates, and multiple network-layer protocols.

The metric that the router uses to reach the destination, and to advertise to other routers, is the sum of the best-advertised metrics from all neighbors and the link cost to the best neighbor.

EIGRP uses neighbor tables to store address and interface information about each of the router’s neighbors. Hello packets advertise hold times, which is the length of time a neighbor can be considered reachable and operational. Topology tables contain all destinations advertised by neighboring routers. For each neighbor, the entry records the advertised metric, which the neighbor stores in its routing table.
A router running EIGRP stores all its neighbors’ routing tables so that it can quickly adapt to alternate routes. If no appropriate route exists, EIGRP queries its neighbors to discover an alternate route. These queries propagate until an alternate route is found. EIGRP sends incremental updates when the state of a destination changes, instead of sending the entire contents of the routing table. EIGRP ensures that only those routers needing the information are updated. This feature minimizes the bandwidth required for EIGRP packets.

EIGRP supports both internal and external routes. Internal routes originate within an EIGRP Autonomous System (AS). Therefore, a directly attached network that is configured to run EIGRP is considered an internal route and is propagated with this information throughout the AS. External routes are learned by another routing protocol or reside in the routing table as static routes. These routes are tagged individually with the identity of their origin.

The following topics describe the tasks you perform to create an EIGRP routing policy:

- Defining EIGRP Routes, page 63-9
- Defining EIGRP Interface Properties, page 63-10
- Redistributing Routes into EIGRP, page 63-12

Related Topics
- Static Routing on Cisco IOS Routers, page 63-50
- RIP Routing on Cisco IOS Routers, page 63-42
- OSPF Routing on Cisco IOS Routers, page 63-19
- BGP Routing on Cisco IOS Routers, page 63-1

## Defining EIGRP Routes

To configure an EIGRP routing policy, you must assign each autonomous system a number, which identifies the autonomous system to other routers. You then must select the networks to which routes will be created. In addition, you can select which interfaces should be passive. Unlike other routing protocols, passive interfaces in EIGRP neither send nor receive routing updates from their neighbors, resulting in the loss of their neighbor relationship.

When you configure EIGRP routing policies, you can also decide whether to enable auto-summarization, which greatly simplifies routing tables and the exchange of routing information by having many subnets represented by a single network entry.

Related Topics
- Defining EIGRP Interface Properties, page 63-10
- Redistributing Routes into EIGRP, page 63-12
- EIGRP Routing on Cisco IOS Routers, page 63-8

### Step 1

Do one of the following:

- (Device view) Select Platform > Routing > EIGRP from the Policy selector, then click the Setup tab in the work area.
- (Policy view) Select Router Platform > Routing > EIGRP from the Policy Type selector. Select an existing policy or create a new one, and then click the Setup tab.

The EIGRP Setup tab is displayed (see EIGRP Page—Setup Tab, page 63-13).
Step 2 On the EIGRP Setup tab, select an EIGRP route from the table, then click **Edit**, or click **Add** to create a route. The EIGRP Setup dialog box appears. See Table 63-6 on page 63-14 for a description of the fields in this dialog box.

Step 3 Enter the autonomous system number for the route. This number identifies the autonomous system to other routers.

Step 4 Enter the addresses of the networks to include in the EIGRP route. You can use a combination of addresses and network/host objects; separate addresses with commas. Click **Select** to select network/host objects from a list of existing objects, or to create new network/host objects. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

Step 5 Enter the addresses of the passive interfaces, which are interfaces that should not send routing updates to their neighbors, if any. Enter the names of one or more interfaces or interface roles; separate addresses with commas. Click **Select** to select interface names or roles from a list of existing objects, or to create new interface role objects. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 6 (Optional) Select **Auto-Summary** to enable the auto summarization of subnet routes into network-level routes. Summarization reduces the size of routing tables, thereby reducing the complexity of the network.

Step 7 Click **OK** to save your definitions. The EIGRP route appears in the table displayed in the EIGRP Setup tab.

---

Defining EIGRP Interface Properties

You can optionally modify the default values of the following two interface properties in a selected EIGRP autonomous system:

- Hello interval.
- Split horizon.

The hello interval defines the interval between hello packets. Routing devices periodically send these packets to each other to dynamically learn of other routers on their directly attached networks. This information is used to discover neighbors and to learn when neighbors become unreachable or inoperative. By default, hello packets are sent every 5 seconds. The default interval for low speed (T1 or slower), nonbroadcast multiaccess (NBMA) media is every 60 seconds.

Split horizon is a feature that prevents route information from being sent back in the direction from which that information originated. If you enable split horizon on an interface (this is the default), update and query packets are not sent to destinations for which this interface is the next hop. This helps to prevent routing loops.

For example, as shown in Figure 63-1, if Router One is connected to Routers Two and Three through a single multipoint interface, and Router One learned about Network A from Router Two, Router One does not advertise the route to Network A over that same multipoint interface to Router Three. Router One assumes that Router Three would learn about Network A directly from Router Two.
Split horizon is enabled by default on all EIGRP interfaces, because it typically optimizes communications among multiple routing devices. However, in certain cases with nonbroadcast networks (such as Frame Relay and SMDS), you might want to disable split split horizon.

If you decide to disable split horizon on an EIGRP interface, keep the following in mind:

- In a hub-and-spoke network, you should disable split horizon only at the hub. This is because disabling split horizon on the spokes greatly increases EIGRP memory consumption on the hub router, as well as the amount of traffic generated on the spoke routers.
- Changing the split horizon setting on an interface resets all adjacencies with the EIGRP neighbors that are reachable over that interface.

**Before You Begin**

- Define at least one EIGRP autonomous system. See Defining EIGRP Routes, page 63-9.

**Related Topics**

- Defining EIGRP Routes, page 63-9
- Redistributing Routes into EIGRP, page 63-12
- EIGRP Routing on Cisco IOS Routers, page 63-8

**Step 1** Do one of the following:

- (Device view) Select **Platform > Routing > EIGRP** from the Policy selector, then click the **Interfaces** tab in the work area.
- (Policy view) Select **Router Platform > Routing > EIGRP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Interfaces** tab.

The EIGRP Interfaces tab is displayed. See Table 63-7 on page 63-15 for a description of the fields on this tab.

**Step 2** On the EIGRP Interfaces tab, select an interface from the table, then click **Edit**, or click **Add** to create an interface definition. The EIGRP Interface dialog box appears. See Table 63-8 on page 63-16 for a description of the fields in this dialog box.

**Step 3** Select the AS number of the autonomous system whose interface properties you want to modify. See Defining EIGRP Routes, page 63-9 for more information about defining an autonomous system.
Step 4 Enter the name of the interface or interface role to define, or click Select to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 5 (Optional) In the Hello Interval field, modify the default interval between hello packets sent over the selected interfaces.

The default is 5 seconds for all interfaces, except for low-speed (T1 or less) NBMA media, for which the default interval is 60 seconds.

Step 6 (Optional) Deselect the Split Horizon check box to disable the split horizon feature. If you disable this feature, the selected interfaces can advertise a route out of the interface from which they learned the route.

Note In general, we recommend that you not disable split horizon unless you are certain that your application requires the change to properly advertise routes. If you disable split horizon on a serial interface, and that interface is attached to a packet-switched network, you must disable split horizon for all routers and access servers in all relevant multicast groups on that network.

Step 7 Click OK to save your definitions locally on the client and close the dialog box. The interface definition appears in the table on the EIGRP Interfaces tab.

Redistributing Routes into EIGRP

Redistribution refers to using a routing protocol, such as EIGRP, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you can redistribute routes from the RIP routing protocol into your EIGRP autonomous system (AS). Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

Before You Begin

- Define at least one EIGRP autonomous system. See Defining EIGRP Routes, page 63-9.

Related Topics

- Defining EIGRP Routes, page 63-9
- Defining EIGRP Interface Properties, page 63-10
- EIGRP Routing on Cisco IOS Routers, page 63-8

Step 1 Do one of the following:

- (Device view) Select Platform > Routing > EIGRP from the Policy selector, then click the Redistribution tab in the work area.

- (Policy view) Select Router Platform > Routing > EIGRP from the Policy Type selector. Select an existing policy or create a new one, and then click the Redistribution tab.

The EIGRP Redistribution tab is displayed. See Table 63-9 on page 63-17 for a description of the fields on this tab.
Step 2 On the EIGRP Redistribution tab, select a row from the EIGRP Redistribution Mappings table, then click **Edit**, or click **Add** to create a mapping. The EIGRP Redistribution Mapping dialog box appears. See Table 63-10 on page 63-18 for a description of the fields in this dialog box.

Step 3 Select an existing EIGRP AS from the displayed list.

Step 4 Select the protocol whose routes you want to redistribute into the selected EIGRP AS.

**Note** You can create a single mapping for each static route, RIP route, BGP AS, EIGRP AS, and OSPF process.

Step 5 (Optional) Under Metrics, modify the default metric (cost) of the redistributed routes by entering values in the fields used to calculate the metric. The metric determines the priority of the routes.

**Note** Entering a metric is optional, but if you do specify a value, you must enter values for all five parameters. You need not define metric values when redistributing one EIGRP process into another.

Step 6 Click **OK** to save your definitions locally on the client and close the dialog box. The redistribution mapping appears in the Redistribution Mapping table in the EIGRP Redistribution tab.

---

**EIGRP Routing Policy Page**

Enhanced Interior Gateway Routing Protocol (EIGRP) is a scalable interior gateway protocol that provides extremely quick convergence times with minimal network traffic.

You can configure EIGRP routing policies from the following tabs on the EIGRP Routing page:

- EIGRP Page—Setup Tab, page 63-13
- EIGRP Page—Interfaces Tab, page 63-15
- EIGRP Page—Redistribution Tab, page 63-17

For more information, see EIGRP Routing on Cisco IOS Routers, page 63-8.

**Navigation Path**

- (Device view) Select **Platform > Routing > EIGRP** from the Policy selector.
- (Policy view) Select **Router Platform > Routing > EIGRP** from the Policy Type selector. Right-click **EIGRP** to create a policy, or select an existing policy from the Shared Policy selector.

**EIGRP Page—Setup Tab**

Use the EIGRP Setup tab to view, create, edit, and delete EIGRP routes.

**Navigation Path**

Go to the EIGRP Routing Policy Page, page 63-13, then click the **Setup** tab.

</tr>
</tbody>
</table>
OSPF Routing on Cisco IOS Routers

Open Shortest Path First (OSPF) is an interior gateway routing protocol that uses link states instead of distance vectors to distribute routing information within a single autonomous system (AS). OSPF propagates link-state advertisements (LSAs) instead of routing table updates, which allows OSPF networks to converge more quickly than RIP networks. You define areas to limit the number of LSAs that need to be propagated to changes that occur within the area.
A router that has interfaces in multiple OSPF areas is called an Area Border Router (ABR). An ABR uses LSAs to send information about available routes to other OSPF routers. A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR). Any router can act as an ABR or ASBR.

The following topics describe the tasks you perform to create an OSPF routing policy:

- Defining OSPF Process Settings, page 63-20
- Defining OSPF Area Settings, page 63-21
- Redistributing Routes into OSPF, page 63-22
- Defining OSPF Interface Settings, page 63-25

Related Topics

- Static Routing on Cisco IOS Routers, page 63-50
- RIP Routing on Cisco IOS Routers, page 63-42
- EIGRP Routing on Cisco IOS Routers, page 63-8
- BGP Routing on Cisco IOS Routers, page 63-1

### Defining OSPF Process Settings

You configure OSPF process parameters by specifying a process ID number, which identifies the OSPF process to other routers, and by deciding whether any interfaces should be passive. Passive interfaces do not send routing updates to their neighbors.

Related Topics

- Defining OSPF Area Settings, page 63-21
- Defining OSPF Interface Settings, page 63-25
- Redistributing Routes into OSPF, page 63-22
- OSPF Routing on Cisco IOS Routers, page 63-19

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Routing > OSPF Process** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Routing > OSPF Process** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The OSPF Process Setup tab is displayed. See Table 63-13 on page 63-35 for a description of the fields on this tab.

**Step 2**

On the OSPF Process Setup tab, select an OSPF process from the table, then click **Edit**, or click **Add** to create a process. The OSPF Setup dialog box appears. See Table 63-14 on page 63-36 for a description of the fields in this dialog box.

**Step 3**

Enter the process ID number in the field provided. The process ID defined here does not need to match the process ID on any other devices.

**Step 4**

Define which interfaces should not send routing updates to its neighbors:

- Click **Edit** under Passive Interfaces to display the Edit Interfaces dialog box. Use this dialog box to define which interfaces should *not* send routing updates to its neighbors.
b. Enter the names of one or more interfaces or interface roles, or click Select to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

c. Click OK to save your changes and return to the OSPF Setup dialog box.

Step 5
Click OK to save your definitions locally on the client and close the dialog box.

Defining OSPF Area Settings

You configure OSPF area settings by associating an area ID with a particular OSPF process, selecting the networks included in the area, and selecting the type of authentication used by the routers in the area. Each OSPF process that you define should contain at least one defined area. If you define more than one area, one area must be area 0. This is called the backbone. All other areas must be physically connected to the backbone. This enables other areas to inject routing information into the backbone, which the backbone distributes to the remaining areas.

You must configure at least one OSPF process before defining OSPF area/network settings for that process.

Related Topics
- Defining OSPF Process Settings, page 63-20
- Defining OSPF Interface Settings, page 63-25
- Redistributing Routes into OSPF, page 63-22
- OSPF Routing on Cisco IOS Routers, page 63-19

Step 1
Do one of the following:
- (Device view) Select Platform > Routing > OSPF Process from the Policy selector, then click the Area tab in the work area.

- (Policy view) Select Router Platform > Routing > OSPF Process from the Policy Type selector. Select an existing policy or create a new one, and then click the Area tab.

The OSPF Process Area tab is displayed. See Table 63-15 on page 63-37 for a description of the fields on this tab.

Step 2
On the OSPF Process Area tab, select an OSPF area from the table, then click Edit, or click Add to create an area. The OSPF Area dialog box appears. See Table 63-16 on page 63-37 for a description of the fields in this dialog box.

Step 3
Select a process ID from the displayed list.

Step 4
Enter an area ID to associate with the selected OSPF process.

Step 5
Enter the addresses of the networks to include in the OSPF area. You can enter a combination of addresses and network/host objects, or click Select to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

Step 6
Select the authentication type to use in the OSPF area: MD5, clear text, or none. We recommend MD5 when security is of concern. Please note the following:
- The authentication type must be the same for all routers and access servers in the same area.
• Specifying clear-text authentication for an area sets the authentication to Type 1 (simple password). All routers on a network must use the same clear-text password to communicate with each other using OSPF.
• MD5 passwords need not be the same throughout an area, but they must be the same between neighbors.
• If you use interface authentication (see Defining OSPF Interface Settings, page 63-25), the authentication type used for the area must match the authentication type used for the interface.

![Step 7](Image)

Click **OK** to save your definitions. The OSPF area appears in the table displayed on the OSPF Area tab.

### Redistributing Routes into OSPF

Redistribution refers to using a routing protocol, such as OSPF, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you can redistribute routes from the RIP routing protocol into your OSPF domain.

Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

Redistributing routes into OSPF from other routing protocols or from static routes causes these routes to become OSPF external routes (Type 1 or Type 2).

Redistributing routes into OSPF involves:

- Defining OSPF Redistribution Mappings, page 63-22
- Defining OSPF Maximum Prefix Values, page 63-23

**Related Topics**

- Defining OSPF Process Settings, page 63-20
- Defining OSPF Area Settings, page 63-21
- Defining OSPF Interface Settings, page 63-25
- OSPF Routing on Cisco IOS Routers, page 63-19

### Defining OSPF Redistribution Mappings

When you define OSPF redistribution mappings, you must select the protocol to redistribute and the OSPF process into which routes from that protocol are redistributed. Additionally, you can manually define the metric, which determines the priority of the redistributed routes, and the type of external OSPF route to create, Type 1 or Type 2.

You can create multiple mappings to the same OSPF process. For example, you can redistribute both RIP and EIGRP routes into the same OSPF process. You can also redistribute routes from other OSPF processes.

**Note**

Redistribution into an OSPF Not-So-Stubby Area (NSSA) creates a special type of link-state advertisement (LSA) called type 7, which can exist only in an NSSA area. An NSSA autonomous system router (ASBR) generates this LSA, and an NSSA area border router (ABR) translates it into a type 5 LSA, which is propagated into the OSPF domain.
Type 1 versus Type 2 External Routes

Two types of OSPF external routes exist, Type 1 and Type 2. The difference between the two is related to how the cost (metric) of the route is calculated. The cost of a Type 1 route is the sum of the external cost and the internal cost used to reach that route. The cost of a Type 2 route is based on the external cost only. By default, external routes are defined as Type 2. However, a Type 1 route is always preferred over a Type 2 route to the same destination.

Before You Begin

- Define at least one OSPF process. See Defining OSPF Process Settings, page 63-20.

Related Topics

- Defining OSPF Maximum Prefix Values, page 63-23
- Redistributing Routes into OSPF, page 63-22

---

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Routing > OSPF Process** from the Policy selector, then click the **Redistribution** tab in the work area.
- (Policy view) Select **Router Platform > Routing > OSPF Process** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The OSPF Process Redistribution tab is displayed. See Table 63-17 on page 63-38 for a description of the fields on this tab.

**Step 2**

On the OSPF Process Redistribution tab, select a row from the OSPF Redistribution Mappings table, then click **Edit**, or click **Add** to create a mapping. The OSPF Redistribution Mapping dialog box is displayed. See Table 63-18 on page 63-40 for a description of the fields in this dialog box.

**Step 3**

Select an existing OSPF process from the displayed list.

**Step 4**

Select the protocol whose routes you want to redistribute into the selected OSPF process.

**Note** You can create a single mapping for each static route, RIP route, BGP AS, EIGRP AS, and OSPF process.

**Step 5**

(Optional) Modify the default metric (cost) of the redistributed routes. The metric determines the priority of the routes.

**Step 6**

Select the Metric Type of external route to create, Type 1 or Type 2. The default is Type 2.

**Step 7**

(Optional) Select the **Limit to Subnets** check box to redistribute only subnetted routes. By default, this option is not selected.

**Step 8**

Click **OK** to save your definitions. The redistribution mapping appears in the Redistribution Mapping table on the OSPF Process Redistribution tab.

---

**Defining OSPF Maximum Prefix Values**

You can define a maximum number of prefixes (routes) that may be redistributed from other protocols or OSPF processes into a selected OSPF process. Setting a limit helps prevent the router from being flooded by too many redistributed routes. For example, without a defined maximum, flooding can occur when BGP is redistributed into OSPF.
When you define a maximum prefix value, you can decide whether to prevent additional routes from being redistributed once this maximum is reached, or whether to only issue a warning.

The redistribution limit applies to all IP redistributed prefixes, including summarized ones. The limit does not apply to default routes or prefixes that are generated as a result of type 7 to type 5 translations.

**Before You Begin**

- Define at least one OSPF process. See [Defining OSPF Process Settings](#).
- Define at least one OSPF redistribution mapping. See [Defining OSPF Redistribution Mappings](#).

**Related Topics**

- [Defining OSPF Redistribution Mappings](#)
- [Redistributing Routes into OSPF](#)

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Routing > OSPF Process** from the Policy selector, then click the **Redistribution** tab in the work area.
- (Policy view) Select **Router Platform > Routing > OSPF Process** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The OSPF Process Redistribution tab is displayed. See Table 63-17 on page 63-38 for a description of the fields on this tab.

**Step 2**

On the OSPF Process Redistribution tab, select a row from the Max Prefix Mapping table, then click **Edit**, or click **Add** to create a definition. The Max Prefix Mapping dialog box appears. See Table 63-19 on page 63-41 for a description of the fields in this dialog box.

**Step 3**

Select an existing OSPF process from the displayed list.

**Step 4**

In the Max Prefix field, enter the maximum number of routes that can be redistributed into the selected OSPF process.

**Step 5**

(Optional) Modify the default threshold percentage. When the number of redistributed routes reaches this threshold, a warning is issued. By default, the threshold value is 75% of the defined maximum prefix value.

**Step 6**

(Optional) Select what should happen when the maximum prefix value is reached:

- Enforce Maximum Route—Prevents additional routes from being redistributed to the selected process.
- Warning Only—Issues an additional warning, but allows route redistribution to continue even after the maximum prefix value is reached.

**Note**

Flooding can result if you allow route redistribution to continue after exceeding the maximum prefix value.

**Step 7**

Click **OK** to save your definitions. The maximum prefix definition appears in the Maximum Prefix table on the OSPF Process Redistribution tab.
Defining OSPF Interface Settings

You can modify a variety of interface-specific OSPF parameters. This procedure describes how to define these parameters. For more information about a particular parameter, see the following topics:

- Understanding Interface Cost, page 63-26
- Understanding Interface Priority, page 63-26
- Disabling MTU Mismatch Detection, page 63-27
- Understanding OSPF Timer Settings, page 63-28
- Blocking LSA Flooding, page 63-27
- Understanding the OSPF Network Type, page 63-29
- Understanding OSPF Interface Authentication, page 63-29

Related Topics

- Defining OSPF Process Settings, page 63-20
- Defining OSPF Area Settings, page 63-21
- Redistributing Routes into OSPF, page 63-22
- OSPF Routing on Cisco IOS Routers, page 63-19

Step 1
Do one of the following:

- (Device view) Select Platform > Routing > OSPF Interface from the Policy selector.
- (Policy view) Select Router Platform > Routing > OSPF Interface from the Policy Type selector. Select an existing policy or create a new one.

The OSPF Interface page is displayed. See Table 63-11 on page 63-30 for a description of the fields on this page.

Step 2
On the OSPF Interface page, select an interface definition from the table, then click Edit, or click Add to create a definition. The OSPF Interface dialog box appears. See Table 63-12 on page 63-32 for a description of the fields in this dialog box.

Step 3
Enter the name of the interface or interface role to define, or click Select to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 4
Define interface authentication. The authentication type you select for the interface must match the authentication type you select for the area (see Defining OSPF Area Settings, page 63-21).

All neighboring routers on the same network must have the same password to be able to exchange OSPF information. For more information, see Understanding OSPF Interface Authentication, page 63-29.

The key ID number can be associated with multiple passwords. This is an easy and secure way to migrate passwords. For example, to migrate from one password to another, configure a password under a different key ID, then remove the first key.

Tip
The key ID number can be associated with multiple passwords. This is an easy and secure way to migrate passwords. For example, to migrate from one password to another, configure a password under a different key ID, then remove the first key.
Understanding Interface Cost

The cost of an OSPF interface is a metric representing the cost of sending a packet over that interface. By default, this cost is calculated using this formula:

\[ \frac{10^8}{\text{bandwidth} \text{ [bits per second]}} \]

For example, if the bandwidth of a Fast Ethernet interface is 10 Mbps (equal to \(10^7\)), the cost of sending packets over that interface is calculated as \(\frac{10^8}{10^7}\) or 10. This formula establishes an inverse relationship between the bandwidth of an interface and its cost; the greater the bandwidth, the lower the cost.

Although cost is a calculated value, you can manually enter the cost of a selected interface.

Understanding Interface Priority

Routers that share a common segment are elected through the Hello protocol to be neighbors on that segment. Election occurs as soon as the routers see themselves listed in their neighbor’s hello packet. Adjacency is the next step. Adjacent routers are routers that proceed beyond the simple Hello exchange to a database exchange.

On each multiaccess (as opposed to point-to-point) segment, OSPF elects one router as the designated router (DR) for that segment. The DR acts as a central point of contact to minimize information exchange. Each router in the segment sends updates to the DR, which in turn relays the information to the other routers. A second router is elected as the backup designated router (BDR) in case the DR goes down.
DR and BDR election is performed via the Hello protocol. The router with the highest OSPF priority becomes the DR for that segment. The same process is then repeated for the BDR. In the case of a tie, the router with the higher router ID (RID) is elected. By default, each interface is given a priority of 1, but you can assign a higher priority to selected interfaces, as required.

Note
The priority setting does not apply to point-to-point, nonbroadcast interfaces.

Disabling MTU Mismatch Detection

The MTU is the largest packet size that a particular interface can handle. If one router sends a DBD packet that is larger than the MTU setting on a neighboring router, the neighboring router ignores the packet. In many cases, an MTU mismatch causes the two routers to become stuck in exstart/exchange state, which prevents OSPF adjacency from being established. This is why it is important that all neighboring routers share the same MTU setting and that MTU mismatch detection be enabled.

You can, however, disable MTU mismatch detection. This is useful in cases where mismatch detection is preventing adjacency from taking place in an otherwise valid setup between two devices with different MTUs.

Blocking LSA Flooding

By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. Although some redundancy is desirable, too much redundancy can waste bandwidth. In certain topologies, such as full mesh, LSA flooding can destabilize the network because of excessive link and CPU usage. Therefore, you can block LSA flooding to selected interfaces on broadcast, nonbroadcast, and point-to-point networks.

Understanding OSPF Timer Settings

OSPF uses a series of timers during operation:

- Hello Interval—Determines how often an interface sends hello packets, which are used to acquire neighbors and act as indicators that the router is still functioning. The smaller the interval, the faster topological changes on the network are detected. However, a smaller interval also results in more traffic being sent over the interface. The hello interval must be the same on all routers and access servers on a specific network.

- Transmit Delay—Determines the delay before an LSA is flooded over the link. The transmit delay setting should take into account the transmission and propagation delays for the interface. These factors are particularly important when configuring low-speed and on-demand links.

- Retransmit Interval—Determines how long to wait before retransmitting an unacknowledged database description (DBD) packet to its neighbors. The retransmit interval setting should be low enough to prevent excessive retransmissions.

  Note You should increase the retransmit interval for serial lines and virtual links.

- Dead Interval—Determines how long an interface should wait before declaring its neighbor to be down. This declaration is caused by an absence of hello packets from the neighbor during this interval. The dead interval setting must be the same for all routers and access servers on a specific network. By default, this interval is four times the hello interval.

Understanding the OSPF Network Type

You can manually configure the OSPF network type on an interface as either broadcast or nonbroadcast multiaccess (NBMA), regardless of the default media type. For example, you can use this feature to configure broadcast networks (such as Ethernet, Token Ring, and FDDI) as NBMA when your network contains routers that do not support multicast addressing. You can also configure NBMA networks (such as X.25, Frame Relay, and SMDS) as broadcast networks, which eliminates the need to configure neighbors.

Configuring NBMA networks as either broadcast or nonbroadcast assumes the existence of virtual circuits (VCs) from every router to every router (fully meshed network). If VCs do not exist between each router, due to cost constraints or the existence of an only partially meshed network, you can configure the OSPF network type as point-to-multipoint. An OSPF point-to-multipoint interface is defined as a numbered point-to-point interface having one or more neighbors. It creates multiple host routes.

If you use the point-to-multipoint network type, routing between two routers that are not directly connected go through a third router that has VCs to both routers. You do not need to configure neighbors when using this feature. OSPF point-to-multipoint networks have the following benefits compared to NBMA and point-to-point networks:

- Point-to-multipoint is easier to configure because it consumes only one IP subnet and does not require neighbor configuration or designated router election.
- It costs less because it does not require a fully meshed topology.
- It is more reliable because it maintains connectivity in the event of VC failure.

Note  
For point-to-multipoint, broadcast networks, you can optionally define neighbors, in which case you should specify the cost to each neighbor. For point-to-multipoint, nonbroadcast networks, you must identify neighbors, but specifying a cost to each neighbor is optional. In both cases, you define neighbors using FlexConfig. See Chapter 7, “Managing FlexConfigs” for more information.

Understanding OSPF Interface Authentication

You define neighbor authentication settings for OSPF interfaces by selecting the interfaces and selecting an authentication type, either MD5 or clear text.

When you use MD5 authentication, neighboring routers must share the same password. When you use clear-text authentication, all routers on the network using OSPF must share the same password.
Whenever you configure an interface with a new key, the router sends multiple copies of the same packet, each authenticated by different keys. The router stops sending duplicate packets when it detects that all of its neighbors have adopted the new key.

**Note**
You should use authentication with all routing protocols when possible, because attackers can use route redistribution between OSPF and other protocols (such as RIP) to subvert routing information.

<tbody>
<tr>
<td>Interface</td>
<td>The OSPF interface to configure. Enter the name of an interface or interface role, or click <strong>Select</strong> to select the object from a list or to create a new one.</td>
</tr>
</tbody>
</table>
| Authentication Type | The authentication type used by the selected interface:  
  - **MD5**—Uses the MD5 hash algorithm for authentication. This is the default.  
  - **Clear Text**—Uses a clear text password for authentication.  
  - **None**—Uses no authentication.  
  **Note** The authentication type used on an interface must match the authentication type defined for the area.  
  **Note** Use plain text authentication only when security is not an issue, for example, to ensure that misconfigured hosts do not participate in routing. |
| Key ID      | The identification number of the authentication key. This number must be shared with all other devices sending updates to, and receiving updates from, the selected device. Valid values range from 1 to 255. |
| Key         | The shared key used for authentication (MD5 or clear text). This key must be shared with all other devices sending updates to, and receiving updates from, the selected device. Enter this key again in the Confirm field.  
  - When using clear text, the key can include any continuous string of characters that can be entered from the keyboard (up to 8 bytes).  
  - When using MD5, the key can include alphanumeric characters only (up to 16 bytes). |
| Cost        | The cost of sending packets over this interface. A value entered here overrides the default calculated cost (10 \(^8\) /bandwidth in bits per second). Valid values range from 1 to 65535. |
| Priority    | The default priority of the interface. The priority is used to determine which routers become the designated router (DR) and backup designated router (BDR) for that segment. The higher the number, the higher the priority.  
  - The default priority is 1. Valid values range from 0 to 255.  
  **Note** To exclude the interface from election as DR or BDR, assign a priority of 0. Configure router priority only for interfaces to multiaccess networks, not point-to-point networks. |

<tr>
<td></td>
<td><strong>Note</strong>  When you configure slow links or on-demand links that queue traffic before sending it in bursts, we recommend that you take these link delays into account when defining this value.</td>
</tr>
<tr>
<td>Retransmit Interval</td>
<td>The interval between LSA retransmissions (in seconds) over the selected interface. The default is 5 seconds. Valid values range from 1 to 65535 seconds.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  We recommend that you increase this value for serial lines and virtual links.</td>
</tr>
<tr>
<td>Dead Interval</td>
<td>The interval (in seconds) after which an interface declares its neighbor dead if no hello packets are received. Valid values range from 1 to 65535 seconds.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  The value of the dead interval is typically the hello interval value multiplied by 4. The dead interval must be the same for all routers and access servers in the network.</td>
</tr>
</tbody>
</table>
OSPF is an interior gateway routing protocol that uses link states instead of distance vectors for path selection. OSPF propagates link-state advertisements (LSAs) instead of routing table updates, which enables OSPF networks to converge quickly.

You can configure OSPF process policies from the following tabs on the OSPF Process page:

- **OSPF Process Page—Setup Tab, page 63-35**
- **OSPF Process Page—Area Tab, page 63-36**
- **OSPF Process Page—Redistribution Tab, page 63-38**

For more information, see **OSPF Routing on Cisco IOS Routers, page 63-19.**

### Table 63-12 OSPF Interface Dialog Box (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| Configure Network Type   | When selected, enables you to select a network type that differs from the default medium used by the interface. When deselected, the network type is equivalent to the default medium used by the interface. For nonbroadcast multiaccess (NBMA) networks (such as ATM and Frame Relay), options are:  
  - Broadcast—Treats the NBMA network as a broadcast network, which eliminates the need to configure neighbors. Use this option when there are virtual circuits from every router to every router (fully meshed network).
  - Point-to-Multipoint—Treats the nonbroadcast network as a series of point-to-point links. This option is easier to configure, less costly, and more reliable than NBMA or point-to-point networks.
  - Point-to-Multipoint Non-Broadcast—Statically maintains the known neighbors of the network. Selecting this option helps avoid the problem of losing neighbors that were learned dynamically through the reception of hello packets.  
  
  **Note** Another option for NBMA networks is to configure neighbors manually using FlexConfigs. See **Understanding FlexConfig Policies and Policy Objects, page 7-2.**  
  
  For broadcast networks (such as Ethernet, Token Ring, and FDDI), you can select:  
  - Non-Broadcast—Treats the broadcast network as a nonbroadcast network.  
  - Point-to-Point—Treats the broadcast network as a point-to-point network. You can use this option, for example, to configure a broadcast network (such as Ethernet) as a nonbroadcast multiaccess (NBMA) network if not all routers in the network support multicast addressing. |
For more information about OSPF interface policies, see OSPF Interface Policy Page, page 63-30.

Navigation Path
- (Device view) Select Platform > Routing > OSPF Process from the Policy selector.
- (Policy view) Select Router Platform > Routing > OSPF Process from the Policy Type selector. Right-click OSPF Process to create a policy, or select an existing policy from the Shared Policy selector.

**OSPF Process Page—Setup Tab**

Use the OSPF Process Setup tab to create, edit, and delete OSPF processes. This includes selecting those interfaces that will remain passive, which means that they will not send routing updates to their neighbors. You can create as many processes for each router as required.

Navigation Path
Go to the OSPF Process Policy Page, page 63-34, then click the Setup tab.

RIP Routing on Cisco IOS Routers

Routing Information Protocol (RIP) is an Interior Gateway Protocol (IGP) that was created for use in small, homogeneous networks. RIP is a distance-vector protocol that sends routing-update messages at regular intervals (in a process called *advertising*) and whenever the network topology changes. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. If a router does not receive an update from another router for 180 seconds or more, it marks the routes served by the non-updating router as being unusable. If there is still no update after 240 seconds, the router removes all routing table entries for the non-updating router. Routing information is exchanged using UDP packets.

RIP evaluates routes by measuring the number of hops (the number of routers traversed) from the source to the destination. A directly connected network has a metric of zero. The maximum hop count allowed by RIP is 15. Any route with a hop count greater than 15 is considered unreachable.

Security Manager supports RIP version 2 only, which is described in RFC 1723. RIP 2 improves on the original RIP by enabling RIP messages to carry more information, which permits the use of a simple authentication mechanism (clear text or MD5) to secure table updates. RIP 2 also supports subnet masks, a critical feature that was not available in the original version of RIP.

The following topics describe the tasks you perform to create a RIP routing policy:

- Defining RIP Setup Parameters, page 63-42
- Defining RIP Interface Authentication Settings, page 63-43
- Redistributing Routes into RIP, page 63-44

**Related Topics**

- Static Routing on Cisco IOS Routers, page 63-50
- OSPF Routing on Cisco IOS Routers, page 63-19
- EIGRP Routing on Cisco IOS Routers, page 63-8
- BGP Routing on Cisco IOS Routers, page 63-1

## Defining RIP Setup Parameters

You configure RIP setup parameters by selecting the networks to include in the route and deciding whether any interfaces should be passive. These interfaces do not send routing updates to their neighbors. Additionally, you can enable auto-summarization, which reduces the size and complexity of the routing tables the router must maintain.

**Related Topics**

- Defining RIP Interface Authentication Settings, page 63-43
- Redistributing Routes into RIP, page 63-44
- RIP Routing on Cisco IOS Routers, page 63-42

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Routing > RIP** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Routing > RIP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.
The RIP Setup tab is displayed (see RIP Page—Setup Tab, page 63-45).

Step 2 Enter the addresses of the directly connected networks whose interfaces are to receive RIP updates. You can use a combination of addresses and network/host objects; separate addresses with commas. Click Select to select network/host objects from a list of existing objects, or to create new network/host objects. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

Step 3 Enter the addresses of the passive interfaces, which are interfaces that should not send routing updates to their neighbors, if any. These interfaces continue to receive RIP routing broadcasts, which they use to populate their routing tables. Enter the names of one or more interfaces or interface roles; separate addresses with commas. Click Select to select interface names or roles from a list of existing objects, or to create new interface role objects. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 4 (Optional) Select the Auto Summary check box to enable the automatic summarization of subnet routes into network-level routes. Summarization reduces the size of routing tables, thereby reducing the complexity of the network.

Defining RIP Interface Authentication Settings

You define neighbor authentication settings for RIP interfaces by selecting the interfaces and then selecting an authentication type, either MD5 or clear text.

Related Topics
- Defining RIP Setup Parameters, page 63-42
- Redistributing Routes into RIP, page 63-44
- RIP Routing on Cisco IOS Routers, page 63-42

Step 1 Do one of the following:
- (Device view) Select Platform > Routing > RIP from the Policy selector, then click the Authentication tab in the work area.
- (Policy view) Select Router Platform > Routing > RIP from the Policy Type selector. Select an existing policy or create a new one, and then click the Authentication tab.

The RIP Authentication tab is displayed. See Table 63-21 on page 63-46 for a description of the fields on this tab.

Step 2 On the RIP Authentication tab, select an interface definition from the table, then click Edit, or click Add to create a definition. The RIP Authentication dialog box appears. See Table 63-22 on page 63-47 for a description of the fields in this dialog box.

Step 3 Enter the name of the interface or interface role for which authentication is defined, or click Select to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition, page 6-65.

Step 4 Define interface authentication (MD5 or clear text).
Chapter 63      Configuring Routing Policies

RIP Routing on Cisco IOS Routers

Note

We do not recommend that you use clear text authentication in RIP packets, because the unencrypted authentication key is sent in every packet. Use plain text authentication only when security is not an issue, for example, to ensure that misconfigured hosts do not participate in routing.

Step 5

Click OK to save your definitions locally on the client and close the dialog box. The defined interface appears on the RIP Authentication tab.

Redistributing Routes into RIP

Redistribution refers to using a routing protocol, such as RIP, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you can redistribute routes from the OSPF routing protocol into your RIP route. Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

When you redistribute into RIP, you can maintain the original metric of the route by redistributing it transparently.

Before You Begin

- Define at least one RIP route. See Defining RIP Setup Parameters, page 63-42.

Related Topics

- Defining RIP Setup Parameters, page 63-42
- Defining RIP Interface Authentication Settings, page 63-43
- RIP Routing on Cisco IOS Routers, page 63-42

Step 1

Do one of the following:

- (Device view) Select Platform > Routing > RIP from the Policy selector, then click the Redistribution tab in the work area.
- (Policy view) Select Router Platform > Routing > RIP from the Policy Type selector. Select an existing policy or create a new one, and then click the Redistribution tab.

The RIP Redistribution tab is displayed. See Table 63-23 on page 63-48 for a description of the fields on this tab.

Step 2

On the RIP Redistribution tab, select a row from the RIP Redistribution Mappings table, then click Edit, or click Add to create a mapping. The RIP Redistribution Mapping dialog box appears. See Table 63-24 on page 63-49 for a description of the fields in this dialog box.

Step 3

Select the protocol whose routes you want to redistribute into RIP.

Note

You can create a single mapping for each static route, BGP AS, EIGRP AS, and OSPF process.

Step 4

Define the metric (cost) of the redistributed routes by doing one of the following:
Select the **Default Metric** check box, then enter the default metric of the redistributed routes. The metric determines the priority of the routes.

Select the **Transparent** check box to maintain the original metric of the routes being redistributed into RIP.

**Step 5**

Click **OK** to save your definitions locally on the client and close the dialog box. The redistribution mapping appears in the Redistribution Mapping table on the RIP Redistribution tab.

---

### RIP Routing Policy Page

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection. Security Manager supports RIP version 2 only, which includes support for neighbor authentication when routing updates are exchanged.

You can configure RIP routing policies from the following tabs on the RIP Routing page:

- **RIP Page—Setup Tab**, page 63-45
- **RIP Page—Authentication Tab**, page 63-46
- **RIP Page—Redistribution Tab**, page 63-48

For more information, see **RIP Routing on Cisco IOS Routers**, page 63-42.

#### Navigation Path

- (Device view) Select **Platform > Routing > RIP** from the Policy selector.
- (Policy view) Select **Router Platform > Routing > RIP** from the Policy Type selector. Right-click **RIP** to create a policy, or select an existing policy from the Shared Policy selector.

### RIP Page—Setup Tab

Use the RIP Setup tab to create, edit, and delete RIP routes.

#### Navigation Path

Go to the **RIP Routing Policy Page**, page 63-45, then click the **Setup** tab.

#### Related Topics

- Defining RIP Setup Parameters, page 63-42

</tbody>
</table>
Static Routing on Cisco IOS Routers

You can configure static routing policies to ensure that the router correctly forwards packets to their destination when a route cannot be built dynamically. By default, static routes have a default administrative distance of 1 (implying a directly connected network), which causes them to override any dynamic routes discovered for the same host or network. You can, however, define a larger administrative distance to a static route so that it does not take precedence over a corresponding dynamic route.

For example, EIGRP routes have a default administrative distance of 5. To have a static route that can be overridden by an EIGRP route, you must specify an administrative distance greater than 5. This feature is useful when you define the static route as a “floating” route, which is inserted into the routing table only when the preferred route is unavailable.

**Tip**

When you use the static route as a backup, “floating” route, specify the interface through which the next hop IP address can be reached instead of entering a specific IP address. Otherwise, the “floating” route is not inserted in the routing table if the primary link fails. For more information, see *Specifying a Next Hop IP Address for Static Routes* on Cisco.com at this URL:

**Related Topics**

- Defining Static Routes, page 63-50

### Defining Static Routes

To define a static route, you must define the IP address (and optionally, the metric) of the hop gateway to which the router forwards packets destined to the selected host or network. You can define as many static routes as required.

**Related Topics**

- Static Routing on Cisco IOS Routers, page 63-50
- RIP Routing on Cisco IOS Routers, page 63-42
- OSPF Routing on Cisco IOS Routers, page 63-19
- EIGRP Routing on Cisco IOS Routers, page 63-8
- BGP Routing on Cisco IOS Routers, page 63-1

**Step 1**

Do one of the following:

- (Device view) Select **Platform > Routing > Static Routing** from the Policy selector.
• (Policy view) Select **Router Platform > Routing > Static Routing** from the Policy Type selector. Select an existing policy or create a new one.

The Static Routing page is displayed. See Table 63-25 on page 63-52 for a description of the fields on this page.

**Step 2** On the Static Routing page, select a static route from the table, then click **Edit**, or click **Add** to create a route. The Static Routing dialog box appears. See Table 63-26 on page 63-53 for a description of the fields in this dialog box.

**Step 3** (Optional) Select the **Use as Default Route** check box to make this route the default route for all unknown outbound packets.

**Step 4** In the Prefix field, enter the address for the destination network, or click **Select** to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

**Step 5** Select a forwarding option:

- To define the router interface that forwards packets to the remote network, select **Forwarding Interface** and enter the name of an interface or interface role. You can click Select to select an interface role from a list or to create a new one. See Understanding Interface Role Objects, page 6-62 and Selecting Objects for Policies, page 6-2.

- To specify the next hop router that receives and forwards packets to the remote network, select **Forwarding IP**, then enter the address in the field provided, or click **Select** to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition, page 6-77.

**Step 6** (Optional) In the Distance Metric field, enter the number of hops to the next hop address for this router. This metric identifies the priority of the static route. If two routing entries specify the same network, the route with the lower metric value (that is, the lower cost) is given a higher priority and is selected.

If no value is specified, the default is 1, which implies a directly connected network.

**Step 7** (Optional) Select the **Permanent route** check box to prevent this static route entry from being deleted, even in cases in which the interface is shut down or the router cannot communicate with the next router.

**Step 8** Click **OK** to save your definitions locally on the client and close the dialog box. The static route appears in the table on the Static Routing page.

---

### Static Routing Policy Page

Use the Static Routing page to create, edit, and delete static routes. For more information, see Defining Static Routes, page 63-50.

**Navigation Path**

- (Device view) Select **Platform > Routing > Static Routing** from the Policy selector.

- (Policy view) Select **Router Platform > Routing > Static Routing** from the Policy Type selector. Right-click **Static Routing** to create a policy, or select an existing policy from the Shared Policy selector.

Managing Cisco Catalyst Switches and Cisco 7600 Series Routers

Cisco Security Manager supports the management and configuration of security services and other platform-specific services on Cisco Catalyst switches and Cisco 7600 Series routers.

You can manage Catalyst switches and 7600 devices configured in VTP transparent or VTP client/server mode. Security Manager manages switches configured in client/server mode by bypassing VLAN database management on the device (including VLAN creation, deletion, and monitoring VLANs in the VLAN database on switches).

This chapter contains the following topics:
- Discovering Policies on Cisco Catalyst Switches and Cisco 7600 Series Routers, page 64-1
- Viewing Catalyst Summary Information, page 64-2
- Viewing a Summary of Catalyst Interfaces, VLANs, and VLAN Groups, page 64-3
- Interfaces, page 64-5
- VLANs, page 64-25
- VLAN Groups, page 64-31
- VLAN ACLs (VACLs), page 64-36
- IDSM Settings, page 64-43

Discovering Policies on Cisco Catalyst Switches and Cisco 7600 Series Routers

You can discover the configurations of your Cisco Catalyst switches and Cisco 7600 Series Routers (as well as the configurations of the services modules and security contexts associated with them) and import the configurations as policies into Security Manager. This makes it possible to add existing devices and manage them with Security Manager without having to configure each device manually, policy by policy. For more information, see Adding Devices to the Device Inventory, page 3-7.

You can discover any command that Security Manager can configure. Discovery ignores unsupported commands, which means that they are left intact on the device even after subsequent deployments. Additionally, in cases where Security Manager can discover the command, but not all the subcommands and keywords related to that command, the unsupported elements are ignored and left intact on the device.
At any time, you can also _rediscover_ the configurations of devices that you are already managing with Security Manager. Be aware, however, that we do not recommend rediscovery generally because performing rediscovery overwrites the policies that you have defined in Security Manager. For more information, see Discovering Policies on Devices Already in Security Manager, page 5-15.

**Note**

We recommend that you perform deployment immediately after you discover policies, _before_ you make any changes to policies or unassign policies from the device. (This recommendation also applies to any services module or security context hosted by the device.) Otherwise, the changes that you configure in Security Manager might not be deployed to the device. See Working with Deployment and the Configuration Archive, page 8-24.

### Viewing Catalyst Summary Information

Use the Catalyst Summary Info page to view high-level system information, including any service modules, ports, and VLANs that Security Manager has discovered.

To view Catalyst summary information, in Device view, right-click a Catalyst switch or Cisco 7600 Series router, then select Catalyst Summary Info, or select **Tools > Catalyst Summary Info**.

**Note**

If Security Manager has not completed discovery for a particular Cisco Catalyst switch or Cisco 7600 Series router, the Catalyst Summary Info page for that device displays this message: “No information is available. This information is acquired during device discovery.”

**Related Topics**
- IDSM Settings Page, page 64-47

</table>
Viewing a Summary of Catalyst Interfaces, VLANs, and VLAN Groups

Use the Summary tab of the Interfaces/VLAN policy to view attributes of all VLANs, VLAN groups, interfaces, and subinterfaces configured on supported Catalyst 6500 Series and 7600 Series chassis and their associated services modules.

To view summary interface information, in Device view, select Interfaces/VLANs from the Policy selector, then click the Summary tab.

Note
The Summary tab is available only for Cisco Catalyst 6500 Series switches and Cisco 7600 Series routers.

### Field Reference

#### Table 64-2 Interfaces/VLANs Page—Summary Tab

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN ID</td>
<td>The VLAN ID associated with an interface or subinterface. The VLAN ID specifies where 802.1Q tagged packets are sent and received on the specified an interface or subinterface; without a VLAN ID, the interface or subinterface cannot send or receive traffic. <strong>Note</strong> All VLAN IDs must be unique among all subinterfaces configured on the same physical interface.</td>
</tr>
<tr>
<td>VLAN Name</td>
<td>Name of the VLAN that corresponds to an interface or subinterface. For example, VLAN003 or Trunk1.</td>
</tr>
<tr>
<td>VLAN Group</td>
<td>Numeric identity of a VLAN group that is configured on the VLAN that a table row describes.</td>
</tr>
<tr>
<td>VLAN Type</td>
<td>Specifies whether a VLAN has access to Layer 2 or Layer 3.</td>
</tr>
<tr>
<td>IP Address/Mask</td>
<td>The IP address and corresponding subnet mask of the VLAN configured on an interface or subinterface.</td>
</tr>
<tr>
<td>Access Port</td>
<td>Displays the assigned name, if a name is assigned, of the access port that a VLAN uses.</td>
</tr>
<tr>
<td>Trunk Port</td>
<td>Specifies which VLANs are permitted to carry traffic over the trunk.</td>
</tr>
<tr>
<td>Slot (-Port)</td>
<td>Associates the chassis slot number (in which the relevant services module is installed) with the port number, as a hyphenated pair in the format x-y, for example 3-1.</td>
</tr>
<tr>
<td>Blade Type</td>
<td>Identifies the kind of services module on which a particular VLAN is configured, such as FWSM or VPNSM.</td>
</tr>
<tr>
<td>Security Context</td>
<td>Identifies the security context associated with an interface, but only if Multiple Mode is active on the installed module and an Admin context is configured for the module.</td>
</tr>
<tr>
<td>Security Context Interface</td>
<td>Displays the physical interface and subinterface IDs for which a security context inspects traffic. The displayed ID can represent a physical interface, a single sub-interface (defined as a range of one), or a range of sub-interfaces.</td>
</tr>
<tr>
<td>Security Level</td>
<td>Displays the security level of an interface, where values range from 0 (the lowest security) to 100 (the highest):</td>
</tr>
<tr>
<td></td>
<td>- For an outside interface, the default is 0.</td>
</tr>
<tr>
<td></td>
<td>- For an inside interface, the default is 100.</td>
</tr>
<tr>
<td></td>
<td>- For an interface in the DMZ, the default is typically from 1 to 99.</td>
</tr>
</tbody>
</table>
Interfaces

You use the Interfaces tab on the Interfaces/VLANs page to view and manage the following types of ports:

- **Access ports**—A switching port that is used to connect host machines or servers. An access port belongs to and carries the traffic of only one VLAN. Traffic is received and sent in native formats with no VLAN tagging.

- **Trunk ports**—A switching port operating at Layer 2 to carry the traffic of multiple VLANs. Traffic is tagged with a VLAN number to differentiate traffic from each VLAN. A trunk port is used to connect switches to switches or to connect switches to routers.

- **Routed ports**—A physical port that acts like a port on a router. A routed port is not associated with a particular VLAN, and it behaves like a regular router interface. You can configure a routed port with a Layer 3 routing protocol.

- **Dynamic ports**—A port that can change dynamically to a trunk port if the neighboring port is configured as a trunk port.

- **Unsupported ports**—Ports on the Catalyst device that are not supported by Security Manager.

To display the Interfaces tab, select a Catalyst device in Device view, select Interfaces/VLANs from the Policy selector, then click the Interfaces tab in the work area.

The following topics describe the actions you can perform when defining interfaces on Catalyst devices:

- **Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers**, page 64-5
- **Deleting Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers**, page 64-7
- **Interfaces/VLANs Page—Interfaces Tab**, page 64-7

**Related Topics**

- VLANs, page 64-25
- VLAN Groups, page 64-31
- VLAN ACLs (VACLs), page 64-36
- Chapter 64, “Managing Cisco Catalyst Switches and Cisco 7600 Series Routers”

**Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers**

You can create access ports, routed ports, or trunk ports on Cisco Catalyst Switches and Cisco 7600 Series Routers, with these restrictions:

- Each interface must have a name.
- You can associate an access port with only one VLAN.
- You can associate a trunk port with one or more VLANs.

**Related Topics**

- Deleting Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers, page 64-7
- Creating or Editing VLANs, page 64-26
- Creating or Editing VLAN Groups, page 64-32
Step 1  (Device view) Select a Catalyst device, select **Interfaces/VLANs** from the Policy selector, then click the Interfaces tab in the work area.

The Interfaces tab is displayed. For a description of the fields on this tab, see **Interfaces/VLANs Page—Interfaces Tab, page 64-7**.

Step 2  Do one of the following:

- To define the attributes of a new interface, click **Add Row**.
- To edit the attributes of an interface, select it in the list, then click **Edit Row**.

Step 3  (Optional) Deselect the **Enable Interface** check box if you want this interface to be in shutdown mode.

Step 4  From the Type list, select **Interface** or **Subinterface**:

Step 5  (Interfaces only) Enter a name for the interface. You can click **Select** to open a dialog box that will help you generate a standard name based on interface type and details about the interface’s location, such as card, slot, and subinterface. For more information on using the dialog box to generate an interface name, see **Interface Auto Name Generator Dialog Box, page 58-12**.

Step 6  (Interfaces only) Select an option from the **Mode** list to specify the port configuration type. The fields in the dialog box vary according to your selection.

Step 7  (Subinterfaces only) Select the parent interface of the subinterface, then enter the ID number.

Step 8  Define or configure the settings for the type that you selected:

- **Access Port**—See **Create and Edit Interface Dialog Boxes—Access Port Mode, page 64-9** for a description of the fields.
- **Routed Port**—See **Create and Edit Interface Dialog Boxes—Routed Port Mode, page 64-12** for a description of the fields.
- **Trunk Port**—See **Create and Edit Interface Dialog Boxes—Trunk Port Mode, page 64-14** for a description of the fields.
- **Dynamic Port**—See **Create and Edit Interface Dialog Boxes—Dynamic Mode, page 64-18** for a description of the fields.
- **Subinterface**—See **Create and Edit Interface Dialog Boxes—Subinterfaces, page 64-22** for a description of the fields.
- **Unsupported**—See **Create and Edit Interface Dialog Boxes—Unsupported Mode, page 64-24** for a description of the fields.

Step 9  From the **Speed** list, select an option to define the speed of the interface.

Step 10  If you defined a specific speed for the interface, and therefore the Duplex list is enabled, select a duplexing option.

Step 11  In the MTU field, enter the maximum transmission unit value.

Step 12  Configure whether to use flow control on inbound (Receive) and outbound (Send) traffic.

Step 13  (Optional) Enter a description for the interface in the **Description** field.

Step 14  Click **OK** to save your definitions locally on the client and close the dialog box.
Deleting Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers

Although you can delete the definition of an interface at any time, use this option with great care. If the relevant device includes the interface definition in any policy definitions, deleting the interface causes these policy definitions to fail when they are deployed to the device.

Related Topics
- Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers, page 64-5
- Interfaces, page 64-5

Step 1  (Device view) Select a Cisco Catalyst switch or Cisco 7600 Series router from the Device selector.
Step 2  Select Interfaces/VLANs from the Policy selector.
Step 3  Click the Interfaces tab in the work area.

The Interfaces tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—Interfaces Tab, page 64-7.
Step 4  Select an interface from the table, then click Delete Row. The interface is deleted.

Interfaces/VLANs Page—Interfaces Tab

Use the Interfaces tab to view and configure interfaces and subinterfaces on supported Cisco Catalyst switches and Cisco 7600 Series routers and their associated services modules (blades).

Navigation Path
(Device view) Select Interfaces/VLANs from the Device selector, then click the Interfaces tab.

### Table 64-4  Create and Edit Interface Dialog Boxes—Access Port Mode (Continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Access Port settings**         | *
| VLAN ID (Select button)          | Displays the interface-specific identity of the VLAN to use in access port mode, if you have selected a VLAN. Otherwise, click *Select* to open the VLAN Selector Dialog Box, page 64-35. The VLAN ID specifies where 802.1Q tagged packets are sent and received on the subinterface; without a VLAN ID, the subinterface cannot send or receive traffic. Valid values range from 1 to 4094. Some VLAN IDs might be reserved on connected devices, so see the device documentation for more information. For multiple context mode, you can only set the VLAN in the system configuration. |
| **Note**                         | All VLAN IDs must be unique among all subinterfaces configured on the same physical interface.                                                                                                   |
| **Tip**                          | To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the `vlan-id dot1q` command using CLI commands or FlexConfigs. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the device. |
| Enable Port Security             | When selected, enables you to restrict input to an interface by limiting the MAC addresses that are allowed to access the port. When deselected, disables port security.                             |
| Max. MAC Addresses               | Applies only when Enable Port Security is selected. The maximum number of secure MAC addresses for the interface. Valid values range from 1 to 4097. Secure MAC addresses are configured dynamically using the MAC addresses of connected devices. |
| **Violation Policy**             | The action to take if a security violation occurs:                                                                                                                                               |
| • Port Security Protect          | Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value.                                                 |
| • Port Security Restrict         | Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value. In addition, it causes the SecurityViolation counter to increment. |
| • Port Security Shutdown         | Immediately puts the interface into the error-disabled state and sends an SNMP trap notification. A security violation occurs if a workstation whose MAC address is not in the address table attempts to access the interface after the maximum number of secure MAC addresses is configured. |
| Enable VACL Capture              | When selected, enables VACL capture. If the capture bit is set, ports with the capture function enabled can receive forwarded packets. When deselected, disables VACL capture. |
Capture VLANs (Select button) Enables you to identify the VLANs where VACLs should receive forwarded VLAN packets. This option is available if you selected the Enable VACL Capture check box.
Enter a comma-separated list of VLAN IDs or click Select to open the VLAN Selector Dialog Box, page 64-35.
VACLs can capture VLAN packets only when they are initially routed or bridged into the VLAN. Only forwarded packets can be captured.

**Common interface settings**

<table>

</table>
Native VLAN (Select button) Enables you to select the Native VLAN to associate with this interface, using the ID specified in the VLAN ID field. (If no VLAN ID is specified for the Native VLAN, the default is 1.) This option applies to you only if you are configuring a physical interface that is meant to serve as an 802.1Q trunk interface. You must first specify DOT1Q as the encapsulation type.

The Native VLAN of a trunk interface is the VLAN to which all untagged VLAN packets are logically assigned. This includes the management traffic associated with the VLAN. When deselected, the Native VLAN is not associated with this interface.

Note The Native VLAN cannot be configured on a subinterface of the trunk interface. Be sure to configure the same Native VLAN value at both ends of the link; otherwise, traffic may be lost or sent to the wrong VLAN.

Click Select to open the VLAN Selector Dialog Box, page 64-35. From here, you can associate a native VLAN with the described interface.

Enable DTP negotiation When selected, enables Dynamic Trunking Protocol (DTP) negotiation. DTP manages trunk auto-negotiation (ISL and 802.1Q) between devices. When deselected, disables DTP negotiation.

Allowed VLANs (Select button) Enables you to specify which VLANs are allowed on the trunk. Enter the VLAN IDs. Use commas to separate multiple VLANs or use a hyphen to indicate a range of VLANs (for example, 12,17,22 or 2-200). Valid IDs range from 1 to 4094.

Or, click Select to open the VLAN Selector Dialog Box, page 64-35. From here, you can select the VLANs to include on the trunk.

Prune VLANs (Select button) Enables you to specify which VLANs are eligible for pruning. Enter the VLAN IDs. Use commas to separate multiple VLANs or use a hyphen to indicate a range of VLANs (for example, 12,17,22 or 2-200.)

Or, click Select to open the VLAN Selector Dialog Box, page 64-35. From here, you can select the VLANs that are eligible for pruning.

Enable VACL Capture When selected, enables VACL capture. If the capture bit is set, ports with the capture function enabled can receive forwarded packets. When deselected, disables VACL capture.

Capture VLANs (Select button) Enables you to identify the VLANs where VACLs should receive forwarded VLAN packets. This option is available if you selected the Enable VACL Capture check box.

Enter a comma-separated list of VLAN IDs, or click Select to open the VLAN Selector Dialog Box, page 64-35.

VACLs can capture VLAN packets only when they are initially routed or bridged into the VLAN. Only forwarded packets can be captured.
Enable Port Security: Applies only to devices running IOS Software Version 12.2(18)SXE2 or later. When selected, enables you to restrict input to an interface by limiting the MAC addresses that are allowed to access the port. When deselected, disables port security.

Note: If you select this option, the Enable DTP Negotiation option is automatically deselected.

Max. MAC Addresses: Applies only when Enable Port Security is selected. The maximum number of secure MAC addresses for the interface. Valid values range from 1 to 4097.

Note: Secure MAC addresses are configured dynamically using the MAC addresses of connected devices.

Violation Policy: The action to take if a security violation occurs:

- Port Security Protect—Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value.
- Port Security Restrict—Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value. In addition, it causes the SecurityViolation counter to increment.
- Port Security Shutdown—Immediately puts the interface into the error-disabled state and sends an SNMP trap notification.

A security violation occurs if a workstation whose MAC address is not in the address table attempts to access the interface after the maximum number of secure MAC addresses is configured.

### Common interface settings

**Speed**

The speed of the physical interface:

- 10—Transmits at 10 Mbps.
- 100—Transmits at 100 Mbps.
- 1000—Transmits at 1,000 Mbps.
- 10000—Transmits at 10,000 Mbps.
- Auto—If Speed is set to Auto, both Speed and Duplex are autonegotiated.
- Non-Negotiate—Disables link negotiation.

**Duplex**

The duplex setting of the interface:

- Auto—Autonegotiates the duplex.
- Half—Sends and receives data, but not at the same time.
- Full—Sends and receives data at the same time.

If the speed is set to Auto, the duplex setting must also be set to Auto.
Create and Edit Interface Dialog Boxes—Dynamic Mode

Use the Create Interface dialog box (or the Edit Interface dialog box) to configure the attributes of physical and virtual interfaces that run in dynamic mode. Dynamic ports can convert the link into a trunk link based on the settings of the neighboring port.

Navigation Path
Go to the Interfaces/VLANs Page—Interfaces Tab, page 64-7, click Add or Edit to open the Create/Edit Interface dialog box, then select Dynamic from the Mode list.

Related Topics

</table>
Create and Edit Interface Dialog Boxes—Unsupported Mode

If you discover an interface configured with a mode that is not supported by Security Manager (such as dot1q-tunnel or private-vlan), the interface is displayed in Unsupported mode. You can view the attributes of this interface, but you cannot make any changes to the configuration unless you first change the mode. All definition fields, other than Mode, are read-only.

Navigation Path

Go to the Interfaces/VLANs Page—Interfaces Tab, page 64-7, select an interface whose mode is defined as Unsupported, then click Add or Edit to open the Create/Edit Interface dialog box.

### VLANs

A VLAN is a switched network that is segmented logically instead of on the basis of geography. For example, a VLAN might interconnect members of a geographically dispersed workgroup. VLANs offer a practical convenience for many organizations because they reduce the need to rearrange the physical placement of personnel, equipment, and network infrastructure. Properly configured VLANs are scalable, secure, and can simplify the tasks of network management.

A VLAN consists of hosts and network devices (such as bridges and routers), connected by a single bridging domain. Traffic between VLANs must be routed.
Security Manager helps you to create VLANs and define VLAN settings for the defined interfaces on Cisco Catalyst switches and Cisco 7600 Series routers, their supported services modules, and their security contexts.

The following topics describe the actions you can perform when defining VLANs on Catalyst devices:

- Creating or Editing VLANs, page 64-26
- Deleting VLANs, page 64-27
- Interfaces/VLANs Page—VLANs Tab, page 64-27

Related Topics
- VLAN Groups, page 64-31
- VLAN ACLs (VACLs), page 64-36
- Chapter 64, “Managing Cisco Catalyst Switches and Cisco 7600 Series Routers”

### Creating or Editing VLANs

You can create a VLAN or reconfigure the attributes of a VLAN.

Related Topics
- Deleting VLANs, page 64-27
- Creating or Editing VLAN Groups, page 64-32
- Creating or Editing VACLs, page 64-37
- Create and Edit VLAN Dialog Boxes, page 64-28
- VLANs, page 64-25

**Step 1**
(Device view) Select a Catalyst device, select Interfaces/VLANs from the Policy selector, then click the VLANs tab in the work area.

The VLANs tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLANs Tab, page 64-27.

**Step 2**
Do one of the following:
- To define the attributes of a new VLAN, click Add Row.
- To edit the attributes of a VLAN, select it in the list, then click Edit Row.

See Create and Edit VLAN Dialog Boxes, page 64-28, for a description of the fields in the dialog box.

**Step 3**
In the VLAN ID field, enter a unique ID number for the VLAN. The number that you enter must not be assigned to any other VLAN in the bridging group.

**Step 4**
(Optional) Enter a name for the VLAN.

**Step 5**
(Optional) If the VLAN is part of a VLAN group, select the group ID, or select Add Group to open the Create VLAN Group dialog box. For more information, see Creating or Editing VLAN Groups, page 64-32.

**Step 6**
From the Status list, specify the status of the VLAN (active or suspended).

**Step 7**
From the Type list, select either Layer 2 or Layer 3.
Step 8  (Optional) For a Layer 3 VLAN, define a switched virtual interface (SVI):

a. To make the SVI active, select the **Enable Interface** check box. An SVI enables routing between VLANs and provides IP host connectivity to the switch. If you do not select this check box, the SVI is created in shutdown mode.

b. Enter the IP address for the SVI.

c. Enter the SVI subnet mask by typing it, or select a netmask value from the Subnet Mask list.

d. Enter an optional description, if required.

Step 9  Do one or both of the following:

- To associate access ports with the VLAN, enter their names in the Access Ports text box or click **Select** to open an interface selector.

- To associate trunk ports with the VLAN, enter their names in the Trunk Ports text box or click **Select** to open an interface selector.

See Interface Selector Dialog Box—VLAN ACL Content, page 64-42 for a description of the fields in the dialog box. For more information about defining ports, see Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers, page 64-5.

Step 10  Click **OK** to save your definitions locally on the client and close the dialog box.

### Deleting VLANs

You can delete a VLAN. However, deleting a VLAN does not delete it from any policy that might reference it. Ensure that your other policies do not use the VLAN before you delete it. When you submit your changes to the database, Security Manager points out any undefined VLANs that are referenced by other policies.

**Related Topics**

- Creating or Editing VLANs, page 64-26
- VLANs, page 64-25

Step 1  (Device view) Select a Cisco Catalyst switch or Cisco 7600 Series router from the Device selector.

Step 2  Select **Interfaces/VLANs** from the Policies selector.

Step 3  Click the VLANs tab in the work area.

The VLANs tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLANs Tab, page 64-27.

Step 4  Select a VLAN from the table, then click **Delete Row**.

The VLAN is deleted.

### Interfaces/VLANs Page—VLANs Tab

Use the VLANs tab to view and configure VLANs on supported Cisco Catalyst switches and Cisco 7600 Series routers.
Navigation Path

- (Device view) Select Interfaces/VLANs from the Device selector, then click the VLANs tab.

VLAN Groups

A VLAN group defines a logical collection of VLANs. The VLAN Groups tab on the Interfaces/VLANs page displays:

- All VLAN groups that are defined on the selected device.
- The service module slots to which a VLAN group is bound.
VLAN Groups

- Which VLANs belong to each VLAN group.

VLAN groups can be used when assigning VLANs to an FWSM security context. A VLAN group can be assigned to multiple FWSMs, and each FWSM can have multiple VLAN groups assigned to it. To perform this assignment, see Add/Edit Security Context Dialog Box (FWSM), page 56-5.

The following topics describe the actions you can perform when defining VLAN groups on Catalyst devices:

- Creating or Editing VLAN Groups, page 64-32
- Deleting VLAN Groups, page 64-33
- Interfaces/VLANs Page—VLAN Groups Tab, page 64-33

Related Topics
- Interfaces, page 64-5
- VLANs, page 64-25
- VLAN ACLs (VACLs), page 64-36
- Chapter 64, “Managing Cisco Catalyst Switches and Cisco 7600 Series Routers”

Creating or Editing VLAN Groups

You can create VLAN groups. When you create a VLAN group, remember that:

- Each group must have an ID.
- You can associate a VLAN group with one or more FWSM modules.
- Each VLAN can be a member of only one VLAN group.

Related Topics
- Deleting VLAN Groups, page 64-33
- Creating or Editing VLANs, page 64-26
- Creating or Editing VACLs, page 64-37
- Interfaces/VLANs Page—VLAN Groups Tab, page 64-33
- VLAN Groups, page 64-31

Step 1  (Device view) Select a Catalyst device, select Interfaces/VLANs from the Policy selector, then click the VLAN Groups tab in the work area.

The VLAN Groups tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLAN Groups Tab, page 64-33.

Step 2  Do one of the following:

- To define the attributes of a new VLAN group, click Add Row.
- To edit the attributes of a VLAN group, select it in the list, then click Edit Row.

See Create and Edit VLAN Group Dialog Boxes, page 64-34, for a description of the fields in this dialog box.

Step 3  In the VLAN Group ID field, enter a unique ID number for the VLAN group. The number that you enter must not be assigned to any other VLAN group.
Step 4 To associate the VLAN group with specific service module slots, enter their slot numbers in the Service Module Slots text box, or click Select to open a selector.

Note Defining this association makes it possible to later assign this VLAN group to a security context on the FWSM. See Add/Edit Security Context Dialog Box (FWSM), page 56-5.

Step 5 Enter the VLANs to add to the VLAN group, or click Select to open a selector.

Step 6 Click OK to save your definitions locally on the client and close the dialog box.

Deleting VLAN Groups

You can delete VLAN groups. Deleting a VLAN group has no affect on the VLANs in the group.

Related Topics
- Creating or Editing VLAN Groups, page 64-32
- VLAN Groups, page 64-31

Step 1 (Device view) Select a Catalyst 6500 Series switch or Cisco 7600 Series router from the Device selector.

Step 2 Select Interfaces/VLANs from the Policy selector.

Step 3 Click the VLAN Groups tab in the work area.

The VLANs tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLAN Groups Tab, page 64-33.

Step 4 Select a VLAN group from the table, then click Delete Row. The VLAN group is deleted.

Interfaces/VLANs Page—VLAN Groups Tab

Use the VLAN Groups tab to view and configure VLAN groups on supported 6500 Series switches and 7600 Series routers.

Note The VLAN Groups tab is available only for Cisco Catalyst 6500 Series switches and Cisco 7600 Series routers.

Navigation Path
- (Device view) Select Interfaces/VLANs from the Device selector, then click the VLAN Groups tab.

</tr>
</tbody>
</table>

VLAN ACLs (VACLs)

Cisco IOS standard or extended ACLs are configured on router interfaces only, and are applied on routed packets only. In contrast, Cisco Catalyst switches and Cisco 7600 Series routers can use VLAN ACLs (VACLs) to control the access of all packets that are bridged within a VLAN or that are routed to or from a VLAN for VACL capture through a WAN interface. VACLs:

- Are processed in hardware.
- Use Cisco IOS ACLs.
- Ignore any Cisco IOS ACL fields that are not supported in hardware.

Note
Security Manager does not support the creation or configuration of MAC ACLs (MACLs), which are named ACLs that are sometimes used with VACLs to filter IPX, DECnet, AppleTalk, VINES, or XNS traffic based on MAC addresses.
When you configure a VACL and apply it to a VLAN, all packets entering the VLAN are checked against the VACL.

If you apply a VACL to a VLAN and you apply an ACL to a routed interface in that same VLAN, any packet coming into the VLAN is first checked against the VACL. Then, if permitted, the packet is checked against the input ACL before it reaches the routed interface.

When a packet is routed from one VLAN to another, it is first checked against the output ACL that is applied to the routed interface. Then, if permitted, the packet is checked against any VACLs that are configured for the destination VLAN.

If a VACL is configured for a packet type, and a packet of that type does not match the VACL, the default action is deny.

**VLAN Access Maps**

Security Manager uses *VLAN access maps* to configure VACLs. Conceptually similar to a route map, a VLAN access map is a container in which you place one or more *statements* (conditions that match an action) and number them by their order of importance. A VLAN access map must also identify the VLANs to which it is applied, contain the map name, and identify at least one VACL sequence.

A VACL sequence must have a sequence number and at least one action, and must match at least one ACL.

Devices evaluate map statements in sequence and you can associate more than one VLAN access map with any device chassis.

To manage a VACL, select a Catalyst device in Device View, then select **Platform > VLAN Access Lists**. You use VLAN access maps to configure VACLs for IP traffic.

The following topics describe the actions you can perform when defining VACLs on Catalyst devices:

- Creating or Editing VACLs, page 64-37
- Deleting VACLs, page 64-38
- VLAN Access Lists Page, page 64-39

**Related Topics**

- VLANs, page 64-25
- VLAN Groups, page 64-31
- Chapter 64, “Managing Cisco Catalyst Switches and Cisco 7600 Series Routers”

### Creating or Editing VACLs

When you can create or edit a VACL, you must:

- Name the VACL.
- Define the VLANs to which the VACL applies.
- Define a sequence map containing at least one VACL sequence.

**Related Topics**

- Deleting VACLs, page 64-38
- Creating or Editing VLANs, page 64-26
- Creating or Editing VLAN Groups, page 64-32
- Create and Edit VLAN ACL Dialog Boxes, page 64-41
Chapter 64 Managing Cisco Catalyst Switches and Cisco 7600 Series Routers

VLAN ACLs (VACLs)

- VLAN Access Lists Page, page 64-39

**Step 1**

Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform > VLAN Access Lists** from the Policy selector.
- (Policy view) Select **Catalyst Platform > VLAN Access Lists**.

The VLAN Access Lists page is displayed. For a description of the fields on this page, see VLAN Access Lists Page, page 64-39.

**Step 2**

Do one of the following:

- To define the attributes of a new VACL, click **Add Row**.
- To edit the attributes of a VACL, select it in the list, then click **Edit Row**.

A dialog box opens. See Create and Edit VLAN ACL Dialog Boxes, page 64-41, for a description of the fields in the dialog box.

**Step 3**

Enter a name for the VACL in the **VLAN ACL Name** field.

**Step 4**

In the VLANs field, specify the VLANs to which the VACL should be applied, or click **Select** to open a VLAN selector.

**Step 5**

Define the sequence map:

a. Click **Add Row** or **Edit Row** beneath the Sequence Map table. A dialog box opens. See Create and Edit VLAN ACL Content Dialog Boxes, page 64-41.

b. Enter a number to identify the sequence.

c. Specify the standard and extended ACLs to assign to the sequence, or click **Select** to select the ACL object from a list or to create a new ACL object. For more information about ACL objects, see Creating Access Control List Objects, page 6-48.

d. Specify the action to perform on traffic that matches the ACLs defined in this sequence. (When you select Redirect as the action, you must specify the physical destination interfaces, or click **Select** to display a selector. See Specifying Interfaces During Policy Definition, page 6-65.)

e. Click **OK** to save your definitions locally on the client and close the dialog box. The sequence is displayed in the Sequence Map table.

f. Repeat the process to add sequences to the sequence map.

g. Use the up and down arrows to reorder the sequences, if required.

**Note**

The order in which you place the sequences is significant. When a flow matches a permit ACL entry, the associated action is taken without checking the remaining sequences. When a flow matches a deny ACL entry, it is checked against the next ACL in the same sequence or the next sequence. If a flow does not match any ACL entry and at least one ACL is configured for that packet type, the packet is denied.

**Deleting VACLs**

You can delete a VACL if it is not being used by any device, policy, or object.
Before You Begin
You must delete all references to the VACL before you can remove it from the database. To locate all references to the VACL, run an object usage report for it. See Generating Object Usage Reports, page 6-13.

Related Topics
- Creating or Editing VACLs, page 64-37
- Interfaces/VLANs Page—VLANs Tab, page 64-27
- VLAN ACLs (VACLs), page 64-36

Step 1 Do one of the following:
- (Device view) Select a Catalyst device, then select Platform > VLAN Access Lists from the Policy selector.
- (Policy view) Select Catalyst Platform > VLAN Access Lists.

The VLAN Access Lists page is displayed. For a description of the fields on this page, see VLAN Access Lists Page, page 64-39.

Step 2 Click in a row to select a VACL, then click Delete.

Step 3 Click OK to save your changes.

VLAN Access Lists Page
Use the VLAN Access Lists page to view and configure VLAN access lists for Cisco Catalyst switches and Cisco 7600 Series routers.

Navigation Path
You can access this page from:
- (Device view) Select Platform > VLAN Access Lists from the Device Policy selector.
- (Device view) Select Catalyst Platform > VLAN Access Lists from the Policy Types selector.

IDSM Settings

When you select a Catalyst device in Device view, then select Platform > IDSM Settings from the Policy selector, a list is displayed that:

- Displays the settings for data ports on Intrusion Detection System Service Modules (IDSMs).
- Helps you to organize IDSM data ports in channel groups.

The IDSM card detects and stops security threats on network connections. The card inspects the traffic that enters its two data ports and drops packets if a security threat is detected. The data port settings define:

- Which traffic is received by the data ports, as defined by the VLAN IDs.
- The sensing mode used by the data ports:
  - Trunk (IPS)—The IDSM performs VLAN bridging between pairs of VLANs within the same data port, operating as an 802.1q trunk. The IDSM inspects the traffic it receives on each VLAN in a VLAN pair and can either forward the packets on the other VLAN in the pair or drop the packet if an intrusion attempt is detected.
  - Capture (IDS)—The IDSM passively monitors network traffic that was copied to the data ports by the Catalyst switch using either VACL capture or SPAN. The data ports operate as 802.1q trunks that can be configured to trunk different VLANs. When operating in this passive mode, the IDSM cannot drop packets in response to a network intrusion attempt, but it can send TCP resets over the data ports in an attempt to block the intrusion.

**Note**

Security Manager supports a subset of IDSM settings on chassis running IOS 12.2(18)SXF4 or later. Trunk (IPS) and Capture (IDS) modes are supported; inline mode is not supported. Security Manager cannot manage IDSM data ports that are part of a spanning tree or access VLAN.

For high-traffic networks, EtherChannel is used to perform load balancing among multiple data ports. These data ports might be located on different IDSM cards within the same Catalyst device.
EtherChannel is also used to redirect traffic in the event of port failure to the remaining ports within the channel group. This resiliency help preserve intrusion detection and prevention without user intervention and with minimum packet loss.

The following topics describe the actions you can perform when defining IDSM settings:

- Creating or Editing EtherChannel VLAN Definitions, page 64-44
- Deleting EtherChannel VLAN Definitions, page 64-45
- Creating or Editing Data Port VLAN Definitions, page 64-46
- Deleting Data Port VLAN Definitions, page 64-47
- IDSM Settings Page, page 64-47

Related Topics

- VLANs, page 64-25

Creating or Editing EtherChannel VLAN Definitions

When defining an EtherChannel VLAN definition, you must:

- Define the slot-port combination containing the data ports to include in the channel group.
- Select the sensing mode used by the data ports.
- Define which VLANs are forwarded to the data ports.

The following restrictions apply:

- You can have a single definition only for each channel group.
- You can have a single definition only for each slot-data port combination. This means that you cannot create an EtherChannel VLAN definition if a data port definition already exists for this slot-data port.

Related Topics

- Deleting EtherChannel VLAN Definitions, page 64-45
- Creating or Editing Data Port VLAN Definitions, page 64-46
- IDSM Settings, page 64-43

Step 1

Do one of the following:

- (Device view) Select a Catalyst device, then select Platform > IDSM Settings from the Policy selector.
- (Policy view) Select Catalyst Platform > IDSM Settings.

The IDSM Settings page is displayed. For a description of the fields on this page, see IDSM Settings Page, page 64-47.

Step 2

Do one of the following:

- To create an IDSM EtherChannel VLAN definition, click Add Row beneath the EtherChannel VLANs table.
- To edit an IDSM EtherChannel VLAN definition, select it in the list, then click Edit Row beneath the table.
The IDSM EtherChannel VLAN dialog box is displayed. For a description of the fields in this dialog box, see Create and Edit IDSM EtherChannel VLANs Dialog Boxes, page 64-49.

**Step 3**  
To assign a channel group number to the Ethernet interface for the VLAN, or to change the channel group number, enter a number in the **Channel Group** text box.

**Step 4**  
To associate the VLAN with the numbered chassis slot where you installed your IDSM services module and to associate one module data port with the VLAN, do one of the following:

- Enter the slot-port number in the **Slot-Ports** text box.
- Click **Select** to open the IDSM Slot-Port Selector dialog box.

**Note**  
Associating one module data port with the VLAN enables you to configure the port at the group level instead of configuring it manually.

**Step 5**  
From the Mode list, select the running mode of the EtherChannel VLAN. If you select Capture, select the check box to configure the specified channel group as a capture destination.

**Note**  
If you do not select this check box, the capture port is created in shutdown mode.

**Step 6**  
To include a VLAN in the specified channel group, do one of the following:

- Enter its numeric ID in the VLAN IDs text box.
- Click **Select** to open the VLAN Selector dialog box.

You can enter or select more than one VLAN ID.

**Step 7**  
Click **OK** to save your definitions locally on the client and close the dialog box.

### Deleting EtherChannel VLAN Definitions

You can delete an EtherChannel VLAN definition on the IDSM.

**Related Topics**
- Creating or Editing EtherChannel VLAN Definitions, page 64-44

- IDSM Settings, page 64-43

**Step 1**  
Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform > IDSM Settings** from the Policy selector.
- (Policy view) Select **Catalyst Platform > IDSM Settings**.  
The IDSM Settings page is displayed. For a description of the fields on this page, see IDSM Settings Page, page 64-47.

**Step 2**  
Click a row in the table to select the VLAN definition to delete.
Step 3  Click **Delete Row**.

---

### Creating or Editing Data Port VLAN Definitions

When defining a data port VLAN definition, you must:

- Define the slot-port combination where the data port is located.
- Select the sensing mode used by the data port.
- Define which VLANs are forwarded to the data port.

The following restrictions apply:

- You may have a single definition only for each data port.
- You cannot create a data port definition if the port is already defined as part of a channel group.

**Related Topics**

- Deleting Data Port VLAN Definitions, page 64-47
- Creating or Editing EtherChannel VLAN Definitions, page 64-44
- IDSM Settings, page 64-43

---

**Step 1**  Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform > IDSM Settings** from the Policy selector.
- (Device view) Select **Catalyst Platform > IDSM Settings**.

The IDSM Settings page is displayed. For a description of the fields on this page, see IDSM Settings Page, page 64-47.

**Step 2**  Do one of the following:

- To create an IDSM data port VLAN definition, click **Add Row** beneath the Data Port VLANs table.
- To edit an IDSM data port VLAN definition, select it in the list, then click **Edit Row** beneath the table.

The IDSM Data Port VLAN dialog box is displayed. For a description of the fields in this dialog box, see Create and Edit IDSM Data Port VLANs Dialog Boxes, page 64-49.

**Step 3**  To associate the VLAN with the numbered chassis slot where you installed your IDSM services module and to associate one module data port with the VLAN, do one of the following:

- Enter the slot-port number in the **Slot-Ports** text box.
- Click **Select** to open the IDSM Slot-Port Selector dialog box.

**Note**  Associating one module data port with the VLAN enables you to configure the port at the group level instead of configuring it manually.

**Step 4**  From the Mode list, select the running mode of the data port VLAN. If you select Capture, select the check box to configure the specified data port as a capture destination.
Note

If you do not select this check box, the capture port is created in shutdown mode.

Step 5
To assign a VLAN to the specified data port, do one of the following:

- Enter its numeric ID in the VLAN IDs text box.
- Click Select to open the VLAN Selector dialog box.

You can enter or select more than one VLAN ID.

Step 6
Click OK to save your definitions locally on the client and close the dialog box.

Deleting Data Port VLAN Definitions

You can delete a data port VLAN definition on the IDSM.

Related Topics
- Creating or Editing Data Port VLAN Definitions, page 64-46

- IDSM Settings, page 64-43

Step 1
Do one of the following:

- (Device view) Select a Catalyst device, then select Platform > IDSM Settings from the Policy selector.
- (Policy view) Select Catalyst Platform > IDSM Settings.

The IDSM Settings page is displayed. For a description of the fields on this page, see IDSM Settings Page, page 64-47.

Step 2
Click a row in the table to select the VLAN definition to delete.

Step 3
Click Delete Row.

IDSM Settings Page

Use the IDSM Settings page to view and configure the VLAN settings for data ports and channel groups on Intrusion Detection System Service Modules (IDSM).

Navigation Path

You can access this page from:

- (Device view) Select Platform > IDSM Settings from the Device Policy selector.
- (Policy view) Select Catalyst Platform > IDSM Settings from the Policy Types selector.

PART 7

Monitoring, Reporting, and Diagnostics
Viewing Events

Event Viewer enables you to selectively monitor, view, and examine events from ASA (including ASA-SM), FWSM and IPS devices. Events are organized into views that you can filter or search to find events that interest you. You can create customized views and filters to fit your needs, or use the predefined views included in the application.

This chapter contains the following topics:

- Introduction to Event Viewer Capabilities, page 65-1
- Overview of Event Viewer, page 65-7
- Preparing for Event Management, page 65-25
- Managing the Event Manager Service, page 65-28
- Using Event Viewer, page 65-34
- Examples of Event Analysis, page 65-51

Introduction to Event Viewer Capabilities

Event Viewer monitors your network for syslog (system log) events from ASA and FWSM devices and security contexts and SDEE (Secure Device Event Exchange) events from IPS devices and virtual sensors. Event Viewer collects these events and provides an interface by which you can view them, group them, and examine their details.

Tip: Event Viewer and its related applications, Report Manager and Health and Performance Monitor, are useful for operational monitoring and troubleshooting of certain types of Cisco devices in your network. These applications do not provide extensive event correlation, compliance reporting, long-term forensics, or the integrated monitoring of both Cisco and non-Cisco devices.

Tip: When working with IPS events, the Report Manager component of Cisco Security Manager reports events individually; the Event Viewer component of Cisco Security Manager displays alerts. In the Event Viewer component, the IPS Summarizer groups events into a single alert, thus decreasing the number of alerts that the IPS sensor sends out.

Tip: Cisco IPS Manager Express (IME) and Cisco Security Manager do not summarize events in precisely the same way.
This section briefly describes some key activities that Event Viewer can facilitate.

This section contains the following topics:

- Historical View, page 65-2
- Real-Time View, page 65-2
- Views and Filters, page 65-3
- Policy Navigation, page 65-3
- Understanding Event Viewer Access Control, page 65-3
- Scope and Limits of Event Viewer, page 65-5
- Deeply Parsed Syslogs, page 65-6

**Historical View**

An historical view is one that displays events from a selected period of time (for example, the last 10 minutes) and does not automatically update as new events are collected. You must refresh the view to see newer events.

Consider the following activities among the many possibilities for employing Event Viewer with an historical view:

- **Troubleshoot Connectivity**—When a report comes in that a user cannot reach a particular server, you can set an historical view (for example, the last 10 minutes) that displays all events that affect that user’s IP address as a source or destination. Then, you can go from a particular displayed event to the policy denying that user’s access to the resource.

- **Tune Signatures**—After setting a view of all IPS messages, or all IPS messages of a given category, you might decide that an event is actually a false positive. You can then cross launch into the associated policy and either tune the signature to exclude the host or lessen the reported severity of the particular event.

Also consider creating an event action filter to modify how the alert is handled. Frequently, event action filters are a better way of dealing with false positives than editing the actual signature. For more information, see Configuring Event Action Filters, page 38-5.

- **Validate Policy Deployment**—After deploying a new or changed policy, you might want to confirm that it is operating effectively by selecting events corresponding to the given policy. For example, you could identify firewall-deny messages triggered by the new policy.

**Real-Time View**

A real-time view displays events as they are received and automatically updates the Event Table in waterfall fashion. Keep in mind that the term “real-time” is not precise. System latency and other factors prevent true real-time system response.

Consider the following activities among the many possibilities for employing Event Viewer with a real-time view:

- **Investigate Attacks in Near Real-time**—By isolating details of a particular source IP address, or a source/destination pair, Event Viewer can provide details about attacks on your monitored devices, or attacks that are going through those devices.

- **Validate Device Activity**—You can examine a device in your network and determine whether it is present and whether it is sending events.
• **View High Threat IPS Events**—You can filter a view to display all events that exceed a certain threat level. On a properly tuned IPS sensor, this should be a manageable flow of events to watch in a real-time view.

### Views and Filters

When you view events in Event Viewer, you open a view. A *view* is a set of filters and other properties, including color rules, selected columns and their positions and widths, and the default time window, that let you define a subset of events. Views help to limit the scope of the events list so that you can more easily find what you are looking for.

Event Viewer includes a number of predefined views. Although you cannot change the filter rules for these views, you can create copies of the views and change the filter rules in your copy. Views you create are called custom views. For more information, see *Creating Custom Views*, page 65-38.

Using filters is key to getting the most from Event Viewer. You can distill from all the events being received a view of only the information that you need or want. You can use the various methods of filtering to reduce the events list, filtering lists that have already been filtered. The following list explains the general filtering features; for more information, see *Filtering and Querying Events*, page 65-40.

• **Time filters**—You can use time filters to limit the events that are loaded into your client as well as to limit the events displayed in the Event Table. With time filtering you can select predefined values, such as the last hour, or specify a particular time range by dates and times. For more information, see *Selecting the Time Range for Events*, page 65-40.

• **Column filters**—You can use column filters to filter events based on a particular value of an event. For example, you could filter on a particular source or destination, or both. For certain columns you can also filter on a range of values or on a policy object. Column filters are part of the view settings for a view. For more information, see *Creating Column-Based Filters*, page 65-42.

• **Quick filters**—You can use quick filters to execute a text-based filter on events listed in the event table. The search is not column-sensitive, showing all events in which the string appears in any column. You can use the Quick Filter drop-down list (shown as a magnifier) to modify the scope of the filter. For more information, see *Filtering on a Text String*, page 65-44.

• **Drilling down with filters**—Aggregating additional filters allows you to become more and more selective, to “drill down” until you can view a particular event or set of events that meet your requirements. The View Settings pane at the top of the Event Monitoring window updates with each additional filter choice you make to show the current aggregate filter definition of the view selected.

### Policy Navigation

You can navigate from a particular event to the policy within Security Manager that governs that event. For more information, see *Looking Up a Security Manager Policy from Event Viewer*, page 65-49.

### Understanding Event Viewer Access Control

The user privileges assigned to your username control what you can do in Event Viewer. If you use local users, or other types of non-ACS access control, then all users have access to Event Viewer. However, the following access limits are imposed:

• You must have system administrator, network administrator, or approver privileges to select or deselect devices for monitoring. See *Selecting Devices to Monitor*, page 65-31.
Introduction to Event Viewer Capabilities

- You must have system administrator privileges to change the Event Management administrative settings page, where you enable or disable the service and configure storage location and other settings, as described in Starting, Stopping, and Configuring the Event Manager Service, page 65-28 and Event Management Page, page 11-22.

If you use ACS to control access to Security Manager, you can also control the following:

- You can control access to the Event Viewer application using the View Event Viewer privilege. Using this privilege, you could prevent certain users from accessing Event Viewer, or create roles that allow access to Event Viewer without allowing access to Report Manager. All default ACS roles are permitted to use Event Viewer.

- You can control which users can enable or disable monitoring for devices using the Modify > Manage Event Monitoring privilege. A user must have this privilege to select devices for monitoring as described in Selecting Devices to Monitor, page 65-31. The default ACS roles that have this permission are system administrator, network administrator, approver, security administrator, and security approver.

- You can control the use of the policy lookup feature. Users must have View Device privileges to the device, and also View privileges to the firewall or IPS policy, to perform policy lookup. If users do not have all permissions, they will get an “Unable to Find Matching Rule” error if they try to look up a matching rule. For more information about policy lookup, see Looking Up a Security Manager Policy from Event Viewer, page 65-49.

- Users can view events on devices only if they have at least View privileges to the device.

- You can control access to the Event Management administrative settings page, where you enable or disable the service and configure storage location and other settings, as described in Starting, Stopping, and Configuring the Event Manager Service, page 65-28 and Event Management Page, page 11-22. The user must have Admin privileges to access this page (or any other administrative settings page). All default ACS roles except help desk can view the page, but only system administrators can change settings.

- You can control the use of network/host and service policy objects for column filters (such as the Device, Source, Destination, Source Service, and Destination Service columns). Users must have the appropriate View Object permissions for network/host, network/host-IPv6, and service objects to use them in filters. For more information on creating column filters, see Creating Column-Based Filters, page 65-42.

For information on integrating Security Manager with Cisco Secure ACS, see the Installation Guide for Cisco Security Manager.
Scope and Limits of Event Viewer

The following table provides details on the functional scope and limits of Event Viewer:

Introduction to Event Viewer Capabilities

Deeply Parsed Syslogs

The structure and contents of standard syslogs and the elements comprised by each are detailed in the System Logs documentation for the device and software version you are using. You can find the documentation on Cisco.com at these locations:

- ASA Devices:  

- FWSM Devices:  

Syslogs other than those listed here are presented as raw syslogs. Only deeply parsed syslogs present the full content carried by the syslog.

The deeply parsed syslogs in Security Manager are detailed in the following table.

<table>
<thead>
<tr>
<th>Syslog Category</th>
<th>Syslog ID</th>
<th>Total Number of Syslogs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flow, Session Syslogs</td>
<td>110002-110003, 209003-209005, 302003-302004, 302009-302010, 302012-302018, 302020-302021,302303-302304, 303002-302005, 313001, 313004, 313005, 313008, 324000-324006, 337001-337009, 431001-431002, 407001-407002, 416001, 418001-418002, 419001-419003, 424001-424002, 450001, 448001, 448001, 609001-609002</td>

Overview of Event Viewer

Use Event Viewer to view events and alerts collected from monitored firewall and IPS devices. For more information about selecting devices for monitoring, see Selecting Devices to Monitor, page 65-31.

To open Event Viewer, do any of the following:

- Select Start > All Programs > Cisco Security Manager Client > Event Viewer from the Windows Start menu (your exact command path might differ), or double-click the Event Viewer icon on the desktop. You are prompted to log in. For more information about starting a Security Manager client application, see Logging In to and Exiting the Security Manager Client, page 1-10.
- Select Launch > Event Viewer from the Configuration Manager or Report Manager applications, or click the Event Viewer button on the Configuration Manager toolbar. Event Viewer is opened using the same user account that you used to log into the other application.
The following illustration and subsequent list explain the basics of Event Viewer.

**Figure 65-1  Event Viewer Main Window**

The following list explains the main Event Viewer window in more detail.

- **(1) Menu Bar**—General commands for performing actions in Event Viewer, including the following menus:
  - File, for operations on views. For information on the commands, see Event Viewer File Menu, page 65-9.
  - View, for operations within a view and general system management. For information on the commands, see Event Viewer View Menu, page 65-10.
  - Launch, for opening the Configuration Manager or Report Manager applications.
  - Help, for opening the online help or for viewing copyright and licensing information.

- **(2) Event Monitoring Window**—The right pane shows the open views. Each open view is represented on separate tabs (you can have up to four open historical views and one real-time view). Note that you can arrange views horizontally or vertically in this space, or even make a view float to a separate window. For more information about how you can arrange or float views, see Floating and Arranging Views, page 65-35.

  For detailed information about the many parts of the event monitoring window, see Event Monitoring Window, page 65-14.
• (3) **View List**—The left pane is a list of views. The list is organized into folders that separate the predefined views from the custom views, which are listed in the My Views folder. The simplest way to open a view is to double-click it, which replaces the currently open view. To open a view without replacing the currently open view, right-click the view and select **Open in New Tab**. For more information on opening views, see Opening Views, page 65-35.

For information about other things you can do with the view list pane, see View List, page 65-12.

• (4) **Status Information**—The lower right portion of the status bar shows the current events per second (EPS) rate and an icon that indicates the current health of the monitoring system. Click the alert status icon to open a bubble that shows statistics for the past five minutes and any current system alerts. From this view, you can click the Details link to see more detailed information; click the alert status icon again to close the bubble. For more information, see Monitoring the Event Manager Service, page 65-29.

### Event Viewer File Menu

The following table describes the commands on the File menu in Event Viewer.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New View</td>
<td>Creates a new custom view. You are prompted for a name and description. See Creating Custom Views, page 65-38. Alternatively, click the <strong>New (+)</strong> button in the view list.</td>
</tr>
<tr>
<td>Open View</td>
<td>Opens a view on a new tab. You are prompted to select the view to open. You can open at most four historical views and one real-time view. See Opening Views, page 65-35. <strong>Tip</strong> You can double-click in the view list to open the view and replace the view that is displayed.</td>
</tr>
<tr>
<td>Save</td>
<td>Saves changes made to the active view, including filters (for custom views only), table preferences such as selected columns, column width, and sort order, the time range, and color rules. See Saving Views, page 65-39. If you want to save filter changes for a predefined view, you must use Save As to create a new custom view.</td>
</tr>
<tr>
<td>Save As</td>
<td>Saves as a custom view the changes you have made to the displayed view. See Saving Views, page 65-39.</td>
</tr>
<tr>
<td>Close View</td>
<td>Closes the displayed view.</td>
</tr>
<tr>
<td>Close All Views</td>
<td>Closes all open views.</td>
</tr>
<tr>
<td>Exit</td>
<td>Closes Event Viewer. Exiting the application closes any floating Event Viewer window that is open.</td>
</tr>
</tbody>
</table>
# Event Viewer View Menu

The following table describes the commands on the View menu in Event Viewer.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mode</td>
<td>Specifies the time interval for selecting the events to display in the event table. From the submenu, select one of the following options:</td>
</tr>
<tr>
<td></td>
<td>- last 10 minutes</td>
</tr>
<tr>
<td></td>
<td>- last 1 hour                                                                    upto to either the limit of the time mode or the event table pagination limit.</td>
</tr>
<tr>
<td></td>
<td>- last 12 hours                                                                  Alternatively, click the <strong>Start</strong> button on the event table toolbar.</td>
</tr>
<tr>
<td></td>
<td>- last 1 day                                                                     Alternatively, click anywhere in the View Settings pane title bar, such as on the icon, on the text, or on the double arrow on the right side of the title bar. Clicking the heading opens and closes the pane.</td>
</tr>
<tr>
<td></td>
<td>- last 1 week                                                                     Alternatively, click <strong>Stop</strong> button on the event table toolbar.</td>
</tr>
<tr>
<td></td>
<td>- is today                                                                        Alternatively, click anywhere in the View Settings pane title bar, such as on the icon, on the text, or on the double arrow on the right side of the title bar. Clicking the heading opens and closes the pane.</td>
</tr>
<tr>
<td></td>
<td>- is yesterday                                                                     Alternatively, click anywhere in the View Settings pane title bar, such as on the icon, on the text, or on the double arrow on the right side of the title bar. Clicking the heading opens and closes the pane.</td>
</tr>
<tr>
<td></td>
<td>- is on . . . (Opens a calendar on which you click to specify a single date.)</td>
</tr>
<tr>
<td></td>
<td>- is between (Opens two calendars on which to specify a beginning and ending date and time.)</td>
</tr>
<tr>
<td></td>
<td>- <strong>Real Time</strong> (Sets the mode to display events as they are received.)</td>
</tr>
<tr>
<td>Customize Column</td>
<td>Changes the columns shown in the event table. The Choose Columns to Display dialog box opens, where you can select the columns that you want to display. For details on the columns available, see Columns in Event Table, page 65-17.</td>
</tr>
<tr>
<td>Start</td>
<td>Initiates retrieving events to update the current view’s event table. The event table then displays events received from the moment you clicked <strong>Start</strong> back to either the limit of the time mode or the event table pagination limit.</td>
</tr>
<tr>
<td>Stop</td>
<td>Stops event retrieval. The event table then displays the events received until the moment you clicked Stop.</td>
</tr>
<tr>
<td>Show View Settings</td>
<td>Opens the View Settings pane, which displays the filters and color settings for the current view. You can alter these settings using the View Settings pane.</td>
</tr>
</tbody>
</table>

Alternatively, click the Time Selector control on the toolbar and select from the same options. See Event Table Toolbar, page 65-15.
### Table 65-4  
**View Menu in Event Viewer (Continued)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show Event Details</td>
<td>Opens the Event Details pane and displays the selected event’s details. Alternatively:</td>
</tr>
<tr>
<td></td>
<td>- Click the expand icon (+) on the left of the Event Details pane title bar.</td>
</tr>
<tr>
<td></td>
<td>- Double-click an event in the event table to display the event details data in a pop-up window.</td>
</tr>
<tr>
<td><strong>Tip</strong></td>
<td>From the Event Details dialog box you can print the event details or you can copy one or more of the detail rows to your clipboard. You can also scroll through the events list using the Next and Previous buttons.</td>
</tr>
<tr>
<td>Manage Monitored Devices</td>
<td>Allows you to select which devices, or groups of devices, can have events displayed in Event Viewer. For more information, see Selecting Devices to Monitor, page 65-31.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> By default, any ASA, FWSM, or IPS device added to the Security Manager inventory is monitored.</td>
</tr>
<tr>
<td>Show Event Store Disk Usage</td>
<td>Opens a window that displays the amount of disk space used as well as the age of the oldest event stored. See Monitoring Event Data Store Disk Space Usage, page 65-32.</td>
</tr>
<tr>
<td>Show Network Host Objects</td>
<td>When selected, the host object name is displayed, if available, instead of the Source or Destination IP address. This option is selected by default.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip</strong> Hover over a host object name to view the IP address associated with that object.</td>
</tr>
<tr>
<td>Reset Layout</td>
<td>Re-establishes the width of the view list pane to its original setting after it has been hidden or manually narrowed or widened.</td>
</tr>
</tbody>
</table>
**View List**

The left pane of the Event Viewer main window displays a list of available views as shown in the following illustration. A *view* is a set of filters and other properties, including color rules, selected columns and their positions and widths, and the default time window, that let you define a subset of events.

![Event Viewer View List](image)

The view list includes the following controls:

- **(1) Push Pin button** — Click the Push Pin icon to control whether the view list pane is opened or closed. If the pin is vertical, the view list remains open unless you maximize the event monitoring window (the right pane). If the pin is horizontal, the view list collapses to the left margin, and you must click the Views heading in the left margin to open the list.

- **(2) Toolbar** — The toolbar contains these buttons:
  - **New button** — Click the New button to create a new custom view. You are prompted for a view name and description. For more information, see Creating Custom Views, page 65-38.
  - **Edit button** — Click the Edit button to change the name or description of the selected custom view. You can edit custom views only. For more information, see Editing a Custom View Name or Description, page 65-38.
  - **Delete button** — Click the Delete button to delete the selected custom view. You can delete custom views only. For more information, see Deleting Custom Views, page 65-40

- **(3) List of views** — The list is organized into folders that separate the predefined views from the custom views, which are listed in the My Views folder. The simplest way to open a view is to double-click it, which replaces the currently open view. To open a view without replacing the currently open view, right-click the view and select **Open in New Tab**. For more information on opening views, see Opening Views, page 65-35.

- **Right-click shortcut menu** — If you right-click on a view, you get a list of additional commands that you can perform:
  - **Open** — Opens the view and uses it to replace the currently active view. If the currently active view contains unsaved changes, you are prompted to save them. If the view is already open, it is brought to the foreground. See Opening Views, page 65-35.
– Open in New Tab—Opens the view in a new tab, so that no existing open views are closed. See Opening Views, page 65-35.

– Edit—Edits the custom view name and description. See Editing a Custom View Name or Description, page 65-38.

– View Description—Displays the description for the view.

- Floating and Arranging Views, page 65-35
Event Monitoring Window

The Event Monitoring window shows the event views that you have opened. From this window, you can configure views and analyze and filter events.

Figure 65-3  Event Monitoring Window

The Event Monitoring window contains these main elements:

- **View tabs (1, 9)**—When you open a view, it is represented as a tab in the window. To change views, click the tab, click the left or right arrow buttons to scroll through the tabs, or click the Open View List button and select the desired view. You can arrange views to be side by side or to float to separate windows by right-clicking the tab name and selecting an appropriate command; for more details, see Floating and Arranging Views, page 65-35.
Note: You can open at most four historical views and one real-time view.

- **View Settings pane (2)**—Use the View Settings pane to define the column filters and color rules to use in a view. You can open and close the pane by clicking anywhere in the heading or by toggling the View > Show View Settings command.

  The View Settings pane contains two tabs: Filter and Color Rules. These tabs are shown along the bottom of the pane. On each tab, the body of the tab shows the current filter or rules; to change a rule, you select it and click the Edit or Delete buttons along the top of the pane, as appropriate. To create new rules, click the Add button.

  You can also add filters using the column filtering controls in the events table, as described in Creating Column-Based Filters, page 65-42. For more information on color rules, see Configuring Color Rules for a View, page 65-37.

- **Event Table Toolbar (3)**—The toolbar above the event table includes shortcut buttons and other controls that relate specifically to the events listed in the table. For a description of the toolbar controls, see Event Table Toolbar, page 65-15.

- **Event Table (4, 5, 8)**—The event table shows the events that match your filter criteria, one event per row. These events might be retrieved from the primary or the extended data store; you do not have to explicitly request data from the extended data store. To see events from a device, you must have View Device privileges to the device.

  The columns that make up the event table can be hidden, resized, reordered, and sorted upon as described in Customizing the Event Table Appearance, page 65-36. For a description of the columns, and how to use the column selector button to choose which columns are shown, see Columns in Event Table, page 65-17.

  If a column has a filter applied to it, an icon appears in the column heading.

- **Time Slider (6)**—For historical views, the time slider shows the current slice of time displayed in the table and the events per second rate as a linear graph. For more information about using the time slider, see Time Slider, page 65-24.

- **Event Details Pane (7)**—The event details pane shows detailed information about the currently selected event. You can open and close the pane by clicking anywhere in the heading or by toggling the View > Show Event Details command. For more information, see Event Details Pane, page 65-25.

### Event Table Toolbar

The following illustration and table explain the elements in the toolbar that resides immediately above the event table in Event Viewer.
## Overview of Event Viewer

<table>
<thead>
<tr>
<th>Callout</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Search Within Results Field (Quick Filter)</td>
<td>This tool is also known as the <em>Quick Filter</em>. Use it to search for a word or phrase as well as to limit the scope of the search to certain columns. Further, you can select whether the search term used should be considered case sensitive, whether wildcards may be used, and whether a match may be partial, case sensitive, exact, or anywhere within a string. This search operates only on the selected view and within the data loaded. For more information, see Filtering on a Text String, page 65-44.</td>
</tr>
<tr>
<td>2</td>
<td>Time Selector (Mode) (Equivalent to View &gt; Mode.)</td>
<td>You use the time selector to do the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Filter the events shown in the event table pane according to the time they were received. See Selecting the Time Range for Events, page 65-40.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Select between a real-time view or historical views. See Switching Between Real-Time and Historical Views, page 65-39.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Determine the time interval loaded in the client. If you are using one of the modes that shows events from the current time into the past, hovering the pointer over the field shows the start and end times for the displayed events. If you are using a specific time interval, the interval is shown in the toolbar.</td>
</tr>
<tr>
<td>3</td>
<td>Events by IP Address Type Selector</td>
<td>You use the events by IP address type selector to filter the list based on the type of IP address included in the events. Options are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>All Events</strong> (Default)—Show all events regardless of the address type. This is the default option.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>IPv4 Events Only</strong>—Show events only if all addresses in the event are in IPv4 format.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>IPv6 Events Only</strong>—Show events only if at least one address in the event is in IPv6 format.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Tip</strong> You cannot save your selection. The next time you open the view, you need to reselect your option if you want something other than the default.</td>
</tr>
<tr>
<td>4</td>
<td>Save (Equivalent to File &gt; Save or File &gt; Save As.)</td>
<td>Click <strong>Save</strong> to save changes to the current view, including filters (for custom views only), table preferences such as selected columns, column width, and sort order, the time range, and color rules. Alternatively, click the down arrow and select <strong>Save As</strong> to save changes as a new custom view. If you want to save filter changes for a predefined view, you must use Save As to create a new custom view. For more information, see Creating Custom Views, page 65-38.</td>
</tr>
</tbody>
</table>
Overview of Event Viewer

Columns in Event Table

The following table lists alphabetically, and describes, all the columns that you can display in a view in Event Viewer. The columns applicable to a particular device vary, as does the presence or absence of event data for a particular event type.

When you save a view, the columns you selected, and their order, are preserved and displayed the next time you open the view. To select which columns to display in the open (and active) view, do one of the following:

- (Preferred method.) Click the Column Chooser icon in the far right of the event table header row (see Event Monitoring Window, page 65-14). The Choose Columns to Display dialog box that opens lists the columns in alphabetical order. You can select or deselect the columns either individually or by using the Select/Unselect All check box. Also, you can click Revert to return to the default column selection for the view.
- Select View > Customize Columns.
- Right-click any column heading and select or deselect a column individually, or select More to open the same dialog box that is used by the View > Customize Columns command.

### Table 65-5   Event Table Toolbar Elements (Continued)

<table>
<thead>
<tr>
<th>Callout</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Start</td>
<td>Click <strong>Start</strong> to reload or restart the listing of events in the Event Table. Clicking Start retrieves any events that have occurred since you originally loaded the table.</td>
</tr>
<tr>
<td></td>
<td>(Equivalent to <strong>View &gt; Start</strong>.)</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Stop</td>
<td>Click <strong>Stop</strong> to halt the listing of events in the Event Table. If you are in a real-time view, the Time Selector indicates the time stopped as well as the time interval that is loaded. Clicking on stop can also halt a query and display the set of events currently loaded in event viewer.</td>
</tr>
<tr>
<td></td>
<td>(Equivalent to <strong>View &gt; Stop</strong>.)</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>Clear</td>
<td>Click <strong>Clear</strong> to empty the event table.</td>
</tr>
</tbody>
</table>
| 8       | Event Enumerator and messages       | The number shown on the right of the toolbar indicates how many events are loaded onto the Event Viewer client. The number grows as events are loaded until either all events matching the filter criteria are displayed, or the pagination limit is reached, whichever is lowest. If you change the pagination limit (see Event Management Page, page 11-22), you must exit Event Viewer and open it again for the new limit to be in effect.  
If your query requires that events be retrieved from the extended event storage area, a message such as “Data being fetched from extended store” appears. Fetching events from the extended storage area typically takes longer than fetching them from the primary storage area. |

**Columns in Event Table**

Most columns other than Description, Event Name, and Receive Time include a filtering function. For more information, see Creating Column-Based Filters, page 65-42.
## Event Viewer Column Descriptions

<table>
<thead>
<tr>
<th>Column Label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAA Group</td>
<td>The AAA group policy.</td>
</tr>
<tr>
<td>AAA Server</td>
<td>The server that handles user requests for access; it performs authentication, authorization, and accounting.</td>
</tr>
<tr>
<td>AAA User</td>
<td>The AAA username.</td>
</tr>
<tr>
<td>ACE Hash1</td>
<td>The hashcode1 and hashcode2 of the access control list entry (ACE).</td>
</tr>
<tr>
<td>ACE Hash2</td>
<td>Hash codes are required for successful policy lookups from syslog 106023 and 106100 events. These hash codes are available only if you deployed the configuration using Security Manager.</td>
</tr>
<tr>
<td>ACL Name</td>
<td>The name or ID of the access control list (ACL).</td>
</tr>
<tr>
<td>Action</td>
<td>The action performed on the flow. For example: Terminated or denied.</td>
</tr>
<tr>
<td>Alert Details</td>
<td>The details regarding the alerts.</td>
</tr>
<tr>
<td>App Name</td>
<td>The name of the application originating the event.</td>
</tr>
<tr>
<td>App Stop Reason</td>
<td>An explanation of how or why the application was shut down.</td>
</tr>
<tr>
<td>App Version</td>
<td>The version of the application originating the event.</td>
</tr>
<tr>
<td>Attack Relevance Rating</td>
<td>A numerical value used to indicate an attack's relevance to its destination target or targets.</td>
</tr>
<tr>
<td>Backplane Interface</td>
<td>The backplane interface, which is identified only when the backplane interface differs from the physical interface.</td>
</tr>
<tr>
<td>Botnet Category</td>
<td>The category showing the reason a domain name is blacklisted, for example, botnet, Trojan, spyware, and so on.</td>
</tr>
<tr>
<td>Botnet Domain</td>
<td>The domain name or IP address in the dynamic filter database to which the traffic was initiated. It can be black listed, white listed, or grey listed.</td>
</tr>
<tr>
<td>Build Time</td>
<td>The date and time of the software build.</td>
</tr>
<tr>
<td>Build Type</td>
<td>The type of build. Typically this is a word such as “release” or “debug.” In some cases, it is the ID of the builder of the application.</td>
</tr>
<tr>
<td>Byte Count</td>
<td>The number of bytes in the data transfer of the connection.</td>
</tr>
<tr>
<td>Call Id</td>
<td>The peer’s Call ID for the session to which this packet belongs.</td>
</tr>
<tr>
<td>Class Map</td>
<td>The class map name.</td>
</tr>
<tr>
<td>Connection Duration</td>
<td>The lifetime of the connection.</td>
</tr>
<tr>
<td>Connection ID</td>
<td>A unique identifier for the connection.</td>
</tr>
<tr>
<td>Connection Limit</td>
<td>The maximum number of connections or sessions.</td>
</tr>
<tr>
<td>Connection Termination Value</td>
<td>A factor for which the connection is terminated, for example, incorrect version or invalid payload-type.</td>
</tr>
<tr>
<td>Current Connection Count</td>
<td>The number of current connections.</td>
</tr>
<tr>
<td>Description</td>
<td>For syslogs this shows the raw message, for IPS it shows a description of the event.</td>
</tr>
</tbody>
</table>
### Table 65-6 Event Viewer Column Descriptions (Continued)

<table>
<thead>
<tr>
<th>Column Label</th>
<th>Description</th>
</tr>
</thead>
</table>
| Destination                  | The IP Address or hostname of the traffic destination (for ASA and FWSM) or the attack target (for IPS). It can be multi-valued and contain IPv4 or IPv6 addresses.  
If View > Show Network Host Objects is selected and a host object is defined that matches the destination IP address, the host object name is displayed.  
**Tip** Hover over a host object name to view the IP address associated with that object. |
| Destination Context Data     | Context buffer indicating the data that was sent just prior to, and immediately after, the alert was triggered. A Base64-encoded representation of the stream data that was sourced by the target. |
| Destination FQDN             | The fully-qualified domain name of the destination IP address, if any.                                                                      |
| Destination Interface        | The destination interface.  
For Etherchannel alerts (426001-426003), this is the name of the Etherchannel interface for which this event occurred. The member interface is identified in the Source Interface column. |
| Destination Locality         | Whether the target address is located inside or outside of a given network as specified by the intrusion.                                    |
| Destination OS               | The target's operating system information.                                                                                                  |
| Destination OS Relevance     | A numerical value indicating the relevance of the destination target OS value.                                                                |
| Destination OS Source        | The source of the Target OS data. Possible values are: learned, imported, or configured.                                                      |
| Destination Service          | The destination port. It can be multi-valued.                                                                                              |
| Destination User Identity    | The username for the traffic destination, if any.                                                                                           |
| Device                       | The source of the event; usually the device ID.  
A device identified as Not Available has been deleted from the Security Manager inventory.                                                |
| Direction                    | The direction of the traffic: inbound or outbound.                                                                                           |
| Event ID                     | A unique sequential number for each event, assigned internally.                                                                            |
| Event Name                   | A user-friendly name given to the event.                                                                                                    |
| Event Summary                | Specifies that this is a summary alert, representing one or more alerts with common characteristics. The numeric value indicates the number of times the signature fired since the last summary alert with a matching initialAlert attribute value. |
| Event Type ID                | For ASA or FWSM, the syslog ID.  
For IPS, this value could be:  
• A combination of Sig Id & Sub-Sig ID (for IPS Alert Events)  
• IPS Status (for IPS Status Events)  
• IPS Error (for IPS Error Events). |

</tr>
<tr>
<td>Policy Map</td>
<td>The policy map name.</td>
</tr>
<tr>
<td>Protocol</td>
<td>The Level-3 or Level-4 protocol.</td>
</tr>
<tr>
<td>Protocol (Non L3)</td>
<td>Some non-Level-3 or -4 protocol seen in the event, for example, TACACS, RADIUS, FTP, or H245.</td>
</tr>
<tr>
<td>Reason</td>
<td>A rationale associated with certain events. For example, a connection tear down may have an associated reason.</td>
</tr>
<tr>
<td>Receive Time</td>
<td>The time the event was received by Security Manager.</td>
</tr>
<tr>
<td>Reputation</td>
<td>The attacker’s reputation score in the range -10.0 to +10.0. A lower (more negative) score indicates a greater likelihood that the host is malicious.</td>
</tr>
<tr>
<td>Result Status</td>
<td>The status of an operation, which indicates whether the operation successfully completed.</td>
</tr>
<tr>
<td>Risk Rating</td>
<td>A value that represents the calculated risk associated with the event.</td>
</tr>
<tr>
<td>Security Context</td>
<td>The security context with which the named interface, specified in the corresponding Interface column, is associated.</td>
</tr>
<tr>
<td>Sensor Event ID</td>
<td>The serial number for an event, which is guaranteed unique within the scope of the originating host.</td>
</tr>
<tr>
<td>Severity</td>
<td>The firewall or IPS severity values.</td>
</tr>
<tr>
<td>SIA Event Name</td>
<td>The event that occurred for the service identified in the SIA Service Name field.</td>
</tr>
<tr>
<td>SIA Service Name</td>
<td>The name of the Service Insertion Architecture (SIA) service for which this event occurred.</td>
</tr>
<tr>
<td>Sig Details</td>
<td>The details of the reported signature that was triggered and resulted in the generation of the alert.</td>
</tr>
<tr>
<td>Sig ID</td>
<td>The Sig ID value is used by the alert originator to identify the activity. It identifies the pre-defined signature defined for this activity.</td>
</tr>
<tr>
<td>Signature Version</td>
<td>The version of the signature definition used to generate an alert.</td>
</tr>
<tr>
<td>Source</td>
<td>The IP Address or hostname of the traffic source (for ASA and FWSM) or the attacker (for IPS). It can be multi-valued and contain IPv4 or IPv6 addresses. If View &gt; Show Network Host Objects is selected and a host object is defined that matches the source IP address, the host object name is displayed.</td>
</tr>
</tbody>
</table>

**Tip** Hover over a host object name to view the IP address associated with that object.
### Table 65-6  Event Viewer Column Descriptions (Continued)

<table>
<thead>
<tr>
<th>Column Label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Context Data</td>
<td>The context buffer indicating the data that was sent just prior to and immediately after the alert was triggered. A Base64-encoded representation of the data stream that was sourced by the attacker.</td>
</tr>
<tr>
<td>Source FQDN</td>
<td>The fully-qualified domain name of the source IP address, if any.</td>
</tr>
<tr>
<td>Source Interface</td>
<td>The source interface. For Etherchannel alerts (426001-426003), this is the name of the interface that is part of the Etherchannel bundle for which this event occurred. The Etherchannel interface is identified in the Destination Interface column.</td>
</tr>
<tr>
<td>Source Locality</td>
<td>Identifies whether the attacker address is located inside or outside of a given network, as specified by the intrusion detection device’s configuration.</td>
</tr>
<tr>
<td>Source Service</td>
<td>The source port.</td>
</tr>
<tr>
<td>Source User Identity</td>
<td>The username associated with the traffic source, if any.</td>

<td>The name of the upgrade package that was uninstalled.</td>
</tr>
<tr>
<td>URI</td>
<td>The URI of the auto-upgrade server directory.</td>
</tr>
<tr>
<td>UTC Offset</td>
<td>The offset attribute of sensor bcal time indicates the number of minutes that must be added to the UTC time to convert to local time at the originating host.</td>
</tr>
<tr>
<td>Virtual Sensor</td>
<td>The name of the virtual sensor associated with the event.</td>
</tr>
<tr>
<td>VLAN Id</td>
<td>The VLAN number associated with packets involved in the activity that triggered the alert.</td>
</tr>
</tbody>
</table>
Overview of Event Viewer

The time slider resides below the events table when you are using an historical view; it is not used with real-time views. The following illustration explains the time slider; the pagination controls on the right are explained in Table 65-7.

You can use the time slider to do the following:

- View the EPS (events per second) trends for the server. You can use the controls on the right to zoom in or out to get a better view of the EPS trends over the time frame that concerns you.
  
  You can also click and drag the background of the time slider to position the time ranges within the window. Moving the background does not affect the selected time range.

- Select a slice of time for displaying events in the table, either by moving the vertical slider or by using the pagination controls. The position of the vertical slider determines the most recent event displayed in the event table. Whenever you alter the time slice, the event table is reloaded with the events that match the time period.

  The time range of the events displayed in the event table is determined by the selected time interval. For more information, see Selecting the Time Range for Events, page 65-40.

The following table explains the pagination controls to the right of the time slider.

### Table 65-7  Time Slider Paging Controls

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Previous page (earlier) and next page (later). The size of page varies according to the selected time mode.</td>
</tr>
<tr>
<td>Note</td>
<td>Using the page controls alternately, for example forward and then back, causes the sort order in the event table to reverse. That is, the latest events go from the top of the table to the bottom, or from the bottom to the top.</td>
</tr>
</tbody>
</table>
Event Details Pane

The Event Details pane (illustrated in Event Monitoring Window, page 65-14) presents information contained within a single event. The information, which is displayed in multiple tabs within the pane, varies according to the richness of the event and the capability of Event Viewer to parse the data. Components include:

- **Displayed Fields Tab**—Displays the fields shown in the Event Table.
- **Details Tab**—Displays all available fields for the selected event. The fields are presented in alphabetical order.
- **Explanation Tab**—Displays a generic explanation for this event type.
- **Related Threats Tab**—Displays threats correlated to the event. (IPS Events only.)
- **Recommended Action Tab**—Displays a generic recommendation for an event of this type. (Syslogs only.)
- **Trigger Packet Tab**—Displays trigger packet data. (IPS Events only.)
- **Context Packet Tab**—Displays context packet data from the Source (Attacker) and Destination (Target). (IPS events only.)

Preparing for Event Management

Before you can view events generated from a device, you must configure the device to work with Event Viewer.

Ensuring Time Synchronization

Standard network management practice includes consideration of time differences and network device synchronization. Typically, this includes the use of a Network Time Protocol (NTP) server. Event Viewer is most easily used with a common time standard. However, it is worth noting that you can view the time an event is received by Security Manager (Receive Time), and for IPS devices, the time the event was generated by a device (Generation Time).

Whenever possible, configure the Security Manager server and the devices it is monitoring with the same NTP server.
Configuring ASA and FWSM Devices for Event Management

Before you can use Event Viewer, or any other application that analyzes syslog events, to view events generated from an ASA (including ASA-SM) or FWSM device, you must configure the logging policies on the device to generate and transmit syslog messages.

**Tip**

Although you can configure devices individually to specify the appropriate logging configuration, it is likely that more than one ASA or FWSM device in your network would use the same logging configuration. Although this topic describes how to configure an individual device, you can also create shared policies and assign them to multiple devices. For more information about configuring and assigning shared policies, see Creating a New Shared Policy, page 5-51 and Modifying Policy Assignments in Policy View, page 5-51.

Besides the logging configuration described here, you can also configure logging for individual access control entries when you configure them either in firewall policies or ACL policy objects. The default is to log denied access only, but you can configuring ACL logging options to provide increased logging.

**Note**

To reliably report events from contexts in multiple-context mode, Cisco Event Viewer requires an IP address for the management interface of each context.

---

**Step 1**

(Device view) Select the ASA or FWSM device or security context, then select Platform > Logging > Syslog > Logging Setup from the Policies selector.

In the policy, select Enable Logging. You can configure other options as needed. For detailed information about the options, see Logging Setup Page, page 51-10.

**Step 2**

Select Platform > Logging > Syslog > Syslog Servers.

Add the Security Manager server’s IP address to the syslog servers table. Configure the server to use the UDP protocol. The default port, 514, is correct unless you configure a different port on the Security Manager Administration Event Management Page, page 11-22.

If you are using other event management applications, such as CS-MARS, also add those servers to this policy.

**Note**

You can use EMBLEM message format if you desire; both traditional and EMBLEM formats are supported. Keep in mind that EMBLEM is not supported by CS-MARS, so do not send EMBLEM-formatted messages to a CS-MARS server.

For detailed information about the options in the Syslog Servers policy, see Syslog Servers Page, page 51-19.

**Step 3**

If you want to configure non-default syslog server settings, such as adding time stamps to syslog messages, changing the severity level of messages, or suppressing the generation of specific messages altogether, configure the Platform > Logging > Syslog > Server Setup policy. For detailed information, see Server Setup Page, page 51-15.

**Step 4**

(Optional) You can configure the Platform > Logging > Syslog > Logging Filters policy to fine-tune the kinds of messages sent to syslog servers. For detailed information about this policy, see Logging Filters Page, page 51-7 and Edit Logging Filters Dialog Box, page 51-8.

Following are some tips for configuring this policy:
• When adding the logging filter, select **Syslog Servers** for Logging Destination.
• You can create a simple filter based on message severity, or you can configure a much more complex filter based on event classes. If you elect to use event classes, you can do the configuration directly in the Logging Filters policy, or you can configure event lists separately in the **Event Lists** policy (see **Event Lists Page**, page 51-3).

**Step 5**  
(Optional) You can configure the **Platform > Logging > Syslog > Rate Limit** policy to limit the quantity of messages generated per time interval, either by message severity or message number. This can help you avoid flooding the syslog server. See **Rate Limit Page**, page 51-12.

**Step 6**  
(Optional, but recommended) You can configure the **Platform > Device Admin > Server Access > NTP** policy to specify a network time protocol server for ASA devices. Using NTP ensures consistent date and time information for easy event correlation. Specify the same NTP server you use for the Security Manager server. If you use different servers, ensure the servers are synchronized. See **NTP Page**, page 50-18.

### Configuring IPS Devices for Event Management

Before you can use Event Viewer to view events generated from an IPS device, you must configure the Allowed Hosts policy on the device to allow the Security Manager server access to the device. Because Security Manager also needs to be configured in the Allowed Hosts policy to allow configuration access, your IPS devices might already be configured correctly. You should also configure the network time protocol (NTP).

Configure the following policies for IPS devices in Device view to enable effective event management on those devices:

• **Platform > Device Admin > Device Access > Allowed Hosts**—(Required) Add the Security Manager server to the table. You can either identify the Security Manager server by its host IP address (for example, 10.100.10.10), or you can specify the network that it is on (for example, 10.100.10.0/24).

  If you are using other event management applications with the device, such as CS-MARS, ensure that you also add those servers to the policy.

  For more information about configuring the Allowed Hosts policy, see **Identifying Allowed Hosts**, page 34-7.

• **Platform > Device Admin > Server Access > NTP**—(Recommended) Configure the same NTP server that you use for the Security Manager server to ensure consistent date and time information for easy event correlation. If you use different servers, ensure the servers are synchronized. For more information, see **Identifying an NTP Server**, page 34-21.

---

**Tip**

Although you can configure devices individually to specify the appropriate allowed hosts and NTP configuration, it is likely that more than one IPS device in your network would use the same configuration. Although this topic describes how to configure an individual device, you can also create shared versions of these policies and assign them to multiple devices. For more information about configuring and assigning shared policies, see **Creating a New Shared Policy**, page 5-51 and **Modifying Policy Assignments in Policy View**, page 5-51.
Managing the Event Manager Service

The Event Manager service enables the use of the Event Viewer application. For Event Viewer to function, the service must be started. There are several tasks that you can perform to configure and manage the overall functioning of the service.

This section contains the following topics:

- Starting, Stopping, and Configuring the Event Manager Service, page 65-28
- Monitoring the Event Manager Service, page 65-29
- Selecting Devices to Monitor, page 65-31
- Monitoring Event Data Store Disk Space Usage, page 65-32
- Archiving or Backing Up and Restoring the Event Data Store, page 65-33

Starting, Stopping, and Configuring the Event Manager Service

The Event Manager service must be running for you to use Event Viewer or Report Manager.

When you install Security Manager, the Event Manager service is automatically enabled unless the server meets the minimum memory requirements that are documented in the Installation Guide for Cisco Security Manager. Although you can manually start the service on a system that does not meet the minimum memory requirements, you might find the performance to be dissatisfactory. The key factors are the number of devices managed and their rate of event generation.

Tip

If you get a message that Event Viewer is unavailable when you select Launch > Event Viewer, but the Enable Event Management option is selected in the Tools > Security Manager Administration > Event Management page, try restarting the Event Manager Service. First, deselect the Enable option and click Save. Wait for the service to stop. Then, select the Enable option, click Save, and wait for the service to finish restarting. You can then try opening Event Viewer again.

The following procedure explains how to start, stop, and configure the Event Manager service.

Related Topics

- Monitoring Event Data Store Disk Space Usage, page 65-32

Step 1

In the main Security Manager window (not Event Viewer), select Tools > Security Manager Administration and select Event Management from the table of contents.

Step 2

Do one of the following:

- To enable, or start, the Event Manager service, select Enable Event Management.
- To disable, or stop, the Event Manager service, deselect Enable Event Management.

You can also change the other settings, such as the event data store location and maximum size, the syslog port to which devices should send events, and the pagination size (which determines the maximum number of events loaded into the event table). You can also configure an extended event storage location to augment your primary storage location. For detailed information about these settings, see Event Management Page, page 11-22.
Chapter 65  Viewing Events

Managing the Event Manager Service

Step 3  Click Save to save your changes.

If you changed the Enable Event Management option, you are prompted to confirm that you want to start or stop the Event Manager Service. If you click Yes, the service is started or stopped immediately, and you are shown a progress indicator and told when the change is completed. Wait until the status change is completed before continuing.

If you change other settings, with the exception of the pagination size, the Event Manager service must be briefly stopped and restarted. You are shown a progress indicator.

Monitoring the Event Manager Service

The Event Manager service processes incoming syslog messages and retrieves SDEE alerts from monitored IPS devices. The amount of data processed varies depending on network activity. There can be times when the events per second (EPS) generated in the network is higher than the service can handle, in which case the service goes into throttle mode, selectively dropping events.

You can monitor the status of the service to identify congestion and address problems that arise. The status of the service is shown in an icon in the lower right corner of the status bar in Event Viewer, as shown in Overview of Event Viewer, page 65-7. The Total EPS indicates the current events per second rate that the service is experiencing. The alert status icon color indicates the following:

- Green dot—There are no problems. All events are being processed normally.
- Yellow dot—There are some warnings, for example, low severity events are being dropped.
- Orange dot—There are more serious issues, for example, low and medium severity events are being dropped.
- Red dot—There is a critical situation, for example, high severity events are being dropped or there is a significant problem with the system, such as problems with the syslog port or with the event data store location.
- Disconnected network wire—The Event Manager service is disabled, either intentionally or due to some server problem; no events are being stored or retrieved. If this is not intentional, restart the Event Manager service as described in Starting, Stopping, and Configuring the Event Manager Service, page 65-28.

To view detailed information, click on the alert status icon. A bubble opens that shows summary statistics for the past five minutes, including the number of events received and dropped and event server alert messages, if any. Click the alert status icon again to close the bubble.

When the bubble is open, you can click the Details link in the bubble to view more detailed information. Clicking the Details link opens the Event Statistics Details dialog box, which shows the following information:

- Last 5 Minutes Statistics:
  - Events Received—The total number of syslog events Received and SDEE alerts retrieved in the past five minutes by the service.
  - Events Dropped—The total number of events or alerts that the service had to drop due to congestion. This number indicates drops from monitored devices only, so the number should be zero in normal circumstances. A non-zero number indicates that the service is in throttle mode; look for messages in the Event Server Alerts section.
- **Events from Unmonitored Devices**—The number of syslog messages sent to the server that came from devices that are not selected for monitoring (as described in Selecting Devices to Monitor, page 65-31).

Events from unmonitored devices are always dropped, but they do place a load on the service. The IP address of the last unmonitored device detected is shown; use the IP address to determine the source of the messages. You can then determine if the device should be added to the monitored devices list, or if you need to alter the device's configuration to remove the Security Manager server from its list of syslog servers.

If the device that is sending messages is outside of your network, adjust the firewall configuration to prevent this syslog traffic from entering your network.

- **Status Information:**
  - **Total Events Per Second (EPS)**—The rate at which events are currently being processed. This measure does not include dropped events.
  - **Event Buffer Used**—The percentage of the shared event buffer that is currently being used to process events. The bar is color-coded to indicate the throttle level:
    - Green—Not in throttle mode.
    - Yellow—Low severity events are being dropped.
    - Orange—Low and medium severity events are being dropped.
    - Red—High severity events are being dropped.
  - **Event Server Alerts**—These messages indicate specific status problems that you might need to address. Table 65-8 explains the messages that you might see with possible solutions.
  - **Copy button**—Click the Copy button to copy the information to the clipboard. The copied information includes HTML markup. You can paste the information into an HTML file.

<table>

Chapter 65  Viewing Events

Managing the Event Manager Service

Selecting Devices to Monitor

All ASA and FWSM devices and security contexts, and IPS devices and virtual sensors, that are added to the Security Manager database are automatically selected for monitoring in Event Viewer.

Note

To reliably report events from contexts in multiple-context mode, Cisco Event Viewer requires an IP address for the management interface of each context.
If you do not want to use Event Viewer with a device, you can deselect the device for monitoring. Note that if an ASA or FWSM device or security context is not configured to use the Security Manager server as a syslog server, you will not get events from the device or security context anyway, so you might not need to deselect an ASA or FWSM that you do not want to monitor.

**Tip**

You cannot monitor Cisco IOS IPS devices in Event Viewer.

**Related Topics**

- Adding Devices to the Device Inventory, page 3-7
- Configuring ASA and FWSM Devices for Event Management, page 65-26
- Configuring IPS Devices for Event Management, page 65-27

**Step 1**

In Event Viewer, select **View > Manage Monitored Device** to open the Manage Monitored Devices dialog box.

The device list shows all devices in the Security Manager inventory to which you have view permissions. You cannot see any devices for which you have no permissions. Any selections you make are limited to the displayed devices. If you do not have permission to select or deselect any devices, the list is read-only and you cannot select devices for monitoring. For more information on access permissions, see Understanding Event Viewer Access Control, page 65-3.

**Step 2**

Ensure that only those devices whose events you want to monitor in Event Viewer are selected. Deselect any undesired devices.

You can change the selection status for all devices in a device group by selecting or deselecting the group.

**Step 3**

Click **OK**.

You might need to wait for the changes take effect in Event Viewer.

**Monitoring Event Data Store Disk Space Usage**

The Event Manager service uses a specified amount of disk space for the primary and extended event data stores. This ensures that the service does not overwhelm the server computer or the extended storage location. You configure the size of the primary and extended event data stores on the **Tools > Security Manager Administration > Event Management** page as described in Event Management Page, page 11-22.

For both the primary and extended locations, when the allocated space is 90% full, the oldest event data is deleted from storage to make room for new data. Data is copied from the primary store to the extended store, if you configure one, so in most cases events deleted from the primary storage continue to be available for querying from the extended storage location, until they are rotated out of the extended storage. (The timing of the copy from the primary to extended data store depends on a number of factors, including the events per second (EPS) rate, the relative size of the primary store to the extended store, and the percentage of the primary data that has already been copied to the extended store.)

You can monitor how much of the allocated space is currently being used, and the age of the oldest event, by selecting **View > Show Event Store Disk Usage** in Event Viewer. The information is displayed as a pie chart that shows the used and unused space in gigabytes (GB) for each location. There is also an indication of the oldest event currently stored in each location.
You can use this information to help you decide whether to increase or decrease the space allocated to each location.

**Tip**

If you decrease the size of either location, and your new size is less than the amount of space currently being used, the oldest events are immediately deleted until your new target size is reached.

### Archiving or Backing Up and Restoring the Event Data Store

The event data store is not included with the regular Security Manager database backup. If you want to archive or back up the event data store, whether the primary or extended location, you must do so separately. You can restore the backups if necessary.

This procedure explains the steps required for backup and restore for the event data store.

**Tip**

When you disable the Event Manager service, events are not written to the data store, so you will miss any events generated during the backup or restore process.

#### Step 1

To back up the event data store:

b. Determine the name of the event data store folder. The folder is shown in the Event Data Store Location field; the default is `NMSROOT\MDC\eventing\database`, where NMSROOT is the installation directory (usually `C:\Program Files\CSCOpx`).

   If you are backing up the extended data store, the location is identified in the Extended Data Store Location field.

c. Deselect the Enable Event Management check box to stop the Event Manager service. Click **Save** to save your changes. You are prompted to verify that you want to stop the service; click **Yes** and wait until you are notified that the service has stopped.

d. Outside of Security Manager, make a copy of the `NMSROOT\MDC\eventing\config\collector.properties` file and the event data store folder. Place the copy on a separate server so that the backup is available in case of hardware failure.

   If you are also backing up the extended data store, make a copy of that folder as well.

e. In the Security Manager client’s **Tools > Security Manager Administration > Event Management** page, select the **Enable Event Management** check box and click **Save**. You are prompted to verify that you want to start the service; click **Yes** and wait until you are notified that the service has started.

#### Step 2

To restore the event data store, use the same process you used to back up the data with the following exceptions:

- Instead of making a copy of the existing event data store, copy the backup into the event data store location. You can optionally delete the existing data before copying in the backup data. However, as long as you do not exceed the data store size limit, you can mix the backup and existing data. (The data store limit is configured in the **Tools > Security Manager Administration > Event Management** page.)
Using Event Viewer

Use Event Viewer to help troubleshoot network problems involving monitored devices. Using views and filtering, you can analyze problems to help identify the cause and possible remedies.

This section contains the following topics:

- Using Event Views, page 65-34
- Filtering and Querying Events, page 65-40
- Performing Operations on Specific Events, page 65-46
- Looking Up a Security Manager Policy from Event Viewer, page 65-49

Using Event Views

When you view events in Event Viewer, you open a view. A view is a set of filters and other properties, including color rules, selected columns and their positions and widths, and the default time window, that let you define a subset of events. Views help to limit the scope of the events list so that you can more easily find what you are looking for.

This section contains the following topics:

- Opening Views, page 65-35
- Floating and Arranging Views, page 65-35
- Customizing the Event Table Appearance, page 65-36
- Switching Between Source/Destination IP Addresses and Host Object Names, page 65-36
- Configuring Color Rules for a View, page 65-37
- Creating Custom Views, page 65-38
- Editing a Custom View Name or Description, page 65-38
- Switching Between Real-Time and Historical Views, page 65-39
- Saving Views, page 65-39
- Deleting Custom Views, page 65-40
**Opening Views**

You can open up to four historical views and one real-time view in Event Viewer. When you open a view, Event Viewer uses the view settings and time range to retrieve events from the event data store and display them in the event table.

- To open a view so that it replaces the currently active open view, do one of the following in Event Viewer:
  - Double-click the view in the views list.
  - Right-click the view in the view list and select **Open**.

- To open a view in a new tab, do one of the following:
  - Select **File > Open View** from the menu bar. The Open a View dialog box opens, which is essentially the same as the view list. Select the view and click **OK**.
  - Right-click the view in the views list and select **Open In New Tab**.

**Floating and Arranging Views**

You can open up to four historical views and one real-time view at one time. When you have multiple views open, they are opened as tabbed windows in the right pane of the main Event Viewer window, in the most recently used area (“tabbed group”) if there is more than one area. The commands to arrange the windows appear if you right-click the tab for the view window as shown in the following illustration.

You have many options for arranging view windows based on your requirements. For example, you might want to compare two views side-by-side, or remove a view from the main window without closing it.

You can use the following techniques to arrange the view windows to get the display that you desire:

- **Floating a view**—To remove a view from the main Event Viewer window without closing it, right-click the view tab and select **Floating**. The view is moved to its own window.
  
  If you have already floated a view, you can select **Floating to** and choose one of the already-floated windows. The view becomes a new tab in that window.

- **Docking a view**—To move a floating view back to the main Event Viewer window, right-click the view tab and select **Docking**.

- **Arranging views horizontally or vertically for side-to-side comparison**—To create a vertical or horizontal arrangement of views to allow for easy comparison, without floating the views, right-click the view tab and select **New Horizontal Group** or **New Vertical Group**. These
commands split the current tabbed group into the selected layout. You must have at least two views open to use these commands. If you have more than two open views, and you want all of them in separate windows, you need to use the command multiple times.

- Move views to different tabbed groups—If you have several open views, and you have arranged them into horizontal or vertical groups, you can move views among the groups by right-clicking the view tab and selecting Move to Next Tab Group or Move to Previous Tab Group. The commands appear only if views are arranged in a manner where such movement is possible.

- Change the orientation of groups—You can switch between horizontal and vertical layouts by right-clicking the view tab and selecting Change Tab Groups Orientation.

**Customizing the Event Table Appearance**

You can customize the appearance of predefined or custom views in the event table to meet your requirements. You can save these changes even in the predefined views.

You can do the following to customize the event table:

- Create column filters to limit the type of events listed. Use the down arrows in the column heading to define the filter as described in Creating Column-Based Filters, page 65-42.
- Create color rules to highlight events based on severity, as described in Configuring Color Rules for a View, page 65-37.
- Change which columns appear in the table by clicking the Column Selector icon to the right of the table heading row, as described in Columns in Event Table, page 65-17.
- Change the width of a column by clicking the right edge of the column heading and dragging it to the desired size.
- Change the order of the columns by clicking the column heading and dragging the column to the position you want.
- Sort the events list by a column by clicking the column heading. The column sorts based on a three-click cycle: ascending, descending, and default order (which is by event reception time).
- Reset the width of the View Selector and Event Monitoring window to their default values by selecting View > Reset Layout.
- Change whether the source and destination columns show IP addresses or host object names, as described in Switching Between Source/Destination IP Addresses and Host Object Names, page 65-36.

**Related Topics:**

- Creating Custom Views, page 65-38
- Saving Views, page 65-39

**Switching Between Source/Destination IP Addresses and Host Object Names**

You can view source and destination IP addresses or you can view the host object name of objects that match a source or destination IP address. By default, the Event Viewer shows host object names when available.

IP address to host name mapping is supported only for the source and destination of events. Also, the mapping applies to Host objects only; Event Viewer will not show an object name when the source or destination of an event matches a Network object, Group object, or Address Range object.
Please clarify the type and content of the object. E.g. is this feature for host type network/host objects only, that is, the single-value host version of the object? does it work for single-value group objects, or for network or range objects?

To switch between source/destination IP addresses and host object names, do the following:

- To see host objects names for any objects that match a source or destination IP address, select View > Show Network Host Objects. This option is selected by default.

Tip Hover over a host object name to view the IP address associated with that object.

Note An IP address to host object name cache is created when Event Viewer is launched. If you define new host objects, you must submit those changes to the database and then close and relaunch Event Viewer for those mappings to be used.

- To see IP addresses in the source and destination columns, deselect View > Show Network Host Objects.

### Configuring Color Rules for a View

You can use color rules to color-code events shown in the event table based on the severity of the event. Color-coding can help you quickly identify the events that you most want to know about.

You can selectively enable and disable color rules by editing them. This allows you to turn them on and off without deleting them.

Tip You can configure color rules for both predefined and custom views. However, you cannot share color rules between views: all color rules are unique to a view. If you want to apply the same rules to multiple views, you must recreate the rules in each view.

To define and enable a color rule, follow these steps:

1. Open the view in which you want to define the color rule (see Opening Views, page 65-35).
2. Click the Color Rules tab in the View Settings pane (see Event Monitoring Window, page 65-14).
3. Do any of the following:
   - To add a new rule, click the Add button. In the Add Color Rule dialog box, configure the rule as follows:
     - Select Enable to make the rule active.
     - Select the severity level for which the rule applies from the Severity list.
     - Use the Foreground (which is the text color), Background, and Font Type (either Bold or Italics) controls to define how the severity should be presented in the table. The Preview Text area shows how your rule will look.
   - To edit a rule, select it and click the Edit button.
   - To delete a rule, select it and click the Delete button.
Creating Custom Views

A custom view is one in which you define the filters in the view settings. Using custom views, you can configure filter rules to pin-point specific areas for monitoring and analysis. Custom views are private and cannot be shared between users.

You basically have two options for creating custom views, creating a view from scratch or from an existing view:

- To create a custom view that has no predefined column filters, do one of the following:
  - Select File > New View from the menu bar.
  - Click the New button above the view list.

Then, enter a name for the view and optionally a description of the view and click OK. The view is added to the My Views folder in the views list.

- To create a custom view based on an existing view, do one of the following:
  - With the desired base view open, click the down arrow on the Save button in the event table toolbar and select Save As, or select File > Save As from the menu bar.
  - Right-click the desired base view in the views list and select Save As.

Then, enter a name for the view and optionally a description of the view and click OK. The view is added to the My Views folder in the views list. The new view has the same filters as the base view.

Note

View names can be up to 128 characters and contain alphanumeric characters, spaces, hyphens (-), underscore characters (_), plus signs (+), periods, and ampersands (&). The description can be up to 1024 characters.

After you create the new view, you can customize it the same way that you can an existing view:

- Define filters in the view settings. See Creating Column-Based Filters, page 65-42.
- Select the columns to display in the event table. See Columns in Event Table, page 65-17.
- Customize the event table appearance. See Customizing the Event Table Appearance, page 65-36.

Related Topics

- Views and Filters, page 65-3
- Event Table Toolbar, page 65-15
- Editing a Custom View Name or Description, page 65-38
- Deleting Custom Views, page 65-40

Editing a Custom View Name or Description

To change the name of a custom view, or the custom view’s description, do one of the following:

- Select the custom view in the view list and click the Edit button above the list.
- Right-click the custom view in the view list and select Edit.

Then, make the desired changes to the custom view name or description and click OK.
View names can be up to 128 characters and contain alphanumeric characters, spaces, hyphens (-), underscore characters (_), plus signs (+), periods, and ampersands (&). The description can be up to 1024 characters.

You cannot change the name or description of a predefined view.

**Switching Between Real-Time and Historical Views**

You can update the events table for any view using either real-time or historical time periods. A real-time view shows events as they are received, whereas an historical view shows a static list of events that is not updated until you click the **Start** button in the event table toolbar.

To switch between real-time and historical time periods in an open view, do the following:

- To see events in real-time, select **View > Mode > Real Time**, or click the Time Selector control in the event table toolbar and select **Real Time**. For help in locating the control on the toolbar, see **Event Table Toolbar**, page 65-15.
- To see events in an historical period, select the desired time frame from the **View > Mode** menu or from the Time Selector control on the event table toolbar. All options other than Real Time are historical views. For more information, see **Selecting the Time Range for Events**, page 65-40.

**Saving Views**

If you edit the settings for a view, you must save it to make those changes permanent. Saving a view saves changes to filters (for custom views only), table preferences such as selected columns, column width, and sort order, the time range, and color rules. If you make filter changes to a predefined view, you must use Save As to create a new custom view.

- To save changes to a view, do one of the following in Event Viewer:
  - Select **File > Save** from the menu bar.
  - Click the **Save** button in the event table toolbar.
  You are asked to confirm that you want to save your changes.

- To save your changes as a new custom view, do one of the following to open the Save View As dialog box:
  - Select **File > Save As** from the menu bar.
  - Click the down arrow on the Save button in the event table toolbar and select **Save As**.
  - Right-click the view in the views list and select **Save As**.

Then, enter a name for the view and optionally a description of the view and click **OK**. The view is added to the My Views folder in the views list.

---

Note View names can be up to 128 characters and contain alphanumeric characters, spaces, hyphens (-), underscore characters (_), plus signs (+), periods, and ampersands (&). The description can be up to 1024 characters.
Deleting Custom Views

You can delete custom views, but you cannot delete predefined views. To delete a custom view, do one of the following:

- Select it in the view list and click the **Delete** (trash can) button above the list.
- Right-click it in the view list and select **Delete**.

You are asked to confirm your deletion.

Filtering and Querying Events

There are many options for filtering the events that appear in the event table. You can reduce the list of events by selecting the appropriate time range, by filtering on elements in specific columns, or even by searching on a text string.

This section contains the following topics:

- Selecting the Time Range for Events, page 65-40
- Using the Time Slider with Filtering, page 65-41
- Refreshing the Event Table, page 65-41
- Creating Column-Based Filters, page 65-42
- Filtering Based on a Specific Event’s Values, page 65-44
- Filtering on a Text String, page 65-44
- Clearing Filters, page 65-45

Selecting the Time Range for Events

Use the Time Selector control in the event table toolbar, or the equivalent **View > Mode** command, to select the time range for displaying events. The event table lists only those events that occur within the selected time range. For help in locating the Time Selector control on the toolbar, see Event Table Toolbar, page 65-15.

For historical views, the time is based on server time, not the time configured on your workstation.

When you change the time range, the table reloads to show events in the selected range. For historical views, you can refresh the events list by clicking **Start** or by doing the other actions described in Refreshing the Event Table, page 65-41.

The following are your options for the time range:

- To view events from the present time into the past, select one of the following time periods: **last 10 minutes**, **last 1 hour**, **last 12 hours**, **last 1 day**, or **last 1 week**.
- To view events from today or yesterday, select **today** or **yesterday**, as desired.
- To view events from a specific day, select **is on** and then select the date from the displayed calendar.
- To view events from a specific date and time range, select **is between** and select the first and last days and times from the displayed calendars.
- To view real-time events, select **Real Time**.
Using the Time Slider with Filtering

You can use the vertical slider control in the time slider to change the start time for the events shown in the event table. This is particularly useful when you want to locate events and you know the approximate time they occurred.

For details on the operation of the time slider, see Time Slider, page 65-24.

To use the time slider to aid filtering, follow these steps:

**Step 1** Open an historical view, or use the Time Selector in the toolbar, or the View > Mode command, to select an appropriate time range, such as Last 10 Minutes. For more information, see Selecting the Time Range for Events, page 65-40.

**Step 2** Move the vertical slider to the approximate time of the events you want to examine.

The event table is reloaded to display events on or before the time you specified with the vertical slider. This time range is shaded in the time slider, and the length of time selected is based on the length of time selected in the Time Selector (for example, 10 minutes for a Last 10 Minute view, or the same length of time selected for an “is between” view). The time range is noted in the Time Selector control, for example:

- 1/29/10 11:09:34 AM - 1/29/10 12:38:19 PM

**Step 3** To locate the events, you can now do any of the following:

- Apply custom column filters. See Creating Column-Based Filters, page 65-42.
- Use the quick filter to search on a text string. See Filtering on a Text String, page 65-44.
- Scroll or page through the event table.
- Use the time slider paging controls to reset the time range forward or back. For more information, see Time Slider, page 65-24.

**Note** The distance moved forward or back when paging in the time slider depends either on the mode (time range) that is set or the number of events the event table can hold. The position of the vertical slider denotes the most recent event loaded in the event table.

Refreshing the Event Table

When you are using an historical mode, such as “last 10 minutes,” the latest events displayed correspond to the time you selected the time range or opened the view. Similarly, if you are in real-time mode and have clicked Stop, the event table does not include events that arrived after you stopped the event stream.

To refresh the events listed in the event table, so that they are current with your selected time range, do any of the following:

- Click Start in the toolbar, or select View > Start. The table is refreshed based on your currently selected time range. For real-time views, the event stream restarts.
- Select a different time range using the Time Selector in the toolbar or the View > Mode command.
- Select a different time slice using the vertical slider or the pagination controls in the time slider below the event table. For more information on using these controls, see Time Slider, page 65-24.
Creating Column-Based Filters

You can filter the event table in Event Viewer based on the contents of specific columns. Column filters are the type of filter contained in the view settings; they define the basic content of the view. Whenever you apply a column filter, the view settings for the view are updated to include the newly selected filter: you must save the view before closing it if you want the new filter to become a permanent part of the view’s definition.

There are many ways in which to define a column filter:

- In the View Settings pane, click the Add button. You are first prompted to select the column on which to base the filter. When you click OK, you are prompted to create the filter.
- In the View Settings pane, select a filter and click the Edit button to change it.
- In the event table, click the down arrow button in the heading of a column and select any of the following from the drop-down list:
  - A specific entry. The drop-down list contains all values currently displayed in the events listed in the table.
  - (All). Select (All) to remove a filter from this column. The event table is updated to show the events that meet your other filter criteria.
  - (Custom). Select (Custom) to create a filter that might have multiple values, negative values, or be based on data not currently contained in the column in the current event table. Selecting (Custom) is essentially the same as creating a filter directly in the View Settings pane.
- In the event table, you can right-click a value and select Filter This Value. This action has the same effect as selecting the value from the drop-down list for the column.
  You can alternatively select Filter Not This Value to create a filter that excludes a value,
- In the event table, you can right-click a value and select Create Filter from Event. You are prompted to select the specific columns to include; the column on which you right-clicked is initially selected, but you can deselect it.

The following procedure explains how to build a custom column-based filter, one in which you are not simply selecting a value from the column’s drop-down list.

Tips

- Column filters are cumulative: for an event to appear in the event table for a view, the event must meet all column filter criteria. You cannot create a set of OR’ed column filters.
- Some columns allow you to select network/host or service policy objects to define the filter criteria. Selecting policy objects can simplify your filters. However, for a policy object to be selectable in a filter, the object must be committed to the database. If you create a new object for filtering purposes, ensure that you submit your changes in Configuration Manager (and if using Workflow mode with an approver, get the changes approved) before attempting to create the filter in Event Viewer.

When using policy objects, the filtering recognizes whether a device-level override is defined for the object. For example, if you use a network/host object that contains 10.10.10.10, and Device A has an override to change the address to 10.10.10.12, events from Device A appear in the list only if the event matches 10.10.10.12. For devices that do not have overrides, the events must match 10.10.10.10. Furthermore, if Device A has an event that matches 10.10.10.10, that event is not listed because it does not match the device-level override. Thus, using policy objects can provide results that vary by device and therefore match more closely to your policy definitions.

If your organization is using ACS to control user access, you must have the appropriate View Object privileges for network/host, network/host-IPv6, and service objects to use them in filters.
You can filter on the contents of most but not all columns. If a column does not have a down arrow, you cannot filter on it. For example, you cannot filter on Description, Event Name, Generation Time, or Receive Time.

The filter icon (a funnel) appears in the heading of a filtered column.

For a description of the available columns, see Columns in Event Table, page 65-17.

**Step 1**  
Do one of the following:

- In the View Settings pane, click the Add button. The Add Custom Filter to a Column dialog box opens. Select the column on which to base the filter and click OK.
- In the View Settings pane, select a filter you want to change and click the Edit button.
- From the drop-down list for a column, select (Custom).
- Right-click any cell in the desired column and select Custom Filter.

The Custom Filter dialog box opens for the selected column.

**Step 2**  
In the Custom Filter dialog box, select the desired values. The following illustration shows a typical example of this dialog box, for the Source column.

Following is a description of the controls you might find in the Custom Filter dialog box. Not all controls appear for every column:

- **Available and Selected Items lists**—In most cases, to select an item you highlight it in the left list, which contains the available values, and click the right arrow to move it to the list of selected values. You can select multiple values. The right list defines the filtered values.

  The items listed in the available values column are determined by the values currently present in the events listed in the events table. For address and service fields, the list also includes policy objects. If there are a lot of available values, you can search for the desired value by typing into the edit box above the list; the list is filtered as you type. Click the down arrow next to the Q to change how your search string is evaluated for matches.

  You can also select, or deselect, values using the following techniques:

  - Type the item into the edit box above the selected values list and click the + button. This technique is useful if there is a large number of available values, or if you want to filter on a value that is not present in the current events list.
- Double-click an item in either list to move it to the other list.
- Click the double-arrow buttons to move all items, regardless of your selection.

**Note**
In a limited number of cases, the Custom Filter dialog box contains a single list. For example, the dialog boxes for the Event Type ID and Device columns contain single selectors. In these cases, make your selection using the check boxes next to the items; selecting a folder selects all items in the folder.

- **Filter on IPv6 Addresses**—For columns that contain addresses, use this option to toggle between listing IPv4 and IPv6 addresses and network/host objects in the available values column. You can filter on either IPv4 addresses or IPv6 addresses, but not both, in a single view.

- **Condition, Not**—Defines the condition applied to the selected items, typically “is in.”
  To create a negative condition, so that selected values define the events to not include in the events table, select the Not option.

**Step 3**
Click OK.

The view settings are updated to include the new filter, and the events table is updated to show only those events that satisfy all filters.

### Filtering Based on a Specific Event’s Values

You can base a new filter on information contained within an event, or a single cell within an event, by right-clicking and choosing a filter command. When you filter using these commands, a column filter is added to the view settings. You can do the following:

- To create a filter based on multiple values in the selected event, select **Create Filter from Event**, then select from the dialog box the values on which to filter. The dialog box lists only those columns that are displayed in the table; the current values are shown in parentheses. For an explanation of the columns, see **Columns in Event Table**, page 65-17.

- To filter on only the value in the cell on which you right-click, select **Filter This Value**.

- To filter to exclude the value in the cell on which you right-click, select **Filter Not this Value**. All events that do not contain the selected value in this column, including all empty cells, are shown in the table.

- To filter on the flow of the selected event, based on source, source service, destination, and destination service, select **Filter This Flow**.

### Filtering on a Text String

Use the quick filter to search for text strings in events. As you type a search keyword, the events table automatically excludes non-matching events as you type. You can search on all columns (the default), or you can select a specific column in which to search.

The following illustration shows the quick filter, which is on the right of the event table toolbar (see **Event Table Toolbar**, page 65-15).
To perform a search, simply type in the search string. To change how the string is evaluated, click the down arrow next to the Q (magnifying glass) in the left of the edit box. You can limit the search scope using these controls:

- **Column name**—Select a specific column to search only within that column. The list includes all columns currently displayed in the table. The default is to search all columns.
- **Case sensitivity**—Select **Case sensitive** or **Case insensitive** to control whether capitalization is considered when selecting matches. The default is case insensitive.
- **Wild card usage**—Select **Use Wild Cards** to have the following characters evaluated as wild cards:
  - * (asterisk)—matches 0 or more characters.
  - ? (question mark)—matches one character.
- **Match method**—Select one of the following to determine the location within a cell that the search string should reside:
  - Match from start—The string must be at the beginning of the cell.
  - Match exactly—The cell must contain all and only the search string.
  - Match anywhere—The string can appear anywhere within the cell.

To remove the search string, simply delete it from the quick filter edit box.

For example, if you want to find events that relate to ports that start with tcp/48, type **tcp/48** into the quick filter. In the following illustration, note that all but six events are filtered out of the table. In this example, the search string is found in the Source Service column for the first five events, but in the Destination Service column for the sixth event. If you know beforehand that you are interested in destination services only, you could select **Destination Service** from the quick filter drop-down list and the table would show the last event only.

### Clearing Filters

When you apply filters to the event table, non-matching events are not displayed. You might find that you need to see the non-matching events. You can either open a different view that applies different (or no) filters, or you can clear filters from the current view.

When clearing filters, the filter definition is removed from the view settings, but the change is not permanent until you click **Save**. Thus, you can remove filters temporarily without redefining the view settings.

You can clear filters one at a time or clear all filters:

- To clear a single filter, so any of the following:
  - Select the filter in the View Settings pane and click **Delete**.
  - Select **(All)** from the drop-down list of a filtered column.
  - Right-click in the filtered column and select **Clear This Filter**.
• To clear all filters, right click in the events table and select Clear all filters.

Performing Operations on Specific Events

You can operate upon a single event in the event table in a variety of ways, which include the following:

• Right-click—Right-clicking a single event in the event table opens a context menu with commands that you can use on the event. For more information about what you can do from the right-click menu, see the following topics:
  - Event Context (Right-Click) Menu, page 65-46
  - Examining Details of a Single Event, page 65-48
  - Copying Event Records, page 65-48
  - Saving Events to a File, page 65-49
  - Filtering Based on a Specific Event’s Values, page 65-44

• Select an event—When you click a single event in the event table it is highlighted and the Event Details pane displays details for that particular event. Hold the Ctrl key to select additional events, or hold the Shift key to select a range of events.

• Double-click an event—Double-clicking a single event in the event table opens the Event Details dialog box, which shows the event information in an easier-to-read format. From the Event Details dialog box, you can print the displayed details or copy some, or all, of the details to the clipboard for pasting into another program. You can use the Next and Previous buttons to scroll through the events listed in the event table. For information on the meaning of the attributes, see Columns in Event Table, page 65-17.

Alternatively, you can right-click on an event and select Show All Details to open the Event Details dialog box.

Event Context (Right-Click) Menu

When you right-click an event in the Event Table, a context menu appears that provides commands that you can use with the selected event. The specific list of available commands depends on the type of event and also the specific cell on which you right-click. The following table explains all of the available commands.

Table 65-9 Event Context Menu

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clear This Filter</td>
<td>Removes the filter defined for this column. The command is available only if you right-click on a cell that is in a filtered column. The filter is removed from the view settings. You must save the view to make your change permanent.</td>
</tr>
<tr>
<td>Clear All Filters</td>
<td>Removes all filters from the view settings. This command is available only if there is at least one column filter. You must save the view to make your change permanent.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Filter This Value</td>
<td>Creates a column filter based on the value in the cell that you right-click. You can create either a positive or negative filter based on the value. The view settings are updated with the new filter and replace any existing filter for this column. You must save the view to make your change permanent.</td>
</tr>
<tr>
<td>Filter Not This Value</td>
<td>The view settings are updated with the new filter and replace any existing filter for this column. You must save the view to make your change permanent.</td>
</tr>
<tr>
<td>Create Filter from Event</td>
<td>Creates a set of column filters based on the values in the selected event. You are prompted to select the specific columns to include; the column on which you right-clicked is initially selected, but you can deselect it. The view settings are updated with the new filters and any existing column filters for the selected columns are replaced. You must save the view to make your changes permanent.</td>
</tr>
<tr>
<td>Custom Filter</td>
<td>Creates a custom column filter, as described in Creating Column-Based Filters, page 65-42. The view settings are updated with the new filter and any existing filters for the selected columns are replaced. You must save the view to make your changes permanent.</td>
</tr>
<tr>
<td>Filter This Flow</td>
<td>Creates a set of column-based filters that present the events related to a specific traffic flow. Filtered columns are source and source service and destination and destination service. The view settings are updated with the new filter and any existing filters for the selected columns are replaced. You must save the view to make your changes permanent.</td>
</tr>
<tr>
<td>Show IPLogs</td>
<td>Opens the IP log for an IPS Alert event using an external packet analyzer tool. You must have a packet analyzer installed and associated with *.pcap file extension.</td>
</tr>
<tr>
<td>Show All Details</td>
<td>Opens the Event Details dialog box for the event, which shows all event information in an easier-to-read format. You can also print the details or copy them to the clipboard. The details are the same as those shown in the Event Details pane below the event table.</td>
</tr>
<tr>
<td>Copy commands</td>
<td>You can use the following commands to copy event data to the clipboard. You can then paste the data into a spreadsheet or other program for your use. For more information, see Copying Event Records, page 65-48.</td>
</tr>
</tbody>
</table>

- Copy Cell—Copies the contents of the cell you right-click to the clipboard.
- Copy Selected Events—Copies the contents of all selected (high-lighted) events to the clipboard.
- Copy All Events—Copies the contents of all listed events to the clipboard.

This command is useful only if you have filtered the event table to a manageable number of events.
Chapter 65      Viewing Events

Using Event Viewer

Examining Details of a Single Event

Each event contains a lot of specific information in many separate fields. Typically, you display a subset of these fields in the event table. When you want to see the complete details of an event, you can use either of the following:

- **Event Details pane**—Select the event and open the Event Details pane below the event table. You can open the pane by clicking anywhere in the “Event Details” title row, or you can select View > Show Event Details from the menu. The Event Details pane organizes the information in tabs. For more information about this pane, see Event Details Pane, page 65-25.

- **Event Details dialog box**—You can open this dialog box by double-clicking the event, or by right-clicking the event and selecting Show All Details. The information is presented as a flat list and shows the information that would be shown on the Details tab in the Event Details pane. For information on the meaning of the attributes, see Columns in Event Table, page 65-17.

The Event Details dialog box includes the following controls:

- Print button—Click this button to print the information. You are prompted to select a printer.

- Copy button—Click the down arrow on this button and select All Rows or Selected Rows. The information is copied to the clipboard, and you can paste it into another application. Note that the Selected Rows command works only if you select at least one row in the table.

- Next, Previous buttons—Click these buttons to scroll through the events currently displayed in the event table. Next moves up and Previous moves down in the table.

Copying Event Records

You can copy single events, multiple events, all events, or even the contents of a single cell to the clipboard. You can then paste the information into another application, such as a spreadsheet or an e-mail message.
You can do the following from the event table:

- **Copy selected events**—To copy one or more selected events, right-click in the event table and select **Copy Selected Events**. The event you right-click does not matter, the copied events are those that are selected (highlighted) in the table.

  Click an event to select it. Hold **Ctrl** key to select additional events, or hold the **Shift** key to select a range of events.

- **Copy the contents of a single cell**—To copy the contents of a single cell in one event, right-click the cell and select **Copy Cell**. You cannot copy cell contents if there is more than one event selected in the table.

- **Copy all events**—To copy all the events shown in the event table, right-click anywhere in the table and select **Copy All Events**.

### Saving Events to a File

Rather than copying events to the clipboard and pasting them into another application, you can directly save events to an HTML or comma-separated values (CSV) file. HTML files are useful for viewing information, whereas you can open a CSV file in a spreadsheet application for further analysis and report generation.

When saving event data, you are prompted to select a folder and enter a file name.

You can do the following from the event table:

- **Save selected events**—To save one or more selected events, right-click in the event table and select either **Save Selected Events as HTML** or **Save Selected Events as CSV**. The event you right-click does not matter, the saved events are those that are selected (highlighted) in the table.

  Click an event to select it. Hold **Ctrl** key to select additional events, or hold the **Shift** key to select a range of events.

- **Save all events**—To save all the events shown in the event table, right-click anywhere in the table and select either **Save All Events as HTML** or **Save All Events as CSV**.

### Looking Up a Security Manager Policy from Event Viewer

In Event Viewer, if an event was generated from an IPS signature policy, or from certain actions related to explicit access rules (such as denied access), you can quickly locate the related signature or access rule from the event itself.

The main reason you would want to perform policy lookup is to adjust a policy based on the events that it is generating. For example, an access rule might be dropping traffic that you actually want to allow. Because you are looking at the event, you know there is a policy that is causing the event, so with a few clicks, you can get from that event to the policy that you need to reconfigure.

You can look up policies from the following types of events:

- **Firewall events**—You can look up policies for the following syslog messages:
  - 106023—Denied IP packet.
  - 106100—Permit/Denied by ACL.
  - 302013—Built TCP (started a TCP session).
  - 302015—Built UDP (started a UDP session).

- **IPS alert events**—All IPS events that have valid signature and sub-signature identifiers.
Tips and Caveats

- You cannot look up firewall policies for events that contain IPv6 addresses. You can look up IPS policies for IPv6 addresses, however.

- When a policy that is based on IP address alone and not on a user name triggers an event, the device looks up the IP address in the Active Directory and if a user name is associated with that IP address, the user name is added to the syslog. Hence, even if a policy does not contain a user name, the resulting syslog might contain it. Policies cannot be created with a destination user and, as a result, this field will not be used during policy lookup.

- If an event is generated for a policy that is configured based on source/destination FQDN, the resulting syslog will not contain the FQDN because of a device defect. In such cases, policy lookup will not work.

- If an event is generated for a policy that is based on user groups, the syslog will contain the specific user name that triggered the event and not the user group. In such cases, policy lookup will not work.

- Hash codes are required for successful policy lookups from syslog 106023 and 106100 events. These hash codes are available only if you deployed the configuration using Security Manager. If policy lookup fails, try deploying the configuration (either to the device or to a file), then try the policy lookup again.

- If you had applied a filter to the device’s policy table, and the rule or signature that generated an event is filtered from the current view, Security Manager cannot highlight it. Clear the filter and try again.

- If the event is caused by an implicit rule, such as the implicit deny any at the end of access rules, Security Manager cannot highlight the rule. It is considered good practice to create an explicit deny any rule at the end of access lists.

- The target policy is always found in Device view, even if the device uses a shared policy. Device view is opened if necessary to highlight the policy.

- For IPS signatures, you might not be able to edit the signature if it is a default signature.

- For access rules, the selected rule is the best match for the event. It is possible that more than one rule would generate the same event if you have overlapping or redundant rules. In these cases, editing the selected rule might not completely eliminate the event, because a subsequent rule might perform the same action. Use the access rules tools to analyze and combine overlapping rules.

- For access rules, multiple rules might permit a packet during session creation, but the first rule only is highlighted.

- If your organization is using ACS to control access, you must have View Device privileges to the device, and also View privileges to the firewall or IPS policy, to perform policy lookup. If you do not have all permissions, you will get an “Unable to Find Matching Rule” error if you try to look up a matching rule.

Step 1  Right-click the event in Event Viewer and select Go To Policy.

Tip  You can identify whether you can look up policies from the event by looking at the Event Name cell in the table. If there is a binoculars icon before the event name, policy lookup is available. Also, if the Go To Policy command is greyed out, you cannot look up policies for that type of event.
Step 2  Security Manager finds the related access rule or IPS signature for the device and highlights it in the policy table. From here, you can edit the policy to view or change it; for detailed instructions, see Configuring Access Rules (IPv4 or IPv6), page 15-7 and Configuring Signatures, page 37-4.
Your changes do not take effect until you submit and deploy the updated configurations.

Examples of Event Analysis

There are many different techniques you can use to analyze and respond to events generated by your network devices. The examples in this section can help you understand some of the things you can do with the Security Manager Event Viewer.

This section contains the following topics:

- Help Desk: User Access To a Server Is Blocked By the Firewall, page 65-51
- Monitoring and Mitigating Botnet Activity, page 65-53
- Removing False Positive IPS Events from the Event Table, page 65-58

Help Desk: User Access To a Server Is Blocked By the Firewall

In this example, the help desk gets a call from a user who cannot access a server. There are many reasons that a user might not be able to access a server, such as:

- Problems at the server’s end of the network, including server down, no network connection, or the server’s firewall is actively preventing access by policy.
- Problems in the network cloud between the user and the server, such as routing problems.
- Problems in the user’s network, which could include workstation problems, physical problems with a network connection (for example, broken wires), problems with the switch port or wireless access point, DNS lookup failures, and so forth.

The Security Manager Event Viewer cannot identify or resolve these problems. However, it can identify whether a firewall that you control is blocking access to the server. This can help you either to rule out the firewall as being the source of the problem, or if it is blocking access, to fix the problem or to inform the user that the server is blocked by policy.

This procedure assumes that you have first determined that access to the server is not being denied by policy and that the firewall should allow access to the server.

Step 1  Ask the user for the IP address of the workstation and server.
Step 2  Open Event Viewer, for example, by selecting Launch > Event Viewer in Configuration Manager.
Step 3  Double-click the Firewall Traffic Events view to open it. Optionally, you can use the All Device Events view if you also want to see if there are any IPS events related to the workstation.

Tip  You can also select the Firewall Denied Events view to see just denial events. However, you might want to see other events related to the user’s workstation.

Step 4  Ask the user to retry the server access.
Step 5  Click the **Start** button, or select **View > Start**, to refresh the event table with the latest events.

Step 6  Type the user’s IP address into the **Search within Results** box. The list of events is filtered as you type, and presents events in which the search string appears in any column. In the following illustration, the event list shows all events in the past 10 minutes for the IP address 10.52.150.50.

*Figure 65-5  Restricting the Events List to One IP Address*

```
<table>
<thead>
<tr>
<th>Received Time</th>
<th>Severity</th>
<th>Event Name</th>
<th>Source</th>
<th>Source Port</th>
<th>Destination</th>
<th>Destination Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>9:21:00:12.01</td>
<td>Warning</td>
<td>156023</td>
<td>10.1.1.1</td>
<td>10.52.150.50</td>
<td>192.168.123</td>
<td>64.100.34.14</td>
</tr>
<tr>
<td>9:21:00:12.01</td>
<td>Warning</td>
<td>156023</td>
<td>10.1.1.1</td>
<td>10.52.150.50</td>
<td>192.168.123</td>
<td>64.100.34.14</td>
</tr>
<tr>
<td>9:21:00:12.01</td>
<td>Warning</td>
<td>156023</td>
<td>10.1.1.1</td>
<td>10.52.150.50</td>
<td>192.168.123</td>
<td>64.100.34.14</td>
</tr>
<tr>
<td>9:21:00:12.01</td>
<td>Warning</td>
<td>156023</td>
<td>10.1.1.1</td>
<td>10.52.150.50</td>
<td>192.168.123</td>
<td>64.100.34.14</td>
</tr>
</tbody>
</table>
```

**Tip**  You can also select the IP address from the Source column’s drop-down list, and the server’s IP address from the Destination column’s drop-down list (or the reverse), to show only events with both the source and destination that interests you. Use the column filters if the search string does not sufficiently reduce the event list for easy analysis.

Step 7  Look for an event that indicates that traffic from the user’s workstation to the server, or from the server to the workstation, was denied. Syslog **106xxx** messages indicate denial actions.

Select the event in the table and open the Event Details pane at the bottom of the window. The tabs in this pane show the complete message information and include plain-language explanations and recommended actions.

Step 8  If the event is message **106023** or **106100**, you can quickly locate the access rule that is denying the connection and fix it. You can identify whether you can look up policies from the event by looking at the Event Name cell in the table. If there is a binoculars icon before the event name, policy lookup is available. Also, if the Go To Policy command is greyed out, you cannot look up policies for that type of event.

**Tip**  If the traffic is denied because of the implicit **deny any** rule at the end of the access list, the Go To Policy command cannot take you to the rule. For tips about rule lookup, see *Looking Up a Security Manager Policy from Event Viewer*, page 65-49.

a.  Right-click the event and select **Go To Policy**. You are taken to Device view with the rule selected. You are notified if a matching rule cannot be found.

b.  Modify the rule so that it allows the desired access. This might be as simple as deleting the rule, or you might have to add a new rule that specifically allows traffic to or from the destination server (place the permit rule above the deny rule). Your organization’s security policy determines the allowable changes. For more information about configuring the access rules policy, see *Configuring Access Rules (IPv4 or IPv6)*, page 15-7.

c.  Submit and deploy the updated configuration to the device. For more information on the deployment process, see *Deploying Configurations in Non-Workflow Mode*, page 8-27 or *Deploying Configurations in Workflow Mode*, page 8-32.

Wait for deployment to complete successfully.
Step 9 Ask the user to try to access the server again. If access is again denied, click Start in Event Viewer to refresh the events list and find the latest denial event.

Tip There might be more than one access rule that can deny communications with the server. The access rule policy is processed in order, top to bottom, so deleting a rule that prevents access can result in a rule that previously was not being hit suddenly becoming active. If you have a very long access rule policy, you could have several rules that you will have to remove one after the other. Alternatively, you could use the Rule Combiner tool to consolidate and simplify your access rules policy; for more information, see Combining Rules, page 12-21.

Step 10 Continue to resolve access denial events until the firewall is no longer blocking access.

Tip You can also use the Packet Tracer tool to simulate traffic going through the ASA device from the workstation to the server. In Device view, right-click the device that is denying access and select Packet Tracer. For more information, see Analyzing an ASA or PIX Configuration Using Packet Tracer, page 68-1.

After resolving all events, if the user still cannot reach the server, you know that the firewall is no longer one of the network elements that is blocking access. Consider other intervening network devices; perhaps a router includes an access rule that blocks the traffic.

Monitoring and Mitigating Botnet Activity

After you configure Botnet Traffic Filtering as described in Chapter 18, “Managing Firewall Botnet Traffic Filter Rules”, you want to monitor it and resolve any problems identified in your network. You can use Security Manager and ASDM to monitor Botnet activity, and mitigate identified problems, as explained in the following sections:

- Understanding the Syslog Messages That Indicate Actionable Events, page 65-53
- Monitoring Botnet Using the Security Manager Event Viewer, page 65-54
- Monitoring Botnet Using the Security Manager Report Manager, page 65-56
- Monitoring Botnet Activity Using the Adaptive Security Device Manager (ASDM), page 65-56
- Mitigating Botnet Traffic, page 65-57

Understanding the Syslog Messages That Indicate Actionable Events

Botnet Traffic Filter events use syslog message numbers 338xxx. However, some messages are informational and require no action on your part.

When viewing syslogs for botnet events, you should be most concerned with the following message numbers. For information on dealing with messages that indicate blacklisted or whitelisted traffic, see Mitigating Botnet Traffic, page 65-57. For detailed descriptions of syslog messages, see the Syslog Message document for your ASA software version at http://www.cisco.com/en/US/products/ps6120/products_system_message_guides_list.html.
• **338001 to 338004**—Indicate blacklisted traffic that the ASA is logging, but the ASA is not stopping the traffic. These messages require immediate attention if you want to stop botnet activity that is in progress.

• **338005 to 338008**—Indicate blacklisted traffic that the ASA is logging and dropping. This indicates that the traffic was covered by a drop rule. Thus, your network is being protected, although you still need to disinfect the victim computer.

• **338201, 338202**—Indicate greylisted traffic that the ASA is logging but not dropping. These messages can indicate an active botnet connection that needs to be handled immediately.

• **338203, 338204**—Indicate greylisted traffic that the ASA is logging and dropping. Your network is protected from this traffic. However, if the greylisted site is legitimate, the fact that the traffic is being dropped might be a problem that requires immediate attention. You can whitelist the greylisted address if you determine it is legitimate and redeploy the configuration, as described in Adding Entries to the Static Database, page 18-5.

• **338305 to 338307, 338310**—The ASA could not download the dynamic filter database. Ensure that you configured DNS lookup on the device, and that there is a routable network path to the Cisco Intelligence Security Operations Center. You might need to contact Cisco Technical Support.

• **338309**—The Botnet Traffic Filter license is not current, and you cannot download the dynamic database. Purchase and install the appropriate license. The Botnet Traffic Filter license is time-based, so you might have had a valid license that expired.

### Monitoring Botnet Using the Security Manager Event Viewer

You can use the Event Viewer application to monitor syslog events generated by an ASA device. The Event Viewer has a predefined view that shows just botnet events.

Botnet messages are in the informational to debug severity levels and are numbered 338xxx.

**Tip**

This procedure assumes the Event Manager service is enabled. If it is not, enable it using the Tools > Security Manager Administration > Event Management page.

**Step 1**

Open Event Viewer, for example, by selecting Launch > Event Viewer in Configuration Manager.

**Step 2**

Double-click **Botnet Events** from the list of predefined views in the left pane. You must double-click to activate the view and load it into the right pane. To verify the view has been opened, ensure that the tab name for the view in the right pane says “Botnet Events.” The following illustration shows an example of the botnet events view.
Step 3 To see the details of a specific event, select it in the table. You can then do the following:

- Double-click the event to see the tabular information presented in a more readable format.
- Open the Event Details section at the bottom of the window. The details pane shows information about the event organized on tabs. The Explanation and Recommended Action tabs include plain-language information about the event and what you might want to do about it.

The following illustration shows the Event Details pane for the Botnet Destination Blacklist message 338004. In this example, the recommended action is shown. The explanation for this message is “This syslog message is generated when traffic to a blacklisted IP address in the dynamic filter database appears.” For information on dealing with this type of event, see Mitigating Botnet Traffic, page 65-57.
Step 4  To narrow the list of events to those generated by a single ASA, click the drop-down arrow in the Device column and select the desired device from the list. If you want to narrow the list to multiple ASAs, select Custom from the drop-down list and select the desired devices in the dialog box that appears.

You can also narrow the list using filters for any of the other columns. Filtering works the same way for all columns: either select the desired value from the drop-down list, or select Custom to create a more complex column filter.

---

### Monitoring Botnet Using the Security Manager Report Manager

You can use the Report Manager application to generate reports on botnet activity. There are predefined reports that show the top infected hosts, the top malware ports, and the top malware sites. For a description of these reports, see Understanding Firewall Summary Botnet Reports, page 66-14.

**Tip**  This procedure assumes the Event Manager service is enabled. If it is not, enable it using the Tools > Security Manager Administration > Event Management page.

**Step 1**  Open Report Manager, for example, by selecting Launch > Report Manager in Configuration Manager.

**Step 2**  Open the desired report from the System > FW > Summary Botnet folder. You can open the report by double-clicking it or by right-clicking and selecting Open Report.

**Step 3**  (Optional) Customize the report to select the desired time range and devices to include in the report. For more information, see Editing Report Settings, page 66-21.

If you want to save your custom settings to generate the report again in the future, click Save As to create a custom report. For more information, see Creating Custom Reports, page 66-20.

**Step 4**  Click Generate Report to retrieve the collected information and display the graphs and tabular data. For more information, see Opening and Generating Reports, page 66-18.

If you want to generate the report on a regular basis, you can configure a schedule as described in Configuring Report Schedules, page 66-29.

---

### Monitoring Botnet Activity Using the Adaptive Security Device Manager (ASDM)

The Adaptive Security Device Manager (ASDM) includes botnet reporting features. A read-only version of ASDM is installed with the Security Manager client as a device manager, and you can start ASDM from within Security Manager.

**Tip**  You can also install the full ASDM application separately. However, any configuration changes that you perform in ASDM are considered out-of-band changes by Security Manager and are overwritten the next time you deploy configurations from Security Manager. If you ever find a need to make configuration changes using ASDM, be sure to rediscover policies on the device in Security Manager so that Security Manager’s view of the configuration is up-to-date.

**Step 1**  In Device view in Configuration Manager, select the ASA device.
Step 2 Select **Launch > Device Manager** to open an ASDM connection to the ASA. You are warned that you cannot make configuration changes. Click **Yes** to continue.

Step 3 In ASDM, view Botnet Traffic Filter monitoring information in the following areas:

- **Home > Firewall Dashboard** includes a Botnet Traffic Filter summary.
- **Monitoring > Botnet Traffic Filter > Reports** includes charts on the top botnet sites, ports, and infected hosts.
- **Monitoring > Logging > Log Buffer** shows historical syslog messages.
- **Monitoring > Logging > Real-Time Log Viewer** shows syslog messages as they are generated.

**Tip** You can also search the dynamic database on the **Configure > Botnet Traffic Filter > Botnet Database** page. This page also allows you to manually start a database download or to purge the dynamic database. These actions do not change the device’s configuration and do not require policy rediscovery in Security Manager.

---

**Mitigating Botnet Traffic**

Botnet traffic mitigation is a two step process:

1. Stop traffic from your network to the botnet control site.
2. Disinfect the victim computers.

The following procedure explains the process in more detail.

Step 1 You see syslog events that indicate that packets are traveling to or from an objectionable address, typically message numbers 338001-338008 or 338201-3382004. For detailed information about these messages, see **Understanding the Syslog Messages That Indicate Actionable Events**, page 65-53.

**Tip** Messages 338201-3382004 are for greylisted traffic. You might want to first determine if the greylisted traffic is truly objectionable before stopping the traffic.

Step 2 Stop the botnet traffic:

- Messages 338005-338008 and 338203-338204 indicate that the ASA is already dropping the traffic for you. Traffic classification drop rules cover the blacklisted or greylisted addresses. See **Enabling Traffic Classification and Actions for the Botnet Traffic Filter**, page 18-7.
- Messages 338001-338004 and 338201-338202 indicate that the ASA is logging the event but not dropping the traffic. The first order of business is to stop this traffic.

You have these options for stopping the botnet traffic if the ASA is not already dropping it because of a drop rule:

- (Preferred method.) Configure a drop rule for the botnet site and redeploy the configuration. See **Enabling Traffic Classification and Actions for the Botnet Traffic Filter**, page 18-7.
- (Second best method.) Log into the ASA using an SSH client, enter privileged EXEC mode, and use the **shun** command to prevent traffic to or from the botnet site. You can also issue this command through ASDM in a CLI window, but you cannot do it from Security Manager. The shun command does not create a permanent rule blocking traffic.
For example, if the botnet site is 10.1.14.14, and the internal infected computer is 10.100.10.10, issue the following commands. The first command blocks all incoming traffic from the botnet command center, the second blocks traffic from the infected computer just to the botnet site.

```
shun 10.1.14.14
shun 10.100.10.10 10.1.14.14
```

(Not recommended.) Although the `shun` command is preferred, you can also create a permanent rule in the interface’s access control list (ACL) that denies traffic to or from the botnet site. With the device selected in Security Manager, select **Firewall > Access Rule**, and create two rules: one that denies the botnet site as the source address, with any destination address; one that denies any source address with the botnet site as the destination address. For service, select IP so that all traffic is blocked. You must deploy the configuration for the rule to take effect.

Creating an access rule is not the preferred method because it creates a permanent rule, whereas botnet sites are transient. Using the Botnet Traffic Filter to dynamically block botnet traffic is a better fit for this type of network attack compared to traditional access rules.

**Step 3** Shut down network access for the infected computer. For example, find the switch port to which the computer is attached, and shut down the port using the switch’s CLI. There might also be wireless access for the computer, so completely shutting down network access might not be a simple task.

**Step 4** Inform the owner of the victim computer that it is infected and dispatch IT personnel to disinfect the computer. Tools and techniques for disinfecting a computer are outside the scope of this document.

### Removing False Positive IPS Events from the Event Table

An IPS appliance or service module (IPS device) triggers an alarm when a given packet or sequence of packets matches the characteristics of known attack profiles defined in the IPS signatures. False positives (benign triggers) occur when the IPS reports certain benign activity as malicious. Because each event requires human intervention to diagnose, spending your time analyzing false-positive events can significantly drain resources.

Due to the nature of the IPS signatures that are used to detect malicious activity, it is almost impossible to completely eliminate false positives without severely degrading the effectiveness of the IPS or severely disrupting the computing infrastructure of an organization (such as hosts and networks). Customized tuning when an IPS is deployed minimizes false positives. Periodic re-tuning is required when the computing environment changes (for example, when new systems and applications are deployed). IPS devices provide a flexible tuning capability that can minimize false positives during steady-state operations.

An example of a false-positive is a network management station that periodically builds a network discovery map by running ping sweeps. A ping sweep triggers the ICMP Network Sweep with Echo signature (signature ID 2100). Thus, ICMP Network Sweep with Echo events that have the IP address of the network management station as the source address are actually expected and desired events.

You have the following options to remove false-positive IPS events from the event table in Event Viewer:

- **Filter out events from known “clean” sources.**

  By filtering out the events, you do not stop their generation, but you also do not see them in the table. Because they are still available (you can remove the filter), you can see the events if some particular network behavior requires that you examine activity from the excluded host.

  There are two main drawbacks to using this technique:

  - The events are still generated, adding events to the event store.
– The filter excludes all events from a host. You cannot create a complex filter that excludes a host/signature ID pair.

The procedure below shows how to filter out events from sources that you identify as clean.

**Create event action filter rules to stop the generation of the false-positive events.**

Event action filter rules are the easiest way to stop generating events, and are thus preferable to editing signatures or creating custom signatures, which is a more difficult task. If you exclude a host in an event action filter rule, the IPS device does not generate alarms or log records when the host triggers the event.

Because you can target specific signatures, rather than making a blanket-exclusion of all events from a host, you can eliminate only those events that you are certain are benign. For example, the following event filter rule removes the Produce Alert action from the ICMP Network Sweep with Echo (2100) signature for the network management station 10.100.15.75. The network management host is identified as the attacker address; the action specified in an event filter rule is actually the action that is removed from the event. Note that if you create an event action override rule to add other alert-producing actions to ICMP Network Sweep with Echo events, you must also remove the override action in this rule.

For more information about configuring event action filter rules, see Configuring Event Action Filters, page 38-5.

The following procedure shows how to use filtering in Event Viewer to remove false positives from the events list. It uses network/host policy objects to accomplish the filtering.

*Tip*

By creating source or destination address filters using network/host objects, you can update the filters simply by changing the contents of the object. You do not need to add or remove filters from your views. Another advantage is that you can proactively create filters for addresses that do not currently appear in the events table; the source/destination column filter controls in Event Viewer list only those addresses that currently appear in listed events.

**Step 1** Create a network/host policy object that includes the IP address of the clean hosts or networks.

a. Select **Manage > Policy Objects** to open the Policy Object Manager window (see Policy Object Manager Window, page 6-4).

b. Select **Networks/Hosts** from the table of contents.

c. Click the **Add Row (+)** button beneath the table of network/host policy objects, and select **Group** as the object type.

d. In the Add Network/Host Group dialog box, enter a name for the object, for example, **IPS_Safe_Hosts**.

e. Select **Enter IPv4 Address Information** and enter the IP address, for example, 10.100.15.75.

f. Click **Add >>** to add the IP address to the Members in Group list.

g. Click **OK** to create the object.

h. Click **Close** to close the Policy Object Manager window.
Step 2  Select **File > Submit** to submit your changes to the database (non-Workflow mode). Keep in mind that all of your configuration changes are submitted, not just the new policy object.

If you are using Workflow mode, you must submit your activity and have it approved, if necessary.

**Tip**  Event Viewer can see only those policy objects that have been submitted to the database, so you must submit your changes before you can create a filter using the object. If you later change the object, you must also submit your changes for the filter to use the new definition of the policy object.

Step 3  Select **Launch > Event Viewer** to open the Event Viewer application.

Step 4  Create a custom view that filters out the network management station:

a. Double-click the predefined view that you want to use as the basis of your custom view, for example, **All IPS Events**. Double-clicking the view in the Views list opens the view. If you already have a custom view that you want to update, open it.

b. Click the down arrow button in the title of the Source column in the events table and select **Custom** to open the Custom Filter for Source dialog box.

**Tip:** You can also get to this dialog box through the View Settings pane by clicking the **Add** button, then selecting Source in the Add Custom Filter to a Column dialog box and clicking **OK**.

c. In the Custom Filter for Source dialog box, select the policy object you created and click the right-arrow button to move it to the selected list. Also, select the **Not** option next to the Condition option. The following illustration shows how the dialog box should look.

![Custom Filter for Source](image)

d. Click **OK**. The filter is added to the view settings and is used to remove events from the table.

e. Select **File > Save As** to save the changes as a new custom view. You are prompted for a view name and description; enter the information and click **OK**.

The following illustration shows what the view settings would look like if you started with the All IPS Events predefined view and named your new view Filtered IPS Events.
Managing Reports

Use the Report Manager application to view security and usage reports for devices and remote access IPsec and SSL VPNs.

This chapter contains the following topics:

- Understanding Report Management, page 66-1
- Overview of Report Manager, page 66-6
- Understanding the Predefined System Reports in Report Manager, page 66-13
- Working with Reports in Report Manager, page 66-18
- Scheduling Reports, page 66-28
- Troubleshooting Report Manager, page 66-31

Understanding Report Management

Use the Report Manager application to view security and usage reports for devices and remote access IPsec and SSL VPNs. These reports can provide useful information about your network.

The Report Manager aggregates information that is collected from monitored devices by the Event Manager service. Thus, to view reports about a device, you must also be monitoring the device in Event Viewer. Some statistics, such as VPN statistics, are obtained directly from the device through regular polling at five minute intervals. Aggregated data is kept for 90 days with data aggregated at 15-minute, hourly, daily, and monthly intervals; 15-minute aggregated data is kept for up to three days, hourly data up to one week. For more information about data aggregation, see Understanding Report Manager Data Aggregation, page 66-4.

You can use Report Manager to develop reports on the following:

- Adaptive Security Appliances (ASA) running ASASoftware releases 8.0 and higher. ASA Software 7.x releases are also supported for VPN reports.

  Note

  VPN reports are not available for Cisco Catalyst 6500 Series ASA Services Modules (ASA-SM), which do not support any VPN configuration. Other types of reports are available for the ASA-SM.

- IPS devices running IPS software release 6.1 and higher (but not IOS IPS devices). This includes dedicated IPS modules installed in ASAs, routers, and switches.

- Remote access IPsec and SSL VPNs hosted on a supported ASA device.
Understanding Report Management

Note

Report Manager does not report on FWSM events even though Event Viewer works with FWSM.

The following topics explain Report Manager and its available reports in more detail, and also describe the other types of reports available in Security Manager:

- Understanding the Types of Reports Available in Security Manager, page 66-2
- Preparing Devices for Report Manager Reporting, page 66-3
- Understanding Report Manager Data Aggregation, page 66-4
- Understanding Report Manager Access Control, page 66-5
- Understanding the Predefined System Reports in Report Manager, page 66-13

Understanding the Types of Reports Available in Security Manager

Security Manager provides a variety of reporting capabilities. The following are the types of reports available:

- **Security and Usage Reports (Report Manager application)**—You can use the Report Manager application to view aggregated information collected by the Event Manager service from monitored devices. Some information is also obtained directly from the devices. These reports can provide information on network security and remote access IPsec and SSL VPN usage.

- **Activity (Configuration Session) Change Reports**—These reports provide detailed information about the policies changed within a specific activity (in Workflow mode) or configuration session (in non-Workflow mode). For more information, see Viewing Change Reports, page 4-16.

- **Out of Band Change Report**—These reports identify inconsistencies between the configuration that exists on a device and the configuration for the device maintained in Security Manager. You can use this information to proactively address these inconsistencies before deploying configurations, where the change will either be overwritten or the deployment will fail, depending on the behavior you select in the deployment job. For more information, see Detecting and Analyzing Out of Band Changes, page 8-44.

- **Audit Report**—This report provides information about changes to Security Manager and the objects contained in the database. The report includes information about the runtime environment, such as logins and authentication failures, changes to objects, such as activity changes and deployments, and changes to managed devices, such as inventory additions and deletions. For more information, see Generating the Audit Report, page 10-17.

- **Inventory Status**—This report provides information on policy deployment status. For more information, see Viewing Inventory Status, page 68-16.

- **Policy Discovery Status reports**—When you discover policies from a device, either while adding it to the inventory or when rediscovering policies on a managed device, the information about the policy discovery is maintained so that you can view it at a later time. For more information, see Viewing Policy Discovery Task Status, page 5-20.

- **Deployment Status reports**—When you deploy configurations to managed devices, information about the deployment is maintained so that you can view it at a later time. For more information, see Viewing Deployment Status and History for Jobs and Schedules, page 8-24.

- **Deployment and Discovery Status reports for troubleshooting**—You can export deployment and policy discovery status reports in a form suitable for sending to Cisco Technical Support (TAC) to help troubleshoot problems. You might also find these reports useful for your own purposes. For more information, see Generating Deployment or Discovery Status Reports, page 10-26.
• **Extranet VPN Configuration Summaries**—You can print, or generate a PDF file of, a summary of the configuration of an Extranet VPN. This summary can include the preshared key used for the connection. You can use this information to maintain a current record of connections between your network and the networks of partners or service providers. For more information, see Viewing a Summary of a VPN Topology’s Configuration, page 23-59.

• **Policy Object Usage report**—This report shows you where a policy object is used, including instances where it is referred to by a policy or another policy object. You can use this information to help determine whether a proposed change to the object will provide the desired effect in all cases where it is used. The information is also helpful if you want to delete an object, because you cannot delete an object that is actively being used by a policy or another policy object. For more information, see Generating Object Usage Reports, page 6-13.

• **Policy Object Override report**—This report shows you all of the device-level overrides currently defined for a policy object, if the object is defined so that overrides are allowed. You can also create and delete overrides from this report. For more information, see Creating or Editing Object Overrides for Multiple Devices At A Time, page 6-17 and Policy Object Overrides Window, page 6-18.

• **Device Manager reports**—Security Manager includes read-only versions of individual device managers, such as the Adaptive Security Device Manager (ASDM), for most supported devices. You can start these device managers directly from Security Manager’s Configuration Manager application and use any type of report available in those device managers. These reports are for a single device, and can augment the reports available through Report Manager. They can also provide status information for devices that are not directly supported by Event Viewer or Report Manager. For more information, see Starting Device Managers, page 68-10.

### Preparing Devices for Report Manager Reporting

Before you can view reports about a device in Report Manager, you must configure the device to send events to Security Manager and configure Security Manager to monitor the device. Report Manager can provide reports only for devices you are monitoring in Event Viewer, so the device configuration for reporting is identical to the configuration for event monitoring.

**Step 1** Configure the devices to send events to Security Manager. You can use Report Manager with the following types of devices:

- **ASA 8.0 and higher**—For the detailed configuration steps, see Configuring ASA and FWSM Devices for Event Management, page 65-26.
- **IPS 6.1 and higher**—For the detailed configuration steps, see Configuring IPS Devices for Event Management, page 65-27.

**Step 2** Ensure that the devices are selected for event management as described in Selecting Devices to Monitor, page 65-31.

**Step 3** Ensure that the Event Manager service is enabled as described in Starting, Stopping, and Configuring the Event Manager Service, page 65-28.
Understanding Report Manager Data Aggregation

Report Manager aggregates information that is collected from monitored devices by the Event Manager service. Thus, to view reports about a device, you must also be monitoring the device in Event Viewer.

Report Manager collects data using two techniques. First, the Event Manager service provides relevant events to Report Manager and then Report Manager decides if it should store those events based on the predefined reports and custom reports that are currently configured. Second, some statistics, such as VPN statistics, are obtained directly from the device through regular polling at five minute intervals.

</table>
Report Manager aggregates this collected information at 15-minute, hourly, daily, and monthly intervals. Fifteen-minute aggregated data is kept a day, hourly data up to five days, and the other data for 90 days. The aggregation schedule occurs at fixed times: 15-minute aggregation occurs at 00, 15, 30, and 45 minutes past the hour; hourly aggregation occurs on the hour (00 minutes); daily aggregation occurs at the change of day (when midnight is reached, the day is aggregated); monthly aggregation occurs at the change of the month.

The aggregation cycle has implications in what you will see in reports:

- Report data does not cover the immediate past. Instead, it covers the most recently completed whole time period of the selected duration. For example, a one-day report covers yesterday, it does not include data for today. In other words, a one day report is not the previous 24 hours starting from the time the report is generated.

- When configuring reports with a custom time period, you cannot select a time period of less than 15 minutes long. A report will always contain at least 15 minutes of aggregated data. Minute entries are rounded to the nearest aggregation time (that is, 00, 15, 30, or 45). You can configure minutes only for custom reports that start and end on the current day.

Also, because hourly data is kept only up to five days, you can specify hours in a custom time period only for the past five days.

- You cannot generate a report for periods that are longer than the device has been monitored. For example, when you start the Event Manager service for the first time, you will not be able to generate a monthly report until after the month changes. This might be only a few days (for example, if you start the service on the twenty-ninth day of the month), or it might be almost a full month (for example, if you start the service on the first day of the month).

The exception to this rule is the custom time period report. Custom time period reports are generated using daily aggregation data, so you can select any custom time period.

---

**Note**

Be aware that your first month of aggregated data might be significantly less than one month’s worth of data. If you compare monthly reports, this might appear as a significant discrepancy when in reality you are comparing 30 days of data to 15 days (as an example).

You can configure the default time interval for predefined system reports and configure time intervals in individual reports. The following topics explain the time controls:

- Configuring Default Settings for Reports, page 66-24
- Editing Report Settings, page 66-21

---

**Understanding Report Manager Access Control**

The user privileges assigned to your username control what you can do in Report Manager. If you use local users, or other types of non-ACS access control, then all users have access to Report Manager and all reports. However, the following access limits are imposed:

- You must have system administrator or network administrator privileges to configure default settings for the predefined system reports. See Configuring Default Settings for Reports, page 66-24.

- You must have system administrator or network administrator privileges to do the following to another user’s schedules: see them, enable or disable them, view results generated from them, or delete them. See the following topics:
  - Viewing Report Schedules, page 66-28
Overview of Report Manager

Use Report Manager to create security and usage reports for ASA and IPS devices, and for remote access IPsec and SSL VPNs hosted on ASA devices. For more information about supported devices and the reports you can generate using Report Manager, see Understanding Report Management, page 66-1.

To open Report Manager, do any of the following:

- Select **Start > All Programs > Cisco Security Manager Client > Report Manager** from the Windows Start menu (your exact command path might differ), or double-click the Report Manager icon on the desktop. You are prompted to log in. For more information about starting a Security Manager client application, see Logging In to and Exiting the Security Manager Client, page 1-10.

- Select **Launch > Report Manager** from the Configuration Manager or Event Viewer applications. Report Manager is opened using the same user account that you used to log into the other application.
The following illustration and subsequent list explain the basics of Report Manager.

Figure 66-1  Report Manager Main Window

The following list explains the main Report Manager window and its call-outs in more detail.

- **Menu Bar (1)**—General commands for performing actions in Report Manager. For a description of the commands, see Report Manager Menus, page 66-8.

- **Main Window Tabs (2)**—The main window area consists of the following tabs:
  - Reports—Use the Reports tab to generate reports on demand, to create custom reports, and to perform other report-oriented tasks. The illustration above, and most of the information in this topic, relates to the Reports tab. For information on the tasks you can perform from the Reports tab, see Working with Reports in Report Manager, page 66-18.
  - Scheduled Reports—Use the Scheduled Reports tab to view and manage report schedules. For more information on the Scheduled Reports tab, see Viewing Report Schedules, page 66-28. For information on the tasks you can perform from the Scheduled Reports tab, see Scheduling Reports, page 66-28.

- **Report List (3)**—The left pane of the Reports tab is a list of reports. The list is organized into folders; the System Reports are predefined reports, whereas the My Reports folder contains the custom reports that you create. Double-click a report to open it, select the report and select File > Open, or right-click the report and select Open Report. For more information about using the report list, see Understanding the Report List in Report Manager, page 66-9.
• **Report Pane (4, 5, 6, 7)**—The right pane of the Reports tab shows the open reports. Each open report is represented on separate tabs (you can have up to five open reports). Note that you can arrange reports horizontally or vertically in this space, or even make a report float to a separate window. For more information about how you can arrange or float reports, see *Arranging Report Windows*, page 66-25.

You can use the Maximize control (7) above the pane to make it take over the entire workspace (hiding the report list). After maximizing the pane, the control changes to a Restore control to return the main window to a two-pane view.

You can use the right and left arrows, and the Show List icon button, to scroll through the open reports or to go directly to a report. However, clicking the tab with the desired report name is the easiest way to go to a report.

The Report Pane includes these areas for each open report:

- **Report Settings pane (5)**—The top part of the report shows the report settings, which are the criteria used to generate the report. You can open and close the settings pane by clicking on the heading, or on the expand/collapse icon button. The heading includes a toolbar that has commands that you can perform on the report. For more information about the settings pane, see *Understanding the Report Settings Pane*, page 66-10.

- **Generated Report Pane and Report Toolbar (6)**—Below the settings pane is an additional toolbar used to generate and manipulate report data. Use these controls to generate the report using the criteria defined in the report settings, to print the report or to export it to PDF or CSV format, or to change the type of graphic displayed in the report.

The bottom part of the report pane is the actual report. This area is empty until you click the Generate Report button. The top of the report shows a graphical representation of the information, the lower page shows the tabular data. For more information, see *Understanding the Generated Report Pane and Toolbar*, page 66-11 and *Opening and Generating Reports*, page 66-18.

### Report Manager Menus

The following table describes the commands on the menus in Report Manager.

<table>
<thead>
<tr>
<th>Menu</th>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File</td>
<td>Open</td>
<td>Opens the report selected in the report list on the Reports tab. See <em>Opening and Generating Reports</em>, page 66-18.</td>
</tr>
<tr>
<td></td>
<td>Save</td>
<td>Saves changes made to the report settings. This command is available for custom reports only. See <em>Saving Reports</em>, page 66-26.</td>
</tr>
<tr>
<td></td>
<td>Save As</td>
<td>Saves the report as a new report. Use this command to create new reports from existing reports. See <em>Saving Reports</em>, page 66-26.</td>
</tr>
<tr>
<td></td>
<td>Close All Reports</td>
<td>Closes the active open report, or closes all open reports. See <em>Closing Report Windows</em>, page 66-27.</td>
</tr>
<tr>
<td></td>
<td>Exit</td>
<td>Exits Report Manager.</td>
</tr>
</tbody>

Understanding the Report List in Report Manager

The left pane of the Reports tab in Report Manager displays a list of available reports, as shown in the following illustration.

Figure 66-2  Report Manager Report List

The Report List includes the following controls (illustration call-outs cited):

- **Quick Filter search box (1)**—Use the quick filter search box to search for reports in the list. The list is filtered as you type, although folders are not opened automatically. The default is to search for the text string anywhere in the report name. However, you can click the down arrow in the Quick Filter box to select a variety of options to change how your search string is evaluated.
Overview of Report Manager

- **List of reports (2)**—The list is organized into folders; the System Reports are predefined reports (explained in Understanding the Predefined System Reports in Report Manager, page 66-13), whereas the My Reports folder contains the custom reports that you create. Double-click a report to open it, or select the report and select **File > Open**. For more information, see Opening and Generating Reports, page 66-18.

- **Right-click shortcut menu (not shown)**—If you right-click on a report, you get a list of additional commands that you can perform, such as opening the report, creating a schedule, or saving the report as a new report.

- **Edit button (3)**—Click the Edit button to change the name of the selected custom report. You can edit custom reports only. For more information, see Renaming Reports, page 66-26.

- **Delete button (4)**—Click the Delete button to delete the selected custom report. You can delete custom reports only. For more information, see Deleting Reports, page 66-27.

- **Push Pin button (5)**—Click the Push Pin icon to control whether the report list pane is opened or closed. If the pin is vertical, the report list remains open unless you maximize the report pane (the right pane). If the pin is horizontal, the report list collapses to the left margin, and you must click the Report List heading in the left margin to open the list.

**Related Topics**
- Overview of Report Manager, page 66-6
- Understanding Report Management, page 66-1
- Working with Reports in Report Manager, page 66-18
- Viewing Report Schedules, page 66-28
- Scheduling Reports, page 66-28

**Understanding the Report Settings Pane**

The top part of the right side of the Reports tab, with a report open, shows the report settings. These settings define the criteria that are used to generate a report. The following illustration shows an example of the report settings pane.
The Report List includes the following controls (illustration call-outs cited):

- **Report tab (3)**—Although not part of the settings per se, each report appears on its own tab. The settings are the top part of the tab. If you right-click the tab itself, you get a menu of commands that allow you to arrange report windows. For more information, see Arranging Report Windows, page 66-25.

- **Heading and toolbar (2)**—The top of the settings pane includes the heading (for example, Top Sources - Settings) and a row of buttons for manipulating the settings. You can open or close the pane by clicking the heading or the up arrow button in the far right of the toolbar. The other buttons have the following functions:
  - Create Schedule button—Creates a new schedule for automatically generating reports based on these settings. For more information, see Configuring Report Schedules, page 66-29.
  - Edit button—Edits the report settings. For more information, see Editing Report Settings, page 66-21.
  - Save As button—Saves the report as a new report. If you edit the settings for a predefined system report, and you want to save your changes, you must use Save As to create a custom report. For more information, see Saving Reports, page 66-26 and Creating Custom Reports, page 66-20.
  - Save button—Saves changes to the settings. You can save changes for custom reports only. For more information, see Saving Reports, page 66-26.
  - Reset button—Resets the settings to the last saved values.
  - Expand/Collapse button (double up/down arrows)—Toggles between opening and closing the report setting pane.

- **Settings display (1)**—Below the heading and toolbar is a summarization of the report settings. Information includes the type of report, the devices included in the report, the time range, a description, the schedules defined for the report, and other properties unique to the report. To change the description, type your changes directly into the Description edit box.

- Scheduling Reports, page 66-28

**Understanding the Generated Report Pane and Toolbar**

The bottom part of the right side of the Reports tab, with a report open, shows the generated report and report toolbar. This pane displays the results of clicking the Generate Report button.
The following illustration shows an example of the generated report pane and its associated report toolbar.

**Figure 66-4  Report Manager Generated Report Pane and Toolbar**

The Report List includes the following controls (illustration call-outs cited):

- **Report toolbar (1)**—The top of the generated report pane is a row of controls for generating and manipulating reports. The controls have the following functions:
  - Generate Report button—Generates a report based on the criteria defined in the report settings (in the upper pane). For more information, see Opening and Generating Reports, page 66-18.
  - Print button—Prints the generated report. For more information, see Printing Reports, page 66-23.
  - Export button—Exports the report. Click the down arrow in the button and select the type of file you want to create: **As PDF** (for Adobe Acrobat) or **As CSV** (for comma-separated values). For more information, see Exporting Reports, page 66-23.
  - Chart Type—Determines the type of graphical chart displayed in the upper part of the report, typically pie, bar, and XY (linear) graphs are available. In some cases, you do not have a choice of chart types. For more information, see Opening and Generating Reports, page 66-18.

- **Graphical view (2, 3, 5)**—The top part of the generated report shows a graphical, color-coded view of the report data, and includes a legend that explains the colors. Also included is the date and time the report was generated.

  At the bottom of the graphical view are the following controls:
  - Up and Down arrows (5)—These icon buttons, to the left of the graphic, allow you to open and close the graphical part of the report.
Understanding the Predefined System Reports in Report Manager

Report Manager includes several predefined system reports that you can use to analyze your network. You can customize these reports to focus on specific sets of devices and time periods or to focus on other configurable parameters.

This section contains the following topics:
- Understanding Firewall Traffic Reports, page 66-13
- Understanding Firewall Summary Botnet Reports, page 66-14
- Understanding VPN Top Reports, page 66-15
- Understanding General VPN Reports, page 66-16
- Understanding IPS Top Reports, page 66-16
- Understanding General IPS Reports, page 66-17

Understanding Firewall Traffic Reports

Report Manager includes predefined system reports that you can use to identify the top destinations, services, and sources for firewall ACL events. The statistics are based on the events collected by the Event Manager service (as displayed in Event Viewer).
Understanding the Predefined System Reports in Report Manager

The following reports are available in the System Reports > FW folder.

- **Top Destinations**—This report ranks the session destinations of all built/deny firewall events received by Security Manager. The report shows the destination IP address, the count of the number of events for each address, and the percentage of the count compared to the sum of all counts in the report.

- **Top Sources**—This report ranks the session sources of all built/deny firewall events received by Security Manager. The report shows the source IP address, the count of the number of events for each address, and the percentage of the count compared to the sum of all counts in the report.

- **Top Services**—This report ranks the destination services of all built/deny firewall events received by Security Manager. TCP and UDP services include the port number. The report shows the service, the count of the number of events for each service, and the percentage of the count compared to the sum of all counts in the report.

The parameters used to define the number of addresses or services to included in the report and the reporting time period are defined in the system defaults as described in Configuring Default Settings for Reports, page 66-24.

You can also edit the report settings and create custom versions of the reports. You can narrow the reports to focus on specific sets of source or destination addresses or services, or on just permit or deny actions, or limit the report to focus on a sub-set of firewall devices, as described in the following topics:

- Editing Report Settings, page 66-21
- Creating Custom Reports, page 66-20

Understanding Firewall Summary Botnet Reports

Report Manager includes predefined system reports that you can use to analyze botnet traffic filtering. The statistics are based on the botnet events collected by the Event Manager service (as displayed in Event Viewer) for blacklisted and gray-listed sites.

For more information about botnet, see Chapter 18, “Managing Firewall Botnet Traffic Filter Rules”.

The following reports are available in the System Reports > FW > Summary Botnet folder.

- **Top Infected Hosts**—This report ranks the top infected hosts for traffic originating from infected hosts to black- or gray-listed sites based on all botnet events received by Security Manager. The report shows the IP address of the infected host with the firewall interface name on which the event was detected in parentheses, the count of the number of connections logged to blacklisted or gray-listed sites for each address, the count of the number of connections that were blocked (dropped) by botnet traffic filtering, and the percentage of the count compared to the sum of all counts in the report.

- **Top Malware Ports**—This report ranks the top destination ports for traffic originating from infected hosts to black or gray-listed sites based on all botnet events received by Security Manager. The report shows the destination malware port, the count of the number of connections logged to blacklisted or gray-listed sites for each port, the count of the number of connections that were blocked (dropped) by botnet traffic filtering, and the percentage of the count compared to the sum of all counts in the report.

- **Top Malware Sites**—This report ranks the top botnet sites (black or gray-listed sites) for all inbound and outbound sessions based on all botnet events received by Security Manager. The report shows the following information:
  - IP Address—The IP address that is indicated as the malicious host in botnet events, either on the black list or the grey list.
– Malware Site—The domain name or IP address in the dynamic filter database to which the traffic was initiated.
– List Type—Whether the site is on the black list or the grey list.
– Connections Logged—The count of the number of connections logged or monitored for each site.
– Connections Blocked—The count of the number of connections that were blocked (dropped) by botnet traffic filtering for each site.
– Threat Level—The botnet threat level for the site, from very low to very high, or none.
– Category—The category of threat the site poses as defined in the botnet database, such as botnet, Trojan, spyware, and so on.

The parameters used to define the number of hosts, ports, or sites in the report and the reporting time period are defined in the system defaults as described in Configuring Default Settings for Reports, page 66-24. You can also edit the report settings and create custom versions of the reports, as described in the following topics:

- Editing Report Settings, page 66-21
- Creating Custom Reports, page 66-20

Understanding VPN Top Reports

Report Manager includes predefined system reports that you can use to identify the top remote access VPN users based on bandwidth usage, duration of connection to your network, and data throughput. Separate reports are provided based on the type of connection made by the user.

These reports are available in the System Reports > VPN folder in the AnyConnect (SSL) Remote Access VPN, Cisco VPN Client (IPsec) Remote Access VPN, and Clientless SSL VPN.

The following reports are available in each folder. Each report is specific to the connection type indicated by the folder name and also included in parentheses in the report name.

- **Top Bandwidth Users**—This report ranks the VPN users who consumed the most bandwidth. The report shows the usernames, the bandwidth in total number of bytes sent and received, and the percentage of reported bandwidth used by each user.

- **Top Duration Users**—This report ranks the VPN users who remained connected to the network for the longest time. The report shows the usernames, the connection duration time in days hours:minutes:seconds format, and the percentage of the reported duration by each user. The chart shows duration in seconds.

- **Top Throughput Users**—This report ranks the VPN users who sent and received data at the highest throughput rate. The report shows the usernames, the throughput for each user in kbps, and the percentage of reported throughput by each user. The throughput is calculated as 8.0*(bandwidth of the user in bytes)/(duration for which the user is connected in seconds*1000.0).

The parameters used to define the number of users included in the report and the reporting time period are defined in the system defaults as described in Configuring Default Settings for Reports, page 66-24. You can also edit the report settings and create custom versions of the reports, including focusing on specific users, as described in the following topics:

- Editing Report Settings, page 66-21
- Creating Custom Reports, page 66-20
Understanding General VPN Reports

Report Manager includes predefined system reports that you can use to analyze general remote access VPN usage in your network. These reports are not specific to the connection types used in the VPN.

The following reports are available in the System Reports > VPN folder.

- **User Report**—This report provides a summary of the bandwidth utilization, connection duration and throughput usage for each remote access VPN user. The report shows the usernames, the bandwidth in total number of bytes sent and received, the connection duration time in `days hours:minutes:seconds` format, and the throughput for each user in kbps. The throughput is calculated as `8.0*(bandwidth of the user in bytes)/(duration for which the user is connected in seconds*1000.0)`.

  Each username appears on a single row, even if the user connected to the VPN uses more than one type of connection. When a user uses more than one type of connection, the statistics for each connection type are added together in the report.

  The default report includes information for all connection technologies and all users. You can customize the report to focus on a single technology type or one or more specific users (see Editing Report Settings, page 66-21).

- **VPN Device Usage Report**—This report provides a summary of the usage statistics for each device that hosts remote access VPN connections. The report shows the device (using the Security Manager display name), the average number of users logged into the VPN at any given time during the reported time range, the total bandwidth of all users in the VPN in bytes (sent and received), the total connection duration time in `days hours:minutes:seconds` format, and the average throughput in kbps at any given time during this report period.

  The default report includes information for all connection technologies. You can customize the report to focus on a single technology type (see Editing Report Settings, page 66-21).

  The parameter used to define the reporting time period is defined in the system defaults as described in Configuring Default Settings for Reports, page 66-24. You can also edit the report settings and create custom versions of the reports, as described in the following topics:

  - Editing Report Settings, page 66-21
  - Creating Custom Reports, page 66-20

Understanding IPS Top Reports

Report Manager includes predefined system reports that you can use to analyze top attackers, victims, and signatures for IPS alerts in your network.

The following reports are available in the System Reports > IPS folder.

- **Top Attackers**—This report ranks the attacker (source) addresses that generated the highest numbers of recorded IPS alerts. The report shows the attacker IP address, the count of the number of alerts for each address, and the percentage of the count compared to the sum of all counts in the report.

  The default report includes information for all attackers, victims, and signatures for both blocked and unblocked actions. You can customize the report to focus on subsets of attackers, victims, or signatures, or limit the analysis to blocked only or unblocked only actions (see Editing Report Settings, page 66-21).
• **Top Victims**—This report ranks the victim (destination) addresses that generated the highest numbers of recorded IPS alerts. The report shows the victim address, the count of the number of alerts for each address, and the percentage of the count compared to the sum of all counts in the report.

The default report includes information for all attackers, victims, and signatures for both blocked and unblocked actions. You can customize the report to focus on subsets of attackers, victims, or signatures, or limit the analysis to blocked only or unblocked only actions (see Editing Report Settings, page 66-21).

• **Top Signatures**—This report ranks the signatures that fired the highest numbers of alerts. The report shows the signature ID number, the name of the signature, the count of the number of alerts for each signature, and the percentage of the count compared to the sum of all counts in the report.

The default report includes information for all attackers, victims, and signatures for both blocked and unblocked actions. You can customize the report to focus on subsets of attackers, victims, or signatures, or limit the analysis to blocked only or unblocked only actions (see Editing Report Settings, page 66-21).

• **Top Blocked/Unblocked Signatures**—This report ranks the signatures that blocked the highest numbers of attacks. The report shows the signature ID number, the name of the signature, the count of the number of alerts for each signature, and the percentage of the count compared to the sum of all counts in the report.

The default report shows blocked actions only. However, you can customize the report to show unblocked only or a combination of blocked and unblocked actions (see Editing Report Settings, page 66-21).

If you want to see blocked or unblocked lists that are limited to specific attacker or victim addresses, or to a subset of signatures, use the Top Signatures report instead of the Top Blocked/Unblocked Signatures report. Customize the report to show blocked only or unblocked only signatures.

• **IPS Target Analysis**—This report provides the top targets by signature and frequency of attack. The report shows the signatures that generated the alerts, the number of alerts, and the victim IP address, and is based on an aggregated view of the Top Signatures and Top Victims reports. The report contains up to ten signatures and five attackers. The information is plotted on a scatter plot, which is the only graphical representation available for the report.

The parameters used to define the number of addresses or signatures to included in the report and the reporting time period are defined in the system defaults as described in Configuring Default Settings for Reports, page 66-24. You can also edit the report settings and create custom versions of the reports, as described in the following topics:

• Editing Report Settings, page 66-21
• Creating Custom Reports, page 66-20

---

**Understanding General IPS Reports**

Report Manager includes predefined system reports that you can use to analyze general IPS activity in your network.

The following reports are available in the System Reports > IPS folder.

• **Inspection/Global Correlation**—This report provides a comparison of alerts generated by global correlation against alerts generated by traditional IPS inspection. The report shows the number and percentage of alerts per IPS inspection method (either Global Correlation or Inspection).
• **IPS Simulation Mode**—This report provides a comparison of alerts in inline (IPS) and promiscuous (IDS or IPS simulation) modes. The report shows the number and percentage of alerts based on mode, either Non Simulation Count (inline) or Simulation Mode Count (promiscuous). The IPS sensor cannot directly block attacks that occur in promiscuous mode.

When working with IPS events, the Report Manager component of Cisco Security Manager reports events individually; the Event Viewer component of Cisco Security Manager displays alerts. In the Event Viewer component, the IPS Summarizer groups events into a single alert, thus decreasing the number of alerts that the IPS sensor sends out.

---

**Tip**

Cisco IPS Manager Express (IME) and Cisco Security Manager do not summarize events in precisely the same way.

The parameter used to define the reporting time period is defined in the system defaults as described in [Configuring Default Settings for Reports, page 66-24](#). You can also edit the report settings and create custom versions of the reports, as described in the following topics:

- Editing Report Settings, page 66-21
- Creating Custom Reports, page 66-20

---

### Working with Reports in Report Manager

Use the Report Manager application to view security and usage reports for devices and remote access IPsec and SSL VPNs. The following topics explain the basics of creating reports. For information on working with report schedules, see [Scheduling Reports, page 66-28](#).

This section contains the following topics:

- Opening and Generating Reports, page 66-18
- Creating Custom Reports, page 66-20
- Editing Report Settings, page 66-21
- Printing Reports, page 66-23
- Exporting Reports, page 66-23
- Configuring Default Settings for Reports, page 66-24
- Saving Reports, page 66-26
- Renaming Reports, page 66-26
- Deleting Reports, page 66-27
- Managing Custom Reports, page 66-27

---

### Opening and Generating Reports

Reports are not static. When you open a report, it contains no data, although it does contain settings that define the data that shall be used to generate the report. Thus, to view a report, you need to open it and then generate it. This procedure explains the process.
Related Topics

- Overview of Report Manager, page 66-6
- Creating Custom Reports, page 66-20
- Troubleshooting Report Manager, page 66-31

Step 1

In Report Manager, do one of the following to open a report:

- Double-click the name of the report in the report list (in the left pane).
- Select the report in the reports list and select File > Open.
- Right-click a report in the reports list and select Open Report.

The report opens with the report settings pane open and the report content area empty.

Tip You can have five reports at most open at one time. You can also collapse the report settings pane to provide more room for viewing the generated report by clicking on any area of the settings toolbar that is not a button that performs another function.

Step 2

(Optional) Verify that the report settings contain the desired values, for example, the desired time window for the report. The settings for system reports are based on the system defaults (which you can configure as described in Configuring Default Settings for Reports, page 66-24). The settings for custom reports are those that were last saved for the report.

If you need to change the settings, click the Edit button in the settings toolbar and make your changes in the Edit Settings dialog box. For more information, see Editing Report Settings, page 66-21.

Tip Be sure to save your changes if you want to make them permanent. If you change the settings for a system report and you want to preserve them, you must use Save As to create a new custom report; you cannot change the settings of a system report from the default settings.

Step 3

Click the Generate Report button below the settings pane to retrieve the report data from the reporting database and to display the resulting information. The information is displayed in two formats:

- Graphical—A graphical representation of the data is shown in the top part of the report. You can select different types of graphics from the Chart menu above the report data: pie, XY (for linear graphs), and bar. If there are more than 10 items in the report (for example, you configured a Top report to show 25 values), all values after the tenth are summarized in the chart as “others.”
  Some reports, such as the IPS Target Analysis report, use scatter plots. For these reports, you do not have the option to select a different graphic type.
- Tabular—The table below the graphic lists the data used to generate the graphic. The table has different columns based on the type of report. Following are sometypical columns; for more detailed information about the content of each report, see Understanding the Predefined System Reports in Report Manager, page 66-13.

  - Rank—The order of the information by magnitude. For example, for a firewall top destinations report, a rank of 1 indicates that the destination is the most used in the evaluated events.
  - (Name of reported characteristic)—There is always a column whose name is based on the characteristic targeted by the report, for example, Source/Destination (IP addresses), Service (protocol and port), or User (usernames).
- Count—The number of times the item appears in an event or related statistic.
- Percentage—The ratio of the reported characteristic to the total sum of that characteristic in the report. The ratio includes only those numbers included in a report, so for example, you could get a different percentage for the same item in a top 10 verses a top 25 report.

**Step 4** (Optional) If desired, you can print the report or export it to a PDF or comma-separated values (CSV) file.

- To print the report, click the **Print** button and select your printer. For more information, see **Printing Reports**, page 66-23.
- To export the report, click the **Export** button and select the file type, PDF or CSV. For more information, see **Exporting Reports**, page 66-23.

**Tip** The report data is not preserved when you close the report. If you want to keep the displayed information, you must print or export the report.

### Creating Custom Reports

You can create custom reports to target specific characteristics that require regular analysis or presentation. For example, you might want to create separate Top Destination firewall reports for different groups of firewall devices so that you can separately analyze activity in separate physical sites. You can also use custom reports to analyze sources, destinations, or services that otherwise do not make it into the top reports.

**Tip** It might take up to one hour for data to be available for a newly-created custom report. If you get the message that no records are found after creating the report, wait an hour and then ensure that the time span for the report is Last 1 Hour.

**Related Topics**
- Opening and Generating Reports, page 66-18
- Overview of Report Manager, page 66-6

**Step 1** Select the report on which you want to base your custom report in the reports list. Open it by double-clicking it, by selecting it and selecting **File > Open**, or by right-clicking and selecting **Open Report**.

**Step 2** Click the **Edit** (pencil) button in the settings toolbar to open the Edit Settings dialog box.

**Note** Do not click the Edit button above the reports list. That edit button allows you to change the name of the report only.

The Edit Settings dialog box is divided into two panes. The left pane lists the available settings pages; the right pane shows the settings for the page selected in the left pane.

**Step 3** Configure the settings so that they define the desired report parameters. For more information, see **Editing Report Settings**, page 66-21.
Step 4  Click the **Save As** button in the settings toolbar, or select **File > Save As**.

Step 5  Enter the name of the report and optionally a description and click **OK**.

Report names can be up to 64 characters and contain alphanumeric characters, spaces, hyphens (-), and the underscore character (_). The description can be up to 1024 characters.

---

### Editing Report Settings

You can change the settings that define the criteria used to generate a report. For custom reports, you can save your changes.

For predefined system reports, you cannot directly save your changes. Instead, you can use Save As to create a new custom report using the updated settings. You can also change the default settings used in all predefined system reports rather than editing report settings, as described in **Configuring Default Settings for Reports**, page 66-24.

**Related Topics**

- Opening and Generating Reports, page 66-18
- Overview of Report Manager, page 66-6
- Creating Custom Reports, page 66-20
- Understanding Report Manager Data Aggregation, page 66-4

---

Step 1  In Report Manager, open the report whose settings you want to change. To open the report, double-click it, select it and select **File > Open**, or right-click it and select **Open Report**.

The report opens with the settings pane open at the top of the report. The settings pane shows the type of report, the devices included in the report, the time range, a description, the schedules defined for the report, and other properties unique to the report.

Step 2  (Optional) Change the Description by typing into the Description edit box in the report settings pane.

Step 3  Click the **Edit** (pencil) button in the settings toolbar to open the Edit Settings dialog box.

**Note**  Do not click the Edit button above the reports list. That edit button allows you to change the name of the report only.

The Edit Settings dialog box is divided into two panes. The left pane lists the available settings pages; the right pane shows the settings for the page selected in the left pane.

Step 4  Edit the settings on the desired pages as follows:

- **Devices**—To change which monitored devices are included in the report. The default is **All Devices**.

  If you want the report to reflect a subset of monitored devices, select **Filter Devices** and then select the desired devices from the list. If a device is in italics, it means that the device is not currently selected for monitoring in Event Viewer; you can select these devices, and the report will include data for the device if it was monitored during the selected time period. You can select a folder to select all the devices in the folder.
The device list is pre-filtered to show devices of the appropriate type only. For example, if you are editing the settings for a firewall report, IPS devices do not appear in the list of selectable devices.

- **Time**—To change the time span used to select events and data to include in the report. The time is based on the Security Manager server time. You can select one of the following options to define the time span:
  - Last 1 Hour—The last full one hour on the zeros, for example, if the current time is 11:45 AM, the Last 1 Hour report shows data from 10:00 to 11:00.
  - Last 1 Day—The last full day, from midnight to midnight. For example, if the current day is Tuesday, the Last 1 Day report shows data from Monday.
  - Last 1 Week—The previous Monday through Sunday.
  - Last 1 Month—The previous month. For example, if the current date is September 29, the Last 1 Month report shows data from August.
  - Custom—Use the Start Date and End Date calendars to select the desired starting and ending times for the report. Click the down arrow, select the desired day and time, then click OK in the calendar widget. Reportable data is kept for 90 days, so you cannot select a date more than 90 days into the past. Additionally, you cannot specify a time if you select a start date more than five days into the past. If you select the current date for the start date, you can also specify minutes for both starting and ending dates, but because report data is aggregated every 15 minutes at 00, 15, 30, and 45 minutes past each hour, minute entries are rounded to the nearest of these figures. The allowed time selection is based on how data is aggregated, as explained in [Understanding Report Manager Data Aggregation, page 66-4](#).

- **Criteria**—To change the other criteria used to define the report. The attributes available on the Criteria settings page are variable. In some cases, there are no selectable criteria. Following is a list of the possible criteria:
  - Top (All “Top” reports.)—The number of items targeted by the report to include. For example, the Top 10 firewall destinations returns the 10 most frequent destinations for firewall events in the configured time range. Select 10, 20, 25, or 50.
  - Service (Firewall reports except Botnet)—The services to include in the report. To specify services, click the Edit button next to the field and select the desired service policy objects. You can select multiple objects.
  - Source IP, Destination IP (Firewall reports except Botnet)—The source and destination IP address fields are separate, but they are functionally the same. They define the IP addresses for sources or destinations to include in the report. You can enter individual addresses, such as 10.100.10.10, or address ranges, such as 10.100.10.10-10.100.10.20. Both IPv4 and IPv6 addresses are accepted. Separate multiple addresses with commas. You can click the Edit button next to the field to open a dialog box where you can more easily create complex lists of addresses and address ranges. However, you cannot use network/host objects to define addresses.

  **Note** Do not specify values for all of the Service, Source IP, and Destination IP criteria in a single report. You can specify the criteria on which the report is based (for example, Service for the Top Services report) plus one other criteria. If you specify all three values, the report will always contain no data.

  - Permit/Deny (Firewall reports except Botnet)—The action reflected in the event, either permitting the matching traffic (Permit), denying the matching traffic (Deny), or either (All). The default is All.
Working with Reports in Report Manager

- Signature ID (IPS top attackers, top signatures, top victims)—The signatures to include in the report. To specify signatures, click the Edit button next to the field and select the desired signatures. You can select a folder to select all signatures in the folder.

Note

In the predefined system reports, you cannot specify values for all three of the Signature ID, Attacker IP, and Victim IP criteria. You can specify a value for the key attribute of the report (for example, Victim IP for the top victims report) plus one of the other values. If you want to configure values for all three criteria, you must create a custom report.

- Attacker IP, Victim IP (IPS top attackers, top signatures, top victims)—The attacker and victim IP address fields are separate, but they are functionally the same. They define the IP addresses for attackers (sources) or victims (destinations) to include in the report. You can enter individual addresses, such as 10.100.10.10, or address ranges, such as 10.100.10.10-10.100.10.20. Both IPv4 and IPv6 addresses are accepted. Separate multiple addresses with commas.

You can click the Edit button next to the field to open a dialog box where you can more easily create complex lists of addresses and address ranges. However, you cannot use network/host objects to define addresses.

- Blocked (IPS top attackers, top blocked/unblocked signatures, top signatures, top victims)—Whether the event resulted in dropped traffic (Blocked), traffic that was not dropped (Unblocked), or either (All).

- Username (VPN user report)—The names of the users to include in the report. The default, an empty list, includes all users. If you want the report to focus on specific users, use the Add (+), Edit (pencil), and Delete (trash can) buttons beneath the table to create the desired list of users.

- Technology (VPN device usage report)—The type of remote access technology to include in the report: All, Clientless (SSL VPN), Full Client (SSL VPN), IPsec RA (IPsec remote access VPN).

Step 5

Click OK in the Edit Settings dialog box to implement your changes.

You can now click the Generate Report button to retrieve the data defined by the settings and display it in the report. You can also use Save or Save As to permanently save the changes to the settings.

Printing Reports

After you generate a report as described in Opening and Generating Reports, page 66-18, you can print it.

To print the report, click the Print button above the report. You are prompted to select a printer.

Exporting Reports

After you generate a report as described in Opening and Generating Reports, page 66-18, you can export it to an Adobe Acrobat (PDF) or comma-separated values (CSV) file.

Exported files include the following information:

- The creation time of the report.
- The settings used to generate the report.
• (PDF only.) The graphical representation of the report data.
• The tabular report data. In PDFs, the information is represented as a table. In CSVs, the information is comma-separated, with the first row being the column headings.

To export the report, click the down arrow in the Export button above the report and select either As PDF or As CSV. You are prompted to select a folder for the report. A default file name is provided, but you can change the file name.

**Configuring Default Settings for Reports**

You can control the default settings that Report Manager uses for System reports. When you change the defaults, you automatically change the settings for all System reports, but the changes do not apply to any reports you saved as custom reports (in the My Reports folder). You must have system administrator or network administrator privileges to change these settings.

While viewing a report, you can edit any system report to specify different values for these settings, either to use temporarily while viewing the report, or to save as a custom report in the My Reports folder.

**Tip**

If you change the settings in a system report, you can return the report to the default settings by clicking the Reset button in the Report Settings toolbar.

**Step 1**

In Report Manager, select Tools > Default Report Settings to open the Default Report Settings dialog box.

**Step 2**

Configure any of the following options:

• **Top**—The number of results listed in any of the “Top” reports, which list the most-often occurring items of the type targeted by the report. For example, if you select 20, the firewall Top Destinations report shows the 20 most often occurring traffic destinations in events reported to Security Manager. The default is 10.

  If you select more than 10, all items after the tenth are summarized as “others” in charts, although the detailed information for each additional item is listed in the report table.

• **Time Range**—The time window for events included in the report:
  
  – Last 1 Hour—The last full one hour on the zeros, for example, if the current time is 11:45 AM, the Last 1 Hour report shows data from 10:00 to 11:00.

  – Last 1 Day—The last full day, from midnight to midnight. For example, if the current day is Tuesday, the Last 1 Day report shows data from Monday.

  – Last 1 Week—The previous Monday through Sunday.

  – Last 1 Month—The previous month. For example, if the current date is September 29, the Last 1 Month report shows data from August.

  For more information on the implications of the time range setting, see Understanding Report Manager Data Aggregation, page 66-4.

• **Default Email Address**—The email address used as the default destination for scheduled reports.

  If you decide you want to return to the installation default values, click **Restore Defaults**.

**Step 3**

Click **Apply** to save your changes, then click **Close** to close the dialog box.
Arranging Report Windows

You can open up to five report windows at one time. Reports are opened as tabbed windows in the right pane of the main Report Manager window, in the most recently used area (“tabbed group”) if there is more than one area. The commands to arrange the windows appear if you right-click the tab for the report window as shown in the following illustration.

You have many options for arranging report windows based on your requirements. For example, you might want to compare two reports side-by-side, or remove a report from the main window without closing it.

You can use the following techniques to arrange the report windows to get the view that you desire:

- **Floating a report**—To remove a report from the main Report Manager window without closing it, right-click the report tab and select Floating. The report is moved to its own window.
  
  If you have already floated a report, you can select Floating to and choose one of the already-floated windows. The report becomes a new tab in that window.

- **Docking a report**—To move a floating report back to the main Report Manager window, right-click the report tab and select Docking.

- **Arranging reports horizontally or vertically for side-to-side comparison**—To create a vertical or horizontal arrangement of reports to allow for easy comparison, without floating the reports, right-click the report tab and select New Horizontal Group or New Vertical Group. These commands split the current tabbed group into the selected layout. You must have at least two reports open to use these commands. If you have more than two open reports, and you want all of them in separate windows, you need to use the command multiple times.

- **Move reports to different tabbed groups**—If you have several open reports, and you have arranged them into horizontal or vertical groups, you can move reports among the groups by right-clicking the report tab and selecting Move to Next Tab Group or Move to Previous Tab Group. The commands appear only if reports are arranged in a manner where such movement is possible:

- **Change the orientation of groups**—You can switch between horizontal and vertical layouts by right-clicking the report tab and selecting Change Tab Groups Orientation.
Saving Reports

If you edit the settings for a report, you must save it to make those changes permanent. However, to save changes to predefined system reports, you must save the report as a custom report.

Tip

When you save a report, you are saving the settings that define the report. You are not saving the generated content of the report. If you want to save the generated content of the report, that is, the graphs and the report data, you must export the report rather than save it.

- To save changes to a custom report, do one of the following in Report Manager:
  - Select File > Save from the menu bar.
  - Click the Save button in the Report Settings toolbar.
- To save your changes as a new custom report, do one of the following to open the Save Report As dialog box:
  - Select File > Save As from the menu bar.
  - Click the Save As button in the Report Settings toolbar.
  - Right-click the report in the reports list and select Save As.

Then, enter a name for the report and optionally a description of the report and click OK. The report is added to the My Reports folder in the reports list.

Note

Report names can be up to 64 characters and contain alphanumeric characters, spaces, hyphens (-), and the underscore character (_). The description can be up to 1024 characters.

Renaming Reports

You can change the name of custom reports, but you cannot change the names of predefined system reports.

Related Topics

- Overview of Report Manager, page 66-6
- Understanding the Report List in Report Manager, page 66-9

Step 1

In Report Manager, select the report whose name you want to change from the reports list. You do not need to open the report; simply select it in the list.

Step 2

Click the Edit (pencil) button above the reports list to open the dialog box that allows you to change the report name.

Step 3

Enter the new name and click OK.

Report names can be up to 64 characters and contain alphanumeric characters, spaces, hyphens (-), and the underscore character (_).
Closing Report Windows

You can close any report by clicking the X icon on the report tab. For reports that you have floated, you can simply click the X icon in the window’s title bar.

Tip

When you close a report, none of the generated report data is preserved. If you want to preserve the generated data, you must print it or export it before you close the report window.

You can also use the following techniques to close the report windows without exiting Report Manager:

- Close a report—Select File > Close Report to close the currently-viewed report, or right-click the desired report tab and select Close.
- Close all reports—Select File > Close All Reports, or right-click any report tab and select Close All.
- Close all reports except one—Right-click the report tab of the report you want to keep open and select Close Others.

Deleting Reports

You can delete custom reports, but you cannot delete predefined system reports.

To delete a custom report, select it in the reports list and click the Delete (trash can) button above the reports list. You are asked to confirm your deletion.

Tip

Deleting a report also deletes any schedules for that report.

If you need to delete another user’s custom report, see Managing Custom Reports, page 66-27.

Managing Custom Reports

If you have system administrator or network administrator privileges, you can view a list of custom reports created by all Report Manager users on this Security Manager server.

To view the list of custom reports, select Tools > Custom Report List to open the Manage Custom Reports dialog box. The list shows the report name, the type of report, the type of device analyzed by the report, and the username of the person who created the custom report.

You can use the following controls to manage custom reports from this page:

- Pagination controls—If there are a lot of custom reports, use the pagination controls to move through the list. You can click the buttons to move to the first page, previous page, next page, or last page, or type the page number into the Page X of Y edit box. You can also click the down arrow in the edit box to change the edit box to work by record number rather than page number.
- Delete button—Click this button to delete the selected report. Any schedules (and schedule results) that use the report are also deleted.
- Refresh button—Click this button to update the list with the latest information.
Scheduling Reports

You can create schedules to regularly generate reports from Report Manager.

This section contains the following topics:

- Viewing Report Schedules, page 66-28
- Configuring Report Schedules, page 66-29
- Viewing Scheduled Report Results, page 66-30
- Enabling and Disabling Report Schedules, page 66-31
- Deleting Report Schedules, page 66-31

Viewing Report Schedules

You can view a list of report schedules that are configured in Report Manager. If you have system administrator or network administrator privileges, the list includes all schedules configured on the server, whether you configured them or another user configured them. Users with lesser privileges can see their own schedules only.

To view the list of report schedules, select the Scheduled Reports tab, and if necessary, the Schedule List sub-tab. The list shows the schedule name, description, the report that will be generated by the schedule, the frequency of report generation, the e-mail addresses to which reports are sent (if any), whether the schedule is enabled or disabled, and the username of the person who created the schedule.

You can use the following controls to manage report schedules from this page:

- Pagination controls—If there are a lot of schedules, use the pagination controls (below the table to the left) to move through the list. You can click the buttons to move to the first page, previous page, next page, or last page, or type the page number into the Page X of Y edit box. You can also click the down arrow in the edit box to change the edit box to work by record number rather than page number.

- Add button—Click this button to add a new schedule. For more information, see Configuring Report Schedules, page 66-29.

- Edit button—Click this button to edit the selected schedule. For more information, see Configuring Report Schedules, page 66-29.

- Delete button—Click this button to delete the selected schedule. For more information, see Deleting Report Schedules, page 66-31.

- Refresh button—Click this button to update the list with the latest information.

- Enable button—Click this button to enable the selected schedule. The button is active only if the selected schedule is disabled. For more information, see Enabling and Disabling Report Schedules, page 66-31.

- Disable button—Click this button to disable the selected schedule. The button is active only if the selected schedule is disabled. For more information, see Enabling and Disabling Report Schedules, page 66-31.
Configuring Report Schedules

You can create schedules to automatically generate reports at set times. The generated reports are e-mailed to identified recipients and are also stored and available for viewing from Report Manager. By scheduling reports, you can easily and efficiently create regular milestone views of network security and usage. This procedure explains how to set up a schedule for a report.

Related Topics
- Overview of Report Manager, page 66-6
- Opening and Generating Reports, page 66-18
- Viewing Report Schedules, page 66-28
- Troubleshooting Report Manager, page 66-31

Step 1 In Report Manager, do one of the following:
- On the Reports tab, open the report for which you are creating a new schedule by double-clicking the name of the report in the report list (in the left pane). Then, click the Create Schedule button in the report settings toolbar.
  
  Note You cannot edit an existing schedule from the Reports tab.

- On the Reports tab, right-click the report on which you are creating a schedule and select Create Schedule. If the report is not already open, it is opened.

- On the Scheduled Reports tab, Schedule List sub-tab, click the Add button below the list of schedules to create a new schedule. To edit an existing schedule, select it in the list and click the Edit button.

The Add or Edit Report Schedule dialog box opens.

Step 2 Configure the following options in the dialog box:
- **Schedule Name**—A name for the schedule, up to 64 characters.
- **Report Name**—Select the name of the report to be generated by the schedule. When you create a schedule from the report settings pane, the name is pre-selected and you cannot change it.
- **Schedule**—Select whether the report shall be generated daily, weekly (once per week), or monthly (once per month). Then, enter the day and time for generating the report:
  - Daily schedules—Select whether the schedule is for Monday through Friday (five days) or Monday through Sunday (all seven days). Enter the time of day (in 24-hour notation) to generate the report.
  - Weekly schedules—Select the day of the week and enter the time of day in 24-hour notation.
  - Monthly schedules—Select whether to generate the report on the first day of the month, the last day, or custom. If you select Custom, enter the day number. Then, enter the time of day in 24-hour notation.
- **Email To**—The email addresses that should be sent the report. Separate multiple addresses with commas. If you do not want reports e-mailed, ensure that the field is empty. Note that for e-mails to be sent successfully, you must configure SMTP on the Security Manager server as described in Configuring an SMTP Server and Default Addresses for E-Mail Notifications, page 1-23.
If the report fails to generate for some reason, notification of the failure is sent to these e-mail addresses.

- **Export Report Format**—Whether to generate the report in Adobe Acrobat (PDF) or comma-separated value (CSV) format. The PDF includes graphics, the CSV does not. For more information on export formats, see Exporting Reports, page 66-23.

- **Description**—A description of the schedule.

- **Status**—Whether the schedule is enabled (reports will be generated) or disabled (reports will not be generated).

**Step 3** Click OK to save the schedule. New schedules are added to the schedules list on the Schedules tab.

### Viewing Scheduled Report Results

Typically, report schedules include e-mail addresses to which generated reports are sent. You can also view reports generated from schedules in Report Manager. If you have system administrator or network administrator privileges, you can view results generated by other users’ schedules.

**Tip** Report Manager maintains a copy of the last report generated by the schedule. You cannot retrieve previously generated reports.

**Related Topics**

- Overview of Report Manager, page 66-6
- Opening and Generating Reports, page 66-18
- Viewing Report Schedules, page 66-28
- Troubleshooting Report Manager, page 66-31

**Step 1** In Report Manager, select the Scheduled Reports tab.

**Step 2** Select the Results sub-tab.

All results that you are authorized to see are listed on this tab. The list shows the schedule name, the name of the report that was generated, the frequency of report generation, the date and time of the last schedule run (when the report was generated), the status of the report generation (Success or Failed), a link to the generated report (in the Last Report column), and the username of the person who created the schedule.

**Tip** If the status of a report is Failed, click the link to see the reason for failure.

**Step 3** Double-click the icon link to the report in the Last Report column to open it. While viewing the report, you can save it to your workstation.

If you cannot find the report you are looking for, click the Refresh button to update the list with the latest information.
Enabling and Disabling Report Schedules

You can enable or disable report schedules to change whether reports are generated based on the schedules. By disabling a schedule, you can prevent reports from being generated without deleting the schedule. If you have system administrator or network administrator privileges, you can enable or disable another user’s schedule.

Related Topics
- Overview of Report Manager, page 66-6
- Viewing Report Schedules, page 66-28

Step 1
In Report Manager, select the Scheduled Reports tab, then if necessary, the Schedule List sub-tab. This tab lists all currently-defined schedules that you are authorized to see.

Step 2
Select the schedule whose status you want to change and click either the Enable or Disable button.

Deleting Report Schedules

You can delete report schedules if you no longer need them. If you have system administrator or network administrator privileges, you can delete another user’s schedule.

Tip
If you do not want to generate reports from a schedule, but you want to keep the schedule definition, you can disable the schedule. Disabled schedules do not generate reports.

Step 1
In Report Manager, select the Scheduled Reports tab, then if necessary, the Schedule List sub-tab. This tab lists all currently-defined schedules that you are authorized to see.

Step 2
Select the schedule and click the Delete button below the list. You are asked to confirm the deletion.

When you delete a schedule, any results of the schedule are also deleted from the server and they are removed from the Results tab.

Troubleshooting Report Manager

Following are some problems you might encounter when using the Report Manager application, and some ways to resolve the problems.

Problem: Report Manager does not open, you get the message “Not able to connect to server.”

Solution: Report Manager requires that the csmReportServer, rptDbEngine, and rptDbMonitor processes be started. Report Manager also relies on the Event Management service VmsEventServer. Ensure that all services are started and running correctly on the Security Manager server.

To view the current state of the processes, log into the Security Manager web interface using http://SecManServer:1741, where SecManServer is the DNS name of the server. From the Security Management Suite home page, click the Server Administration link to open CiscoWorks Common Services at the Admin page. Click Processes in the TOC on the left side of the window to open the list...
of processes that displays their current states. Select these processes and click **Start** to start them. If necessary, you might want to stop them, and then restart them. Wait for the processes to fully restart, then try again to open Report Manager.

**Problem:** When generating a report, you get the message “No records found.”

**Solution:** This message indicates that there were no event records in the event data storage location that relate to the report type and the configured settings, or that the required Report Manager aggregation cycle has not completed. Investigate the following:

- Ensure that devices of the appropriate type are selected for monitoring as described in **Selecting Devices to Monitor**, page 65-31.

- Ensure that these devices are appropriately configured for sending events to Security Manager, and that events from the device appear in Event Viewer. Ensure that the device and Security Manager are using the same syslog port. For information on configuring the devices, see **Configuring ASA and FWSM Devices for Event Management**, page 65-26 and **Configuring IPS Devices for Event Management**, page 65-27. To check the syslog port that Security Manager is using, view the setting on the **Tools > Security Manager Administration > Event Management** page in Configuration Manager.

- For IPS devices, ensure that the certificate has not expired. Check the certificates table by selecting **Manage > IPS > IPS Certificates** in Configuration Manager and regenerate the certificate if necessary.

- The report settings might specify a time period in which no aggregated data exists for the report. Data is aggregated every 15 minutes, 1 hour (on the hour), and 1 day (at midnight). Try changing the time parameters of the report. See **Editing Report Settings**, page 66-21. Consider the following:
  - To see a Last 1 Hour report, a change of hour must occur since initially starting the Event Manager service. For example, if you start the service at 10:05, hourly reports are available only after 11:00.
  - To see a Last 1 Day report, a change of day must occur since initially starting the Event Manager service. For example, if you start the service at 10:05, you must wait until after midnight to see a daily report.
  - To see a Last 1 Week report, at least one full day cycle must occur. Weekly reports are based on daily reports.
  - To see a Last 1 Month report, at least one full month must pass since starting the service.
  - To see a custom time period report, at least one daily cycle must occur.

- If you create a new custom report, it might take up to one hour for data to become available. Also, ensure that the time period is Last 1 Hour until the report is old enough to have data for other time periods.

**Problem:** You cannot get reports for a specific device.

**Solution:** Investigate the following:

- The device must have been selected for event management during the reporting time-frame as described in **Selecting Devices to Monitor**, page 65-31. Even if a device is selected, Report Manager might not support all devices that are supported for Event Viewer. For information on the supported device types, see **Understanding Report Management**, page 66-1.

- The report settings might exclude the device. Unless the report settings indicate that All Devices are considered in the report, check the device selection to ensure the device is included. See **Editing Report Settings**, page 66-21.

- The report settings might specify a time period in which no data exists for the device. Try changing the time parameters of the report. See **Editing Report Settings**, page 66-21.
If your organization uses Cisco Secure ACS to control access to the application, you can view reports on a device only if you have at least View privileges to the device. Check whether you have the required permissions.

**Problem:** You cannot see data in certain IPS predefined reports after specifying values for each of signature, victim IP, and attacker IP.

**Solution:** The top attackers, top victims, and top signatures predefined reports include criteria for signature, victim IP address, and attacker IP address. However, you cannot configure all three criteria in a predefined report. Instead, you can configure the criteria on which the report is based (for example, victim IP address for the top victims report) plus one, and only one, of the remaining values. Note that this limitation does not apply to the other criteria, such as Blocked and Top.

**Problem:** You cannot see data in certain Firewall predefined reports after specifying values for each of service, source IP, and destination IP.

**Solution:** The top destinations, top services, and top sources predefined reports include criteria for service, source IP address, and destination IP address. However, you cannot configure all three criteria in a predefined report. Instead, you can configure the criteria on which the report is based (for example, service for the top services report) plus one, and only one, of the remaining values. Note that this limitation does not apply to the other criteria, such as Permit/Deny and Top.

**Problem:** Statistics for VPN reports are not available.

**Solution:** VPN statistics are partially obtained directly from the device rather than from events stored in the event data storage location. To obtain the statistics, Report Manager must be able to log into the device and use show commands. Ensure that the device properties for your VPN devices have the correct credentials for logging in.

**Problem:** Scheduled reports are not getting sent to recipients.

**Solution:** Ensure that the SMTP server is configured correctly and that a valid source e-mail address is configured for Security Manager. For more information, see Configuring an SMTP Server and Default Addresses for E-Mail Notifications, page 1-23.
Health and Performance Monitoring

The Health and Performance Monitor (HPM) application lets you monitor key health and performance data for ASA devices, IPS devices, and VPN services by providing network-level visibility into device status and traffic information.

A variety of views are provided—All Devices, Firewall Devices, IPS Devices, VPN Summary, and so on—and you can create your own customized views. A configurable listing of device alerts is also available.

This ability to monitor key network and device metrics lets you quickly detect and resolve device malfunctions and bottlenecks in the network.

This chapter contains the following topics:

- Health and Performance Monitor Overview, page 67-1
- HPM Access Control, page 67-3
- Preparing for Health and Performance Monitoring, page 67-4
- Launching the Health and Performance Monitor, page 67-4
- Managing Monitored Devices, page 67-5
- HPM Window, page 67-6
- Monitoring Devices, page 67-16
- Alerts and Notifications, page 67-24

Health and Performance Monitor Overview

The Health and Performance Monitor is a stand-alone application that you can launch from the other stand-alone Security Manager applications (Configuration Manager, Event Viewer, Report Manager, and Image Manager); from the Windows Start menu; or from its icon on your desktop.

The HPM application complements the Event Viewer and Report Manager applications, as follows:

- **Event Viewer** – Monitors your network for syslog (system log) events from ASA and FWSM devices and their security contexts, and for SDEE (Secure Device Event Exchange) events from IPS devices and virtual sensors. These events include firewall traffic information, NAT events, failover events, IPS alerts, and so on. Event Viewer collects and displays this information, organized into a variety of views. See Chapter 65, “Viewing Events” for more information.
Health and Performance Monitor Overview

- **Report Manager** – Collects, displays and exports network usage and security information for ASA and IPS devices, and for remote-access IPsec and SSL VPNs. These reports aggregate security data such as top sources, destinations, attackers, victims, as well as security information such as top bandwidth, duration, and throughput users. Data is also aggregated for hourly, daily, and monthly periods. See Chapter 66, “Managing Reports” for more information.

- **Health and Performance Monitor** (HPM) – Monitors and displays key health, performance and VPN data for ASA and IPS devices in your network. This information includes critical and non-critical issues, such as memory usage, interface status, dropped packets, tunnel status, and so on. You also can categorize devices for normal or priority monitoring, and set different alert rules for the priority devices.

  You can add notes to displayed alerts, you can “acknowledge” them, and you can clear them. When an alert is cleared, it is removed from the Alerts display; however, the alert information is retained in a database for 30 days. See Alerts: Acknowledging and Clearing, page 67-31 for more information about adding notes, and acknowledging and clearing alerts.

  **Note** You can use the Alerts History window to access and view previously cleared alerts, as described in Alerts: History, page 67-32.

This section contains the following topics:

- Trend Information, page 67-2
- Monitoring Multiple Contexts, page 67-3

**Trend Information**

The Health and Performance Monitor periodically polls monitored devices for status and performance data. This information is used for alert generation, and to display real-time views and historical trends based on aggregated data.

Trends are displayed graphically for a specific set of metrics. Each trend for the currently selected device is represented as a graph generated for a chosen time interval. Comparing current values with the weekly averages for CPU and memory usage, for example, can provide an operational context for the selected device. Available trend intervals for monitored devices are one hour, 24 hours, and one week.

Metrics used for generating trends include:

- CPU usage
- Memory usage (only for single-context devices)
- Connections per second (firewall devices)
- Translations per second (firewall devices)
- Inspection load (IPS devices)
- Missed packets as a percentage (IPS devices)
- Number of VPN tunnels
- Number of RA VPN sessions
- Total VPN throughput
- Firewall throughput
- Total dropped packets (firewall interfaces)
For additional graphical information about the health and performance of a specific device, you can launch the related device manager by right-clicking the device entry and choosing Device Manager from the pop-up menu. See Starting Device Managers, page 68-10 for more information about the device managers.

**Monitoring Multiple Contexts**

The Health and Performance Monitor can monitor single- and multiple-context ASA devices. For multiple-context devices, each context is monitored and displayed as if it was a separate device.

Each context will be polled separately for all applicable metrics, with HPM polling a maximum of five contexts at a time from any given device. For devices with more than five contexts, data will be acquired from each successive batch of five contexts, with each batch being polled progressively during successive polling cycles. This means that all contexts may not be updated at the same time.

For multiple-context devices, basic device health—memory usage, device status, and so on—is monitored only on the physical device (that is, from the system context), while traffic data—number of connections, number of translations, dropped packets and so on—are monitored at context level.

For virtual contexts, CPU usage data are used only for pattern analysis, not for alert generation. Only interface-status alerts will be generated for virtual contexts.

**HPM Access Control**

The privileges assigned to your user name control what you can do in Health and Performance Monitor. If you use local users, or other types of non-ACS access control, then all users have access to HPM. However, the following access limits are imposed:

- You must have system administrator privileges to enable or disable Health and Performance Monitoring in Security Manager, as described in Health and Performance Monitoring Page, page 11-25.
- You must have system administrator, network administrator, or approver privileges to select or deselect devices for monitoring, as described in Managing Monitored Devices, page 67-5.
- You also must have system administrator, network administrator, or approver privileges to configure alerts and notifications, as described in Alerts: Configuring, page 67-27.

If you use ACS to control access to Security Manager, you can also control the following:

- You can control access to the Health and Performance Monitor application using the View > Health and Performance Monitor privilege (part of Role Management in ACS). Using this privilege, you could prevent certain users from accessing HPM, or create roles that allow access to HPM without allowing access to Event Viewer or Report Manager. All default ACS roles are permitted to use the Health and Performance Monitor application.
- Use the Modify > Policies > HPM Monitoring privilege to control which users can select and deselect the devices that are monitored (see Managing Monitored Devices, page 67-5), configure alerts and notifications (see Alerts: Configuring, page 67-27), and annotate and acknowledge alerts (see Alerts: Acknowledging and Clearing, page 67-31). All default ACS roles except Help Desk and Super Admin have this permission.
- Users can view health and performance information for a device only if they have at least View privileges for the device.
- You can control access to the Health and Performance Monitoring administrative settings page (in Security Manager’s Configuration Manager) where HPM is enabled or disabled, as described in Health and Performance Monitoring Page, page 11-25. The user must have the Modify > Policies > HPM Admin privilege to access this page (or any other administrative settings page). All default ACS roles except Help Desk can view the page, but only System Administrators can change the setting.

For information on integrating Security Manager with Cisco Secure ACS, see the Installation Guide for Cisco Security Manager.

Preparing for Health and Performance Monitoring

In order to use the Health and Performance Monitor (HPM), you must configure Security Manager, enable the HPM application, and configure device monitoring, as follows:

- Basic Threat Detection must be enabled on ASA 8.0+ devices in order to monitor metrics such as ACL Dropped Packets, Scanning Threat Dropped Packets, Inspection Dropped Packets, and Syn Attack Dropped Packets. (Basic Threat Detection is enabled by default on these ASA devices.)

- To receive alert notifications via email, you must have configured the SMTP server and administrator email ID on the System Preferences page of the Security Manager server. See the Installation Guide for Cisco Security Manager for more information. (Specifying email addresses for alert notifications from the Health and Performance Monitor application is described in Alerts: Configuring, page 67-27.)

- Health and Performance Monitoring must be enabled in Security Manager, as described in Health and Performance Monitoring Page, page 11-25.

- In HPM, specify the devices to be monitored, in both Normal and Priority modes, as described in Managing Monitored Devices, page 67-5.

- Enable and configure the device threshold values and state-change rules that define when alerts and email notifications are triggered. This process is described in Alerts: Configuring, page 67-27.

**Note**

We also recommend configuring monitored devices to use a Network Time Protocol (NTP) server for synchronized timing. See NTP Page, page 50-18 for more information.

After you have completed these steps, HPM begins polling the specified devices and displays health information and alerts.

Launching the Health and Performance Monitor

Use the Health and Performance Monitor (HPM) to view status information and alerts collected from monitored firewall and IPS devices across your network. For more information about selecting devices for monitoring, see Managing Monitored Devices, page 67-5.

To launch HPM, do any one of the following:

- Choose All Programs > Cisco Security Manager Client > Health and Performance Monitor from the Windows Start menu (your command path may differ slightly).

- Double-click the Health and Performance Monitor icon on your system desktop.
Managing Monitored Devices

Managing Monitored Devices

The HPM device selector is used to add and remove devices from both the “normal” and “priority” monitoring lists. You can also use the device selector to transfer devices between the two lists.

To use the HPM device selector:

Step 1  Choose Device Selector from the Tools menu to open the device selector window; the device-management screen is displayed.

The All Devices section on the left lists all ASA and IPS devices in the Security Manager inventory that can be monitored. (For example, HPM supports monitoring of version 7.0.1 and later IPS sensors only. Earlier IPS versions are not displayed in the device selector.)

All devices currently assigned to the Normal monitoring list and the Priority monitoring list are displayed in the two sections on the right side of the window.

Step 2  To add a device to the Normal list, select the device in the All Devices list and then click the > button between the All Devices list and the Normal Monitored Devices list.

The procedure for moving a device to the Priority Monitored Devices list is the same: use the > button between the All Devices list and that list.

Step 3  To remove a device from either Monitored list, returning it to the All Devices list, select the device and then click the appropriate < button.

Step 4  To transfer a device from one Monitored list to the other, highlight that entry and click the Up or Down button to move it to the upper or lower list respectively.

Step 5  Click Next at the bottom of the window to display the VPN-selector screen.

All monitored devices are listed; each entry includes a checkbox for remote-access (RA) and one for site-to-site (S2S) VPN selection. You can use the List Filter field on this page to filter the list, as described in Using The List Filter Fields, page 67-15.

Step 6  Select the types of VPN to be monitored on specific devices by checking the appropriate boxes.

Step 7  Click Save to save and apply your changes, and close the device selector.
HPM Window

The Health and Performance Monitor (HPM) application window is where you view status information and alerts collected from monitored firewall and IPS devices, as well as remote-access (RA) and site-to-site (S2S) VPN information, across your network.

Note

See Managing Monitored Devices, page 67-5 for information about specifying the devices to be monitored.

The following illustration presents the primary features of the HPM window.

Figure 67-1 Health and Performance Monitor Window

The HPM window consists of three main elements:

1. Monitoring button.
2. Alerts button.
3. Quick-launch buttons.
4. Monitoring/Alerts display area.
• **Monitoring button (1)** – Click this button to view device and VPN health and performance data. See [HPM Window: Monitoring Display, page 67-21](#) for more information.

• **Alerts button (2)** – Click this button to view a table of alerts in the window’s display area. See [HPM Window: Alerts Display, page 67-25](#) for more information.

• **Quick-launch buttons (3)** – Click any button to cross-launch the related Security Manager client application.

• **Monitoring/Alerts display area (4)** – This section of the window displays either Monitoring information for devices and VPNs, or a table of alerts generated by monitored devices. The Monitoring and Alerts buttons are used to switch back and forth between these two displays.

### Working with Table Columns

You can customize the different tables of information presented in HPM as follows:

- Sort a table such entries in a particular column are in ascending or descending order.
  - Click a column heading—anywhere but on a drop-down menu button—to sort the table such that the column entries are in ascending order (indicated by a small grey up-arrow).
  - Click the heading again to sort the entries are in descending order (indicated by a small grey down-arrow).
  - Click the heading again to return the table to its original order of display (the direction icon is removed).

- Hide and show various columns; the columns available for display depend on the particular table.

- Apply a column filter, meaning the table displays only entries that fit the specified criteria.

This section contains the following topics:

- Showing and Hiding Table Columns, page 67-7
- Column-based Filtering, page 67-13

### Showing and Hiding Table Columns

You can customize the different tables presented in HPM by hiding and showing various columns of information; the columns available for display depend on the particular table.

> **Note**
>
> The column headings are menus that you can use to further filter the table by hiding or showing entries according to chosen parameters, as described in Column-based Filtering, page 67-13.

To show or hide specific columns displayed for a table:

1. Click the Columns button on the right side of the column headings to open the Choose Columns to Display dialog box.
   - All columns available for the current view are listed.
2. Select and deselect the columns to be shown and hidden.
3. Click OK to close the dialog box.
   - Only the selected columns are displayed for this table.

The following topics describe the individual columns available for various tables:
You can customize the tables presented in the Monitoring pane for the device-related views by hiding and showing various columns of information; the columns available for display depend on the particular view.

The order of the entries in the Choose Columns to Display dialog box reflects the ordering of the columns when displayed. (However, the ordering of the rows in the following table does not necessarily reflect ordering of the columns as displayed.) See Showing and Hiding Table Columns, page 67-7 for information about opening the Choose Columns to Display dialog box.

The following table presents all available data columns for the device-related Monitoring views: Priority Devices, IPS Devices, Firewall Devices, All Devices, and all custom views based on these system views. Some of the listed columns are not available for specific views, as indicated.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Available in View</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority (always selected)</td>
<td>IPS, Firewall</td>
<td>Priority monitoring is indicated by a star; this field is blank for a normally monitored device.</td>
</tr>
<tr>
<td>Alerts</td>
<td>IPS, Firewall</td>
<td>Device alerts—a red dot indicates one or more critical alerts (and possibly warnings), while a yellow dot indicates one or more warnings only. The field is blank for a device with no alerts. You can “hover” the mouse pointer over the dot to view a pop-up displaying the number of critical alerts and the number of warnings on the device.</td>
</tr>
<tr>
<td>Receive Time</td>
<td>IPS, Firewall</td>
<td>Poll date and time for this entry (format is: day-of-week MMM DD HH:MM:SS your-time-zone YYYYY).</td>
</tr>
<tr>
<td>Device Name</td>
<td>IPS, Firewall</td>
<td>Name of this device, as provided in the Security Manager inventory.</td>
</tr>
<tr>
<td>IP Address</td>
<td>IPS, Firewall</td>
<td>IP address of this device.</td>
</tr>
<tr>
<td>Health Status</td>
<td>IPS, Firewall</td>
<td>Current overall health of the device: Critical, Warning, or Normal.</td>
</tr>
</tbody>
</table>

**Note** Overall health is defined by the most critical of any of the health metrics. For instance, if all the selected metrics on the device are normal except for one that is critical, overall device health becomes critical.
### Table 67-1  Available Table Columns for Device-related Views (Continued)

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Available in View</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Status</td>
<td>IPS, Firewall</td>
<td>Status of the device’s connection to the network: Connected, Not Connected, or Authentication Error. Any information displayed for a Not Connected device is from the indicated Receive Time, prior to connection failure.</td>
</tr>
<tr>
<td>Memory (%)</td>
<td>IPS, Firewall</td>
<td>Memory usage as a percentage of the total available.</td>
</tr>
<tr>
<td>CPU (%)</td>
<td>IPS, Firewall</td>
<td>CPU usage as a percentage of the total available.</td>
</tr>
<tr>
<td>Model</td>
<td>IPS, Firewall</td>
<td>Device type and model number. For example, ASA 5510, or IPS 4270.</td>
</tr>
<tr>
<td>Version</td>
<td>IPS, Firewall</td>
<td>Software version running on this device.</td>
</tr>
<tr>
<td>Inspection Load (%)</td>
<td>IPS</td>
<td>Inspection load on the device when polled, as a percentage.</td>
</tr>
<tr>
<td>Missed Packet(%)</td>
<td>IPS</td>
<td>Dropped packets as a percentage of total packets inspected.</td>
</tr>
<tr>
<td>MainApp Status</td>
<td>IPS</td>
<td>Current MainApp status: Up or Down.</td>
</tr>
<tr>
<td>License Expiration Status</td>
<td>IPS</td>
<td>Status of the sensor’s license, based on red and yellow threshold values set on the sensor: Normal, Warning, or Critical.</td>
</tr>
<tr>
<td>Bypass Mode</td>
<td>IPS</td>
<td>Whether bypass mode is enabled on the sensor: Yes or No.</td>
</tr>
<tr>
<td>Event Retrieval Status</td>
<td>IPS</td>
<td>Status of the IPS event retrieval: Normal, Warning, or Critical.</td>
</tr>
<tr>
<td>Global Correlation Status</td>
<td>IPS</td>
<td>For a sensor participating in global correlation, its update status: Normal (last update was successful), Warning (no successful update within the past day [86,400 seconds]), or Critical (no successful update within the last three days [259,200 seconds]).</td>
</tr>
<tr>
<td>Signature Level</td>
<td>IPS</td>
<td>The number of the most recent signature update applied to this sensor; for example, S574.</td>
</tr>
<tr>
<td>Analysis Engine Memory (%)</td>
<td>IPS</td>
<td>Percentage of memory assigned to the Analysis Engine currently in use.</td>
</tr>
<tr>
<td>Firewall Mode</td>
<td>Firewall</td>
<td>Operating mode of this device: Routed or Transparent.</td>
</tr>
<tr>
<td>Context Mode</td>
<td>Firewall</td>
<td>Context mode of this device: Single or Multiple.</td>
</tr>
<tr>
<td>Connections</td>
<td>Firewall</td>
<td>Number of active connections when device was polled.</td>
</tr>
</tbody>
</table>
Table 67-1  Available Table Columns for Device-related Views (Continued)

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Available in View</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Xlates</td>
<td>Firewall</td>
<td>Address translation counter.</td>
</tr>
<tr>
<td>Connection Rate</td>
<td>Firewall</td>
<td>Number of connections established per second.</td>
</tr>
<tr>
<td>Translation Rate</td>
<td>Firewall</td>
<td>Number of translations per second.</td>
</tr>
<tr>
<td>Failover Status</td>
<td>Firewall</td>
<td>If this device is part of a failover pair, its current state: Active or Standby.</td>
</tr>
<tr>
<td>Host Role</td>
<td>Firewall</td>
<td>If this device is part of a failover pair, its current role: Primary or Secondary.</td>
</tr>
<tr>
<td>Peer Role</td>
<td>Firewall</td>
<td>If this device is part of a failover pair, current role of its peer device: Primary or Secondary.</td>
</tr>
<tr>
<td>Peer Status</td>
<td>Firewall</td>
<td>If this device is part of a failover pair, current status of its peer: Active or Standby Ready.</td>
</tr>
<tr>
<td>Used Memory (MB)</td>
<td>Firewall</td>
<td>Amount of memory (in megabytes) in use when device was polled.</td>
</tr>
<tr>
<td>Free Memory (MB)</td>
<td>Firewall</td>
<td>Amount of memory available (in megabytes) when device was polled.</td>
</tr>
<tr>
<td>Max. Connections</td>
<td>Firewall</td>
<td>Peak number of connections.</td>
</tr>
<tr>
<td>Max. Xlates</td>
<td>Firewall</td>
<td>Peak number of address translations.</td>
</tr>
<tr>
<td>Throughput (Kbps)</td>
<td>Firewall</td>
<td>Average device throughput in kilobits per second.</td>
</tr>
<tr>
<td>ACL Dropped Packets</td>
<td>Firewall</td>
<td>The number of packets dropped because they failed an access control list rule.</td>
</tr>
<tr>
<td>Scanning Threat Dropped Packets</td>
<td>Firewall</td>
<td>If scanning threat detection is enabled, the number of packets dropped because they failed scanning threat inspection. If not enabled, “NA” is displayed.</td>
</tr>
<tr>
<td>Inspection Dropped Packets</td>
<td>Firewall</td>
<td>If application inspection is enabled, the number of packets dropped because they failed application inspection. If not enabled, “NA” is displayed.</td>
</tr>
<tr>
<td>Syn Attack Dropped Packets</td>
<td>Firewall</td>
<td>Number of packets dropped because of SYN flooding.</td>
</tr>
<tr>
<td>Total Interface Dropped Packets</td>
<td>Firewall</td>
<td>Total number of dropped packets on all interfaces.</td>
</tr>
</tbody>
</table>

* All of these columns are available in the All Devices and Priority Devices views.

Note: You can view the number of per-interface dropped packets on the tabbed Interface panel presented in the detail section for the selected device.

Table Columns: VPN-related Views

You can customize the tables presented in the Monitoring pane for the VPN-related views by hiding and showing various columns of information; the columns available for display depend on the particular view.
The order of the entries in the Choose Columns to Display dialog box reflects the ordering of the columns when displayed. (However, the ordering of the rows in the following table does not necessarily reflect ordering of the columns as displayed.) See Showing and Hiding Table Columns, page 67-7 for information about opening the Choose Columns to Display dialog box.

The following table presents all available data columns for the VPN-related Monitoring views: Remote Access Users (RA), Site-to-Site Tunnels (S2S), VPN Summary, and all custom views based on these system views. Some of the listed columns are not available for specific views, as indicated.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Available in View</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Receive Time (always selected)</td>
<td>RA, S2S, Summary</td>
<td>Poll date and time for this entry (format is: day-of-week MMM DD HH:MM:SS your-time-zone YYYY).</td>
</tr>
<tr>
<td>User Name</td>
<td>RA</td>
<td>User log-in name used to establish this session.</td>
</tr>
<tr>
<td>User Group Policy</td>
<td>RA</td>
<td>The name of the ASA VPN user group to which this user belongs.</td>
</tr>
<tr>
<td>Gateway</td>
<td>RA</td>
<td>IP address of the VPN gateway to which the user is connected.</td>
</tr>
<tr>
<td>Assigned IP</td>
<td>RA</td>
<td>Private IP address assigned to the remote client for this session; also known as the “inner” or “virtual” IP address.</td>
</tr>
<tr>
<td>Public IP</td>
<td>RA</td>
<td>Publicly routable IP address assigned to the client.</td>
</tr>
<tr>
<td>Connection Initiation Time</td>
<td>RA</td>
<td>Time and date (HH:MM:SS day-of-week MMM DD YYYY) when connection was initiated. Time is displayed in 24-hour Coordinated Universal Time (UTC) notation.</td>
</tr>
<tr>
<td>Duration</td>
<td>RA</td>
<td>Elapsed time (HH:MM:SS) between the session initiation and the most-recent device poll.</td>
</tr>
<tr>
<td>Client Version</td>
<td>RA</td>
<td>VPN client software, and version, running on the remote peer; for example, AnyConnect Windows 3.0, or Mozilla 4.0.</td>
</tr>
<tr>
<td>EndPoint OS</td>
<td>RA</td>
<td>Operating system in use on remote peer; for example, Windows or Windows NT.</td>
</tr>
<tr>
<td>Authentication Method</td>
<td>RA</td>
<td>User password, certificate, or preshared key.</td>
</tr>
<tr>
<td>Encryption</td>
<td>RA, S2S</td>
<td>Data encryption algorithm this session is using.</td>
</tr>
<tr>
<td>Tunnel Type</td>
<td>RA, Summary (as “Type”)</td>
<td>Connection protocol: DTLS, TLS, or IPsec.</td>
</tr>
<tr>
<td>Throughput</td>
<td>RA, S2S</td>
<td>Bytes received plus bytes transmitted.</td>
</tr>
<tr>
<td>Session ID</td>
<td>RA</td>
<td>Identifier assigned to this session.</td>
</tr>
<tr>
<td>Device ID</td>
<td>RA</td>
<td>Identifier assigned to the device, if available.</td>
</tr>
<tr>
<td>Inactive Time</td>
<td>RA</td>
<td>Amount of time this session has been inactive.</td>
</tr>
<tr>
<td>Firewall Name</td>
<td>S2S, Summary</td>
<td>Name of this device, as provided in the Security Manager inventory.</td>
</tr>
<tr>
<td>IP Address</td>
<td>S2S, Summary</td>
<td>IP address of this device.</td>
</tr>
</tbody>
</table>
You can customize the Alerts table by hiding and showing various columns of information. The order of the entries in the Choose Columns to Display dialog box reflects the ordering of the columns when displayed. (However, the ordering of the rows in the following table does not necessarily reflect ordering of the columns as displayed.) See Showing and Hiding Table Columns, page 67-7 for information about opening the Choose Columns to Display dialog box.

### Table 67-2    Available Table Columns for VPN-related Views (Continued)

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Available in View</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Endpoint</td>
<td>S2S</td>
<td>IP address of local tunnel interface.</td>
</tr>
<tr>
<td>Remote Endpoint</td>
<td>S2S</td>
<td>IP address of remote tunnel interface.</td>
</tr>
<tr>
<td>Local Subnet</td>
<td>S2S</td>
<td>Address of local protected subnet.</td>
</tr>
<tr>
<td>Remote Subnet</td>
<td>S2S</td>
<td>Address of remote protected subnet.</td>
</tr>
<tr>
<td>Uptime</td>
<td>S2S</td>
<td>Current duration of this tunnel.</td>
</tr>
<tr>
<td>Connection Time</td>
<td>S2S</td>
<td>Time and date (HH:MM:SS day-of-week MMM DD YYYY) when connection was initiated. Time is displayed in 24-hour Coordinated Universal Time (UTC) notation.</td>
</tr>
<tr>
<td>Status</td>
<td>S2S</td>
<td>Tunnel connection status; this will always be Up. (HPM cannot present information about tunnels that have gone down.)</td>
</tr>
<tr>
<td>Active</td>
<td>Summary</td>
<td>Current active sessions (S2S, IPSec RA, client-based SSL RA, and clientless SSL RA).</td>
</tr>
<tr>
<td>Peak</td>
<td>Summary</td>
<td>Peak numbers of concurrent sessions (S2S, IPSec RA, client-based SSL RA, and clientless SSL RA).</td>
</tr>
<tr>
<td>Users</td>
<td>Summary</td>
<td>Current remote user total (S2S, IPSec RA, client-based SSL RA, and clientless SSL RA).</td>
</tr>
<tr>
<td>Inactive Sessions</td>
<td>Summary</td>
<td>Number of inactive sessions.</td>
</tr>
<tr>
<td>Total VPN Throughput</td>
<td>Summary</td>
<td>Sum of all VPN traffic; that is, sum of RA and S2S throughput values.</td>
</tr>
</tbody>
</table>

### Alert Table Columns

You can customize the Alerts table by hiding and showing various columns of information.

The order of the entries in the Choose Columns to Display dialog box reflects the ordering of the columns when displayed. (However, the ordering of the rows in the following table does not necessarily reflect ordering of the columns as displayed.) See Showing and Hiding Table Columns, page 67-7 for information about opening the Choose Columns to Display dialog box.

### Table 67-3    Available Data Columns for the Alerts Table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device Name (always selected)</td>
<td>Name of this device on which this alert was triggered, as provided in the Security Manager inventory.</td>
</tr>
<tr>
<td>Device Type</td>
<td>Type of device: ASA or IPS.</td>
</tr>
<tr>
<td>Severity</td>
<td>Alert severity: Critical, Warning, or Normal.</td>
</tr>
<tr>
<td>Status</td>
<td>Current device status: Active or Acknowledged.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the alert. For example, “Device Health Critical” or “Device Polling: Authentication Error.”</td>
</tr>
</tbody>

<tr>
<td>First Seen</td>
<td>Date and time when this alert was first logged (day-of-week MMM DD, YYYY HH:MM:SS AM/PM). Time is based in your time zone.</td>
</tr>
<tr>
<td>Last Seen</td>
<td>Date and time when this alert was first logged (day-of-week MMM DD, YYYY HH:MM:SS AM/PM). Time is based in your time zone.</td>
</tr>
<tr>
<td>Notes</td>
<td>You can annotate an alert when you acknowledge it. Any annotations are displayed in this field. See Alerts: Acknowledging and Clearing, page 67-31 for more information.</td>
</tr>
</tbody>
</table>

Column-based Filtering

You can filter the various tables in HPM based on the contents of specific columns. When you apply a column filter, the table is filtered to include only those entries with the specified criteria in that column.

Note

See Working with Table Columns, page 67-7 for other methods of altering table displays.

Tips

- Column filters are cumulative: for an entry to appear in the filtered table, it must meet all column filter criteria. You cannot create a set of ORed column filters.
- You can filter on the contents of most but not all columns. If a column does not have a down arrow, you cannot filter on it. For example, you cannot filter on Receive Time in All Devices view.
- The filter icon (a funnel) appears in the heading of a filtered column.
- For a description of the available columns, see Showing and Hiding Table Columns, page 67-7.

To filter a table according to a particular column parameter:

Step 1

Click the down-arrow in the heading of a column and choose one of the following from the drop-down menu:

- **All** – Choose **All** to remove or “undo” a filter from this column. The table is updated to show all entries for this parameter. For example, if you filtered the Severity column of the Alerts table to display only Critical alerts, choosing this option will re-display all Critical and Warning alerts.
- **Custom** – Choose **Custom** to open the Custom Filter dialog box where you can create a custom filter based on the information in that column. See Custom Filtering, page 67-13 for more information.
- A specific entry – The drop-down menu includes all values relevant to the column; choose one to display only that group of entries. For example, choosing **Critical** from the Severity column of the Alerts table filters the table to display only Critical alerts.

Custom Filtering

The following procedure explains how to create a custom column-based filter, one in which you are not simply selecting a value from the column’s drop-down list. Refer to Column-based Filtering, page 67-13 for information about other column-based filtering options.
Step 1  
Click the down-arrow in the heading of a column and choose (Custom) from the drop-down menu. The Custom Filter dialog box for that column opens.

Step 2  
In the Custom Filter dialog box, select the desired values. The following illustration shows a typical example of this dialog box.

These are the controls you might find in the Custom Filter dialog box (not all controls appear for every instance):

- **Condition** – Choose the condition applied to the selected Values.
  
  Typically this is **is in**, meaning each of the Values you select must be “in” a column in order for that entry to be displayed in the filtered table.

- **Not** – Check this box to create a negative Condition.
  
  With **is in** as the chosen Condition, this would mean the selected Values cannot be in the column. In other words, the table is filtered such that entries with these Values in the column are not displayed.

- **Values** list – A few instances of the dialog box present one list of Values from which to select: simply check the desired options.

  Available and selected **Values** lists – In most cases, the dialog box presents two Values lists, as shown in the previous illustration. To select a value for the custom filter, highlight it in the left list, which contains available values for the column, and click the right arrow to add it to the list of selected values on the right. You can select multiple values.

  The items in the available Values list are determined by the values currently present in the selected column of the source table.

  If there are a lot of available values, you can search for a specific value by typing in the List Filter field above the list. For more information, see Using The List Filter Fields, page 67-15.

  You can also select, or deselect, values using the following techniques:

  - Type a Value name into the text field above the selected Values list and click the + button; the Value is added to the selected Values. This technique is useful if there is a large number of available Values, or if you want to filter on a value that is not present in the available Values list.

  - Double-click an item in either list to move it to the other list.

  - Click one of the double-arrow buttons to move all items from one list to the other, regardless of any selected values.
Step 3  Click **OK** to close the dialog box.

The table is updated to show only those entries that satisfy all currently applied filters.

---

**Using The List Filter Fields**

A List Filter field is provided above the devices and VPNs lists in the Monitoring display, above the alerts table in the Alerts display, above the device list on the VPN page of the Device Selector, and in the View Cleared Alerts window. In each case, you can use the List Filter field to quickly locate any entries in the related table that contain a specified text string.

*Note*  The found text can be part of any data field associated with an entry. For example, as you type “license” into the Alerts List Filter field, the Alerts table is filtered to show only those alerts related to imminent license expiration. (Any matched entries are listed even if the relevant data column—in this example, Detail—is not displayed, which could cause confusion. See Showing and Hiding Table Columns, page 67-7 for more information about hiding table columns.)

---

**Figure 67-2  Health and Performance Monitor: List Filter Field**

<table>
<thead>
<tr>
<th>1</th>
<th>Filter-parameters button.</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Clear button.</td>
</tr>
</tbody>
</table>

To search for a specific text string in the devices list, the VPNs list, the Alertstable, or the View Cleared Alerts window:

- Click in the List Filter field to place the text cursor, and then begin typing.

  These are “live filter” fields. That is, as you type each character, entries that do not include your current text string are removed from the list or table. For example, suppose in an extensive list of alerts there is one with a Status of “Device Health Critical,” and that none of the other alerts include any text strings containing the letters *hea*. You want to use the List Filter field to quickly locate that one alert, so you begin to enter the word “health.” That alert is the only one displayed after you have typed the first three letters.

To clear a List Filter field:

- Click the clear button at the right side of the field.

  This button appears when you begin typing in the field. (You also can highlight the characters and press the Delete or Backspace key on your keyboard.)

When you clear the List Filter field, all entries in the list are again displayed.
You can tune the filter results by specifying the information (columns) searched, by selecting case sensitivity or insensitivity, by allowing wildcards or regular expressions, and by specifying where in a returned string your characters must be located.

To change the List Filter criteria:

1. Click the filter-parameters button (magnifying glass) at the left side of the List Filter field to open the parameters menu.
2. Choose an option.

   The menu consists of four sections:
   - A list of all available information types—these entries correspond to the columns that can be displayed for that particular list or table. You can choose All, or alternatively you can choose individual entries.
   - Case sensitive and Case insensitive – Choose one or the other. If you choose Case sensitive, found text must match not only the characters you enter, but also their as-typed case.
   - Use wildcards and Use regular expression – Choose one or the other. The following wildcards are recognized:
     - * (asterisk) – Match zero or more characters at that location in the string.
     - ? (question mark) – Match one character at that location in the string.
     - Match from start, Match exactly, and Match anywhere – Choose one. Match from start means that the string you enter must be found at the beginning of an entry, although it can be part of a larger set of characters. Match exactly requires that the string you enter exactly match the entire column entry. Match anywhere means the string can be found anywhere within an entry, and it can be part of a larger set of characters.
3. Repeat Steps 1 and 2 to change another parameter.

**Monitoring Devices**

The HPM Monitoring display presents View controls, view panels, and detailed information about the currently selected device, as described in HPM Window: Monitoring Display, page 67-21.

To switch to the Monitoring screen:

- Click the Monitoring button below the HPM menu bar.
  (Click the Alerts button to return to the Alerts screen.)

---

**Note**

See Managing Monitored Devices, page 67-5 for information about specifying the devices to be monitored.

This section contains the following topics:

- Managing Device Views, page 67-17
- HPM Window: Monitoring Display, page 67-21
Managing Device Views

“Views” provide the means to filter and organize the information displayed in the Monitoring pane of the HPM application. Various system views are provided—for example, All Devices, Firewall Devices, Remote Access Users Details, and so on—and you can create custom views that organize the information in other ways, such as geographic device location.

The left pane of the HPM main window displays a list of available views as shown in the following illustration.

*Figure 67-3 Health and Performance Monitor: Views Pane*

The Views pane includes the following controls:

1. **(1) Push Pin button** – Click the Push Pin button to control display of the Views list. When the list is displayed as a pane of the HPM window (the pin is vertical), click the button to collapse the pane into the left edge of the window, leaving a labeled tab; the Monitoring pane is expanded to fill the HPM window.
You can “hover” your mouse pointer over the tab to “pop out” the Views list; it remains visible as long as the pointer is over the tab or in the list area (the pin is horizontal). You also can click anywhere in the title bar—except on the pin itself—to keep the list “popped out.”

Click the pin once again to re-establish the Views list as an open pane; the Monitoring pane contracts to make room for it.

- (2) List of views – The list is organized into folders: System Views and My Views. Click an entry in either folder to open that view in the Monitoring pane, as described in Views: Opening and Closing, page 67-18. See Views: Custom, page 67-20 for information about creating new views in the My Views folder.

- Right-click shortcut menu – You can right-click any entry in the View list to access a pop-up menu of view-related commands:
  - Save As – Save the view as a new custom view. See Views: Custom, page 67-20.
  - Delete – Delete that custom view.
  - Set as default view – Use this command to designate the view that is always displayed whenever you launch the HPM application.

This section contains the following topics:

- Views: Opening and Closing, page 67-18
- Views: Tiling Horizontally or Vertically, page 67-19
- Views: Floating and Docking, page 67-19
- Views: Custom, page 67-20

### Views: Opening and Closing

All available views are listed in the Views pane, on the left side of the HPM window. The Monitoring pane displays open views, with each open view presented as a separate tabbed panel. (See HPM Window: Monitoring Display, page 67-21 for more information about this window.)

You can detach views so they “float” in separate windows. For more information, see Views: Floating and Docking, page 67-19.

To display a new view in the Monitoring pane:

- Click the desired entry in the Views list.

  The view appears as a tabbed panel in the Monitoring pane; it is automatically selected and displayed.

To switch to another open view:

- Click the desired tab in the Monitoring pane; that view is displayed.
- Right-click any tab and choose Next or Previous to display the view to the right or left of that tabbed view.
- Click the Scroll Back and Scroll Forward buttons to the right of the tabs to display the view to the left or right of the current view.
To close a view:

- Click the close button in that tab.
- Right-click the tab and choose the Close.
- Right-click the tab and choose Close Others to close all open views except the one you right-clicked.
- Right-click any tab and choose Close All to close all open views.

Views: Tiling Horizontally or Vertically

Rather than displaying a single view such that it fills the Monitoring pane, you can tile two or more of the views, either horizontally or vertically, for easy comparison.

For example, if you tile two views horizontally, one view fills the upper half of the Monitoring pane, while the other fills the lower half. Similarly, tiling two views vertically fills the left-hand half of the pane with one view, with the other view filling the right half. Further, you can tile more than two views—the pane is subdivided equally for each view.

To create two horizontal or vertical tiles:

- Right-click one of the tabs and choose New Horizontal Group or New Vertical Group.

The selected view and the other view(s) are distributed to share the Monitoring pane equally, either horizontally or vertically depending on your choice.

Note that if there are more than two views open when you choose one of these commands, the selected view is tiled, with the remaining group of tabbed views displayed as the other tile. You can then repeat this process with the remaining tabbed views, increasing the number of visible tiles, as desired.

You can also move an existing tile to another tile:

- Right-click the tab and choose Move to Next Tab Group or Move to Previous Tab Group.

The selected view is added to the next tile (below or to the right, depending on tile orientation), or to the previous tile (above or to the left). These commands are available only if the tiled views are arranged in a manner where such movement is possible.

To change the orientation of the views, switching from horizontal to vertical tiling, or vice versa:

- Right-click any tab and choose Change Tab Groups Orientation.

This command is available only when two or more tiled views are displayed.

Views: Floating and Docking

You can detach tabbed views so they “float” as separate windows, and you can “dock” floating views, returning them to the Monitoring pane as tabbed views.

To detach a view as a floating window:

- Right-click that tab and choose Floating.

A standard window opens, displaying the selected view.

To move another tabbed view from the Monitoring pane to an already-open floating-view window:

- Right-click the tab and choose the window from the Floating to submenu.

The right-clicked view is added to the existing window as another tabbed panel.
To return a floating view to the Monitoring pane as a tabbed panel:

- Right-click the view’s tab in the window and choose Docking.

That view is returned to the Monitoring pane.

**Note**

As a standard window, you can minimize, maximize and close a floating view, as you would any other window.

### Views: Custom

The Health and Performance Monitor provides seven System Views. In addition, you can create any number of custom views, each of which is based on an existing view. You also can edit and delete custom views.

The various views are presented in the Views pane of the Monitoring display, organized into two folders: System Views and My Views (the latter folder contains your custom views). The Monitoring display is described in HPM Window: Monitoring Display, page 67-21.

Follow these steps to create a new custom view:

1. In the Views list, select the view on which the new view is to be based. This can be a System View or an existing custom view.
2. Choose Save As from the File menu to open the Save View As dialog box.
   You also can right-click the selected view and choose Save As from the pop-up menu to open the dialog box.
3. Provide a Name for the new view, and optionally a Description.
4. Specify the devices to be monitored for this view: check and clear entries in the device-selector area of the dialog box.
5. Click Save to close the dialog box and add the new view to the My Views folder.

Follow these steps to edit an existing custom view:

1. Under My Views, select the view.
2. Choose Edit from the File menu to open the Save View As dialog box.
   You also can right-click the selected view and choose Edit from the pop-up menu.
3. Edit the Name and Description, as necessary.
4. Check and clear entries in the device selector to change the devices monitored for this view.
5. Click Save to close the dialog box.

Follow these steps to delete an existing custom view:

1. Under My Views, select the view.
2. Choose Delete from the File menu.
   You also can right-click the selected view and choose Delete from the pop-up menu.
3. Confirm that you want the view deleted.
   That view is removed from the Views list.
HPM Window: Monitoring Display

The HPM window provides two different information displays: Monitoring and Alerts. Click the Monitoring button to access the Monitoring display.

The Monitoring display consists of two primary panes: Views and Monitoring. The Views pane presents a list of available views. Click an entry in this list to open that View as a tabbed panel in the Monitoring pane.

The Monitoring pane can present multiple tabbed views, most of which display several sections. Click a tab to bring that view to the front.

Note

The Remote Access Users and the Site-to-Site Tunnels views each display only a single table of information, as described in Monitoring Views: VPN, RA and S2S, page 67-24. The following descriptions focus mainly on the other available system views.

The following illustration presents the primary features of the Monitoring display and the panel sections.

Figure 67-4 Health and Performance Monitor: the Monitoring Display

1. Views list.
2. Monitoring view controls.
3. Summary of all devices.
4. Status of devices and VPNs.
5. Selected device details.
The Monitoring display consists of five main elements:

- **Views list (1)** – This pane lists all views available—click an entry in this list to open that view in the Monitoring pane. The views are organized into System Views, provided as part of the program, and My Views, which are custom views you have created. See Managing Device Views, page 67-17 for information about the Views pane, and Views: Custom, page 67-20 for information about managing custom views.

- **Monitoring view controls (2)** – A labeled tab appears here for each view you open; click any tab to bring that view to the front. You also can use the Scroll Backward and Scroll Forward buttons to step backward or forward through the tabbed views. Alternately, open the Show List drop-down menu on the right and choose a label to make that the active view.

- **Summary of all devices (3)** – Provides aggregate information for all devices represented by this view. Expand or collapse this section by clicking the button on the right side. The device-summary section is described in greater detail in Monitoring Views: Devices Summary, page 67-22.

- **Device-status list (4)** – All devices or VPNs included in this view are listed here; see Monitoring Views: Device Status List, page 67-22 for more information about this list. Use the List Filter field in this section to filter the list, as described in Using The List Filter Fields, page 67-15.

- **Selected device details (5)** – This section provides detailed information about the device or VPN currently highlighted in the device list. The device-details section is described in greater detail in Monitoring Views: Device Details, page 67-23.

This section contains the following topics:

- Monitoring Views: Devices Summary, page 67-22
- Monitoring Views: Device Status List, page 67-22
- Monitoring Views: Device Details, page 67-23

### Monitoring Views: Devices Summary

The HPM Monitoring display presents tabbed views, each of which provides detailed information about the device or VPN currently selected, as described in HPM Window: Monitoring Display, page 67-21. All device-related views (that is, all but the Remote-Access Users and Site-to-Site Tunnels views), include a Summary section, as described here.

This devices Summary, which you can show and hide by clicking the button on the right side of its title bar, displays a snapshot of the aggregate Health Status and Alert Status for all the devices or VPNs relevant to the current view. For example, if you are viewing the Firewall Devices panel, the status summaries are for all monitored firewall devices only.

### Monitoring Views: Device Status List

The HPM Monitoring display presents detailed information about the device or VPN currently selected, as described in HPM Window: Monitoring Display, page 67-21. All device-related Views (that is, all but the Remote-Access Users and Site-to-Site Tunnels views), include a table of monitored devices or VPNs relevant to the current view.

This table displays “at-a-glance” status information for every monitored device or VPN—each is represented by an entry in this table. (Again, the list includes only those elements relevant to the current view. For example, the list in the Firewall Devices view does not include entries for IPS devices.)
You can resize the table columns, you can show and hide columns, and the column headings are menus you can use to filter the table by hiding or showing devices according to chosen parameters. See Showing and Hiding Table Columns, page 67-7 for more information about these options.

When you select an entry in this list, detailed information for that device is displayed in the device-details area below the table, as described in Monitoring Views: Device Details, page 67-23.

With the All Devices, Firewall Devices, IPS Devices, and Priority Devices views (and any custom device-related views), you can right-click the highlighted entry and choose Device Manager from the pop-up menu to open the appropriate external device manager for that device—that is, ASDM for an ASA, and IDM for an IPS sensor—where you can “drill down” into the health and performance data for that device. See Starting Device Managers, page 68-10 for more information about the device managers.

**Monitoring Views: Device Details**

The HPM Monitoring display presents views and detailed information about the device or VPN currently selected, as described in HPM Window: Monitoring Display, page 67-21. All device-related Views (that is, all but the Remote-Access Users and Site-to-Site Tunnels views), provide three or four tabbed panels of detailed information for the individual device or VPN currently selected in the device-status table above it.

For the All Devices, Firewall Devices, IPS Devices, and Priority Devices views, the tabbed panels are:

- **Health** – A “snapshot” of device status, including graphic displays for certain metrics. With firewall and IPS devices, the top section of this panel includes:
  - The Health field indicates general overall status, and can be Normal, Warning, or Critical, based on number and type of alerts triggered on the device. Click the i button for a pop-up view of current device metrics.
  - The Alerts field indicates current alert level; also can be Normal, Warning, or Critical. The numbers of triggered Critical and Warning alerts are indicated, followed by a View hyperlink. Click the link to switch to the Alerts display with only the alerts for this device listed.

  **Note**
  For IPS devices, certain health-metric thresholds must be configured separately on the individual devices—that is, outside of HPM. Therefore, it is possible for the health of an IPS device to be critical, for example, without any indication in HPM. See Alerts Configuration: IPS, page 67-28 for additional information.

- **Device Information** – A read-only listing of device-specific information such as device name, IP address, device type and model number, and so on.

- **Traffic** – Device-specific traffic information, some of which is also presented in graphical form. For example, average number of connections and number of translations for firewall devices (over the most-recent polling period), and average inspection load and percentage of missed packets for IPS sensors (over the most-recent polling period).

- **Interfaces** – A listing of all interfaces defined on the device, with current status information.

For the VPN Summary view, the tabbed panels are:

- **VPN Usage** – Several graphs presenting information such as active site-to-site tunnels, active remote-access sessions, and total throughput. This includes historical trending information for active Site-to-Site tunnels, active IPSec remote-access users, active SSL VPN clientless users, and active SSL VPN with client users.
Alerts and Notifications

The Health and Performance Monitor (HPM) provides trend information, alerts, and notifications regarding the performance and health of monitored devices. You can monitor the overall health of your network—including network user and device resource utilization—by quickly scanning the status of individual devices and groups of devices.
Specific device-level trend information is available for hourly, daily and weekly intervals. Alerts are displayed prominently, with easy navigation to the relevant HPM data. You also can acknowledge and annotate individual alerts.

These alerts are based on threshold values and state-change rules that you have configured: you specify thresholds that define Critical, Warning, and Normal levels for various metrics, and you can configure rules for certain state changes such as interface failure.

Further, there are two levels of device monitoring. Initially all devices are unmonitored. However, you can designate devices to be monitored at a “normal” level, or at a “Priority” level—you define a separate set of alert definitions for each level. Priority devices are polled and reported on more frequently, and failure parameters are more stringent.

You also can enable email alert notifications. If configured, an email is sent to the specified address(es) whenever an alert is generated. You can provide multiple addresses for each category of alerts (Firewall and IPS).

**Note**

An email notification is sent the first time an alert is logged, and when the severity of an alert changes from warning to critical (but not vice-versa). No notification is issued if a device returns to the Normal state.

This section contains the following topics:

- HPM Window: Alerts Display, page 67-25
- Alerts: Configuring, page 67-27
- Alerts: Viewing, page 67-31
- Alerts: History, page 67-32

**HPM Window: Alerts Display**

The HPM window provides two different information displays: Monitoring and Alerts. Click the Alerts button to access the Alerts display.

The following illustration presents the primary features of the Alerts display.
The Alerts display consists of seven main elements:

- **Alerts button (1)** – The HPM window displays either Monitoring information for devices and VPNs, or a table of alerts generated by monitored devices. Click the Alerts button to view the alerts table.

- **List Filter field (2)** – You can use this field to filter the alerts displayed in the table; only those alerts containing the specified text are listed. Refer to Using The List Filter Fields, page 67-15 for more information.

- **Alerts table (3)** – This table lists all alerts for all currently monitored devices. The alerts displayed can be filtered using the List Filter field. You also can show and hide various columns of information for each alert. See Alerts and Notifications, page 67-24 for more information.

- **Refresh button (4)** – Click this button to update all alerts ahead of the normal polling cycles.

- **Clear button (5)** – When one or more alerts are selected, you can click this button to open the Clear dialog box. Click the Clear button in the dialog box to close it and clear the highlighted alerts from the table.
Alerts and Notifications

Chapter 67      Health and Performance Monitoring

Alerts: Configuring

The alerts and email notifications provided by HPM are based on threshold values and state-change rules that you configure in the Alerts Configuration dialog box.

The Alerts Configuration dialog box consists of two tabbed panels: IPS for IPS sensor-related alerts, and FW for firewall-related alerts. Each panel presents groups of options in sections—use the expand/collapse button to show or hide a particular section.

Note

You can enable and disable a particular alert without expanding that section; simply check or clear the box preceding the section heading—the current settings are used and retained.

There are two levels of device monitoring: normal or “standard” priority and “active” priority. Active priority devices are polled and reported on more frequently, and failure parameters are more stringent. You can designate up to 10% of all monitored devices for Priority monitoring. See Managing Monitored Devices, page 67-5 for more information about device selection.

Follow these steps to configure alert reporting and notifications for both Standard and Priority devices:

Step 1
Choose Alert Configuration from the Tools menu to open the Alerts Configuration dialog box.

Step 2
On the IPS panel, configure IPS-related alerts—if necessary, click the IPS tab to display the panel.

1. To enable email Notifications when IPS alerts are generated, enter one or more valid addresses in the Email Addresses field; separate multiple addresses with commas.

2. Use the checkboxes in the section headings to enable and disable specific alerts. Expand a section to update those alert definitions. The IPS parameters are described in Alerts Configuration: IPS, page 67-28.

Note
An email notification is sent the first time an alert is logged, and when the severity of an alert changes from warning to critical (but not vice-versa). No notification is issued if a device returns to the Normal state.
Step 3 On the FW panel, configure firewall-related alerts—click the FW tab to display the panel.

1. To enable email Notifications when firewall alerts are generated, enter one or more valid addresses in the Email Addresses field; separate multiple addresses with commas.

2. Use the checkboxes in the section headings to enable and disable specific alerts. Expand a section to update those alert definitions. The FW parameters are described in Alerts Configuration: Firewall, page 67-29.

Step 4 Click Save to save your changes and close the dialog box.

Alerts Configuration: IPS

The alerts and status information collected from monitored IPS devices are configured on the IPS panel of the Alerts Configuration dialog box. Refer Alerts: Configuring, page 67-27 to for information about opening the dialog box, accessing the IPS panel, and providing email addresses for IPS-related Notifications.

The IPS-alert configuration parameters are grouped into sections that can be expanded and collapsed. Each section includes a checkbox next to its heading; use this checkbox to enable or disable that alert. When expanded, each section provides access to the settings used to define the alert.

The IPS alert and status configuration parameters are described in the following table. Each parameter can be configured separately for Priority Devices and Standard Devices. (Specifying devices for priority and standard monitoring is described in Managing Monitored Devices, page 67-5.)

Note Some of the following alert settings require specific related parameters to be configured on the monitored IPS sensors themselves. For example, if license-expiration-policy (health-monitor command) is not enabled on a particular sensor, license-expiration messages are not generated by that sensor and therefore no occurrences are tallied for it by HPM.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CollaborationApp Status</td>
<td>Errors generated by the CollaborationApp application are tallied. Alerts and Notifications are generated when the number of errors tallied reaches the specified Occurrences value.</td>
</tr>
<tr>
<td>SensorApp Status</td>
<td>Errors generated by the SensorApp application are tallied. Alerts and Notifications are generated when the number of events reaches the specified Occurrences value.</td>
</tr>
<tr>
<td>Bypass Mode</td>
<td>Any time bypass mode is triggered, one Occurrence is tallied for this setting. Alerts and Notifications are generated when the number of Occurrences reaches the value specified.</td>
</tr>
<tr>
<td>Interface Status</td>
<td>The status of each enabled interface is polled periodically. Each “down” result for any given interface is tallied as one Occurrence for that interface. Alerts and Notifications are generated when the number of Occurrences reaches the value specified.</td>
</tr>
<tr>
<td>License Expiration</td>
<td>A license-expiration threshold can be configured on each IPS sensor, and whenever this threshold is crossed, a status message is issued.</td>
</tr>
</tbody>
</table>

Table 67-4 IPS Alerts Configuration
Alerts and Notifications

Alerts Configuration: Firewall

The alerts and status information collected from monitored firewall devices are configured on the FW panel of the Alerts Configuration dialog box. Refer Alerts: Configuring, page 67-27 to for information about opening the dialog box, accessing the FW panel, expanding and collapsing sections, and providing email addresses for FW-related Notifications.

The firewall-alert configuration parameters are grouped into sections that can be expanded and collapsed. Each section includes a checkbox next to its heading; use this checkbox to enable or disable that alert. When expanded, each section provides access to the settings used to define the alert.

Some section headings also include Consider for Device Health checkboxes. Checking one of these boxes means that particular information is considered when determining overall health of each device.

The FW alert and status configuration parameters are described in the following table.

<table>
<thead>
<tr>
<th>Table 67-5</th>
<th>Firewall Alerts Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Setting</td>
<td>Description</td>
</tr>
<tr>
<td>Peer Status</td>
<td>The status of the link to the device’s failover peer is polled periodically. Each failed contact attempt is tallied as one Occurrence. Alerts and notifications are generated when the number of occurrences reaches the values specified here. For Priority devices and for Standard devices: choose Critical or Warning to specify the type of alert generated, and then specify the number of occurrences necessary to trigger the alert.</td>
</tr>
</tbody>
</table>
Table 67-5   Firewall Alerts Configuration (Continued)

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Status</td>
<td>The status of each enabled device interface is polled periodically. Each “down” result for any given interface is tallied as one Occurrence for that interface. Alerts and notifications are generated when the number of occurrences reaches the values specified here. For Priority devices and for Standard devices: choose <strong>Critical</strong> or <strong>Warning</strong> to specify the type of alert generated, and then specify the number of occurrences necessary to trigger the alert. <strong>Note</strong> Check <strong>Consider for Device Health</strong> in the header to include these data in device-health calculations.</td>
</tr>
</tbody>
</table>
| CPU Usage          | An Occurrence is tallied each time CPU usage exceeds the specified Threshold percentage. Alerts and notifications are generated when the number of occurrences reaches the values specified here. **Note** Check **Consider for Device Health** in the header to include these data in device-health calculations. For Priority devices and for Standard devices, you can enable either or both **Critical** and **Warning** CPU Usage alerts:  
  1. Check the appropriate box to enable the **Threshold** and **Occurrence** fields.  
  2. Specify a **Threshold** percentage by clicking the up or down arrows, or by highlighting the existing value and typing a number.  
  3. In the **Occurrence** field, specify the number of times the specified Threshold must be exceeded before the critical or warning alert is issued. |
| Memory Usage       | An Occurrence is tallied each time memory usage exceeds the specified Threshold percentage. Alerts and notifications are generated when the number of occurrences reaches the values specified here. **Note** Check **Consider for Device Health** in the header to include these data in device-health calculations. For Priority devices and for Standard devices, you can enable either or both **Critical** and **Warning** Memory Usage alerts:  
  1. Check the appropriate box to enable the **Threshold** and **Occurrence** fields.  
  2. Specify a **Threshold** percentage by clicking the up or down arrows, or by highlighting the existing value and typing a number.  
  3. In the **Occurrence** field, specify the number of times the specified Threshold must be exceeded before the critical or warning alert is issued. |
Alerts: Viewing

All alerts generated for monitored devices are displayed as a table in an alternate screen of the HPM window. The Alerts table is updated automatically as devices are polled for status information. You can also click the Refresh button, above the table on the right side, to update the table.

These alerts are based on the threshold values and state-change rules you have configured. See Alerts: Configuring, page 67-27 for more information.

Note
See Managing Monitored Devices, page 67-5 for information about specifying the devices to be monitored.

To switch to the Alerts screen:
- Click the Alerts button below the HPM menu bar.
- (Click the Monitoring button to return to the Monitoring screen.)

The Alerts listing is a basic table, consisting of rows and columns, with each row representing one alert from a given device. Each column provides specific information about that alert: device name, alert severity, time recorded, and so on. (See HPM Window: Alerts Display, page 67-25 for more about the Alerts screen.)

Note
The column headings are menus that you can use to filter the table by hiding or showing alerts according to chosen parameters. For example, you might choose to display alerts for only a particular device, and then choose only critical alerts for that device. See Working with Table Columns, page 67-7 for more information.

In addition to scrolling the Alerts table, you can view sets of specific alerts:
- Use the List Filter field above this table to filter the list. See Using The List Filter Fields, page 67-15 for more information.
- Use the View Cleared Alerts window to view previously cleared alerts for a selected set of devices over a specified time range. See Alerts: History, page 67-32 for more information.

You also can acknowledge alerts, clear alerts, and edit alert notes:
- You can acknowledge an alert, or clear it, as described in Alerts: Acknowledging and Clearing, page 67-31.
- To add to an existing alert note, click Notes field for that entry in the table to open the Enter Notes dialog box—used to view and add notes to an alert. Available only when a single alert with an existing note is selected in the table.

Alerts: Acknowledging and Clearing

All alerts generated for monitored devices are displayed in the Alerts table, as described in Alerts: Viewing, page 67-31. You can add notes to individual alerts, and you can acknowledge or clear alerts individually or in groups.

To select an alert, click that entry in the Alerts table. You can Shift-click another alert to select the group between the two, and you can Ctrl-click various rows to select multiple non-contiguous alerts.
When an alert is selected in the table, you can:

- Click the Acknowledge button to open the Acknowledge Alert dialog box, used to add a note to, and then mark the selected alert(s) as acknowledged. You can acknowledge multiple alerts at one time.
  
  Enter text in the Notes field in this dialog box (this is optional), and then click OK. The dialog box closes and the alerts are marked as acknowledged with a timestamp displayed in the Notes column.

- Click the Clear button to open the Clear Alert dialog box, used to add a note to, and then remove the selected entries from the Alerts table.
  
  Enter text in the Notes field in this dialog box (this is optional), and then click OK. The dialog box closes and the selected alerts are removed from the Alerts table.

Note: Alerts can be cleared automatically by HPM if you change the relevant threshold(s). Like alerts you have cleared, these alerts can be viewed in the View Cleared Alerts window (see Alerts: History, page 67-32).

Notes and other information for cleared alerts are saved in an Alerts database for 30 days.

**Alerts: History**

All alerts generated for monitored devices are displayed as a table in the HPM window. You can filter the table by any visible column parameter, as described in Alerts: Viewing, page 67-31.

You also can use the View Cleared Alerts window to access and view previously cleared alerts; you specify a set of devices and a time range. (Clearing alerts is described in Alerts: Acknowledging and Clearing, page 67-31.)

Note: Notes and other information for cleared alerts is maintained in an Alerts database for 30 days—you cannot access alerts more than 30 days old.

Follow these steps to open and use the View Cleared Alerts window:

1. In the Alerts screen, click the View Cleared Alerts button next to the List Filter field to open the View Cleared Alerts window. (See Alerts: Viewing, page 67-31 for more information about accessing the Alerts screen of the HPM window.)

2. Specify the alert View Settings; these define the set of alerts you wish to view:
   - Specify the devices of interest; **All** devices are selected by default. To select a particular set of devices:
     - Click the **Select** button to open the Select Devices dialog box.
     - Select the desired device(s); deselect any devices you wish to exclude.
     - Click **OK** to close the Select Devices dialog box.
   - Specify the types of Alerts to display: select or deselect **Critical**, **Warning** and **Normal**.
   - Define the desired **Time Range** by choosing a From date and time, and a To date and time. All alerts with a First Seen time within this range will be displayed.
     
     From and To each present a standard drop-down calendar used to select a month and day.
Use the time field below each calendar to specify the precise start or end time, respectively. Highlight a digit and click the up or down arrow, or simply type the desired number. You can also click the **Now** button to specify the present moment.

3. Click the **Search** button to display the defined set of alerts.

Note that the View Cleared Alerts window provides a List Filter field that you can use to filter the cleared-alerts display. Using this field is described in Using The List Filter Fields, page 67-15.

Refer to Working with Table Columns, page 67-7 for other methods of filtering this table.
High network availability is a requirement for large enterprises and service providers. Network managers face various challenges to providing high availability, including unscheduled downtime, lack of expertise, insufficient tools, complex technologies, business consolidation, and competing markets. Network monitoring, problem diagnosis and troubleshooting are essential to meeting and overcoming these challenges.

Monitoring involves the study of network activity and device status to identify anomalous events and behaviors. Quickly diagnosing and correcting network and system faults such as outages and degradations increase service availability, and thus tools to isolate, analyze and correct problems are essential.

The main Security Manager tool for monitoring device events is Event Viewer (see Chapter 65, “Viewing Events”). In addition to Event Viewer, the following topics describe additional monitoring, troubleshooting and diagnostic tools that are available with Security Manager:

- Analyzing an ASA or PIX Configuration Using Packet Tracer, page 68-1
- Analyzing Connectivity Issues the Using Ping, Trace Route, or NS Lookup Tools, page 68-4
- Using the Packet Capture Wizard, page 68-8
- Starting Device Managers, page 68-10
- Viewing Inventory Status, page 68-16
- Integrating CS-MARS and Security Manager, page 68-18

### Analyzing an ASA or PIX Configuration Using Packet Tracer

Packet tracer is a policy debugging tool for ASA and PIX security appliances running version 7.2.1+ that are not operating in transparent mode. It inspects the active policies currently running on the appliance. Without having to generate real traffic, you can analyze how traffic between two addresses traverses the security appliance, whether it is dropped or allowed. If the result is unexpected, you can determine where the issue exists and update the corresponding policy in Security Manager to resolve it.

Packet tracer presents a step-by-step analysis of how a simulated packet is processed by the security appliance’s active configuration. It traces the packet’s flow through the active firewall modules, such as route lookup, access lists, NAT translations, and VPN. The set of active modules changes based on the type of packet configured and the active configuration. For example, if no VPN policies are configured, the VPN module is not evaluated.
You can inspect the simulated packet’s traversal rather than having to generate network traffic, enable syslog messages, and manually review resulting syslog messages. Packet tracer details the actions enforced by the active configuration on the packet. If a configuration command causes the packet to be dropped, the reason is provided, such as “Drop-reason: (telnet-not-permitted) Telnet not permitted on least secure interface.”

You can trace the life span of a simulated packet through the security appliance to see whether the packet is behaving as expected. Packet tracer uses include the following:

- Debug all packet drops in a production network.
- Verify the configuration is working as intended.
- Show all rules applicable to a packet including the CLI that defines the rule.
- Show a time line of packet changes in a data path.
- Trace packets in the data path.
- If the packet is blocked or permitted by some explicit access rule, you can use a short-cut to go to the policy so that you can edit the rule.

**Tips:**

- Packet Tracer is also available in the ASDM application and the ASA command line, and the Security Manager version is equivalent to the ASDM version. For an example of using Packet Tracer from ASDM and the CLI to analyze a configuration, see PIX/ASA 7.2(1) and later: Intra-Interface Communications.
- Before you can use packet tracer on a device, you must submit your policy changes at least once after adding the device to the inventory.
- Packet tracer analyzes only the active configuration running on a device. Therefore, you cannot use packet tracer to test proposed configurations before they are deployed and running on the device. Do not use packet tracer on a device with pending configuration changes—deploy the changes first and then use packet tracer to ensure the packet tracer results are valid.

To use Packet Tracer:

**Step 1** (Device view) Right click on the ASA or PIX 7.2.1+ device and select **Packet Tracer** on the shortcut menu to open the Packet Tracer window.

**Step 2** Select the interface you want to test from the **Interfaces** list. The list contains all interfaces defined on the device.

**Step 3** Model the packet that you want to trace by configuring the following fields:

- **Packet Type**—Select whether you are tracing a TCP, UDP, ICMP, or IP packet.
- **Source, Destination IP Address**—Select from the following address types and enter the host addresses for both ends of the communication (from source to destination):
  - IP Address of the host.
  - User (source only). For example, DOMAIN\Administrator. The IP address mapped to the user is used for the trace. You must enable identity-aware firewall by configuring identity options to use this type of address.
  - FQDN, or fully-qualified domain name, of the host. For example, host.example.com. You must configure DNS to use this type of address.
- **Source, Destination Port (TCP and UDP only)**—Enter, or select, the port numbers that represent the traffic type. The selection list uses names that equate to the standard port numbers for the named application. For example, selecting **http** and entering **80** is the same.
• **Type, Code, ID (ICMP only)**—When modeling an ICMP packet, you must enter values in all of these fields:
  
  – **Type**—Select the ICMP packet type or enter the equivalent number. The list includes all main ICMP types. For a complete list of types and related codes, see RFC 1700 at [http://www.ietf.org/rfc/rfc1700.txt](http://www.ietf.org/rfc/rfc1700.txt) and search for “ICMP Type Numbers.”
  
  – **Code**—Enter 0 unless you are modeling a packet type that has non-zero codes. These are destination unreachable (type 3, codes 0-12), redirect (type 5, codes 0-3), time exceeded (type 11, codes 0-1), and parameter problem (type 12, codes 0-2). See RFC 1700 for code explanations, and note that additional codes might have been introduced in other RFCs.
  
  – **ID**—You must enter a value for ID even though the field is used for a limited number of message types only. The ID is used for ICMP types that include request and reply versions, such as echo and echo request, to help match replies to requests. The value should be between 1-255.

• **Protocol (IP only)**—Enter the number that identifies the next level protocol. For a complete list of protocol codes, see RFC 1700 at [http://www.ietf.org/rfc/rfc1700.txt](http://www.ietf.org/rfc/rfc1700.txt) and search for the “Protocol Numbers” heading. As of the writing of this topic, numbers 1-54 and 61-100 represent values assigned to actual protocols from the accepted range of 0-255.

**Step 4** If you want to see the progress of the trace while it is happening, select **Show animation**. Otherwise, the window is not updated with the results until the trace is completed.

**Step 5** Click **Start** to trace the packet.

The policies are examined, and the bottom of the window shows the results in two forms: graphical and detailed information. The graphical view summarizes the phases evaluated in the packet’s path. Checkmarks indicate the packet passed the phase, a red X indicates the packet was dropped at that point.

The detailed information organizes the results in folders that correspond to the phases, with an Action column that indicates the results of the phase (checkmark for passed, red X for dropped). To open a folder, click its heading. Detailed information can include the specific configuration commands evaluated and the data derived from **show** commands. The final folder, named Result, summaries the results of the trace.

**Tips:**

• If the packet is allowed or denied by an explicit access rule, then you can jump to that rule. Select the Access-List folder to open it, then click the **Show access rule** link at the top of the section. You are taken to the Access Rule policy with the rule highlighted; you can edit the rule as desired. If a packet is dropped due to an implicit drop rule, the Show access rule link is not available because the rule does not exist in the policy table.

• If the device is shut down or not reachable due to a network failure during the analysis, an error message stating “Device Connectivity is Failed” appears.

• If you start a new trace, the information shown is cleared automatically. However, you can clear it yourself by clicking **Clear**.
Analyzing Connectivity Issues the Using Ping, Trace Route, or NS Lookup Tools

You can use the Ping or Trace Route tools to investigate and troubleshoot your network configuration and connectivity. You typically run these commands in the device, from within Security Manager by specifying specific launch points and parameters. This causes Security Manager to generate the corresponding command. NS Lookup, on the other hand, is typically run from the Security Manager client.

### Table 68-1 Profiles of the Ping, Trace Route, and NS Lookup Troubleshooting Commands

<table>
<thead>
<tr>
<th>Tool</th>
<th>Profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ping</td>
<td>Use Ping to test whether a particular host is reachable across an IP network and to measure the round-trip time for packets sent from the local host to a destination computer. This can include measuring the local host’s own interfaces using ICMP messages. See Analyzing Configuration Using Ping, page 68-4 for details on using this tool.</td>
</tr>
<tr>
<td>Trace Route</td>
<td>Use trace route to show the route taken by packets across an IP network. The system returns the number of hops taken and the addresses of each device traversed. See Analyzing Configuration Using TraceRoute, page 68-6 for details on using this tool.</td>
</tr>
<tr>
<td>NS Lookup</td>
<td>Use NS lookup (namespace lookup) to issue an NS lookup command from a device so you can test the contents of the DNS server that the queried device uses. See Analyzing Configuration Using NS Lookup, page 68-7 for details on using this tool.</td>
</tr>
</tbody>
</table>

### Applicability

The Ping tool is applicable on the following devices: ASA (7.0 – 8.3), PIX [6.3(1-5) to 8.0(2-4)], FWSM [2.2(1) – 4.1(1)], all IOS. It is not applicable to IPS.

The Trace Route tool is applicable on the following devices: ASA [7.2(1) and onward], PIX [6.3(1-5) to 8.0(2-4)], and all IOS. It is not applicable to FWSM nor IPS.

The NS Lookup tool is not supported in any of the devices managed by CSM; rather, you run it from the CSM client using the Windows API.

### Analyzing Configuration Using Ping

The ping tool, by default uses the ICMP echo request and echo reply messages to test reachability to a remote system. You can also choose to employ TCP to ping. In its simplest form, ping simply confirms that an IP packet is capable of getting to and getting back from a destination IP address. A ping is sent to an IP address and it returns a reply. This process enables network devices to discover, identify, and test each other. From within Security Manager, you can designate both the network device from which to issue the ping command, and the target of the echo request. This tool generally returns two pieces of information: whether the source can reach the destination (and, by inference, vice versa), and the round-trip time (RTT, typically in milliseconds).
You can use the Ping diagnostic tool in a variety of ways, including:

- **Ping to a security appliance**—Ping an interface on another security appliance to verify that it is up and responding.

- **Loopback testing of two interfaces**—Initiate a ping from one interface to another on the same security appliance, as an external loopback test to verify basic “up” status and operation of each interface.

- **Ping through a security appliance**—Ping packets originating from the Ping tool may pass through an intermediate security appliance on their way to a device. The echo packets also pass through two of its interfaces as they return. You can use this to perform a basic test of the interfaces, operation, and response time of the intermediate unit.

- **Ping to test intermediate communications**—Initiate a ping from a security appliance interface to a network device that is known to be functioning correctly and returning echo requests. If you receive the echo, you confirm physical connectivity and the correct operation of any intermediate devices.

**Tip**
From within the Event Manager, you can right-click on an event to open the Ping Tool and ping the associated device.

---

**Step 1**
In Device view, select **Tools > Ping, TraceRoute and NS Lookup . . .**  
The Ping, TraceRoute and NS Lookup dialog box appears.

**Step 2**
From the device selector, select the device from which to issue the **Ping** command.  
The selected device is listed in the top right of the dialog box.

**Note**
To employ TCP for the ping, select TCP for the Packet Type. (The default packet type is ICMP)

**Step 3**
In Hostname/IPv4 address, enter the IP address of the host network/host policy object to be pinged.  
Alternatively, click **Select** to choose a host network/host object that defines the host network/host policy object to be pinged.

**Step 4**
Enter a timeout value. [Optional]

**Step 5**
Click **Ping**.  
The results are displayed in the lower window area.

Example Ping output:

```
Sending 5, 100-byte ICMP Echos to out-pc, timeout is 2 seconds:
!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

Example Ping unsuccessful output:

```
Sending 5, 100-byte ICMP Echos to 10.132.80.101, timeout is 2 seconds:
????
Success rate is 0 percent (0/5)
```
Analyzing Connectivity Issues the Using Ping, Trace Route, or NS Lookup Tools

You can click Clear Output to remove the previous response from the Ping output area.
For additional details on the ping command, see Troubleshooting TCP/IP on Cisco.com.

Analyzing Configuration Using TraceRoute

The Traceroute tool helps you to determine the route that packets will take to their destination. The tool prints the result of each probe sent. Every line of output corresponds to a TTL value in increasing order.

Traceroute can return useful information about TCP/IP connectivity across your network. The following table shows some of the codes that can be returned by the Traceroute utility, along with their possible cause.

<table>
<thead>
<tr>
<th>Table 68-2</th>
<th>Traceroute Output Symbols</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output Symbol</td>
<td>Description</td>
</tr>
<tr>
<td>*</td>
<td>No response was received for the probe within the timeout period.</td>
</tr>
<tr>
<td>nn msec</td>
<td>For each node, the round-trip time (in milliseconds) for the specified number of probes.</td>
</tr>
<tr>
<td>!N</td>
<td>ICMP network unreachable.</td>
</tr>
<tr>
<td>!H</td>
<td>ICMP host unreachable.</td>
</tr>
<tr>
<td>!P</td>
<td>ICMP unreachable.</td>
</tr>
<tr>
<td>!A</td>
<td>ICMP administratively prohibited.</td>
</tr>
<tr>
<td>?</td>
<td>Unknown ICMP error.</td>
</tr>
</tbody>
</table>

Step 1
In Device view, select Tools > Ping, TraceRoute and NS Lookup . . .
The Ping, TraceRoute and NS Lookup dialog box appears.

Tip
From within the Event Manager, you can right-click on an event to open the TraceRoute page and trace the route of the associated device.

Step 2
Select the Trace Route tab.
The Trace Route page appears.

Step 3
From the device selector, select the host from which the route is traced.

Step 4
Enter the IPv4 Address/Hostname to specify the address or name of the host to which the route is traced.
Alternatively, click Select to choose a host network/host object that defines the IP address.
Step 5 Specify values, as required, for the following:

**Table 68-3  Traceroute Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Timeout</strong> [optional]</td>
<td>The amount of time, in seconds, to wait for a response before the connection times out. The default is three seconds.</td>
</tr>
<tr>
<td><strong>Port</strong> [optional]</td>
<td>The destination port used by the UDP probe messages. The default is 33434.</td>
</tr>
<tr>
<td><strong>Probes per hop</strong></td>
<td>The number of probes to be sent at each TTL level. The default is three.</td>
</tr>
<tr>
<td><strong>TTL Min</strong> [optional]</td>
<td>The minimum TTL value for the first probes. (Default is 1.)</td>
</tr>
<tr>
<td><strong>TTL Max</strong> [optional]</td>
<td>The maximum TTL value for the first probes. (Default is 30.)</td>
</tr>
</tbody>
</table>

Step 6 If desired, select Specify Source Interface or IP Address, and then do one of the following:
- Select a source Interface from the drop-down list
- Enter an IP Address

Step 7 If desired, select Reverse Resolve to reverse between displaying the address or hostname.

Step 8 If desired, select ICMP to use that protocol rather than IP.

Step 9 Click Trace.

The traceroute terminates when the packet reaches the destination or when the TTL Max value is reached. The hops taken and the device address corresponding to each hop are displayed.

---

**Analyzing Configuration Using NS Lookup**

You use the NS Lookup tool to look up a remote host address when you have the hostname, or to look up the hostname when you have the address.

Unlike the Ping and Traceroute tools, NS Lookup is done on the Security Manager client.

Step 1 In Device view, select Tools > Ping, TraceRoute and NS Lookup . . .

The Ping, TraceRoute and NS Lookup dialog box appears.

Step 2 Select the NS Lookup tab.

Step 3 Enter an address or hostname in IPv4Address/Hostname.

Alternatively, click Select to choose a host network/host object that defines the IP address.

Step 4 Optionally, to employ a particular DNS server in the lookup, enter the server’s name or address in DNS Server.

Step 5 Click Lookup.

The system displays the particular address/hostname pair, as well as the DNS server used in the lookup.
Using the Packet Capture Wizard

You can use the Packet Capture Wizard to configure, run, view, and save captures for troubleshooting errors. The captures can be run using preconfigured access lists or using match criteria of packet parameters such as source and destination addresses/ports on one or more interfaces. The wizard runs one capture on each of the ingress and egress interfaces. You can save the captures on the Cisco Security Manager client computer to examine them using a packet analyzer.

The captures can be run using pre-configured access-lists or using match criteria of packet parameters such as source, destination address/port on one or more interfaces.

Please note the following:

- You can only use the Packet Capture Wizard on firewall devices (PIX, ASA, or FWSM).
- Packet capture based on packet match criteria is only supported on devices running ASA version 7.2(3) or later. For other devices, packet capture can only be performed based on access-lists.

To use the Packet Capture Wizard:

**Step 1**
Launch the Packet Capture Wizard using one of the following methods:

- Select **Tools > Packet Capture Wizard**.
- (Device view) Right-click on an ASA, PIX, or FWSM device and select **Packet Capture** on the shortcut menu. Proceed to **Step 3**.
- (Event Viewer) Right-click on an event from an ASA, PIX, or FWSM device and select **Packet Capture** on the shortcut menu. Proceed to **Step 3**.

**Step 2**
If you launched the Packet Capture Wizard from the Tools menu, select the device on which you want to capture packets and click **Next**. The Security Devices list contains only devices on which packet capture can be run.

**Step 3**
Select the ingress interface from the drop-down list.

**Note**
You cannot select the same interface as ingress and egress in the same wizard.

**Step 4**
In the Packet Match Criteria area, do one of the following:

- To specify the access list to use for matching packets, select the **Access-List** radio button, and then choose the access list from the drop-down list.

- To specify packet parameters, select the **Packet Parameters** radio button and complete the following fields:
  - Specify the source and destination in the Source Host / Network and Destination Host / Network fields, respectively. You can use any of the following to specify the source or destination:
  - Network/host object. Enter the name of the object or click **Select** to select it from a list. You can also create new network/host objects from the selection list.
  - Host IP address, for example, 10.10.10.100.
  - Network address, including subnet mask, in either the format 10.10.0.24 or 10.10.0.255.255.255.0.
  - Choose the protocol type to capture from the drop-down list. Available protocol types to capture are ah, eigrp, esp, gre, icmp, icmp6, igmp, igmp, ip, ipinip, nos, ospf, pcp, pim, ssn, tcp, or udp.
If the protocol is ICMP, select the ICMP type from the drop-down list. Available types include ALL, alternate-address, conversion-error, echo, echo-reply, information-reply, information-request, mask-reply, mask-request, mobile-redirect, parameter-problem, redirect, router-advertisement, router-solicitation, source-quench, time-exceeded, timestamp-reply, timestamp-request, traceroute, or unreachable.

If the protocol is TCP or UDP, specify the source and destination port services. Available options include the following:

- To include all services, choose All Services.
- To indicate specific services, choose an appropriate operator from the drop-down list (=, !=, >, <, or range) and then select one of the following: aol, bgp, chargen, cifs, citrix-ica, ctiqbe, daytime, discard, domain, echo, exec, finger, ftp, ftp-data, gopher, h323, hostname, http, https, ident, imap4, irc, kerberos, klogin, kshell, ldap, ldaps, login, lotusnotes, lpd, netbios-ssn, nfs, nntp, pcanywhere-data, ping-auto-rp, pop2, pop3, pptp, rsh, rtsp, sip, smtp, sqlnet, ssh, snmp, tacacs, talk, telnet, uucp, whois, or www. The >, <, and range operators function based on the port number assigned to the selected service.

When using the range operator, a second drop-down list is enabled. Use the two drop-down lists to select the starting and ending services in the range you want to specify. The service with the lower corresponding port number should be selected in the first drop-down list, and the service with higher corresponding port number should be selected in the second drop-down list.

**Step 5** Click Next to proceed to the Select egress interface step.

**Step 6** Select the egress interface from the drop-down list.

**Note** You cannot select the same interface as ingress and egress in the same wizard.

**Step 7** In the Packet Match Criteria area, do one of the following:

**Note** The Packet Match Criteria option (Access-list or Packet Parameters) you selected for the ingress interface will also be used for the egress interface. Also, if you used packet parameters for matching on the ingress interface, the protocol definition you used will also be used for the egress interface.

- If you are using an access list to match packets, choose the access list from the drop-down list.
- If you are using packet parameters to match packets, the parameters used for ingress are also used for egress.

**Step 8** Click Next to proceed to the Set buffer parameters step.

**Step 9** Specify the buffer parameters by configuring the following fields:

In the Buffer Parameters area, you specify the buffer size and packet size. The buffer size is the maximum amount of memory that the capture can use to store packets. The packet size is the longest packet that the capture can hold. We recommend that you use the longest packet size to capture as much information as possible.

- **Read capture buffer every 10 seconds**—Select this option to automatically retrieve captured data every 10 seconds. You must use the circular buffer when selecting this option.
- **Use a circular buffer**—Select this option to continue capturing packets after the buffer is full. When you choose this setting, if all the buffer storage is used, the capture starts overwriting the oldest packets.
• **Buffer Size**—Enter the number of bytes (between 1534 and 33554432) that the capture can use to store packets.

• **Maximum Packet Size**—Enter the number of bytes (between 14 and 1522) that the capture can use to store a single packet. Use the largest value, 1522, to capture as much information as possible.

**Step 10** Click Next to proceed to the Summary step, which shows the traffic selectors and buffer parameters that you have entered.

**Step 11** Click Next to proceed to the Run, View & Save step.

**Step 12** From the Run, View & Save step, you can do the following:

• Click **Start Capture** to begin capturing packets.

• Click **Stop Capture** to stop capturing packets.

• Click **Display Capture Packets** to fetch the next set of captured packets from the device and update the buffer status bar. This button is only enabled if the Read capture buffer every 10 seconds option was not selected during the Set buffer parameters step.

• Click the **Launch Network Sniffer** button above the Ingress Capture window or the Egress Capture window to view the corresponding ingress or egress capture using an external packet analyzer tool. You must have a packet analyzer installed and associated with *.pcap file extension.

• Click **View Data in Larger Window** to view the packet capture data side-by-side in a larger window.

• Click **Save captures** to display the Save Capture dialog box. Choose the format in which you want to include the captures: ASCII or PCAP. You have the option of saving either the ingress capture or the egress capture.

• Click **Clear Device Buffer** to remove the current content and allow room in the buffer to capture more packets.

**Note** We recommend saving captures prior to clearing the device buffers. If you do not save captures prior to clearing the device buffers, captured data will be lost.

**Step 13** Click **Finish** to exit the wizard.

---

**Starting Device Managers**

You can start a device manager to view a device’s configuration and status from within Security Manager. You can start device managers for ASA, ASA-SM, PIX, FWSM, IPS, and IOS devices. Each device manager includes several monitoring and diagnostic features that provide information regarding the services running on the device and a snapshot of the overall health of the system. You can use these device managers to view the existing device configuration and to monitor current status, but you cannot use it to apply configuration changes to the device.

**Note** You cannot start device managers for IPS virtual sensors.

To start a device manager, select the device in Device view, right-click and select **Device Manager**. You can also start the device manager by selecting **Launch > Device Manager**.
When you start a device manager from Security Manager, the device manager executable is downloaded to your client system; the device manager does not need to be installed on the network device. The first time you start a device manager, it takes time to download the software to your workstation (you are shown a progress bar). (If you run into problems, review the tips in Troubleshooting Device Managers, page 68-12.)

Security Manager selects the most appropriate device manager version based on the operating system running on the network device. Subsequent communications with the selected device are completely transparent. By starting a device manager from Security Manager, you eliminate the need to open an HTTPS connection between your client system and the device you want to monitor.

---

When you start a device manager session, Security Manager opens a version of the manager that is appropriate for the operating system software version running on the device. However, Security Manager might not open the most recently-available version of the device manager if new device manager versions have been released after the release of the Security Manager version you are using. When you start the device manager, check its version (for example, select Help > About in the device manager window); if there is a more recent device manager available with features that you require, you must install and use that device manager outside of Security Manager to use those new features.

Keep in mind that if you use an external device manager running on the device to modify device configurations directly, these changes are considered out-of-band by Security Manager, and might be subsequently overwritten when you next deploy configurations from Security Manager. For more information about out-of-band changes, and what you can do to identify and recreate them, see the following topics:

- Understanding How Out-of-Band Changes are Handled, page 8-12
- Detecting and Analyzing Out of Band Changes, page 8-44

Security Manager starts only one instance of a device manager per device, and closes the device manager when you exit Security Manager, or when the idle-session timeout period is exceeded. You can have more than one device manager window open at one time (connected to different devices).

The following table outlines the device managers you can launch from Security Manager.

---

### Table 68-4 Device Managers Available in Security Manager

<table>
<thead>
<tr>
<th>Device Manager</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDM</td>
<td>The IPS Device Manager (IDM) lets you monitor IPS sensors and modules that are part of the Security Manager inventory. See the IDM documentation for more information about using this device manager.</td>
</tr>
<tr>
<td>PDM</td>
<td>The PIX Device Manager (PDM) lets you monitor PIX 6.x devices and early FWSMs, specifically FWSM releases 1.1, 2.2 and 2.3 in single- or multiple-context modes. See the PDM documentation for more information about using this device manager.</td>
</tr>
<tr>
<td>ASDM</td>
<td>The Adaptive Security Device Manager (ASDM) lets you monitor ASA, ASA-SM, PIX 7.x+, and FWSM 3.x+ devices. See the ASDM documentation for more information about using this device manager.</td>
</tr>
</tbody>
</table>
Troubleshooting Device Managers

If you can successfully deploy configurations to a device, Security Manager should be able to open a device manager session with the device (as described in Starting Device Managers, page 68-10). However, if you have problems making a connection or using one that is open, consider the following troubleshooting tips, which are divided into basic tips and tips for using multiple device managers.

Basic Device Manager Troubleshooting Tips

- Generally, the credentials configured for the device in the Security Manager inventory are used to start the device manager. However, some versions of SDM require that you enter a user name and password when the device manager is started. If you get an error that says device credentials are missing, or they are not valid, update the Device Properties Credentials page with a username and password that can log into the device. In Device view, right-click the device and select Device Properties. For more information, see Viewing or Changing Device Properties, page 3-37 and Device Credentials Page, page 3-41.

- All users associated with any of the CiscoWorks Common Services roles have permission to start device managers from Security Manager, with the exception of the Help Desk role or any of the predefined Cisco Secure ACS roles. Ensure you have appropriate permissions.

- SSL/HTTPS must be enabled on the target device to provide secure communications between Security Manager and the device. An error message is displayed if SSL is not enabled on the device. See Understanding Device Communication Requirements, page 2-1 for more information.

- You might need to modify Cisco Security Agent, or other anti-virus and network firewall software, on the Security Manager system and on your workstation to allow the device manager service (xdm-launcher.exe) to be started.

- Ensure that Security Manager is correctly configured for contacting and communicating with the target device. Specifically verify device properties such as identity, operating system and credentials. Select the desired device, right-click and choose Device Properties. Verify the settings on the General and Credentials pages. You can test whether Security Manager can connect to the device by selecting the Credentials tab and clicking Test Connectivity (see Testing Device Connectivity, page 9-1).
• Device managers can be started for FWSMs and ASAs running in transparent mode (Layer 2 firewall) or routed mode (Layer 3 firewall), and supporting a single security context or multiple security contexts. For FWSM and ASA devices running multiple security contexts, you must define a unique management IP address for each security context.

• If you get a message saying that the platform is not supported for device manager launch, but you believe the platform should be supported based on information in this guide, consider the relative newness of the operating system version running on the device and the age of the Security Manager software version you are using. If you are using very recent operating systems, but a relatively older version of Security Manager, you might need to upgrade Security Manager (or apply a service pack), contact Cisco Technical Support, or simply install the latest device manager on the network device and use it outside of Security Manager. Before using a device manager outside of Security Manager, review the information on out-of-band changes in Starting Device Managers, page 68-10.

Multiple Device Manager Sessions Troubleshooting Tips

• Starting multiple device managers might affect the performance of both the Security Manager server and your client. On the client, memory requirements and performance impact are proportional to the number of device managers launched. On the server, a large number of requests to start device managers or retrieve current information from the device can have an adverse impact on performance.

• The maximum number of persistent HTTPS connections that can be established with any one device from all clients depends on the device type and model. An error message is displayed if you attempt to exceed this limit.

For example, a single PIX 6.x allows multiple clients to each have one browser session open, supporting up to 16 concurrent PDM sessions. An FWSM (1.1, 2.2, or 2.3) allows up to 32 PDM sessions for the entire module, with a maximum of five concurrent HTTPS connections per context. Refer to the appropriate device documentation for information about specific limits.

Access Rule Look-up from Device Managers

A set of access rules is associated with each device interface. These rules are presented in the form of an ordered list or table. This list is often referred to as an access-control list (ACL), with each rule in the list known as an access-control entry (ACE). When deciding whether to forward or drop a packet, the device tests the packet against each access rule in the order listed. When a rule is matched, the device performs the specified action, either permitting the packet into the device for further processing, or denying entry. If the packet does not match any rule, the packet is denied.

Activity on your firewall or router can be monitored through syslog messages. If logging is enabled on the device, whenever an access rule that is configured to generate syslog messages is matched—for example, a connection was attempted from a denied IP address—a log entry is generated.

For the device to generate log entries, logging must be enabled on the device (on the Logging Setup Page for ASA/PIX devices and the Logging policies for IOS devices, described in Logging on Cisco IOS Routers, page 61-1), and the individual access rules must be configured to generate log messages when they are matched (in the Advanced and Edit Options Dialog Boxes, page 15-15).

You can monitor syslog messages in device managers launched from Security Manager. For certain device managers, you can also look up the access rule in Security Manager that generated a particular message from the monitoring window. The access rule that triggered the syslog entry is highlighted in Security Manager on a first-match basis, even if there are multiple matches.
This access rule look-up is available through SDM for all managed routers running IOS, and through ASDM for managed PIX and ASA devices (including ASA-SM) running version 8.0(3) and above, and FWSM devices running version 3.1 and above.

The following topics describe how to look up access rules in Security Manager from a device manager:

- Navigating to an Access Rule from ASDM, page 68-14
- Navigating to an Access Rule from SDM, page 68-15

### Navigating to an Access Rule from ASDM

In an ASDM device manager launched from Security Manager, you can monitor system log messages in the Real-time Log Viewer window and the Log Buffer window. You can select a syslog message displayed in either window and navigate to the access-control rule in Security Manager that triggered the message, where you can update the rule as necessary.

The Real-time Log Viewer is a separate window that lets you view syslog messages as they are logged. The separate Log Buffer window lets you view messages present in the syslog buffer.

You can look up access rules associated with the following syslog message IDs:

- 106023 – Generated when an IP packet is denied by the access rule. This message appears even when logging is not enabled for the rule.
- 106100 – If logging is enabled for a matched access rule (in the Advanced and Edit Options Dialog Boxes, page 15-15), this message provides information about the traffic flow, depending on the parameters set. This message provides more information than message 106023, which logs only denied packets.

This procedure describes how to look up an access rule in Security Manager from ASDM’s Real-time Log Viewer or Log Buffer windows.

**Related Topics**

- Access Rule Look-up from Device Managers, page 68-13
- Navigating to an Access Rule from SDM, page 68-15

---

**Step 1** Select a PIX, ASA, ASA-SM, or FWSM in the Security Manager device inventory.

**Step 2** Select Launch > Device Manager to start ASDM. For more information about starting device managers, see Starting Device Managers, page 68-10.

**Step 3** In the ASDM window, click the Monitoring button to display the Monitoring panel; click Logging in the left pane to access the log-viewing options.

**Step 4** Select either Real-time Log Viewer or Log Buffer.

**Step 5** Click the View button to open the selected log-viewing window.

**Note** The View button is not displayed if logging is not enabled on the device.

Each syslog message listed in the window includes the following information: message ID number, date and time the message was generated, the logging level, and the network or host addresses from which the packet was sent and received.

**Step 6** To view the access rule that triggered a specific syslog message, select the message and click the Show Rule button in the ASDM toolbar (or right-click the message and choose Go to Rule in CSM from the pop-up menu).
Chapter 68  Using External Monitoring, Troubleshooting, and Diagnostic Tools

Starting Device Managers

The Security Manager client window is activated and the Access Rules page appears with the rule highlighted in the rules table. If the syslog entry was triggered by an access rule not referenced in the current Security Manager activity, an error message appears.

Navigating to an Access Rule from SDM

In an SDM device manager launched from Security Manager, you can view a log of events categorized by security level under the Syslog tab of the Logging window. You can select a syslog message and navigate to the access-control rule in Security Manager that triggered the message, where you can update the rule as necessary.

The Monitor > Logging option in SDM offers four log tabs; Syslog is the only one of these offering the Security Manager access-rule look-up option. The router contains a log of events categorized by severity level. The Syslog tab displays the router log, even if log messages are being forwarded to a syslog server.

On Cisco IOS devices, syslog messages are generated for access rules configured with the log or log-input keywords. The log keyword produces a message when a packet matches the rule. The log-input keyword produces a message that includes ingress interface and source MAC address, in addition to the packet’s source and destination IP addresses and ports. When identical packets are matched, the message is updated at five-minute intervals with the number of packets permitted or denied in the previous five minutes.

This procedure describes how to look up an access rule in Security Manager from the Syslog tab of SDM’s Logging panel.

Related Topics
- Access Rule Look-up from Device Managers, page 68-13
- Navigating to an Access Rule from ASDM, page 68-14

Step 1  Select an IOS router in the Security Manager device inventory.

Step 2  Select Launch > Device Manager to start SDM. For more information about starting device managers, see Starting Device Managers, page 68-10.

Step 3  In the SDM window, click the Monitoring button to display the Monitoring panel; click Logging in the left pane to access the log-viewing options.

The Logging pane appears with Syslog tab displayed.

Step 4  To view the access rule that triggered a specific syslog message, select the message and click the Go to Rule in CSM button above the table of log messages.

The Security Manager client window is activated and the Access Rules page appears with the rule highlighted in the rules table. If the syslog entry was triggered by an access rule not referenced in the current Security Manager activity, an error message appears.
Viewing Inventory Status

You can view a summary of device properties for all devices that you are authorized to view. The summary includes device contact information and all device configurations, indicating which settings are local and which are using a shared policy, and indicating any policy object overrides in effect. You can also view the status of configuration deployment to the device.

The report is in table format, allowing you to organize information by filtering, sorting, reordering and removing columns. You can also export the table contents to a comma-separated values (CSV) file on the Security Manager server.

Step 1
In Device view, select **Tools > Inventory Status** to open the Inventory Status Window, page 68-16.

Step 2
Select the device whose detailed status you want to view in the upper table. The detailed information is shown in the tabs in the lower pane. The information is organized into folders; click the +/- icons to open and close folders, or double-click the folder name. The following tabs are available:

- **Inventory**—Lists summary information about the selected device’s device properties, deployment methods, device group membership, and the parent device for modules.
- **Policy**—Lists the current status of the policies that can be configured for the selected device, whether the policy is unassigned (not defined), a local policy, or a shared policy.
- **Policy Object Overrides**—Lists policy objects that have overrides defined for the selected device.
- **Status**—Lists status messages from Security Manager deployment jobs for the selected device, organized by event type.

An event is a notification that a managed device or component has experienced an abnormal condition. Multiple events can occur simultaneously on a single monitored device or service module.

Security Manager displays only the most-recent event of each type. To view historical status information, use the Deployment Manager.

Step 3
Click **Close** to close the Inventory Status window.

Inventory Status Window

Use the Inventory Status window to view device properties and status for the devices that you are allowed to view. This window summarizes device information so that you do not have to open the device properties for each individual device.

In addition to device property information, you can view summary information about how the policies on each device are configured (whether local, shared, or not configured) and the policy objects that have overrides for each device. You can also view the status of configuration deployment to the device.

The Inventory Status window contains two panes. Use the upper pane to view a complete listing of all devices, to sort the devices by attribute, or to filter out certain ones. Use the lower pane to view the device property details of the device selected in the upper pane.

**Navigation Path**
Select **Tools > Inventory Status**.

Integrating CS-MARS and Security Manager

While Cisco Security Manager lets you centrally manage security policies and device settings in your network, the Cisco Security Monitoring, Analysis and Response System (CS-MARS) is a separate application that monitors devices and collects event information, including syslog messages and NetFlow traffic records, with much more extensive network monitoring capabilities than Security Manager. CS-MARS aggregates and presents massive amounts of network and security data in an easy-to-use format. Based on information derived from CS-MARS reports, you can edit device policies in Security Manager to counter security threats.

Specifically, if you use Security Manager to configure firewall access rules and IPS signatures, you can configure CS-MARS to collect information related to those policies and make it available to Security Manager users. By registering the CS-MARS servers with Security Manager, users can navigate directly from a specific access rule or IPS signature to a CS-MARS report window, pre-populated with query criteria for that rule or signature.

Similarly, CS-MARS users can view the Security Manager policies related to specific CS-MARS events. This bi-directional mapping of specific events to the policies that triggered them, combined with the ability to immediately modify the policies, can dramatically reduce the time spent configuring and troubleshooting large or complex networks.

To enable this cross-communication, you must register your CS-MARS servers with Security Manager, and register your Security Manager server with the CS-MARS servers. You must also register the specific devices with each application. Then, when working with firewall access rules or IPS signatures for a device, a Security Manager user can quickly view real-time and historical event information related to that rule or signature.

The following sections explain how to enable and use CS-MARS and Security Manager cross-communication:

- Checklist for Integrating CS-MARS with Security Manager, page 68-18
- Looking Up CS-MARS Events for a Security Manager Policy, page 68-23
- Looking Up a Security Manager Policy from a CS-MARS Event, page 68-27

Checklist for Integrating CS-MARS with Security Manager

To enable the cross-communication between CS-MARS and Security Manager (as described in Integrating CS-MARS and Security Manager, page 68-18), you must identify the applications to each other and ensure that devices managed by both applications are configured appropriately. The following table describes the integration steps.

If you have problems with cross-communications, see Troubleshooting Tips for CS-MARS Querying, page 68-22.
Integrating CS-MARS and Security Manager

- Looking Up a Security Manager Policy from a CS-MARS Event, page 68-27

Configuring the Security Manager Server to Respond to CS-MARS Policy Queries

CS-MARS must be allowed access to the Security Manager server so that it can perform policy lookup queries and obtain policy information.
Integrating CS-MARS and Security Manager

If you are using Common Services AAA authentication on the server (for example, Cisco Secure ACS), you must update the administrative access settings to ensure that CS-MARS has the necessary client access to the Security Manager server.

Define a user account in Security Manager that CS-MARS can use to perform queries. A separate account is recommended to provide a specific audit trail on the Security Manager server. This account must be assigned one of the following Common Services roles:

- Approver
- Network Operator
- Network Administrator
- System Administrator

Users with the Help Desk security level can only view the policy look-up table in CS-MARS; that is, they cannot cross-launch Security Manager to modify policies.

Note

When you register a Security Manager server with CS-MARS, if you choose to prompt for Security Manager credentials for policy table look-up, a separate CS-MARS account in Common Services for authentication purposes might not be necessary.

For more information on adding users and associating roles with them in Common Services, see the User Guide for CiscoWorks Common Services.

Related Topics

- Registering CS-MARS Servers in Security Manager, page 68-20
- Discovering or Changing the CS-MARS Controllers for a Device, page 68-21

Registering CS-MARS Servers in Security Manager

As described in Checklist for Integrating CS-MARS with Security Manager, page 68-18, you must register your CS-MARS controllers with Security Manager to enable cross-communication between the applications if you intend to use the applications together.

Then, when a user looks up events for a device, Security Manager identifies the CS-MARS controller that is collecting events for that device. If more than one CS-MARS controller is collecting events for a device, the user can select which to use. You can also specify the correct CS-MARS controller to use in the Device Properties window for each device. (See Discovering or Changing the CS-MARS Controllers for a Device, page 68-21 for more information.)

Note

For information about the CS-MARS versions explicitly supported by Security Manager, see the Release Notes for Cisco Security Manager for this version of the product. If you do try to use a version that is not explicitly supported, you cannot use CS-MARS versions earlier than 4.3.4 or 5.3.4.

Step 1

Choose Tools > Security Manager Administration and select CS-MARS in the table of contents to display the CS-MARS Page, page 11-4.

Step 2

Click the Add button to add a CS-MARS server. The New CS-MARS Device dialog box opens (see New or Edit CS-MARS Device Dialog Box, page 11-5 for detailed information).
Step 3  In the New CS-MARS Device dialog box, enter the IP address or fully qualified DNS host name of the
server, and a user name and password for logging into the server. If you add a local controller, the user
name you enter can be either a local account or a global account. Choose the type of account from the
User Type list.

Tip  If you are using CS-MARS Global Controllers, add them instead of individual Local Controllers.
By adding Global Controllers, Security Manager can identify the correct Local Controller for a
device, without you having to add each Local Controller. When you add a Global Controller, do
not add the individual Local Controllers monitored by the Global Controller.

Click Retrieve From Device to get the server’s authentication certificate. Click Accept when the
certificate is presented to you.

Click OK when finished. The New CS-MARS Device dialog box closes and the server is added to the
CS-MARS device list.

Step 4  From the When Launching CS-MARS list, choose whether you want users to be prompted to log in to
the CS-MARS server when they request event status, or whether Security Manager should automatically
log in to CS-MARS using the credentials provided when the user logged in to Security Manager.

If you elect to use Security Manager credentials, the necessary user accounts must be configured in
CS-MARS. Refer to the CS-MARS documentation for more information.

Step 5  Click Save on the CS-MARS page to save your changes.

Discovering or Changing the CS-MARS Controllers for a Device

If you use the Cisco Security Monitoring, Analysis and Response System (CS-MARS) controllers to
monitor devices, you can register them in Security Manager and then view syslogs and events that are
related to firewall access or IPS signature rules for individual devices.

Security Manager can automatically discover the CS-MARS controllers that monitor a device when you
try to view events related to a rule. If more than one controller monitors a device, you are prompted to
select which controller to use.

You can also proactively select the CS-MARS controller for a device in its Device Properties window.
Similarly, if you ever need to change the CS-MARS controller assigned to a device, you can change the
selection in its Device Properties window. This procedure explains how to discover or change the
CS-MARS controller for a device from its Device Properties window.

Before You Begin
The CS-MARS controller that monitors the device must already be registered with Security Manager on
the CS-MARS administration page (Tools > Security Manager Administration > CS-MARS). For
more information, see Registering CS-MARS Servers in Security Manager, page 68-20.

Step 1  In Device view, do one of the following in the Device selector to open the Device Properties dialog box:
• Double-click a device.
• Right-click a device and choose Device Properties.
• Select a device and choose Tools > Device Properties.

Step 2  Click General in the table of contents to open the General properties page (see General Page,
page 3-38).
Step 3  In the CS-MARS Monitoring group, click **Discover CS-MARS**. Security Manager determines which registered controller is monitoring the device, if any. If there are more than one, you are prompted to select which CS-MARS controller to use.

---

**Troubleshooting Tips for CS-MARS Querying**

Use the following troubleshooting tips to help you identify and resolve problems you might encounter when using CS-MARS and Security Manager together:

- HTTPS is required for communication between the Security Manager server and CS-MARS.
- Interface names are not case-sensitive in Security Manager, but they are in CS-MARS. For example, “outside” and “Outside” are considered exclusive by a CS-MARS appliance, while they are equivalent in Security Manager. Further, syslog messages use lower case for all interface names. As a result, when you perform a query for a Security Manager policy from an event generated in CS-MARS, the interface name logged in the syslog event might not match the interface name in that policy in Security Manager. To avoid this problem, use lower case for all interface names, and in the definition of interface roles, in CS-MARS.
- To query for CS-MARS events from Security Manager policies, the Security Manager client must be on the same side of a network address translation (NAT) boundary as the CS-MARS appliance and the Security Manager server. Similarly, when the CS-MARS client is not on the same side of a NAT boundary as the CS-MARS appliance and the Security Manager server, you can look up Security Manager policies, but in read-only mode. However, you cannot start the Security Manager client from the read-only policy look-up table. The Security Manager client must be on the same side of the NAT boundary as the CS-MARS appliance and the Security Manager server if you want to start the client from CS-MARS to modify a matching policy.
- For FWSM, PIX and ASA devices on which multiple independent security contexts exist, to query for CS-MARS events, you must define a unique management IP address in Security Manager for each security context. Also, the host name and reporting IP address for each virtual context must be configured before adding it to CS-MARS. Otherwise, event look-up from policies on these contexts fails.
- For all IPS device and service policies, a default signature policy is assigned to the device when you do not discover IPS policies, or when you remove the configured policies from the device. If you try to perform event look-up from the default signature, a “Policy not found” error message is displayed. However, if you edit the default signature and save it, you can then navigate to events in CS-MARS.
- If object grouping or rule optimization is enabled for an access rule defined in Security Manager and the associated access-list commands on the device do not match the optimized rules, no events are displayed in CS-MARS.
- If logging is not enabled for an access rule, a warning message is displayed, and you can only look up traffic-flow events for those rules.
- When supported by the device, Security Manager uses access-control entry (ACE) hashcodes as additional keywords when querying CS-MARS for syslog messages generated by an ACE, and large access-control lists (ACLs) might contain thousands of such hashcodes. If the number of keywords, or the sum of the number of sources, destinations, and protocols for an ACE or a signature exceeds the query limit of 150, an error message is displayed. The error message indicates the probable cause and recommended action.
Problems with the synchronization between rules and reported events can occur in the following situations:

- The device has been added to Security Manager, but the configuration or changes to it have not been saved to the database. This is especially true for access rules that have been changed but not deployed since the device was added to CS-MARS.
- Access rules exist on the device for which there are no corresponding rules in Security Manager, and vice versa. Be sure all devices are added to Security Manager, and that access rules are configured on them using Security Manager.
- Traffic in the “wrong” direction triggering events for which there is no defined rule. For example, outbound traffic on a higher-security-level interface on which only inbound-traffic rules have been defined.

If you perform a policy lookup from CS-MARS and the Security Manager client is active, the query is performed on all policies within the open activity or configuration session plus what is saved in the database (the committed configurations). If the Security Manager client is not active, only committed policies are considered.

Related Topics
- Checklist for Integrating CS-MARS with Security Manager, page 68-18
- Looking Up CS-MARS Events for a Security Manager Policy, page 68-23
- Registering CS-MARS Servers in Security Manager, page 68-20

Looking Up CS-MARS Events for a Security Manager Policy

After you integrate CS-MARS and Security Manager, you can look up events in CS-MARS that relate to specific firewall access rules or IPS signatures.

When CS-MARS receives events, they are parsed, “sessionized,” written to an event buffer, and then written to the database. Sessionizing takes two forms: with a session-oriented protocol, such as TCP, the session encompasses the initial handshake to the connection tear-down; with a sessionless protocol, such as UDP, the session start and end times are based more on first and last packets tracked within a restricted time period—packets that fall outside of the time period are considered parts of other sessions.

Because of there is a difference between newly-received and fully processed data, you can look up either real-time or historical events:

- **Real-time**—Because sessionization takes time, keeping an event in cache for up to two minutes, you can use the real-time event query to view events right after parsing, providing access to the most current data received.

  When you query for real-time events, the query is run automatically, based on the policy values obtained from Security Manager, and the results are displayed in the CS-MARS Query Results window. This real-time event viewer lets you monitor CS-MARS traffic in near real-time, as raw events streaming to CS-MARS, before they are sessionized, with a maximum delay of five seconds. You also can elect to view the sessionized event stream by clicking Edit in the Query Results window and then choosing “Sessionized events” from the Realtime drop-down menu. Note that more delay is possible when there are many events in a session.

- **Historical**—Historical event reports help you identify trends over longer periods of time than is possible with real-time monitoring. When you query for historical events, the CS-MARS Query Criteria: Result window opens. You can either run the query immediately, or save the criteria as a “report” to run at a later time. For historical events, the Result Format is the All Matching Events option, and the Filter By Time value is set to the previous 10 minutes.
Chapter 68      Using External Monitoring,Troubleshooting, and Diagnostic Tools

Integrating CS-MARS and Security Manager

The following topics explain event lookup in more detail:

- Viewing CS-MARS Events for an Access Rule, page 68-24
- Viewing CS-MARS Events for an IPS Signature, page 68-26

Viewing CS-MARS Events for an Access Rule

From the Firewall > Access Rules policy in Security Manager, you can select an access rule and view related event information in CS-MARS. You can view real-time or historical events matching the rule, the traffic flow, the source address, or the destination address. You can view events for any device that supports access rules, including ASA, PIX, FWSM, routers, and switches.

Firewall access rules are presented in the form of an ordered list or table. When deployed, this policy becomes an access-control list (ACL), with each entry in the list known as an access-control entry (ACE). (For more detailed information, see Understanding Access Rules, page 15-2.)

When deciding whether to forward or drop a packet, a device tests the packet against each access rule in the ordered list. If you enable logging for an access rule, the results of the test are recording according to your per-rule log settings. Some devices, such as ASA, generate log entries for denied access even if you do not configure logging explicitly. For information on creating access rules, including logging options, see Configuring Access Rules (IPv4 or IPv6), page 15-7.

You can query CS-MARS for real-time or historical events related to an access rule for the following types of traffic. To use the commands, right-click the rule and select them from the context menu.

- **Flow**—A traffic flow is defined by the rule’s source and destination IP addresses, protocol, and ports. The reported flow events include connection set-up and tear-down. Logging need not be enabled for the access rule to record this information.

  To view flow-related events, use the following right-click commands:

  - **Show Events > Realtime > Matching this Flow**—To view real-time query results in CS-MARS for events matching this traffic flow. You can change the query criteria in the CS-MARS window at any time, applying new parameters to alter the real-time results.
  
  - **Show Events > Historical > Matching this Flow**—Opens the historical query criteria page in CS-MARS with fields populated based on the selected rule’s traffic flow. Edit the rule parameters and query criteria as desired, and click **Apply** to continue. Next, in the Query window, you can submit the query or save it for later submission and re-use.

- **Rule**—If logging is enabled for the rule (in the Advanced and Edit Options Dialog Boxes, page 15-15), the device sends syslog messages to CS-MARS to record the logged events (assuming CS-MARS monitors the device). This query includes the access-rule parameters, including available keyword information. Reported events do not include connection set-up and tear-down.

  To view rule-related events, use the following right-click commands:

  - **Show Events > Realtime > Matching this Rule**—To view real-time query results in CS-MARS for events matching this rule (flow parameters plus keywords); results begin scrolling within five seconds. You can change the query criteria in the CS-MARS window at any time, applying new parameters to alter the real-time results.
  
  - **Show Events > Historical > Matching this Rule**—Opens the historical query criteria page in CS-MARS with fields populated based on the access rule (flow parameters plus keywords). Edit the rule parameters and query criteria as desired, and click **Apply** to continue. Next, in the Query window, you can submit the query, or save it for later submission and re-use.

- **Source or Destination**—If you right-click the Source or Destination cell in an access rule entry, you also can choose to view real-time or historical events matching the rule’s source or destination IP address.
To view events for a source or destination address, right-click the address in the Source or Destination cell and choose one of the following commands (the specific command differs depending on the cell you select):

- **Show Events > Realtime > Matching this Source/Destination**—To view real-time query results in CS-MARS for events with a matching source or destination address. You can change the query criteria in the CS-MARS window at any time, applying new parameters to alter the real-time results.

- **Show Events > Historical > Matching this Source/Destination**—Opens the historical query criteria page in CS-MARS with fields populated based on the access rule’s source or destination address. Edit the rule parameters and query criteria as desired, and click **Apply** to continue.

Next, in the Query window, you can submit the query, or save it for later submission and re-use.

Security Manager provides the following information to CS-MARS as criteria for a traffic-flow or access-rule event queries:

- **Device details**—General information about the device, such as host name, domain name, management IP address, and display name.
- **Source addresses**—Source addresses of hosts and the network/host objects expanded to display the networks or collections of IP addresses.
- **Destination addresses**—Destination addresses of hosts and the network/host objects expanded to display the networks or collections of IP addresses.
- **Service**—Protocol and port information.
- **Event Type**—“Built/teardown/permitted IP connection” for permit rules and “Deny packet due to security policy” for deny rules.
- **Keyword (rule events only, not provided for traffic-flow queries)**—ACL name and ACE hashcode, if available, connected by the logical operator OR.

On Version 7.0 or later PIX and ASA devices, each access rule is assigned an MD5 hashcode, which is included in the syslogs generated by that rule. Large ACLs can include thousands of access rules. Used as query keywords, these hashcodes can help produce more-accurate event matches. If a device does not support hashcodes, a warning is displayed that query results might be inaccurate because of keyword ambiguity; you can proceed with the query, and then edit the query keyword list and resubmit.

**Tips:**

- You can query on only one access rule at a time.
- When NAT or PAT is configured on a security device, the source and destination addresses are mapped to pre-translation and post-translation addresses, respectively, and the translated addresses are used when Security Manager sends a query to CS-MARS. For inbound access rules, the destination address is considered the pre-translation address, and for outbound access rules, the source address is considered the post-translation address.
- If the device is monitored by multiple CS-MARS controllers, you are prompted to select the CS-MARS instance to be used.
- Depending on how credentials verification is set up on your system, you might be prompted to log into CS-MARS. For more information, see **Registering CS-MARS Servers in Security Manager**, page 68-20.
Integrating CS-MARS and Security Manager

Related Topics

Viewing CS-MARS Events for an IPS Signature

When an IPS or IOS IPS device detects and reports a network intrusion by comparing incoming traffic to a configured signature, a syslog message is generated on the device. If the device is monitored by CS-MARS, an incident is generated in CS-MARS after the log associated with the signature is obtained from the device. Looking up the events associated with a specific signature lets you quickly identify attacks and tune your device configuration to minimize or prevent intrusions.

To view reported network intrusion events in CS-MARS, you can select one or more entries in the Signatures policy for a device in Security Manager and navigate to the CS-MARS Query page to view real-time and historical events.

When you look up real-time events for a signature, the query is run automatically and the results displayed in CS-MARS. However, when you look up historical events for a signature, the values sent by Security Manager to CS-MARS are used to populate the query fields. You can modify the query fields as desired, and then run the query, or save it for later use.

Security Manager provides the following signature information to CS-MARS as query criteria:
- Device details—General information about the device, such as host name, domain name, management IP address, and display name.
- Keyword—Signature ID, subsignature ID, and virtual sensor name, if applicable.

For virtual sensors, the name of the sensor is included as a keyword criterion along with other device information and signature parameters.

Related Topics
- Looking Up CS-MARS Events for a Security Manager Policy, page 68-23
- Viewing CS-MARS Events for an Access Rule, page 68-24

Step 1 (Device view) With an IPS or IOS IPS device selected, select IPS > Signatures > Signatures to display the Signatures Page, page 37-4.

Step 2 Right-click the desired entry in the signatures table, or select multiple entries before right-clicking one of them, and choose one of the following commands from the Show Events menu:
- **Realtime**—To view real-time query results in CS-MARS for events matching this signature; results begin scrolling within five seconds. Use this option to view raw events as they stream to CS-MARS.
  - You can change the query criteria in the CS-MARS Query Results window at any time, applying new parameters to alter the real-time results.
- **Historical**—Opens the historical query criteria page in CS-MARS with fields populated based on the signature parameters. Edit the parameters and query criteria as desired, and click **Apply** to continue. Next, in the Query window, you can submit the query or save it for later submission and re-use. You can edit the query and save it as a report if you want to run it again later.
Tips:

- If a signature is disabled, you are warned and asked if you want to proceed to event lookup.
- If the device is monitored by multiple CS-MARS controllers, you are prompted to select the CS-MARS instance to be used.
- Depending on how credentials verification is set up on your system, you might be prompted to log into CS-MARS. For more information, see Registering CS-MARS Servers in Security Manager, page 68-20.
- All custom signatures are categorized as “Unknown Device Event Type” events in CS-MARS.
- A default signature is assigned to an IPS device if you elect not to discover IPS policies when adding the device to the Security Manager inventory, or when you remove configured IPS policies from the device. If you try to look up events from the default signature, a “Policy not found” error message is displayed. However, if you edit the default signature and save it, you can then query for related events in CS-MARS.
- Events of type Packet Data and Context Data are not displayed in the query results because these events are not triggered by signature rules.

---

Looking Up a Security Manager Policy from a CS-MARS Event

The User Guide for Cisco Security MARS Local and Global Controllers contains detailed information about how to look up policies based on events shown in CS-MARS. The information includes extensive troubleshooting information to help resolve any problems you might have, plus a checklist of what you must configure in CS-MARS to enable the interaction.

The main reason you would want to perform policy lookup is to adjust a policy based on the events that it is generating. For example, an access rule might be dropping traffic that you actually want to allow. Because you are looking at the event, you know there is a policy that is causing the event, so with a few clicks, you can get from that event to the policy you need to reconfigure.

The general process for looking up a policy based on a device-generated event is as follows. Note that the Security Manager client must be installed on your system to perform policy lookup.

Related Topics

- Viewing CS-MARS Events for an Access Rule, page 68-24
- Viewing CS-MARS Events for an IPS Signature, page 68-26

---

Step 1
Find the event in CS-MARS in the Query Results or Incident Details pages.

For more information on the syslog and NetFlow events you can use for querying access rules, see the following topics:

- System Log Messages Supported for Policy Look-up, page 68-28
- NetFlow Event Reporting in CS-MARS, page 68-30

Step 2
Click the Security Manager icon in the Reporting Device cell for the event. You might be prompted to log into Security Manager, based on how you configured CS-MARS.

If more than one device in Security Manager matches the event characteristics, you are prompted to select a device.
Step 3  Detailed information is obtained from Security Manager and presented based on whether the event is for an access rule or IPS signature:

- **Access rule**—The access rules are displayed in CS-MARS in a read-only window with the rule that matches the event highlighted.

  If you decide to edit a rule, click the rule number, and you are taken to the rule in the Access Rule policy in the Security Manager client. You can then make your edits, save them, and then deploy configurations. Remember that your changes are not made to the device until you deploy them.

  For more information on configuring access rules, see Configuring Access Rules (IPv4 or IPv6), page 15-7.

- **IPS Signature**—Signature details are displayed in CS-MARS in a read-only window.

  To edit the signature, click **Edit Signature**, and you are taken to the signature in the Signatures policy, where you can make your changes. For more information, see Editing Signature Parameters (Tuning Signatures), page 37-18.

  If you decide you want to instead remove specific actions from an event, or remove the event entirely, and prevent further processing by the sensor, click **Add Filter**. This opens the Add Event Filter dialog box in Security Manager, where you can configure an event filter. For more information, see Filter Item Dialog Box, page 38-9.

  As with access rules, your changes do not take effect until you deploy the new configuration.

---

**System Log Messages Supported for Policy Look-up**

When you configure access rules on security appliances and IOS devices, you can configure logging options in the Advanced and Edit Options Dialog Boxes, page 15-15 that generate system log (syslog) messages. On devices with multiple contexts, each security context includes its own logging configuration and generates its own messages. If Security Manager is configured to interoperate with CS-MARS, these messages are reported to CS-MARS and you can query for the reported information on a per-rule basis.

For additional information about each of these message IDs, see the System Message Guide of the relevant product documentation.

**Security-appliance messages**

Security-appliance syslog messages begin with a percent sign (%) and are structured as follows:

```
%(ASA | PIX | FWSM)-Level-Message_number: Message_text
```

For example:

```
%ASA-2-302013: Built outbound TCP connection 42210
```

Note that additional information, such as date and timestamp, precedes these messages. The specific additional information depends on the type of device.
A unique six-digit number identifies each message (302013 in the preceding example). The following security-appliance syslog message IDs are supported for Security Manager-to-CS-MARS queries. If you change the logging level of a security appliance, be sure these messages are generated at the new level.

<table>
<thead>
<tr>
<th>Message ID</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>106023</td>
<td>An IP packet was denied by the access rule. This message is recorded even if logging is not enabled for the rule; this is the Default Logging option.</td>
</tr>
<tr>
<td>106100</td>
<td>An IP packet was permitted or denied by the access rule. Additional information is provided, based on the logging level defined for the rule in the Advanced and Edit Options Dialog Boxes, page 15-15.</td>
</tr>
<tr>
<td>302013</td>
<td>A TCP connection between two hosts was created.</td>
</tr>
<tr>
<td>302014</td>
<td>A TCP connection between two hosts was torn down.</td>
</tr>
<tr>
<td>302015</td>
<td>A UDP connection between two hosts was created.</td>
</tr>
<tr>
<td>302016</td>
<td>A UDP connection between two hosts was torn down.</td>
</tr>
<tr>
<td>302020</td>
<td>A ICMP connection between two hosts was created.</td>
</tr>
<tr>
<td>302021</td>
<td>A ICMP connection between two hosts was torn down.</td>
</tr>
</tbody>
</table>

**Router messages**

On Cisco IOS routers, syslog messages are also generated for access rules. The first packet that triggers the access list causes an immediate logging message, and subsequent packets are collected over five-minute intervals before they are displayed or logged. Each logging message includes the access list number, whether the packet was permitted or denied, the source IP address of the packet, and the number of packets from that source permitted or denied in the prior five-minute interval.

The following IOS syslog message IDs are supported for Security Manager-to-CS-MARS queries.

<table>
<thead>
<tr>
<th>Message ID</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>%SEC-6-IPACCESSLOGP</td>
<td>A packet matching the log criteria for the given access list was detected: TCP and UDP.</td>
</tr>
<tr>
<td>%SEC-6-IPACCESSLOGS</td>
<td>A packet matching the log criteria for the given access list was detected: IP address.</td>
</tr>
<tr>
<td>%SEC-6-IPACCESSLOGDP</td>
<td>A packet matching the log criteria for the given access list was detected: ICMP.</td>
</tr>
<tr>
<td>%SEC-6-IPACCESSLOGNP</td>
<td>A packet matching the log criteria for the given access list was detected: all other IPv4 protocols.</td>
</tr>
</tbody>
</table>

**Note**

If an excessive number of syslog messages are being generated and reported to CS-MARS, use the Advanced and Edit Options Dialog Boxes, page 15-15 to change the logging level for those access rules that are producing the largest number of messages. You can also look at changing the logging policies on the device to limit the types of messages generated.
NetFlow Event Reporting in CS-MARS

Event reporting in CS-MARS can include NetFlow events from an ASA 8.1+ device.

NetFlow Security Event Logging uses NetFlow version 9 fields and templates to efficiently deliver security telemetry in high-performance environments. NetFlow Security Event Logging scales better than syslog messaging, while offering the same level of detail and granularity in logged events. The ASA NetFlow implementation exports only significant events in the life of a flow, rather than exporting data about flows at regular intervals. The following flow events are exported:

- Flow creation
- Flow tear-down
- Flows denied by an access rule

The ASA also exports syslog messages that contain the same information. If you enable NetFlow on a device, you can consider disabling the equivalent syslog messages. Disabling equivalent syslog messages can help avoid the potential performance degradation caused by generating and processing both NetFlow records and syslog messages representing the same event. The following table lists syslog messages with an equivalent NetFlow event; the NetFlow Event IDs and Extended Event IDs are included. For information on how to disable NetFlow equivalent syslog messages, see Server Setup Page, page 51-15.

<table>
<thead>
<tr>
<th>Syslog ID</th>
<th>Syslog Description</th>
<th>NetFlow Event ID</th>
<th>Extended Event ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>302013</td>
<td>TCP, UDP, GRE, and ICMP connection creation.</td>
<td>1 = Flow Created.</td>
<td>0 = Ignore.</td>
</tr>
<tr>
<td>302015</td>
<td>TCP, UDP, GRE, and ICMP connection creation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>302017</td>
<td>TCP, UDP, GRE, and ICMP connection creation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>302020</td>
<td>TCP, UDP, GRE, and ICMP connection creation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>302014</td>
<td>TCP, UDP, GRE, and ICMP connection tear-down.</td>
<td>2 = Flow Deleted.</td>
<td>0 = Ignore, or &gt; 2000 = ASP drop reasons.</td>
</tr>
<tr>
<td>302016</td>
<td>TCP, UDP, GRE, and ICMP connection tear-down.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>302018</td>
<td>TCP, UDP, GRE, and ICMP connection tear-down.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>302021</td>
<td>TCP, UDP, GRE, and ICMP connection tear-down.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>710003</td>
<td>An attempt to connect to the device’s interface was denied.</td>
<td>3 = Flow Denied.</td>
<td>1003 = To-the-box flow denied due to configuration.</td>
</tr>
<tr>
<td>106015</td>
<td>A TCP flow was denied because the first packet was not a SYN packet.</td>
<td>3 = Flow Denied.</td>
<td>1004 = Flow denied because first packet was not a TCP SYN packet.</td>
</tr>
<tr>
<td>313001</td>
<td>An ICMP packet to the device was denied.</td>
<td>3 = Flow Denied.</td>
<td>1003 = To-the-box flow denied due to configuration.</td>
</tr>
<tr>
<td>313008</td>
<td>An ICMP v6 packet to the device was denied.</td>
<td>3 = Flow Denied.</td>
<td>1003 = To-the-box flow denied due to configuration.</td>
</tr>
<tr>
<td>106100</td>
<td>An access rule was hit.</td>
<td>1 = Flow Created (if ACL permitted the flow). 3 = Flow Denied (if ACL denied the flow).</td>
<td>0 = If Flow permitted by ACL. 1001 – Flow denied by Ingress ACL. 1002 – Flow denied by Egress ACL.</td>
</tr>
</tbody>
</table>
For the Flow Denied NetFlow event, an Extended Event ID indicates the reason for denial, as shown in the following table.

<table>
<thead>
<tr>
<th>Extended Event ID</th>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>FLOW DENIED</td>
<td>The flow was denied by an Ingress ACL.</td>
</tr>
<tr>
<td>1002</td>
<td>FLOW DENIED</td>
<td>The flow was denied by an Egress ACL.</td>
</tr>
<tr>
<td>1003</td>
<td>FLOW DENIED</td>
<td>The security appliance denied an attempt to connect to the interface service.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, this message appears (with the service SNMP) when the security appliance receives an SNMP request from an unauthorized SNMP management station.</td>
</tr>
<tr>
<td>1004</td>
<td>FLOW DENIED</td>
<td>The flow was denied because the first packet was not a TCP SYN packet.</td>
</tr>
<tr>
<td>&gt; 2000</td>
<td>FLOW DELETED</td>
<td>Values above 2000 represent various reasons for a flow being terminated.</td>
</tr>
</tbody>
</table>
PART 8

Image Management
Using Image Manager

Image Manager is a tool to simplify the distribution and management of images on internal and edge firewall devices in your network. It enables you to:

- Download and maintain a repository of different types and versions of images
- Evaluate images
- Analyze impact of upgrading images to the devices in the network
- Prepare for and plan an upgrade
- Reliably upgrade devices, with sufficient fallback and recovery mechanisms built in to ensure minimal network downtime

This chapter contains the following topics:

- Getting Started with Image Manager, page 69-1
- Working with Images, page 69-7
- Working with Bundles, page 69-10
- Working with Devices, page 69-13
- About Image Updates on Devices Using Image Manager, page 69-16
- Working with Jobs, page 69-26
- Troubleshooting Image Management, page 69-31

Getting Started with Image Manager

Image Manager contains four main sections that are used for managing your images, working with the devices that you will need to update, and performing image installations on those devices. For more information on these areas of Image Manager, see the following topics:

- Working with Images, page 69-7
- Working with Bundles, page 69-10
- Working with Devices, page 69-13
- About Image Updates on Devices Using Image Manager, page 69-16
- Working with Jobs, page 69-26
Before working with Image Manager, you should review the sections that follow:

- the platforms that are supported by this feature,
- the configuration settings you can change to control how the feature works, and
- the steps that are necessary to ensure your devices are configured to work with Image Manager.

This section contains the following topics:

- Image Manager Supported Platforms and Versions, page 69-2
- Image Manager Supported Image Types, page 69-3
- Administrative Settings for Image Manager, page 69-4
- Bootstrapping Devices for Image Manager, page 69-6

### Image Manager Supported Platforms and Versions

Image Manager is available only for ASA devices. The following devices support Image Manager:

- All legacy ASA models—ASA 5505/10/20/40/80
- ASA 5585/10/20/40/60
- ASA 5512/15/25/35/45
- ASA-SM module for Catalyst 6K

The following devices are not supported and are filtered out in the devices tab of the Image Manager unified view:

- PIX firewall
- FWSM blade
- ASA device managed by AUS
- Devices unmanaged in Security Manager
- Other device types—IPS and Routers

Image Manager supports both Routed mode and Transparent mode devices.

**Note**

Single Context, Multi-context, and Active/Standby Failover modes are supported. Active/Active configuration is not supported.

Image Manager supports image upgrade for ASA device version from 7.x onwards. The target image version that can be used to upgrade is not restricted. But, image upgrade to the highest ASA version supported in Security Manager 4.3, that is ASA version 8.4(4), has been tested.

**Warning**

Image downgrade is not restricted, but is done at your own risk. Image Manager does not validate downgrade cases.
Image Manager Supported Image Types

Image Manager supports the following types of images:

- ASA System software
- ASDM image
- VPN images [includes Cisco Secure Desktop (CSD), AnyConnect, and Hostscan]
- SSLVPN Plug-in images (For example: RDP, SSH, ICA, and others)

Image Manager completely manages the ASA system software and the ASDM images on the ASA devices, i.e., it performs loading of the image, activating the image by modifying configuration, and even reloading the device if required to complete the image upgrade process.

Handling of SSL VPN Images

Image Manager only reliably copies SSL VPN images to the ASA device. No configuration or activation commands are added for SSL VPN images by Image Manager. The configuration of the images must still be done using Configuration Manager.

The following files are not managed in Image Manager and have to be configured and deployed from Configuration Manager as in earlier versions of Security Manager:

- CSD Configuration XML
- AnyConnect Client Profile files
- DAP Configuration XML
- Full Customization XML files

After the SSL VPN images have been copied to the device using Image Manager, the remote access VPN policies must be configured in Configuration Manager to make use of these images. The Remote Access VPN policies that must be configured are located at the following paths in Configuration Manager:

- **CSD Package**—Remote Access VPN > Dynamic Access > Cisco Secure Desktop group box
- **HostScan Package**—Remote Access VPN > Dynamic Access > Cisco Secure Desktop group box
- **Anyconnect Image**—Remote Access VPN > SSL VPN > Other Settings > Client Settings tab
- **Plug-ins**—Remote Access VPN > SSL VPN > Other Settings > Plug-in tab

**Note**

The SSL VPN binary files must be present on the device flash before referencing them in VPN policy. If not, Security Manager will present an error message informing the user to use Image Manager to push these files to the device before deploying the configuration.

Image Manager does not validate the compatibility of the SSL VPN files that are pushed to the ASA. But Configuration Manager will complain when incompatible files are referenced in the Remote Access VPN policies.
Administrative Settings for Image Manager

Image Manager introduces new administrative settings. These administrative settings must be configured as part of Configuration Manager.

To configure administrative settings for Image Manager, do the following:

---

**Step 1** Go to Configuration Manager > Tools > Security Manager Administration.

The Cisco Security Manager - Administration page appears.

**Step 2** Configure workflow settings:

- Select **Workflow**.

  a. To require that Install Jobs be approved explicitly by an assigned approver before they are installed on devices, select **Require Deployment & Install Image Approval**. If you select this option, make sure you configure appropriate email notification settings. For more information, see the Workflow Page, page 11-48.

  b. Click **Save**.

**Step 3** Configure debug settings:

- Select **Debug Options** and from the drop-down list for Image Manager Debug Level, select the debug level you want.

  **Tip** The levels include: Severe, Error, Warning, Info and Debug. The default log level is Error.

  **Note** The log files are stored as follows:

  - The server logs are located at: %NMSROOT%\MDC\log\operation\vmssharedsvcs.log and %NMSROOT%\MDC\tomcat\logs\stdout.log
  - The client logs are located at: <Client Install Dir>\logs\*.log

  b. Click **Save**.

**Step 4** Configure Cisco.com credentials:

- Select **Image Manager**.

  The Image Manager page appears.

  a. If you have credentials to connect to Cisco.com configured already at Tools > Security Manager Administration > IPS Updates > Update Server and wish to reuse the same for Image Manager, then check the **Use IPS Updates Settings** check box. This is also the default behavior.

  **Note** Only Cisco.com is supported, not Local Server.
c. On the Image Manager page, deselect the **Use IPS Updates Settings** check box if you want to specify a set of credentials for Image Manager explicitly. The fields on the Image Manager page become operable.

d. Complete the following fields:
   - Username
   - Password
   - Confirmation

e. Optionally, complete the Proxy Server Settings to configure a proxy, if required.
   1. Select the **Enable Proxy** check box.
   2. Complete the following fields to define the proxy:
      - IP or Hostname
      - Port
      - Username
      - Password
      - Confirmation (of Password)

f. Click **Test Connection** test connectivity to Cisco.com with the configured settings.

Click **Save**.

**Step 5** Configure Purge Interval for Image Install Jobs

a. Select Image Manager.

b. Enter a purge value to specify how many days should pass between purges, in the Purge Jobs Older Than field.

**Note** Pressing the Purge Now button immediately purges the Image Installation jobs satisfying the Purge Interval criteria.

**Step 6** Configure Image Backup Settings

a. Select Image Manager.

b. To include the repository as part of the standard backup, select **Include Repository**.

**Caution** Ensure that you have sufficient hard disk space on the Security Manager server as the image files consume a lot of space.

**Note** You can click the Reset button to reset the values to the last saved values before the current change.

c. Click **Save**.

**Step 7** Click **Close** to close the Administration window.
Bootstrapping Devices for Image Manager

The bootstrapping in Image Manager is essentially the same as that which you perform in Configuration Manager for ASA devices.

To bootstrap a device for Image Management, do the following:

---

**Step 1** Configure HTTPS on the device(s) to manage ASA in Security Manager.

a. Ensure that the HTTP server is enabled.

b. Add the Security Manager server IP address as an allowed host for HTTP management on the device.

---

**Step 2** Ensure that the configuration register setting is set to boot with the image list in the running configuration.

a. Register value: 0x1,0x3,0x5, 0x7, 0x9

   **Note** Register value: 0x1 is the recommended setting.

b. Do not set to boot to **rommon** mode. (Otherwise device will not be rebooted and the image upgrade will be aborted.

---

**Step 3** In Security Manager, go to Tools > Security Manager Administration > Device Communication > SSL Certificate Parameters. In the SSL Certificate Parameters area, set PIX/ASA/FWSM Device Authentication Certificates to Do not use certificate authentication.

---

**Step 4** Ensure that there is sufficient space in the flash memory of the device(s) to hold the images you intend to load.

   **Tip** If necessary, you can delete other images you do not intend to use from the device(s).

---

**Step 5** Perform the following steps to upgrade devices in Active/Active failover setup:

a. Add the active/active devices to Configuration Manager.

b. Manually convert the pair to active/standby by forcing all the failover groups on one device to be **active** and on the other to be **standby**.

   **Note** Do not discover the devices in Security Manager.

c. Create an image upgrade job on the active device of the pair, and run the image upgrade job.

d. After the upgrade has occurred, manually convert the pair back to active/active configuration.

e. Rediscover in Security Manager only the device inventory for the unit that was converted to standby.
Step 6  
We recommend that you unmanage the BootImage/Configuration policy for ASA, as follows:

a. In Security Manager, navigate to Tools > Administration > Policy Management.

b. Uncheck the Boot Image/Configuration policy selection.

Note  
Image Manager configures boot image and ASDM image as part of the image installation job. So, if the Boot Image/Configuration policy is not unmanaged, then any configuration deployment after the image installation will remove these boot commands added by Image Manager. To prevent this, the Boot Image/Configuration policy should be unmanaged in Security Manager. This can be done from Security Manager administration settings -> Device Exception Settings -> Firewall Policies Node.

Step 7  
We recommend that the device not be set as a priority monitored device in HPM.

Step 8  
Ensure that all configuration changes on the device are submitted and deployed.

Working with Images

Image Manager provides access to images on Cisco.com. When an image shows a location of Repository, it means that image has already been downloaded (either from Cisco.com or from a local file system). Conversely, an image that shows location as Cisco.com has not been downloaded into the repository. Navigating to the Repository Images in the Images section of the selector enables you to examine a list of all the images. You can also filter, sort, and search the images available. Filtering, in particular, is a good way to navigate within Image Manager. Beginning with all images, you can use the headings in the main repository view to locate images by a variety of attributes including name, version, and type.

Note  
Only images that are downloaded to Image Repository can be used for image upgrade jobs.

This section contains the following topics:

- View All Images, page 69-7
- Download Images to the Repository, page 69-9

View All Images

When you first open Image Manager, or when you select All Images from the selector, the system displays a complete list of images. This list includes both those images in the repository as well as those on Cisco.com (which have not yet been downloaded). Some of the VPN image files are bundled with the Security Manager installation and are shown in the repository from the first time onwards. Image Manager will display a warning about credentials not being configured when the Image Manager client is launched for the first time, or until the credentials are configured under Security Manager administration settings for Image Manager.
This view can be re-ordered by any of the listed image attributes. For example, you can list the images by size. The attributes that you can sort on include:

- **Download State** - This is the first column and is shown as icons. The icons are actionable, and you can double-click the icon in this column to start the download of an image from Cisco.com, or to abort an ongoing image download, or to delete an image from the repository. Note that the icons change during each of these actions. (A green arrow indicates an image on Cisco.com, a red cross indicates an image that has already been downloaded, and another icon indicates that a download is in progress.)
- **Image (name)**
- **Type**
- **Version**
- **Location**
- **Size**
- **Description**
- **Comments** (you can add and edit comments for an image).

To view all images, do the following:

---

**Step 1**  
Check for new images available on Cisco.com

a. Configure the credentials for reaching Cisco.com by navigating to Tools > Security Manager Administration > Image Manager.

b. In the upper right corner, click the double arrow **Check for Updates** icon.

c. Ensure that the CCO account has permissions to download crypto images. Otherwise, navigate to the link and accept the agreement, and then retry the operation.

The system displays “**Updating**” while it checks for updates. When finished, it reads: **Last updated at: <timestamp>**, and you can view the new images available in the All Images view.

**Step 2**  
Click **All Images** in the selector.

The system displays the image list.

**Step 3**  
To re-order the list, click on any of the column headings.

The list of images is reordered according to the selected attribute.

**Step 4**  
To filter the list, use the Image Manager’s search window to enter a key string. For example, you could enter the digits of a version number.

---

**Note**  
Also, you can use the filter settings in some of the column headings to filter the list shown.
**Download Images to the Repository**

You can download images to the repository either from Cisco.com or from a local file system.

**Tip**
Images can also be downloaded from the Compatible Images tab. For details see [Manage Images on a Device, page 69-14](#).

To add an image file to your Security Manager repository, do the following:

**Step 1**
To download images from Cisco.com, do the following:

a. From the All Images view double-click the **Start Download** icon in the first column.

**Tip**
Ensure that the credentials to Cisco.com are configured and you have authorization to download the images.

**Note**
Image Manager displays an error message if the image to be downloaded already exists in the repository.

b. When completed, select Repository Images and view the image in the listing.

**Tip**
You can also select multiple images and download them all at once by right-clicking them and using the context-sensitive menu.

**Tip**
By sorting the list on Update Time, you can easily view the most recent image.

**Step 2**
To download images from a local file system, do the following:

a. From the toolbar in the Repository Images view, click the **Download image from file system** icon (found on the far left).

The Download from File System dialog box appears.

b. Use the Browse feature to select the Import location and to select the image to be imported.

c. Click **OK**.

d. Click **OK** in the Download image from file system dialog box.

e. Observe the progress of the download.

**Note**
If the image to be downloaded already exists in the repository, the system displays an error.
f. When completed, select a device group in Security Manager and view the image in the listing.

Tip
By sorting the list on Update Time, you can easily view the most recent image.

g. Alternatively, you can download an image file using the drag-and-drop method. For example, you can drag a file from your desktop and simply drop it on the Image Manager application. Or, as another alternative, you can select multiple images, right-click on the selected images, and select Download.

Working with Bundles

Bundles are groups of compatible images that you define. You can use bundles to simplify repetitive operations, by grouping images that are pre-validated to work together as a logical group. For example, you might define bundles that reflect ASA and ASDM pairs to ensure that you deploy both types in a single operation. The following types of images can be part of a bundle:

- ASA system software
- ASDM image
- VPN images (including csd, AnyConnect, Hostscan)
- Plug-ins (including rdp, ssh, ica, owa, and others)

Multiple system software images cannot be included in the same bundle.

Caution
The Image Manager does not stop you from adding incompatible images as part of a bundle. You must determine this compatibility. The ASA and ASDM Compatibility matrix is located at: http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html#wp42231.

Tip
Throughout Image Manager there are operations where you can choose to apply an image, multiple images, or a (predefined) bundle of images.

This section contains the following topics:
- Creating Bundles, page 69-11
- View Images by Bundle, page 69-11
- Renaming Bundles, page 69-12
- Deleting Bundles, page 69-12
- Deleting Images from Bundles, page 69-12
Creating Bundles

You can define bundles of images to simplify your Image Manager. Bundles are particularly useful when you have a group of images upon which you regularly operate.

To create a bundle, do the following:

**Step 1** From the Bundles heading in the selector, click the Add Bundle (plus sign) icon.

**Step 2** In the Create Bundle dialog box that opens, enter the name for the new bundle.

**Step 3** Click OK.

The bundle is listed under the Bundles heading in the selector.

**Step 4** From the Images section of the selector, select an image to be bundled. Then click on the Release Notes tab. Finally, examine the compatibility table in the applicable release notes to ensure there are no conflicts with the other images to be bundled.

---

**Caution**

The Image Manager does not stop you from adding incompatible images as part of a bundle. It is the responsibility of the user to determine this compatibility. The ASA and ASDM Compatibility matrix is located at: [http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrix.html#wp42231](http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrix.html#wp42231).

**Step 5** With compatibility determined, drag and drop each image onto the bundle.

---

**Note** Multiple system software images cannot be included in the same bundle.

**Tip** You can select a range of images to drag and drop by selecting the first image in the range and then, with the Shift key pressed, selecting the last image in the range. You can select multiple images by clicking those images while keeping the Ctrl key pressed. You can also select a range of images and then add additional images to your selection by using the Ctrl key method. To move multiple images to a bundle, drag using the right mouse button.

---

View Images by Bundle

You can view the images that have been added to a bundle.

To view the images in a bundle, do one of the following:

**Step 1** To view the images contained within all bundles:

a. Under the Bundles heading in the selector, click the top-level Bundles folder.

   All the bundles are listed, together with the images contained within each.

b. You can expand or collapse any of the bundles to make viewing easier. To expand all bundles or collapse all bundles, use the Expand All and Collapse All buttons at the top of the main window.
Working with Bundles

Chapter 69      Using Image Manager

Step 2 To view the images for a specific bundle:
   a. Under the Bundles heading in the selector, select a bundle.
      The list of images for the selected bundle is displayed in the main window.

Renaming Bundles

Bundles can easily be renamed to provide better organization or to more accurately reflect the contents of the bundle.

To rename a bundle, do the following:

Step 1 From the Bundles heading in the selector, select a bundle.
Step 2 Right-click the bundle name and, from the drop-down list, select Rename Bundle.
      The Rename Bundle dialog box appears.
Step 3 Type the new bundle name.
Step 4 Click OK.
      The new bundle name appears in the selector under Bundles.

Deleting Bundles

Bundles that are no longer needed can be deleted.

To delete a bundle, do the following:

Step 1 Select the bundle.
Step 2 From the Bundles heading in the selector, click Delete (the red X icon).

Deleting Images from Bundles

If you wish to change the contents of a bundle, you can delete any of the images that are defined as part of a bundle.

To delete images from bundle, do the following:

Step 1 Select the bundle.
Step 2 Right-click on the image(s) to be removed.
Step 3 Select Delete Image from Bundle.
Working with Devices

The following topics explain how to work with devices in Image Manager.

This section contains the following topics:

- Viewing Device Inventory, page 69-13
- Manage Images on a Device, page 69-14
- View Device Memory, page 69-15
- Configuring the Image Install Location, page 69-15

Viewing Device Inventory

You can use the Device Summary page to quickly view the devices on your network and their attributes.

Within the selector panel on the left is an area called Devices. From that area you can display all devices by selecting All (or you could select a location or group of devices you have defined). After you have chosen the scope of device selection, the corresponding devices are displayed in the upper panel of the Device Summary page. The upper window of the Device Summary page displays the following attributes, as applicable, for each device:

- Device
- System SW Version
- ASDM Version
- AnyConnect Version
- Secure Desktop Version
- Hostscan Version

When you select a particular device, the lower window of the Device Summary page displays the five tabbed pages of details for that device. These pages and associated details include:

- **Summary**—Display Name, Device Type, IP Address, Hostname, Domain Name, Serial Number, Running OS Version, Target OS Version, RAM, Failover Mode, Image Install Location
- **Storage** (The number and capacity of flash memory units)—Name, Size, Path, Type, Disk Usage
- **Running Images** (The images presently operating)—Name, Type, Version, Path, Size
- **Compatible Images** (The images that are compatible to the device)—Image, Type, Version, Location, Size, Description, Comment

**Note** Details are shown in this tab only when a single device is selected. Otherwise, the tab is blank.

- **History** (Chronological view of Image Installation Jobs and Configuration Deployment Jobs that have been executed on the device.)—Job Name, Changed By, State, Last Action, Tickets
Manage Images on a Device

You can use the Image Management tool to review, download, and remove the images on the ASA device(s) you select.

To review, download, or remove ASA images on a device, do the following:

---

**Step 1** Select a device group from the Devices area of the selector panel.

The main window displays the Device Summary. The Device summary lists the devices and the associated system software versions.

**Step 2** From the upper pane of the Device Summary page, select a device.

The lower pane displays details of the selected device.

**Step 3** Select the Storage tab in the lower pane and then check the amount of free space listed under Disk Usage.

---

**Tip** The device may have more than one storage area, for example, disk1. Be sure to scroll down to see secondary (flash) storage capacity.

---

**Step 4** Note the available disk space on the device.

**Step 5** To remove one or more images from the device to free up space, select one or more images in the Storage Tab and click Delete at the top of the Storage Tab.

---

**Tip** Alternatively, you can select one or more images, right-click and click Delete.

---

**Tip** If you delete an image that is currently active and is being referenced, Image Manager displays a warning message.

---

**Step 6** To download an image from the device, select the image and click Download at the top of the Storage tab. Select the location on the local file system to which to download the image and click OK.

A dialog appears showing the progress of the download from the device. After the download is completed, the downloaded image is shown in Explorer.

**Step 7** Select the Compatible Images tab in the lower pane.

The system displays images that are compatible to the device.

**Step 8** To install the compatible image(s) onto the device do the following:

a. Select the image to be added to the device.

b. Double-click the download icon.

   The image is downloaded to the repository.

c. Select the image and then select Install from the context menu.

   The Install wizard appears and the system installs the image. Please see Install Compatible Images on Devices, page 69-25 for details.
View Device Memory

You can use Image Manager to determine the memory capacity and application of a device in your network.

To view the details of the memory on a device, do the following:

**Step 1**
From the Devices area of the selector panel, choose the device to examine.

Details of the selected device appear in upper window of the Device Summary page.

**Step 2**
In the upper panel, examine the RAM listing.

**Caution**
Image Manager warns you if there is insufficient RAM on a device to load the new image. However, the system does not stop you from performing such an image upgrade. (This is in contrast with Configuration deployment, where the deployment job stops if there is insufficient RAM.)

Configuring the Image Install Location

ASA devices have a default flash (disk0) where all the images reside. By default, Image Manager copies images to disk0 of the ASA device. When the ASA device is configured with an external disk (that is, disk1), Image Manager allows you to choose between the two disks, disk0 or disk1, when loading images on the ASA device.

**Note**
The capability to load images on an external disk is very useful for storing large images such as those for AnyConnect and CSD, as disk0 can run out of space quickly with even a few of these larger images.

For configuring Image Manager to use the external disk, do the following:

**Step 1**
Select the device from the Devices area of the selector.

**Step 2**
View the Summary information on the right pane.

The available disks on the device are listed in the Image Install Location drop-down list. For a device with external disk, disk0 and disk1 would be listed.

**Step 3**
Select the external disk, disk1, from the Image Install Location drop-down list and click **Apply**.

All future image installation jobs for the device will load the images to disk1.

**Tip**
The configuration of the external disk can be verified by performing an image install operation. After the job is complete, view the contents of disk1 in the Storage tab of the device in Image Manager. It should list the newly installed images.
About Image Updates on Devices Using Image Manager

How does Image Manager update images on ASA device?

Image Manager follows the standard documented procedure to upgrade the stand-alone ASA devices with several built-in checks to ensure reliable image upgrade. Image Manager uses the HTTPS protocol to copy images to the ASA device, performs configuration changes to activate the new image (ensuring fallback to the older image in case of any error), and finally reloads the device if required, with the new image.

For upgrade of the failover pair, Image Manager follows the hitless upgrade procedure listed at: http://www.cisco.com/en/US/products/ps6120/products_configuration_example09186a0080b20f35.shtml. The image is copied to both the units and then configuration change is done to activate the image that is synced to both units. First the standby is reloaded via the active unit and after ensuring that the standby has been upgraded successfully to the new version, the current active is reloaded. After both the units are upgraded to the new version, the failover pair upgrade is marked successful.

There are restrictions for image upgrade in failover ASA pair. We recommend that, while performing image upgrades on failover ASA pair using Image Manager, you ensure the following restrictions are satisfied:

- The two units in a failover configuration should have the same major (first number) and minor (second number) software version.
- **Maintenance Release**: You can upgrade from any maintenance release to any other maintenance release within a minor release. For example, you can upgrade from 7.0(1) to 7.0(4) without first installing the maintenance releases in between.
- **Minor Release**: You can upgrade from a minor release to the next minor release. **You cannot skip a minor release**. For example, you can upgrade from 7.0 to 7.1. Upgrading from 7.0 directly to 7.2 is not supported for zero-downtime upgrades; you must first upgrade to 7.1
- **Major Release**: You can upgrade from the last minor release of the previous version to the next major release. For example, you can upgrade from 7.9 to 8.0, assuming that 7.9 is the last minor version in the 7.x release.

Device State Changes During and After Image Update

Image upgrade is a critical operation and hence there is a need to depict visually, and inform users of, all image update operations. Thus, three new device states have been introduced:

- **Upgrade In Progress**—The device is put into this state whenever an image install job starts on the device. This state is automatically reset by the system after the image update operation is completed on the device.
- **Maintenance**—The device is put into Maintenance state when the image install job fails on the device and the device becomes unreachable after the image install operation. You need to manually reset this state to normal/operational state after taking necessary steps to bring back the device online by manually correcting issues due to upgrade or by rolling back the image.
- **Configuration Required**—For certain cases of image upgrade (like from ASA 8.2 to ASA 8.3), there are significant changes in the device configuration as part of the image upgrade which renders the policy configuration model in Security Manager incompatible with the device configuration. In such cases, even if the image upgrade operation may be successful, you must perform some operations, like rediscovery of device, to ensure that after upgrade, Security Manager’s configuration policy model and the device configuration are in tandem. Thus, after an image upgrade, if some additional configuration is required to be made in Configuration Manager to make the device operational, the device is put into Configuration Required state. Even in the case where VPN images are deployed using Image Manager, the device is put into Configuration Required state.
since this requires the user to configure these images in the VPN policies using Configuration Manager. The \textit{Configuration Required} state indicates that there are changes to be done in Configuration Manager to make the device functional in Security Manager after the image update operation. You can make the suggested changes and, after you are satisfied with your configuration changes, you can manually bring the device back to \textit{Operational} state.

\begin{itemize}
  \item Validating a Proposed Image Update on a Device, page 69-17
  \item Using the Image Installation Wizard to Install Images on Devices, page 69-20
  \item Install Bundled Images on Devices, page 69-24
  \item Install Compatible Images on Devices, page 69-25
  \item Install Images on Selected Devices, page 69-25
\end{itemize}

\section*{Validating a Proposed Image Update on a Device}

You can validate the image update job on one or more devices prior to actually performing it. The following list details the various validations that are performed:

\begin{itemize}
  \item Insufficient disk space on the ASA device to accommodate the selected images.
    An error is displayed in this case. You must navigate to the Storage tab for that device and delete one or more images to make space. Then retry the upgrade validation operation.
  \item Insufficient RAM on the device to run the new image as recommended in: Release Notes for the Cisco ASA 5500 Series, 8.4(x).
    Image Manager will warn you if there is insufficient RAM on the device to load the new image. However, this will not stop you from performing an image upgrade. This is in contrast with Configuration deployment, wherein the deployment job stops if there is insufficient RAM.
  \item Configuration changes that have been submitted but not yet deployed to the device. These changes need to be deployed before starting the image update job. Otherwise, the configuration changes may become incompatible with the upgraded image version on the device.
  \item Warn if the selected image(s) is (are) incompatible with the device type, e.g., if non-SNMP images are selected for ASA 5585 device types.
\end{itemize}
Chapter 69  Using Image Manager

About Image Updates on Devices Using Image Manager

Note  This warning only occurs when you are using the drag-and-drop method. For other flows, the incompatible images/devices are filtered out in step 2 of the Image Install Wizard.

- Warn if the device is being updated to a version that is unsupported on Security Manager.
- Warn if the new image version is the same as or lower than the version running on the device.
- An image upgrade to ASA Version 8.3 from any lower version would require the device to be re-discovered in Security Manager. There were major changes in the NAT configuration introduced in ASA version 8.3 that are incompatible with previous ASA versions. Likewise, there were major changes to the NAT policy model in Security Manager for Version 8.3. Hence, when a device is upgraded to ASA 8.3, that device is put into the Configuration Required state to indicate to the Configuration user that some changes are required in Configuration Manager to make the device operational. After rediscovering the device in Security Manager, the user can right-click the device in the device tree and select Make Device Operational to bring it back to normal state.
- An image upgrade from ASA Version 8.3.x to 8.4.2 or higher also requires rediscovery of the device in Security Manager because of incompatible changes in PAT configuration in ASA Version 8.4.2. In this case also, the device state is changed to the Configuration Required state after the image upgrade.
- An image upgrade from ASA Version 7.x to 8.x introduces major changes in the SSLVPN configuration both on the device and in Security Manager. Because of these incompatible changes, the device must be deleted from Security Manager after the image upgrade and then added again. The device is put into the Configuration Required state to notify the user to act upon these warnings.
- Any VPN image, such as an AnyConnect, CSD, or Hostscan image, being loaded using Image Manager warns the user if the existing VPN image was part of a shared policy being assigned to the current device or other devices. A warning is issued to also copy the new image to all the devices to which the shared policy is assigned so that the shared policy can be updated for all the devices seamlessly without the loss of policy sharing.
- Warn when the standby unit in a failover pair in not reachable. This is an error that will cause the job to be aborted.
- Warning for upgrade of Active/Standby failover pair. The version being upgraded should comply with the recommendations listed at: ASA/PIX: How to Use the CLI to Upgrade the Software Image on a Failover Pair.
- Warning for upgrade of Active/Active failover pair that the image update job will be aborted unless the pair is converted to Active/Standby (that is, if all the failover groups are active on one physical unit).

To validate an image installation, do the following:

Step 1  From the File menu, select Validate.
The Validate Image Assignments window opens.

Step 2  Click Add Assignment.
The Image Assignment window opens.

Step 3  In the Image Assignment window, from the drop-down list, select either:

- Select Images and Assign to Devices
- Select Devices and Assign to Images
Tip

The same result is obtained by assigning images to devices or by assigning devices to images.

Step 4

Select one or more items (images or devices) by moving them to the window on the right.

Tip

You can use pre-defined bundles rather than images by clicking Bundles and selecting the bundle.

Step 5

Click Next and assign the other item (images or devices).

The Confirm Assignments window appears.

Step 6

Examine and confirm the assignments that you have specified.

Tip

You can continue to add or remove assignments, as required.

Step 7

Click Finish.

The Validate Assignments window appears.

Step 8

Click Start Validation.

The validation status of the assignment is shown in the Validation column. It shows either Warning or Successful or Error.

Step 9

Click on the display of Warning or Successful or Error.

A lower pane window opens.

Step 10

According to the validation status, do one of the following:

- **Error**—Examine the potential reasons for the error and correct as necessary.
- **Warning**—Examine the potential reasons for the warning and correct as necessary.
- **Successful**—No action required.

Tip

Be sure to display and examine all the errors or warnings by using the window slider bar on the right.

Step 11

After addressing the warnings or errors shown, you can proceed to create the job using the Image Install wizard.

Step 12

Optionally, you can right-click on an assignment element in the Validate Image Assignments window and modify or delete it before proceeding.

Step 13

You can also right-click on an assignment and select Copy Table. This copies the assignment details and the validation status and notes. You can then paste the contents to Notepad or another program as a CSV file to be used as reference.
Using the Image Installation Wizard to Install Images on Devices

You can use this feature to create a job to assign and install images on devices. An assignment is simply an association of an image and a device that defines an installation job.

**Note**
If you have the workflow function enabled, you must perform the additional steps described for obtaining authorization before you can accomplish installation.

**Note**
You can choose to operate upon any arbitrary set of devices.

To create a job to install images on devices, do the following:

**Step 1**
Go to Files > Open Image Installation Wizard.

The Image Installation Wizard dialog box appears.

**Tip**
The Image Installation Wizard can be invoked in several ways. In addition to invoking the Wizard from the menu, as described here, you can invoke it when you do any one of the following things: (1) install images by the drag-and-drop method; (2) right-click on a device or bundle; or (3) select a device, navigate to the Compatible Image tab, select one or more images from the table, right-click, and select the **Install** option.

**Step 2**
On the lower left, click **Add Assignment**.

The Image Assignments dialog box appears.

**Step 3**
From the drop-down list on the top, select whether you want to assign images to devices, or devices to images.

**Step 4**
Move items (devices or images) from the list on the left to the selected items list on the right. Then click **Next**. You can also select bundles, instead of images, by clicking the Bundles tab.

**Tip**
When pairing images and devices to define assignments, you can proceed with images and then devices, or devices and then images. The order of this selection does not matter.

**Step 5**
Review the assignment definition in the Confirm Assignments dialog box and click **Finish**.

**Tip**
At this point you can choose to add additional assignment pairs, as desired, by clicking **Add Assignment**.

**Step 6**
When you are finished defining assignments, click **Start Validation**. Wait until the system displays Validation Complete.

**Step 7**
Examine the status in the Validation column on the Assignments tab of the Wizard dialog box. It shows either Warning or Successful or Error.
Step 8  Determine what steps are necessary according to the status:
- **Error**—Examine the potential reasons for the error and correct as necessary.
- **Warning**—Examine the potential reasons for the warning and correct as necessary.
- **Successful**—No action required.

Step 9  Right-click on the assignment for more options:
- **Move Up/Move Down**—Select these options for a multi-device job when you want to change the order in which the devices will get updated. This feature can be used to order or sequence the devices when the Install Images to Devices job option is set to Sequential.
- **Delete/Delete All**—You choose these options to remove one or all devices from the image upgrade job.
- **Copy Table**—Use this to copy the warning messages to some text editor or spreadsheet program for reference.
- **Test File copy**—Use this option to check whether files can be copied between Security Manager Image repository and ASA device flash using https protocol.

**Tip**  Be sure to display and examine all the errors or warnings by using the windows slider bar on the right.

Step 10  If you want the installation job scheduled for a particular time, select the **Schedule** tab and specify the date and time.

Step 11  To set properties of the installation job, select the **Properties** tab.
- a. Edit the **Name**, if desired. (The default is Image install Job—<timestamp>)
- b. Edit the **Description**, if desired.
- c. Select a **Ticket ID**, if desired.

**Tip**  This option is available only if Ticket Management is enabled from the Security Manager administration menu. You have to select the ticket ID from the drop-down list of existing tickets. (Image Manager displays an error if no ticket is selected.)

- d. Set the **On Error** option. (Default is Stop Installation, alternative is Continue Operation.)
- e. Set the **Backup Current Image** option. (Default is Yes, alternative is No.)

**Tip**  This is only applicable for system software images

- f. Set the **Install images to devices in** option. (Default is parallel, alternative is Sequential.)
- g. Select one of three operations:
  - Install image and reboot device
  - Install image but do not reboot device
  - Only copy image onto devices
- h. If you are using Workflow, you can optionally configure the following approval options:
About Image Updates on Devices Using Image Manager

Tip

These are located in the top frame in Job properties for the job.

- **Action**—
- Approve
- Reject
- Deploy
- Submit

If you reject a job, the status is set to Rejected, after which you discard the job. When you discard a job the status is shown as Discarded and all the job’s action buttons are disabled.

If you approve a job, the status is set to Approved. Then, you must click Deploy to start the image upgrade job.

Tip

You can check running commentary by selecting the Details tab and clicking **Show Progress**.

After you deploy a job, the job status is shown as either Deployed or Failed. The History tab in the bottom pane (for the selected job) only is activated in WF mode and displays one of two job action flows:

- Creating/Edit-In-use/Submitted/Rejected/Discarded
- Creating/Edit-In-use/Submitted/Approved/Deploying/Deployed (or Failed)

**Submit the job**—This is checked by default

**Approver email**—The email address list of approvers

**Submitter email**—The email address of the person submitting the job

i. You can change job properties by clicking **Edit**.

j. Refer to **Viewing Install Jobs, page 69-28** for additional job viewing options.

**Step 12**

Note that Tickets must referenced in the Image Manager Install Job Wizard and that Tickets can only be created from Configuration Manager. An error occurs if no ticket is selected from the drop-down list.

**Step 13**

Click **Install**.

The Jobs page appears and the install job is shown with its status as Deploying.

**Note**

If a schedule was selected for the job, the job state is shown as Scheduled. The job will start deploying at the scheduled time and, at that time, the job state changes to Deploying.

**Note**

If workflow is enabled for Image Install Jobs, then the job state is changed to either Submitted or Edit-in-Use. In this mode, the job can be deplyed only after it has been approved. Please refer to **Image Installation Job Approval Workflow, page 69-30** for details on the job states in the workflow mode.
Tip

You can halt the job by clicking **Abort**. Please see *Aborting an Image Installation Job*, page 69-29 for important information about aborting an installation job.

You can discard a job before the scheduled run time by clicking **Discard**.

---

**Step 14**

When the job starts deploying, notice the change in the state of the devices to **Update in progress** state in the device tree in Configuration Manager and Image Manager. A green progress icon appears beside the device in the device tree.

**Step 15**

View the details of the job and its progress while it is in deploying state. Please see *Viewing Install Jobs*, page 69-28 for details.

**Step 16**

Wait for the job to complete.

The job state is changed to **Deployed** if all the devices are successfully updated. The job state is changed to **Failed** if one or more devices failed in the job.

**Step 17**

Notice the change in state of the device(s) in the device tree after the job is complete.

If the image update is successful and there are no further configuration changes required in Configuration Manager, the device will be moved back to **Operational** state. If there are configuration changes required on the device after the update, then device is moved to **Configuration Required** state. Clicking on the device in the device tree brings up a balloon tip with details of the state and actions to be taken to move the device state back to **Operational**.

If the image update fails on the device and the device is rendered unreachable during the image update operation, the device is put to **Maintenance** state.

**Step 18**

Verifying the image update:

a. Click on the device in the device tree in Image Manager.

b. Go to the Summary tab to view the updated Running OS version.

c. Go to the Running Images tab to view the new running images after the image update.

d. Select the device in Configuration Manager.

e. Right-click the device and select **Device Properties**.

f. Notice the new image version updated in Running OS Version field.

g. Go to **Configuration Manager > Manage > Configuration Archive**.

h. From the device CLI, enter **sh ver**

   The updated OS version should be displayed.

i. Select the device in the left device tree.

j. View the Configuration Archive versions in the right pane and notice the latest entry with the Archival Source as **Image Manager**.

k. Select the archived entry and click **View**.

l. Compare this entry with the previous archived version to view the configuration changes made by Image Manager during image update. You can view the boot commands being prepended for the new ASA system software image and/or ASDM image command being added for the new ASDM image.

m. Email notification will be sent to configured recipients with the status of the Image Upgrade job if email notification is configured in Image Manager administration settings.
Step 19  If the device is set to *Configuration Required* or *Maintenance* state after the image update operation, follow the steps below to complete the post-image update requirements to make the device functional from Configuration Manager:

a. Click on the device in the device tree in Configuration Manager or Image Manager.
   A balloon tip appears showing the device information.

b. View the contents of the balloon tip. Review the reason for the device being set to the *Configuration Required* or *Maintenance* state. Review also the recommended actions to be taken.

c. Perform the recommended actions.

d. Right-click the device in the device tree and select **Make Device(s) Operational**.
   The device is moved to *Operational* state and the icon beside the device in the device tree is removed.

---

**Install Bundled Images on Devices**

You can use the Image Manager tool to assign and install compatible images that are grouped as bundles. Bundles simplify repetitive operations and can ensure consistent actions are taken on a group of devices.

To selectively install an image bundle on a device or device group, do the following:

---

**Step 1** Drag and drop the bundle onto a device or device group.

The Install images on devices dialog box appears with device and images in the bundle pre-assigned. If the bundle is dropped onto a device group, all the devices in the group are automatically selected and assigned to the images in the bundle.

---

**Step 2** Investigate any assignment validation errors or warnings listed in the Install images on devices dialog box.

**Tip** You can choose to schedule the job and also modify the default properties for the job. Please see Using the Image Installation Wizard to Install Images on Devices, page 69-20 for details on scheduling a job and configuring job properties.

---

**Step 3** When your warnings are corrected (or you determine them to be insignificant) click **Install**.

**Note** Alternatively, you can right-click a bundle and select **Install** to launch the Image Installation wizard with the bundle pre-selected. You can then choose the devices and click **Install** to install the bundle on the selected devices.
Install Compatible Images on Devices

You can use Image Manager to install compatible images on devices.

To selectively install one or more compatible images on a device or device group, do the following:

**Step 1** Select a device in the Devices area of the selector and navigate to the Compatible Images tab.

**Step 2** Select one or more Repository images in the Compatible Images tab.

**Step 3** Right-click a selected image and click **Install**.

The Image Installation wizard appears with the selected images pre-assigned or moved to the right pane in the Select Image page.

**Step 4** Click **Next**.

The Select Devices page of the wizard is displayed.

**Step 5** Select the devices to which you want to install, and then click **Next**.

The Confirm Assignments page of the wizard is displayed.

**Step 6** Confirm the devices and images assignments, and then click **Finish**.

The Install images on selected devices dialog box appears with the devices and image(s) assigned.

**Step 7** Click **Start Validation** in the upper-right corner of the Assignments tab. Investigate any assignment validation errors or warnings listed in the Install images on devices dialog box.

**Tip** You can choose to schedule the job and also modify the default properties for the job. Please see Using the Image Installation Wizard to Install Images on Devices, page 69-20 for details on scheduling a job and configuring job properties.

**Step 8** When your warnings are corrected (or you determine them to be insignificant), click **Install**.

The image installation job is created. Please see Using the Image Installation Wizard to Install Images on Devices, page 69-20 for the remaining steps to monitor the job progress and verify the image update.

**Note** Alternatively, to install one or more images on a device or device group, you can drag multiple images from the Repository view and drop them onto a device or device group. Then, click **Install** to install the selected image(s) on the selected device(s).

Install Images on Selected Devices

You can use Image Manager to upgrade the images on a set of devices that you select.

To install images on a selected set of devices, do the following:

**Step 1** Select a device group in the Devices area of the selector.

**Step 2** View the listing of devices in the group in the right pane.
Working with Jobs

This section details the set of functions that assists in the performance of the image installation jobs. An image installation job may be immediately run, or it may be scheduled to run at a specified time and date. As Image Manager jobs tend to be time-consuming, the job management functions enable you to perform these operations in the background. Image Manager incorporates an optional ticketing system that enables you to easily locate a job or jobs by means of a unique Ticket ID.

You should understand that the details of a particular job are defined and validated before being run.

Note When a ticket is discarded, Image Management jobs assigned to that ticket will not be discarded automatically. If required, you must search for pending Image Manager jobs with that ticket ID in Image Manager and delete those jobs.
This section contains the following topics:

- Viewing Image Installation Job Summary, page 69-27
- Viewing Install Jobs, page 69-28
- Aborting an Image Installation Job, page 69-29
- Retry a Failed Image Install Job, page 69-29
- Roll Back a Deployed Job, page 69-30
- Image Installation Job Approval Workflow, page 69-30

**Viewing Image Installation Job Summary**

You can use the Image Manager tool to monitor image installation and deployment jobs. You can view the history and status of jobs that Image Manager has performed, as well as the summary, details, or history of any particular job.

**Note** Comprehensive details of job state changes are available in Configuration Manager (see Job States in Non-Workflow Mode, page 8-4 or Job States in Workflow Mode, page 8-6). For an Audit Report navigate to Configuration Manager > Manage > Audit Report.

To view a summary of image installation jobs, do the following:

**Step 1** In the selector, under Jobs, click **Install Jobs**.

The main window displays the Jobs list in the upper pane.

**Step 2** Examine the details of the Jobs list, which may include:

- **Name**—The name of the job. By default the name includes a time stamp.
- **Last Action**—Date of the last action.
- **Status**—Whether the job has deployed, failed, or is underway.
- **Changed By**—Who started the job.
- **Description**—Job description.
- **Schedule**—Job schedule.
- **Ticket ID(s)**—When ticketing mode is enabled, every image install job must have a ticket ID. Tickets (if used) enable you to track changes.

**Note** Image Manager does not provide ticket management. Tickets are handled by Configuration Manager. Tickets are created in Configuration Manager and are referenced in Image Update jobs.

**Step 3** Optionally, you can find and select a single job about which more information is then displayed in the lower pane. This includes:

- Summary
- Details
- History
Tip While viewing the lower pane Details tab, you can select a device and then view a log of the job in the lower right pane.

Note These are dockable windows. You can customize the default view.

Viewing Install Jobs

You can view the details associated with a particular Image Management job.

To view the details associated with a job, do the following:

Step 1 In the selector, under Jobs, click Install Jobs.

Tip The Status column in the Jobs selector indicates whether a job is Submitted, Approved, Deployed, In Progress, or Failed.

The main window displays the Jobs list in the upper pane.

Step 2 Select a job to examine.

Tip To find a particular job, you can sort the Jobs list by any of the column headings, including Name, Last Action (chronology), Status (e.g., Deployed, Failed), Description, and so forth. You can also find a particular job by using the search window to enter a filtering string.

Note The location of the jobs folder is CSM-ROOT\files\vms\jobs directory.

Step 3 Examine job summary information by clicking Summary in the lower pane.

The lower pane displays job summary information including Image Management Job Name, Devices to be Deployed, Devices Deployed Successfully, and Devices Deployed with Errors.

Step 4 Examine job summary details by clicking Details in the lower pane.

Details of the Devices, New Image, Old Image, and the device status are displayed.

Step 5 Examine the Commentary on the devices in the job by clicking the vertical Commentary tab on the far right. This shows the progress of the image install operation on the device.

Step 6 Examine the Transcript of the devices in the job by clicking the vertical Transcript tab on the far right. This shows the chronology of the commands executed on the device and their responses.

Step 7 Examine job history details by clicking History in the lower pane. This shows the history of the transition in the job state.
Aborting an Image Installation Job

You can abort an image installation job by clicking \textbf{Abort} from the Jobs page. This option is effective only for multi-device jobs:

\begin{itemize}
  \item If the Sequential option is selected, then all the devices on which the job has not yet started will be aborted.
  \item If Parallel is selected, then all the devices till that batch will undergo image upgrade. All devices from the next batch onwards will be aborted.
\end{itemize}

\textbf{Note} If the job involves a single device, then Abort will have no effect after the job begins and the job will always run to completion.

Retry a Failed Image Install Job

If your attempts to deploy an image to one or more devices fails, you can retry the job. However, you should retry the entire job and not attempt to simply continue from a failed step.

To retry a failed job, do the following:

\begin{enumerate}
  \item To determine that an installation job has failed, go to the Jobs section in the selector and click \textbf{Install Jobs}.
  \item Determine the status of the job in question by examining the Status column.
  \begin{itemize}
    \item A green check icon with the word Deployed indicates success. A red X icon indicates failure.
  \end{itemize}
  \item Investigate possible reasons for job failure.
  \item Select the failed image install job from the job list and click \textbf{Retry} from the toolbar atop the upper pane.
  \item As required, you can change the images, devices, schedule, or job properties to be used.
  \item From within the Install Images on Devices window click \textbf{Install}.
  \item Determine that the retried attempt is successful by observing the newly created job.
\end{enumerate}
Roll Back a Deployed Job

You can roll back the changes from a deployed image installation job.

To roll back a Deployed job, do the following:

**Step 1**

From the job list, select the image install job to be rolled back and click **Rollback** from the toolbar atop the upper pane.

The Install Images on Devices window appears. You can observe the validation warnings as you would in a normal install job.

**Step 2**

As required, you can change the images, devices, schedule, or job properties to be used in the rollback.

**Step 3**

From within the Install Images on Devices window click **Install**.

**Step 4**

Determine that the rollback attempt is successful by monitoring the newly created job.

Image Installation Job Approval Workflow

Image update is a critical operation that has the potential to cause downtime for devices and your network. Hence, change control and management for image install operations is crucial. Change management for image installation jobs is done using the Deployment Workflow framework of Configuration Manager. This ensures that all image installation jobs need to be approved before getting executed or deployed.

To use workflow with image installation jobs, do the following:

**Step 1**

Enable workflow for image installation jobs:

a. In Configuration Manager, select **Tools > Security Manager Administration > Workflow**.

b. If workflow is not already enabled, select **Enable Workflow**.

c. Select **Require Deployment & Install Image Approval**.

d. Configure the email address of the person responsible for approving the image installation job in the Job/Schedule Approver field. For more information, see Workflow Page, page 11-48.

e. Click **Save** and then **Close**.

f. Launch Image Manager and navigate to **Install Jobs**. Notice the new buttons available in the Menu bar for job state transitions in workflow mode: Submit, Approve, Reject, and Deploy.

**Step 2**

To create and execute an image installation job with workflow enabled:

a. Use any of the previously documented procedures to create an image installation job. See About Image Updates on Devices Using Image Manager, page 69-16.

Note

There is an additional option in the Properties tab to Submit the Job. Check this option to automatically submit the job for approval after creation of the job.

b. Once the image installation job is created, note the state of the job in the Image Install Jobs View.

c. Select the job and click **Submit** to submit the job for approval if automatic submit option was not selected while creating the job.
The job Approver (user with Approver role/privileges) receives an email notification to approve the job.

d. The Approver can log in to Security Manager, launch Image Manager, and navigate to the job.

e. The Approver clicks Approve to approve the job after reviewing the details of the upgrade, that is, image being upgraded to, job properties, schedule, and so on.

Job state is changed to Approved. The creator of the job receives an email that the job has been approved. Now the job can be deployed.

f. If the Approver is not convinced after reviewing the job details, he can choose to reject the job by clicking Reject.

The job state is moved to Rejected. The creator of the job receives an email that job has been rejected. A rejected job will not be deployed.

Note A rejected job will not be deployed. It can be edited and resubmitted for approval or it has to be discarded.

g. Once the job is approved, the job can be deployed by clicking Deploy.

The job state is changed to Deploying and image install job execution is started.

h. If the job is rejected or any other changes are required to be made for a job, the job can be edited by clicking Edit.

The Image Assignments page of the wizard showing all the devices and images is displayed. The user can modify the Job Properties, schedule and even delete some device-to-image assignments and submit the job for approval again by clicking Submit.

i. If a job has not started executing, then the user can dismiss the job by clicking Discard.

The job is moved to Discarded state. A discarded job does not execute and cannot be edited or moved to any other state.

j. If the changed job is acceptable to the approver, he can approve the job this time and the job can be deployed as mentioned above.

k. Once the deploying job completes execution it will be moved to Deployed state if the image installation is successful or it will be moved to Failed state if the image installation operation fails.

**Troubleshooting Image Management**

This section addresses steps you can take to troubleshoot Image Management in response to particular symptoms.

**No data for devices in Image Manager, after Security Manager upgrade.** Any one of the following operations that first contacts the device will collect the image inventory for the device:

- Rediscover the device choosing to discover only Device Inventory
- Perform a live deployment to device
- Perform an Image Install operation to the device

**Image Download from Cisco.com Fails**

- Go to Configuration Manager > Tools > Security Manager Administration.
Troubleshooting Image Management

- Select Image Manager.
- Click Test Connection to ensure the server is reachable.
- Check %NMSROOT%/MDC/athena/config/****-CCOMetaData.xml for error in downloading metadata information for particular MDF IDs.

Image Download from Cisco.com Fails with Message: "User not authorized to download file"
- Go to Configuration Manager > Tools > Security Manager Administration.
- Select Image Manager.
- Click Test Connection to ensure the server is reachable.
- Register your acceptance of the Cisco Encryption Software Usage Handling and Distribution Policy.

Tip
The policy is found at: http://tools.cisco.com/legal/k9/controller/do/k9Check.x?eind=Y.

Image Download from Cisco.com is Slow
- Ensure proxy is configured
- Trace route from Security Manager to Cisco.com

Check for Updates Fails
Go to the Security Manager administrative settings page and test connectivity to Cisco.com. Check %NMSROOT%/MDC/athena/config/****-CCOMetaData.xml for an error in downloading metadata information for particular MDF IDs.

Image Download from External File System or Network Fileshare Fails
- Check that you have proper permissions/credentials for the external file system or fileshare.
- Open the fileshare on the client, drag the image and drop it on Image Manager.

Image Copy Failure –"HTTP 413 Error"
- Right-click Device in Image Manager > Test File Copy To Device
- Check Error Message in vmssharedsvcs.log
- If you encounter an HTTP 413 error, split the job to contain a smaller number of images in one job

Image Copy Failure –"Not enough space on disk"
- Check Device > Storage View for files on device and free space in the Image Install Location.
- If Device > Storage View shows files, then delete files from Storage to make space and retry.
- If Device > Storage View does not show files, either because it is a greenfield device or it is a Security Manager upgrade setup, rediscover only the device inventory on the device and then delete files from Storage view to make space.

Image Install Job failure –Error: "Invalid flash device"
- Check if flash exists on the device:
  - Right-click on device in IM > Test File Copy to Device
– Connect to device, and check whether it is a multiple-context device that is being managed as a single context device in Security Manager
– Rediscover the device selecting to discover System Context. Then, retry the image install job.

**Image Upgrade Job on Active/Standby pair fails**

- Error: "This host is not the 'active' device in the failover pair" - Ensure that the failover pair is managed in Security Manager via the IP address of the active device in the failover pair and not the IP address of the standby device.
- Error: "Secondary device is not in standby-ready state" - Ensure that the devices in the failover pair are up and the standby device is in standby-ready state. Job will abort if standby device is in failed state

**Image Install Job failure –Error: "SWIM1114: Device could not be reached after upgrade"**

- Manually check if device is reachable. Solution: After image upgrade, device has to be re-added in Security Manager or change the Admin option to "Do not check certificate authentication"
- Check whether Tools > Admin > Device Communication > SSL Certificate Parameters > PIX/ASA/FWSM Device Authentication Certificates is set to "Retrieve while adding devices."
- After image upgrade, ensure the device has re-added in Security Manager. Otherwise, change the Admin option to "Do not check certificate authentication."
