To open the Network Information policy, do one of the following:

- (Device view) Select **IPS > Event Actions > Network Information** from the Policy selector.
- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Network Information**, then select an existing policy or create a new one.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Network Information**, then select an existing policy or create a new one.

Configuring Target Value Ratings

You can assign target value ratings to your network assets. The target value rating is one of the factors used to calculate the risk rating value for each alert. It identifies the perceived importance of a network asset, which you identify by its IP address.

You can develop a security policy that is more stringent for valuable corporate resources and looser for less important resources. For example, you could assign a target value rating to the company web server that is higher than the target value rating you assign to a desktop node. In this example, attacks against the company web server have a higher risk rating than attacks against the desktop node. Events with a higher risk rating trigger more severe signature event actions.

You can configure four value ratings. From highest value to lowest: Mission Critical, High, Medium, Low, No Value (zero value).

For a detailed explanation of how risk rating is calculated, see Calculating the Risk Rating in *Installing and Using Cisco Intrusion Prevention System Device Manager 7.0* on Cisco.com.

Tip If you are configuring target value ratings on a device that uses IPS 6.0 software lower than 6.0(5), you might also want to update the OS Identification tab of the Network Information policy to get around a software bug, even if you do not need to create OS maps. For detailed information, see Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only) , on page 1731.

Related Topics

- Configuring IPS Event Action Network Information , on page 1727
- Understanding the IPS Event Action Process , on page 1711

Step 1 Do one of the following to open the Network Information policy:

- (Device view) Select **IPS > Event Actions > Network Information** from the Policy selector, then click the **IPv4 Target Value Ratings** tab or the **IPv6 Target Value Ratings** tab.
- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Network Information**, then select an existing policy or create a new one. Click the **IPv4 Target Value Ratings** tab or the **IPv6 Target Value Ratings** tab.
- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Network Information**, then select an existing policy or create a new one. Click the **IPv4 Target Value Ratings** tab.

Note Cisco IOS IPS devices do not support IPv6.

The tab shows the target value ratings that are already configured, showing the IP addresses associated with each configured ratings category. The table can have at most five entries, one per rating category.

Step 2 Configure the desired target value ratings categories:

- To add a new ratings category, click the **Add Row (+)** button beneath the table and fill in the Add Target Value Rating dialog box. In the dialog box, select the rating you want to add, enter the host, network, and address ranges to associate with the category, and click **OK**. For more information, see Target Value Rating Dialog Box , on page 1729.

For IPv4 addresses, you can specify a single network/host object, or a comma-separated list of host, network, or address ranges, such as 10.10.10.10, 10.10.10.0/24, or 10.10.10.2-10.10.10.254. Addresses that you enter in the network format are converted to address ranges. For IPv6 addresses, use IPv6 addressing conventions.

- To edit the IP addresses in an existing ratings category, select the category and click the **Edit Row (pencil)** button. You cannot change the value rating.
- To remove a rating, select it and click the **Delete Row** button.

Target Value Rating Dialog Box

Use the Add or Edit Target Value Rating dialog box to associate the IP addresses of your assets to a ratings category. IP addresses are IPv4 when you open the Target Value Rating dialog box from the IPv4 Target Value Ratings tab; they are IPv6 from the IPv6 tab.

Navigation Path

From the IPv4 Target Value Rating tab or the IPv6 Target Value Rating tab of the IPS Event Actions Network Information policy, click the **Add Row** button beneath the Target Value Ratings table, or select a row in the table and click the **Edit Row** button. For information on opening the IPv4 Target Value Rating tab or the IPv6 Target Value Rating tab, see Configuring Target Value Ratings , on page 1728.

Field Reference

Table 533: Target Value Rating Dialog Box

Element	Description
Value	The target value rating to associate with the specified addresses. From highest to lowest importance: Mission Critical, High, Medium, Low, No Value. This list includes only those value ratings that you have not already configured in the target value ratings table. You change this option when editing a ratings category.
target-address	The IP addresses of the network assets assigned to this value rating. You can specify addresses using the following techniques: • Enter the name of a single network/host object, or click **Select** to select an object from a list or to create a new one. The object can contain a group of networks, hosts, and address ranges. • A comma-separated list of host or network addresses or address ranges. For example, using IPv4, 10.10.10.0/24, 10.10.10.10, 10.10.10.2-10.10.10.254. Addresses that you enter in the network format are converted to address ranges; for example, 10.10.10.0/24 is converted to 10.10.10.0-10.10.10.255.

Understanding Passive OS Fingerprinting

Passive operating system (OS) fingerprinting is enabled by default on IPS 6.0+ sensors and the IPS contains a default vulnerable OS list for each signature.

Passive OS fingerprinting lets the sensor determine the OS that hosts are running. The sensor analyzes network traffic between hosts and stores the OS of these hosts with their IP addresses. The sensor inspects TCP SYN and SYNACK packets exchanged on the network to determine the OS type.

The sensor then uses the OS of the target host OS to determine the relevance of the attack to the victim by computing the attack relevance rating component of the risk rating. Based on the relevance of the attack, the sensor may alter the risk rating of the alert for the attack or the sensor may filter the alert for the attack. You can then use the risk rating to reduce the number of false positive alerts (a benefit in IDS mode) or definitively drop suspicious packets (a benefit in IPS mode). Passive OS fingerprinting also enhances the alert output by reporting the victim OS, the source of the OS identification, and the relevance to the victim OS in the alert.

Passive OS fingerprinting consists of three components:

- Passive OS learning.

Passive OS learning occurs as the sensor observes traffic on the network. Based on the characteristics of TCP SYN and SYNACK packets, the sensor makes a determination of the OS running on the host of the source IP address.

- User-configurable OS identification.

You can configure OS host mappings, which take precedence over learned OS mappings.

- Computation of attack relevance rating and risk rating.

The sensor uses OS information to determine the relevance of the attack signature to the targeted host. The attack relevance is the attack relevance rating component of the risk rating value for the attack alert.

There are three sources of OS information. The sensor ranks the sources of OS information in the following order:

1. Configured OS mappings—OS mappings that you enter on the OS Identification tab of the Event Actions Network Information policy. You can configure different mappings for each virtual sensor. For more information, see Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only) , on page 1731.

   We recommend configuring OS mappings to define the identity of the OS running on critical systems. It is best to configure OS mappings when the OS and IP address of the critical systems are unlikely to change.

2. Imported OS mappings—OS mappings imported from Management Center for Cisco Security Agents (CSA MC).

   Imported OS mappings are global and apply to all virtual sensors. For information on configuring the sensor to use CSA MC, see Configuring the External Product Interface , on page 1640.

3. Learned OS mappings—OS mappings observed by the sensor through the fingerprinting of TCP packets with the SYN control bit set.

   Learned OS mappings are local to the virtual sensor that sees the traffic.

When the sensor needs to determine the OS for a target IP address, it consults the configured OS mappings. If the target IP address is not in the configured OS mappings, the sensor looks in the imported OS mappings.

If the target IP address is not in the imported OS mappings, the sensor looks in the learned OS mappings. If it cannot find it there, the sensor treats the OS of the target IP address as unknown.

Tip You can configure Event Action Filter rules to use the OS relevancy value of the target, and configure signatures to identify the OSes vulnerable to a signature.

Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only)

Use the OS Identification tab on the Event Actions Network Information policy to configure operating system (OS) host mappings, which take precedence over learned OS mappings. On the OS Identifications tab you can add, edit, and delete configured OS maps. You can move them up and down in the list to change the order in which the sensor computes the attack relevance rating and risk rating for that particular IP address and OS type combination.

Note OS Identification applies to IPS 6.0+ sensors only and does not apply to Cisco IOS IPS devices.

You can also move them up and down in the list to change the order in which the sensor resolves the OS associated with a particular IP address. Configured OS mappings allow for ranges, so for network 192.168.1.0/24 you might define the following:

IP Address Range Set	OS
192.168.1.1	IOS
192.168.1.2-192.168.1.10,192.168.1.25	UNIX
192.168.1.1-192.168.1.255	Windows

More specific mappings should be at the beginning of the list. Overlap in the IP address range sets is allowed, but the entry closest to the beginning of the list takes precedence.

Tip There is a bug in IPS 6.0 versions lower than 6.0(5) related to the Network Information policy. Even if you change nothing on the OS Identification tab, but you make configuration changes to the Threat Value Ratings tab, Security Manager configures the device to use the **any** variable for restricting OS mappings to addresses. This can result in your monitoring application showing “any” as the event locality for all events. The solution is to upgrade the IPS version on your sensor. The workaround is to enter a non-default value in the **Restrict to these IP Addresses** field on the OS Identification tab, even if you are not configuring specific OS mappings. For example, enter 0.0.0.1-255.255.255.255 instead of “any” or 0.0.0.0-255.255.255.255.

Navigation Path

- (Device view) Select **IPS > Event Actions > Network Information** from the Policy selector, then click the **OS Identification** tab.

- (Policy view, IPS appliances and service modules) Select **IPS > Event Actions > Network Information**, then select an existing policy or create a new one. Click the **OS Identification** tab.

Related Topics

- Configuring IPS Event Action Network Information , on page 1727
- Understanding the IPS Event Action Process , on page 1711

Field Reference

Table 534: OS Identification Tab

Element	Description
Enable Passive OS Fingerprinting	When selected, lets the sensor perform passive OS analysis. You must enable this option for any of the maps configured on this page to be used. Passive OS fingerprinting functions as part of the sensor. As the sensor analyzes network traffic between hosts, the sensor stores the identity of the OS running on the hosts alongside the IP addresses of the hosts. The sensor determines the identity of the OSes on the hosts by inspecting characteristics of the packets exchanged on the network. The sensor then uses the target system's OS information to compute the ARR (Attack Relevance Rating) component for the RR (Risk Rating). The RR can then be used to drop suspicious packets. For more information about passive OS fingerprinting, see Understanding Passive OS Fingerprinting , on page 1730.
Restricted to these IP Addresses	Restricts attack relevance rating calculation to the specified addresses. You can specify addresses using the following techniques: • Enter the name of a single network/host object, or click **Select** to select an object from a list or to create a new one. The object can contain a group of networks, hosts, and address ranges. • A comma-separated list of host or network addresses or address ranges. For example, 10.10.10.0/24, 10.10.10.10, 10.10.10.2-10.10.10.254.
OS Maps table	The list of OS mappings, showing the IP addresses of the hosts and the operating systems to which they are mapped. When looking for a match, the sensor goes from top to bottom and selects the first rule that matches the IP address. • To add a mapping, click the **Add Row** button and fill in the Add OS Map dialog box (see OS Map Dialog Box , on page 1733). • To edit a mapping, select the rule and click the **Edit Row** button. • To delete a map, select it and click the **Delete Row** button. • To change the priority of a rule, select it and click the **Up** or **Down** arrow buttons until the rule is positioned correctly.

OS Map Dialog Box

Use the Add or Edit OS Map dialog box to map a host through its IP address to an OS type. Create mappings only if you want to statically assign an OS type to an IP address. Because the sensor uses passive OS fingerprinting to discover the OS associated with an IP address, you might not want to create any mappings, or create mappings only for mission-critical devices that have static IP addresses. Update any mappings that you create if you install devices with different operating systems on the address.

Navigation Path

From the OS Identification tab of the IPS Event Actions Network Information policy, click the **Add Row** button beneath the OS Maps table, or select a row in the table and click the **Edit Row** button. For information on opening the OS Identification tab, see Configuring OS Identification (Cisco IPS 6.x and Later Sensors Only) , on page 1731.

Field Reference

Table 535: OS Map Dialog Box

Element	Description
IP Addresses	The IP addresses for this mapping. You can specify addresses using the following techniques: • Enter the name of a single network/host object, or click **Select** to select an object from a list or to create a new one. The object can contain a group of networks, hosts, and address ranges. • A comma-separated list of host or network addresses or address ranges. For example, 10.10.10.0/24, 10.10.10.10, 10.10.10.2-10.10.10.254.
OS Type	The operating system running on the identified hosts. Select the most appropriate option from the list. You can select multiple options (using Ctrl+click) to indicate that there is more than one possible OS. **Tip** Because these mappings take precedence over learned mappings, you probably are better off not assigning General OS, Other, or Unknown OS. The sensor might be able to learn the actual OS through passive OS fingerprinting and provide a better matching. For more information, see Understanding Passive OS Fingerprinting , on page 1730.

Configuring Settings for Event Actions

Use the Event Actions Settings policy to configure general settings that apply globally to event action rules. The defaults for these options are appropriate for most situations, so change them only if you are certain that your situation requires non-default behavior.

To configure the Event Actions Settings policy, do one of the following:

- (Device view) Select **IPS** > **Event Actions** > **Settings** from the Policy selector.
- (Policy view, IPS appliances and service modules) Select **IPS** > **Event Actions** > **Settings**, then select an existing policy or create a new one.

- (Policy view, Cisco IOS IPS devices) Select **IPS (Router) > Event Actions > Event Action Settings**, then select an existing policy or create a new one.

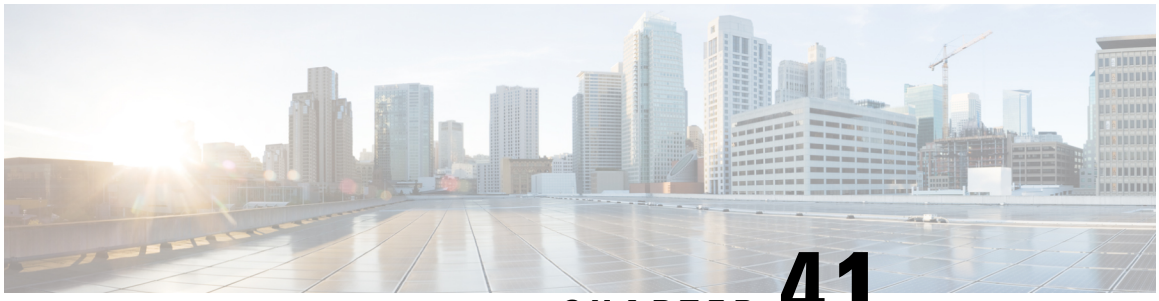
The following table describes the options you can configure. Note that the options available for Cisco IOS IPS devices are more limited than those available for IPS appliances and service modules.

Tip Do not disable the Summarizer except for troubleshooting purposes. If you disable the Summarizer, every signature is set to Fire All with no summarization. Note that you do not need to change the state of the Meta Event Generator. Cisco has discontinued the use of Meta signatures, and they have all been retired.

Table 536: Event Actions Settings Policy

Element	Description
Enable Event Action Override (All device types.)	When selected, enables override rules as defined on the Event Action Overrides page. You can add an event action override to add actions to an event based on specific details about that event. For configuring override rules, see Configuring Event Action Overrides , on page 1722.
Enable Event Action Filters (All device types.)	When selected, enables the filter rules as defined on the Event Action Filters page. You can configure event action filters to remove specific actions from an event or to discard an entire event and prevent further processing by the sensor. For configuring event action filters rules, see Configuring Event Action Filters , on page 1714.
Enable Event Action Summarizer (IPS appliances and service modules only.)	When selected, enables the Summarizer component. The Summarizer groups events into a single alert, thus decreasing the number of alerts the sensor sends out. By default, the Summarizer is enabled. If you disable it, all signatures are set to Fire All with no summarization. If you configure individual signatures to summarize, this configuration is ignored when the Summarizer is not enabled. The Report Manager component of Cisco Security Manager reports events individually. The Event Viewer component of Cisco Security Manager displays alerts. As stated above, the Summarizer groups events into a single alert, thus decreasing the number of alerts the sensor sends out. **Tip** Cisco IPS Manager Express (IME) and Cisco Security Manager do not summarize events in precisely the same way.
Enable Meta Event Generator (IPS appliances and service modules only.)	Cisco recommends that you do not change the state of the Meta Event Generator. Cisco has discontinued the use of Meta signatures, and they have all been retired.

Element	Description
Enable Threat Rating Adjustment (IPS appliances and service modules only.)	When selected, enables threat rating adjustment, which adjusts the risk rating. If disabled, risk rating is equal to threat rating. Available in sensors running IPS 6.0+ software only. The Threat Rating feature provides a single view of the threat environment of the network. Threat Rating minimizes alarms and events through a customized view that shows only events with a high Threat Rating value. The Threat Rating value is derived as follows: • Dynamic adjustment of event Risk Rating based on success of response action • If response action was applied, Risk Rating is deprecated (Threat Rating < Risk Rating) • If response action was not applied, Risk Rating remains unchanged (Threat Rating = Risk Rating) The result is a single value by which the threat risk is determined.
Deny Attacker Duration in seconds (All device types.)	The number of seconds to deny the attacker inline. The range is 0 to 518400. The default is 3600.
Block Attack Duration in minutes (IPS appliances and service modules only.)	The number of minutes to block a host or connection. The range is 0 to 10000000. The default is 30.
Maximum Number of Denied Attackers (IPS appliances and service modules only.)	Limits the number of denied attackers possible in the system at any one time. The range is 0 to 100000000. The default is 10000.
Enable One Way TCP Reset (IPS appliances and service modules only.)	When selected, enables a one-way TCP reset for deny packet inline actions for TCP-based alerts. Available only for sensors running IPS 6.1+ software. The one-way TCP reset operates for inline mode only and is an automatic addition to the deny packet inline actions. It sends a TCP reset to the victim of the alert, thus creating a black hole for the attacker and clearing the TCP resources of the victim. **Tips** • In inline mode, all packets entering or leaving the network must pass through the sensor. • An inline sensor denies packets for any alert with a risk rating of greater than or equal to 90. It also issues a one-way TCP reset on TCP alerts with a risk rating of greater than or equal to 90.



CHAPTER 41

Managing IPS Anomaly Detection

Note From 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any enhancements as IPS is now End of Life. For more information, see EOL notice.

Anomaly detection is designed to recognize network congestion caused by worm traffic that exhibits scanning behavior. Anomaly detection also will identify infected hosts on the network that are scanning for other vulnerable hosts.

Anomaly detection is enabled by default, but there are some configuration settings you should adjust to use it effectively.

Note The sensor must use IPS software version 6.x or later to configure anomaly detection. In addition, Cisco IOS IPS and the AIP-SSC-5 do not support anomaly detection.

This chapter contains the following topics:

Understanding Anomaly Detection

The anomaly detection component of the sensor detects worm-infected hosts. This enables the sensor to be less dependent on signature updates for protection again worms and scanners, such as Code Red and SQL Slammer and so forth. The anomaly detection component lets the sensor learn normal activity and send alerts or take dynamic response actions for behavior that deviates from what it has learned as normal behavior.

Note Anomaly detection does not detect email-based worms, such as Nimda.

Anomaly detection detects the following two situations:

- When the network starts on the path of becoming congested by worm traffic.
- When a single worm-infected source enters the network and starts scanning for other vulnerable hosts.

The following topics explain anomaly detection in more detail:

Worm Viruses

Worm viruses are automated, self-propagating, intrusion agents that make copies of themselves and then facilitate their spread. Worm viruses attack a vulnerable host, infect it, and then use it as a base to attack other vulnerable hosts. They search for other hosts by using a form of network inspection, typically a scan, and then propagate to the next target. A scanning worm virus locates vulnerable hosts by generating a list of IP addresses to probe, and then contacts the hosts. Code Red worm, Sasser worm, Blaster worm, and the Slammer worm are examples of worms that spread in this manner.

Anomaly detection identifies worm-infected hosts by their behavior as a scanner. To spread, a worm virus must find new hosts. It finds them by scanning the Internet using TCP, UDP, and other protocols to generate unsuccessful attempts to access different destination IP addresses. A scanner is defined as a source IP address that generates events on the same destination port (in TCP and UDP) for too many destination IP addresses.

The events that are important for TCP are non-established connections, such as a SYN packet that does not have its SYN-ACK response for a given amount of time. A worm-infected host that scans using TCP generates non-established connections on the same destination port for an anomalous number of IP addresses.

The events that are important for UDP are unidirectional connections, such as a UDP connection where all packets are going in only one direction. A worm-infected host that scans using UDP generates UDP packets but does not receive UDP packets on the same IP address within a time-out period on the same destination port for multiple destination IP addresses.

The events that are important for other protocols, such as ICMP (protocol number 1), are from a source IP address to many different destination IP addresses, that is, packets that are received in only one direction.

Caution If a worm virus has a list of IP addresses it should infect and does not have to use scanning to spread itself (for example, it uses passive mapping—listening to the network as opposed to active scanning), it will not be detected by anomaly detection worm policies. Worm viruses that receive a mailing list from probing files within the infected host and email this list will not be detected, because no Layer 3 or Layer 4 anomaly is generated.

Anomaly Detection Modes

Anomaly detection initially conducts a “peacetime” learning process when the most normal state of the network is reflected. Anomaly detection then derives a set of policy thresholds that best fit the normal network. This is done in two phases: an initial learning mode phase, followed by the ongoing operational detect mode phase.

Anomaly detection has the following modes:

- Learning accept mode (initial setup)

Although anomaly detection is in detect mode by default, it conducts an initial learning accept mode for the default period of 24 hours. We assume that during this phase no attack is being carried out. Anomaly detection creates an initial baseline, known as a knowledge base, of the network traffic. The default interval value for periodic schedules is 24 hours and the default action is rotate, meaning that a new knowledge base is saved and loaded, and then replaces the initial knowledge base after 24 hours.

Keep the following in mind:

- Anomaly detection does not detect attacks when working with the initial knowledge base, which is empty. After the default of 24 hours, a knowledge base is saved and loaded and now anomaly detection also detects attacks.
- Depending on your network complexity, you may want to have anomaly detection in learning accept mode for longer than the default 24 hours. You configure the mode in the Virtual Sensors policy; see Defining A Virtual Sensor , on page 1669. After your learning period has finished, edit the virtual sensor and change the mode to Detect.

- Detect mode

For ongoing operation, the sensor should remain in detect mode. This is for 24 hours a day, 7 days a week. Once a knowledge base is created and replaces the initial knowledge base, anomaly detection detects attacks based on it. It looks at the network traffic flows that violate thresholds in the knowledge base and sends alerts. As anomaly detection looks for anomalies, it also records gradual changes to the knowledge base that do not violate the thresholds and thus creates a new knowledge base. The new knowledge base is periodically saved and takes the place of the old one thus maintaining an up-to-date knowledge base.

- Inactive mode

You can turn anomaly detection off by putting it in inactive mode. Under certain circumstances, anomaly detection should be in inactive mode, for example, if the sensor is running in an asymmetric environment. Because anomaly detection assumes it gets traffic from both directions, if the sensor is configured to see only one direction of traffic, anomaly detection identifies all traffic as having incomplete connections, that is, as scanners, and sends alerts for all traffic flows.

The following example summarizes the default anomaly detection configuration. If you add a virtual sensor at 11:00 pm and do not change the default anomaly detection configuration, anomaly detection begins working with the initial knowledge base and only performs learning. Although it is in detect mode, it cannot detect attacks until it has gathered information for 24 hours and replaced the initial knowledge base. At the first start time (10:00 am by default), and the first interval (24 hours by default), the learning results are saved to a new knowledge base and this knowledge base is loaded and replaces the initial knowledge base. Because the anomaly detection is in detect mode by default, now that anomaly detection has a new knowledge base, the anomaly detection begins to detect attacks.

Anomaly Detection Zones

By subdividing the network into zones, you can achieve a lower false negative rate. A zone is a set of destination IP addresses. There are three zones, each with its own thresholds: internal, illegal, and external.

The external zone is the default zone with the default Internet range of 0.0.0.0-255.255.255.255. By default, the internal and illegal zones contain no IP addresses. Packets that do not match the set of IP addresses in the internal or illegal zone are handled by the external zone.

We recommend that you configure the internal zone with the IP address range of your internal network. If you configure it in this way, the internal zone is all the traffic that comes to your IP address range, and the external zone is all the traffic that goes to the Internet.

You can configure the illegal zone with IP address ranges that should never be seen in normal traffic, for example, unallocated IP addresses or part of your internal IP address range that is unoccupied. An illegal zone can be very helpful for accurate detection, because we do not expect any legal traffic to reach this zone. This allows very low thresholds, which in turn can lead to very quick worm virus detection.

Knowing When to Turn Off Anomaly Detection

Anomaly detection assumes that it gets traffic from both directions. If the sensor is configured to see only one direction of traffic, you should turn off anomaly detection. Otherwise, when anomaly detection is running in an asymmetric environment, it identifies all traffic as having incomplete connections, that is, as scanners, and sends alerts for all traffic flows.

You turn off anomaly detection in the Virtual Sensors policy. Edit the virtual sensor for which you are disabling anomaly detection, and change the Anomaly Detection Mode to Inactive. For information on editing virtual sensors, see Editing Policies for a Virtual Sensor , on page 1673.

Configuring Anomaly Detection Signatures

The Traffic Anomaly engine contains nine anomaly detection signatures covering three protocols (TCP, UDP, and other). Each signature has two subsignatures, one for the scanner and the other for the worm-infected host (or a scanner under worm attack). When anomaly detection discovers an anomaly, it triggers an alert for these signatures. All anomaly detection signatures are enabled by default and the alert severity for each one is set to high.

When a scanner is detected but no histogram anomaly occurred, the scanner signature fires for that attacker (scanner) IP address. If the histogram signature is triggered, the attacker addresses that are doing the scanning each trigger the worm signature (instead of the scanner signature). The alert details state which threshold is being used for the worm detection now that the histogram has been triggered. From that point on, all scanners are detected as worm-infected hosts.

The following anomaly detection event actions are possible:

- Produce alert—Writes the event to the Event Store.
- Deny attacker inline—(Inline only) Does not transmit this packet and future packets originating from the attacker address for a specified period of time.
- Log attacker packets—Starts IP logging for packets that contain the attacker address.
- Deny attacker service pair inline—Blocks the source IP address and the destination port.
- Request SNMP trap—Sends a trap notification to an SNMP trap destination. To use this action, you must configure SNMP trap hosts as described in Configuring SNMP , on page 1621.
- Request block host—Sends a request to ARC to block this host (the attacker). To use this action, you must configure blocking devices as described in Configuring IPS Blocking and Rate Limiting , on page 1765.

You can add actions to the signatures either directly, in the Signatures policy, or to events generated by the signatures based on risk rating in the Event Actions Overrides policy.

The following table lists the anomaly detection worm signatures.

Table 537: Anomaly Detection Worm Signatures

Signature ID	Subsignature ID	Name	Description
13000	0	Internal TCP Scanner	Identified a single scanner over a TCP protocol in the internal zone.
13000	1	Internal TCP Scanner	Identified a worm attack over a TCP protocol in the internal zone; the TCP histogram threshold was crossed and a scanner over a TCP protocol was identified.
13001	0	Internal UDP Scanner	Identified a single scanner over a UDP protocol in the internal zone.
13001	1	Internal UDP Scanner	Identified a worm attack over a UDP protocol in the internal zone; the UDP histogram threshold was crossed and a scanner over a UDP protocol was identified.
13002	0	Internal Other Scanner	Identified a single scanner over an Other protocol in the internal zone.
13002	1	Internal Other Scanner	Identified a worm attack over an Other protocol in the internal zone; the Other histogram threshold was crossed and a scanner over an Other protocol was identified.
13003	0	External TCP Scanner	Identified a single scanner over a TCP protocol in the external zone.
13003	1	External TCP Scanner	Identified a worm attack over a TCP protocol in the external zone; the TCP histogram threshold was crossed and a scanner over a TCP protocol was identified.
13004	0	External UDP Scanner	Identified a single scanner over a UDP protocol in the external zone.
13004	1	External UDP Scanner	Identified a worm attack over a UDP protocol in the external zone; the UDP histogram threshold was crossed and a scanner over a UDP protocol was identified.
13005	0	External Other Scanner	Identified a single scanner over an Other protocol in the external zone.
13005	1	External Other Scanner	Identified a worm attack over an Other protocol in the external zone; the Other histogram threshold was crossed and a scanner over an Other protocol was identified.
13006	0	Illegal TCP Scanner	Identified a single scanner over a TCP protocol in the illegal zone.

Signature ID	Subsignature ID	Name	Description
13006	1	Illegal TCP Scanner	Identified a worm attack over a TCP protocol in the illegal zone; the TCP histogram threshold was crossed and a scanner over a TCP protocol was identified.
13007	0	Illegal UDP Scanner	Identified a single scanner over a UDP protocol in the illegal zone.
13007	1	Illegal UDP Scanner	Identified a worm attack over a UDP protocol in the illegal zone; the UDP histogram threshold was crossed and a scanner over a UDP protocol was identified.
13008	0	Illegal Other Scanner	Identified a single scanner over an Other protocol in the illegal zone.
13008	1	Illegal Other Scanner	Identified a worm attack over an Other protocol in the illegal zone; the Other histogram threshold was crossed and a scanner over an Other protocol was identified.

Configuring Anomaly Detection

Use the Anomaly Detection policy to configure anomaly detection settings. The Virtual Sensors policy also contains a setting important for anomaly detection.

This procedure explains the overall configuration of anomaly detection. Before configuring these settings, read the following topics:

- Understanding Anomaly Detection , on page 1737
- Worm Viruses , on page 1738
- Anomaly Detection Modes , on page 1738
- Anomaly Detection Zones , on page 1739
- Knowing When to Turn Off Anomaly Detection , on page 1740
- Configuring Anomaly Detection Signatures , on page 1740

Step 1 Do one of the following to open the Anomaly Detection policy you want to modify:

- (Device view) Select **IPS** > **Anomaly Detection** from the Policy selector.
- (Policy view) Select **IPS** > **Anomaly Detection** from the Policy selector. Select an existing policy or create a new one.

The Anomaly detection policy includes these tabs:

- **Operation Settings**—Defines the worm timeout and identifies any IP addresses that should be ignored by anomaly detection.
- **Learning Accept Mode**—The configuration for learning mode, including how the knowledge base is handled.

- **Internal Zone, Illegal Zone, External Zone**—The zones of your network that you define. You can configure unique settings for each zone. For an explanation of the zones, see Anomaly Detection Zones , on page 1739.

Step 2 Click the **Operation Settings** tab, if necessary, and configure the following:

- **Worm Timeout**—The time in seconds for the worm termination timeout. The range is 120 to 10,000,000 seconds. The default is 600 seconds. For an explanation of how this timeout is used, see Understanding Anomaly Detection Thresholds and Histograms , on page 1746.
- **Enable Ignored Addresses** and **Source/Destination Addresses to Ignore**—Whether you are configuring a list of addresses that should be ignored while anomaly detection is processing. You can specify a list of source addresses (those that initiate a scan) or destination addresses (the hosts that are scanned).

The addresses can be single host (such as 10.100.10.1), a range of addresses (such as 10.100.10.0-10.100.10.255), or network/host objects that contain single hosts, address ranges, or a combination of hosts and ranges. Click **Select** to select objects from a list or to create new objects.

Step 3 Click the **Learning Accept Mode** tab and define how the knowledge base will be generated and used. For detailed information, see Configuring Anomaly Detection Learning Accept Mode , on page 1744.

Step 4 Configure the internal, illegal, and external zones:

- Define the internal and illegal zones—The internal zones are the IP addresses of your internal network, the network that you manage. The illegal zone should represent IP address ranges that should never be seen in normal traffic, for example, unallocated IP addresses or part of your internal IP address range that is unoccupied.

Click the **Internal Zone** and **Illegal Zone** tabs in turn and configure the following on the **General** tab:

- **Enable this zone**—Whether the zone will be processed by anomaly detection.
- **Service Subnets**—The IP addresses that comprise the zone. The default (0.0.0.0) is that no address is included in the zone. Replace 0.0.0.0 to define addresses for the zone.

The addresses can be single host (such as 10.100.10.1), a range of addresses (such as 10.100.10.0-10.100.10.255), or network/host objects that contain single hosts, address ranges, or a combination of hosts and ranges. Click **Select** to select objects from a list or to create new objects.

- Decide whether to enable the external zone—The external zone comprises all IP addresses that are not configured for the internal or illegal zones. You do not explicitly assign addresses to this zone. On the **External Zone** tab, **General** sub-tab, you can enable or disable the zone using the **Enable this zone** checkbox. The external zone is enabled by default.
- Configure scanner thresholds and histograms—Each zone has sub-tabs for **TCP Protocol**, **UDP Protocol**, and **Other Protocols**. On these tabs, you can configure non-default settings for specific services that override the learned histograms. For detailed information about configuring these settings, see Configuring Anomaly Detection Thresholds and Histograms , on page 1747.

At this point, you have finished configuring the basic anomaly detection settings.

Step 5 (Device view only.) Configure the anomaly detection mode. This setting is defined in the **Virtual Sensors** policy. Consider the following tips to select the correct policy:

- If you configured the anomaly detection policy on a virtual sensor (other than vs0, which is represented by the parent IPS device), you must select the parent IPS device, then select the Virtual Sensors policy.

- If you configured the Anomaly Detection policy as a shared policy in Policy view, select the IPS device to which the policy is assigned, or that hosts a virtual sensor to which the policy is assigned.

Then, complete the following steps in the Virtual Sensors policy:

a) Select the desired virtual sensor in the table and click the **Edit Row** button.
b) In the Modify Virtual Sensors dialog box, select the appropriate option for the Anomaly Detection Mode setting: Detect, Inactive, Learn. The default and normal operational mode is Detect. However, if you are using asymmetric normalizer mode, you might want to set the anomaly detection mode to Inactive. For detailed information about these modes, see Anomaly Detection Modes , on page 1738. For information about the other settings in this dialog box, see Virtual Sensor Dialog Box , on page 1671.
c) If you placed anomaly detection in Learning mode, remember to change the mode to Detect after the desired learning period has completed.

Step 6 Add additional actions to the anomaly detection signatures, if desired. For example, you might want to add a deny action so that attacks are dropped. You can alternatively configure event action overrides to add actions based on risk rating. For more information, see Configuring Anomaly Detection Signatures , on page 1740.

Step 7 Manage the knowledge base, if necessary.

If you configured the knowledge base to automatically rotate (on the Learning Accept Mode tab), then the knowledge base is refreshed automatically and manual intervention is not necessary.

If you configured anomaly detection to only save new databases, and not use them, then you need to manually load updated knowledge bases periodically. You cannot do this in Security Manager; use the IPS Device Manager (IDM) instead.

Using IDM (or IME), you can load, delete, and rename knowledge bases, and upload them to or download them from an external server. For more information about what you can do, see the online help for IDM or IME.

Configuring Anomaly Detection Learning Accept Mode

Use the Learning Accept Mode tab of the Anomaly Detection policy to configure whether you want the sensor to create a new knowledge base every so many hours. You can configure whether the knowledge base is created and loaded (Rotate) or saved (Save Only). You can schedule how often and when the knowledge base is loaded or saved.

The default generated filename is YYYY-Mon-dd-hh_mm_ss (that is, year-month-day-hour_minute_second),where Mon is a three-letter abbreviation of the current month.

The knowledge base has a tree structure and contains the following information:

- Knowledge base name
- Zone name
- Protocol
- Service

The knowledge base holds a scanner threshold and a histogram for each service. If you have learning accept mode set to automatic and the action set to rotate, a new knowledge base is created every 24 hours and used in the next 24 hours. If you have learning accept mode set to automatic and the action is set to save only, a

new knowledge base is created but not loaded, and the current knowledge base is used. If you do not have learning accept mode set to automatic, no knowledge base is created.

Tip Although you can use Security Manager to configure how knowledge bases are generated, you cannot manage the knowledge bases themselves. Use the IPS Device Manager (IDM), or IPS Manager Express (IME) instead. Using IDM (or IME), you can load, delete, and rename knowledge bases, and upload them to or download them from an external server. For more information about what you can do, see the online help for IDM or IME.

Related Topics

- Anomaly Detection Modes , on page 1738
- Configuring Anomaly Detection , on page 1742
- Understanding Anomaly Detection Thresholds and Histograms , on page 1746

Step 1 Do one of the following to open the Anomaly Detection policy you want to modify:

- (Device view) Select **IPS > Anomaly Detection** from the Policy selector.
- (Policy view) Select **IPS > Anomaly Detection** from the Policy selector. Select an existing policy or create a new one.

Step 2 Click the **Learning Accept Mode** tab and configure the following options:

- **Automatically accept learning knowledge base**—Whether to have the sensor automatically update the knowledge base. If you do not select this option, anomaly detection does not automatically create a new knowledge base, and you cannot configure the other options on this tab.
- **Action**—Whether to rotate or save the knowledge base when it is created.

If you choose **Rotate** (the default), the new knowledge base is created and loaded according to the schedule you define. If you choose **Save Only**, the new knowledge base is created but not loaded. You can examine it and decide whether to load it into anomaly detection using IDM or IME.

Step 3 In the **Schedule** field, select the schedule for generating a new knowledge base. The default schedule is periodic starting at 10 AM and running for 24 hours. Options are:

- **Periodic**—Base the schedule on a recurring period. Configure the following options:
  - **Start Time**—The starting time for the learning window in hh:mm:ss format (24-hour clock).
  - **Learning Interval in hours**—How long you want anomaly detection to learn from the network before creating a new knowledge base.
- **Calendar Schedule**—Base the schedule on specific times of day and days of the week. The dialog box changes to show Time of Day and Days of the Week tables. These times apply to every day selected; you cannot specify different times for different days.
  - To add a time or day, click the **Add Row (+)** button beneath the appropriate table. The time is in hh:mm:ss format (24-hour clock). For day, select the day from the list.

- To edit an existing time or day, select it and click the **Edit Row (pencil)** button.
- To delete a time or day, select it and click the **Delete Row (trash can)** button. Ensure that you have at least one time and one day configured.

Understanding Anomaly Detection Thresholds and Histograms

Anomaly detection uses thresholds and histograms to determine if scanning behavior is an attack.

During learning mode, anomaly detection develops histograms for each TCP and UDP port, and for other protocols, to create a baseline of the normal behavior of your network (see Anomaly Detection Modes , on page 1738). For example, the histogram for a TCP port lists the "normal" number of source addresses that make incomplete connections to a certain number of destination addresses during a minute. The histograms contain three buckets: low number of destination addresses (5), medium number (20), and high number (100). (The destination buckets are a fixed number.) Separate histograms are kept for each service and zone (see Anomaly Detection Zones , on page 1739).

For example, learning mode might develop the following histogram for TCP port 80:

Number of Destination Addresses	Number of Source Addresses
Low (5)	18
Medium (20)	6
High (100)	2

In addition to these learned histograms, the anomaly detection scanner has a threshold setting that you configure. You configure a general scanner threshold, and you can override the threshold (configuring a different value) for any specific service (TCP port, UDP port, or other protocol). Each zone has its own thresholds.

When anomaly detection moves to detect mode, where it is actively scanning for worms, the thresholds and histograms are used as follows:

- Histograms are ignored until the threshold for the service is exceeded. For example, consider the above table for TCP/80 traffic. If the threshold is set at 200 (the default), a scanner must scan 200 hosts in a minute to trigger a scanner alert. If 7 source addresses scanned 50 hosts (which is an anomaly in the histogram, which expects no more than 6 hosts scanning 20-99 destinations), but a single scanner scanned only 100 addresses, no alert is generated, and no anomaly is detected.
- When the scanner threshold is exceeded, anomaly detection uses the histogram to determine if the service is under worm attack. In this example, if a source scans more than 200 destinations, anomaly detection evaluates the collected activity in the network. Because 7 hosts have scanned 50 hosts, a worm alert is generated.

When under worm attack, anomaly detection stops learning and clears the current learning information. It also temporarily lowers the thresholds.

- When a worm attack is detected, the worm timeout counter is started. When the timeout is reached, the scanner is reset. If the worm attack continues, new alerts are generated. You configure the worm timeout on the Operation Settings tab of the Anomaly Detection policy.

If you leave the defaults in place, anomaly detection generates histograms based on what it learns about your network from the network's actual behavior. However, if you understand your network you can fine-tune these histograms to reduce false positives, creating your own definition of expected (or desired or tolerated) behavior for each TCP/UDP port or other protocol, for each zone. You can create your own histograms for only those services that interest you, and leave the defaults for all other ports. Additionally, you can configure the general scanner threshold for each zone, and configure different thresholds for specific services.

For information on configuring thresholds and histograms, see Configuring Anomaly Detection Thresholds and Histograms , on page 1747.

Configuring Anomaly Detection Thresholds and Histograms

Anomaly detection uses thresholds and histograms to determine if scanning behavior is an attack. In most cases, you can use the default thresholds and the histograms that anomaly detection generates during learning mode (see Anomaly Detection Modes , on page 1738). However, you might want to fine-tune these settings. Changing the thresholds is a more likely change than creating your own histograms.

Before you configure these settings, read Understanding Anomaly Detection Thresholds and Histograms , on page 1746. You must understand how thresholds and histograms are used together to configure them.

Step 1 Do one of the following to open the Anomaly Detection policy you want to modify:

- (Device view) Select **IPS > Anomaly Detection** from the Policy selector.
- (Policy view) Select **IPS > Anomaly Detection** from the Policy selector. Select an existing policy or create a new one.

Step 2 Click the tab for the zone whose thresholds or histograms you want to change. You configure separate values for each zone: **Internal Zone**, **Illegal Zone**, **External Zone**. For an explanation of the zones, see Anomaly Detection Zones , on page 1739.

The tabs for each zone contain four sub-tabs: General, TCP Protocol, UDP Protocol, and Other Protocols. The General tab defines the IP addresses for the zone and whether the zone is enabled (the External zone includes all IP addresses not specified for the other zones, you do not configure specific addresses for the External zone).

The other tabs are where you define thresholds and histograms.

Step 3 Select the tab for the protocol for which you want to modify thresholds or histograms: **TCP Protocol**, **UDP Protocol**, **Other Protocol**.

On each tab, configure the following options:

- **Enabled**—Whether anomaly detection is enabled for the protocol. You can turn off detection for all of TCP, UDP, or for all non-TCP/UDP protocols with this option. If you deselect the option, any other settings configured on the tab are ignored.
- **Destination Port Map** or **Protocol Number Map** table—This table lists the TCP/UDP ports, or other protocols, for which you are configuring non-default mappings. By default, all ports and protocols are enabled and use the default scanner threshold.

Add items to this table only if you want to: disable detection for a port or protocol; set a different threshold value for a port or protocol; or configure an explicit histogram for a port or protocol, which will be used instead of the learned histogram.

- To add a mapping, click the **Add Row (+)** button and fill in the Add Dest or Protocol Map dialog box. For detailed information, see Dest Port or Protocol Map Dialog Box , on page 1748.
- To edit a mapping, select it and click the **Edit Row (pencil)** button.
- To delete a mapping, select it and click the **Delete Row (trash can)** button. Deleting a mapping returns the service to the default settings.
- **Scanner Threshold**—The threshold for all TCP, UDP, or other protocols. This threshold is used for all services except those for which you configured a scanner override in the mapping table. The range is 5 to 1000. The default is 200.
- **Threshold Histogram**—The default histogram for all TCP, UDP, or other protocols. This histogram is used for all services except those for which you configured a scanner override in the mapping table.

The content of this table is fixed; you cannot add or delete items. However, you can select a row and click **Edit Row (pencil)** to change the number of source addresses configured for a threshold setting. See Histogram Dialog Box , on page 1749.

Step 4 Repeat the process for each combination of zone and protocol for which you are defining non-default settings.

Dest Port or Protocol Map Dialog Box

Use the Add or Modify Dest Port Map dialog box to add or modify destination port scanner settings for TCP or UDP, and the Add or Modify Protocol Map dialog box to add or modify scanner settings for other protocols.

Before you configure these settings, read the following topics:

- Understanding Anomaly Detection Thresholds and Histograms , on page 1746
- Configuring Anomaly Detection Thresholds and Histograms , on page 1747

Tip You do not need to add a port or protocol to have anomaly detection look for worm attacks against it. By default, all ports and protocols are processed. You need to configure specific settings only if you want to turn off detection on a specific port or protocol, or if you want non-default thresholds or histograms.

Navigation Path

In the Anomaly Detection policy, on the **TCP Protocol**, **UDP Protocol**, or **Other Protocol** sub tabs on the Internal Zone, Illegal Zone, or External Zone tabs, click the **Add Row** button beneath the Destination Port Map or Protocol Number Map tables, or select a row and click the **Edit Row** button. For more information on the steps required to get here, see Configuring Anomaly Detection Thresholds and Histograms , on page 1747.

Field Reference

Table 538: Destination Port or Protocol Map Dialog Box

Element	Description
Destination Port Number (Dest Port Map dialog box only.)	The destination port number for which you are defining non-default values. The range is 0 to 65535. Enter a single port number, or the name of a port list object that contains a single port number. Click **Select** to select an object from a list or to create a new one.
Protocol Number (Protocol Map dialog box only.)	The protocol number for non-TCP/UDP protocols. For a list of protocol numbers, see RFC 1700 at http://www.ietf.org/rfc/rfc1700.txt and search for "Protocol Numbers." Look for a heading (at the time of this writing, the second search hit). The range is 0 to 255. For example, ICMP is protocol 1.
Enabled	Whether to enable this service. If you do not enable the service, the associated port or protocol is not processed by anomaly detection.
Override Scanner Settings	Whether to override the scanner settings for this service or protocol. You must select this option to enable the remaining fields on the dialog box.
Scanner Threshold	The scanner threshold for this port or protocol. The range is 5 to 1000. The default is 200.
Threshold Histogram table	The histograms for this port or protocol. If you leave the table empty, the default histograms are used. You can have up to three rows, for low, medium, and high numbers of destination addresses, with different threshold levels (source addresses) for each. • To add a threshold, click the **Add Row** button and fill in the Histogram Dialog Box , on page 1749. The Add button is disabled if you already have three rows. • To edit a threshold, select it and click the **Edit Row** button. You cannot change the destination bucket to one that is already defined in the table. • To delete a threshold, select it and click the **Delete Row** button. Any buckets not included in the table use the default histogram for the bucket.

Histogram Dialog Box

Use the Histogram dialog box to create or modify entries in a histogram. The histograms you create or modify override the default histograms that anomaly detection generates. For detailed information about how these histograms are used, see:

- Understanding Anomaly Detection Thresholds and Histograms , on page 1746
- Configuring Anomaly Detection Thresholds and Histograms , on page 1747

Navigation Path

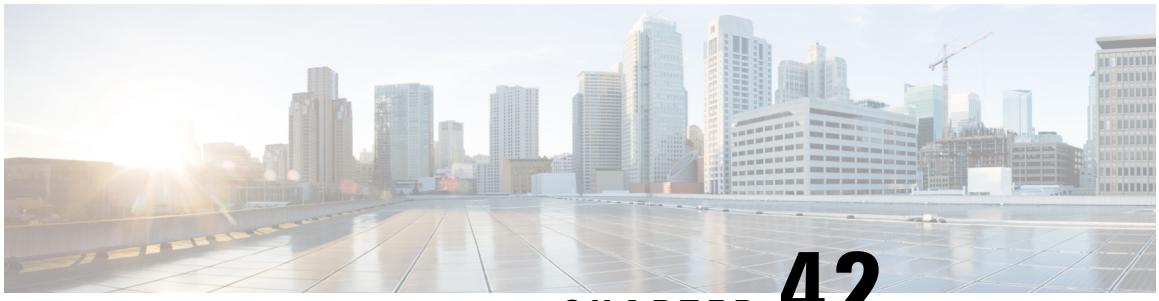
Do one of the following from the Anomaly Detection policy (see Configuring Anomaly Detection , on page 1742):

- On the TCP Protocol, UDP Protocol, or Other Protocol sub tabs on the Internal Zone, Illegal Zone, or External Zone tabs, select a row in the Threshold Histogram table and click the **Edit Row** button.
- On the Add or Modify Dest or Protocol Map dialog boxes, click the **Add Row** button, or select a row and click the **Edit Row** button. For information on opening the map dialog boxes, see Dest Port or Protocol Map Dialog Box , on page 1748.

Field Reference

Table 539: Histogram Dialog Box

Element	Description
Number of Destination IP Addresses	The histogram bucket you are defining. The buckets have a fixed number of destination addresses: Low (5 addresses); Medium (20); High (100). **Tip** A histogram can have a single entry for each destination bucket (low, medium, high). Thus, you cannot change this value to one that is already defined in the histogram you are editing.
Number of Source IP Addresses	The number of source addresses that are allowed to simultaneously scan the associated number of destination addresses. Enter the desired number. The range is 0 to 4096. If you are editing a histogram, the current value is shown.



CHAPTER 42

Configuring Global Correlation

Note From 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any enhancements as IPS is now End of Life. For more information, see EOL notice.

You can configure global correlation so that your sensors are aware of network devices with a reputation for malicious activity and can take action against them. Global correlation allows you to dynamically use information about malicious activity collected from networks around the globe to change the risk rating of events that have known bad devices as their source.

To configure global correlation, your sensor must be running IPS 7.0+ software. Global correlation is not available on Cisco IOS IPS devices.

This chapter contains the following topics:

Understanding Global Correlation

You can configure global correlation so that your sensors are aware of network devices with a reputation for malicious activity and can take action against them. Participating IPS devices in a centralized Cisco threat database, the SensorBase, receive and absorb global correlation updates. The reputation data contained in the global correlation updates is factored into the analysis of network traffic, which increases IPS efficacy, because traffic is denied or allowed based on the reputation of the source IP address. The participating IPS devices send data back to the Cisco SensorBase Network, which results in a feedback loop that keeps the updates current and global.

Tip The Botnet Traffic Filter feature of adaptive security appliances (ASA) is another dynamic feature you can deploy in your network to defend against malicious activity. Configuring global correlation on IPS devices, and Botnet Traffic Filtering on ASA firewalls, can be an effective combined security implementation. For more information about Botnet Traffic Filtering, see Managing Firewall Botnet Traffic Filter Rules, on page 907.

There are three main features of global correlation:

- Global Correlation Inspection—The IPS uses the global correlation reputation knowledge of attackers to influence alert handling and to deny actions when attackers with a bad score are seen on the sensor. For more information about reputation, see Understanding Reputation , on page 1752.
- Reputation Filtering—Applies automatic deny actions to packets from known malicious sites.
- Network Participation—The sensor sends alert and TCP fingerprint data to the SensorBase Network so that other users can share in the community knowledge. For more information, see Understanding Network Participation , on page 1753.

Global correlation has the following goals:

- Dealing intelligently with alerts thus improving efficacy.
- Improving protection against known malicious sites.
- Sharing telemetry data with the SensorBase Network to improve visibility of alerts and sensor actions on a global scale.
- Simplifying configuration settings.
- Automatic handling of the uploads and downloads of the information.

Tip You can use Report Manager to generate reports comparing the number of alerts generated by global correlation to those generated by traditional IPS inspection. For information on the Inspection/Global Correlation report, see Understanding General IPS Reports , on page 2766. For information on generating reports, see Opening and Generating Reports , on page 2767.

For information on how to configure global correlation, see the following topics:

- Global Correlation Requirements and Limitations , on page 1754
- Configuring Global Correlation Inspection and Reputation , on page 1755
- Configuring Network Participation , on page 1757

Understanding Reputation

Similar to human social interaction, reputation is an opinion toward a device on the Internet. Reputation indicates the probability that a particular attacker IP address will initiate malicious behavior based on its known past activity. Reputation enables the installed base of IPS sensors to collaborate using the existing network infrastructure and identify network devices that are likely to be malicious or infected.

By collecting data about devices and assigning reputation scores to them, the global correlation database provides important data that the IPS sensor can use to adjust the risk rating of an attack. Risk rating is the probability that a network event is malicious. Each signature has an associated risk rating. If you enable global correlation, the IPS sensor computes a score based on the reputation of an attacker and adds this score to the risk rating of the event. The updated risk rating is then used by your event action override and filter policies to help determine what actions to take for the event.

Thus, you might have an event that is initially configured to simply produce an alert. But, if the attacker has a bad reputation, the IPS might increase the risk rating to a number high enough that it triggers an event action override rule that adds the Deny Packet Inline action. Thus, for some source devices, the event simply produces an alert, but for others, the event drops the packet in addition to producing the alert.

Tip The Produce Alert action is added to an event whenever global correlation raises the risk rating of the event, or when global correlation adds the Deny Packet Inline or Deny Attacker Inline actions.

Because the global correlation database changes rapidly, the sensor must periodically download global correlation updates from the global correlation servers.

Using reputation scores to adjust the risk rating of an event improves the efficacy of the sensor by improving the following metrics:

- False positives as a percentage of actionable events.
- False negatives as a percentage of threats that do not result in actionable events.
- Actionable events as a percentage of all events.

Related Topics

- Understanding Global Correlation , on page 1751
- Configuring Network Participation , on page 1757
- Configuring Global Correlation Inspection and Reputation , on page 1755
- Configuring Network Participation , on page 1757

Understanding Network Participation

Network participation lets Cisco collect nearly real-time data from sensors around the world. Sensors installed at customer sites can send data to the SensorBase Network. These data feed in to the global correlation database to increase reputation fidelity. Communication between sensors and the SensorBase Network involves an HTTPS request and response over TCP/IP.

There are three modes for Network Participation:

- **Off**—The Network Participation server does not collect data, track statistics, or try to contact the Cisco SensorBase network.
- **Partial Participation**—The Network Participation server collects data, tracks statistics, and communicates with the SensorBase network. Data considered to be potentially sensitive is filtered out and never sent.

Note Configuring the sensor for partial network participation limits a third party from extracting reconnaissance information about your internal network from the global correlation database.

- **Full Participation**—The Network Participation server collects data, tracks statistics, and communicates with the SensorBase network. All data collected is sent.

If you select partial or full participation, you are prompted to accept a participation agreement. You must accept the agreement to participate or you cannot change the participation mode.

The following table explains the data collected and the purpose of collecting it.

Table 540: Network Participation Data Sharing and Usage

Participation Level	Type of Data	Purpose
Partial	Protocol attributes (TCP maximum segment size and options string, for example).	Tracks potential threats and helps Cisco to understand threat exposure.
	Attack type (signature fired, including signature ID and version, risk rating, and reputation, for example).	Used to understand current attacks and attack severity.
	Connecting IP address and port.	Identifies attack source.
	Summary IPS performance (CPU utilization, memory usage, inline vs promiscuous, for example).	Tracks product efficacy.
Full	Victim IP address and port.	Detects threat behavioral pattern.

To configure network participation, the IPS device requires at least 100 MB of available memory, a network connection to the sensor, and a network connection to the Internet. For information on configuring network participation, see Configuring Network Participation , on page 1757.

Global Correlation Requirements and Limitations

The following list explains the requirements that you must meet to configure and successfully use global correlation on IPS devices. It also explains some limitations.

- **Valid license**—You must have a valid sensor license for global correlation features to function. You can still configure and display statistics for the global correlation features, but the global correlation databases are cleared and no updates are attempted. Once you install a valid license, the global correlation features are reactivated. For information on configuring licenses, see Updating IPS License Files , on page 1777.
- **Agree to Network Participation disclaimer**—If you decide to configure network participation, you must accept the disclaimer. For more information, see Understanding Network Participation , on page 1753 and Configuring Network Participation , on page 1757.
- **External connectivity for sensor and a DNS server or HTTP proxy**—Global correlation requires the sensor to connect to the Cisco SensorBase Network. Domain name resolution is also required for these features to function. You can either configure the sensor to connect through an HTTP proxy server that

has a DNS client running on it, or you can assign an Internet routeable address to the management interface of the sensor and configure the sensor to use a DNS server. For more information, see Identifying DNS Servers , on page 1637 and Identifying an HTTP Proxy Server , on page 1638.

- **Sensor in inline mode**—The sensor must operate in inline mode so that the global correlation features can increase efficacy by being able to use the inline deny actions.
- **Sensor and IPS version that supports the global correlation features**—The sensor must run IPS 7.0+ software. You cannot configure global correlation on Cisco IOS IPS devices.
- **Sufficient available memory**—To configure network participation, the IPS device requires at least 100 MB of available memory.
- **Firewall access for port 80, 443 traffic**—Because global correlation updates occur through the sensor management interface, any firewall that lies between the sensor and the internet must allow traffic on ports 80 and 443. You can also use an HTTP proxy (see Identifying an HTTP Proxy Server , on page 1638).
- **Exposure to external traffic**—The global correlation database contains external IP addresses only, so if you position a sensor in an internal lab that has no interaction with outside networks, you might never receive global correlation information. The feature will have no effect.
- **Bypass mode might be triggered during global correlation updates**— As with signature updates, when the sensor applies a global correlation update, it might trigger bypass. Whether bypass is triggered depends on the traffic load of the sensor and the size of the signature or global correlation update. If bypass mode is turned off, an inline sensor stops passing traffic while the update is being applied.
- **No IPv6 address support**—Global correlation inspection and the reputation filtering deny features do not support IPv6 addresses. For global correlation inspection, the sensor does not receive or process reputation data for IPv6 addresses. The risk rating for IPv6 addresses is not modified for global correlation inspection. Similarly, network participation does not include event data for attacks from IPv6 addresses. And finally, IPv6 addresses do not appear in the deny list.

Related Topics

- Understanding Global Correlation , on page 1751

- Understanding Network Participation , on page 1753
- Configuring Global Correlation Inspection and Reputation , on page 1755
- Configuring Network Participation , on page 1757

Configuring Global Correlation Inspection and Reputation

Use the Inspection/Reputation policy to configure the sensor to use updates from the SensorBase Network to adjust the risk rating of events. The global correlation client on the sensor determines which updates are available and applicable to the sensor by communicating with the global correlation update server and a file server. The global correlation update server provides the server manifest document to the sensor, which identifies which updates are available and how to obtain them from a file server. The sensor downloads the update files from the file server using the information in the server manifest.

When you configure global correlation, updates are automatic and happen at regular intervals, approximately every five minutes by default, but this interval can be modified by the global correlation server. The sensor initially gets a full update and then applies an incremental update periodically.

If you turn on global correlation, you can choose how aggressively you want the deny actions to be enforced against malicious hosts. You can then enable reputation filtering to deny access to known malicious hosts. If you only want a report of what could have happened, you can enable Test Global Correlation. This puts the sensor in Audit mode, and actions the sensor would have performed are generated in the events.

Tip When you view IPS events in Event Viewer, there are several columns specific to global correlation that you can add to the event table; these columns are not shown by default, so you must add them to your view. To monitor global correlation in general, use the IPS device manager (IDM) and look at the Sensor Health gadget. Use either the full IDM or open a read-only copy from Security Manager by right-clicking the device in Device view and selecting **Device Manager**.

Before You Begin

- You must also configure a DNS server or HTTP proxy for global correlation to function. For details, see Identifying DNS Servers , on page 1637 or Identifying an HTTP Proxy Server , on page 1638.
- There are several configuration requirements and limitations that you should be aware of before configuring global configuration. For details, see Global Correlation Requirements and Limitations , on page 1754.

Related Topics

- Understanding Global Correlation , on page 1751
- Understanding Reputation , on page 1752
- Configuring Network Participation , on page 1757

Step 1 Do one of the following to open the Inspection/Reputation policy:

- (Device view) Select **IPS > Global Correlation > Inspection/Reputation** from the Policy selector.
- (Policy view) Select **IPS > Global Correlation > Inspection/Reputation** from the Policy Type selector. Select an existing policy or create a new one.

Step 2 Configure the following settings:

- **Global Correlation Inspection**—Whether to enable global correlation inspection. When turned on, the sensor uses updates from the SensorBase Network to adjust the risk rating. Deselect this option to disable inspection.
- **Global Correlation Influence**—How aggressively the sensor uses global correlation information to initiate deny actions. Select one of the following:
  - **Permissive**—Has the least aggressive effect on deny actions.
  - **Standard**—(The default.) Has a moderately aggressive effect on deny actions.
  - **Aggressive**—Has a very aggressive effect on deny actions.

- **Reputation Filtering**—Select whether you want reputation filtering **on** or **off**. When turned on, the sensor denies access to malicious hosts that are listed in the global correlation database.
- **Test Global Correlation**—Whether to place global correlation in audit mode. In audit mode, reputation filtering does not deny access to known malicious hosts; only a report of what could have happened is generated.

Audit mode allows you to test the global correlation features without actually denying any hosts. If you decide the effects are desirable, you can deselect this option to activate reputation filtering.

Configuring Network Participation

Use the Network Participation policy to configure the sensor to send data to the SensorBase Network. You can configure the sensor to fully participate and send all data to the SensorBase Network, or you can configure the sensor to collect the data but to omit potentially sensitive data, such as the destination IP address of trigger packets. For detailed information about network participation and the data that is collected, see Understanding Network Participation , on page 1753.

Related Topics

- Understanding Global Correlation , on page 1751
- Understanding Reputation , on page 1752
- Global Correlation Requirements and Limitations , on page 1754
- Configuring Global Correlation Inspection and Reputation , on page 1755

Step 1 Do one of the following to open the Network Participation policy:

- (Device view) Select **IPS > Global Correlation > Network Participation** from the Policy selector.
- (Policy view) Select **IPS > Global Correlation > Network Participation** from the Policy Type selector. Select an existing policy or create a new one.

Step 2 Select the level of participation from the **Network Participation** list:

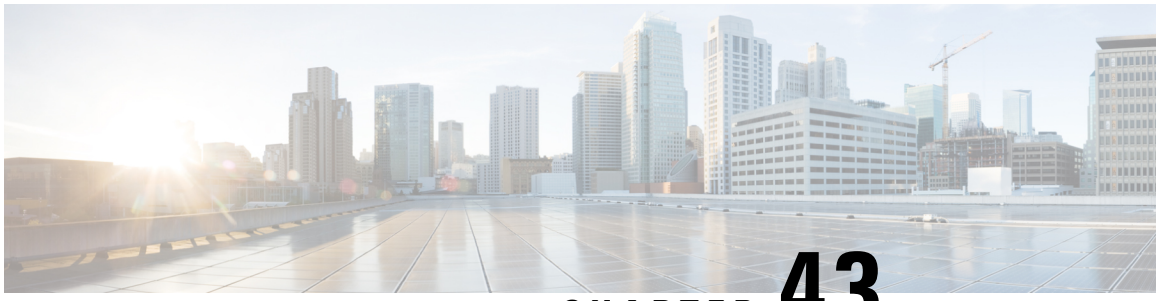
- **Off**—No data is contributed to the SensorBase network.
- **Partial**—Data is contributed to the SensorBase network but potentially sensitive information is withheld.

Note Configuring the sensor for partial network participation limits a third party from extracting reconnaissance information about your internal network from the Global Correlation database.

- **Full**—All data is contributed to the SensorBase network.

Step 3 If you select Full or Partial, when you click Save, the Network Participation Disclaimer dialog box opens, prompting you to read and accept a disclaimer. Carefully read the disclaimer. Click **Agree** if you agree to it.

If you click **Disagree**, you cannot enable network participation. Change the setting to Off and save the policy.



CHAPTER 43

Configuring Attack Response Controller for Blocking and Rate Limiting

You can configure an IPS device to implement blocks or rate limits to control attacks. Blocking and rate limiting are primarily of use when operating in promiscuous mode. When operating in inline mode, it is much more efficient to have the IPS drop traffic itself. Blocking and rate limiting are actions that other devices implement at the request of the IPS; thus, configuring blocking and rate limiting is a more complex configuration than simple inline denies.

To configure blocking or rate limiting, you must identify the network device that performs the blocking. A network device that performs blocking is called a blocking device. Many network devices can be used to support blocking: Cisco IOS routers and Catalyst 6500 switches, Cisco security appliances (ASA, PIX, and FWSM), and Catalyst 6500/7600 devices running the Catalyst operating system. You can also configure another IPS device to act as a main blocking sensor.

Understanding IPS Blocking

The Attack Response Controller (ARC) component of the IPS is responsible for managing network devices in response to suspicious events by blocking access from attacking hosts and networks. ARC blocks the IP address on the devices it is managing. It sends the same block to all the devices it is managing, including any other main blocking sensors. ARC monitors the time for the block and removes the block after the time has expired.

Note ARC is formerly known as Network Access Controller. Although the name has been changed, the IPS documentation and configuration interfaces contain references to Network Access Controller, nac, and network-access.

ARC completes the action response for a new block in no more than 7 seconds. In most cases, it completes the action response in less time. To meet this performance goal, you should not configure the sensor to perform blocks at too high a rate or to manage too many blocking devices and interfaces. We recommend that the maximum number of blocks not exceed 250 and the maximum number of blocking items not exceed 10. To calculate the maximum number of blocking items, a security appliance counts as one blocking item per

blocking context. A router counts as one blocking item per blocking interface/direction. A switch running Catalyst software counts as one blocking item per blocking VLAN. If the recommended limits are exceeded, ARC might not apply blocks in a timely manner or might not be able to apply blocks at all.

For security appliances configured in multiple-context mode, Cisco IPS does not include VLAN information in the block request. Therefore you must make sure the IP addresses being blocked are correct for each security appliance. For example, the sensor is monitoring packets on a security appliance customer context that is configured for VLAN A, but is blocking on a different security appliance customer context that is configured for VLAN B. Addresses that trigger blocks on VLAN A might refer to a different host on VLAN B.

Note Blocking is not supported on the FWSM on the admin context in multiple-context mode.

There are three types of blocks:

- Host block—Blocks all traffic from a given IP address.

To configure the IPS to initiate automatic host blocks when a signature is triggered, add the **Request Block Host** event action to a signature, or add it to events based on risk rating using the event action override policy. See Configuring Event Action Overrides , on page 1722 and Configuring Signatures , on page 1680.

- Connection block—Blocks traffic from a given source IP address to a given destination IP address and destination port. Multiple connection blocks from the same source IP address to either a different destination IP address or destination port automatically switch the block from a connection block to a host block.

To configure the IPS to initiate automatic connection blocks when a signature is triggered, add the **Request Block Connection** event action to a signature, or add it to events based on risk rating using the event action override policy.

- Network block—Blocks all traffic from a given network.

You can initiate host and connection blocks manually or automatically when a signature is triggered. You can only initiate network blocks manually. You cannot initiate network blocks from within Security Manager; use the IPS Device Manager instead.

Tip Connection blocks and network blocks are not supported on security appliances (firewalls). Security appliances only support host blocks with additional connection information.

Note Do not confuse blocking with the ability of the sensor to drop packets. The sensor can drop packets when the following actions are configured for a sensor in inline mode: deny packet inline, deny connection inline, and deny attacker inline.

On Cisco IOS Software devices (routers and Catalyst 6500 series switches), ARC creates blocks by applying ACLs; on Catalyst 6500/7600 devices that run the Catalyst operating system, ARC creates blocks by applying VACLs. ACLs and VACLs permit or deny passage of data packets through interface directions or VLANs. Each ACL or VACL contains permit and deny conditions that apply to IP addresses. The security appliances use the **shun** command instead of ACLs.

Tip For a list of the specific devices and operating system versions that you can configure as blocking devices, see the supported device information in the chapter "Configuring Attack Response Controller for Blocking and Rate Limiting" in the *Installing and Using Cisco Intrusion Prevention System Device Manager* publication for your IPS software version. These publications are available on Cisco.com at http://www.cisco.com/en/US/products/hw/vpndevc/ps4077/products_installation_and_configuration_guides_list.html

The following topics explain more about IPS blocking:

Strategies for Applying Blocks

Blocking is performed only when an event occurs and the event includes the Request Block Connection or Request Block Host event actions. These event actions are not typically needed when you operate the IPS in inline mode, where you use Deny actions to drop undesired traffic.

The following are situations in which you might want to implement blocking actions:

- Promiscuous mode—When running in promiscuous mode, the IPS cannot implement Deny actions. Thus, if you want to prevent traffic from a host, you must implement blocking.
- Inline mode—In inline mode, you can implement Deny actions to immediately drop undesired traffic. However, you might want to add blocking actions to protect other segments of your network.

For example, suppose that your network consists of five subnets, A, B, C, D, and E, and that each of these segments has an inline IPS device monitoring it. If the IPS for subnet A identifies an attack, the IPS can use Deny actions to protect subnet A, but also use Request Block actions to configure the firewalls that protect B, C, D, and E to shun the attacker before the attack can target those other subnets. In this example, you would want to designate a single IPS as the main blocking sensor and have the other four IPS sensors perform blocking through the main blocking sensor.

Use the following techniques to add the request block actions to an event:

- Event Action Override policy—Configure an event action override rule to add the action to all events based on the event's risk rating. This is a simple approach. You could add the request block action for the same risk ratings used for adding Deny actions. For more information, see Configuring Event Action Overrides , on page 1722.
- Signatures policy—You can add the request block actions to individual signatures. This requires editing each signature to add the action. This can be a time-consuming approach, but it allows you to configure blocking for just the types of events that concern you most. For more information, see Configuring Signatures , on page 1680.

- Understanding the Main Blocking Sensor , on page 1764
- Understanding Interface Modes , on page 1648
- Configuring IPS Blocking and Rate Limiting , on page 1765
- Blocking Page , on page 1766

Understanding Rate Limiting

Attack Response Controller (ARC) is responsible for rate limiting traffic in protected networks. Rate limiting lets sensors restrict the rate of specified traffic classes on network devices. Rate limit responses are supported for the Host Flood and Net Flood engines, and the TCP half-open SYN signature. ARC can configure rate limits on network devices running Cisco IOS 12.3 or later. Main blocking sensors can also forward rate limit requests to blocking forwarding sensors.

To add a rate limit to a signature, you must add the Request Rate Limit action. You can then edit the signature parameters to set the percentage for these signatures in the Event Actions Settings folder.

Tip You can also manually implement rate limits, but you cannot do so using Security Manager; use the IPS Device Manager instead.

On the blocking device, you must not apply a service policy to an interface/direction that is configured for rate limiting. If you do so, the rate limit action will fail. Before configuring rate limits, confirm that there is no service policy on the interface/direction, and remove it if one exists. ARC does not remove the existing rate limit unless it is one that ARC had previously added.

Rate limits use ACLs, but not in the same way as blocks. Rate limits use ACLs and class-map entries to identify traffic, and policy-map and service-policy entries to police the traffic.

Understanding Router and Switch Blocking Devices

You can use routers or Catalyst 6500/7600 devices running Cisco IOS Software, or Catalyst 6500/7600 devices running the Catalyst operating system, to implement IPS blocking in your network. When you use routers or switches, Attack Response Controller (ARC) configures extended ACLs (on IOS devices) or VLAN ACLs (on Catalyst OS devices) to implement the blocks. These ACLs and VACLs are created and managed in the same way.

Rate limits also use ACLs, but not in the same way as blocks. Rate limits use ACLs and class-map entries to identify traffic, and policy-map and service-policy entries to police the traffic.

Tip IPS considers Catalyst 6500/7600 devices that run Cisco IOS Software to be equivalent to routers. When you add these devices as blocking devices, add them as routers.

When you configure a router interface or switch VLAN as a blocking interface, you can optionally specify the names of pre- and post-ACLs or VACLs. Although specifying ACL or VACL names is optional, if you

have configured ACLs or VACLs on the interface or VLAN, you must identify them to the IPS or ARC will remove them from your device configuration.

The pre- and post-ACL/VACL have the following uses:

- The Pre-Block ACL/VACL is mainly used for permitting what you do not want the sensor to ever block. When a packet is checked against the ACL/VACL, the first line that gets matched determines the action. If the first line matched is a permit line from the Pre-Block ACL/VACL, the packet is permitted even though there may be a deny line (from an automatic block) listed later in the ACL/VACL. The Pre-Block ACL/VACL can override the deny lines resulting from the blocks.
- The Post-Block ACL/VACL is best used for additional blocking or permitting that you want to occur on the same interface or direction. If you have an existing ACL on the interface or direction that the sensor will manage, that existing ACL can be used as a Post-Block ACL/VACL. If you do not have a Post-Block ACL/VACL, the sensor inserts permit ip any any at the end of the new ACL/VACL.

If you are managing the IOS Software blocking device in Security Manager, you can identify the ACL name by selecting the blocking device, then selecting **Tools > Preview Config**. Look for the **ip access-group** command in the interface configuration, and check the direction. For example, the following lines show that there is an ACL named CSM_FW_ACL_GigabitEthernet0/1 in the In direction attached to the GigabitEthernet0/1 interface.

```
interface GigabitEthernet0/1
  ip access-group CSM_FW_ACL_GigabitEthernet0/1 in
```

In this example, if you configure GigabitEthernet0/1 in the In direction as a blocking interface, ensure that you specify CSM_FW_ACL_GigabitEthernet0/1 as a pre- or post-ACL. In most cases, you should specify the ACL as the post-ACL, so that the relatively short IPS blocking ACL first filters out undesirable traffic before the blocking device implements your other access rules.

Because Security Manager does not manage Catalyst OS devices, you must examine a Catalyst OS device configuration outside of Security Manager to determine VACL names. Keep in mind that a Catalyst 6500/7600 device that runs IOS Software can also have VACLs, but the IPS does not do VLAN blocking on Catalyst 6500/7600 VLANs when the device is running IOS Software.

When the sensor starts up, it reads the contents of the two ACL/VACLs. It creates a third ACL/VACL with the following entries in this order, and this combined ACL/VACL is applied to the interface or VLAN:

1. A **permit** line with the sensor IP address or, if specified, the NAT address of the sensor.

If you select the Allow Sensor IP address to be Blocked option on the General tab of the Blocking policy, this permit entry is not added. For more information, see General Tab, IPS Blocking Policy , on page 1768.

1. Pre-Block ACL/VACL, if specified.
2. Any active blocks generated by the IPS (deny statements).
3. The Post-Block ACL/VACL, if specified.

If you do not specify a Post-Block ACL/VACL, a **permit ip any any** entry is added to allow all unfiltered traffic. Note that this negates the normal implicit deny any that ends interface ACLs.

When using Catalyst OS, IDSM-2 inserts **permit ip any any capture** at the end of the new VACL.

If ARC is managing a device and you need to configure the ACL/VACLs on that device, you should disable blocking first. You want to avoid a situation in which both you and ARC could be making a change at the

same time on the same device. This could cause the device or ARC to fail. If you need to modify the Pre-Block or Post-Block ACL/VACL, do the following:

1. Disable blocking on the sensor.

Because you are making a temporary change, you can disable and then reenable blocking by using the IPS Device Manager (IDM) on the device. Alternatively, you can deselect the Enable Blocking option on the General tab of the Blocking policy in Security Manager, then deploy the configuration to the IPS sensor. To reenable blocking, select the Enable Blocking option again and deploy the configuration to the IPS sensor.

1. Make the changes to the configuration of the device. For example, if you manage the blocking device in Security Manager, deploy the updated configuration and wait for the device to reload.
2. Reenable blocking on the sensor.

Understanding the Main Blocking Sensor

Multiple sensors (blocking forwarding sensors) can forward blocking requests to a specified main blocking sensor, which controls one or more devices. The main blocking sensor is the ARC running on a sensor that controls blocking on one or more devices on behalf of one or more other sensors. When a signature fires that has blocking or rate limit requests configured as event actions, the sensor forwards the block or rate limit request to the main blocking sensor, which then performs the block or rate limit.

When you add a main blocking sensor, you reduce the number of blocking devices per sensor. For example, if you want to block on 10 firewalls and 10 routers with one blocking interface/direction each, you can assign 10 to the sensor and assign the other 10 to a main blocking sensor.

You configure main blocking sensors on the Primary Blocking Sensors tab of the Blocking policy, as described in Blocking Page , on page 1766.

When configuring main blocking sensors, keep the following tips in mind:

- Two sensors cannot control blocking or rate limiting on the same device. If this situation is needed, configure one sensor as the main blocking sensor to manage the devices and the other sensors can forward their requests to the main blocking sensor.
- On the blocking forwarding sensor, identify which remote host serves as the main blocking sensor; on the main blocking sensor you must add the blocking forwarding sensors to its access list using the Allowed Hosts policy. See Identifying Allowed Hosts , on page 1620.
- If the main blocking sensor requires TLS for web connections, you must configure the ARC of the blocking forwarding sensor to accept the X.509 certificate of the main blocking sensor remote host. Sensors by default have TLS enabled, but you can change this option. For more information, seePrimary Blocking Sensor Dialog Box , on page 1771 .
- Typically the main blocking sensor is configured to manage the network devices. Blocking forwarding sensors are not normally configured to manage other network devices, although doing so is permissible.
- Only one sensor should control all blocking interfaces on a device.

Configuring IPS Blocking and Rate Limiting

If you use the Request Block Host, Request Block Connection, or Request Rate Limit actions on any signatures, or add them to events using the event action override policy, you must configure blocking devices. If you do not use these actions, there is no need to configure blocking devices.

Before you configure blocking, read the following topics:

- Understanding IPS Blocking , on page 1759
- Strategies for Applying Blocks , on page 1761
- Understanding Rate Limiting , on page 1762
- Understanding Router and Switch Blocking Devices , on page 1762
- Understanding the Main Blocking Sensor , on page 1764

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Security** > **Blocking** from the Policy selector.
- (Policy view) Select **IPS** > **Platform** > **Security** > **Blocking**, then select an existing policy or create a new one.

For an overview of the blocking policy, see Blocking Page , on page 1766.

Step 2 On the General tab, change any settings where you want non-default values. However, the default values are appropriate for most networks. For detailed information about the settings, see General Tab, IPS Blocking Policy , on page 1768.

Step 3 Click the **User Profiles** tab and create the user profiles that are required to log into the blocking devices.

- To add a profile, click the **Add Row** button and fill in the Add User Profile dialog box (see User Profile Dialog Box , on page 1770).
- To edit a profile, select it and click the **Edit Row** button.
- To delete a profile, select it and click the **Delete Row** button. Before you delete a profile, ensure that it is not currently being used by a blocking device.

Step 4 If you need to use a main blocking sensor, as described in Understanding the Main Blocking Sensor , on page 1764, click the **Primary Blocking Sensors** tab and do the following:

- To add a main blocking sensor, click the **Add Row** button and fill in the Add Main Blocking Sensor dialog box (see Primary Blocking Sensor Dialog Box , on page 1771).
- To edit a main blocking sensor, select it and click the **Edit Row** button.
- To delete a main blocking sensor, select it and click the **Delete Row** button.

Step 5 Identify the blocking devices (unless you will use main blocking sensors only). You must add the devices to the correct tab:

- **Routers** tab—For all Cisco IOS Software devices, including Catalyst 6500 switches that are running IOS Software.
- **Firewalls** tab—For ASA, PIX, and FWSM.

- **Catalyst 6K** tab—For Catalyst 6500/7600 devices that are running the Catalyst operating system.

On each tab, the configuration steps are the same:

- To add a device, click the **Add Row** button and fill in the Add Router, Firewall, or Cat6K Device dialog box (see Router, Firewall, Cat6K Device Dialog Box , on page 1771).
- To edit a device, select it and click the **Edit Row** button.
- To delete a device, select it and click the **Delete Row** button.

Step 6 Click the **Never Block Hosts and Networks** tab and identify the hosts and networks that should never be blocked. These lists affect blocking actions, but they do not affect limiting actions. Identify your trusted networks and hosts:

- To add a host or network, click the **Add Row** button beneath the appropriate table and fill in the Add Never Block Host or Network dialog box (see Never Block Host or Network Dialog Boxes , on page 1775).
- To edit a host or network, select it and click the **Edit Row** button.
- To delete a host or network, select it and click the **Delete Row** button.

Blocking Page

Use the Blocking page to configure IPS sensor blocking properties. Configure the blocking policy only if you use the Request Block Connection, Request Block Host, or Request Rate Limit event actions in your signatures or event actions policies. Blocking hosts are used only for events to which these actions are assigned.

Tip The list of hosts and networks to never block applies only to the Request Block Connection and Request Block Host event actions. The list does not affect rate limiting, nor does it affect any of the Deny actions such as Deny Packet Inline. To exempt hosts and networks from Deny or rate limiting actions, use event action filter rules, specify the hosts and networks as Attackers, and remove the actions from events. For more information, see Configuring Event Action Filters , on page 1714.

Navigation Path

- (Device view) Select **Platform** > **Security** > **Blocking** from the Policy selector.
- (Policy view) Select **IPS** > **Platform** > **Security** > **Blocking**, then select an existing policy or create a new one.

Field Reference

Table 541: IPS Blocking Policy

Element	Description
General tab	The basic settings required to enable blocking and rate limiting. For information about the options on the General tab, see General Tab, IPS Blocking Policy , on page 1768.
User Profiles tab	The connection credential information profiles for logging into the blocking devices. Before you define a blocking device, create the user profile required to log into the device. The table shows the profile name, username, and the passwords, which are masked with a fixed number of asterisks. • To add a profile, click the **Add Row** button and fill in the Add User Profile dialog box (see User Profile Dialog Box , on page 1770). • To edit a profile, select it and click the **Edit Row** button. • To delete a profile, select it and click the **Delete Row** button. Before you delete a profile, ensure that it is not currently being used by a blocking device.
Primary Blocking Sensors tab	The main blocking IPS sensors (see Understanding the Main Blocking Sensor , on page 1764). A main blocking sensor manages blocks for other IPS devices. The table shows the IP address (or network/host object) of the main blocking sensor, the username and password for logging into it, the port used for connections, and whether TLS is used for login. • To add a main blocking sensor, click the **Add Row** button and fill in the Add Primary Blocking Sensor dialog box (see Understanding the Main Blocking Sensor , on page 1764). • To edit a main blocking sensor, select it and click the **Edit Row** button. • To delete a main blocking sensor, select it and click the **Delete Row** button.
Router tab	The IOS routers and Catalyst 6500/7600 devices (that are running IOS Software) to be used as blocking or rate limiting devices. The table shows the IP address (or network/host object) of the device, the communication method used to log into it, the NAT address of the sensor (0.0.0.0 if NAT is not used), the name of the profile that is used for logging into the device, and the device's response capabilities (blocking, rate limiting, or both). • To add a router, click the **Add Row** button and fill in the Add Router Device dialog box (see Primary Blocking Sensor Dialog Box , on page 1771). • To edit a router, select it and click the **Edit Row** button. • To delete a router, select it and click the **Delete Row** button.

Element	Description
Firewall tab	The ASA, PIX, and FWSM devices to be used as blocking devices. The table shows the IP address (or network/host object) of the device, the communication method used to log into it, the NAT address of the sensor (0.0.0.0 if NAT is not used), and the name of the profile that is used for logging into the device. • To add a firewall, click the **Add Row** button and fill in the Add Firewall Device dialog box (see Router, Firewall, Cat6K Device Dialog Box , on page 1771). • To edit a firewall, select it and click the **Edit Row** button. • To delete a firewall, select it and click the **Delete Row** button.
Catalyst 6K tab	The Catalyst 6500/7600 devices that are using Catalyst software to be used as blocking devices. The table shows the IP address (or network/host object) of the device, the communication method used to log into it, the NAT address of the sensor (0.0.0.0 if NAT is not used), and the name of the profile that is used for logging into the device. **Tip** Do not use this tab for Catalyst 6500/7600 devices that run Cisco IOS Software. Instead, use the Router tab. • To add a Catalyst OS device, click the **Add Row** button and fill in the Add Cat6K Device dialog box (see Router, Firewall, Cat6K Device Dialog Box , on page 1771). • To edit a Catalyst OS device, select it and click the **Edit Row** button. • To delete a Catalyst OS device, select it and click the **Delete Row** button.
Never Block Hosts and Networks	The hosts and networks that should never be blocked. Hosts and networks are shown in separate tables. The tables show the IP address or network/host object for the host or network. These lists do not affect rate limiting actions, nor do they apply to Deny actions. • To add a host or network, click the **Add Row** button beneath the appropriate table and fill in the Add Never Block Host or Network dialog box (see Never Block Host or Network Dialog Boxes , on page 1775). • To edit a host or network, select it and click the **Edit Row** button. • To delete a host or network, select it and click the **Delete Row** button.

General Tab, IPS Blocking Policy

Use the General tab of the Blocking policy to configure the basic settings required to enable blocking and rate limiting.

Navigation Path

- (Device view) Select **Platform** > **Security** > **Blocking** from the Policy selector. If necessary, select the **General** tab.
- (Policy view) Select **IPS** > **Platform** > **Security** > **Blocking**, then select an existing policy or create a new one. If necessary, select the **General** tab.

Related Topic

- Configuring IPS Blocking and Rate Limiting , on page 1765
- Blocking Page , on page 1766

Field Reference

Table 542: General Tab, IPS Blocking Policy

Element	Description
Log All Block Events and Errors	Whether to log events that follow blocks from start to finish and any error messages that occur. When a block is added to or removed from a device, an event is logged. You may not want all these events and errors to be logged. Disabling this option suppresses new events and errors. The default is enabled. **Note** Log all block events and errors also applies to rate limiting.
Enable NVRAM Write	Whether to have the router write to non-volatile RAM (NVRAM) when Attack Response Controller (ARC) first connects. If enabled, NVRAM is written each time the ACLs are updated. The default is disabled. Enabling NVRAM writing ensures that all changes for blocking and rate limiting are written to NVRAM. If the router is rebooted, the correct blocks and rate limits will still be active. If NVRAM writing is disabled, a short time without blocking or rate limiting occurs after a router reboot. Not enabling NVRAM writing increases the life of the NVRAM and decreases the time for new blocks and rate limits to be configured.
Enable ACL Logging	Whether to have ARC append the log parameter to block entries in the access control list (ACL) or VLAN ACL (VACL). This causes the device to generate syslog events when packets are filtered. This option applies to routers and switches only. The default is disabled.
Allow Sensor IP address to be Blocked	Whether the sensor IP address can be blocked. The default is disabled. **Tip** If you allow the sensor address to be blocked, the IPS does not add an explicit permit entry to the interface ACL to allow the IPS address. You must ensure that the IPS address is permitted by the device ACL or the IPS cannot implement blocking on the device.
Enable Blocking	Whether to enable the blocking and rate limiting of hosts. The default is enabled. **Note** When you enable blocking, you also enable rate limiting. When you disable blocking, you also disable rate limiting. This means that ARC cannot add new or remove existing blocks or rate limits.
Max Blocks	The maximum number of entries to block. The range is 1 to 65535. The default is 250.

Element	Description
Max Interfaces	The maximum number of interfaces for performing blocks. For example, a PIX 500 series security appliance counts as one interface. A router with one interface counts as one, but a router with two interfaces counts as two. The maximum number of interfaces is 250 per device. The default is 250. You use Max Interfaces to set an upper limit on the number of devices and interfaces that ARC can manage. The total number of blocking devices (not including main blocking sensors) cannot exceed this value. The total number of blocking items also cannot exceed this value, where a blocking item is one security appliance context, one router blocking interface/direction, or one Catalyst Software switch blocking VLAN. **Note** In addition, the following maximum limits are fixed and you cannot change them: 100 interfaces per device, 250 security appliances, 250 routers, 250 Catalyst Software switches, and 100 main blocking sensors.
Max Rate Limits	The maximum number of rate limit entries. The maximum rate limit must be equal to or less than the maximum blocking entries. The range is 1 to 32767. The default value is 250.

User Profile Dialog Box

Use the Add or Modify User Profile dialog box to add or modify a user profile for an IPS blocking device. The profile defines a username and passwords that the IPS device can use to log into and configure the router, switch, or firewall that will implement IPS blocking.

Although you can save a profile that has a profile name only, the requirements for username, password, and enable password are determined by the device. You must specify the items required by the device to enter configuration mode, or the IPS cannot configure blocking on the device.

Navigation Path

From the IPS Blocking policy, select the User Profiles tab and click the **Add Row** button or select an existing sensor and click the **Edit Row** button. For information on opening the Blocking policy, see Blocking Page , on page 1766.

Field Reference

Table 543: User Profile Dialog Box

Element	Description
Profile Name	The name of the profile, up to 64 alphanumeric characters.
Username	The username to use when logging into the blocking device.
Password	The login password for the username, if required.
Enable Password	The enable password for entering Privileged EXEC Mode (enable mode), if required.

Primary Blocking Sensor Dialog Box

Use the Add or Modify Primary Blocking Sensor dialog box to configure a main blocking sensor. For more information about main blocking sensors, see Understanding the Main Blocking Sensor , on page 1764.

Navigation Path

From the IPS Blocking policy, select the Primary Blocking Sensors tab and click the **Add Row** button or select an existing sensor and click the **Edit Row** button. For information on opening the Blocking policy, see Blocking Page , on page 1766.

Field Reference

Table 544: Primary Blocking Sensor Dialog Box

Element	Description
IP Address	The IP address of the main blocking sensor. Enter the IP address or the name of a network/host policy object that contains a single host address, or click **Select** to select an object from a list or to create a new one.
Username	The username to use to log in to the main blocking sensor. The user account must be an active account configured on the main blocking sensor.
Password	The login password for the username.
Port	The port on which to connect on the main blocking sensor. The default is 443.
TLS	Whether to use TLS. If you select the TLS option, you must configure the ARC of the blocking forwarding sensor to accept the TLS/SSL X.509 certificate of the main blocking sensor remote host. (The blocking forwarding sensor is any device to which you are assigning this blocking policy.) The easiest way to configure the blocking forwarding sensor to accept the X.509 certificate is to use the IPS Device Manager (IDM) to log into the sensor, choose **Configuration > Sensor Management > Certificates > Trusted Hosts > Add Trusted Host**, and add the main blocking sensor as a trusted host. Alternatively, you can log into the sensor CLI, enter configuration mode, and use the **tls trusted-host ip-address** command.

Router, Firewall, Cat6K Device Dialog Box

Use the Add or Modify Router, Firewall, or Cat6K Device dialog box to configure a device as a blocking device for an IPS sensor. The name of the dialog box indicates the type of device you are adding:

- Router—IOS Software routers and Catalyst 6500/7600 devices. These devices can do rate limiting as well as blocking. See Understanding Router and Switch Blocking Devices , on page 1762.
- Firewall—ASA and PIX appliances.
- Cat6K—Catalyst 6500/7600 devices that are running Catalyst OS software.

Tip If the Catalyst 6500/7600 runs Cisco IOS Software, add the device as a router on the Router tab. Do not add the device to the Cat6K tab.

Navigation Path

From the IPS Blocking policy, select the Router, Firewall, or Catalyst 6K tab and click the **Add Row** button or select an existing row and click the **Edit Row** button. For information on opening the Blocking policy, see Blocking Page , on page 1766.

Field Reference

Table 545: Router, Firewall, Cat6K Device Dialog Boxes

Element	Description
IP Address	The IP address of the device. Enter the IP address or the name of a network/host policy object that contains a single host address, or click **Select** to select an object from a list or to create a new one.
Communication Type	The communication mechanism used to log in to the blocking device (SSH 3DES, SSH DES, Telnet). The default is SSH 3DES. If you choose SSH 3DES or SSH DES, you must add the device to the known hosts list. The easiest way to add the device to the known hosts list is to use the IPS Device Manager (IDM) to log into the sensor, choose **Configuration > Sensor Management > SSH > Known Host Keys > Add Known Host Key**, and add the device address. Alternatively, you can log into the sensor CLI, enter configuration mode, and use the **ssh host-key** command.
NAT Address	The NAT address of the sensor, if any is used between the sensor and the blocking device. Enter the NAT address or the name of a network/host policy object that contains a single host address, or click **Select** to select an object from a list or to create a new one. Leave the default 0.0.0.0 if NAT is not used.
Profile Name	The login profile used to log in to the blocking device. You must create this profile on the User Profiles tab of the blocking policy or the IPS cannot successfully use this blocking device.

Element	Description
Interfaces and directions where blocks will be applied (table) (Routers only.)	The interfaces on the device that should be used for blocking or rate limiting. The table shows the interface name, direction, and the names of existing ACLs that the IPS device should incorporate into the blocking ACL. If the interface already has an ACL configured for the specified direction, you must specify that ACL name as a pre- or post-ACL or the IPS removes the ACL. These ACLs are used for blocking only, not for rate limiting. • To add an interface, click the **Add Row** button and fill in the Add Router Block Interface dialog box (see Router Block Interface Dialog Box , on page 1773). • To edit an interface, select it and click the **Edit Row** button. • To delete an interface, select it and click the **Delete Row** button.
Response Capabilities (Routers only.)	The actions that this router can implement. Use Ctrl+click to select multiple actions (highlighted actions are selected). Options are: • **Block**—The router can implement blocks in response to Request Block Connection and Request Block Host actions. • **Rate Limit**—The router can implement rate limits in response to Request Rate Limit actions.
VLANs where blocks will be applied (table) (Catalyst 6500/7600 devices running the Catalyst operating system only.)	The VLANs on the device that should be used for blocking. The table shows the VLAN name and the names of existing VLAN ACLs (VACL) that the IPS device should incorporate into the blocking VACL. If the VLAN already has a VACL configured, you must specify that VACL name as a pre- or post-VACL or the IPS removes the VACL. • To add a VLAN, click the **Add Row** button and fill in the Add Cat6K Block VLAN dialog box (see Cat6k Block VLAN Dialog Box , on page 1774). • To edit a VLAN, select it and click the **Edit Row** button. • To delete a VLAN, select it and click the **Delete Row** button.

Router Block Interface Dialog Box

Use the Add or Modify Router Block Interface dialog box to configure a blocking interface on a router or IOS Software Catalyst 6500/7600 device that is configured as an IPS blocking device. The IPS sensor uses the interface for blocking actions.

Navigation Path

From the Add or Modify Router Device dialog box, click the **Add Row** button beneath the interfaces table, or select a row in the table and click the **Edit Row** button. For information on opening the Router Device dialog box, see Router, Firewall, Cat6K Device Dialog Box , on page 1771.

Field Reference

Table 546: Router Block Interface Dialog Box

Element	Description
Interface Name	The name of the interface on the router that the IPS should use for blocking. Enter the name exactly as it is configured on the router (for example, GigabitEthernet0/1).
Direction	The direction to apply the blocking ACL, In or Out.

Pre ACL Name
Post ACL Name
	The ACLs to combine with the blocking entries that the IPS creates to implement blocking actions. The Pre ACL is added before the blocking ACL, and the Post ACL is added after the blocking ACL. For more information, see Understanding Router and Switch Blocking Devices , on page 1762.
	Tip If you have configured an ACL on the interface in the specified direction, you must specify the name of the ACL in the Pre or Post ACL Name field or the ACL will be removed from the interface. When you identify an interface and direction as a blocking interface, the IPS takes control of the ACL on that interface/direction.
	If you are managing the blocking device in Security Manager, you can identify the ACL name by selecting the blocking device, then selecting **Tools > Preview Config**. Look for the **ip access-group** command in the interface configuration, and check the direction. For example, the following lines show that there is an ACL named CSM_FW_ACL_GigabitEthernet0/1 in the In direction attached to the GigabitEthernet0/1 interface.
	`interface GigabitEthernet0/1`
	`  ip access-group CSM_FW_ACL_GigabitEthernet0/1 in`
	In this example, if you configure GigabitEthernet0/1 in the In direction as a blocking interface, ensure that you specify CSM_FW_ACL_GigabitEthernet0/1 as a pre- or post-ACL. In most cases, you should specify the ACL as the post-ACL, so that the relatively short IPS blocking ACL first filters out undesirable traffic before the blocking device implements your other access rules.

Cat6k Block VLAN Dialog Box

Use the Add or Modify Cat6k Block VLAN dialog box to configure a blocking VLAN on a Catalyst 6500/7600 device that runs the Catalyst operating system and that is configured as an IPS blocking device. The IPS sensor uses the VLAN for blocking actions.

Tip If the Catalyst 6500/7600 runs Cisco IOS Software, add the device as a router, not a Cat6K.

Navigation Path

From the Add or Modify Cat6K Device dialog box, click the **Add Row** button beneath the VLANs table, or select a row in the table and click the **Edit Row** button. For information on opening the Cat6K Device dialog box, see Router, Firewall, Cat6K Device Dialog Box , on page 1771.

Field Reference

Table 547: Cat6k Block VLAN Dialog Box

Element	Description
VLAN	The number of the VLAN on the Catalyst 6500/7600 device that the IPS should use for blocking. The number can be 1 to 4094 and must be defined on the device.
Pre VACL Name Post VACL Name	The VLAN ACLs to combine with the blocking entries that the IPS creates to implement blocking actions. The Pre VACL is added before the blocking VACL, and the Post VACL is added after the blocking VACL. For more information, see Understanding Router and Switch Blocking Devices , on page 1762. **Tip** If you have configured a VACL on the VLAN, you must specify the name of the VACL in the Pre or Post VACL Name field or the VACL will be removed from the VLAN. When you identify a VLAN as a blocking interface, the IPS takes control of the VACL on that VLAN. Typically, you would specify the VACL name as the post-VACL.

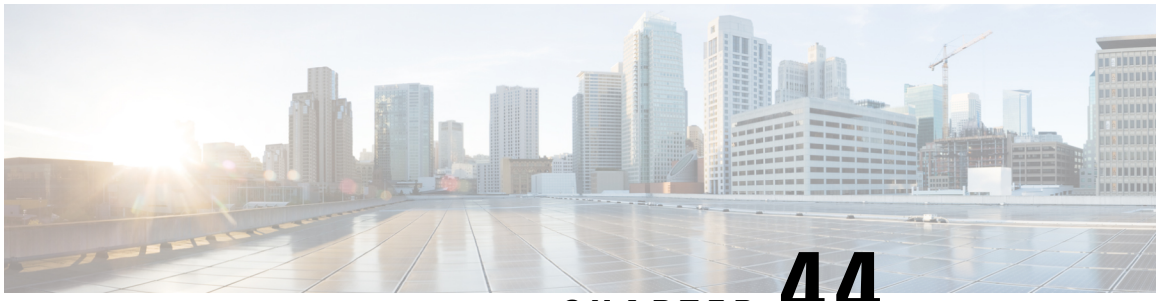
Never Block Host or Network Dialog Boxes

Use the Add or Modify Never Block Host or Network dialog boxes to specify a host or network that should never be subject to blocking. The name of the dialog box indicates whether you are adding a host or network address.

Enter the IP address or the name of a network/host policy object that specifies the address. You can also click **Select** to select an object from a list or to create a new object. When selecting objects, the object can contain a single entry of the appropriate type. Host addresses do not have subnet masks (for example, 10.100.10.1), whereas network addresses have masks (for example, 10.100.10.0/24).

Navigation Path

From the IPS Blocking policy, select the Never Block Hosts or Networks tab and click the **Add Row** button or select an existing row and click the **Edit Row** button. Hosts and networks are listed in separate tables, so ensure that you click the buttons associated with the desired table. For information on opening the Blocking policy, see Blocking Page , on page 1766.



CHAPTER 44

Managing IPS Sensors

To perform day-to-day sensor management, you typically need to use a device manager such as the IPS Device Manager (IDM). Security Manager is focused on policy and event management.

However, the following topics describe some management activities that you can perform using Security Manager:

- Managing IPS Licenses , on page 1777
- Managing IPS Updates , on page 1780
- Managing IPS Certificates , on page 1786
- Rebooting IPS Sensors , on page 1788

Managing IPS Licenses

The following topics explain how to manage licenses for IPS devices:

Updating IPS License Files , on page 1777

Managing IPS Updates , on page 1780

Managing IPS Certificates , on page 1786

Updating IPS License Files

You can use Security Manager to update the licenses for IPS devices. This procedure explains how to update the licenses manually by retrieving them from Cisco.com or from a license file on the Security Manager server. For information about setting up automatic license updates, see Automating IPS License File Updates , on page 1779.

Before You Begin

If you use Cisco.com, you must first configure the IPS Update server to be Cisco.com, so that you can specify the username and password. You must use Cisco.com for licensing if you are using a device that requires it; for example, an IPS 4270 or an AIP SSM-40 in an ASA device requires a Cisco.com account. For information on configuring Cisco.com as the IPS Update server, see Configuring the IPS Update Server , on page 1780.

If you use local licenses, you must download them directly to the Security Manager server file system. You cannot do this through Security Manager; you must log into Windows on the server to download the licenses.

Related Topics

• Redeploying IPS License Files , on page 1778

Step 1 Select **Tools > Security Manager Administration** and select **Licensing** from the table of contents.

Step 2 Click the **IPS** tab (see IPS Tab, Licensing Page , on page 571).

The table lists all IPS devices in the device inventory and displays the status of their licenses. The status can be valid, invalid, expired, no license, or trial license. The expiration date for the license is also shown. Click **Refresh License** to update the table with the latest license information from the devices (you can select one or more devices to limit the scope of the refresh).

To update licenses, do one of the following:

- To update devices with licenses obtained directly from Cisco.com—Select the devices you want to update and click **Update Selected via CCO**. A dialog box opens that lists the devices that can be updated from Cisco.com, which might not be all of the devices you selected. Review the list and click **OK**. The status of the update task is shown in the License Update Status Details dialog box (see License Update Status Details Dialog Box , on page 575).

To successfully update the license using this method, you must have a Cisco.com support contract that includes the serial numbers of the selected devices.

Tip The Cisco software license server (SWIFT) that contains the licenses might block requests from the same server for more than 9 licenses within a three minute period. Thus, you should select fewer than 9 devices at a time when performing manual license updates.

- To update devices with licenses that you have copied to the Security Manager server—Click **Update from License File**. A dialog box opens where you can select the license files. Click **Browse** to select them from the Security Manager local file system. You can select more than one license file. When you have selected the desired files, click **OK** to have them applied to the devices.

Redeploying IPS License Files

If an attempt to apply an IPS license update to a device fails, you can redeploy the update. Redeployment works only if you have already attempted to apply an update and a license file is associated with the IPS device.

Related Topics

- Updating IPS License Files , on page 1777
- Automating IPS License File Updates , on page 1779

Step 1 Select **Tools > Security Manager Administration** and select **Licensing** from the table of contents.

Step 2 Click the **IPS** tab (see IPS Tab, Licensing Page , on page 571).

Step 3 Select the devices to which you want to redeploy licenses and click **Redeploy Selected Licenses**. A dialog box opens listing devices whose licenses you are redeploying. Click **OK** to perform the update.

The status of the update task is shown in the License Update Status Details dialog box (see License Update Status Details Dialog Box , on page 575).

Automating IPS License File Updates

Security Manager can automatically apply IPS license updates to your IPS devices on a regular schedule. To successfully configure automatic updates, you must have a Cisco.com support contract that includes the serial numbers of your IPS devices.

Tip Security Manager applies new licenses only if the downloaded license has an expiration date further into the future than the one replaced or if the license information is different.

Before You Begin

You must first configure the IPS Update server to be Cisco.com, so that you can specify the Cisco.com username and password. For information on configuring Cisco.com as the IPS Update server, see Configuring the IPS Update Server , on page 1780.

Related Topics

- Updating IPS License Files , on page 1777
- Redeploying IPS License Files , on page 1778

Step 1 Select **Tools > Security Manager Administration** and select **Licensing** from the table of contents.

Step 2 Click the **IPS** tab (see IPS Tab, Licensing Page , on page 571).

Step 3 Select **Download and apply licenses** and configure the following settings:

- **Days before the expiration date**—Select the number of days before a license expires that Security Manager should download an updated license. The default is 1 day.
- **Discover devices daily at**—Select the time of day when Security Manager should download licenses. At this time, Security Manager will check the license status on the devices, and contact Cisco.com for new licenses for devices that have no license, have expired licenses, or that have licenses that will expire within the number of days you selected.
- **Email License Update Results**—Select whether Security Manager should send e-mail notification of license update results. E-mails are sent with license expiration status and for license update job results. If you select this option, enter one or more e-mail addresses in the **Email Notification** field. Separate multiple addresses with commas.

For the e-mails to be sent, you must configure an SMTP server as described in Configuring an SMTP Server and Default Addresses for E-Mail Notifications , on page 27.

Step 4 Click **Save** to save your changes.

Managing IPS Updates

You can use Security Manager to apply sensor and signature updates to your IPS devices and shared policies. Through Security Manager, you can download updates and either set up automatic updates or apply them manually.

Signature updates are available only for IPS 5.1(4) and later.

Tip If you have problems applying patches, service packs, or signature updates, check the time on your IPS sensor. If the time on the sensor is ahead of the time on the associated certificate, the certificate is rejected and the update may fail. Use the Network Time Protocol (NTP) to maintain accurate time on an IPS sensor. For information on configuring NTP on the sensor, see Identifying an NTP Server , on page 1636.

The IPS packages included with Security Manager do not include the package files that are required for updating IPS devices. You must download IPS packages from Cisco.com or your local update server before you can apply any updates. The downloaded versions include all required package files and replace the partial files that are included in the Security Manager initial installation.

The following topics describe how to use Security Manager to manage IPS updates:

Configuring the IPS Update Server

To apply IPS sensor and signature updates, Security Manager must download the updates to the Security Manager server from an identified IPS Update server.

You can use Cisco.com as the IPS Update server. Using Cisco.com ensures that the latest updates are available to you at their earliest availability. However, if you cannot use Cisco.com for some reason, you can set up your own local IPS Update web server, manually download updates to it, and configure Security Manager to obtain the updates from your local server.

Tip If you are using a device that requires a Cisco.com login for updating licenses, such as an IPS 4270 or an AIP SSM-40 in an ASA device, you must configure the IPS Update server as Cisco.com. You cannot use a local server.

Related Topics

- Automating IPS Updates , on page 1782
- Manually Applying IPS Updates , on page 1783

Step 1 Select **Tools > Security Manager Administration** and select **IPS Updates** from the table of contents to open the IPS Updates page (see IPS Updates Page , on page 559).

Step 2 In the Update Server area, click **Edit Settings** to open the Edit Update Server Settings dialog box (see Edit Update Server Settings Dialog Box , on page 564).

Step 3 Enter the identifying information for your server. Based on the server type selected in the Update From field:

- Cisco.com—Enter a Cisco.com username and password. The user account you specify must have applied for eligibility to download strong encryption software. To verify the account has the appropriate permissions, go to Cisco.com and try to download an IPS update package. You will be prompted to accept the appropriate agreements if the account is not already qualified.
- Local server—Enter the IP address or DNS host name of your server, a username and password if you require a log in before allowing access, and the path to the folder that contains the files. For the path, do not enter the entire URL; enter only the path portion of the URL (for example, the path in http://servername/IPSpath is IPSpath). Also add IIS configuration settings:
  - Home Directory should have listing enabled.
  - Documents should have Default Content Page disabled.

Enter certificate information. Before you can download an IPS package, you must accept the Cisco.com certificate. You must accept the certificate from both the "Image Meta-data locator" site and the download site of the IPS packages to start downloading images successfully (see Edit Update Server Settings Dialog Box , on page 564).

If your network requires a proxy server to get from the Security Manager server to the IPS Update server, select **Enable Proxy Server** and enter the information for the proxy server.

Click **OK** to save your changes.

Step 4 Click **Save** on the IPS Updates page. Your changes are not completely saved unless you click **Save**.

Step 5 Test the connectivity to the IPS Update server by clicking **Download Latest Updates**. A dialog box opens. Click **Start** to have Security Manager log into the update server, check for new updates, and download them. The dialog box displays the results of the operation.

If you are using Cisco.com and experience a download failure, double-check the user account to ensure it has the required permissions for downloading strong encryption software.

Checking for IPS Updates and Downloading Them

You can use Security Manager to check for IPS sensor and signature updates and download them to the Security Manager server, where you can apply them to your IPS devices and policies.

You can manually download IPS updates, automate IPS update downloads, or download them when you try to manually apply them to a device. The following procedure explains how to manually check for updates and download them. For information on configuring automatic downloads, see Automating IPS Updates , on page 1782. For information on downloading updates while manually applying them to devices or policies, see Manually Applying IPS Updates , on page 1783.

Before You Begin

You must configure the IPS Update server as described in Configuring the IPS Update Server , on page 1780.

Related Topics

- Automating IPS Updates , on page 1782
- Manually Applying IPS Updates , on page 1783

Step 1 Select **Tools > Security Manager Administration** and select **IPS Updates** from the table of contents to open the IPS Updates page (see IPS Updates Page , on page 559).

Step 2 Review the status information in the Update Status group, and do any of the following:

- Click **Check for Updates**. A dialog box opens to display the results of the operation. Click **Start** to have Security Manager log into the IPS Update server and check for updates.
- Click **Download Latest Updates**. A dialog box opens to display the results of the operation. Click **Start** to have Security Manager log into the IPS Update server, check for updates, and download them to the Security Manager server.

Tip If a Cisco.com download fails, ensure that the account you are using has applied for eligibility to download strong encryption software. For details, see the description of User Name in Edit Update Server Settings Dialog Box , on page 564.

Automating IPS Updates

You can automatically apply sensor image and signature updates to compatible IPS devices to ensure that they are up to date. If desired, you can partially automate the updates to maintain the desired level of control over the process.

Tip If you later decide that you did not want to apply a signature update, you can revert to the previous update level by selecting the Signatures policy on the device, clicking the **View Update Level** button, and clicking **Revert**.

Tip If you do not manage IPS devices, consider taking the following performance tuning step. In *$NMSROOT* \MDC\ips\etc\sensorupdate.properties, change the value of packageMonitorInterval from its initial default value of 30,000 milliseconds to a less-frequent value of 600,000 milliseconds. Taking this step will improve performance somewhat. [*$NMSROOT* is the full pathname of the Common Services installation directory (the default is C:\Program Files\CSCOpx).]

Before You Begin

You must configure the IPS Update server as described in Configuring the IPS Update Server , on page 1780.

Related Topics

- Checking for IPS Updates and Downloading Them , on page 1781
- Manually Applying IPS Updates , on page 1783

- Understanding IPS Network Sensing , on page 1613
- Deploying Configurations in Non-Workflow Mode , on page 408
- Deploying Configurations in Workflow Mode , on page 414

Step 1 Select **Tools > Security Manager Administration** and select **IPS Updates** from the table of contents to open the IPS Updates page (see IPS Updates Page , on page 559).

Step 2 In the Auto Update Settings group in the lower portion of the page, select an auto update mode to establish the extent of automation. Choices include:

- Download, Apply, and Deploy Updates—Security Manager checks for updates according to your schedule, downloads them to the Security Manager server, applies them to the selected devices and policies, and starts a deployment job to update the affected devices. This choice ensures that your devices are running the latest updates with minimal effort for your operations staff.
- Disable Auto Update—Security Manager does not perform any automatic actions for IPS updates.
- Check for Updates—Security Manager checks for updates according to your schedule and updates the information in the Update Status group. No devices or policies are updated.
- Download Updates—Security Manager checks for updates according to your schedule and downloads any new updates to the Security Manager server.
- Download and Apply Updates—Security Manager checks for updates according to your schedule, downloads them, and applies them to the selected devices and policies. You must separately create a deployment job to deploy the changes to the affected devices.

Step 3 Click **Edit Update Schedule** to open a dialog box where you can specify the schedule for the operation. Select the starting date, enter the starting time in 24-hour format (hh:mm), and select whether the schedule should be by the hour, day, week, month, or a one-time event. Click **OK** to save the schedule.

Step 4 (Optional) Enter an e-mail address in the Notify Email field. Security Manager will notify this user when a package is available for download or has been downloaded, applied, or deployed. You can enter more than one address by separating the addresses with commas.

Step 5 Select the devices and shared policies you want to automatically update in the Apply Update To selector. Use the Type field to toggle between local policies (for devices) and shared policies.

To select a device or policy, click it in the selector and click the **Edit Row** button (the pencil icon below the selector). This action opens the Edit Auto Update Settings dialog box. Select the types of updates you want to apply: minor sensor updates and service packs or service packs only, and the signature update level. Click **OK** to save your changes. The devices to which the policy apply are added to the Devices to be Auto Updated list. A message will indicate if you need to submit your changes for the change to take effect.

Step 6 Click **Save**.

Manually Applying IPS Updates

You can manually apply image and signature updates to compatible IPS devices using the Apply IPS Update wizard. Use this procedure with policies and devices that you did not configure for automatic updates (as described in Automating IPS Updates , on page 1782).

When applying signature updates, the wizard displays those signatures in the update that are not configured on the target IPS devices. You can configure the new signatures before they are applied.

When applying image and signature updates, only those devices to which the updates can be applied are available for selection. Inapplicable devices are grayed out. If you hover the mouse pointer over a grayed out device, a tooltip displays the reason for graying out the device. A device can be grayed out even if a signature update applies to it but if the required engine upgrade or generic packages are not available. Following are some of the instances when devices might be grayed out and the corresponding tooltip labels:

- If the version of the selected signature or sensor package is lower than the version of the target IPS device, Security Manager grays out the device and a mouse-over tooltip displays the message "Selected package is inapplicable".
- If you try to use Security Manager to upgrade an IPS device from version 7.2.2, with SNMP policy configured, to version 7.3.1, a mouse-over tooltip displays the message "Selected upgrade is not recommended. Unassign the SNMP policy on the device and deploy it to continue with the upgrade to 7.3.1". This is because SNMPv3 is not supported in IPS version 7.3.1.
- If you try to use Security Manager to perform a signature update that does not contain one or more threat profiles applied to the device, Security Manager grays out the device and a mouse-over tooltip displays the message "Currently applied threat profile is not applicable to this signature version". It does not allow the signature update to be successfully applied. You must remove the existing threat profile and then proceed with the signature update.

Tip If you later decide that you did not want to apply a signature update, you can revert to the previous update level by selecting the Signatures policy on the device, clicking the **View Update Level** button, and clicking **Revert**.

Before You Begin

Configure the IPS Update server as described in Configuring the IPS Update Server , on page 1780.

Related Topics

- Checking for IPS Updates and Downloading Them , on page 1781
- Selecting a Signature Category for Cisco IOS IPS , on page 1794

Note This note describes a difference between the update packages for IPS 7.1.3 and those used for earlier versions. When you open the Apply IPS Update wizard (Tools > Apply IPS Update), the first page of the wizard lists the sensor and signature update packages that are available. Beginning with IPS 7.1.3, a single update package is used for all supported platforms, such as IPS-4270 and ASA-SSE-AIP-85; example: IPS-CSM-K9-7.1.3.zip. Prior to IPS 7.1.3, a separate package was used for each supported platform; example: IPS-CS-MGR-SSC_5-K9-6.2-4-E4.zip.

Step 1 Select **Tools > Apply IPS Update** to open the Apply IPS Update wizard.

Step 2 On the first page of the wizard, select the update that you want to apply. This page lists the sensor and signature updates that are available. Do the following on this page:

- To update the list of packages, click **Download Latest Updates**. Security Manager logs into the IPS Update server and downloads the updates that have become available since the last download. This works only if you have configured an update server as described in Configuring the IPS Update Server , on page 1780. You can also update the list of packages by doing the following:
  - Configure automatic downloads on the IPS Updates page (select **Tools > Security Manager Administration > IPS Updates**). For more information, see IPS Updates Page , on page 559.
  - Manually download the updates to the CSCOpx\MDC\ips\updates folder in the product installation folder (typically Program Files) on the Security Manager server.

You can also check for updates without downloading them by clicking **Check for Updates**. The Update Status information is the same as described in IPS Updates Page , on page 559.

- Select the signature or sensor update you want to apply to your IPS devices in the Updates Downloaded table. Use the **Type** field to toggle between the types of updates (you can select only one update to apply):
  - **Sensor Updates**—Displays the filename, the major, minor, service pack, and patch versions, as well as the supported engine release. You must apply all major sensor updates, however, minor updates are cumulative.
  - **Signature Updates**—Displays the filename, the signature number, and the supported engine release. Signature updates are cumulative; however, applying them as separate packages allows you to separate your work into more manageable units if you intend to tune the updates to match the specific needs of your network.

Note The engine package is not listed on the update page, but Security Manager implicitly pushes the engine package automatically in the case of a signature update that requires a higher engine version. (This occurs only when updating a device with the particular version that the engine package requires.)

Click **Next** to continue.

Step 3 On the second page of the wizard, select the local signature policies (representing devices not assigned to any shared signature policy) and shared signature policies you want to update from the Apply Updates To list. Use the **Type** field to toggle between the types of policies. You can select any combination of local and shared policies. When you select a policy, the devices that use the policy are selected for update.

To select all applicable devices or shared policies, click **Select All**. To erase your selection and start over, click **Deselect All**. These buttons apply only to the displayed list.

IPS devices to which the update does not apply are grayed out in the Apply Updates To list, and you cannot select them. When you select a device that can be updated, it is listed in the Devices Assigned to Selected Policies list; these are the only devices that will be updated. If you select a shared policy, all devices that are using the policy appear in the selected policies list, but the devices to which the update does not apply are grayed out.

Tip The engine release controls which devices you can select for sensor updates; you can apply the update only to devices that use the same engine version, regardless of the release version. For example, if your device is running 6.0(5) E3, you can update to 6.1(1) E3 but not to 6.1(1) E2. You also cannot apply a 6.1(1) E3 update to a device running 6.1(1) E2. If you want to update the engine version, select a signature update with the higher engine version, and Security Manager will update the engine level automatically while updating the signatures. For example, if the device has the 6.1(1) E2 version and needs to have the E3 engine package applied, choose the signature package that requires the E3 engine and apply it to the device; doing so applies the engine package automatically to the device while updating the signatures. Thus, if the device you want to update is grayed out, click **Back** and change your update selection.

If you are applying a signature update, and you want to edit the signatures before applying them, click **Next** to continue. Otherwise, click **Finish** to apply your update to the policies.

Step 4 (Optional) On the third page of the wizard, modify the signatures as desired.

The signatures list displays the new and modified signatures between the signature level of the selected update and the lowest signature level among the selected devices. If the selected devices include both IPS sensors and Cisco IOS IPS devices, the signatures for these devices appear on separate tabs.

Click the link in the ID number to read the description for the signature on Cisco.com. The Status column indicates whether the signature is new or modified (see the visual description of the icons on the wizard page).

To edit a signature, select it in the table and click the Edit button below the table (the pencil icon). For help in understanding the signature, click **Help** in the dialog box that the Edit button opens.

For details on available signature information, see Signatures Page , on page 1680. In the Signature Summary Table, you can also add custom signatures and delete signatures, but you cannot do that on this page of the Apply IPS Update Wizard.

Click **Finish** to apply your update to the policies and to save your edits.

Step 5 Submit your changes and deploy them to the devices. For information on creating deployment jobs, see these topics:

- Deploying Configurations in Non-Workflow Mode , on page 408
- Deploying Configurations in Workflow Mode , on page 414

Managing IPS Certificates

When you configure Security Manager to use SSL (HTTPS) to communicate with your IPS devices, the certificate configured on the device must match the certificate stored in Security Manager's certificate store. Mismatched certificates will result in communication failures during policy discovery or deployment.

IPS devices use self-signed certificates that have a fixed validity period of about 2 years. When the certificate expires, you need to regenerate the certificate and update the certificate store with the new certificate.

Security Manager includes a utility that you can use to synchronize the certificate store with the certificate defined on the device, to regenerate expired certificates, and to view the status of certificates (including expiration dates) on the IPS devices that you manage.

Tip If you are using HTTP for communication with the IPS devices, certificates are not used and you cannot manage them. IPS device communication settings are configured in the Security Manager Administration Device Communication page (see Device Communication Page , on page 532).

The following procedure explains how to manage your IPS certificates with Security Manager.

Related Topics

- Table Columns and Column Heading Features , on page 51
- Filtering Tables , on page 50
- Manually Adding SSL Certificates for Devices that Use HTTPS Communications , on page 461
- Security Certificate Rejected When Discovering Device , on page 462
- Invalid Certificate Error During Device Discovery , on page 463

Step 1 Select **Manage > IPS > IPS Certificates** to open the IPS Certificates dialog box.

Tip The list shown in this dialog box is not automatically refreshed. Click **Refresh** whenever you open the dialog box to ensure that you are looking at the most current certificate expiration information.

The dialog box lists all IPS sensors that are in the inventory according to their Security Manager display name. Not all columns are displayed (right-click any cell heading to select additional columns). The main columns of interest are the following:

- **Certificate Mismatch?**—Whether the certificate defined on the device is the same as that in Security Manager. This field is blank if the certificate is unavailable or non-retrievable; otherwise, it can have these values:
  - **No**—The device and Security Manager have the same certificate. No action is required.
  - **Yes**—The device and Security Manager have different certificates. If the certificate has not expired, select the device and click **Sync Certificates** to replace the certificate in the Security Manager certificate store with the certificate from the device.
- **Valid Until on Device, Valid From on Device**—These two separate columns show the date range within which the certificate is valid. The certificate expires after the Valid Until date is reached. Consider regenerating the certificate as this date approaches.
- **Certificate Status on Device**—Shows the current status of the certificate as it exists on the device:
  - **Valid Certificate**—The certificate is good and within the validity date range.
  - **Expired Certificate**—The certificate has passed its Valid Until date and is now expired. Select the device and click **Regenerate Certificate** to create a new valid certificate on the device and to have the certificate loaded into the Security Manager certificate store.
  - **Certificate Not Yet Valid**—The certificate has not yet reached its Valid From date and cannot be used yet. This might indicate a mismatch between the time settings on the device and on the Security Manager server. Ensure that the time settings are the same (consider using an NTP server). Consider regenerating the certificate.
  - **Unavailable – Refresh to get Cert Info**—The certificate is not currently in the Security Manager certificate store. Click **Refresh** to have Security Manager retrieve the certificate from the device and load it into the certificate store.
  - **Nonretrievable – Cert Info not available**—Security Manager was not able to log into the device and retrieve the certificate, or you are using HTTP for communications. Select the device and click **Refresh**.

If refresh does not resolve the problem, ensure that the device is operating normally (that it is not down), and then check the device properties to ensure that correct credentials are configured for access (see Viewing or Changing Device Properties , on page 109). If credentials are not the problem, also check the Allowed Hosts policy configured on the device and ensure that the Security Manager server is included as an allowed host (see Identifying Allowed Hosts , on page 1620). You can also log into Windows on the Security Manager server and use ping to see if there is a route between the server and the IPS device.

- **Thumbprint on CSM, Thumbprint on Device**—These separate columns show the thumbprint for the certificate in the certificate store and on the device.

Step 2 Use any of the following buttons to perform the indicated actions. Except where indicated, if you do not select one or more devices before clicking the button, the action is performed on all listed devices, which can be time-consuming if

there are a lot of IPS devices. You are warned before an operation is performed on all devices and given the option to stop it.

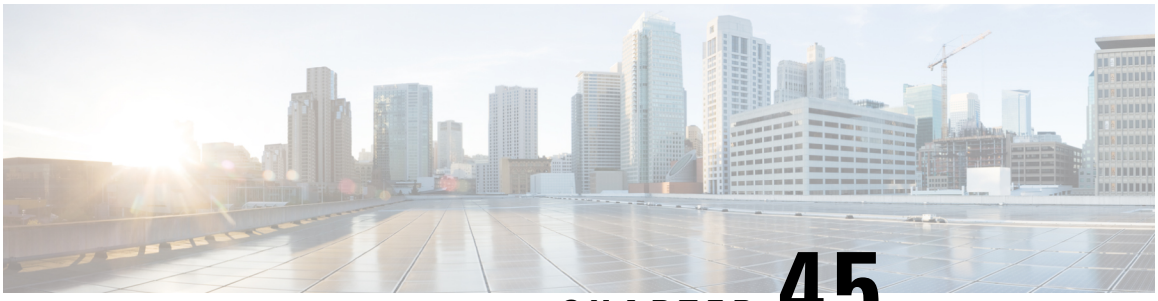
- **Sync Certificate**—Synchronize the certificate information in the Security Manager certificate store with the certificate on the device. The device certificate replaces the one in the certificate store.
- **Regenerate Certificate**—Generate a new certificate on the device and then load the new certificate into the certificate store.
- **Refresh**—Refresh the status information by having Security Manager contact the devices and retrieve certificate information, such as validity dates, and compare the certificate with the one in the certificate store. This action updates the Certificate Status on Device column and also determines whether there is a certificate mismatch.
- **Export**—Exports the entire certificates table to a comma-separated values (CSV) file. You cannot export less than the entire table. You are prompted for a file name and folder on the Security Manager server.

Rebooting IPS Sensors

You can reboot an IPS sensor from Security Manager.

To reboot the sensor, select it in Device view, right-click and select **Reboot Device**. You are asked to confirm that you want to reboot.

Security Manager does not provide status information on the reboot process.



CHAPTER 45

Configuring IOS IPS Routers

Some Cisco IOS routers, such as integrated services routers (ISRs), include native IPS capabilities based on IPS 5.1 software. You can configure some basic IPS inspection on these devices to supplement IPS sensor inspection or to support small networks.

This chapter contains the following topics:

Understanding Cisco IOS IPS

You can use Cisco Security Manager with the Cisco IOS Intrusion Prevention System (IOS IPS) to manage intrusion prevention on Cisco routers that use supported Cisco IOS Software releases 12.4(11)T2 and later.

The Cisco IOS IPS acts as an in-line intrusion prevention sensor, watching packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When it detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE).

You can configure Cisco IOS IPS to choose the appropriate response to various threats. The Signature Event Action Processor (SEAP) can dynamically control actions that are to be taken by a signature event on the basis of parameters such as fidelity, severity, or target value rating. You can configure these actions in Security Manager through the Signatures and Event Actions policies.

When packets in a session match a signature, Cisco IOS IPS can take any of the following actions, as appropriate:

- Send an alarm to a syslog server or a centralized management interface.
- Drop the packet.
- Reset the connection.
- Deny traffic from the source IP address of the attacker for a specified amount of time.
- Deny traffic on the connection for which the signature was seen for a specified amount of time.

Cisco developed its Cisco IOS software-based intrusion-prevention capabilities and Cisco IOS Firewall with flexibility in mind, so that individual signatures could be disabled in case of false positives. Generally, it is preferable to enable both the firewall and Cisco IOS IPS to support network security policies. However, each of these features can be enabled independently and on different router interfaces.

For an overall understanding of the Cisco IOS IPS configuration process, see . Overview of Cisco IOS IPS Configuration , on page 1792

This section contains the following topics:

Understanding IPS Subsystems and Support of IOS IPS Revisions

Cisco Security Manager automatically supports minor revisions of IOS IPS. To identify minor revisions that are supported, the IPS subsystem version is needed.

The IPS subsystem version is a version number used to keep track of Cisco IOS IPS feature changes. The subsystem number is show in the device properties (right-click the device and select **Device Properties**). You can also use the command **show subsys name ips** at a command line on the router that is running Cisco IOS IPS to show the detailed Cisco IOS IPS subsystem version. The 3.x subsystems are equivalent to IPS 5.x. For a list of the supported subsystems by Cisco IOS Software release, see the *Supported Devices and Software Versions for Cisco Security Manager* on Cisco.com for this release of Security Manager.

An IPS subsystem version is minor if the version difference is limited at postfix. For example, a revision from 3.0.1 to 3.0.2 is considered minor. For another example, 3.0.1 to 3.1.1 is also considered a minor version change. However, minor revisions that include new features are not automatically supported by Cisco Security Manager.

Cisco IOS IPS Signature Scanning with Lightweight Signatures

The addition of Cisco IOS IPS signature scanning with lightweight signatures in Cisco IOS Release 15.0(1)M is an enhancement to Cisco IOS IPS that allows loading of larger signatures sets, without consuming significant additional memory or reducing the memory consumed by an existing signature set, by loading equivalent lighter-weight signatures. These signatures are referred to as lightweight signatures.

Security Manager can discover and tune custom signatures with LWEs on ISRs and modular access routers. Security Manager supports the following features for signatures with LWEs on ISRs and modular access routers:

- New signature types
- Signature categories
- New default signature category recognition
- New engine update levels
- Licensing status—bypassed, expired, or not installed

Router Configuration Files and Signature Event Action Processor (SEAP)

As of Cisco IOS Release 12.4(11)T, signature definition files (SDFs) are no longer used by Cisco IOS IPS. Thus, you cannot not use the deprecated built-in signature sets, 128.sdf, 256.sdf, and attack-drop.sdf, with Security Manager.

Instead, routers access signature definition information through a directory that contains three configuration files—the default configuration, the delta configuration, and the SEAP configuration. You configure the location using the **IPS > General Settings** policy.

SEAP is the control unit responsible for coordinating the data flow of a signature event. It allows for advanced filtering and signature overrides on the basis of the Event Risk Rating (ERR) feedback. ERR is used to control the level in which a user chooses to take actions in an effort to minimize false positives.

Signatures once stored in NVRAM are now stored in the delta configuration file.

Cisco IOS IPS Limitations and Restrictions

Cisco IOS IPS routers do not support all the features that are supported by dedicated IPS sensor appliances and service modules. In addition, routers that support IOS IPS might not allocate as much memory to IPS functionality as an IPS sensor does. The following limitations and restrictions are important:

- When configuring an IOS IPS device, select only the signatures that you need. If you select all signatures that are available in Security Manager, you might exceed the memory available on the IOS IPS router and deployment can fail, the device might fail to load all of the signatures, or performance might be significantly degraded. If you encounter deployment failures, select a reduced set of signatures and then redeploy the configuration to the device.
- Security Manager-managed routers being configured to use IOS-IPS for the first time cannot use the auto-update process for signature updates. You must first update the router before you use the auto-update process. Follow these steps:
  1. Push an E3 signature, for example, S317.
  2. Push an intermediate signature, for example, S470.
  3. Push the first E4 signature, for example, S485.
  4. Push subsequent E4 signatures until you reach the desired level. Note that each delta should be less than 10 MB in size.

After you have updated the router, you can use the auto-update process to update the signatures. The auto-update process will be successful as each incremental change will not exceed the memory available on the router. For information on configuring automatic updates, see Automating IPS Updates , on page 1782.

- Virtual sensors are not supported by IOS IPS.
- When using event action filters with an IOS IPS router, only a subset of IPS actions are available for removal from an event that meets the criteria of the event action filter. For more information on available event actions, see Filter Item Dialog Box , on page 1719 and Understanding IPS Event Actions , on page 1712.
- IOS IPS is based on IPS Software 5.1. Therefore, features introduced in later versions of IPS Software are typically not available in IOS IPS. For example, you cannot configure the following features:
  - Global correlation.

- Anomaly detection.
- OS identification in the event action network identification policy.

Overview of Cisco IOS IPS Configuration

There are a wide variety of devices on which you can configure the Intrusion Prevention System. From a configuration point-of-view, you can separate the devices into two groups: dedicated appliances and service modules (for routers, switches, and ASA devices) that run the full IPS software; and IPS-enabled routers running Cisco IOS Software 12.4(11)T and later (Cisco IOS IPS).

The following procedure is an overview of IPS configuration on a Cisco IOS IPS router. For dedicated IPS devices, including IPS service modules installed in a router, see Overview of IPS Configuration , on page 1617.

Cisco IOS IPS is a more limited feature meant for branch offices and small to medium sized networks, or to distribute IPS throughout a network. You typically cannot employ as many signatures in a Cisco IOS IPS router compared to a dedicated appliance. You also cannot configure advanced features such as global correlation, because Cisco IOS IPS is based on IPS Software version 5.1. When configuring Cisco IOS IPS devices, you are mostly configuring standard router policies, because the device is a router that is running a few IPS features. In comparison, the platform policies for IPS appliances and service modules are specific to IPS software.

Tip Before configuring Cisco IOS IPS, read *Cisco IOS Intrusion Prevention System Deployment Guide* on Cisco.com.

Step 1 Install and connect the device to your network. Install the device software and perform basic device configuration. Install the licenses required for all of the services running on the device. The amount of initial configuration that you perform influences what you will need to configure in Security Manager. For information about required basic settings, see:

- Setting Up SSL on Cisco IOS Routers , on page 60
- Setting Up SSH , on page 62
- Configuring Licenses on Cisco IOS Devices , on page 68
- Initial Preparation of a Cisco IOS IPS Router, on page 1793
- Selecting a Signature Category for Cisco IOS IPS , on page 1794

Step 2 Add the device to the Security Manager device inventory (see Adding Devices to the Device Inventory , on page 77). When you add the device be sure to make the following selections:

- When adding from Network or Export File, ensure that you select **IPS Policies** for policy discovery.
- When adding from Configuration File or by Manual Definition, ensure that you select **IPS** from the **Options** list, or the device will not be IPS-capable from Security Manager's point of view.

Step 3 Configure the IPS general settings to specify the location of the IPS files on the router. For more information, see Configuring General Settings for Cisco IOS IPS , on page 1795.

Step 4 Configure the IPS interface rules to enable IPS and to identify the interfaces on which traffic will be subject to IPS inspection. For more information, see Configuring IOS IPS Interface Rules , on page 1797.

Step 5 Configure IPS signatures and event actions. Event action policies are easier to configure than creating custom signatures, so try to use event action filters and overrides to modify signature behavior before trying to edit specific signatures. For more information, see the following topics:

- Configuring Event Action Rules, on page 1711
- Configuring Signatures , on page 1680

Step 6 Maintain the device:

- Update and redeploy configurations as necessary.
- Apply updated signature and engine packages. For information about checking for updates, applying them, and setting up regular automated updates, see Managing IPS Updates , on page 1780.

Initial Preparation of a Cisco IOS IPS Router

Before you add a Cisco IOS IPS router to the Security Manager inventory, you need to perform some preparatory steps. The white paper Getting Started with Cisco IOS IPS with 5.x Format Signatures provides a step-by-step explanation of a basic configuration. Although you could do some of the steps after adding the router to Security Manager, such as configuring interface rules, you should do at least the basic steps.

The following procedure explains the steps you are required to complete in the CLI. These steps are required because Security Manager either cannot complete them, or it is simply easier to do it in the CLI (as a one-time configuration). The white paper includes additional steps that you can complete in the CLI, and Security Manager can discover your configuration when you add the device to the inventory. The more you do in CLI, the less you will have to configure in Security Manager.

Tip You also must complete the basic router configuration steps as explained in Setting Up SSL on Cisco IOS Routers , on page 60, Setting Up SSH , on page 62, and Configuring Licenses on Cisco IOS Devices , on page 68. The following steps apply to the IPS configuration only.

Step 1 Create a directory for IPS files on flash. For example, the following command creates a directory named ips:

Example:

```
router# mkdir ips
Create directory filename [ips]?
Created dir flash:ips
```

At this point, you can optionally configure the router to use this directory for IPS, or you can do it later in Security Manager (in the IPS > General Settings policy). Use the following commands to configure it in CLI:

Example:

```
router# configure terminal
router(config)# ip ips config location flash:ips
```

Step 2 Configure the Cisco IOS IPS crypto key. The crypto key is used to verify the digital signature for the main signature file (sigdef-default.xml) whose contents are signed by a Cisco private key to guarantee its authenticity and integrity at every release.

You can obtain the CLI required for the key from http://download-sj.cisco.com/cisco/ciscosecure/ids/sigup/5.0/ios/realm-cisco.pub.key.txt (login to Cisco.com is required).

Tip Configuring the key through the CLI is probably the easiest way to do it. Alternatively, you can configure it in Security Manager by assigning the IOS_IPS_PUBLIC_KEY pre-defined FlexConfig object to the router's FlexConfig policy. For more information about FlexConfigs, see Managing Flexconfigs, on page 341.

a) Open the text file and copy its contents to the clipboard (select all text then press Ctrl+C).
b) If necessary, enter **configure terminal** at the router CLI prompt.
c) Paste the copied text file at the router prompt.
d) Exit configuration mode.
e) Enter the **show run** command to confirm that the key was correctly configured.

Step 3 Syslog is configured for IPS notifications by default. If you want to use SDEE for notifications, enable SDEE:

Example:

```
router# configure terminal
router(config)# ip ips notify sdee
```

Step 4 Select a signature category to compile. For detailed information, see Selecting a Signature Category for Cisco IOS IPS , on page 1794.

Selecting a Signature Category for Cisco IOS IPS

Cisco IPS appliances and Cisco IOS IPS with IPS 5.x format signatures operate with signature categories. All signatures are grouped into categories; the categories are hierarchical. An individual signature can belong to more than one category. Top-level categories help to define general types of signatures. Subcategories exist beneath each top-level signature category. (For a list of supported top-level categories, use your router CLI help (?) with the **category** command.)

Router memory and resource constraints prevent a router from loading all Cisco IOS IPS signatures. Thus, it is recommended that you load only a selected set of signatures that are defined by the categories. Because the categories are applied in a "top-down" order, you should first retire all signatures, followed by "unretiring" specific categories. Retiring signatures enables the router to load information for all signatures, but the router does not build the parallel scanning data structure.

Retired signatures are not scanned by Cisco IOS IPS, so they do not fire alarms. If a signature is irrelevant to your network or if you want to save router memory, you should retire signatures, as appropriate.

Security Manager does not manage the signature category command. You cannot configure it directly with a policy. However, you can configure the FlexConfig policy to include a FlexConfig object that configures the command. There is a pre-defined object, IOS_IPS_SIGNATURE_CATEGORY, that you can use. If you want to configure a different category than basic, make a copy of the object and edit it. For information on how to use FlexConfigs, see Managing Flexconfigs, on page 341.

Tip If you do not use the **category** command to select a subset of IPS signatures that the device will attempt to compile, Security Manager will configure the category command to enable the IOS IPS Basic category to prevent the device resources from being overloaded. You can change the category manually on the device to select another set of signatures to compile. We recommend that you configure the category before adding the device to Security Manager; however, this is not possible if you add the device through manual definition.

The following example shows how to first retire all signatures, then to configure the basic category and unretire the basic signatures:

```
Router> enable
Router# configure terminal
Router(config)# ip ips signature-category
Router(config-ips-category)# category all
Router(config-ips-category-action)# retired true
Router(config-ips-category-action)# exit
Router(config-ips-category)# category ios_ips basic
Router(config-ips-category-action)# retired false
Router(config-ips-category-action)# exit
```

Configuring General Settings for Cisco IOS IPS

Use the General Settings page to specify the global settings used for Cisco IOS IPS properties defined for a particular router. The default settings are appropriate for most situations; however, you must specify an IPS configuration file location. If storing the configuration file on the router, you must first create the directory as described in Initial Preparation of a Cisco IOS IPS Router, on page 1793.

Navigation Path

- (Device view) Select **IPS > General Settings** from the Policy selector.
- (Policy view) Select **IPS (Router) > General Settings**, then select an existing policy or create a new one.

Related Topics

- Overview of Cisco IOS IPS Configuration , on page 1792
- Understanding Cisco IOS IPS , on page 1789

Field Reference

Table 548: General Settings Page

Element	Description
Block Traffic when IPS engine is unavailable	Whether to block all inspected traffic if the IPS engine is not available, for example, when the signature engine is being built or if it fails to build. If you select this option, any traffic specified for inspection is dropped if IPS cannot process it (also known as fail-closed mode). Otherwise, traffic is allowed to pass in accordance with the other rules in place on the router (the default).
Apply Deny Action On	Where to apply ACL entries to drop traffic for Deny Attacker Inline or Deny Flow Inline events. Select one of the following values: • **Ingress Interface** (the default)—Enforce the deny action on the interface attached to the network from which the traffic originated. • **IPS enabled interfaces**—Enforce the deny action on the interface on which the triggered IPS rule is applied. Enabling this option causes IOS IPS to apply the ACLs directly to the IPS interfaces, and not to the interfaces that originally received the attack traffic. If the router is not performing load balancing, do not enable this setting. If the router is performing load balancing, we recommend that you enable this setting.
SDEE Properties	
Maximum Subscriptions	The maximum number of concurrent SDEE subscriptions allowed, in the range of 1-3. An SDEE subscription is a live feed of SDEE events. The default is 1.
Maximum Alerts	The maximum number of SDEE alerts that you want the router to store, in the range of 10-2000. Storing more alerts uses more router memory. The default is 200.
Maximum Messages	The maximum number of SDEE messages that you want the router to store, in the range of 10-500. Storing more messages uses more router memory. The default is 200.
IPS Config Location Properties	

Element	Description
IPS Config Location	The location where the router will save IOS IPS specific configuration files. These configuration files are automatically updated every time the IOS IPS configuration is changed or updated from Security Manager. When the router reboots, the IOS IPS configuration is retrieved and restored from these configuration files. To specify a location on the router, enter the name of the directory. The directory must already exist; Security Manager does not create it. For example, flash:ips. **Note** If the router has a LEFS-based file system, you will be unable to create a directory in router memory. In this case, flash: is used as the config location. To specify a location on a remote system, specify the protocol and path of the URL needed to reach the location. For example, if you want to save the config files to an HTTP server, then enter http://172.27.108.5/ips-cfg. Supported servers for saving the IOS IPS configuration files are: http://, https://, ftp://, rcp://, scp://, and tftp://.
Max retries	When storing configuration files on a remote system, how many times the router is to attempt to contact the remote system. The default is 1.
Timeout seconds between retries	When storing configuration files on a remote system, how long the router is to wait before attempting to contact the configuration location again. The default is 1.

Configuring IOS IPS Interface Rules

Note From version 4.17, though Cisco Security Manager continues to support IOS and IPS features/functionality, it does not support any bug fixes or enhancements.

Use the IPS Interface Rules policy to enable IPS inspection on Cisco IOS IPS routers and to specify the interfaces that will be subject to IPS inspection. You can identify a subset of the traffic on the interface that is subject to inspection by configuring an ACL and by specifying the traffic direction relative to the interface.

Related Topics

- Overview of Cisco IOS IPS Configuration , on page 1792
- Understanding Cisco IOS IPS , on page 1789

Step 1 Do one of the following to open the Interface Rules policy you want to modify:

- (Device view) Select **IPS > Interface Rules** from the Policy selector.
- (Policy view) Select **IPS (Router) > Interface Rules** from the Policy selector. Select an existing policy or create a new one.

The policy shows any existing interface rules, including the rule name, the name of the ACL that defines which traffic is inspected (if any), and the interface and traffic direction that is inspected. If no ACL is specified, all traffic on the interface in the specified direction is inspected.

Although the rules are numbered, the sequence of rules has no effect on IPS processing.

Step 2 Select **Enable IPS** to enable the deployment of IOS IPS configuration to the device.

If Enable IPS is unchecked, IPS rules are removed from all the router interfaces, which disables IPS. Also, no signature or event action policy will be deployed.

Step 3 Configure the interface rules. The rules identify the interfaces, and traffic direction on the interface, that will be inspected by IPS. The rules can optionally include an ACL to identify a subset of traffic for inspection.

- To add a rule, click the **Add Row (+)** button and fill in the Add IPS Rule dialog box. For detailed information, see IPS Rule Dialog Box , on page 1798.
- To edit a rule, select it and click the **Edit Row (pencil)** button.
- To delete a rule, select it and click the **Delete Row (trash can)** button.

IPS Rule Dialog Box

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

Use the Add or Edit IPS Rule dialog box to identify the traffic flows to be inspected using the active signature policy.

Navigation Path

From the Interface Rules policy, click the **Add Row** button to add a new rule, or select a rule and click the **Edit Row** button. For information on opening the Interface Rules policy, see Configuring IOS IPS Interface Rules , on page 1797.

Field Reference

Table 549: Add or Edit IPS Rule Dialog Box

Element	Description
Rule Name	The unique name for this IPS rule. IPS rule names are not case sensitive. You cannot use a rule name that contains the same characters as another one previously defined but using a different case. For example MYRULE and MyRule are the same.

Element	Description
ACL Name	The name of the ACL policy object that defines which traffic should be subject to IPS inspection. If you do not specify an ACL, all traffic on the interface/direction pairs listed in the Interface Pairs table is subject to inspection. **Tip** If you create an ACL, permit entries identify traffic that is subject to inspection, whereas deny entries identify traffic that is exempt from inspection. Remember that there is an implicit deny any any rule at the end of the ACL, so if your intention is simply to identify exempt traffic, be sure to add a permit any any rule at the end of the ACL. Enter the name of the ACL policy object, or click **Select** to select it from a list or to create a new object.
Interface Pairs table	The interfaces and traffic direction pairs that are subject to IPS inspection. • To add a pair, click the **Add Row (+)** button and fill in the Adding Pair dialog box. See Pair Dialog Box , on page 1799. • To edit a pair, select it and click the **Edit Row (pencil)** button. • To delete a pair, select it and click the **Delete Row (trash can)** button.

Pair Dialog Box

Use the Adding or Editing Pair dialog box to identify the interface and traffic direction pair to add to a Cisco IOS IPS interface rule. For information on configuring interface rules, see Configuring IOS IPS Interface Rules , on page 1797.

Navigation Path

From the Add or Edit IPS Rule dialog box, click the **Add Row** button to add a new pair, or select a pair and click the **Edit Row** button. For information on opening the Add or Edit IPS Rule dialog box, see IPS Rule Dialog Box , on page 1798.

Field Reference

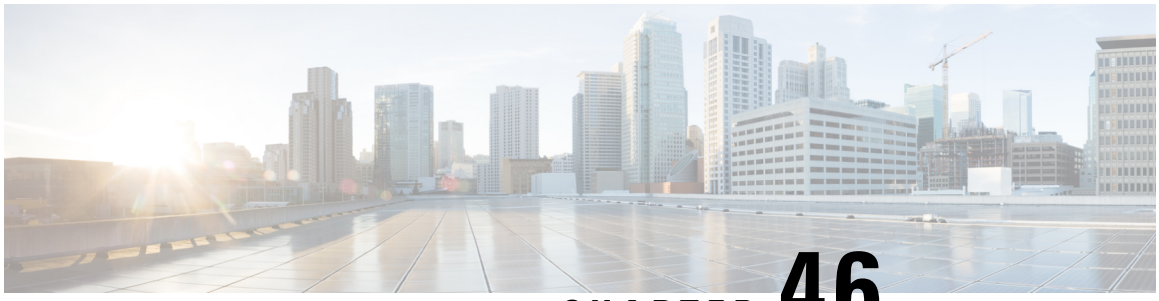
Table 550: Adding or Editing Pair Dialog Box

Element	Description
Direction	The traffic direction, with respect to the interface, on which IPS inspection should be performed. Select one of the following: • **In** (default)—The IPS rule should be applied to inbound traffic. • **Out**—The IPS rule should be applied to outbound traffic. • **Both**—The IPS rule should be applied to both inbound and outbound traffic.

Element	Description
Interfaces	The interface on which to apply this IPS rule. Enter the name of an interface or interface role object, or click **Select** to select the interface or interface role from a list or to create a new interface role. If you use interface roles, the rule is applied to all interfaces on the device that are defined by the role. The interfaces that match the role cannot conflict with an existing rule. You cannot specify the same interface for more than one interface rule.

PART V

PIX/ASA/FWSM Device Configuration



CHAPTER 46

Managing Firewall Devices

Note From version 4.17, though Cisco Security Manager continues to support Cisco Catalyst switches, PIX, FWSM, IOS devices, and IPS, it does not support any bug fixes or enhancements.

The following topics describe configuration and management of security services and policies on Cisco security devices: Adaptive Security Appliances (ASAs), PIX Firewalls, and the Catalyst 6500 series switch Services Modules—that is, Firewall Services Modules (FWSMs) and ASA-SMs.

This chapter contains the following topics:

Firewall Device Types

Security Manager can discover and manage a variety of Cisco security appliances or firewall devices, most notably the following:

- PIX 500 Series firewall devices
- ASA 5500 Series security appliances including the Cisco Virtual Security Appliance (ASAv)
- Firepower 3100 series firewall devices
- Security-specific Catalyst Services Modules

PIX 500 Series

The Private Internet eXchange (PIX) 500 Series firewall appliances are no longer sold, however they are still supported and a great many are still in use world-wide.

ASA 5500 Series

The Adaptive Security Appliance (ASA) 5500 Series devices provide comprehensive security services, including context-aware firewall capabilities and real-time threat defense. The ASA 5500 has replaced the

PIX 500 as Cisco's primary security appliance. Visit the Cisco ASA 5500 Series Adaptive Security Appliance page on cisco.com for more information.

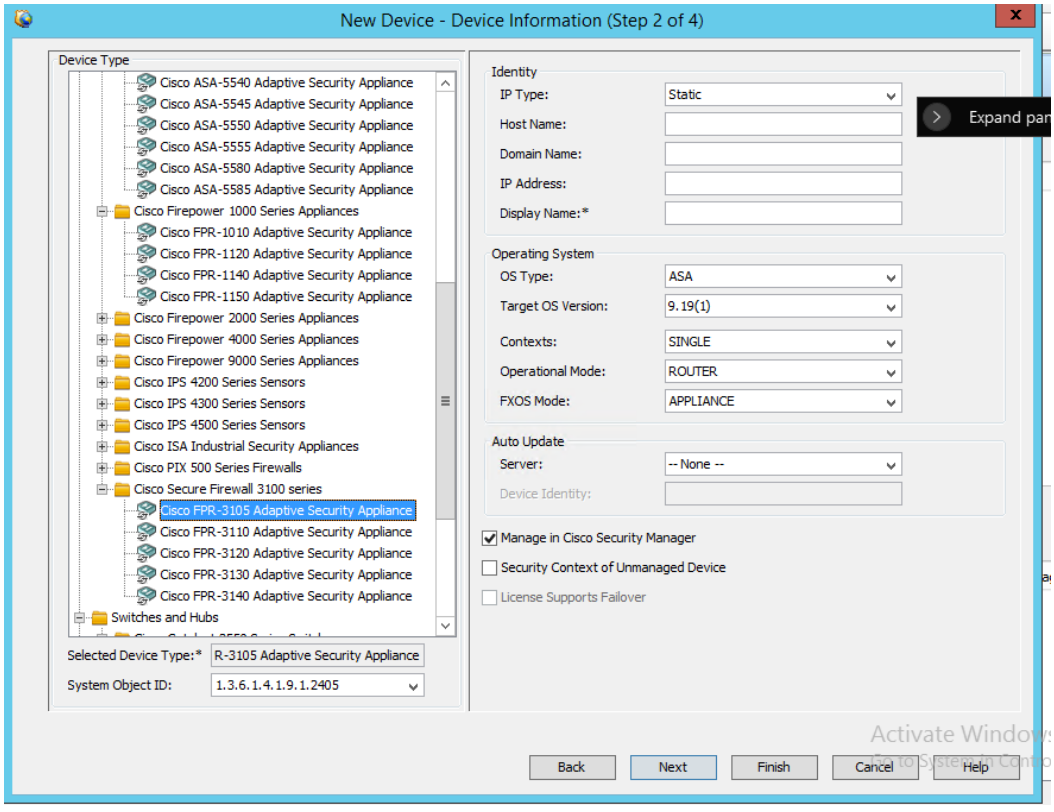
The Cisco ASAv Virtual Appliance, introduced in ASA 9.2(1), brings full firewall functionality to virtualized environments to secure data center traffic and multi-tenant environments. The ASAv runs on VMware vSphere. Although the ASAv is a virtual device, it is managed like other ASA devices in Security Manager. For more information about the ASAv, seehttp://www.cisco.com/c/en/us/support/security/virtual-adaptive-security-appliance-firewall/tsd-products-support-series-home.html .

Note The ASAv does not support the following ASA features: Clustering, Multiple context mode, Active/Active failover, Ether channels, and Shared Secure Client Premium Licenses.

Firepower 3100 Series

Firepower 3100 series firewall devices support is intoroduced for ASA 9.17(1) devices in CSM 4.24.

Note Secure Firewall 3105 device support is introduced for ASA 9.19(1) and above devices in CSM.



Catalyst Services Modules

A variety of Services Modules (SMs) are available for the Catalyst 6500 switch, including two that provide firewall and security services. These are blade-type modules that are installed directly into the switch chassis.

The Firewall Services module (FWSM) allows any port on the switch to operate as a firewall port, integrating firewall security inside the network structure.

The Adaptive Security Appliance service module (ASA-SM) provides high-speed security services across Layers 2 through 7, and you can install up to four ASA-SM blades in a single switch, providing scalability to 64 Gbps.

Note While the ASA-SM is a blade installed in a Catalyst 6500 switch—much like the FWSM physically—it is an ASA device, and it is documented as such. That is, refer to ASA-related topics for information about the ASA-SM. Where necessary, caveats and differences between the Service Module and the ASA appliance are noted.

Default Firewall Configurations

Firewall devices are shipped with certain settings already configured. When you manually add a newly installed firewall device to Cisco Security Manager, you should discover (import) the pre-set or default policies for that device. Importing these policies into Security Manager prevents them being unintentionally removed the first time you deploy a configuration to that device. For more information about importing policies, see Discovering Policies , on page 178.

Cisco Security Manager provides a set of configuration files that contain default policies for a number of device types and versions. These configuration files are located in the directory: <*install_dir*> \CSCOpx\MDC\fwtools\pixplatform\ (for example, C:\Program Files\CSCOpx\MDC\fwtools\pixplatform\ ).

The file name indicates device type, operating system version, context support, and operation type. For example, “FactoryDefault_FWSM2_2_MR.cfg” is the configuration file for an FWSM, version 2.2, with support for Multiple contexts, operating in Routed mode. Similarly, “FactoryDefault_ASA7_0_1_ST.cfg” is the configuration file for an ASA, version 7.0.1, in Single-context, Transparent mode.

Refer to Interfaces in Single and Multiple Contexts , on page 1808 for more about security contexts, and Interfaces in Routed and Transparent Modes , on page 1807 for more about routed and transparent operation.

See Adding Devices from Configuration Files , on page 91 for information about adding new devices from the supplied configuration files.

Configuring Firewall Device Interfaces

The Interfaces page displays configured physical interfaces, logical interfaces, and redundant interfaces, as well as hardware ports and bridge groups, for the selected device. From this page, you can add, edit and delete interfaces; enable communication between interfaces on the same security level; and manage VPDN groups and PPPoE users.

Note The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: Hardware Ports and Interfaces. Similarly, the Interfaces page displayed for the Catalyst 6500 services modules (ASA-SMs and FWSMs) operating in transparent mode also presents two tabbed panels: Interfaces and Bridge Groups.

Navigation Path

To access the Interfaces page, select a security device in Device View and then select **Interfaces** from the Device Policy selector.

This section contains the following topics:

- Understanding Device Interfaces , on page 1806
- Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835
- Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881

Understanding Device Interfaces

An interface is a point of connection between a security device and some other network device. Interfaces are initially disabled; thus, as an essential part of firewall configuration, interfaces must be enabled and configured to allow appropriate packet inspection and forwarding.

There are two types of interface: physical and logical, where a physical interface is the actual slot on the device into which a network cable is plugged, and a logical interface is a virtual port assigned to a specific physical port. Generally, physical ports are referred to as interfaces, while logical ports are referred to as subinterfaces, virtual interfaces, VLANs, or EtherChannels, depending on their function. The number and type of interfaces you can define varies with appliance model and type of license purchased.

Note On devices running version 6.3 of the PIX operating system, the labels “physical” and “logical” are used, rather than “interface” and “subinterface.” Also, transparent mode and multiple contexts are not supported on these devices.

Subinterfaces let you divide a physical interface into multiple logical interfaces that are tagged with different VLAN IDs. Because VLANs keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or security appliances. This feature is particularly useful in multiple-context mode, allowing you to assign unique interfaces to each context.

As a general rule, interfaces attach to router-based networks, and subinterfaces attach to switch-based networks. All subinterfaces must be associated with a physical interface that is responsible for routing allowed traffic correctly.

If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. The physical interface must be enabled for the subinterface to pass traffic, but do not name the physical interface to ensure it does not pass traffic. However, if you do want to let the physical interface pass untagged packets, you can name the interface as usual. See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for information about naming an interface.

Note The ASA 5505, combining switch and security appliance features, is a special case in that you configure both physical switch ports and logical VLAN interfaces. See Understanding ASA 5505 Ports and Interfaces , on page 1809 for more information.

The Catalyst 6500 services modules (ASA-SMs and FWSMs) do not include any external physical interfaces—instead, they use internal VLAN interfaces. For example, assume you assign VLAN 201 to an FWSM inside interface, and VLAN 200 to the outside interface. You assign these VLANs to physical switch ports, and hosts connect to those ports. When communication occurs between VLANs 201 and 200, the FWSM is the only available path between the VLANs, forcing traffic to be statefully inspected.

See the following sections for additional information about device interfaces:

- Interfaces in Routed and Transparent Modes , on page 1807

- Configuring Redundant Interfaces , on page 1811
- Configuring EtherChannels , on page 1812
- Configuring VNI Interfaces , on page 1818
- Configuring Tunnel Interface, on page 1826

Security Appliance Configurations

Firewall devices allow a variety of configurations, and the configuration determines how to define the interfaces associated with a specific device. The following table outlines the various configurations.

Table 551: Security Appliance Configurations

Device Type	Operational Mode (Router or Transparent)	Context Support (Single or Multiple)
PIX 6.3.x	N/A	N/A
PIX 7.0+/ASA	Router or Transparent	Single
PIX 7.0+/ASA, or security context of unmanaged PIX 7.0+/ASA	Router or Transparent	Multiple (see Checklist for Configuring Multiple Security Contexts , on page 2288)
FWSM, or security context of unmanaged switch (multiple mode)	Router or Transparent	Single or Multiple

Interfaces in Routed and Transparent Modes

Beginning with ASA/PIX 7.0 and FWSM 2.2.1, you can configure a security device to operate in one of two modes: *routed* or *transparent* . (The PIX 6.3 operates only in routed mode.)

In routed mode, the security appliance acts as a gateway or router for connected networks: it maintains IP addresses for its interfaces, and inspects and filters traffic traversing these interfaces based on IP address (Layer 3) information. In this mode, each device interface is connected to a different IP subnet, and has its own IP address on that subnet. Routed mode supports up to 256 interfaces in single mode or per context, with a maximum of 1000 interfaces divided between all contexts.

In transparent mode, the security appliance operates as a Layer 2 (data link) device, or transparent bridge, and is often referred to as a "bump in the wire," or a "stealth firewall." In this mode, you can define only two interfaces: inside and outside. The interfaces do not require IP addresses; they use VLAN IDs to forward inspected traffic. However, if the device includes a dedicated management interface, you can use it—either the physical interface or a subinterface—as a third interface for device-management traffic.

Note Cisco Security Manager does not populate the interface information for FWSM 2.x devices during discovery.

Bridge Groups

Beginning with the ASA 8.4.1 and FWSM 3.1, in transparent mode, you can increase the number of interfaces available to a device or context through use of bridge groups. You can configure up to eight bridge groups; on an FWSM each group can contain two interfaces; on an ASA 9.7.1 (Cisco Security Manager 4.13) each group can contain upto 64 interfaces. See Add/Edit Bridge Group Dialog Box , on page 1876 for more information.

Interfaces in Single and Multiple Contexts

Security "contexts" allow a single physical device to operate as multiple, independent firewalls. In multiple-context mode, each context defines a single virtual firewall, complete with its own configuration. Each context acts as a unique virtual firewall that inspects and filters traffic traversing the interfaces allocated to that context. Each context is "unaware" of other contexts defined on the same security appliance.

As with a single-context, routed-mode device, interfaces on a multiple-context device connect to router-based networks, subinterfaces connect to switch-based networks, and each subinterface must be associated with an interface that routes allowed traffic correctly.

However, you cannot define IP addresses, the routed-mode portion of the configuration, or identify the management interface until you have defined and deployed the contexts. But you cannot define a security context until you have defined the necessary interfaces and subinterfaces.

In other words, you must enable and configure the interfaces and subinterfaces on a device that will provide multiple security contexts (in either routed or transparent mode) before you can define and configure the security contexts themselves.

About Asymmetric Routing Groups

In some situations, return traffic for a session may be routed through a different interface than the one from which it originated. Similarly, in failover configurations, return traffic for a connection that originated on one unit may return through the peer unit. This most commonly occurs when two interfaces on a single FWSM, or two FWSMs in a failover pair, are connected to different service providers and the outbound connection does not use a NAT address. By default, the FWSM drops the return traffic because there is no connection information for that traffic.

You can prevent return traffic being dropped by assigning the VLAN interfaces on which this is likely to occur to an asymmetric routing (ASR) group. When a member interface receives a packet for which it has no session information, it checks the session information for other interfaces that are members of the same group.

If a match is not found, the packet is dropped. If a match is found, one of the following actions occurs:

- If the incoming traffic originated on a different interface on the same FWSM, some or all of the Layer 2 header is rewritten and the packet is re-injected into the stream.
- If the incoming traffic originated on a peer unit in a failover configuration, some or all of the Layer 2 header is rewritten and the packet is redirected to the other unit. This redirection continues as long as the session is active.

Note In failover configurations, you must enable Stateful Failover for session information to be passed from the standby unit or failover group to the active unit or failover group.

To assign an FWSM virtual interface to an asymmetric routing group, simply specify an ASR Group ID in the Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+) , on page 1850. If the group does not exist, it is created and the interface assigned to it.

You must repeat the assignment for each interface that will participate in this ASR group. You can create up to 32 ASR groups and assign a maximum of eight interfaces to each group.

Note The upstream and downstream routers must use one MAC address per VLAN, and have different MAC addresses for different VLANs, to allow the redirection of packets from a standby unit to an active unit in failover configurations.

Understanding ASA 5505 Ports and Interfaces

The ASA 5505 is unique in that it includes a built-in switch, and there are two kinds of ports and interfaces that you need to configure:

- Physical switch ports – The ASA 5505 has eight Fast Ethernet switch ports that forward traffic at Layer 2, using the switching function in hardware. Two of these ports are power-over-Ethernet (PoE) ports. You can connect these ports directly to user equipment such as PCs, IP phones, or DSL modems. Or you can connect to another switch.
- Logical VLAN interfaces – In routed mode, these interfaces forward traffic between VLAN networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces forward traffic between the VLANs on the same network at Layer 2, using the configured security policy to apply firewall services.

To segregate the switch ports into separate VLANs, you assign each switch port to a VLAN interface. Switch ports on the same VLAN can communicate with each other using hardware switching. But when a switch port on one VLAN attempts to communicate with a switch port on another VLAN, the ASA 5505 applies the security policy to the traffic, and routes or bridges between the two VLANs.

Note Subinterfaces and redundant interfaces are not available on the ASA 5505.

Navigation Path

The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: *Hardware Ports* and *Interfaces* . To access these panels, select an ASA 5505 in Device View and then select **Interfaces** from the Device Policy selector.

Configuring ASA 5505 Switch Ports and Interfaces

Refer to Configuring Hardware Ports on an ASA 5505 , on page 1874 for information about configuring the switch ports.

Refer to Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840 for information about configuring the interfaces.

Related Topics

- Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835

Configuring Subinterfaces (PIX/ASA)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

Subinterfaces let you divide a physical interface into multiple logical interfaces that are tagged with different VLAN IDs. Because VLANs keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or security appliances. This feature is particularly useful in multiple-context mode, letting you assign unique interfaces to each context.

Note If you use subinterfaces, you typically do not also want the physical interface to pass traffic, as the physical interface passes untagged packets. Because the physical interface must be enabled for the subinterface to pass traffic, do not name the physical interface to ensure it does not pass traffic. However, if you do want to let the physical interface pass untagged packets, you can name the interface as usual.

Note This option is available only on PIX 7.0+ and non-5505 ASA devices.

Defining Subinterfaces

Follow these steps to configure a subinterface in the Add/Edit Interface (ASA/PIX 7.0+) dialog box, which is accessed from the device Interfaces page (see Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835).

1. Choose **Subinterface** as the interface **Type** in the Add/Edit Interface dialog box.

The VLAN ID and Subinterface ID fields appear below the Hardware Port, Name and Security Level fields.

1. Choose the desired **Hardware Port** from the list of previously defined interface ports. If you do not see a desired interface ID, be sure that Interface is defined and enabled.
2. **VLAN ID** – Provide a VLAN ID for this subinterface: enter a value between 1 and 4094. The specified VLAN ID must not be in use on any connected device.

Some VLAN IDs might be reserved on connected switches; see the switch documentation for more information. In multiple-context mode, you can only set the VLAN ID in the system configuration.

1. **Secondary VLAN ID** – Provide a secondary VLAN ID value for this subinterface; this enables the ASA to map the packets that arrive on the ASA on the secondary VLAN to a primary VLAN. configure: Enter a value between 1 and 4090.The secondary VLAN ID must be unique and not be the same as a VLAN ID. A secondary VLAN is supported on devices running ASA 9.5.2 or later in single context, in routed or firewall mode or as an L2 cluster.

Note You can add multiple VLAN IDs, separated by a space or a comma. You can also specify a range of VLAN IDs for e.g. 56-78.

1. **Subinterface ID** – Provide an integer between 1 and 4294967293 as the Subinterface ID. The number of subinterfaces allowed depends on your platform.

For subinterface port identification, this ID is appended to the chosen Hardware Port. For example, *GigabitEthernet0.4* represents the subinterface assigned an ID of 4, operating on the port GigabitEthernet0.

Note You cannot change the Subinterface ID after you set it.

1. Continue configuring this interface, as described in Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840.

Configuring Redundant Interfaces

Beginning with Security Manager 3.2.2, you can define logical “redundant” interfaces to increase security appliance reliability. A redundant interface is a specific pair of physical interfaces, with one designated as active (or primary) and the other as standby (or secondary). If the active interface fails, the standby interface becomes active and starts passing traffic. This feature is separate from device-level failover, but you can configure redundant interfaces as well as failover, if desired. You can configure up to eight redundant interface pairs.

A redundant interface functions as a single interface (inside, outside, etc.), with only one of the member pair active at any one time. This redundant interface is configured normally, with a unique interface name, security level and IP address. Note that each member interface must be of the same type (e.g., GigabitEthernet), and cannot have a name, security level, or IP address assigned. In fact, do not configure any options other than Duplex and Speed on the member interfaces.

The redundant interface uses the MAC address of the first physical interface that you specify. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. Alternatively, you can explicitly assign a MAC address to the redundant interface; this address is then used regardless of the member interface MAC addresses. In either case, when the active interface fails over to the standby, the same MAC address is maintained so that traffic is not disrupted.

Note This option is available only on PIX 8.0+ and non-5505 ASA devices.

Defining Redundant Interfaces

Follow these steps to configure two physical interfaces as a single logical "redundant interface" in the Add/Edit Interface (ASA/PIX 7.0+) dialog box, which is accessed from the device Interfaces page (see Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835).

1. Choose **Redundant** as the interface **Type** in the Add/Edit Interface dialog box.

The Redundant ID, Primary Interface and Secondary Interface options appear.

1. Provide an identifier for this redundant interface in the **Redundant ID** field; valid IDs are the integers from 1 to 8.
2. **Primary Interface** – Choose the primary member of the redundant interface pair from this list of available interfaces. Available interfaces are presented by Hardware Port IDs, as named interfaces cannot be used for a redundant interface pair.
3. **Secondary Interface** – Choose the secondary member of the redundant interface pair from this list of available interfaces. Available interfaces are presented by Hardware Port IDs, as named interfaces cannot be used for a redundant interface pair.

Note Member interfaces must be enabled and of the same type (e.g., GigabitEthernet), and cannot have a Name, IP Address, or Security Level assigned. In fact, do not configure any options other than Duplex and Speed on the member interfaces.

1. Continue configuring this interface, as described in Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840.

Configuring EtherChannels

Beginning with ASA 8.4.1, you can define logical EtherChannel interfaces. An EtherChannel, also called a port-channel interface, is a logical interface consisting of a bundle of individual Ethernet links (a channel group). This provides increased bandwidth and fault tolerance compared to the individual links.

An EtherChannel interface is configured and used in the same manner as a single physical interface. You can configure up to 48 EtherChannels, each of which consists of between one and eight active Fast Ethernet, Gigabit Ethernet, or Ten-Gigabit Ethernet ports. For ASA 9.2(1), the number of active interfaces increased to 16.

Note You cannot use a redundant interface as part of an EtherChannel, nor can you use an EtherChannel as part of a redundant interface. You cannot use the same physical interfaces in a redundant interface and an EtherChannel interface. You can, however, configure both types on the ASA if they do not use the same physical interfaces.

EtherChannel MAC Addressing

All interfaces that are part of a channel group share the same MAC address. This makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. By default, the EtherChannel uses the MAC address of the lowest-numbered member interface as its MAC address.

Alternatively, you can manually configure a MAC address for the port-channel interface. We recommend doing so in case the channel interface membership changes. For example, if you remove the interface that provides the port-channel MAC address, the port-channel is assigned the MAC address of the next lowest numbered interface, causing traffic disruption. Manually assigning a unique MAC address to the EtherChannel interface prevents this disruption. (Note that in multiple-context mode, you can assign unique MAC addresses to interfaces assigned to an individual context, including EtherChannel interfaces.)

About Management Only EtherChannel Interfaces

You can specify an EtherChannel group as a management-only interface, but note the following caveats:

- Routed mode – You must explicitly configure the EtherChannel to be Management Only in the Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840. Any non-management interface added to the management-only port-channel is treated as a management port. If you add an interface already defined as management-only to the management-only group, that attribute is ignored on the physical interface. Similarly, you cannot designate an interface as management-only if it is already a member of a management-only port-channel.
- Transparent mode – In this mode, members of a management-only EtherChannel can themselves only be management-only ports. Thus, when a management-only member is added to a transparent-mode EtherChannel, the channel inherits the management-only designation, while the designation is removed from the member interface. Conversely, when such an interface is removed from the EtherChannel, the designation is restored on the individual interface.

Using an EtherChannel Interface as a Failover Link

If an EtherChannel interface is specified as a failover link, all state-sync traffic for that link will travel over a single physical interface. Should that physical interface fail, the state-sync traffic will then traverse another physical interface that is part of the EtherChannel aggregated link. If there are no remaining available physical interfaces in the EtherChannel link specified for failover, the ASA falls back to the redundant interface, if one is specified.

While an EtherChannel interface is being used as an active failover link, changes to that EtherChannel configuration are not allowed. You can change the EtherChannel configuration of that link only by disabling either the link or failover, as follows:

- Disable the EtherChannel link while the configuration changes are being made, and then reactivate it (failover will not occur while the link is disabled).
- Disable failover while the configuration changes are being made, and then re-enable it (failover will not occur in the interim).

Note As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named. Further, none of the EtherChannel's member interfaces can be named.

Defining EtherChannels on an ASA

Follow these steps to configure multiple physical interfaces as a single logical EtherChannel interface in the ASA Add Interface or Edit Interface dialog boxes, which are accessed from the device Interfaces page (see Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835).

Step 1 Choose **EtherChannel** as the interface Type.

The EtherChannel ID and interface-selection options appear on the General panel of the dialog box; the Load Balancing, LACP Mode, and Active Physical Interfaces: Minimum and Maximum fields appear on the Advanced panel.

Step 2 Provide an identifier for this EtherChannel in the EtherChannel ID field; valid IDs are the integers from 1 to 48. This number is appended to "Port-channel" to identify the EtherChannel in the Interface column of the table on the device's Interfaces page.

Step 3 **Available Interfaces** – Specify the members of this port-channel group by select one or more interfaces in this list of available interfaces, and then click the >> button to add them to the member list on the right.

Note All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

You can assign up to 16 interfaces to a channel group. For ASA 9.2(1) and later, each channel group can have up to 16 active interfaces. For switches that support only 8 active interfaces and ASA versions earlier than 9.2(1), only eight interfaces can be active, the remaining interfaces can act as standby links in case of interface failure. Alternatively, you can create a static EtherChannel by setting LACP Mode to On (on the Advanced panel, as described below), which means all interfaces in the group can pass traffic.

Note After assigning interfaces to this EtherChannel group, you can edit the LACP Port parameters for each member interface, as described in Editing LACP Parameters for an Interface Assigned to an EtherChannel , on page 1815.

Step 4 Click the **Advanced** tab to display that panel.

Step 5 Choose a **Load Balancing** option in the EtherChannel section. See About EtherChannel Load Balancing , on page 1816, for more information about this option.

Step 6 Select the desired **LACP Mode**; the default is Active, which means up to eight interfaces are active, while up to eight are in stand-by mode, as determined by the Minimum and Maximum values under Active Physical Interfaces.

If you select On, a static port-channel is created in which all member interfaces are all "on," meaning you can have up to 16 ports passing traffic, with no stand-by ports. When you select this option, the Mode for all interfaces assigned to this EtherChannel group is switched to On (if the Mode for each is not already On). See Editing LACP Parameters for an Interface Assigned to an EtherChannel , on page 1815, for more information about this mode.

Step 7 Specify the Minimum and Maximum number of Active Physical Interfaces for this EtherChannel.

As mentioned, an EtherChannel can consist of between 1 and 8 active links for ASA devices earlier than 9.2(1) or between 1 and 16 active links for ASA 9.2(1)+. Use these fields to indicate the minimum and maximum number of interfaces that can be active in this channel group at any given time. If your switch does not support 16 active interfaces, be sure to set the maximum to 8 or fewer.

Step 8 Continue configuring this interface, as described in Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840.

Note The EtherChannel **LACP System Priority** for this device is specified in the Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881 dialog box.

Editing LACP Parameters for an Interface Assigned to an EtherChannel

After assigning interfaces to an EtherChannel (port-channel) group, you can edit the LACP Port parameters for each member interface, as described here.

Note This feature is available only on ASA 8.4.1+ devices.

The Link Aggregation Control Protocol (LACP) directs aggregation of physical Fast Ethernet, Gigabit Ethernet, or Ten-Gigabit Ethernet interfaces into an EtherChannel group, and updating the remote partner device with current information after it finds a compatible set of ports and assigns a unique value called an "operational key" to the group. Note that operational key assignment is automatic; you cannot configure it.

Caution These LACP parameters are not available when the EtherChannel is assigned as a failover link.

LACP System Priority

Every LACP-enabled device has a unique system ID that is formed by combining a System Priority identifier and the system's MAC address. In certain situations, two EtherChannel-linked systems may need to change the operational key assigned to a set of ports to allow optimal aggregation. In such a situation, the system with higher priority is allowed to dynamically modify the operational key value assigned to the ports to achieve better aggregation. The system with the lower priority is not allowed to change the operational keys. The System Priority identifier is user-configurable, as described in Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881.

LACP Port Parameters

Port identification is provided by a unique number assigned to every group interface; this identifier is formed by combining a configurable Port Priority number and the port number assigned to the interface.

The port identifier provides port aggregation priority. Ports are considered for active use in an aggregation starting with the port that has highest aggregation priority in the system, and working down through an ordered list of port identifiers. The use of this port aggregation priority makes aggregation predictable and reproducible by selecting the links for aggregation in the same manner when all links are running LACP concurrently.

In addition, you can configure the priority of each port to administratively control the set of stand-by ports. For example, the port with the lowest priority will be considered last for group aggregation and will be become a stand-by port (assuming enough members are assigned to the group to allow stand-by ports).

Related Topics

- Configuring EtherChannels , on page 1812

Editing LACP Port Parameters for an Existing EtherChannel Interface

Follow these steps to edit an existing EtherChannel-assigned interface:

Step 1 In the table on the device's Interfaces page, select an interface that is a Member of a Port-channel group. (See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for information about accessing and using this table.)

Step 2 Click **Edit Row** to open the Edit Interface dialog box for that interface.

Only the Enable Interface check box, the LACP Port parameters, and the Description field can be altered.

Step 3 Edit the **LACP Port** parameters as necessary:

- **Priority** – This number is combined with the port number assigned to the interface to produce a unique port identification number. This value can be 1 to 65535, with higher numbers signifying lower priorities. The default is 32768. This parameter applies only when the port is in Active or Passive mode.
- **Mode** – Choose one of these LACP modes:
  - **Active** – In Active mode, a port initiates LACP exchanges with the partner device and periodically sends updates to the partner. Active LACP reflects the port's preference to participate in the protocol regardless of the partner's control mode.
  - **Passive** – A Passive-mode port does not initiate LACP exchanges, but upon receiving a request from the partner, the port will start exchanging LACP information with the partner. Passive mode is useful when it is not clear if the remote port supports LACP.

Some devices may show undesired behavior when they do not have LACP enabled and they receive periodic LACP updates. However, for channeling to operate correctly, at least one port must be configured in Active mode.

- - **On** – Use this mode to configure a static port-channel in which all member interfaces are "on," with no stand-by ports. No negotiation takes place and most restrictions associated with the other two modes do not apply; for example, the speed and duplex settings do not have to be the same for all member ports, and all member ports remain Active. Note that the remote ports also must be On. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

- **VSS or vPC Switch ID** – Identifies the Virtual Switching System (VSS) or Virtual Port Channel (vPC) switch ID to which the interface is connected.

Step 4 Continue editing this interface, as described in Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840.

About EtherChannel Load Balancing

Traffic in an EtherChannel is distributed across the individual bundled links in a deterministic fashion; however, the load is not necessarily balanced equally across all the links. Instead, frames are forwarded on a specific link as a result of a hashing algorithm. This algorithm uses a specific field or combination of fields in the packet header to produce a fixed Result Bundle Hash (RBH) value that indicates which link to use.

The algorithm can use one or a combination of the following packet-header fields to determine link assignment: source IP address, destination IP address, source MAC address, destination MAC address, TCP/UDP port numbers, or VLAN IDs. The field combination used by the algorithm is chosen from the **Load Balancing** list (on the Advanced tab of the ASA's Add Interface and Edit Interface dialog boxes); these options are described in the following section. For additional information, see Configuring EtherChannels , on page 1812.

For example, suppose source MAC address (*src-mac*) is the chosen field: when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source MAC address of each

incoming packet. Therefore, to provide load balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel (and the MAC addresses learned by the device do not change).

Similarly, with destination MAC address forwarding, when packets are forwarded to an EtherChannel, each packet is distributed across the ports in the channel based on the packet's destination host MAC address. Thus, packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

Therefore, when choosing a load-balancing option, use the option that provides the greatest variety in your configuration. For example, if most of the traffic on a channel is going only to a single MAC address, choosing the destination MAC address results in most of the traffic always using the same link in the channel. Alternatively, using source addresses or IP addresses might result in better load balancing, while a method that uses the source and destination addresses along with UDP or TCP port numbers can distribute traffic much differently.

Note This option is available only on ASA 8.4.1+ devices.

Load Balancing Options

When defining a single logical EtherChannel interface in the ASA Add/Edit Interface dialog box, choose one of the following **Load Balancing** options (on the Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+) , on page 1850) to specify the basis of load distribution:

- **dst-ip** – Load distribution is based on the destination-host IP address only; the source of the packets is not considered. Each packet with the same destination IP address is forwarded over the same link.
- **dst-ip-port** – Load distribution is based on the destination-host IP address and TCP/ UDP port. This option offers more granularity and a little more complexity than destination IP address alone.
- **dst-mac** – Load distribution is based on the destination host MAC address of incoming packets.
- **dst-port** – Distribution is based on the destination port; that is, a TCP or UDP port and not a physical interface.
- **src-dst-ip** – Distribution is based on source and destination IP addresses—source and destination IP addresses are paired for hash calculations. This method provides more granularity than destination IP address, for example: packets to the same destination can be forwarded over different links in a port-channel if they are coming from a different IP source.
- **src-dst-ip-port** – Distribution calculation considers source and destination IP addresses, and TCP/ UDP ports. Provides even greater granularity and distribution.
- **src-dst-mac** – Calculation is based on source and destination MAC address pairing.
- **src-dst-port** – Load distribution is based on source and destination TCP/UDP port.
- **src-ip** – Based on source host IP address only.
- **src-ip-port** – Source IP address and TCP/UDP port.
- **src-mac** – Source MAC address only.
- **src-port** – Source TCP/UDP port only.

- **vlan-dst-ip** – Destination IP address and VLAN ID pairing.
- **vlan-dst-ip-port** – Combination of destination IP address, TCP/UDP port, and VLAN ID.
- **vlan-only** – VLAN ID only.
- **vlan-src-dst-ip** – Source and destination IP address, and VLAN ID.
- **vlan-src-dst-ip-port** – Source and destination IP address, TCP/UDP port, and VLAN ID.
- **vlan-src-ip** – Source IP address and VLAN ID.
- **vlan-src-ip-port** – Source IP address, TCP/UDP port, and VLAN ID.

Configuring VNI Interfaces

VNI interfaces are similar to VLAN interfaces: they are virtual interfaces that keep network traffic separated on a given physical interface by using tagging. You apply your security policy directly to each VNI interface. All VNI interfaces are associated with the same VTEP interface.

To configure VXLAN, you must first Configuring VXLAN Policy , on page 1886 and then create a VNI interface and associate the configured VXLAN policy to the VNI interface.

When VNI Interface is the chosen Type in the Add Interface or Edit Interface dialog box, the dialog box presents three tabbed panels of options: General, Advanced and IPv6.The following sections describe how to configure VNI interfaces using the three tabbed panels:

- VXLAN , on page 1886
- VNI Interfaces—General Tab, on page 1818
- VNI Interfaces—Advanced Tab, on page 1820
- VNI Interfaces—IPv6 Tab, on page 1821

VNI Interfaces—General Tab

When VNI Interface is the chosen Type in the Add Interface or Edit Interface dialog box, the dialog box presents three tabbed panels of options: General, Advanced and IPv6. The options provided by the **General** panel are described in this section.

Navigation Path

You can access the General panel in the Add Interface and Edit Interface dialog boxes, which are accessed from the ASA Interfaces page, as described in Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835.

Field Reference

Table 552: General tab: Add/Edit Interface Dialog Box (ASA)

Element	Description
Enable Interface	Check this box to enable the VNI interface if not already enabled.
Name	Enter the Interface Name. The name is a text string up to 48 characters, and is not case-sensitive. You can change the name by reentering this command with a new value.
Security Level	Enter the Security Level, between 0 (lowest) and 100 (highest).
VXLAN	
VNI ID	Enter the VNI ID, between 1 and 10000. This ID is just an internal interface identifier.
VNI Segment ID	Enter the VNI Segment ID, between 1 and 16777215. The segment ID is used for VXLAN tagging.
Multicast Group IP Address	(Single Mode) Enter the Multicast Group IP Address. If you do not set the multicast group for the VNI interface, the default group from the VTEP source interface configuration is used, if available. If you manually set a VTEP peer IP for the VTEP source interface, you cannot specify a multicast group for the VNI interface. Multicast is not supported in multiple context mode.
NVE Mapped to VTEP Interface	Check the NVE Mapped to VTEP Interface check box. This setting associates the VNI interface with the VTEP source interface.
IP Type	Select the IP Type from the available options.
Static IP	IP Address—(Routed Mode) In the IP Address area, configure an IPv4 address. To configure IPv6, click the IPv6 tab. Subnet Mask—Specify the Subnet Mask.
Use DHCP	DHCP Learned Route Metric—(Required)To assign an administrative distance to the learned route, enter a value between 1 and 255 in the DHCP Learned Route Metric field. If this field is left blank, the administrative distance for the learned routes is 1. Obtain Default Route using DHCP—(Optional) Select this option to obtain a default route from the DHCP server so that you do not need to configure a default static route. Enable Tracking for DHCP Learned Route—(Optional) If Obtain Default Route using DHCP is selected, you can select this option to enable route tracking via a specific Service Level Agreement (SLA) monitor. The following option becomes available: Tracked SLA Monitor—Required if Enable Tracking for DHCP Learned Route is selected. Enter or Select the name of the SLA monitor object that defines the route tracking (connectivity monitoring) to be applied to this interface.

Element	Description
Description	(Optional) Specify a description for the interface.

Table 553: General tab: Add/Edit Interface Dialog Box (ASAv)

Element	Description
Enable Interface	Check this box to enable the VNI interface if not already enabled.
Name	Enter the Interface Name. The name is a text string up to 48 characters, and is not case-sensitive. You can change the name by reentering this command with a new value.
Security Level	Enter the Security Level, between 0 (lowest) and 100 (highest).
VXLAN	
Proxy Single-Arm	Select the proxy single arm to support the AWS GWLB for ASAv devices. **Important** You must enable AWS in ASAv device with hypervisors XENAWS or KVMAWS to view and configure Proxy Single-Arm in CSM UI. ASAv30 is the minimum supported platform for the Proxy Single-Arm configuration.
VNI ID	Enter the VNI ID, between 1 and 10000. This ID is just an internal interface identifier.
VNI Segment ID	Enter the VNI Segment ID, between 1 and 16777215. The segment ID is used for VXLAN tagging.
Multicast Group IP Address	(Single Mode) Enter the Multicast Group IP Address. If you do not set the multicast group for the VNI interface, the default group from the VTEP source interface configuration is used, if available. If you manually set a VTEP peer IP for the VTEP source interface, you cannot specify a multicast group for the VNI interface. Multicast is not supported in multiple context mode.
NVE Mapped to VTEP Interface	Check the NVE Mapped to VTEP Interface check box. This setting associates the VNI interface with the VTEP source interface.
IP Type	Select the IP Type from the available options.
Static IP	IP Address—(Routed Mode) In the IP Address area, configure an IPv4 address. To configure IPv6, click the IPv6 tab. Subnet Mask—Specify the Subnet Mask.

VNI Interfaces—Advanced Tab

When VNI Interface is the chosen Type in the Add Interface or Edit Interface dialog box, the dialog box presents three tabbed panels of options: General, Advanced and IPv6. The options provided by the **Advanced** panel are described in this section.

Navigation Path

You can access the Advanced tab in the Add Interface and Edit Interface dialog boxes, which are accessed from the ASA Interfaces page, as described in Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835.

Related Topics

- Configuring VNI Interfaces , on page 1818

- VNI Interfaces—IPv6 Tab, on page 1821

Field Reference

Table 554: Advanced tab: Add/Edit Interface Dialog Box (ASA)

Element	Description
Active MAC Address	Use the Active MAC Address field to manually assign a private MAC address to the interface
Standby MAC Address	The Standby MAC Address field can be used to set a standby MAC address for use with device-level failover.
Roles	All interface roles assigned to this interface are listed in this field. Role assignments are based on pattern matching between the Name given to this interface and all currently defined Interface Role objects in Cisco Security Manager. Interface role objects are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces.
DHCP Relay Servers	Enter the IP address or select a Networks/Hosts object representing the interface-specific DHCP server to which DHCP requests on this interface are relayed. Use a comma to separate multiple values. You can configure a maximum of 4 interface-specific DHCP relay servers and a maximum of 10 global and interface-specific DHCP relay servers combined.
DHCP Relay Trust Info (Option 82)	Specifies that you want to trust this DHCP client interface. You can configure interfaces as trusted interfaces to preserve DHCP Option 82.

VNI Interfaces—IPv6 Tab

When VNI Interface is the chosen Type in the Add Interface or Edit Interface dialog box, the dialog box presents three tabbed panels of options: General, Advanced and IPv6. The options provided by the **IPv6** panel are described in this section.

Navigation Path

You can access the IPv6 panel in the Add Interface and Edit Interface dialog boxes, which are accessed from the ASA Interfaces page, as described in Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835.

Field Reference

Table 555: IPv6 tab: Add/Edit Interface Dialog Box (ASA)

Element	Description
Enable IPv6	Check this box to enable IPv6 and configure IPv6 addresses on this interface. You can deselect this option to disable IPv6 on the interface, but retain the configuration information.
Enforce EUI-64	When selected, use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link is enforced. When this option is enabled on an interface, the source addresses of IPv6 packets received on the interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the interface identifier in an IPv6 packet is not in the Modified EUI-64 format, the packet is dropped and the following system log message is generated: %PIX|ASA-3-325003: EUI-64 source address check failed. Address format verification is performed only when a flow is created. Packets from an existing flow are not checked. Additionally, address verification can be performed only for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address. The Modified EUI-64 format interface identifier is derived from the 48-bit link-layer (MAC) address by inserting the hex number FFFE between the upper three bytes (OUI field) and the lower 3 bytes (serial number) of the link-layer address. To ensure the chosen address is from a unique Ethernet MAC address, the next-to-lowest order bit in the high-order byte is inverted (universal/local bit) to indicate the uniqueness of the 48-bit address. For example, an interface with a MAC address of 00E0.B601.3B7A would have a 64-bit interface ID of 02E0:B6FF:FE01:3B7A.

Element	Description
DAD Attempts	To specify the number of consecutive neighbor solicitation messages that are sent on an interface during duplicate address detection (DAD), enter a number from 0 to 600 in this field. Entering 0 disables duplicate address detection on the interface. Entering 1 configures a single transmission without follow-up transmissions; this is the default. Duplicate address detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection uses neighbor solicitation messages to verify the uniqueness of unicast IPv6 addresses. When duplicate address detection identifies a duplicate address, the state of the address is set to DUPLICATE and the address is not used. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface and an error message similar to the following is issued: %PIX-4-DUPLICATE: Duplicate address FE80::1 on outside If the duplicate address is a global address of the interface, the address is not used and an error message is issued, similar to that shown previously for a duplicate link-local address. All configuration commands associated with the duplicate address remain as-configured while the state of the address is set to DUPLICATE. If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address, and all other IPv6 address associated with the interface are regenerated (that is, duplicate address detection is performed only on the new link-local address).
NS Interval	The interval between IPv6 neighbor solicitation retransmissions, in milliseconds. Valid values range from 1000 to 3600000 milliseconds; the default value is 1000 milliseconds. **Note** This value is included in all IPv6 router advertisements sent out on this interface.
Reachable Time	The amount of time, in milliseconds, within which a remote IPv6 node is considered still reachable, after initial reachability was confirmed. Valid values range from 0 to 3600000 milliseconds, the default value is 0. When 0 is used for the value, the reachable time is set as undetermined—it is up to the receiving devices to set and track reachable time. A configured time enables detection of unavailable neighbors. A shorter time allows detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.
Managed Config Flag	Whether or not to set the flag "managed-config-flag" in the IPv6 router advertisement packet.
Other Config Flag	Whether or not to set the flag "other-config-flag" in the IPv6 router advertisement packet.

Element	Description
Enable RA	When checked, IPv6 router advertisement transmissions are enabled on the interface. The following options are enabled: • **RA Lifetime** – The "router lifetime" value specifies how long nodes on the local link should consider the security appliance as the default router on the link. Valid values range from 0 to 9000 seconds; the default is 1800 seconds. Entering 0 indicates that the security appliance should not be considered a default router on the selected interface. Any non-zero value should not be less than the following RA Interval value. **Note** This value is included in all IPv6 router advertisements sent out on this interface. • **RA Interval** – The interval between IPv6 router advertisement transmissions on this interface. Valid values range from 3 to 1800 seconds, (or from 500 to 1800000 milliseconds if the following RA Interval in Milliseconds option is checked); the default is 200 seconds. The interval between transmissions should be less than or equal to the RA Lifetime value if it is non-zero. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the desired value. • **RA Interval in Milliseconds** – Checking this option indicates that the provided RA Interval value is in milliseconds, rather than seconds.
Interface IPv6 Addresses	The IPv6 addresses assigned to the interface are specified in this section of the dialog box. • **Link-Local Address** – To override the link-local address that is automatically generated for the interface, enter the desired IPv6 link-local address in this field. The link-local address is composed of the link-local prefix FE80::/64 and the interface ID in Modified EUI-64 format. For example, an interface with a MAC address of 00E0.B601.3B7A would have a link-local address of FE80::2E0:B6FF:FE01:3B7A. An error will occur if another host is using the specified address. • **Enable Address Auto-Configuration** – Select this option to enable automatic configuration of IPv6 addresses on the interface using stateless autoconfiguration. The addresses are configured based on the prefixes received in Router Advertisement (RA) messages. If a link-local address has not been configured, then one is automatically generated for this interface. An error occurs if another host is already using the generated link-local address. • **Trust the DHCP Servers for default gateway**– Select this radio button to install a default route from Router Advertisements that come from a trusted source - the directly-connected network. • Ignore trust and accept router advertisements – Select this radio button to install a default route from Router Advertisements that come from another network. • The table in this section displays the IPv6 addresses assigned to this interface. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.) Add Row and Edit Row open the IPv6 Address for Interface Dialog Box , on page 1864.

Element	Description
Interface IPv6 Prefixes	Use the table in this section to configure which IPv6 prefixes (that is, the network portion of the IPv6 addresses) are included in IPv6 router advertisements. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.) Add Row and Edit Row open the IPv6 Prefix Editor Dialog Box , on page 1866.

Configuring Loopback Interface

When a WAN link goes out of service or unreachable then the corresponding S2S VPN link also becomes unreachable. To overcome this challenge, ASA 9.19.1 is enhanced to support the configuration of loopback interface which will keep the VPN links intact.

VTI loopback interface is supported only for Regular IPsec VTI with hub and spoke, and point-to-point VPN topologies. VTI loopback interface is not supported for other topologies like full mesh, extranet VPN, and RAVPN Policies.

The following section describes how to configure the tunnel interface:

- Loopback—General Tab

Loopback—General Tab

In the Add Interface or Edit Interface dialog box, when you select Loopback from the Type drop-down, the dialog box displays three tabs: General, Advanced, and IPv6. This section describes the options provided by the **General** panel.

Navigation Path

You can access the General panel from the ASA Interfaces page, as described in Managing Device Interfaces, Hardware Ports, and Bridge Groups .

Field Reference

Table 556: General tab: Add/Edit Interface Dialog Box (ASA)

Element	Description
Enable Interface	Check this box to enable the tunnel interface if not already enabled.
Name	Enter the interface name. The name is a text string up to 48 characters, and is not case-sensitive. You can change the name by re-entering this command with a new value.
Loopback ID	Enter the unique tunnel ID, between 0 and 10413. This ID is an internal interface identifier. The specified ID is mapped with the interface name.
IP Type	From the drop-down, select Static IP. • IP Address—(Routed Mode) In the IP Address area, configure an IPv4 address. To configure IPv6, click the IPv6 tab. • Subnet Mask—Specify the subnet mask.

Element	Description
Description	(Optional) Specify a description for the interface.

Configuring Tunnel Interface

Cisco Security Manager 4.13 supports route based VPN method for the Site-to-Site VPN. This support requires configuration of the static crypto map access list and mapping it to an interface. Due to this requirement, Large Enterprises and Virtual Private Clouds need to track all remote subnets and include them in the crypto map access list. To overcome this challenge, ASA 9.7.1 is enhanced to support the route based VPN method using the VTI (Virtual Tunnel Interface). Thus, beginning with Cisco Security Manager 4.13, you can define tunnel interface for the VPN and its associated IPSec policy.

VTI is supported only for Regular IPsec with Hub and Spoke, and Point to Point VPN topologies. VTI is not supported for other topologies like Full Mesh Topology, Extranet VPN Topology and RAVPN Policies.

In a multi- hub and multi- spoke scenario, for the tunnel interface to establish connectivity from one peer to another peer, ensure interface roles are applied to the hubs and spokes.

You can now configure IPv6 addresses in the Virtual tunnel interfaces (VTI) and enable the IPsec tunnel mode for IPv6. You can also configure IPv6 tunnel source or destination interfaces. If you configure tunnel interface for Regular IPSec VTI with both IPv4 and IPv6 addresses, IPv4 is used by default. From Cisco Security Manager version 4.23 onwards, the IPv6 address is supported only for Regular IPSec VTI under Point-to-Point and Hub-and-Spoke topologies.

You can now configure up to 1024 named VTIs for a device. Based on the platform model used, there might be discrepancies with the number of VTIs that can be configured. In such cases, you can configure the maximum number of VTIs in Cisco Security Manager with the limit set on ASA.

Note The BGPv6 address is supported in the IPv6 Family for Regular IPSec VTI under Point-to-Point and Hub-and-Spoke topologies for ASA 9.16(1) and higher version devices. The configured BGPv6 address should match with the tunnel IP address, else it triggers a validation error.

Note Ensure you add the pre-shared key manually after the discovery of IPv6 Regular IPSec VTI topology.

The following sections describe how to configure tunnel interface:

- Tunnel—General Tab, on page 1826
- Configuring IPSec Policy for Tunnel Interface, on page 1829

Tunnel—General Tab

In the Add Interface or Edit Interface dialog box, when you select Tunnel from the Type drop-down, the dialog box displays three tabs: General, Advanced, and IPv6. This section describes the options provided by the **General** panel.

Navigation Path

You can access the General panel from the ASA Interfaces page, as described in Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835.

Related Topics

- Configuring Tunnel Interface, on page 1826

Field Reference

Table 557: General tab: Add/Edit Interface Dialog Box (ASA)

Element	Description
Enable Interface	Check this box to enable the tunnel interface if not already enabled.
Name	Enter the Interface Name. The name is a text string up to 48 characters, and is not case-sensitive. You can change the name by reentering this command with a new value.
Tunnel Interface	
Tunnel ID	Enter the unique Tunnel ID, between 0 and 10413. This ID is an internal interface identifier. The specified ID is mapped with the interface name. The Name and the ID pair must be unique. This field is mandatory for Regular IPSEC VTI VPN.
Source Interface	Enter the source interface to be used for creating the VTI, IP address shall be picked up from this interface. Click the Select button to choose the source interface from the available interfaces. For more information, see Selecting Objects for Policies , on page 230. • IPv6-Check this box to enter the IPv6 address. • Source IPv6 Address-Enter the source IPv6 address. **Note** Tunnel source and destination pair must be unique.
Destination IP/Hostname	The tunnel destination IP address to be used for the VTI. Beginning with 4.14, Cisco Security Manager allows you to specify a Hostname as the destination IP. **Note** Tunnel source and destination pair has to be unique.
Enable IPSec Tunnel Mode	Check this box to pass the IPv4 or IPv6 tunnel protection mode. Following are the two IPSec Tunnel Modes: • IPv4-Select IPv4 to pass IPv4 as the tunnel protection mode, currently, only IPSec is supported. IPv4 network would be encapsulated in the tunnel. • IPv6-Select IPv6 to pass IPv6 as the tunnel protection mode, currently, only IPSec is supported. IPv6 network would be encapsulated in the tunnel.

Element	Description
IPv4 Mode	Check the check box to pass IPv4 as the tunnel protection mode, currently, only IPSec is supported. IPv4 network would be encapsulated in the tunnel.
IPSec Profile	Enter the IPSec profile to be attached to the tunnel interface. A policy object must have been created in the Policy Object Manager. For information on creating Policy Object, refer Configuring IPSec Policy for Tunnel Interface, on page 1829. **Note** If you select IPSec profiles with different IKEV1 transform sets for the peers, Cisco Security Manager will create the tunnel interface, but the connectivity between the two peers will not be established. To choose the profile from the IPSec Object Selector dialog, click the Select button. For more information, see Selecting Objects for Policies , on page 230. **Note** When you specify the policy, ensure tunnel name is entered. Cisco Security Manager displays error message when the Name field is blank.
Profile	Enter the IPSec profile to be attached to the tunnel interface. A policy object must have been created in the Policy Object Manager. For information on creating Policy Object, refer Configuring IPSec Policy for Tunnel Interface, on page 1829. **Note** If you select IPSec profiles with different IKEV1 transform sets for the peers, Cisco Security Manager will create the tunnel interface, but the connectivity between the two peers will not be established. To choose the profile from the IPSec Object Selector dialog, click the Select button. For more information, see Selecting Objects for Policies , on page 230. **Note** When you specify the policy, ensure tunnel name is entered. Cisco Security Manager displays error message when the Name field is blank.
IPv4 Unnumbered	Assign the IPv4 loopback in this field. Click the Select button to choose the loopback. For more information, see Selecting Objects for Policies , on page 230.
IPv6 Unnumbered	Assign the IPv6 loopback in this field. Click the Select button to choose the loopback. For more information, see Selecting Objects for Policies , on page 230.
IP Type	From the drop-down, select Static IP. • IP Address—(Routed Mode) In the IP Address area, configure an IPv4 address. To configure IPv6, click the IPv6 tab. • Subnet Mask—Specify the Subnet Mask.
Description	(Optional) Specify a description for the interface.

Establishing Regular IPSec VPN Tunnel

The following checkpoints (while configuring the Tunnel - Configuring Tunnel Interface, on page 1826) help you to successfully establish the Regular IPSec VPN Tunnel connectivity:

1. You must enter Tunnel ID value.
2. Source interface must be configured and must be reachable to its peer through ISP or routing.
3. You must enter the peer source interface IP address in the Destination IP field.
4. For the IPSec Profile field:
   a. Select the same IKEV1 transform set for both the peer devices.
   b. In Point-to-Point topology, either one of the peers must be the responder.
   c. In Hub and Spoke topology, select the Hub as the responder; select all spokes as initiators.
5. IPV4 mode must be configured for enabling the interesting traffic.
6. You must enter IP address to establish the VPN, dynamic IP address is not supported.
7. Select Static or BGP routing for enabling the interesting traffic. In case of firewall policy, VTI is supported only in static routing.

Note Cisco Security Manager displays error message if BGP/Static route is not configured properly for Point-to-Point topology, and Hub and Spoke topology with one hub and one spoke. For Multi hub/spoke scenario, the error message is not displayed.

Configuring IPSec Policy for Tunnel Interface

Use the IPsec Policy page to configure the IPsec policy used during IKE Phase 1 and IKE Phase 2 negotiations for Regular IPsec with Hub and Spoke and Point to Point VPN topologies.

You can now enable BGPv6 for Regular IPSec VTI under Point-to-Point and Hub-and-Spoke topologies. You can also configure IPv6 ip addresses on the Family tab of BGP page.

Navigation Path

- Choose **Manage > Policy Objects** to open the Policy Object Manager. Under All Object Types, click **IPSec Profile**. To add a profile, click the Add button.

Field Reference

Table 558: IPsec Profile

Element	Description
Name	Name of the IPSec policy.
Description	Description for the policy.

Element	Description
IKE Version	Choose the relevant IKE version— IKEv1 or IKEv2. **Note** Beginning with 4.14, Cisco Security Manager supports IKEv2. However, at a time, you can choose only one version of IKE.
IKEv1 Transform Sets	The IKEv1 transform sets to be used for your tunnel policy. Transform sets specify which authentication and encryption algorithms are used to secure the traffic in the tunnel. You can select up to 11 transform sets. For more information, see Understanding Transform Sets , on page 1170. Transform sets may use only tunnel mode IPsec operation. You can associate more than one IKEv1 Transform Sets. If more than one of your selected transform sets is supported by both peers, the transform set that provides the highest security is used. **Note** For the tunnel to be functional, IKEv1 transform set on both peers should be the same. Click **Select** to select the IPSec transform set policy objects to use in the topology. If the required object is not yet defined, you can click the **Create (+)** button beneath the available objects list in the selection dialog box to create a new one. For more information, see Configuring IPSec IKEv1 or IKEv2 Transform Set Policy Objects , on page 1177. This field is not available for IKEv2.
IKEv2 IPSec Proposal (ASA 9.8(1) Onwards)	Click **Select** to select the IPSec proposals to be used for your tunnel policy. Cisco Security Manager allows you to select more than one proposals. If the required object is not yet defined, you can click the **Create (+)** button beneath the available objects list in the selection dialog box to create a new one. For more information, see Configuring IPSec IKEv1 or IKEv2 Transform Set Policy Objects , on page 1177. **Note** Beginning with Cisco Security Manager 4.23, DH group 31 is supported for IPsec profile and IKEv2 on ASA 9.16(1) and later devices. This field is not available for IKEv1.
Trustpoint (ASA 9.8(1) Onwards)	Click **Select** to select the CA servers for issuing certificates to the participating IPSec network devices. The peers that are configured with this policy obtains digital certificates from the selected CA server. You can specify only one trustpoint. For IKEv1, when trustpoint is used for authentication, the initiator should have the trustpoint specified under IPSec profile's trustpoint configuration; and for responder, the trustpoint should be specified under tunnel-group CLI (similar to non-VTI configuration). **Note** When trustpoint configuration is used as authentication in Site-to-site VPN, IKE profile should be in certificate. For the tunnel to be up, activity validation is required between IKE profile CLI and tunnel group CLI in site-to-site VPN manager for VTI VPN. For IKEv2, when trustpoint is used for authentication, the trustpoint CLI is specified under tunnel-group CLI for both initiator and responder.

Element	Description
Certificate Chain (ASA 9.8(1) Onwards)	Select the check box to enable sending of the certificate chain for authorization. A certificate chain includes the root CA certificate, identity certificate, and key pair.
Responder Only	Check this check box to set the peer that is associated with this policy acts as the responder. Ensure only one of the peer is configured with the responder only settings.
Enable Perfect Forward Secrecy (PFS) Modulus Group	Whether to enable the use of Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. In IPsec negotiations, PFS ensures that each new cryptographic key is unrelated to any previous key. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the **Modulus Group** list. For an explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use , on page 1156. The following Modulus Groups are not supported for IKEv1. Ensure you do not select them for IKEv1: • group19 • group20 • group21 • group24 • group1 **Note** Beginning with Cisco Security Manager 4.23, DH group 31 is supported for IPsec profile and IKEv2 on ASA 9.16(1) and later devices. **Note** Beginning with Cisco Security Manager 4.19, DH group 1 option is not supported for ASA 9.12(1) and later devices.
Lifetime (Seconds) Lifetime (Kilobytes)	The global lifetime settings for the Crypto IPsec security association (SA). You can specify the IPSec lifetime in seconds, in kilobytes, or both. • Seconds—The number of seconds an SA will exist before expiring. Enter a value within the range 120-2147483647 seconds. • Kilobytes—The volume of traffic (in kilobytes) that can pass between IPsec peers using a given SA before it expires. Valid values depend on the device type. Enter a value within the range 10-2147483647. To allow unlimited you can select Enable Unlimited Lifetime (Kilobytes) check box.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.
Allow Value Override per Device	Select to allow the properties of this object to be redefined on individual devices. If you allow device overrides, you can click the Edit button to create, edit, and view the overrides. The Overrides field indicates the number of devices that have overrides for this object.

Note DH groups 2, 5, and 24 will not be supported for ASA 9.14(1) and later devices.

Configuring VLAN Interface

Beginning with version 4.20, Cisco Security Manager supports L2 hardware switching on Cisco FPR-1010 Adaptive Security Appliance. To avail the L2 switching support, you need to configure the respective VLAN interface.

VLAN Interface—General Tab

In the Add Interface or Edit Interface dialog box, when you select VLAN Interface from the Type drop-down list, the dialog box displays five tabs: General, Advanced, IPv6, Switch Port, and Power Over Ethernet.

Note You cannot configure Switch Port and Power Over Ethernet for VLAN Interface.

Navigation Path

Select **Interfaces > Add Interface** from the Device Policy selector and choose VLAN Interface from the Type drop-down list.

Field Reference

Table 559: General tab: Add/Edit Interface Dialog Box

Element	Description
Enable Interface	Check this box to enable the VLAN interface if not already enabled.
Management Only	Check this box to enable the Management Only feature. This reserves the interface for device administration where traffic for only this device is accepted; pass-through traffic for other interfaces and devices is rejected.
Name	Enter the Interface Name. The name is a text string up to 48 characters, and is not case-sensitive. You can change the name by reentering this command with a new value.
Security Level	Enter the Security Level, between 0 (lowest) and 100 (highest).
L2 VLAN ID	Enter the L2 VLAN ID, between 0 (lowest) and 4090 (highest). This is a mandatory field.
No Forward Interface VLAN ID	Enter the No Forward Interface VLAN ID, between 0 (lowest) and 4090 (highest).

Element	Description
Route Map	Select the Route Map from the Route Map Object Selector dialog box. Choose a desired filter to be applied, from the Filter drop-down list or create a new filter using the Create Filter option.
IP Type	Select the IP Type from the available options: Static IP, Use DHCP, and PPPoE (PIX and ASA 7.2+).
Static IP	IP Address—(Routed Mode) In the IP Address area, configure an IPv4 address. To configure IPv6, click the IPv6 tab. Subnet Mask—Specify the Subnet Mask.
Use DHCP	DHCP Learned Route Metric—(Required) To assign an administrative distance to the learned route, enter a value between 1 and 255 in the DHCP Learned Route Metric field. If this field is left blank, the administrative distance for the learned routes is 1. Obtain Default Route using DHCP—(Optional) Select this option to obtain a default route from the DHCP server so that you do not need to configure a default static route. Enable Tracking for DHCP Learned Route—(Optional) If Obtain Default Route using DHCP is selected, you can select this option to enable route tracking via a specific Service Level Agreement (SLA) monitor. The following option becomes available: Tracked SLA Monitor—Required if Enable Tracking for DHCP Learned Route is selected. Enter or Select the name of the SLA monitor object that defines the route tracking (connectivity monitoring) to be applied to this interface.

Element	Description
PPPoE (PIX and ASA 7.2+)	This enables Point-to-Point Protocol over Ethernet (PPPoE) for automatic assignment of an IP address from a PPPoE server on the connected network; this option is not supported with failover. On selecting PPPoE (PIX and ASA 7.2+) from the IP Type drop-down, the following options become available: VPDN Group Name (required)—Choose the Virtual Private Dialup Network (VPDN) group that contains the authentication method and user name/password to use for network connection, negotiation, and authentication. See Managing VPDN Groups , on page 1885 for more information. IP Address—If provided, this static IP address is used for connection and authentication, instead of a negotiated address. Subnet Mask—The subnet mask to be used in conjunction with the provided IP Address. PPPoE Learned Route Metric (required)—Assign an administrative distance to the learned route. Valid values are 1 to 255; defaults to 1. All routes have a value or “metric” that represents its priority of use. (This metric is also referred to as “administrative distance.”) When two or more routes to the same destination are available, devices use administrative distance to decide which route to use. Obtain Default Routing Using PPPoE—Select this option to obtain a default route from the PPPoE server. This sets the default routes when the PPPoE client has not yet established a connection. When using this option, you cannot have a statically defined route in the configuration. Enable Tracking for PPPoE Learned Route—If Obtain Default Route using PPPoE is selected, you can select this option to enable route tracking for PPPoE-learned routes. When selected, the following options become available. Dual ISP Interface—If you are defining interfaces for dual ISP support, choose Primary or Secondary to indicate which connection you are configuring. Tracked SLA Monitor—Required if Enable Tracking for DHCP Learned Route is selected. Enter or Select the name of the SLA monitor object that defines the route tracking (connectivity monitoring) to be applied to this interface.

Element	Description
Description	(Optional) Specify a description for the interface.

Managing Device Interfaces, Hardware Ports, and Bridge Groups

The Interfaces page displays the interfaces, subinterfaces, redundant interfaces, virtual interfaces (VLANs), and EtherChannel interfaces, as well as the hardware ports and bridge groups, configured on the selected device, and lets you add, edit and delete them.

The types of interface available depend on device type, operating system version, and mode (routed or transparent). For example, EtherChannel interfaces are available only on ASA 8.4.1 and later devices, in both routed and transparent mode. See Understanding Device Interfaces , on page 1806 for more information.

Note The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: Interfaces and **Hardware Ports**. Similarly, the Interfaces page displayed for both Firewall Services Modules (FWSMs), version 3.1 and later, and ASAs version 8.4.1 and later, operating in transparent mode also present two tabbed panels: Interfaces and **Bridge Groups**. Links to configuration information for these features are included in the following procedure.

Each security device must be configured, and each active interface must be enabled. Inactive interfaces can be disabled. When disabled, the interface does not transmit or receive data, but its configuration information is retained.

If you bootstrapped a new security device, the set-up feature configures only the addresses and names associated with the inside interface. You must define the remaining interfaces on that device before you can specify access and translation rules for traffic traversing that security device.

Transparent firewall mode allows only two interfaces to pass traffic; however, if your platform includes a dedicated management interface, you can use it (either the physical interface or a subinterface) as a third interface for management traffic.

Follow these general steps to manage security-device interfaces and related options. You can add, edit and delete configured interfaces, subinterfaces, redundant interfaces, virtual interfaces (VLANs), EtherChannel interfaces, hardware ports, and bridge groups, according to the type of device selected.

Step 1 Ensure Device View is your present application view; if necessary, click the **Device View** button on the toolbar.

Note For more information on using the Device View to configure device policies, see Managing Policies in Device View and the Site-to-Site VPN Manager , on page 196.

Step 2 Select the security device you want to configure.

Step 3 Select **Interfaces** in the Device Policy selector.

The Interfaces page is displayed. The information displayed, and the page itself, varies based on the selected device type and version, the operational mode (routed versus transparent), and whether the device hosts single or multiple contexts.

Note that the Interfaces page for ASA 5505 devices presents two tabbed panels: Hardware Ports and Interfaces. Similarly, the Interfaces page displayed for both FWSMs (version 3.1 and later) and ASAs (version 8.4.1 and later), operating in transparent mode also presents two tabbed panels: Interfaces and Bridge Groups.

Step 4 Add, edit and delete interfaces and related options, as necessary.

The Interfaces pages/panels and the Bridge Groups and Hardware Ports panels present standard Security Manager tables, with Add Row, Edit Row and Delete Row buttons, which are described in Using Tables , on page 50.

The actual dialog box presented when you click the Add Row or Edit Row button depends on the type of device (and panel) you have selected. Refer to the following topics for device-specific dialog box information:

- Add/Edit Interface Dialog Box (PIX 6.3) , on page 1836
- Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840
- Configuring Hardware Ports on an ASA 5505 , on page 1874
- Add/Edit Bridge Group Dialog Box , on page 1876

Step 5 To manage Advanced Interface settings, including enabling communication between interfaces with the same security level, click the Advanced button at the bottom of the Interfaces page to open the Advanced Interface Settings dialog box. See Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881 for more information.

Step 6 When you are finished adding, editing and deleting interfaces, click **Save** at the bottom of the window to save your interface definitions to the Cisco Security Manager server.

Add/Edit Interface Dialog Box (PIX 6.3)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

Table 560: Add/Edit Interface Dialog Box (PIX 6.3)

Element	Description
Enable Interface	Enables this interface to pass traffic. In addition to this setting, you must specify an IP Type and a Name before traffic can pass according to your security policy. You must enable a physical interface before traffic can pass through any enabled subinterfaces.
Type	Choose the type of interface: • **Physical** – VLAN is on the same network as its underlying hardware interface. • **Logical** – VLAN is associated with a logical interface.

Element	Description
Name	Provide an interface name up to 48 characters in length. The Name should be a memorable name for the interface that relates to its use. Supported interface names are: • Inside—Connects to your internal network. Must be most secure interface. • DMZ—Demilitarized zone (Intermediate interface). Also known as a perimeter network. • Outside—Connects to an external network or the Internet. Must be least secure interface.
Hardware Port	When defining a physical network interface, this value represents the name identifies the interface type and its slot or port in the device. When you add a logical network interface, you can choose any enabled physical interface to which you want to add a logical interface. If you do not see the desired hardware port, verify that the interface is enabled. Valid values are: • ethernet0 to ethernet*n* . • gb-ethernet*n* . where *n* represents the number of network interfaces in the device.
IP Type	The IP Type defines the type of IP addressing used for the interface; choose **Static IP** or **Use DHCP**, as described in Device Interface: IP Type (PIX 6.3) , on page 1839. (The PPPoE option is not applicable to PIX 6.3 devices.) **Note** You can configure DHCP only on the outside interface of a security appliance.

Element	Description
Speed and Duplex	Lists the speed options for a physical interface; not applicable to logical interfaces. Choose one of the following options: • auto – Sets Ethernet speed automatically. The auto keyword can be used only with the Intel 10/100 automatic speed-sensing network interface card. • 10baset – 10-Mbps Ethernet half-duplex. • 10full – 10-Mbps Ethernet full-duplex. • 100basetx – 100-Mbps Ethernet half-duplex. • 100full – 100-Mbps Ethernet full-duplex. • 1000auto – 1000-Mbps Ethernet to auto-negotiate full- or half -duplex. **Tip** We recommend that you do not use this option to maintain compatibility with switches and other devices in your network. • 1000full – Auto-negotiate, advertising 1000-Mbps Ethernet full-duplex. • 1000full nonnegotiate – 1000-Mbps Ethernet full-duplex. • aui – 10-Mbps Ethernet half-duplex communication with an AUI cable interface. • bnc – 10-Mbps Ethernet half-duplex communication with a BNC cable interface. **Note** We recommend that you specify the speed of the network interfaces in case your network environment includes switches or other devices that do not handle autosensing correctly.
MTU	Specify the maximum packet size in bytes; that is, the maximum transmission unit (MTU). The value depends on the type of network connected to the interface. Valid values are 300 to 65535 bytes. Default is 1500.
Physical VLAN ID	For a physical interface, enter the VLAN ID, between 1 and 4094. This VLAN ID must not be in use on connected devices.
Logical VLAN ID	Provide the alias, a value between 1 and 4094, for the VLAN associated with this logical interface. This value is required if the logical interface Type is selected.
Security Level	Specify the security level of the interface: enter a value between 0 (least secure) and 100 (most secure). The security appliance lets traffic flow freely from an inside network to an outside network (lower security level). Many other security features are affected by the relative security level of two interfaces. • The *outside* interface is always 0. • The *inside* interface is always 100. • DMZ interfaces are between 1 and 99.

Element	Description
Roles	For more information on roles and how to define and use them, see Understanding Interface Role Objects , on page 303. All interface roles assigned to this interface are listed in this field. Role assignments are based on pattern matching between the Name given to this interface and all currently defined Interface Role objects in Cisco Security Manager. Interface role objects are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces. For more information on roles and how to define and use them, see Understanding Interface Role Objects , on page 303.

Device Interface: IP Type (PIX 6.3)

A PIX 6.3 security device requires IP addressing for its interfaces; however, firewall interfaces do not have IP addresses until you assign them.

The Add/Edit Interface dialog box presented for a PIX 6.3 security device includes the section **IP Type**, where you specify the type of IP addressing for the interface and provide related parameters, as described here. See Add/Edit Interface Dialog Box (PIX 6.3) , on page 1836 for information about the other sections of the dialog box.

Note The IP Type options presented for other security appliances are described in Device Interface: IP Type (PIX/ASA 7.0+) , on page 1870.

In the Add/Edit Interface dialog box, choose a method for address assignment from the **IP Type** list, and then provide related parameters, as follows:

- **Static IP** – Provide a static **IP Address** and **Subnet Mask** that represents the security device on this interface's connected network. The IP address must be unique for each interface.

The Subnet mask can be expressed in dotted decimal format (for example, 255.255.255.0), or by entering the number of bits in the network mask (for example, 24). Beginning from Version 4.13, Cisco Security Manager allows 255.255.255.254 for a point to point interface. Do not use 255.255.255.255 for an interface connected to the network because this will stop traffic on that interface. If you omit the Subnet Mask value, a "classful" network is assumed, as follows:

- • The Class A netmask (255.0.0.0) is assumed if the first octet of the IP Address is 1 through 126 (i.e., addresses 1.0.0.0 through 126.255.255.255).
  - The Class B netmask (255.255.0.0) is assumed if the first octet of the IP Address is 128 through 191 (i.e., addresses 128.0.0.0 through 191.255.255.255).
  - The Class C netmask (255.255.255.0) is assumed if the first octet of the IP Address is 192 through 223 (i.e., addresses 192.0.0.0 through 223.255.255.255).

Note Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry.

- **Use DHCP** – Enables Dynamic Host Configuration Protocol (DHCP) for automatic assignment of an IP address from a DHCP server on the connected network. The following options become available:
  - **Obtain Default Route using DHCP** – Check this box to obtain a default route from the DHCP server so that you do not need to configure a default static route.
  - **Retry Count** – The number of times the PIX will resend the DHCP request. Valid values are 4 to 16; the default is 2
- **PPPoE (PIX and ASA 7.2+)** – This option does not apply to PIX 6.3 devices.

Note You can configure DHCP only on the outside interface of a firewall device.

Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

These Add Interface and Edit Interface dialog boxes are used to define and configure interfaces, subinterfaces, redundant, and EtherChannel interfaces on PIX 7.0+, ASA, FPR, and FWSM devices. You can access the Add/Edit Interface dialog boxes from the Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for more information.

Note From version 4.24, Cisco Security Manager supports FPR-3100 series devices for ASA 9.17(1) and above devices.

Note The ASA 5505, combining switch and security appliance features, is a special case in that you configure both physical switch ports and logical VLAN interfaces. Thus, the Interfaces page displayed for ASA 5505 devices presents two tabbed panels: **Hardware Ports** and **Interfaces**. See Understanding ASA 5505 Ports and Interfaces , on page 1809 for more information.ASA 8.4.1+ and FWSM 3.1+ devices operating in transparent mode also present two tabbed panels: **Interfaces** and **Bridge Groups**. See Add/Edit Bridge Group Dialog Box , on page 1876 for information about configuring bridge groups.

Many of the parameters presented in these dialog boxes vary according to device type and version, operational mode (routed versus transparent), and whether the device hosts a single or multiple contexts.

Note If you intend to use an interface for failover, you can define that interface in the Add Interface dialog box but do not configure it; instead, use the Failover page. In particular, do not specify an interface Name, as this parameter disqualifies the interface from being used as the failover link.

Using the Add Interface and Edit Interface Dialog Boxes

The following steps outline the general use of these dialog boxes:

1. An interface Type drop-down list appears at the top of the Add Interface and Edit Interface dialog boxes.

Note Catalyst 6500 services modules (ASA-SMs and FWSMs) and the ASA 5505 do not present the Type list.

Depending on device type, operating-system version and operating mode (router or transparent), the Type options presented will be two, three or all of the following:

- • **Physical Interface** – Choose this option to configure a physical interface on the device.
  - **Sub-Interface** – Choose this option to configure a logical interface (or VLAN connection) associated with a previously defined physical interface. Refer to Configuring Subinterfaces (PIX/ASA) , on page 1810 for more information.
  - **Redundant** – Choose this option to configure two physical interfaces as a single logical "redundant interface." Refer to Configuring Redundant Interfaces , on page 1811 for more information.
  - **EtherChannel** – Choose this option to configure a logical interface consisting of a bundle of up to eight individual Ethernet links; this bundle is known as an EtherChannel, or a port-channel interface. (This option is available only on ASA 8.4+ devices.) Refer to Configuring EtherChannels , on page 1812, for more information.
  - VNI Interface – Choose this option to configure a VNI interface. They are virtual interfaces that keep network traffic separated on a given physical interface by using tagging. You apply your security policy directly to each VNI interface. All VNI interfaces are associated with the same VTEP interface. Refer to Configuring VNI Interfaces , on page 1818, for more information.
  - Loopback–Choose this option to configure the VTI loopback interface to support the configuration of site-to-site VPN topologies. VTI loopback interface, when enabled, helps in overcoming the path failures when the VPN tunnels are unreachable. Refer to Configuring Loopback Interface, for more information.
  - Tunnel– Choose this option to configure a logical interface -VTI, to support route based VPN method for the Site-to-Site VPN topologies. Refer to Configuring Tunnel Interface, on page 1826, for more information.
- Below the Type option, the dialog boxes present up to three tabbed panels. Again, this depends on device type, operating-system version and operating mode.

The PIX 7.0+ Add Interface and Edit Interface dialog boxes present two tabbed panels: General and Advanced. The ASA 7.0+ Add Interface and Edit Interface dialog boxes present three tabbed panels: General, Advanced and IPv6.

The FPR-3100 Add Interface and Edit Interface dialog boxes present three tabbed panels: General, Advanced and IPv6.

- • Configure the General options, as appropriate. This panel is described in Add/Edit Interface Dialog Box: General Tab (PIX 7.0+/ASA/FWSM) , on page 1842.

- Configure the Advanced-panel options, as appropriate. This panel is described in Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+) , on page 1850.
- Configure the IPv6 options, as appropriate. This panel is described in Configuring IPv6 Interfaces (ASA/FWSM) , on page 1860.
- Configure the Switch Port options, as appriopriate. For more information on the options, see Add/Edit Interface Dialog Box: Switch Port Tab, on page 1873.
- Configure the Power Over Ethernet options, as appriopriate. For more information on the options, see Add/Edit Interface Dialog Box: Power Over Ethernet Tab, on page 1873.

- When you have finished configuring this interface, click **OK** to close the dialog box and return to the device Interfaces page.

Add/Edit Interface Dialog Box: General Tab (PIX 7.0+/ASA/FWSM)

The Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840, is used to define and configure interfaces, subinterfaces, VLAN interfaces, and redundant, and EtherChannel interfaces on firewall devices. You can access the Add/Edit Interface dialog box from the Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for more information.

Note In the following descriptions, the term "interface" may be used generically to refer to any of these types of interface.

The General panel of this dialog box is used to configure general interface settings, including Name, Security Level and IP Type parameters. Note that many of the parameters presented in this panel vary according to device type and version, operational mode (routed versus transparent), and whether the device hosts a single or multiple contexts. Thus, some of the options in the following table may not appear for the device you are configuring.

Table 561: General tab: Add/Edit Interface Dialog Box

Element	Description
Enable Interface	Enables this interface to pass traffic. By default, all physical interfaces are shut down. Traffic cannot traverse an interface of any type if the interface is not enabled. If you are defining a logical interface such as a subinterface, enable the physical interface it will be associated with before defining the subinterface. If you are defining a redundant interface or an EtherChannel interface, enable the member interfaces before defining the group interface. When you check this option, you must also specify a Name and, in routed mode, an IP Type (or IP Address and Subnet Mask on an FWSM or ASA-SM) before traffic can pass according to your security policy. In multiple-context mode, if you allocate a physical or logical interface to a context, the interface is enabled by default in the context. However, before traffic can pass through the context interface, you must also enable the interface in the system configuration. If you shut down an interface in the system execution space, that interface is shut down in all contexts in which it shared.
Management Only	Reserves this interface for device administration. Only traffic for management of this device is accepted; pass-through traffic for other interfaces and devices is rejected. You cannot set a Primary or Secondary ISP interface to be Management Only. Defining a management-only EtherChannel interface has certain member-interface restrictions. See Configuring EtherChannels , on page 1812, for more information. **Note** This is not available on devices in transparent mode. If an interface is assigned as Management Only, then Route Map cannot be assigned to that interface. In other words, either Management Only or Route Map can be assigned to an interface but not both.

Element	Description
Interface	On the ASA 5505, the Hardware Port is specified on the Hardware Ports panel (see Configuring Hardware Ports on an ASA 5505 , on page 1874). Also, this option is not part of Catalyst 6500 services module (ASA-SM and FWSM) configuration. For a physical interface, provide the specific hardware port assigned to the interface: enter a physical port ID, which includes network type, slot and port number, in the form: *type[slot/]port* . This is also the name by which subinterfaces can be associated with the interface. The network type specified for the physical interface can be either Ethernet or GigabitEthernet; on the ASA 5580, TenGigabitEthernet is also available. This field provides automatic pattern matching: if you begin typing with the letter e, “Ethernet” is inserted into the field. Similarly, typing the letter g produces “GigabitEthernet.” Therefore, valid values are: • Ethernet0 to Ethernet*n* • GigabitEthernet0 to GigabitEthernet*n* • GigabitEthernets /*n* • TenGigabitEthernets /*n* (ASA 5580 only) where *s* represents a slot number, and *n* represents a port number, up to the maximum number of network ports in the slot or device. For an ASA 5500 series appliance, enter the type and a slot/port pair; for example, *gigabitethernet0/1* . Ports that are built into the chassis are assigned to slot 0, while ports on the 4-Port Gigabit Ethernet Security Services Module (4GE SSM) are assigned to slot 1. When you enter a slot/port pair, the Media Type options are enabled. The ASA 5500 series appliances also include a **management** interface type. The management interface is a Fast Ethernet interface designed for device-management traffic only, and is specified as *management0/0* . You can, however, use this physical interface for through traffic if desired (be sure the Management Only option is not selected). Thus, in transparent firewall mode, you can use the management interface in addition to the two interfaces allowed for through traffic. You can also add subinterfaces to the management interface to provide management in each security context in multiple-context mode. If you are defining a subinterface, you can simply choose the desired Hardware Port from a list of previously defined ports (you must also supply a VLAN ID). If you do not see a desired interface ID, be sure that Interface is defined and enabled.

Element	Description
Name	Provide an identifier for this interface of up to 48 characters in length. The name should be a memorable name for the interface that relates to its use. However, if you are using failover, do not name interfaces that you are reserving for failover communications; this includes an EtherChannel intended for failover, as well as its member interfaces. Also, do not name interfaces intended for use as a member of a redundant-interface pair. Certain names are reserved for specific interfaces, in accordance with the interface naming conventions of the security appliance. As such, these reserved names enforce default, reserved security levels, as follows: • Inside – Connects to your internal network. Must be the most secure interface. • DMZ – "Demilitarized zone" attached to an intermediate interface. DMZ is also known as a perimeter network. You can name a DMZ interface any name you choose. Typically, DMZ interfaces are prefixed with "*DMZ*" to identify the interface type. • Outside – Connects to an external network or the Internet. Must be the least secure interface. Similarly, a subinterface name typically identifies its associated interface, in addition to its own unique identifier. For example, *DMZoobmgmt* could represent an out-of-band management network attached to the DMZ interface. **Note** Again, **do not name the interface if you intend to use it for failover, or as a member of a redundant interface**. See Configuring Redundant Interfaces , on page 1811 for more information.
Security Level	Specify the security level of the interface: enter a value between 0 (least secure) and 100 (most secure). The security appliance lets traffic flow freely from an inside network to an outside network (lower security level). Many other security features are affected by the relative security level of two interfaces. • The *outside* interface is always 0. • The *inside* interface is always 100. • DMZ interfaces are between 1 and 99.

Element	Description
Media Type	When Interface is the chosen Type and you enter a hardware port ID with slot/port numbers in the Hardware Port field, these options are enabled. (These options apply to ASA slot/port interfaces only.) For all ASA 5500 series appliances, except the 5505, ports that are built into the chassis are assigned to slot 0, while ports on the 4GE SSM are assigned to slot 1. By default, all connectors used on an ASA are RJ-45 connectors. However, the ports on the 4GE SSM can include fiber SFP connectors. As part of the interface configuration for one of these fiber-based connections, you must change the Media Type setting from the default (RJ45) to the fiber-connector setting (SFP). Fiber-based interfaces do not support duplexing and have a fixed speed, so the Duplex option is disabled, and the Speed options are limited to auto and nonegotiate. Select the connector type used by this slot-1 interface: • **RJ45** – The port uses RJ-45 (copper) connectors. • **SFP** – The port uses fiber SFP connectors. Required for 10-Gigabit Ethernet cards.
VLAN ID	When Subinterface is the chosen interface Type, or when you are defining a logical interface on a device operating in transparent mode, on an ASA 5505, or on a Catalyst 6500 services module (ASA-SM or FWSM), provide a VLAN ID for this interface. For PIX/ASA devices running operating system 7.2(2)18 or earlier, valid VLAN IDs are 1 to 1001; with version 7.2(2)19 or later, valid IDs are 1 to 4090. For Catalyst 6500 services modules, valid IDs are 1 to 4096. The specified VLAN ID must not be in use on any connected device. Some VLAN IDs might be reserved on connected switches; see the switch documentation for more information. In multiple-context mode, you can only set the VLAN ID in the system configuration. See Configuring Subinterfaces (PIX/ASA) , on page 1810 for more information.
Subinterface ID	When Subinterface is the chosen interface Type, or when defining an interface on a device operating in transparent mode, provide an integer between 1 and 4294967293 as the Subinterface ID. For subinterface port identification, this ID is appended to the chosen Hardware Port. For example, *GigabitEthernet0.4* represents the subinterface assigned an ID of 4, operating on the port GigabitEthernet0. **Note** You cannot change the Subinterface ID after you set it.
Route Map	Select the Route Map from the Route Map Object Selector dialog box. **Note** Except VNI Interface, all other interface types support Policy Based Routing for ASA devices running the software version 9.4(1) or later. VNI Interface supports Policy Based Routing for ASA devices running the software version 9.5(1) or later.

Element	Description
IP Type	**PIX 7.0+ and ASA (except the 5505 in transparent mode) only.** The IP Type defines the type of IP addressing used for the interface; choose **Static IP**, **Use DHCP**, or **PPPoE** (as described in Device Interface: IP Type (PIX/ASA 7.0+) , on page 1870). **Note** You can configure DHCP and PPPoE only on the outside interface of a security appliance.
IP Address Subnet Mask	**Catalyst 6500 services modules (ASA-SMs and FWSMs) in routed mode only.** Use these two fields to assign an IP address and subnet mask to the VLAN interface. The IP address must be unique for each interface. The Subnet Mask can be expressed in dotted decimal format (for example, 255.255.255.0), or by entering the number of bits in the network mask (for example, 24). Till Version 4.12, 255.255.255.254 and 255.255.255.255 were not to be used for an interface connected to the network because it would stop traffic on that interface. Beginning from Version 4.13, /31 subnet mask (or 2555.2555.255.254) is supported for a point to point interface connected to the network. Cisco Security Manager displays a warning message on saving the interface record. If you omit the Subnet Mask value, a “classful” network is assumed, as follows: • The Class A netmask (255.0.0.0) is assumed if the first octet of the IP Address is 1 through 126 (that is, addresses 1.0.0.0 through 126.255.255.255). • Subnet Mask The Class B netmask (255.255.0.0) is assumed if the first octet of the IP Address is 128 through 191 (that is, addresses 128.0.0.0 through 191.255.255.255). • The Class C netmask (255.255.255.0) is assumed if the first octet of the IP Address is 192 through 223 (that is, addresses 192.0.0.0 through 223.255.255.255). **Note** Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry.
Description	You can enter an optional description of up to 240 characters on a single line, without carriage returns. In multiple-context mode, the system description is independent of the context description. For a failover or state link, the description is fixed as “LAN Failover Interface,” “STATE Failover Interface,” or “LAN/STATE Failover Interface,” for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link.
Redundant Interface; these options not available on ASA 5505 devices or Catalyst 6500 services modules (ASA-SMs and FWSMs).	

Element	Description
Redundant ID	When Redundant Interface is the chosen interface Type, provide an identifier for this redundant interface; valid IDs are the integers from 1 to 8. See Configuring Redundant Interfaces , on page 1811 for more information.
Primary Interface Secondary Interface	When Redundant Interface is the chosen interface Type, choose the primary member of the redundant interface pair from the Primary Interface list of available interfaces. Available interfaces are presented by Hardware Port IDs, as named interfaces cannot be used for a redundant interface pair. Similarly, choose the secondary member of the redundant interface pair from the Secondary Interface list of available interfaces. **Note** Member interfaces must be enabled and of the same type (e.g., GigabitEthernet), and cannot have a Name, IP Address, or Security Level assigned. In fact, do not configure any options other than Duplex and Speed on the member interfaces.
These options available on ASA 5505 devices only.	
Block Traffic To	Restricts this VLAN interface from initiating contact with the VLAN chosen here.
Backup Interface	Choose a VLAN interface as a backup interface, for example, to an ISP. The backup interface does not pass traffic unless the default route through the primary interface fails. To ensure that traffic can pass over the backup interface, be sure to configure default routes on both the primary and backup interfaces so that the backup interface can be used when the primary fails.
Active MAC Address Standby MAC Address	Use the Active MAC Address field to manually assign a private MAC address to the interface; the Standby MAC Address field can be used to set a standby MAC address for use with device-level failover. Refer to Device Interface: MAC Address , on page 1872 for more information about these fields.
EtherChannel Interface options; available on ASA 8.4.1+ devices only.	
EtherChannel ID	When EtherChannel is the chosen interface Type, enter an identifier for this EtherChannel (also referred to as a “port-channel”). Valid values are 1 to 48—you can define up to 48 port-channel groups. See Configuring EtherChannels , on page 1812, for more information.

Element	Description
Available Interfaces/Members in Group	When EtherChannel is the chosen interface Type, you can assign interfaces to this EtherChannel group by selecting them in the Available Interfaces list and then clicking the >> button to add them to the members list to the right. You can assign up to 16 interfaces to a channel group. For ASA 9.2(1) and later, each channel group can have up to 16 active interfaces. For switches that support only eight active interfaces and for ASA versions earlier than 9.2(1), only eight interfaces can be active, the remaining interfaces can act as standby links in case of interface failure. Alternatively, you can create a static EtherChannel by setting LACP Mode to On (on the Advanced tab, see Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+) , on page 1850), which means all interfaces in the group can pass traffic. **Note** All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the type and speed for the group. See Configuring EtherChannels , on page 1812, for more information.

Add/Edit Interface Dialog Box: Cisco Firepower 9000 (General and Advanced tabs)

For the elements supported in Cisco Firepower 9000 devices for the General and Advanced tabs, see the Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840. In addition, the following changes are applicable only to Cisco Firepower 9000 devices.

Table 562: Add/Edit Interface Dialog Box Cisco Firepower 9000

Element	Description
Type	Choose the type of interface. Redundant Interfaces are not supported in Cisco Firepower 9000 devices.
Management Only Individual	Applicable only in Cisco Firepower 9000 devices and only if the device is in cluster mode. **Note** You cannot enable both Management Only and Management Only Individual check boxes at the same time. You can configure Cluster pool only when Management Only Individual check box is selected.
Name	Provide an interface name up to 48 characters in length. The Name should be a memorable name for the interface that relates to its use. The Interface name must begin with “Ethernet” and must have the following format: Ethernet[slot]/[port]/sub-port, where, • slot is between 1 and 3 • port is between 1 and 8 • sub-port is between 1 and 4 • sub-port is not applicable for slot 1

Element	Description
The following elements are not supported in Cisco Firepower 9000 devices:	
Media Type (General Tab)	
Duplex(Advanced Tab)	
Speed (Advanced Tab)	
Available Interfaces/Members in Group (General Tab)	
Load Balancing (Advanced Tab)	
LACP Mode (Advanced Tab)	
VSS or vPC Switch ID (Advanced Tab)	
Active Physical Interfaces (Advanced Tab)	
Span EtherChannel across the ASA Cluster (Advanced Tab)	
Enable load balancing between switch pairs in VSS or vPC mode (Advanced Tab)	
Member Interface Configuration (Advanced Tab)	

Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+)

The Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840, is used to define and configure interfaces, subinterfaces, redundant, and EtherChannel interfaces on ASA and PIX 7.0+ devices. You can access the Add/Edit Interface dialog box from the Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for more information.

The Advanced panel of this dialog box is used to configure basic interface settings, including Duplex, Speed, and maximum transmission unit (MTU) parameters, as described in the following table.

Related Topics

- Add/Edit Interface Dialog Box: General Tab (PIX 7.0+/ASA/FWSM) , on page 1842
- Configuring IPv6 Interfaces (ASA/FWSM) , on page 1860

Table 563: Advanced tab: Add/Edit Interface Dialog Box (ASA/PIX 7.0+)

Element	Description
Duplex	Lists the duplex options for the interface, including Auto, Full, Half, or N/A, depending on the interface type. For TenGigabitEthernet (ASA 5580 only), Duplex is automatically set to Full. **Note** This option is not available when Subinterface or Redundant is the chosen Interface type.

Element	Description
Speed	

Element	Description
	Lists the speed options (in bits per second) for a physical interface; not applicable to logical interfaces. The speeds available depend on the interface type. • auto • 10 • 100 • 1000 • 10000 (set automatically for a TenGigabitEthernet interface; available only on ASA 5580) • nonegotiate **Note** This option is not available when Subinterface or Redundant is the chosen Interface type. The port PID for the management interfaces must be specified in the path C:\Program Files (x86)\CSCOpx\MDC\athena\config\csm.properties.The supported speed options for management interfaces are as follows: • 1000 • 10000 • Detect SFP The configurable speed options for RJ 45 interfaces supported from Ethernet1/1 to Ethernet1/8 for FPR-3100 devices are as follows: • 10 • 100 • 1000 The following combination of speed options are not supported in RJ45 interfaces: • 1000 and duplex half • auto and duplex half The configurable speed options for an SFP port (from Ethernet1/9 to Ethernet1/16) are identified based on the SFP port PID which you can configure in CSM.properties. The port PID for the SFP ports must be specified in the path C:\Program Files (x86)\CSCOpx\MDC\athena\config\csm.properties. **Note** You cannot configure half-duplex value for SFP ports, only full duplex is allowed. • The supported speed options for FPR-3110 and FPR-3120 are as

Element	Description
	follows: • 1000 • 10000 • no-negotiate • sfp-detect • The supported speed options for FPR-3130 and FPR-3140 are as follows: • 1000 • 10000 • 25000 • no-negotiate • sfp-detect The configurable speed options for FPR-3100 series devices for the EPM ports (from Ethernet2/1 to Ethernet2/8) are identified based on the module type from device show inventory. The EPM ports must be specified in the path C:\Program Files (x86)\CSCOpx\MDC\athena\config\csm.properties. The supported speed options are as follows: • FPR-X-NM-8X10G module: • 1000 • 10000 • no-negotiate • sfp-detect • FPR-X-NM-8X25G module: • 1000 • 10000 • 25000 • no-negotiate • sfp-detect • FPR-X-NM-4X40G module: • 40000 • sfp-detect • no-negotiate

Element	Description
FEC Mode	If you choose **Physical Interface**, you can configure the **FEC Mode** to reduce errors in data transmission over noisy channels. **FEC Mode** supports **Physical Interface** hardware ports from Ethernet1/9 to Ethernet1/16. The default value is auto. **FEC Mode** configuration is supported in the following Firepower devices: • FPR-3130 • FPR-3140 Following are the available FEC mode values: • auto • cl108-rs • cl74-fc • disable **Note** FEC Mode configuration is applicable to ASA 9.17(1) and higher devices only. FEC Mode is not applicable to Management Interfaces.
Negotiate-Auto	If you choose **Physical Interface**, you can configure the **Negotiate-Auto** whenever there is an interop issue with the peer. **Negotiate-Auto** configuration is supported in the following Firepower devices: • FPR-3110 • FPR-3120 • FPR-3130 • FPR-3140 **Note** **Negotiate-Auto** configuration is applicable to ASA 9.17(1) and higher devices only. Negotiate-Auto (AP-port) is not applicable to Management Interfaces and not supported if the interfaces are the member of port channel interface.

Element	Description
Enable Flow Control	If you choose **Physical Interface**, you can configure the **Enable Flow Control** option to control the packet flow. **Enable Flow Control** send configuration is supported in the following Firepower devices: • FPR-3110 • FPR-3120 • FPR-3130 • FPR-3140 **Note** **Enable Flow Control** configuration is applicable to ASA 9.18(1) and higher devices only.
MTU	Specify the maximum packet size in bytes; that is, the maximum transmission unit (MTU). The value depends on the type of network connected to the interface. Valid values are 300 to 65535 bytes. Default is 1500 for all types except PPPoE, for which the default is 1492. In multiple-context mode, set the MTU in the context configuration.
Active MAC Address Standby MAC Address	**Available only on PIX 7.2+ and ASA 7.2+ devices.** Use the Active MAC Address field to manually assign a private MAC address to the interface; the Standby MAC Address field can be used to set a standby MAC address for use with device-level failover. Refer to Device Interface: MAC Address , on page 1872 for more information about these fields.
Roles	All interface roles assigned to this interface are listed in this field. Role assignments are based on pattern matching between the Name given to this interface and all currently defined Interface Role objects in Cisco Security Manager. Interface role objects are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces. For more information on roles and how to define and use them, see Understanding Interface Role Objects , on page 303.
MAC Address	Site specific MAC address.
Site ID	Site ID to specify the site the current unit belongs to.
Beginning with Security Manager version 4.9 for ASA devices running the software version 9.5(1) or later, you can use inter-site clustering for Spanned EtherChannels in routed mode. To avoid MAC address flapping, configure a site ID for each cluster member so that a site-specific MAC address for each interface can be shared among a site's units.	
EtherChannel Interface options; available on ASA 8.4.1+ devices only.	

Element	Description
Load Balancing	When EtherChannel is the chosen interface Type (on the General panel), choose a load-balancing method for the channel links. See About EtherChannel Load Balancing , on page 1816, for more information about this option.
LACP Mode	Select the desired **LACP Mode**; the default is Active, which means up to eight interfaces are active, while up to eight are in stand-by mode, as determined by the Minimum and Maximum values under Active Physical Interfaces. If you select On, a static port-channel is created in which all member interfaces are all "on," meaning you can have up to 16 ports passing traffic, with no stand-by ports. When you select this option, the Mode for all interfaces assigned to this EtherChannel group is switched to On (if the Mode for each is not already On). See Editing LACP Parameters for an Interface Assigned to an EtherChannel , on page 1815, for more information about this mode.
Active Physical Interfaces	When EtherChannel is the chosen interface Type (on the General panel), specify the minimum and maximum number of interfaces that can be active for this EtherChannel group: • **Minimum** – Specify the minimum number of active interfaces for this group. For ASA 9.2(1)+, you can specify a value from 1 to 16; for earlier versions, enter a value from 1 to 8. If the active interfaces in the channel group falls below this value, then the port-channel interface goes down, and could trigger a device-level failover. • **Maximum** – Specify the maximum number of interfaces that can be active. For ASA 9.2(1)+, you can specify a value from 1 to 16; for earlier versions, enter a value from 1 to 8. For 16 active interfaces, be sure that your switch supports the feature (for example, the Cisco Nexus 7000 with F2-Series 10 Gigabit Ethernet Module). If your switch does not support 16 active interfaces, be sure to set this command to 8 or fewer. Interfaces available to the channel are selected on the General tab of this dialog box (Add/Edit Interface Dialog Box: General Tab (PIX 7.0+/ASA/FWSM) , on page 1842). Specifying 3, 5, 6, or 7 active ports in an EtherChannel bundle provides poor load balancing, because some ports get up to twice the load of others. We recommend specifying 2, 4, or 8 active ports per EtherChannel to achieve effective load balancing. (A value of 1 provides no load balancing at all.)
DHCP Relay options; available on ASA-SM 9.1.2+ devices only.	

Element	Description
DHCP Relay Servers	Enter the IP address or select a Networks/Hosts object representing the interface-specific DHCP server to which DHCP requests on this interface are relayed. Use a comma to separate multiple values. You can configure a maximum of 4 interface-specific DHCP relay servers and a maximum of 10 global and interface-specific DHCP relay servers combined. **Note** IPv6 is not supported for interface-specific servers. When a DHCP request enters an interface, the DHCP servers to which the ASA relays the request depends on your configuration. You can configure the following types of servers: • Interface-specific DHCP servers—When a DHCP request enters a particular interface, then the ASA relays the request only to the interface-specific servers. • Global DHCP servers—When a DHCP request enters an interface that does not have interface-specific servers configured, the ASA relays the request to all global servers. If the interface has interface-specific servers, then the global servers are not used. For more information, see DHCP Relay Page , on page 2004.
DHCP Relay Trust Info (Option 82)	Specifies that you want to trust this DHCP client interface. You can configure interfaces as trusted interfaces to preserve DHCP Option 82. **Note** You can also trust all DHCP client interfaces. For more information, see DHCP Relay Page , on page 2004. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the ASA DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then the ASA will drop that packet by default. You can now preserve Option 82 and forward the packet by identifying an interface as a trusted interface.
Secure Group Tagging options; available on ASA 9.3.1+ devices only. SGT plus Ethernet Tagging, also called Layer 2 SGT Imposition, enables the ASA to send and receive security group tags on Ethernet interfaces using Cisco proprietary Ethernet framing (EtherType 0x8909), which allows the insertion of source security group tags into plain-text Ethernet frames. The ASA inserts security group tags on the outgoing packet and processes security group tags on the incoming packet, based on a manual per-interface configuration. This feature allows inline hop-by-hop propagation of endpoint identity across network devices and provides seamless Layer 2 SGT Imposition between each hop. **Note** Supported only on physical interfaces, VLAN interfaces, port channel interfaces, and redundant interfaces. Not supported on logical interfaces or virtual interfaces, such as BVI, TVI, and VNI.Does not support failover links or cluster control links.	
Enable secure group tagging for Cisco TrustSec	Enables SGT plus Ethernet Tagging (also called Layer 2 SGT Imposition).

Element	Description
Tag egress packets with secure group tags	Enables propagation of a security group tag (called sgt) on an interface.
Assign a static secure group tag to all ingress packets	Applies a static security group tag to incoming traffic from the peer. If enabled, you must specify the SGT number to use in the Secure Group Tag field.
Secure Group Tag	Specifies the SGT number to apply to incoming traffic from the peer. Valid values are from 2-65519.
Trusted Interface	Indicates that ingress traffic on the interface should not have its existing SGT overwritten with the static SGT specified.
ASA Cluster (Layer 3); available on ASA 5580 and 5585 devices in cluster mode only. Supported by all interfaces when ASA cluster is in Router mode and supported by management interface when ASA cluster is in Transparent mode.	
IPv4 Address Pool	Enter or select the IPv4 Pool object that represents the pool of addresses to use.
MAC Address Pool	Enter or select the MAC Pool object that represents the pool of MAC addresses to use.
ASA Cluster (Layer 2); available on ASA 5580 and 5585 devices in cluster mode only. Supported on EtherChannel interfaces for ASA clusters. Not supported on Management interface when ASA cluster is in Transparent mode.	
Span EtherChannel across the ASA Cluster	Select to configure an EtherChannel that spans all ASAs in the cluster, and provides load balancing as part of the EtherChannel operation.
Enable load balancing between switch pairs in VSS or vPC mode	(Optional) If you are connecting the ASA to two switches in a Virtual Switching System (VSS) or Virtual Port Channel (vPC), then you should enable load balancing by checking the **Enable load balancing between switch pairs in VSS or vPC mode** check box. This feature ensures that the physical link connections between the ASAs to the VSS (or vPC) pair are balanced.
Member Interface Configuration	Identifies the LACP mode for the interface and the Virtual Switching System (VSS) or Virtual Port Channel (vPC) switch to which a given interface is connected, 1 or 2.
Advanced tab options specific to ASA 5505 devices (routed mode only)	
Block Traffic To	Restricts this VLAN interface from initiating contact with the VLAN chosen here.
Backup Interface	Choose a VLAN interface as a backup interface, for example, to an ISP. The backup interface does not pass traffic unless the default route through the primary interface fails. To ensure that traffic can pass over the backup interface, be sure to configure default routes on both the primary and backup interfaces so that the backup interface can be used when the primary fails.

Element	Description
Advanced tab options specific to FWSM 3.1+ devices	
Bridge Group	For an FWSM 3.1+ operating in transparent mode, this read-only field indicates the Bridge group to which this interface is assigned. See Add/Edit Bridge Group Dialog Box , on page 1876 for more information.
ASR Group	To add this interface to an asymmetric routing group, enter the ASR group number in this field. Stateful failover must be enabled for asymmetric routing support to function properly between units in failover configurations. Valid values for ASR group range from 1 to 32. See About Asymmetric Routing Groups , on page 1808 for more information.
Pause Frame for Flow Control options When a network interface gets over loaded, flow control allows it to send PAUSE requests to the devices sending it data to allow the over loaded condition to clear. If flow control is not enabled and an over loaded condition occurs, the device will drop packets. When the receiving part of the interface reaches the high water mark, the transmitting part of the interface starts to generate pause frames. The remote device is expected to stop / reduce the transmission of packets for the pause time mentioned in the pause frame. If the receiving part of the interface is able to clear its queue or reaches the low water mark within the pause time, the transmitting part of the interface sends out a special pause frame that mentions the pause time as zero.This enables the remote device to start to transmit packets. If the receiving part of the interface still works on the queue, once the pause time expires, the transmitting part of the interface sends a new pause frame again with a new pause time. **Note** Pause Frame for flow control is supported only on physical interfaces on ASA 8.2 and above, in the single and multi-context mode. It is not supported on logical interfaces or virtual interfaces, such as BVI, TVI, and VNI.	
Enable Pause Frame	(Optional) Enables transmission of pause frame for flow control.
Use Default Values	(Optional) Uses default values for Low Watermark, High Watermark and Pause Time, based on the device. If this is unchecked, specify the values as per the Device specific Pause Frame Flow Control values reference table.
Low Watermark (in Kilobytes)	Enter a value for the low-water mark. After the interface sends a pause frame, when the buffer usage is reduced below the low-water mark, the interface sends an “transmission on’ frame. The remote device can resume transmitting data.
High Watermark (in Kilobytes)	Enter a value for the high-water mark.When the buffer usage exceeds the high-water mark, the interface sends a pause frame.
Pause Time	Enter a value for the pause refresh threshold value, between 0 and 65535 slots. Each slot is the amount of time to transmit 64 bytes, so the time per unit depends on your link speed. The remote device can resume traffic after receiving an transmission on frame, or after the transmission off frame expires, as controlled by this timer value in the pause frame. If the buffer usage is consistently above the high-water mark, pause frames are sent repeatedly, controlled by the pause refresh threshold value.

Table 564: Device specific Pause Frame Flow Control values

Device Type	Low Watermark Range (in Kb)	Default Low Watermark (in Kb)	High Watermark Range(in Kb)	Deafult High Watermark(in Kb)	Range of Pause Time	Default Pause Time
ASA 5515	0-20	8	0-20	16	0-65535	26624
ASA 5525	0-20	8	0-20	16	0-65535	26624
ASA 5545	0-20	8	0-20	16	0-65535	26624
ASA 5510	0-48	16	0-48	24	0-65535	26624
ASA 5585	Values are not supported; only “flowcontrol send on” is supported.					
ASA 5506	1-25	3	1-25	8	1-65535	18432
ISA-3000-2C2F	0-64	27	0-64	34	0-65535	26624
ISA-3000-4C	0-64	27	0-64	34	0-65535	26624
1783-SAD4T0S	0-64	27	0-64	34	0-65535	26624

Configuring IPv6 Interfaces (ASA/FWSM)

When Interface, Subinterface, Redundant, or EtherChannel is the chosen Type in the Add Interface or Edit Interface dialog box, the dialog box presents three tabbed panels of options: General, Advanced and IPv6. The options provided by the **IPv6** panel are described in this section.

Note These options are available only on ASA 7 .0+ devices in routed mode; ASA 8.2+ devices in transparent mode; and FWSM 3.1+ devices in routed mode.

Navigation Path

You can access the IPv6 panel in the Add Interface and Edit Interface dialog boxes, which are accessed from the ASA or FWSM Interfaces page, as described in Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835.

Field Reference

Table 565: IPv6 tab: Add/Edit Interface Dialog Box (ASA/FWSM)

Element	Description
Enable IPv6	Check this box to enable IPv6 and configure IPv6 addresses on this interface. You can deselect this option to disable IPv6 on the interface, but retain the configuration information.
Enforce EUI-64	When selected, use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link is enforced. When this option is enabled on an interface, the source addresses of IPv6 packets received on the interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the interface identifier in an IPv6 packet is not in the Modified EUI-64 format, the packet is dropped and the following system log message is generated: %PIX|ASA-3-325003: EUI-64 source address check failed. Address format verification is performed only when a flow is created. Packets from an existing flow are not checked. Additionally, address verification can be performed only for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address. The Modified EUI-64 format interface identifier is derived from the 48-bit link-layer (MAC) address by inserting the hex number FFFE between the upper three bytes (OUI field) and the lower 3 bytes (serial number) of the link-layer address. To ensure the chosen address is from a unique Ethernet MAC address, the next-to-lowest order bit in the high-order byte is inverted (universal/local bit) to indicate the uniqueness of the 48-bit address. For example, an interface with a MAC address of 00E0.B601.3B7A would have a 64-bit interface ID of 02E0:B6FF:FE01:3B7A.

Element	Description
DAD Attempts	To specify the number of consecutive neighbor solicitation messages that are sent on an interface during duplicate address detection (DAD), enter a number from 0 to 600 in this field. Entering 0 disables duplicate address detection on the interface. Entering 1 configures a single transmission without follow-up transmissions; this is the default. Duplicate address detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection uses neighbor solicitation messages to verify the uniqueness of unicast IPv6 addresses. When duplicate address detection identifies a duplicate address, the state of the address is set to DUPLICATE and the address is not used. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface and an error message similar to the following is issued: %PIX-4-DUPLICATE: Duplicate address FE80::1 on outside If the duplicate address is a global address of the interface, the address is not used and an error message is issued, similar to that shown previously for a duplicate link-local address. All configuration commands associated with the duplicate address remain as-configured while the state of the address is set to DUPLICATE. If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address, and all other IPv6 address associated with the interface are regenerated (that is, duplicate address detection is performed only on the new link-local address).
NS Interval	The interval between IPv6 neighbor solicitation retransmissions, in milliseconds. Valid values range from 1000 to 3600000 milliseconds; the default value is 1000 milliseconds. **Note** This value is included in all IPv6 router advertisements sent out on this interface.
Reachable Time	The amount of time, in milliseconds, within which a remote IPv6 node is considered still reachable, after initial reachability was confirmed. Valid values range from 0 to 3600000 milliseconds, the default value is 0. When 0 is used for the value, the reachable time is set as undetermined—it is up to the receiving devices to set and track reachable time. A configured time enables detection of unavailable neighbors. A shorter time allows detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.
Managed Config Flag	Whether or not to set the flag "managed-config-flag" in the IPv6 router advertisement packet.
Other Config Flag	Whether or not to set the flag "other-config-flag" in the IPv6 router advertisement packet.

Element	Description
Enable RA	When checked, IPv6 router advertisement transmissions are enabled on the interface. The following options are enabled: • **RA Lifetime** – The "router lifetime" value specifies how long nodes on the local link should consider the security appliance as the default router on the link. Valid values range from 0 to 9000 seconds; the default is 1800 seconds. Entering 0 indicates that the security appliance should not be considered a default router on the selected interface. Any non-zero value should not be less than the following RA Interval value. **Note** This value is included in all IPv6 router advertisements sent out on this interface. • **RA Interval** – The interval between IPv6 router advertisement transmissions on this interface. Valid values range from 3 to 1800 seconds, (or from 500 to 1800000 milliseconds if the following RA Interval in Milliseconds option is checked); the default is 200 seconds. The interval between transmissions should be less than or equal to the RA Lifetime value if it is non-zero. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the desired value. • **RA Interval in Milliseconds** – Checking this option indicates that the provided RA Interval value is in milliseconds, rather than seconds.
Interface IPv6 Addresses	The IPv6 addresses assigned to the interface are specified in this section of the dialog box. • **Link-Local Address** – To override the link-local address that is automatically generated for the interface, enter the desired IPv6 link-local address in this field. The link-local address is composed of the link-local prefix FE80::/64 and the interface ID in Modified EUI-64 format. For example, an interface with a MAC address of 00E0.B601.3B7A would have a link-local address of FE80::2E0:B6FF:FE01:3B7A. An error will occur if another host is using the specified address. • **Enable Address Auto-Configuration** – Select this option to enable automatic configuration of IPv6 addresses on the interface using stateless autoconfiguration. The addresses are configured based on the prefixes received in Router Advertisement (RA) messages. If a link-local address has not been configured, then one is automatically generated for this interface. An error occurs if another host is already using the generated link-local address. • **Trust the DHCP Servers for default gateway**– Select this radio button to install a default route from Router Advertisements that come from a trusted source - the directly-connected network. • Ignore trust and accept router advertisements – Select this radio button to install a default route from Router Advertisements that come from another network. • The table in this section displays the IPv6 addresses assigned to this interface. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.) Add Row and Edit Row open the IPv6 Address for Interface Dialog Box , on page 1864.

Element	Description
Interface IPv6 Prefixes	Use the table in this section to configure which IPv6 prefixes (that is, the network portion of the IPv6 addresses) are included in IPv6 router advertisements. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.) Add Row and Edit Row open the IPv6 Prefix Editor Dialog Box , on page 1866.
Interface IPv6 DHCP	Use this section to enable the DHCPv6 Prefix Delegation client on one or more interfaces. The ASA obtains one or more IPv6 prefixes that it can subnet and assign to inside networks. Typically, the interface on which you enable the prefix delegation client obtains its IP address using the DHCPv6 address client; only other ASA interfaces use addresses derived from the delegated prefix. Select one of the following: • Server Pool – Select this to configure the IPv6 DHCP pool that contains the information you want the DHCPv6 server to provide. You can configure separate pools for each interface if you want, or you can use the same pool on multiple interfaces. Use the Add Row and Edit Row buttons in the DHCP Pool Selector dialog to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.)Add Row and Edit Row open the Add or Edit DHCPv6 Pool Dialog Box , on page 1868. OR • Client Prefix Delegation Name – Enable the DHCPv6 Prefix Delegation client by entering a name for the prefix(es) obtained on this interface. Valid values are a string not exceeding 200 characters. • DHCPv6 Prefix Hint – Use the Add Row button to provide one or more hints about the delegated prefix that you want to receive. Typically you want to request a particular prefix length, such as ::/60, or if you have received a particular prefix before and want to ensure you get it again when the lease expires, you can enter the whole prefix as the hint. If you enter multiple hints (different prefixes or lengths), then it is up to the DHCP server which hint to honor, or whether to honor the hint at all. **Note** If the prefix suggested as the hint is a valid prefix in the associated local prefix pool and is not assigned elsewhere, the server delegates the client-suggested prefix. Otherwise, the hint is ignored and a prefix is delegated from the free list in the pool. • • Enable DHCP – Select this to obtain an address using DHCPv6. Optionally, select Enable Default Route to obtain a default route from Router Advertisements.
Note If a DHCPv6 client or Server Pool is configured on an IPv6 Interface, the same interface cannot be used to configure DHCPv6 Relay.	

IPv6 Address for Interface Dialog Box

This dialog box is used to add or edit an IPv6 address assigned to an ASA or FWSM interface. Multiple IPv6 addresses can be assigned to the interface in the IPv6 panel of the Add Interface or Edit Interface dialog box.

Note This dialog box is available only on ASA 7.0+ devices in routed mode; ASA 8.2+ devices in transparent mode; and FWSM 3.1+ devices in routed mode.

Navigation Path

You can access the IPv6 Address for Interface dialog box:

- From the IPv6 panel of the ASA or FWSM Add Interface and Edit Interface dialog boxes.
- From the Management IPv6 page of an ASA 5505 in transparent firewall mode (version 8.2 and 8.3 devices only).

Click the Add Row or Edit Row buttons beneath the table in the Interfaces IPv6 Addresses section to open the dialog box.

Field Reference

Table 566: IPv6 Address for Interface Dialog Box

Element	Description
Prefix Name	(Optional) Enter a prefix name to use a delegated prefix. Valid values are a string not exceeding 200 characters. **Tip** 'DHCP' is a reserved word; Cisco Security Manager will not accept it as Prefix Name. **Note** Make sure that the DHCPv6 Prefix Delegation Client is enabled on this ASA Interface. For more information, see the Interface IPv6 DHCP element in the Table 565: IPv6 tab: Add/Edit Interface Dialog Box (ASA/FWSM) , on page 1861.

Element	Description
Address/Prefix Length	Enter an IPv6 network address to be assigned to the interface, with its Prefix Length appended, where the Prefix Length integer indicates how many of the high-order, contiguous bits of the address comprise network portion of the address. A slash (/) must precede the Prefix Length. For example, 3FFE:C00:0:1::/64. Typically, the delegated prefix will be /60 or smaller so you can subnet to multiple /64 networks. /64 is the supported subnet length if you want to support SLAAC for connected clients. You shuld specify an address that completes the /60 subnet, for example ::1:0:0:0:1. Enter :: before the address in case the prefix is smaller than /60. For example, if the delegated prefix is 2001:DB8:1234:5670::/60, then the global IP address assigned to this interface is 2001:DB8:1234:5671::1/64. The prefix that is advertised in router advertisements is 2001:DB8:1234:5671::/64. In this example, if the prefix is smaller than /60, the remaining bits of the prefix will be 0's as indicated by the leading ::. For example, if the prefix is 2001:DB8:1234::/48, then the IPv6 address will be 2001:DB8:1234::1:0:0:0:1/64.
EUI-64	If this box is checked, the EUI-64 interface ID will be used in the low-order 64 bits of the IPv6 address. If the value specified for the Prefix Length is greater than 64 bits, the prefix bits have precedence over the interface ID. An error occurs if another host is using the specified address. The Modified EUI-64 format interface ID is derived from the 48-bit link-layer (MAC) address by inserting the hex number FFFE between the upper three bytes (OUI field) and the lower 3 bytes (serial number) of the link layer address. To ensure the chosen address is from a unique Ethernet MAC address, the next-to-lowest order bit in the high-order byte is inverted (universal/local bit) to indicate the uniqueness of the 48-bit address. For example, an interface with a MAC address of 00E0.B601.3B7A would have a 64 bit interface ID of 02E0:B6FF:FE01:3B7A.
IPv6 Address Pool	Enter or select the IPv6 Pool object that represents the pool of addresses to use.

IPv6 Prefix Editor Dialog Box

This dialog box is used to add or edit an IPv6 prefix (that is, the network portion of an IPv6 address), providing control over individual parameters, including whether the prefix should be included in IPv6 router advertisements. Multiple prefixes can be configured in the IPv6 panel of the ASA or FWSM Add Interface or Edit Interface dialog box.

Note This dialog box is available only on ASA 7.0+ devices in routed mode; ASA 8.2+ devices in transparent mode; and FWSM 3.1+ devices in routed mode.

By default, prefixes configured as addresses on an interface are advertised in router advertisements. If you configure specific prefixes for advertisement, then only those prefixes are advertised. The valid and preferred lifetimes are counted down in real time. Alternately, a date can be set to specify the expiration of a prefix. When the expiration is reached, the prefix is no longer advertised.

Navigation Path

You can access the IPv6 Prefix Editor dialog box from the IPv6 panel of the Add Interface and Edit Interface dialog boxes: click the Add Row or Edit Row buttons beneath the table in the Interfaces IPv6 Prefixes section in either of those dialog boxes.

Field Reference

Table 567: IPv6 Prefix Editor Dialog Box

Element	Description
Address/Prefix Length	Enter an IPv6 network address, with its Prefix Length appended, where the Prefix Length integer indicates how many of the high-order, contiguous bits of the address represent the network portion of the address. A slash (/) must precede the Prefix Length. For example, 3FFE:C00:0:1::/64.
Default	If this box is checked, the settings in this dialog box will apply to all prefixes, rather than a single address. (When checked, the Address/Prefix Length field is disabled.)
No Advertisements	When checked, hosts on the local link cannot use the specified prefix in advertisements.
Off Link	When checked, the specified prefix is “off-link”; that is, not locally reachable on the link. When on-link (the default), the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link.
No Auto-Configuration	When checked, hosts on the local link cannot use the specified prefix for IPv6 autoconfiguration. When auto-configuration is on (the default), hosts on the local link can use the specified prefix for IPv6 autoconfiguration.

Element	Description

Prefix Lifetime	You can expand this section of the dialog box to display the following expiration options:
	• **Lifetime Duration** – Select this option to define prefix expiration as a length of time; the following options are enabled:
	  • **Valid Lifetime** – The amount of time (in seconds) that the specified IPv6 prefix is advertised as being valid. Enter a value from 0 to 4294967295 seconds. The maximum value represents infinity (that is, the lifetime does not expire), which can also be specified by the checking the **Infinite** box. The default is 2592000 (30 days).
	  • **Preferred Lifetime** – The amount of time (in seconds) that the specified IPv6 prefix is advertised as being preferred. Enter a value from 0 to 4294967295 seconds. The maximum value represents infinity (that is, the lifetime does not expire), which can also be specified by the checking the **Infinite** box. The default is 604800 (7 days). The Preferred Lifetime must be less than or equal to the Valid Lifetime.
	• **Lifetime Expiration Date** – Select this option to define prefix expiration as a specific date. Note that acceptable values for this date can range from today's date to one year from today's date. The following options are enabled:
	  • **Valid** – The prefix is advertised as being valid until this date and time are reached. Enter a date in the form Mmm dd yyyy (that is, three-letter month abbreviation, two-digit date, and four-digit year), or click the calendar icon to select a date from a scrolling calendar. Also, enter the time of expiration on the specified date, in the form hh:mm , based on a 24-hour clock.
	  • **Preferred** – The prefix is advertised as being preferred until this date and time are reached. Enter a date in the form Mmm dd yyyy (that is, three-letter month abbreviation, two-digit date, and four-digit year), or click the calendar icon to select a date from a scrolling calendar. Also, enter the time of expiration on the specified date, in the form hh:mm , based on a 24-hour clock. The Preferred date and time must be earlier than or equal to the Valid date and time.

Add or Edit DHCPv6 Pool Dialog Box

This dialog box is used to add or edit the DHCPv6 Server Pool. For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature, you can configure the ASA to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the ASA. The ASA only accepts IR packets, and does not assign addresses to the clients.

Navigation Path

- Choose **Policy Objects** from the **Manage** menu, or click the Policy Object Manager button in the button bar, to open the Policy Object Manager pane in the lower section of the Configuration Manager window. Select **Pool Objects > DHCPv6 Pool Object** from the Object Type Selector. Right-click inside the work area and select **New Object** (and select an object type), or right-click a row and select **Edit Object**; you also can use the related buttons at the bottom of the pane to open either dialog box.

OR

- You can access the Add DHCPv6 Pool dialog box from DHCPv6 Pool Selector dialog box: click the Add Row or Edit Row buttons beneath the Available DHCPv6 Pool table. The DHCPv6 Pool Selector dialog box can been accessed from the Server Pool radio button in the Interface IPv6 DHCP section of the IPv6 panel of the Add Interface and Edit Interface dialog box.

Related Topics

- Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835

Field Reference

Table 568: Add DHCPv6 Pool Dialog Box

Element	Description
Name	The DHCPv6 Pool name should not exceed 200 characters. Object names are not case-sensitive.

• Configure parameters on one or more tabs, to provide responses to IR messages to clients.
• For each of these tabs, specify the following as appropriate:
  • DNS/SIP/ NIS/ NISP/ SNTP Server: Enter a server name. Make sure that the IPv6 addresses are in the correct format. For more information on IPv6 address format, see http://www.ietf.org/rfc/rfc2373.txt .
  • DNS/ SIP/NIS/NISP Domain Name: Enter a domain name. Domain names must begin and end with a digit/letter, only letters, digits and hyphen are allowed as internal characters, labels are separated by a dot.Each label must be up to 63 characters and the entire host name has a maximum of 255 characters. For more information on domain names format, see http://www.ietf.org/rfc/rfc1123.txt .
Note The import command uses one or more parameters that the ASA obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and in the import command.	

Server tab	(Optional) Specify DNS Server Name and Domain Name.
SIP tab	(Optional) Specify SIP Server Name and SIP Domain Name.
NIS tab	(Optional) Specify NIS Server Name and NIS Domain Name.
NISP tab	(Optional) Specify NISP Server Name and NISP Domain Name.
SNTP tab	(Optional) Specify SNTP Server Name.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.

Element	Description
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the **Edit** button to create, edit, and view the overrides. The **Overrides** field indicates the number of devices that have overrides for this object.

Device Interface: IP Type (PIX/ASA 7.0+)

A security device operating in single-context, routed mode requires IP addressing for its interfaces; however, firewall interfaces do not have IP addresses until you assign them. Note that in transparent mode, the device acts as an access-control bridge (a "bump in the wire")—you assign different VLANs to each interface, but IP addressing is not necessary.

The Add/Edit Interface dialog box presented for an independent ASA or PIX 7.0+ device in single-context, routed mode includes the section **IP Type**, where you specify the type of IP addressing for the interface and provide related parameters, as described here. (The IP Type section of the Add/Edit Interface dialog box for PIX 6.3 devices is described in Device Interface: IP Type (PIX 6.3) , on page 1839.)

In multiple-context mode, interface IP addresses are set in the context configuration.

Note Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry.Also, do not specify IP Type information for an interface you intend to use as a redundant interface.

Step 1 In the Add/Edit Interface dialog box, choose a method for address assignment (**Static IP**, **Use DHCP**, or **PPPoE (PIX and ASA 7.2+)**) from the **IP Type** list, and then provide related parameters, as follows:

- **Static IP** – Provide a static **IP Address** and **Subnet Mask** that represents the security device on this interface's connected network. The IP address must be unique for each interface.

The Subnet mask can be expressed in dotted decimal format (for example, 255.255.255.0), or by entering the number of bits in the network mask (for example, 24). Beginning from Version 4.13, Cisco Security Manager allows you to use 255.255.255.254 for point to point interface. Do not use 255.255.255.255 for an interface connected to the network because this will stop traffic on that interface. If you omit the Subnet Mask value, a "classful" network is assumed, as follows:

- • The Class A netmask (255.0.0.0) is assumed if the first octet of the IP Address is 1 through 126 (i.e., addresses 1.0.0.0 through 126.255.255.255).
  - The Class B netmask (255.255.0.0) is assumed if the first octet of the IP Address is 128 through 191 (i.e., addresses 128.0.0.0 through 191.255.255.255).
  - The Class C netmask (255.255.255.0) is assumed if the first octet of the IP Address is 192 through 223 (i.e., addresses 192.0.0.0 through 223.255.255.255).

Note Do not use addresses previously used for routers, hosts, or any other firewall device commands, such as an IP address in the global pool or a static NAT entry.

- **Use DHCP** – Enables Dynamic Host Configuration Protocol (DHCP) for automatic assignment of an IP address from a DHCP server on the connected network. The following options become available:
  - **DHCP Learned Route Metric** (required) – Assign an administrative distance to the learned route. Valid values are 1 to 255. The administrative distance for learned routes defaults to 1.

All routes have a value or "metric" that represents its priority of use. (This metric is also referred to as "administrative distance.") When two or more routes to the same destination are available, devices use administrative distance to decide which route to use.

-
  - **Obtain Default Route using DHCP** – Select this option to obtain a default route from the DHCP server so that you do not need to configure a default static route. See also Configuring Static Routes , on page 2223.
  - **Enable Tracking for DHCP Learned Route** – If Obtain Default Route using DHCP is selected, you can select this option to enable route tracking via a specific Service Level Agreement (SLA) monitor. The following option becomes available:
  - **Tracked SLA Monitor** – Required if Enable Tracking for DHCP Learned Route is selected. Enter or Select the name of the SLA monitor object that defines the route tracking (connectivity monitoring) to be applied to this interface. See Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996 for more information.

- **PPPoE (PIX and ASA 7.2+)** – Enables Point-to-Point Protocol over Ethernet (PPPoE) for automatic assignment of an IP address from a PPPoE server on the connected network; this option is not supported with failover. The following options become available:
  - **VPDN Group Name** (required) – Choose the Virtual Private Dialup Network (VPDN) group that contains the authentication method and user name/password to use for network connection, negotiation and authentication. See Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996 for more information.
  - **IP Address** – If provided, this static IP address is used for connection and authentication, instead of a negotiated address.
  - **Subnet Mask** – The subnet mask to be used in conjunction with the provided IP Address.
  - **PPPoE Learned Route Metric** (required) – Assign an administrative distance to the learned route. Valid values are 1 to 255; defaults to 1.

All routes have a value or "metric" that represents its priority of use. (This metric is also referred to as "administrative distance.") When two or more routes to the same destination are available, devices use administrative distance to decide which route to use.

-
  - **Obtain Default Route using PPPoE** – Select this option to obtain a default route from the PPPoE server; sets the default routes when the PPPoE client has not yet established a connection. When using this option, you cannot have a statically defined route in the configuration.
  - **Enable Tracking for PPPoE Learned Route** – If Obtain Default Route using PPPoE is selected, you can select this option to enable route tracking for PPPoE-learned routes. The following options become available:
  - **Dual ISP Interface** – If you are defining interfaces for dual ISP support, choose Primary or Secondary to indicate which connection you are configuring.

- **Tracked SLA Monitor** – Required if Enable Tracking for DHCP Learned Route is selected. Enter or Select the name of the SLA monitor object that defines the route tracking (connectivity monitoring) to be applied to this interface. See Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996 for more information.

Note You can configure DHCP and PPPoE only on the outside interface of a firewall device. If you have already configured PPPoE on the outside interface, it is no longer available as an option.

Step 2 Continue configuring the device interface in the Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840.

Device Interface: MAC Address

By default, a physical interface uses its "burned-in" MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

A redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then its MAC address changes to match the MAC address of the interface that is now listed first. If you manually assign a MAC address to the redundant interface, that is used regardless of the physical-interface MAC addresses.

Similarly, all interfaces assigned to an EtherChannel group share the same MAC address. By default, the EtherChannel uses the MAC address of the lowest-numbered member interface. However, you can manually configure a MAC address for the EtherChannel to prevent traffic disruption should the low-numbered interface be removed from the group.

You also might want to assign unique MAC addresses to subinterfaces. For example, your service provider might control access based on MAC addresses.

Further, if you use failover, you can provide a standby MAC address. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Note The following options appear only on the Advanced tab of the Add Interface and Edit Interface dialog boxes presented by PIX 7.2+ and ASA 7.2+ devices.

(Optional) To manually assign a private MAC address to the current interface:

Step 1 In the Add/Edit Interface dialog box, provide the desired MAC address in the **Active MAC Address** field.

MAC addresses are provided in *H.H.H* format, where *H* is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE.

Note In some cases, you may have to press the Tab key after entering the Active MAC Address to activate the Standby MAC Address field.

Step 2 If desired, provide a **Standby MAC Address** for use with device-level failover.

If the active unit fails over and the standby unit becomes active, the new active unit begins using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Step 3 Continue configuring the device interface in the Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840.

Add/Edit Interface Dialog Box: Switch Port Tab

The Switch Port panel in the Add/Edit Interface dialog box is used to configure settings such as Mode, Access VLAN ID, Trunk Type, and VLAN ID on Firepower 1010 devices.

Navigation Path

You can access the Add/Edit Interface dialog box from the Interfaces page. Select the Enable Switchport check box to configure these settings.

Field Reference

Table 569: Switch Port Tab: Add/Edit Interface Dialog Box

Element	Description
Enable Switchport	Check this box to enable switchport on the selected interface. Unchecking this option disables the switchport on the interface but retains the configuration information.
Mode	Select one of the two modes avaialble: Access or Trunk
Access VLAN ID	This dialog box gets enabled only when Access mode is selected. Enter a value between 0 and 4190. The VLAN ID configured in the interface is entered here.
Trunk Type	Select one of the two trunk types available: Allowed or Native.
VLAN ID	Enter the VLAN ID(s) for this port, according to the chosen mode.
Enable Protected	Select this option to prevent this port from communicating with other switch ports on the same VLAN.

Add/Edit Interface Dialog Box: Power Over Ethernet Tab

The Power Over Ethernet (POE) in the Add/Edit Interface dialog box is used to configure power consumption mode and wattage. Beginning with ASA 9.13(1), this feature is supported on Firepower 1010 devices and and is a part of physical interface for ports Ethernet1/7 and Ethernet1/8.

The POE feature allows you to configure the physical interface such that the power is delivered automatically to the connected device, in accordance to the class limiting wattage; the power is cut off from the specified port, Ethernet1/7 or Ethernet1/8; and the wattage required for the specified port is preset in milliwatts, without LLDP negotiation.

Field Reference

Table 570: Switch Port Tab: Add/Edit Interface Dialog Box

Element	Description
Dsiable POE	Check this box to cut off the power to the specified port (Ethernet 1/7 or Ethernet 1/9)
Cosumption Mode	Select the power consumption mode: • **Auto** (default) - Select this to deliver the power automatically to the connected devices as per the class limiting wattage. • **Configure** - Select this to specify the consumption wattage manually, that is required for the selected port.
Consumption Wattage	Specify the consumption wattage (in milliwatts) required for the selected port.

Configuring Hardware Ports on an ASA 5505

The Interfaces page displayed for ASA 5505 devices presents two tabbed panels: *Hardware Ports* and *Interfaces* . The table on the Hardware Ports panel displays currently configured switch ports for the selected ASA 5505.

Use the Configure Hardware Ports dialog box to configure the switch ports on an ASA 5505, including setting the mode, assigning a switch port to a VLAN, and setting the Protected option. (The following dialog-box parameter descriptions also describe the fields in the Hardware Ports table.)

Caution The ASA 5505 does not support Spanning Tree Protocol for loop detection in the network. Therefore, you must ensure that any connection with the appliance does not end up in a network loop.

Navigation Path

You can access the Configure Hardware Ports dialog box by clicking Add Row or Edit Row on the Hardware Ports panel of the ASA 5505 Interfaces page. See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for more information.

Related Topics

- Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840

Field Reference

Table 571: Configure Hardware Ports Dialog Box

Element	Description
Enable Interface	Select this option to enable this switch port. You can deselect this option to disable the port, but retain its configuration information.
Isolated	Select this option to prevent this port from communicating with other isolated or "protected" switch ports on the same VLAN. You might want to prevent switch ports from communicating with each other if the devices on those ports are primarily accessed from other VLANs, if you do not need to allow intra-VLAN access, and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three Web servers, you can isolate the Web servers from each other if you apply the Isolated option to each switch port. The inside and outside networks can both communicate with all three Web servers, and vice versa, but the Web servers cannot communicate with each other.
Hardware Port	Choose the switch port that you are configuring; all device ports are listed.
Mode	Choose a mode for this port: • **Access Port** – Sets the port to access mode. Each access port can be assigned to one VLAN. • **Trunk Port** – Sets the port to trunk mode using 802.1Q tagging. Trunk ports can carry multiple VLANs using 802.1Q tagging. Trunk mode is available only with the Security Plus license. Trunk ports do not support untagged packets, there is no native VLAN support, and the appliance drops all packets that do not contain a tag.
VLAN ID	Enter VLAN ID(s) for this port, according to the chosen Mode: • For Access Port mode, enter the ID of the VLAN to which this switch port is to be assigned. • For Trunk Port mode, you can enter multiple VLAN IDs, and multiple ID ranges (such as 4-8), separated by commas. **Note** For devices running operating system 7.2(2)18 or earlier, valid VLAN IDs are 1 to 1001; with version 7.2(2)19 or later, valid IDs are 1 to 4090.
Duplex	Choose a duplex option for the port: **Full**, **Half**, or **Auto**. The Auto setting is recommended, and the default. If you set Duplex to anything other than Auto for PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

Element	Description
Speed	Choose a speed for the port: **10**, **100**, or **Auto**. The Auto setting is recommended, and the default. If you set Speed to anything other than Auto for PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power. The default Auto setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either Speed or Duplex must be set to Auto to enable Auto-MDI/MDIX for the interface. If you explicitly set both Speed and Duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled.

Add/Edit Bridge Group Dialog Box

A transparent firewall connects the same network on its inside and outside interfaces, and supports only the two interfaces per context. However, you can increase the number of interfaces available to a context through use of bridge groups. You can configure up to eight bridge groups; on an FWSM each group can contain two interfaces; on an ASA 9.6.1 each group can contain 64 interfaces.

Each bridge group connects to a separate network. Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the security appliance—traffic must exit the security appliance to be routed by an external router back to another bridge group in the security appliance.

You might want to use more than one bridge group if you do not want the overhead of security contexts, or want to maximize your use of security contexts. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration. For complete security policy separation, use security contexts with one bridge group in each context.

Starting from Cisco Security Manager 4.13, the Bridge-group Virtual Interface (BVI) feature is extended to the routed firewall mode. Routed firewalls are implemented by means of configuring bridge-groups. A user can configure up to eight bridge groups and on an ASA 9.7.1 (Cisco Security Manager 4.13) each group can contain upto 64 interfaces. On versions prior to Cisco Security Manager 4.13, a user can configure a maximum of two bridge groups; with each group containing a maximum limit of four interfaces. In addition to the BVI features supported in the transparent mode, the routed firewall mode includes support for the following additional communication modes:

- Inter BVI communication
- BVI to Data Port communication (Layer 2 to Layer 3) and vice versa

For FWSM 3.1+ and ASA 8.4.1+ devices in transparent mode, the Interfaces page displays two tabbed panels: Interfaces and Bridge Groups. The following information applies to the Bridge Groups panel and the Add/Edit Bridge Group dialog box; refer to Add/Edit Interface Dialog Box (PIX 7.0+/ASA/FPR/FWSM) , on page 1840 for information about the Interfaces panel.

Navigation Path

You can access the Add/Edit Bridge Group dialog box from the Bridge Groups panel of the Interfaces page.

Field Reference

Table 572: Add/Edit Bridge Group Dialog Box

Element	Description
General Tab	
Bridge Group	Enter a name for this bridge group.
Name	Provide an identifier for this interface of up to 48 characters in length. The name should be a memorable name for the interface that relates to its use. However, if you are using failover, do not name interfaces that you are reserving for failover communications; this includes an EtherChannel intended for failover, as well as its member interfaces. Also, do not name interfaces intended for use as a member of a redundant-interface pair. Certain names are reserved for specific interfaces, in accordance with the interface naming conventions of the security appliance. As such, these reserved names enforce default, reserved security levels, as follows: • Inside – Connects to your internal network. Must be the most secure interface. • DMZ – "Demilitarized zone" attached to an intermediate interface. DMZ is also known as a perimeter network. You can name a DMZ interface any name you choose. Typically, DMZ interfaces are prefixed with "*DMZ* " to identify the interface type. • Outside – Connects to an external network or the Internet. Must be the least secure interface. Similarly, a subinterface name typically identifies its associated interface, in addition to its own unique identifier. For example, *DMZoobmgmt* could represent an out-of-band management network attached to the DMZ interface. **Note** Again, **do not name the interface if you intend to use it for failover, or as a member of a redundant interface**. See Configuring Redundant Interfaces , on page 1811 for more information.
ID	Enter an identifier for this bridge group; can be an integer between 1 and 100.
Security Level	Assign a security level to the VLAN interface. Valid values are from 0-100; 100 is the most secure.
Available Interfaces	Choose from a list of available interfaces or VLANs to assign to this bridge group; all available interfaces are listed. **Note** Starting from ASA 9.7.1(Cisco Security Manager 4.13), a maximum of 64 interfaces are supported per bridge group.

Element	Description
Members in Group	Displays the number of interfaces in the current bridge group
IP Type	Select the IP type for the interface. • Static IP - Assign an IP address and subnet mask for the bridge-group interface. • DHCP - Use DHCP to obtain an IP address for the interface. • Obtain Default Route using DHCP - When selected, Cisco Security Manager uses the default route supplied by the DHCP server.
IP Address	Enter or Select a management IP address for the bridge group. A transparent firewall does not participate in IP routing. Thus, the only IP configuration required for a bridge group is this management IP address. This address is the source address for traffic originating on the security appliance, such as system messages or communications with AAA servers. You can also use this address for remote management access. **Note** IPv6 addresses are not supported for bridge groups.
Netmask	Network mask for the specified IP address. You can express the value in dotted decimal format (for example, 255.255.255.0) or by entering the number of bits in the network mask (for example, 24). **Note** Do not use 255.255.255.255 for an interface connected to the network because this will stop traffic on that interface.
Description	You can enter an optional description for this bridge group.
IPv6 Tab	
Enable IPv6	Check this box to enable IPv6 and configure IPv6 addresses on this bridge group. You can deselect this option to disable IPv6 on the bridge group, but retain the configuration information.

Element	Description
Enforce EUI-64	When selected, use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link is enforced. When this option is enabled on a bridge group, the source addresses of IPv6 packets received on the bridge group interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the interface identifier in an IPv6 packet is not in the Modified EUI-64 format, the packet is dropped and the following system log message is generated: %PIX|ASA-3-325003: EUI-64 source address check failed. Address format verification is performed only when a flow is created. Packets from an existing flow are not checked. Additionally, address verification can be performed only for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address. The Modified EUI-64 format interface identifier is derived from the 48-bit link-layer (MAC) address by inserting the hex number FFFE between the upper three bytes (OUI field) and the lower 3 bytes (serial number) of the link-layer address. To ensure the chosen address is from a unique Ethernet MAC address, the next-to-lowest order bit in the high-order byte is inverted (universal/local bit) to indicate the uniqueness of the 48-bit address. For example, an interface with a MAC address of 00E0.B601.3B7A would have a 64-bit interface ID of 02E0:B6FF:FE01:3B7A.
DAD Attempts	To specify the number of consecutive neighbor solicitation messages that are sent on a bridge group interface during duplicate address detection (DAD), enter a number from 0 to 600 in this field. Entering 0 disables duplicate address detection on the interface. Entering 1 configures a single transmission without follow-up transmissions; this is the default. Duplicate address detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection uses neighbor solicitation messages to verify the uniqueness of unicast IPv6 addresses. When duplicate address detection identifies a duplicate address, the state of the address is set to DUPLICATE and the address is not used. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface and an error message similar to the following is issued: %PIX-4-DUPLICATE: Duplicate address FE80::1 on outside If the duplicate address is a global address of the interface, the address is not used and an error message is issued, similar to that shown previously for a duplicate link-local address. All configuration commands associated with the duplicate address remain as-configured while the state of the address is set to DUPLICATE. If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address, and all other IPv6 address associated with the interface are regenerated (that is, duplicate address detection is performed only on the new link-local address).
NS Interval	The interval between IPv6 neighbor solicitation retransmissions, in milliseconds. Valid values range from 1000 to 3600000 milliseconds; the default value is 1000 milliseconds. **Note** This value is included in all IPv6 router advertisements sent out on this interface.

Element	Description
Reachable Time	The amount of time, in milliseconds, within which a remote IPv6 node is considered still reachable, after initial reachability was confirmed. Valid values range from 0 to 3600000 milliseconds, the default value is 0. When 0 is used for the value, the reachable time is set as undetermined—it is up to the receiving devices to set and track reachable time. A configured time enables detection of unavailable neighbors. A shorter time allows detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.
Managed Config Flag	Whether or not to set the flag "managed-config-flag" in the IPv6 router advertisement packet.
Other Config Flag	Whether or not to set the flag "other-config-flag" in the IPv6 router advertisement packet.
Enable RA	When checked, IPv6 router advertisement transmissions are enabled on the interface. The following options are enabled: • **RA Lifetime** – The “router lifetime” value specifies how long nodes on the local link should consider the security appliance as the default router on the link. Valid values range from 0 to 9000 seconds; the default is 1800 seconds. Entering 0 indicates that the security appliance should not be considered a default router on the selected interface. Any non-zero value should not be less than the following RA Interval value. **Note** This value is included in all IPv6 router advertisements sent out on this interface. • **RA Interval** – The interval between IPv6 router advertisement transmissions on this interface. Valid values range from 3 to 1800 seconds, (or from 500 to 1800000 milliseconds if the following RA Interval in Milliseconds option is checked); the default is 200 seconds. The interval between transmissions should be less than or equal to the RA Lifetime value if it is non-zero. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the desired value. • **RA Interval in Milliseconds** – Checking this option indicates that the provided RA Interval value is in milliseconds, rather than seconds.

Element	Description
Interface IPv6 Addresses	The IPv6 addresses assigned to the bridge group interface are specified in this section of the dialog box. • **Link-Local Address** – To override the link-local address that is automatically generated for the interface, enter the desired IPv6 link-local address in this field. The link-local address is composed of the link-local prefix FE80::/64 and the interface ID in Modified EUI-64 format. For example, an interface with a MAC address of 00E0.B601.3B7A would have a link-local address of FE80::2E0:B6FF:FE01:3B7A. An error will occur if another host is using the specified address. • **Enable Address Auto-Configuration** – Select this option to enable automatic configuration of IPv6 addresses on the interface using stateless autoconfiguration. The addresses are configured based on the prefixes received in Router Advertisement (RA) messages. If a link-local address has not been configured, then one is automatically generated for this interface. An error occurs if another host is already using the generated link-local address. • **Trust the DHCP Servers for default gateway**– Select this radio button to install a default route from Router Advertisements that come from a trusted source - the directly-connected network. • Ignore trust and accept router advertisements – Select this radio button to install a default route from Router Advertisements that come from another network. • The table in this section displays the IPv6 addresses assigned to this interface. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.) Add Row and Edit Row open the IPv6 Address for Interface Dialog Box , on page 1864.
Interface IPv6 Prefixes	Use the table in this section to configure which IPv6 prefixes (that is, the network portion of the IPv6 addresses) are included in IPv6 router advertisements. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.) Add Row and Edit Row open the IPv6 Prefix Editor Dialog Box , on page 1866.

Advanced Interface Settings (PIX/ASA/FWSM)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

Advanced configuration options are available for interfaces on FWSMs and ASA/PIX 7.0+ devices operating in single-context mode and for ASA 9.0+ devices operating in single-context mode or multi-context mode.

These are general device-related settings; that is, they are not applied to individual interfaces.

Note The information in this section does not apply to PIX 6.3 devices, nor to security devices in multiple-context mode.

The Advanced Interface Settings dialog box includes the following elements:

- MAC Address Auto - Enable this option to automatically assign private MAC addresses to each shared context interface. You can also, optionally, set a user-defined prefix as part of the MAC address. The prefix is a decimal value between 0 and 65535. If you do not enter a prefix, then the ASA generates a default prefix. This prefix is converted to a 4-digit hexadecimal number. The prefix ensures that each ASA uses unique MAC addresses (using different prefix values), so you can have multiple ASAs on a network segment, for example,
- **Traffic between interfaces with same security levels** – This parameter controls communication between interfaces and subinterfaces on the same security level. If you enable same security interface communication, you can still configure interfaces at different security levels as usual. Refer to Enabling Traffic between Interfaces with the Same Security Level , on page 1883 for more information.
- **PPPoE Users button** – Click this button to open the PPPoE Users dialog box, where you can add, edit and delete PPPoE users, as described in Managing the PPPoE Users List , on page 1884. This option is available only for ASA and PIX 7.0+ devices.
- **VPDN Groups (PIX and ASA 7.2+)** – This table lists currently defined VPDN Groups. The buttons below the table are used to add, edit and delete VPDN group entries, as described in Managing VPDN Groups , on page 1885.
- **LACP System Priority (ASA 8.4.1+)** – All systems participating in EtherChannel link aggregation require a Link Aggregation Control Protocol (LACP) System Priority. The value can be 1 to 65535, with the higher number signifying lower priority. The default is 32768.

This value is combined with the system MAC address to form the system's LACP identifier, and thus is applicable only for EtherChannel interfaces. See Configuring EtherChannels , on page 1812, for more information.

Note Additional LACP parameters are available in the Edit Interface dialog box for individual interfaces assigned to an EtherChannel; see Editing LACP Parameters for an Interface Assigned to an EtherChannel , on page 1815, for more information.

Note LACP System Priority is not supported in Cisco Firepower 9000 devices.

- **Static Port Priority (ASA 9.2.1+ Cluster in Spanned mode)** – Disables dynamic port priority in LACP. Some switches do not support dynamic port priority, so this parameter improves switch compatibility. Enabling static port priority enables support of 16 active spanned EtherChannel members. Without this parameter, only 8 active members and 8 standby members are supported. If you enable this parameter, then you cannot use any standby members; all members are active. This parameter is not part of the bootstrap configuration, and is replicated from the control unit to the member units.

Note If you enable Static Port Priority, 16 nodes can be part of a cluster instead of 8 nodes.

- **Director-Localization** – In Geo clustering where, multiple Data Center sites are supported, the inter-cluster round-trip time (RTT) latency is higher than intra-DC. This delay impacts the performance of applications like the VoIP media stream. Beginning with 4.13, the director localization is used to minimize the RTT latency and the delays in performance lookup messages. Enabling this option makes the flow owner and director to be in the same DC site, so that the flow owner lookup is done in local DC site, and the traffic is contended within the same site.

Note Director-localization is not supported in Cisco Firepower 2100 Series, Firepower 4000 Series, and Firepower 9000 Series devices.

- Enable Site Redundancy—Beginning with 4.16, you can enable site redundancy to protect flows from a failed site. The site redundancy can be enabled only on the Control unit and will be replicated to the member units in the cluster group. If the connection backup owner is at the same site as the owner, then an additional backup owner will be chosen from another site to protect flows from a failed site. Director localization and site redundancy are separate features; you can configure one or the other, or configure both.

Note Site redundancy is not supported in Cisco Firepower 2100 Series, Firepower 4000 Series, and Firepower 9000 Series devices.

Navigation Path

You can open the Advanced Interface Settings dialog box by clicking the Advanced button at the bottom of the Interfaces page (for non-5505 ASAs, PIX 7.0+ devices, and FWSMs), or at the bottom of the Interfaces tab on the ASA 5505 Ports and Interfaces page.

Related Topics

- Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835

Enabling Traffic between Interfaces with the Same Security Level

The Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881 dialog box presented for a single-context security device includes the “Traffic between interfaces with the same security level” drop-down list, as described in this section.

By default, interfaces or subinterfaces on the same security level cannot communicate with each other. Allowing communication between same-security interfaces provides the following benefits:

- You can configure more than 101 communicating interfaces.

If you use different levels for each interface and do not assign any interfaces to the same security level, you can configure only one interface per level (0 to 100).

- You can allow traffic to flow freely between all same-security interfaces without access lists.

Note If you enable NAT control, you do not need to configure NAT between same-security-level interfaces.

Step 1 In the Advanced Interface Settings dialog box, choose the option that identifies how you want this device to handle **Traffic between interfaces with the same security levels**:

- **Disabled**—Communication between interfaces on the same security level is not allowed.
- **Inter-interface**—Enables traffic flows between interfaces with the same security level setting. When this option is enabled, you are not required to define translation rules to enable traffic flow between interfaces in the firewall device.
- **Intra-interface**—Enables traffic flows between subinterfaces with the same security level setting. When this option is enabled, you are not required to define translation rules to enable traffic flow between subinterfaces assigned to an interface.
- **Both**—Allows both intra- and inter-interface communications among interfaces and subinterfaces with the same security level.

Step 2 Continue with Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881 configuration, or click OK to close the Advanced Interface Settings dialog box.

Managing the PPPoE Users List

Point-to-Point Protocol over Ethernet (PPPoE) allows standard PPP communication between a security device and an external ISP, via an Ethernet interface on the device. To establish a communication link, the device must provide authentication credentials and obtain network parameters. This is accomplished using a Virtual Private Dialup Network (VPDN) group, which basically consists of established PPPoE user credentials (i.e., a user name and password) and an authentication protocol. See Managing VPDN Groups , on page 1885 for more information about VPDN groups.

The PPPoE user credentials available for use with VPDN groups are maintained in the PPPoE Users dialog box, which you can access from the Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881 dialog box, and from the Add/Edit VPND Group dialog boxes.

Adding and Editing PPPoE Users

The PPPoE Users dialog box presents a table of currently defined PPPoE users, along with standard Add Row, Edit Row, and Delete Row buttons. The Add Row button opens the Add PPPoE User dialog box; the Edit Row button opens the virtually identical Edit PPPoE User dialog box.

Enter or edit the following PPPoE user parameters, and then click OK to close the Add (Edit) PPPoE User dialog box and return to the Advanced Interface Settings dialog box.

Note PPPoE user options are not available on Firewall Service Modules (FWSMs).

Field Reference

Table 573: Add and Edit PPPoE User Dialog Boxes

Element	Description
Username	The name assigned to this user account; generally provided by the external ISP.
Password	The password assigned to this user account; also generally provided by the external ISP.
Confirm	Re-enter the password.
Store Username and Password in Local Flash	If checked, this PPPoE user information will be stored in the device's local flash memory, ensuring it cannot be inadvertently overwritten.

Managing VPDN Groups

A Virtual Private Dialup Network (VPDN) group—basically an established PPPoE user and an authentication protocol—is used by a security device to contact an external ISP and authenticate itself, in order to establish a PPPoE communications link and obtain network parameters. (See Managing the PPPoE Users List , on page 1884 for information about establishing PPPoE users.)

Available VPDN groups are maintained in the Advanced Interface Settings dialog box, which opens when you click the Advanced button at the bottom of the Interfaces page, as described in Advanced Interface Settings (PIX/ASA/FWSM) , on page 1881.

Adding and Editing VPND Groups

The Advanced Interface Settings dialog box includes a table of currently defined VPDN groups, and standard Add Row, Edit Row, and Delete Row buttons. The Add Row button opens the Add VPDN Group dialog box; the Edit Row button opens the virtually identical Edit VPDN Group dialog box.

Enter or edit the following VPDN group parameters, and then click OK to close the Add (Edit) VPDN Group dialog box and return to the Advanced Interface Settings dialog box.

Note VPDN group options are not available on Firewall Service Modules (FWSMs).

Field Reference

Table 574: Add and Edit VPND Group Dialog Boxes

Element	Description
Group Name	A name to identify this group in Security Manager; up to 63 characters.

Element	Description
PPPoE Username	The name identifying the PPPoE credentials to be used by this group for authentication with an ISP; choose from the list of available PPPoE users. Choose **Edit User** from this list to open the PPPoE Users dialog box, where you can add or edit a user for this option. Refer to Managing the PPPoE Users List , on page 1884 for information about creating and editing users.
PPP Authentication	Select the PPP Authentication method: • **PAP** – Password Authentication Protocol, with exchange of credentials in clear text. • **CHAP** – Challenge Handshake Authentication Protocol, with encrypted credential exchange. • **MSCHAP** – Microsoft's CHAP, version 1 only.

VXLAN

Virtual eXtensible LANs (VXLAN) act as Layer 2 virtual networks over Layer 3 physical networks to stretch Layer 2 networks. VXLAN provides the same Ethernet Layer 2 network services as VLAN does, but with greater extensibility and flexibility. Compared to VLAN, VXLAN offers the following benefits:

- Flexible placement of multitenant segments throughout the data center.
- Higher scalability to address more Layer 2 segments—up to 16 million VXLAN segments.

Beginning with version 4.9, Security Manager supports VXLAN for ASA, ASAv, and ASASM devices on version 9.4(1) and later.

Note VxLAN is not supported on FWSM devices.

To configure VXLAN, follow these steps:

1. Configuring VXLAN Policy , on page 1886
2. Create a Configuring VNI Interfaces , on page 1818 and associate the configured VXLAN policy to the VNI interface.

Configuring VXLAN Policy

To configure VXLAN you must first configure VXLAN policy and then create a VNI interface and associate the configured VXLAN policy to the VNI interface. This section describes how to configure VXLAN policy.

Navigation Path

To access the VXLAN page, go to **Device View**, select an ASA, ASAv, or ASASM device and then click **VxLAN** from **Policies**.

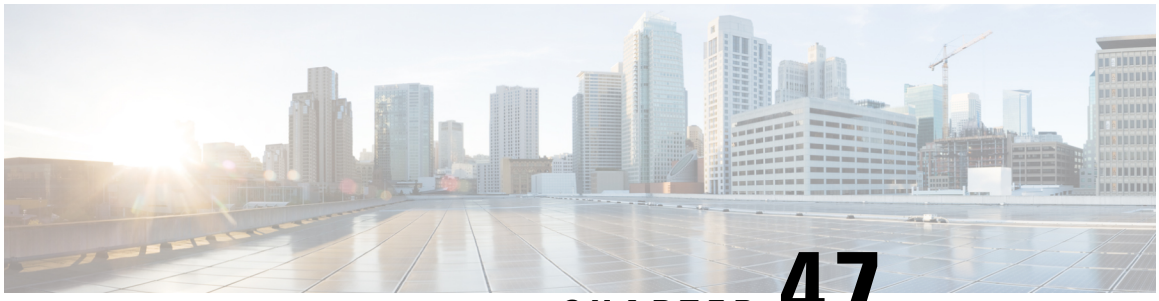
Related Topics

- VXLAN , on page 1886
- Configuring VNI Interfaces , on page 1818

Field Reference

Table 575: VxLAN

Element	Description
Enable VXLAN Port Number VXLAN Destination Port	Check this box if you want to change the value of the VXLAN Destination Port from the default 4789. If checked, enter a numeric value in the range from 1024 to 65535.
Network Virtualization Endpoint (NVE)	
Enable NVE	When selected, it enables you to select the VTEP Tunnel Interface.
VXLAN NVE No	The value of VXLAN NVE Number is "1". You cannot edit this value.
Enable VxLan NVE or GENEVE Encapsulation	Enable NVE Encapsulation—Select this checkbox to enable NVE Encapsulation using VXLAN. Enable Geneve Encapsulation—Select this option to enable Geneve Encapsulation using VXLAN.
VTEP Tunnel Interface	Click Select and choose the VTEP Tunnel Interface.
Enable VTEP IP Address Or Multicast Traffic Address	Select one of the following: • Peer VTEP IP Address—Manually specify the peer VTEP IP address. If you specify the peer IP address, you cannot use multicast group discovery. Multicast is not supported in multiple context mode. You can only specify one peer for the VTEP. Note that the peer VTEP IP address must be reachable from the VTEP Tunnel Interface, else deployment will fail. If you have used peer IP address in VXLAN policy, you cannot configure multicast IP address on the Interface page, including the VNI interface. • Default Multicast IP Address—Specify a default multicast group for all associated VNI interfaces. The range of IP addresses is from 224.0.0.0 to 239.255.255.255. If you do not configure the multicast group per VNI interface, then this group is used. If you configure a group at the VNI interface level, then that group overrides this setting. • Enable Geneve Port Number—Check this box to change the Geneve Destination Port value. The default value is 6081. Enter a numeric value between 1024 and 65535. **Note** For the default port number 6081, CSM does not build the delta configuration.
Save	Click Save to save the VXLAN settings.



CHAPTER 47

Configuring Bridging Policies on Firewall Devices

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 device that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. The security appliance connects the same network on its inside and outside ports, acting as an access-control bridge; you assign different VLANs to each interface, and IP addressing is not used

About Bridging on Firewall Devices

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 device that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. The security appliance connects the same network on its inside and outside ports, acting as an access-control bridge; you assign different VLANs to each interface, and IP addressing is not used.

Thus, you can easily introduce a transparent firewall into an existing network—IP re-addressing is unnecessary—and maintenance is facilitated because there are no complicated routing patterns to troubleshoot and no NAT configuration.

Although the transparent-mode device acts as a bridge, Layer 3 traffic, such as IP traffic, cannot pass through the security appliance unless you explicitly permit it with specific access rules. The only traffic allowed through a firewall without an access list is ARP traffic, which you can control using ARP inspection, and IPv6 neighbor discovery.

When the security appliance runs in transparent mode, the outgoing interface of a packet is determined by performing a MAC address lookup instead of a route lookup. Route statements can still be configured, but

they apply only to security appliance-originated traffic. For example, if your syslog server is located on a remote network, you must use a static route so the security appliance can reach that subnet.

Starting from Cisco Security Manager 4.13, the Bridge-group Virtual Interface (BVI) feature is extended to the routed firewall mode. Routed firewalls are implemented by means of configuring bridge-groups. A user can configure up to eight bridge groups and on an ASA 9.7.1 (Cisco Security Manager 4.13) each group can contain upto 64 interfaces. On versions prior to Cisco Security Manager 4.13, a user can configure a maximum of two bridge groups; with each group containing a maximum limit of four interfaces. In addition to the BVI features supported in the transparent mode, the routed firewall mode includes support for the following additional communication modes:

- Inter BVI communication
- BVI to Data Port communication (Layer 2 to Layer 3) and vice versa

To configure a transparent firewall, use the following policies. When configuring an ASA/PIX/FWSM device in multiple-context mode, configure these policies on each transparent security context.

- **Firewall > Access Rules**—Access rules control layer 3 and higher traffic using extended access control lists. In routed mode, some types of traffic cannot pass through the security appliance even if you allow it in an access list. For example, you can establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on access rules. Likewise, protocols like HSRP or VRRP can pass through the security appliance. However, the transparent-mode security appliance does not pass CDP packets.

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can provide those functions. For example, by using access rules, you can allow DHCP traffic to pass (instead of the unsupported DHCP relay feature), or multicast traffic such as that created by IP/TV.

For more information, see Understanding Access Rules , on page 717 and Configuring Access Rules , on page 723.

- **Firewall > Transparent Rules**—Transparent rules control non-IP layer 2 traffic using Ethertype access control lists. For example, you can configure rules to allow AppleTalk, IPX, BPDUs, and MPLS to pass through the device. For more information, see Configuring Transparent Firewall Rules , on page 1009.
- **Platform > Bridging > ARP Table**, **ARP Inspection** and **IPv6 Neighbor Cache**—Use these policies to control the types of ARP and IPv6 traffic allowed through the bridge. If desired, you can configure static ARP and IPv6 neighbor cache entries and drop any traffic not defined by those static rules. Enable ARP inspection so that if a mismatch between the MAC address, the IP address, or the interface occurs, the security appliance drops the packet. This helps prevent ARP spoofing. For more information, see ARP Table Page , on page 1892 and ARP Inspection Page , on page 1894.

Note The ARP Table and IPv6 Neighbor Cache are the only bridging policies available for non-transparent ASA/PIX/FWSM devices.

- **Platform > Bridging > MAC Address Table** and **MAC Learning**—Use these policies to configure static MAC-IP address mappings and to enable or disable MAC learning. MAC learning is enabled by default, which allows the appliance to add MAC-IP address mappings as traffic passes through the interface. If you want to prevent all traffic except from static entries, you can disable MAC learning. For more information, see MAC Address Table Page , on page 1896 and MAC Learning Page , on page 1897.

- **Platform > Bridging > Management IP**
- and **Platform > Bridging > Management IPv6**—Use these policies to configure a management IP address that Security Manager can use to communicate with the device.

Note The Management IP and Management IPv6 pages are not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

If you change the management IP address, you also need to update the device properties for the device or security context. Follow these steps:

- Change the management IP address, save and submit your changes.
- Deploy your changes to the device.
- In Device view, select the device or security context, then select **Tools > Device Properties**. On the General page, enter the new management IP address in the IP Address field. On the Credentials tab, update the username and password fields with account credentials that can log into the management interface. Security Manager will now use this address and user account for subsequent deployments and device communication.

For more information, see Management IP Page , on page 1899.

Bridging Support for FWSM 3.1

Note From version 4.17, though Cisco Security Manager continues to support FWSM features/functionality, it does not support any bug fixes or enhancements.

Although FWSM 3.1 can support multiple L2 interface pairs, Security Manager lets you specify no more than two L2 interfaces (a single interface pair), and one associated management IP address. That means only one bridge group with two named interfaces associated is provisioned with a management IP address. If the device configuration contains a maximum of one bridge group and two named interfaces, it is valid for discovery. All other scenarios result in an error message and the commands are ignored during discovery. Furthermore, discovery will not show any bridge-group information in Security Manager, although the bridge-group commands will be generated during deployment. Bridge group 1 will be deployed and used in transparent rule policies if no bridge group exists in the device configuration.

ARP Table Page

Use the ARP Table page to add static ARP entries that map a MAC address to an IP address and identifies the interface through which the host is reached.

Navigation Path

- (Device view) Select **Platform > Bridging > ARP Table** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > ARP Table** from the Policy Type selector. Right-click **ARP Table** to create a policy, or select an existing policy from the Shared Policy selector.

- MAC Learning Page , on page 1897
- Management IP Page , on page 1899

Field Reference

Table 576: ARP Table Page

Element	Description
Timeout (seconds)	The amount of time, between 60 and 4294967 seconds, before the security appliance rebuilds the ARP table. The default is 14400 seconds. Rebuilding the ARP table automatically updates new host information and removes old host information. You might want to reduce the timeout because the host information changes frequently. **Note** The timeout applies to the *dynamic* ARP table, and not the static entries contained in the ARP table.
ARP Table	
Interface	The interface to which the host is attached.
IP Address	The IP address of the host.
MAC Address	The MAC address of the host.

Element	Description
Alias Enabled	Indicates whether the security appliance performs proxy ARP for this mapping. If this setting is enabled and the security appliance receives an ARP request for the specified IP address, it responds with the security appliance MAC address. When the security appliance receives traffic destined for the host belonging to the IP address, the security appliance forwards the traffic to the host MAC address that you specify in this command. This feature is useful if you have devices that do not perform ARP, for example. **Note** In transparent firewall mode, this setting is ignored and the security appliance does not perform proxy ARP.

Add/Edit ARP Configuration Dialog Box

Use the Add/Edit ARP Configuration dialog box to add a static ARP entry that maps a MAC address to an IP address and identifies the interface through which the host is reached.

Navigation Path

You can access the Add/Edit ARP Configuration dialog box from the ARP Table page. For more information about the ARP Table page, see .

Related Topics

Field Reference

Table 577: Add/Edit ARP Configuration dialog box

Element	Description
Interface	The name of the interface to which the host network is attached.
IP Address	The IP address of the host.
MAC Address	The MAC address of the host; for example, 00e0.1e4e.3d8b.
Enable Alias	When selected, enables proxy ARP for this mapping. If the security appliance receives an ARP request for the specified IP address, it responds with the security appliance MAC address. When the security appliance receives traffic destined for the host belonging to the IP address, the security appliance forwards the traffic to the host MAC address that you specify in this command. This feature is useful if you have devices that do not perform ARP, for example. **Note** In transparent firewall mode, this setting is ignored and the security appliance does not perform proxy ARP.

ARP Inspection Page

Use the ARP Inspection page to configure ARP inspection for a transparent firewall. ARP inspection is used to prevent ARP spoofing.

Navigation Path

- (Device view) Select **Platform > Bridging > ARP Inspection** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > ARP Inspection** from the Policy Type selector. Right-click **ARP Inspection** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 578: ARP Inspection Page

Element	Description
ARP Inspection Table	
Interface	The name of the interface to which the ARP inspection setting applies.
ARP Inspection Enabled	Indicates whether ARP inspection is enabled on the specified interface.
Flood Enabled	Indicates whether packets that do not match any element of a static ARP entry should be flooded out all interfaces except the originating interface. If there is a mismatch between the MAC address, the IP address, or the interface, the security appliance drops the packet. If you do not select this check box, all non-matching packets are dropped. **Note** The dedicated management interface, if present, never floods packets even if this parameter is set to flood.

Add/Edit ARP Inspection Dialog Box

Use the Add/Edit ARP Inspection dialog box to enable or disable ARP inspection for a transparent firewall interface.

Navigation Path

You can access the Add/Edit ARP Inspection dialog box from the ARP Inspection page. For more information about the ARP Inspection page, see ARP Inspection Page , on page 1894.

Related Topics

- About Bridging on Firewall Devices , on page 1889
- ARP Inspection Page , on page 1894

Field Reference

Table 579: Add/Edit ARP Inspection dialog box

Element	Description
Interface	The name of the interface for which you are enabling or disabling ARP inspection.
Enable ARP Inspection on this interface	When selected, enables ARP inspection on the specified interface.
Flood ARP packets	When selected, packets that do not match any element of a static ARP entry are flooded out all interfaces except the originating interface. If there is a mismatch between the MAC address, the IP address, or the interface, the security appliance drops the packet. If you do not select this check box, all non-matching packets are dropped. **Note** The dedicated management interface, if present, never floods packets even if this parameter is set to flood.

Managing the IPv6 Neighbor Cache

Use the IPv6 Neighbor Cache page to manage static IPv6 neighbor entries that map a MAC address to an IPv6 address, and identify the interface through which the neighbor host is reached, to provide address-resolution functions for IPv6. This is available on ASA 7.0+ devices only.

Note The IPv6 Neighbor Cache entries are the IPv6 equivalent of the static ARP entries, managed on the ARP Table Page , on page 1892.

If an entry for a specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry. Static entries in the IPv6 neighbor discovery cache are not modified by the neighbor discovery process.

The IPv6 Neighbor Cache page is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons. (These are standard buttons, as described in Using Tables , on page 50.) The Add Row button opens the Add IPv6 Neighbor Cache Configuration dialog box, and Edit Row opens the Edit IPv6 Neighbor Cache Configuration dialog box. Other than the titles, the two dialog boxes are identical.

Note Ensure that IPv6 is enabled on at least one interface before trying to add a neighbor.

Field Reference

Table 580: Add/Edit IPv6 Neighbor Cache Configuration dialog boxes

Element	Description
Interface	Enter or Select the name of the interface on which to add the neighbor.
IP Address	Enter the IPv6 address that corresponds to the local data-link address. (If an entry for the specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry.)
MAC Address	Enter the local data-line (hardware) MAC address of the host; for example, 00e0.1e4e.3d8b.

MAC Address Table Page

Use the MAC Address Table page to add static MAC address entries to the MAC Address table. The table associates the MAC address with the source interface so that the security appliance knows to send any packets addressed to the device out the correct interface.

Navigation Path

- (Device view) Select **Platform > Bridging > MAC Address Table** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > MAC Address Table** from the Policy Type selector. Right-click **MAC Address Table** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 582: Add/Edit MAC Table Entry dialog box

Element	Description
Interface	The interface to which the MAC address is associated.
MAC Address	The MAC address; for example, 00e0.1e4e.3d8b.

MAC Learning Page

Use the MAC Learning page to enable or disable MAC address learning on an interface. By default, each interface learns the MAC addresses of entering traffic, and the security appliance adds corresponding entries to the MAC address table. You can disable MAC address learning if desired; however, unless you statically add MAC addresses to the table, no traffic can pass through the security appliance.

Navigation Path

- (Device view) Select **Platform > Bridging > MAC Learning** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > MAC Learning** from the Policy Type selector. Right-click **MAC Learning** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 584: Add/Edit MAC Learning dialog box

Element	Description
Interface	The interface to which the MAC learning setting applies.
MAC Learning Enabled	When selected, the security appliance learns MAC addresses from traffic entering the interface.

Management IP Page

A transparent firewall does not participate in IP routing. The only IP configuration required for the device is specification of a management IP address, which is used as the source address for traffic originating on the device, such as system messages or communications with AAA servers. You can also use this address for remote-management access.

For IPv4 traffic, the management IP address is required to pass any traffic.

Note In addition to the management IP address for the device, you can configure an IP address for the Management 0/0 or 0/1 management-only interface. This IP address can be on a separate subnet from the main management IP address.

Use the Management IP page to set the management IP address for a security device, or for a context in transparent firewall mode.

Navigation Path

- (Device view) Select **Platform > Bridging > Management IP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > Management IP** from the Policy Type selector. Right-click **Management IP** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 585: Management IP Page

Element	Description
Management IP Address	The management IP address.
Subnet Mask	The subnet mask that corresponds to the management IP address.

Management IPv6 Page (ASA 5505)

A transparent firewall does not participate in IP routing. The only IP configuration required for the device is specification of a management IP address, which is used as the source address for traffic originating on the device, such as system messages or communications with AAA servers. You can also use this address for remote-management access.

For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations. If you configure the global address, a link-local address is automatically configured on each interface, so you do not also need to specifically configure a link-local address. However, if you do not configure a global management address, you need to configure interface link-local addresses, as described in Configuring IPv6 Interfaces (ASA/FWSM) , on page 1860. Note that you can configure both IPv6 and IPv4 management addresses on a device.

On an ASA 5505 in transparent mode, use the Management IPv6 page to enable IPv6, configure neighbor solicitation, and manage IPv6 interface addresses.

Note This page is available only on ASA 5505 version 8.2 and 8.3 devices in transparent mode.

Navigation Path

- (Device view) Select **Platform > Bridging > Management IPv6** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Bridging > Management IPv6** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

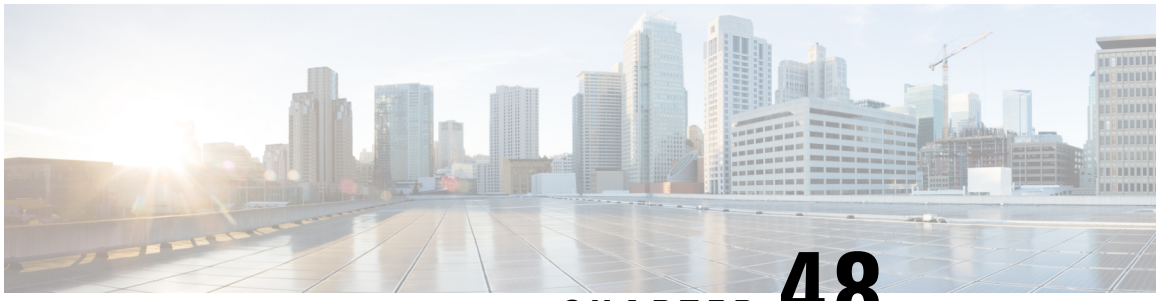
Related Topics

- About Bridging on Firewall Devices , on page 1889
- ARP Table Page , on page 1892
- ARP Inspection Page , on page 1894
- MAC Address Table Page , on page 1896
- MAC Learning Page , on page 1897

Field Reference

Table 586: Management IPv6 Page

Element	Description
Enable IPv6	Check this box to enable IPv6 and configure IPv6 management-interface addresses. You can deselect this option to disable IPv6, but retain the configuration information.
DAD Attempts	To specify the number of consecutive neighbor solicitation messages that are sent on an interface during duplicate address detection (DAD), enter a number from 0 to 600 in this field. Entering 0 disables duplicate address detection. Entering 1 configures a single transmission without follow-up transmissions; this is the default. Duplicate address detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection uses neighbor solicitation messages to verify the uniqueness of unicast IPv6 addresses. When duplicate address detection identifies a duplicate address, the state of the address is set to DUPLICATE and the address is not used. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface and an error message similar to the following is issued: %PIX-4-DUPLICATE: Duplicate address FE80::1 on outside If the duplicate address is a global address of the interface, the address is not used and an error message is issued, similar to that shown previously for a duplicate link-local address. All configuration commands associated with the duplicate address remain as-configured while the state of the address is set to DUPLICATE. If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address, and all other IPv6 address associated with the interface are regenerated (that is, duplicate address detection is performed only on the new link-local address).
NS Interval	The interval between IPv6 neighbor solicitation retransmissions, in milliseconds. Valid values range from 1000 to 3600000 milliseconds; the default value is 1000 milliseconds.
Reachable Time	The amount of time, in milliseconds, within which a remote IPv6 node is considered still reachable, after initial reachability was confirmed. Valid values range from 0 to 3600000 milliseconds, the default value is 0. When 0 is used for the value, the reachable time is set as undetermined—it is up to the receiving devices to set and track reachable time. A configured time enables detection of unavailable neighbors. A shorter time allows detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.
Interface IPv6 Addresses	The IPv6 address(es) assigned to the management interface are listed in this table. Use the Add Row, Edit Row, and Delete Row buttons below this table to manage these entries. (These are standard buttons, as described in Using Tables , on page 50.) Add Row and Edit Row open the IPv6 Address for Interface Dialog Box , on page 1864.



CHAPTER 48

Configuring Device Administration Policies on Firewall Devices

The Device Admin section contains pages for configuring device administration policies for firewall devices.

This chapter contains the following topics:

About AAA on Security Devices

Authentication-Authorization-Accounting (AAA) enables the security appliance to determine who a user is (authentication), what the user can do (authorization), and what the user did (accounting). You can use authentication alone, or with authorization and accounting. Authorization always requires a user to be authenticated first. You also can use accounting alone, or with authentication and authorization.

Authentication-Authorization-Accounting provides an extra level of protection and control for user access beyond access lists alone. For example, you can create an ACL that allows all outside users to access Telnet on a server on the DMZ network. If you want to limit user access to the server when you may not always know the IP addresses of these users, you can enable AAA to allow only authenticated and/or authorized users to make it through the security appliance. (The Telnet server enforces authentication, too; the security appliance prevents unauthorized users from attempting to access the server.)

- **Authentication**—Authentication grants access based on user identity. Authentication establishes user identity by requiring valid user credentials, which are typically a user name and password. You can configure the security appliance to authenticate the following items:

- Administrative connections to the security appliance using Telnet, SSH, HTTPS/ASDM, or serial console.
- The **enable** command.

- **Authorization**—Authorization controls user capabilities after users are authenticated. Authorization controls the services and commands available to each authenticated user. If you do not enable authorization, authentication alone would provide the same access to services for all authenticated users.

If you need the control that authorization provides, you can configure a broad authentication rule, and then have a detailed authorization configuration. For example, you might authenticate inside users who attempt to access any server on the outside network, and then use authorization to limit the outside servers that a particular user can access.

The security appliance caches the first 16 authorization requests per user, so if the user accesses the same services during the current authentication session, the security appliance does not resend the request to the authorization server.

- **Accounting**—Accounting tracks traffic that passes through the security appliance, providing a record of user activity. If you enable authentication for that traffic, you can account for traffic per user. If you do not authenticate the traffic, you can account for traffic per IP address. Accounting information includes when sessions start and stop, user name, the number of bytes that pass through the security appliance for the session, the service used, and the duration of each session.

Preparing for AAA

AAA services depend upon the use of the Local database or at least one AAA server. You can also use the Local database as a fallback for most services provided by an AAA server. Before you implement AAA, you should configure the Local database and configure AAA server groups and servers.

Configuration of the Local database and AAA servers depends upon the AAA services you want the security appliance to support. Regardless of whether you use AAA servers, you should configure the Local database with user accounts that support administrative access, to prevent accidental lock-outs and, if so desired, to provide a fallback method when AAA servers are unreachable. For more information, see Configuring User Accounts , on page 1995.

The following table provides a summary of AAA service support by each AAA server type and by the Local database. You manage the Local database by configuring user accounts on the **Platform > Device Admin > User Accounts** page (see Configuring User Accounts , on page 1995). You establish AAA server groups and add individual AAA servers to the server groups using the **Platform > Device Admin > AAA** page.

Table 587: Summary of AAA Support

AAA Service	Database Type							
	Local	RADIUS	TACACS+	SDI	NT	Kerberos	LDAP	HTTP Form
Authentication of...								
VPN users	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes 1
Firewall sessions	Yes	Yes	Yes	No	No	No	No	No

AAA Service	Database Type							
	Local	RADIUS	TACACS+	SDI	NT	Kerberos	LDAP	HTTP Form
Administrators	Yes	Yes	Yes	No	No	No	No	No
Authorization of...								
VPN users	Yes	Yes	No	No	No	No	Yes	No
Firewall sessions	No	Yes 2	Yes	No	No	No	No	No
Administrators	Yes 3	No	Yes	No	No	No	No	No
Accounting of...								
VPN connections	No	Yes	Yes	No	No	No	No	No
Firewall sessions	No	Yes	Yes	No	No	No	No	No
Administrators	No	Yes	Yes	No	No	No	No	No

1 HTTP Form protocol supports single sign-on authentication for WebVPN users only.

2 For firewall sessions, RADIUS authorization is supported with user-specific ACLs only, which are received or specified in a RADIUS authentication response.

3 Local command authorization is supported by privilege level only.

Local Database

The security appliance maintains a Local database that you can populate with user accounts, which contain, at a minimum, a user name. Typically, you assign a password and a privilege level to each user name, although passwords are optional. You can manage Local user accounts on the **Platform > Device Admin > User Accounts** page (see Configuring User Accounts , on page 1995).

If you enable command authorization using the Local database, the security appliance refers to the assigned user privilege level to determine what commands are available. By default, all commands are assigned either privilege level 0 or level 15.

Note If you add users to the Local database with access to the CLI and whom you do not want to enter privileged mode, you should enable command authorization. Without command authorization, users can access privileged mode (and all commands) at the CLI using their own password if their privilege level is 2 or greater (2 is the default). Alternatively, you can use RADIUS or TACACS+ authentication for console access so the user will not be able to use the login command, or you can set all local users to level 1 so you can control who can use the system enable password to access privileged mode.

You cannot use the local database for network access authorization.

The user accounts in the Local database can provide fallback support for console and enable-password authentication, for command authorization, and for VPN authentication and authorization. This behavior is designed to help you prevent accidental lock-out from the security appliance.

For users who need fallback support, we recommend that their user names and passwords in the Local database match their user names and passwords on the AAA servers. This provides transparent fallback support. Because the user cannot determine whether a AAA server or the local database is providing the service, using user names and passwords on AAA servers that are different than the user names and passwords in the Local database means that the user cannot be certain which user name and password should be given.

For multiple-context mode, you can configure user names in the system execution space to provide individual logins at the CLI using the **login** command; however, you cannot configure any **aaa** commands that use the local database in the system execution space.

Note VPN functions are not supported in multiple mode.

AAA for Device Administration

You can authenticate all administrative connections to the security appliance, including:

- Telnet
- SSH
- Serial console
- ASDM
- VPN management access

You can also authenticate administrators who attempt to enter enable mode. You can authorize administrative commands. You can have accounting data for administrative sessions and for commands issued during a session sent to an accounting server.

You can configure AAA for device administration using the **Platform > Device Admin > AAA** page (see About AAA on Security Devices , on page 1903).

AAA for Network Access

You can configure rules for authenticating, authorizing, and accounting for traffic passing through the firewall by using the **Firewall > AAA Rules** page (see Managing Firewall AAA Rules, on page 685). The rules you create are similar to access rules, except that they specify whether to authenticate, authorize, or perform accounting for the traffic defined; and which AAA server group the security appliance is to use to process the AAA service request.

AAA for VPN Access

AAA services for VPN access include the following:

- User account settings for assigning users to VPN groups, configured on the **Platform > Device Admin > User Accounts** page (see Configuring User Accounts , on page 1995).

- VPN group policies that can be referenced by many user accounts or tunnel groups, configured on the **Remote Access VPN > RA VPN Policies > User Group Policy** or **Site to Site VPN > User Group Policy** page.
- Tunnel group policies, configured on the **Remote Access VPN > RA VPN Policies > PIX7.0/ASA Tunnel Group Policy** or **Site to Site VPN > PIX7.0/ASA Tunnel Group Policy** page.

Configuring AAA - Authentication Tab

The AAA page presents three tabbed panels; the **Authentication** panel is presented when you navigate to the AAA page. Use these options to control privileged access to the device console, to restrict access by connection type, and to define access messages.

Use the Authorization Tab , on page 1909 to control the services and commands available to authenticated users.

Use the Accounting Tab , on page 1910 to activate tracking of console traffic, providing a record of user activity.

Navigation Path

- (Device view) Select **Platform > Device Admin > AAA** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > AAA** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- About AAA on Security Devices , on page 1903
- Configuring User Accounts , on page 1995

Using the Authentication Tab

Use the Authentication tab to enable authentication for administrator access to the security appliance. The Authentication tab also lets you configure the prompts and messages a user sees when authenticated by an AAA server.

The device will prompt for a user name and password before you can enter commands. If the authentication server is offline, wait until the console login request times out. You can then access the console with the firewall username and the enable password.

Field Reference

Table 588: Authentication Tab

Element	Description
Require AAA Authentication to allow use of privileged commands	

Element	Description
Enable	Requires authentication from an AAA server to allow a user to access EXEC mode on the firewall. This option allows up to three attempts to access the firewall console. If this number is exceeded, an "access denied" message is displayed. When checked, the Server Group field is enabled.
Server Group	Enter or Select the name of an AAA server to contact for user authentication.
Use LOCAL when server group fails	Check this box to use the LOCAL database as back-up if the selected server fails. (This option is not enabled until you provide a Server Group.)
Require AAA Authentication for the following types of connections	
Select the connections that require authentication. For each type, users are allowed up to three attempts to access the firewall console. If this number is exceeded, an "access denied" message is displayed. Select each connection option individually: • **HTTP** – Require AAA authentication when a user initiates an HTTPS connection to the firewall console. • **Serial** – Require AAA authentication when a user initiates a connection to the firewall console via the serial console cable. • **SSH** – Require AAA authentication when a user initiates a Secure Shell (SSH) connection to the console. • **Telnet** – Require AAA authentication when a user initiates a Telnet connection to the firewall console. For each selected connection, provide a Server Group and indicate whether the LOCAL database is used as a back-up: • **Server Group** – Enter or Select the name of an AAA server to contact for user authentication. • **Use LOCAL when server group fails** – Check this box to use the LOCAL database as back-up if the selected server fails. (This option is not enabled until you provide a Server Group.)	
Authentication Prompts	
Login Prompt	Enter the prompt a user will see when logging in to the security appliance.
Accepted Message	Enter the message displayed when successfully authenticated.
Rejected Message	Enter the message displayed when authentication fails for any reason.
Rejected Message for Invalid Credentials	Enter the message displayed when authentication fails following entry of unknown or invalid credentials. Available only on FWSM 3.2+ devices.

Element	Description
Rejected Message for Expired Password	Enter the message displayed when authentication fails following entry of an expired password. Available only on FWSM 3.2+ devices.
Maximum Local Authentication Failed Attempts	Specify the number of times the device will try to authenticate a user in the LOCAL database before that account is locked; valid values are 1 through 16. Available only on ASA/PIX 7.01+ and FWSM 3.11+ devices.
Login History	Check this to enable the login history reporting feature. When enabled, information about all the administrative login attempts is collected and displayed on the ASA, immediately after a successful login. This includes the following information: • Date and time of the last login • Location of last login (terminal or IP address) • Number of unsuccessful login attempts since the last successful login. • Number of successful login attempts occurring during an organization-defined time period. **Note** This feature is enabled by default.
Duration (Optional)	Enter the number of days for which login events will be saved. When no value is specified here, the login history is unbounded. **Note** The default value is 90 days.

Authorization Tab

The Authorization tab allows you to configure authorization for accessing firewall commands.

Navigation Path

You can access the Authorization tab from the AAA page; see Configuring AAA - Authentication Tab , on page 1907.

Related Topics

- About AAA on Security Devices , on page 1903
- Accounting Tab , on page 1910

Field Reference

Table 589: Authorization Tab

Element	Description
Enable Authorization for Command Access Server Group Use LOCAL when server group fails	Requires authorization for accessing firewall commands. Specify the server group to use for authorization. Uses the LOCAL server group if the selected server group fails.
Enable Authorization for exec shell access (ASA 8.0(2)+ only)	When selected, enables management authorization. After enabling management authorization, specify whether to use the remote server or the local database for authorization: • **Local Server**—the local user database is the source for the username entered and the Service-Type and Privilege-Level attributes assigned. • **Remote Server**—the same server is used for both authentication and authorization.
Auto Enable Authorization for exec shell access (ASA 9.1(5)+ only)	Allows users with sufficient privileges from the login authentication server to be placed directly in privileged EXEC mode. Otherwise, users are placed in user EXEC mode. These privileges are determined by the Service-Type and Privilege-Level attributes that are required to enter each EXEC mode. To enter privileged EXEC mode, users must have a Service-Type attribute of Administrative and a Privilege Level attribute of greater than 1 assigned to them. This option is not supported in the system context. However, if you configure Telnet or serial authentication in the admin context, then authentication also applies to sessions from the switch to the ASASM.
Enable Authorization for HTTP Connection Server Group Use LOCAL when server group fails (ASA 9.4(1)+ only)	When selected, authorization via HTTP is enabled. Authorization of username is disabled by default. Select the server group to use for authorization. Uses the LOCAL server group if the selected server group fails.

Accounting Tab

Use the Accounting tab to enable accounting for access to the firewall device and for access to commands on the device.

Navigation Path

You can access the Accounting tab from the AAA page; see Configuring AAA - Authentication Tab , on page 1907.

Related Topics

- About AAA on Security Devices , on page 1903
- Authorization Tab , on page 1909

Field Reference

Table 590: Accounting Tab

Element	Description
Require AAA Accounting for privileged commands	
Enable	When selected, enables the generation of accounting records to mark the entry to and exit from privileged mode for administrative access via the console.
Server Group	Specify the server or group of RADIUS or TACACS+ servers to which accounting records are sent.
Require AAA Accounting for the following types of connections	
Connection type	Specify the connection types that will generate accounting records: • **HTTP**—Enable or disable the generation of accounting records to mark the establishment and termination of admin sessions created over HTTP. Valid server group protocols are RADIUS and TACACS+. • **Serial**—Enable or disable the generation of accounting records to mark the establishment and termination of admin sessions that are established via the serial interface to the console. Valid server group protocols are RADIUS and TACACS+. • **SSH**—Enable or disable the generation of accounting records to mark the establishment and termination of admin sessions created over SSH. Valid server group protocols are RADIUS and TACACS+. • **Telnet**—Enable or disable the generation of accounting records to mark the establishment and termination of admin sessions created over Telnet. Valid server group protocols are RADIUS and TACACS+.
Server Group	Specify the server or group of RADIUS or TACACS+ servers to which accounting records are sent.
Require Accounting for command access	
Enable	When selected, enables the generation of accounting records for commands entered by an administrator/user.

Element	Description
Server Group	Provides a drop-down menu from which you can choose the server or group of RADIUS or TACACS+ servers to which accounting records are sent.
Privilege Level	Minimum privilege level that must be associated with a command for an accounting record to be generated. The default privilege level is 0.

Configuring Banners

You can use the Banner page to specify Session (exec), Login, Message-of-the-Day (motd), and ASDM banners for a security appliance or shared policy.

Note In Cisco Security Manager 4.22, the Banner page is updated to support a new **ASDM Banner** that can be configured, in addition to the existing banners.

Note If you use the token $(hostname) or $(domain) in a banner, it is replaced with the host name or domain name of the security appliance. When you enter the $(system) token in a context configuration, the context uses the banner configured in the system configuration.

Spaces in banner text are preserved; however, tabs cannot be entered. Multiple lines in a banner are created by entering a separate line of text for each line you wish to add. Each line is then appended to the end of the existing banner. If the line is empty, a carriage return (CR) is added to the banner.

There is no limit on the length of a banner other than RAM and flash-memory limits. You can only use ASCII characters, including new-line (press the Enter key), which counts as two characters. When accessing the security appliance through Telnet or SSH, the session closes if there is not enough system memory available to process the banner messages, or if a TCP write error occurs when attempting to display the banner messages.

Step 1 To configure banners, access the Banner page:

- (Device view) Select **Platform > Device Admin > Banner** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Banner** from the Policy Types selector. Select an existing policy from the Policies selector, or create a new one.

Step 2 In the **Session (exec) Banner** field, enter the text you want the system to display as a banner before displaying the enable prompt.

Step 3 In the **Login Banner** field, enter the text you want the system to display as a banner before the password login prompt when accessing the security appliance using Telnet.

Step 4 In the **Message-of-the-Day (motd) Banner** field, enter the text you want the system to display as a message-of-the-day banner.

Step 5 In the **ASDM Banner** field, specify the text you need the system to shown you as an ASDM banner after logging in. This banner does not support or allow question marks in the text. Security Manager will present an activity validation error even if one of your shared policies contains a question mark.

Step 6 To replace a banner, change the contents of the appropriate box.

Step 7 To remove a banner, clear the contents of the appropriate box.

Configuring Boot Image/Configuration Settings

Use the Boot Image/Configuration page to specify which configuration file the security appliance will use at start-up. You can also specify the path to an Adaptive Security Device Manager (ASDM) configuration file.

If you do not specify a boot-image location, the first valid image on internal flash memory will be chosen to launch the system.

Note This page is available only on ASA and PIX 7.0+ devices

Navigation Path

- (Device view) Select **Platform > Device Admin > Boot Image/Configuration** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Boot Image/Configuration** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 591: Boot Image/Configuration Page

Element	Description
Boot Config Location	Enter the path to and name of the configuration file to be used when the system is loaded. On an ASA, you can use any of the following syntactical constructs: • **disk0:**/[*path/*]*filename* The value “disk0” represents the internal flash card. You can also use “**flash**” instead of “**disk0**,” as they are aliased: • **flash:**/[*path/*]*filename* • **disk1:**/[*path/*]*filename* The value “disk1” represents the external flash card. On a PIX device, you can use only the “flash” syntax; that is: • **flash:**/[*path/*]*filename*

Element	Description
ASDM Image Location	The location and name of the ASDM software image to be used when ASDM sessions are initiated. (You can use ASDM to monitor both ASA and PIX devices.) On a PIX device, as with the Boot Config Location, you are restricted to only the "flash" syntax. On an ASA, as with the Boot Config Location, you can use the "disk0," "flash," or "disk1" constructs. In addition, you can specify an image file on a TFTP server, as follows • **tftp:**//[*user* [*:password*]@]*server* [*:port*]/[*path/*]*filename*
Boot Images Table	This table lists any alternate configuration files you have defined; you can specify up to four. The first available image in this list is used if you did not specify a primary file in the Boot Config Location field, or if that file is unavailable. This is a standard Security Manager table; use the up-arrow, down-arrow, Add Row, Edit Row, and Delete Row buttons below the table to manage these entries, as described in Using Tables , on page 50. The Add Row and Edit Row open the Images Dialog Box , on page 1914, used to add and edit the paths to alternate configuration files. **Note** On an ASA, the first (and only the first) entry in this table can refer to an ASDM configuration file on a TFTP server. If the device cannot reach the TFTP server, it will attempt to load the next image file in the list.

Images Dialog Box

Use the Images dialog box to add or edit a configuration file entry in the Boot Images table on the Boot Image/Configuration page.

Navigation Path

You can access the Images dialog box from the Boot Image/Configuration page. For more information, see Configuring Boot Image/Configuration Settings , on page 1913.

Field Reference

The Images dialog box contains one field, used to define the path to a boot image or configuration file, as follows:

Table 592: Images Dialog Box

Element	Description
Image File	Enter the path to and name of the configuration file to add to the ordered Boot Images list. On a PIX device, you can use only the "flash" syntax; that is: • **flash:**/[*path/*]*filename* On an ASA, you can use any of the following syntactical constructs: • **disk0:**/[*path/*]*filename* The value "disk0" represents the internal flash card. You can also use "**flash**" instead of "**disk0**," as they are aliased: • **flash:**/[*path/*]*filename* • **disk1:**/[*path/*]*filename* The value "disk1" represents the external flash card. In addition, on an ASA, you can specify an ASDM image file on a TFTP server, as follows • **tftp:**//[*user* [*:password*]@]*server* [*:port*]/[*path/*]*filename* Note that you can specify only one TFTP location, and it must be listed first in the Boot Images table on the Boot Image/Configuration page.

Configuring CLI Prompt

You can use the CLI Prompt page to customize the prompt used by ASA 7.2(1)+ devices during CLI sessions. By default, the prompt shows the hostname of the ASA. In multiple context mode, the prompt also displays the context name. You can display the following items in the CLI prompt:

Note The attributes that are available differ by ASA version:

cluster-unit (ASA 9.1.1+ only)	Displays the cluster unit name. Each unit in a cluster can have a unique name.
context	(Multiple mode only) Displays the name of the current context.
domain	Displays the domain name.
hostname	Displays the hostname.
management-mode (ASA 9.2.1+ only)	Displays the management mode.
priority	Displays the failover priority as pri (primary) or sec (secondary).

state	Displays the traffic-passing state or role of the unit. For failover, the following values appear for the state: • act—Failover is enabled, and the unit is actively passing traffic. • stby— Failover is enabled, and the unit is not passing traffic and is in a standby, failed, or another inactive state. • actNoFailover—Failover is not enabled, and the unit is actively passing traffic. • stbyNoFailover—Failover is not enabled, and the unit is not passing traffic. This condition might occur when there is an interface failure above the threshold on the standby unit. For grouping, the following values are displayed for state: • control • data For example, in the prompt ciscoasa/cl2/slave, the hostname is ciscoasa, the unit name is cl2, and the state is data.

Step 1 Access the CLI Prompt page by doing one of the following:

- (Device view) Select **Platform > Device Admin > CLI Prompt** from the Device Policy selector.

Note For devices in multiple context mode, the CLI Prompt page is only available in the system context. In the admin context, the CLI Prompt page is not available.

- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > CLI Prompt** from the Policy Types selector. Select an existing policy from the Policies selector, or create a new one.

Step 2 Customize the CLI prompt by doing the following:

- To add an attribute to the prompt, select the attribute in the Available Members list and then click >>. The attribute is moved from the Available Members list to the Selected Members list.

You can add multiple attributes to the prompt. The order in which the attributes are added to the Selected Members list will dictate the order in which they are shown in the CLI prompt.

Note For ASA 9.1.1+, you can configure up to six attributes for the CLI prompt. For earlier ASA versions, you can only configure up to five attributes.

- To remove an attribute from the prompt, select the attribute in the Selected Members list and then click <<. The attribute is moved from the Selected Members list to the Available Members list.

Setting the Device Clock

Use the Clock page to set the date and time on the selected device.

Note This page is not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

To dynamically set the time using an NTP server, see NTP Page , on page 2021; time derived from an NTP server overrides any time set manually on the Clock page.

Note In multiple-context mode, set the time in the system context only.

Navigation Path

- (Device view) Select **Platform > Device Admin > Clock** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Clock** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 593: Clock Page

Element	Description
Device Time Zone	Choose a time zone for the device. These options represent Greenwich Mean Time (GMT) plus or minus a number of hours. **Note** Changing the time zone on the device may drop the connection to any installed Security Services modules (SSMs).
Daylight Savings Time (Summer Time)	Choose a daylight savings time option, and if necessary, specify when and how daylight savings time is applied: **None** – Choose this option to disable automatic correction for daylight savings time. **Set by Date** – Choose this option to specify the date and time when daylight savings time begins and ends for a specific year. If you use this option, you will need to reset the dates every year. **Set by Day** – Choose this option to specify the start and end dates for daylight saving time using the month, week, and day on which daylight savings time begins and ends. This option also lets you set a recurring date range that you do not need to alter yearly.
Set by Date The following three parameters appear in a Start section and an End section. Use the two sets to define when daylight savings time starts and ends.	
Date	Enter the date on which daylight savings time begins or ends, in MMM DD YYYY format (for example, Jul 15 2011). You also can click the calendar icon to select the date from a pop-up calendar.

Element	Description
Hour	Choose the hour, from 00 to 23, in which daylight savings time begins or ends.
Minute	Choose the minute, from 00 to 59, at which daylight savings time begins or ends.
Set by Day	
Specify Recurring Time	Check this box to enable the Start and End parameters, which are used to set a recurring start and end for daylight savings time that you do not need to alter yearly.
The following five parameters appear in a Start section and an End section. Use the two sets to define when daylight savings time starts and ends.	
Month	Choose the month in which daylight savings time begins or ends.
Week	Choose the week of the month in which daylight savings time begins or ends. You can select a numerical value that corresponds to the week—1 through 4—or you can specify the first or last week in the month by choosing **first** or **last**. For example, if the day might fall in the partial fifth week, choose last.
Weekday	Choose the day of the week on which daylight savings time begins or ends.
Hour	Choose the hour, from 0 to 23, in which daylight savings time begins or ends.
Minute	Choose the minute, from 00 to 59, at which daylight savings time begins or ends.

Enabling/Disabling FIPS

Beginning with 4.15, Cisco Security Manager provides an option to enable or disable the Federal Information Processing Standards (FIPS) mode on the ASA devices. When you enable FIPS mode with FOM, instead of legacy methods implemented in Cisco SSL versions, the FIPS 140-2 standard compliant cryptographic methods implemented in the FOM is used for signature and verification purposes. This feature is supported only on ASA 9.8.2 or later devices.

Note To configure FIPS mode on a device, you must reboot the device manually.

Before you enable FIPS, ensure the following are configured on ASA:

1. DH group is set to 14 or ECDH group is set to 19, 20, or 21.
2. The Device Identity Certificate key type is set to RSA and the key size is 2048 or above.

Navigation Path

- (Device view) Select **Platform > Device Admin > FIPS** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > FIPS** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 594: FIPS Page

Element	Description
FIPS	Select the check box to enable FIPS on the device. This option is available only for ASA 9.8.2 or above. **Note** You must reboot the device after enabling or disabling FIPS for the configuration to take effect.

Enabling Customer Success Network

Beginning with version 4.20, Cisco Security Manager provides an option to enable Customer Success Network, which helps avail the features enabled on ASA devices and leverage the same mechanism of Smart Call Home (SCH). Because the data SCH collects are mostly outdated and the features added since the release of SCH do not report the exact status, Customer Success Network is being introduced. This feature is supported on ASA 9.13.1 and later devices.

Note A feature must be considered “enabled” only when it is configured and ready to use. If a feature is configured but does not work, it must not be considered “enabled”.

Navigation Path

- (Device view) Select **Platform > Device Admin > Customer Success Network** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Customer Success Network Policy** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 595: Customer Success Network Page

Element	Description
Customer Success Network	Select the **Enable Customer Success Network** check box to enable it on the device. This option is available only for ASA 9.13.1 and later devices.

Configuring Umbrella Global Policy

Beginning with version 4.18, Cisco Security Manager supports configuring Umbrella global policy. Cisco Umbrella Branch is a cloud based security service, which first inspects the DNS traffic, and then examines suspicious HTTP/(S) traffic. The Umbrella connector intercepts DNS packets and redirects the interesting DNS queries to the Umbrella resolver for resolution. Once the DNS response is received, it forwards the response to the host. This feature is supported only on ASA 9.10.1 or later devices.

After configuring Umbrella service, ensure that the Umbrella DNS policy-map is also configured.

Navigation Path

- (Device view) Select **Platform > Device Admin > Umbrella** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Umbrella** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 596: Umbrella Page

Element	Description
Umbrella	Select the check box to apply the global Umbrella configuration for the selected device (ASA 9.10.1 or later).
Token	The token value of the ASA device on registering with the Umbrella server. Cisco Security Manager throws an error message if this value is less than 64 characters.
Public Key	The public key value of the ASA device on registering with the Umbrella server. This value must be 64 hexa-decimal digits and less than 80 characters, else Cisco Security Manager will display an error message.
EDNS Flow Timeout	The configured EDNS timeout value. The Umbrella time-out for edns-flow must be between <0:0:0> and <1193:0:0>, else Cisco Security Manager will display error message.
IPv4 Resolver	The IPv4 address of the non-default Cisco Umbrella DNS servers that you want to use to resolve DNS requests. Ensure a valid IPv4, else Cisco Security Manager will display an error message.
IPv6 Resolver	The IPv6 address of the non-default Cisco Umbrella DNS servers that you want to use to resolve DNS requests. Ensure a valid IPv6, else Cisco Security Manager will display an error message.
Regular Expression Class	Use regular expression class to match the local domain bypass for which Umbrella should be bypassed.
Regular Expression	Use regular expression to match the local domain bypass for which Umbrella should be bypassed.

Configuring Device Credentials

Use the Credentials page to specify the user credentials Security Manager will use when contacting this device. You can also change the Enable password and the Telnet/SSH password on the device.

This user name-password combination lets you log into the device (in EXEC mode) if you connect to the security appliance using an HTTP, HTTPS, Telnet, or SSH session. You also can specify a separate password specifically for Telnet and SSH sessions. (Further, you can define separate credentials for HTTP/HTTPS connections on the Device Credentials Page , on page 114 in the Device Properties window.)

The Enable password lets you access privileged EXEC mode after you log in.

Tip The Username, Password, and Enable Password on this page are linked to the Credentials settings in the Device Properties window. When you update these parameters and then deploy the changes to the device, Security Manager uses the existing credentials defined in the Device Properties to log into the device and deploy changes. After successful deployment, the Device Properties credentials are updated to match these settings. For more information about Credentials in Device Properties, see Device Credentials Page , on page 114.

Navigation Path

- (Device view) Select **Platform > Device Admin > Credentials** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Credentials** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Danger Since several user accounts may exist on each device, applying a shared Credentials policy to multiple devices will update only the Enable Password on each device; the Username and Password provided in the shared policy are not applied (nor is the Telnet/SSH password). The Enable Password is sufficient for subsequent access to PIX/ASA/FWSM devices, unless external authentication such as AAA or TACACS+ is configured, in which case the Enable Password alone is not sufficient. In this situation, you must manually update the Username, Password and Enable Password on each device that uses external authentication.

Related Topics

- Configuring User Accounts , on page 1995

Field Reference

Table 597: Credentials Page

Element	Description
Username	Enter a user name for logging into the device. The name must be at least four characters; the maximum is 64 characters. Entries are case-sensitive.

Element	Description
Password Confirm	Provide a password for logging into the device (EXEC mode) with the specified Username. This password must be at least three characters; the maximum is 32 characters. Entries are case-sensitive. Re-enter the user password in the Confirm field. **Note** We recommend a password length of at least 8 characters.
Privilege Level	Choose a privilege level for this user; available values are 1 through 15. Level 1 allows EXEC-mode access only, the default level for log-in; level 15 allows Privileged EXEC-mode access; that is, access to the Enable mode. Other levels must be explicitly defined on the device.
Enable password	
Password as encrypted	Select Plain Text or Encrypted.
Password encrypt type	Select MD5 or PBKDF2.
Enable Password Confirm	You can specify an Enable password that lets this user access Privileged EXEC mode after logging in. Entries are case-sensitive. Re-enter the Enable password in the Confirm field. **Note** For Plain Text passwords: • The length of MD5 password should be three to 32 characters. • The length of PBKDF2 password should be 33 to 127 characters. Ensure PBKDF2 password has correct `sha` key values to avoid deployment failure. **Note** If you configure user authentication for Enable access, each user has their own password and this password is not used. See Configuring AAA - Authentication Tab , on page 1907 for more information.
Telnet/SSH Password Confirm	You can specify a password that provides access to EXEC mode when connecting to the device via a Telnet or SSH session. This password must be at least three characters; the maximum is 32 characters. Entries are case-sensitive. Re-enter the Telnet/SSH password in the Confirm field. **Note** If you configure user authentication for Telnet or SSH access, each user has their own password and this password is not used. See Configuring AAA - Authentication Tab , on page 1907 for more information.

Managing Mount Points

Use the Mount Points page to make a Common Internet File System (CIFS) or a File Transfer Protocol (FTP) file system accessible to the security appliance.

Note When you create an FTP-type mount point, the FTP server must have a UNIX directory listing style. Microsoft FTP servers have the MS-DOS directory listing style as their default.

The File Mount Point Configuration table lists the configured mount points. The File Mount Point Configuration table is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons. (These are standard buttons, as described in Using Tables , on page 50.) The Add Row button opens the Add Mount Point Configuration dialog box, and Edit Row opens the Edit Mount Point Configuration dialog box. Other than the titles, the two dialog boxes are identical. For more information, see Add/Edit Mount Point Configuration Dialog Box , on page 1923.

Note This feature is available only on ASA 8.0(2)+ devices. Mount points are supported in router mode only. For ASA versions between 8.0(2) and 9.x, mount points are not supported in multiple-context mode. Mount points are supported in the Admin context on ASA 9.x+ devices in multiple-context, routed mode.

Navigation Path

- (Device view) Select **Platform > Device Admin > Mount Points** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Mount Points** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Add/Edit Mount Point Configuration Dialog Box

Use the Add/Edit Mount Point Configuration dialog box to add or edit a mount point entry in the File Mount Point Configuration table on the Mount Points page. You use mount points to make a Common Internet File System (CIFS) or a File Transfer Protocol (FTP) file system accessible to the security appliance.

Navigation Path

You can access the Add/Edit Mount Point Configuration dialog box from the Mount Points page. For more information, see Managing Mount Points , on page 1922.

Field Reference

Table 598: Add/Edit Mount Point Configuration Dialog Box

Element	Description
Enable Mount Point	Whether the file system is mounted or unmounted (available or unavailable).

Element	Description
Connection Type	Select the type of file system to mount: • **cifs**—Specifies that the file system being mounted is CIFS, a file system that provides volume-mounting capabilities for CIFS-shared directories. • **ftp**—Specifies that the file system being mounted is FTP, a Linux kernel module, enhancing the Virtual File System (VFS) with FTP volume-mounting capabilities that allow you to mount FTP-shared directories. **Note** When you create an FTP-type mount point, the FTP server must have a UNIX directory listing style. Microsoft FTP servers have the MS-DOS directory listing style as their default.
Mount Point Name	Specifies the name of the mount point. The mount point name is used when other CLI commands refer to the filesystem already mounted on the security appliance. A maximum of 31 characters are allowed for the mount point name.
Server Name/IP Address	Specifies the predefined name (or the IP address in dotted decimal notation) of the CIFS or FTP file-system server.
Username	Specifies the authorized username for file-system mounting.
Password Confirm	Identifies the authorized password for file-system mounting.
Encrypt Password	Select to indicate that the password supplied is in encrypted format.
Share Name (CIFS only)	Explicitly identifies a specific server share (a folder) by name to access file data within a server.
Domain Name (CIFS only)	For CIFS file systems only, this argument specifies the Windows NT domain name. A maximum of 63 characters is permitted.
Mode (FTP only)	Identifies the FTP transfer mode as either active or passive.
Path (FTP only)	Specifies the directory pathname to the specified FTP file-system server. Question marks and spaces are not allowed in the pathname and will be suppressed.

IP Client

The IP Client page lists the interface name and the IP version. You can use the configured IP Client for integrated routing and bridging support on Firepower 2100 Series devices. The IP Client page has the standard options to Add, Edit and Delete the entries.

Note This feature is available only on ASA 9.8.2+ Firepower 2100 Series single context devices. No multi context support for IP-Client.

Navigation Path

- (Device view) Select **Platform** > **Device Admin** > **IP Client** from the Device Policy selector.

Note The menu appears only for a Firepower 2100 Series device.

- (Policy view) Select **PIX/ASA/FWSM Platform** > **Device Admin** > **IP Client** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Add/Edit IP Client Dialog Box

Use the Add/Edit IP Client dialog box to add or edit a IP Client entry in the IP Client table on the IP Client page. You use IP Client settings to support integrated routing and bridging on Firepower 2100 Series devices.

Navigation Path

You can access the Add/Edit IP Client dialog box from the IP Client page. For more information, see IP Client, on page 1924.

Field Reference

Table 599: Add/Edit IP Client Dialog Box

Element	Description
IP Version	The IP address of the device. It can be an IPv4 or an IPv6 address.
Interface	Select the interface pertaining to the Firepower 2100 Series device.

The preview configuration page displays the IP Client configuration with IPv6 suffixed for IPv6 interfaces. For IPv4 interfaces, only the interface name is displayed.

App Agent

Use the App Agent page to configure the App Agent settings. You can specify the heartbeat interval and retry count.

Note App-Agent is available only on Firepower 2100 Series, Firepower 4000 Series, and Firepower 9000 Series devices. In Cisco Security Manager, App-Agent in Firepower 2100 Series device is supported from 9.8.2+; App-Agent in Firepower 4000 Series, and Firepower 9000 Series device is supported from 9.6.2+.

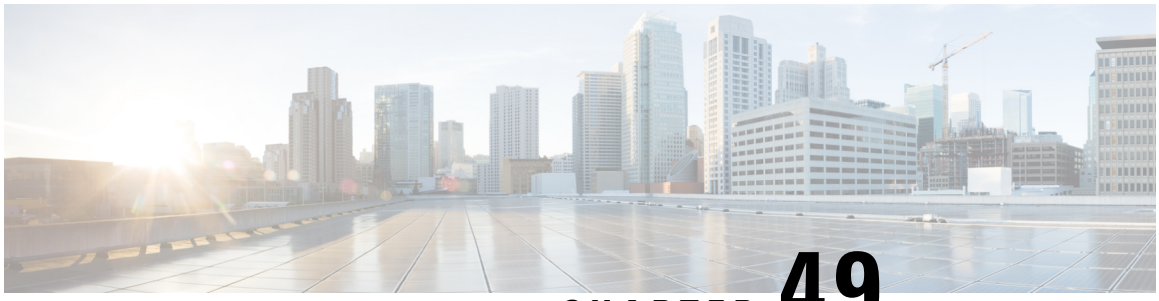
Navigation Path

- (Device view) Select **Platform > Device Admin > App Agent** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > App Agent** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 600: App Agent Page

Element	Description
Interval	Enter the app agent heartbeat interval. From ASA 9.6.2 to ASA 9.8.1, App-Agent heartbeat value can be between 300 to 6000 ms. For ASA 9.8.2+ devices, App-Agent heartbeat interval value can be between 100 to 6000 ms. **Note** Cisco Security Manager will display an error message if you do not enter values in multiples of 100.
Retry Count	Enter the retry count between 3 to 10.
Save	Click to save the configuration.



CHAPTER 49

Configuring Device Access Settings on Firewall Devices

The Device Access section, located under the Device Admin folder in the Policy selector, contains pages for defining access to firewall devices.

This chapter contains the following topics:

Configuring Console Timeout

Use the Console page to specify a timeout value for inactive console sessions. When the time limit you specify is reached, the console session is closed.

In the **Console Timeout** field, enter the number of minutes a console session can remain idle before the device closes it. Valid values are 0 to 60 minutes. To prevent a console session from timing out, enter 0.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Console** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > Console** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

HTTP Page

Use the table on the HTTP page to manage the interfaces configured to access the HTTP server on a device, as well as HTTP redirect to HTTPS on those interfaces. You also can enable or disable the HTTP server on the device from this page. Administrative access by the specific device manager requires HTTPS access.

Note To redirect HTTP, the interface requires an access list that permits HTTP. Otherwise, the interface cannot listen to port 80, or to any other port that you configure for HTTP.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > HTTP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > HTTP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 601: HTTP Page

Element	Description
HTTP Interface table	Use the Add Row, Edit Row, and Delete Row buttons below this table to manage device interfaces on which HTTP-to-HTTPS redirect is configured. Add Row and Edit Row open the HTTP Configuration Dialog Box , on page 1929.
Fetch user name from certificate settings	Select this option to set the rules for extracting a username from the certificate. Enter the following: • Enable HTTP username from certificate—Check this box to get the HTTP username from the certificate for authentication. • Pre-fill user name—Check the Pre-fill Username checkbox to enable the use of this name for authentication. When enabled, this username, along with the password entered by the user, are used for authentication. Choose one of the following options: **Note** This feature is supported only in devices running ASA software version 9.4(1) or later. • Use the Entire DN as the username—Select this option if you want to use the entire DN as the username. This option is disabled by default.

Element	Description
Fetch user name from certificate settings (contd..)	• Specify individual DN fields as the username—Choose from the Primary DN Field and Secondary DN Field drop-down values to specify which attributes and additional attributes to use to derive the username. This option is enabled by default. • C—Country: the two-letter country abbreviation which conforms to the ISO 3166 country abbreviations. • CN—Common Name: the name of a person, system, or other entity. Not available as a secondary attribute. • DNQ—Domain Name Qualifier. • EA—Email address. • GENQ—Generational qualifier. • GN—Given name. • I—Initials. • L—Locality: the city or town where the organization is located. • N—Name. • O—Organization: the name of the company, institution, agency, association, or other entity. • OU—Organizational Unit: the subgroup within the organization (O). • SER—Serial number. • SN—Surname. • SP—State/Province: the state or province where the organization is located. • T—Title. • UID—User Identifier. • UPN—User Principal Name. • Use LUA Script generated by ASDM—Choose this option if you want to use the LUA script that is generated by ASDM. This option is disabled by default.
Enable HTTP Server	Enables or disables the HTTP server on the device. When enabled, you can specify a communications **Port** for the server. The Port range is 1 to 65535; the default is 443.

HTTP Configuration Dialog Box

Use the HTTP Configuration dialog box to add or edit a host or network that will be allowed to access the HTTP server on the device via a specific interface; you also can enable and disable HTTP redirect.

Navigation Path

You can access the HTTP Configuration dialog box from the HTTP Page , on page 1928.

Field Reference

Table 602: HTTP Configuration Dialog Box

Element	Description
Interface Name	Enter or Select the interface on which access to the HTTP server on the device is allowed. **Note** Beginning with Cisco Security Manager version 4.17, you can configure BVI interface for HTTP on ASA 9.9.2 devices and above. However, in multi-context, "Transparent" mode security context only supports BVI interface.
IP Address/Netmask	Enter the IP address and netmask, separated by a forward slash ("/") of the host or network that is permitted to establish an HTTP connection with the device. Alternately, you can click Select to select a Networks/Hosts object. **Note** Beginning with version 4.13, Cisco Security Manager supports policies—Groups, Hosts, Address Range, and Network for IPv6 devices.
Enable Authentication Certificate	Select this option to require user certificate authentication in order to establish an HTTP connection. On ASA and PIX 8.0(2)+ devices, you can specify the authentication **Port**.
Certificate Maps	Select the Certificate Map name that you configured in Remote Access VPN > certificate to Connection Profile Maps > Rules. For more information, see Map Rule Dialog Box (Upper Table) , on page 1365. None is selected by default. This feature is available beginning with Security Manager version 4.12 for ASA 9.6(2) or later devices. This option is supported for single, multi, routed and transparent contexts for ASA devices.
Redirect port	The port on which the security appliance listens for HTTP requests, which it then redirects to HTTPS. To disable HTTP redirect, ensure that this field is blank.

Configuring ICMP

Use the table on the ICMP page to manage Internet Control Message Protocol (ICMP) rules, which specify the addresses of all hosts or networks that are allowed or denied ICMP access to specific interfaces on the security device.

Note Starting from ASA 8.2(1) ICMP IPv6 was supported in the transparent firewall mode.

The ICMP rules control ICMP traffic that terminates on any device interface. If no ICMP control list is configured, the device accepts all ICMP traffic that terminates at any interface, including the outside interface. However, by default, the device does not respond to ICMP echo requests directed to a broadcast address.

It is recommended that permission is always granted for the ICMP Unreachable message (type 3). Denying ICMP Unreachable messages disables ICMP Path MTU discovery, which can halt IPsec and PPTP traffic. See RFC 1195 and RFC 1435 for details about Path MTU Discovery.

If an ICMP control list is configured, the device uses a first match to the ICMP traffic, followed by an implicit deny all. That is, if the first matched entry is a permit entry, the processing of the ICMP packet continues. If the first matched entry is a deny entry, or an entry is not matched, the device discards the ICMP packet and generates a syslog message. If an ICMP control list is not configured, a permit rule is assumed in all cases.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > ICMP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > ICMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Note ICMP IPv6 support is not available for PIX and FWSM devices.

Field Reference

Table 603: ICMP Page

Element	Description
ICMP Rules Table	Use the Add Row, Edit Row, and Delete Row buttons below this table to manage ICMP rules. Add Row opens the Add ICMP dialog box, while Edit Row opens the Edit ICMP dialog box. See Add and Edit ICMP Dialog Boxes , on page 1931 for information about these dialog boxes.
ICMP Unreachable Parameters	
Rate Limit	For ICMP traffic that terminates at an interface on this device, the maximum number of ICMP Unreachable messages the device can transmit per second. This value can be between 1 and 100 messages per second; the default is 1 message per second.
Burst Size	The burst size for ICMP Unreachable messages; this can be a value between 1 and 10. **Note** This parameter is not currently used by the system, so you can choose any value.

Add and Edit ICMP Dialog Boxes

Use the Add ICMP dialog box to add an ICMP rule, which specifies a host/network that is allowed or denied the specified ICMP access on the specified device interface.

Note The Edit ICMP dialog box is virtually identical to the Add ICMP dialog box, and is used to modify existing ICMP rules. The following descriptions apply to both dialog boxes.

Navigation Path

You can access the Add or Edit ICMP dialog boxes from the Configuring ICMP , on page 1930.

Note While adding an ICMP policy, make sure that the network and service is of the same type i.e. IPv6 networks support IPv6 services.

Field Reference

Table 604: Add and ICMP Dialog Boxes

Element	Description
Action	Whether this rule permits or denies the selected ICMP Service message from the specified Network on the specified Interface. Choose: • **Permit** – ICMP messages from the specified networks/hosts are allowed to the specified interface. • **Deny** – ICMP messages from the specified networks/hosts to the specified interface are dropped.
ICMP Service	Enter or Select the specific ICMP service message to which the rule applies.
Interface	Enter or Select the device interface to which these ICMP messages are directed.
Network	Enter a host name, IPv4 or IPv6 address, or Select a Networks/Hosts object, to define the specified ICMP message source.

Configuring Management Access

Use the Management Access page to enable or disable access on a high-security interface so you can perform management functions on the device. You can enable this feature on an internal interface to allow management functions to be performed on the interface over an IPsec VPN tunnel. You can enable the Management Access feature on only one interface at a time.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Management Access** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > Management Access** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Enabling and Disabling Management Access

In the **Management Access Interface** field, enter the name of the device interface that is to permit management access connections. You can click Select to select the interface from a list of interface objects.

You can enable the Management Access feature on only one interface at a time.

Clear the Management Access Interface field to disable management access.

Configuring Management Session Quota Limits

Beginning with 4.19, Cisco Security Manager allows you to configure enforcement of limits for the maximum number of admin sessions across all connection types and usernames, and for maximum number of concurrent sessions per username as well as per protocol limits on ASA 9.12(1) devices or later. The configured session concurrence limits is enforced prior to authenticating the incoming administrative session.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Management Session Quota** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > Management Session Quota** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Note The sequence of enforcement on the session limits would be—user limit followed by aggregate limit, and then by protocol limit.

Field Reference

Table 605: Add and ICMP Dialog Boxes

Element	Description
Aggregate	The maximum number of admin sessions across all connection types. The default is 15. You can configure the limit between 1 and 15.
HTTP	Enter management session quota limit for HTTP between 1 and 5. The default value is 5.
SSH	Enter management session quota limit for SSH between 1 and 5. The default value is 5.
Telnet	Enter management session quota limit for Telnet between 1 and 5. The default value is 5.
User	Enter management session quota limit for the user between 1 and 5. There is no default value specified for user limit.

Configuring Secure Shell Access

Use the Secure Shell page to configure rules that permit administrative access to a security device using the SSH protocol. The rules restrict SSH access to a specific IP address and netmask. Any SSH connection attempts that comply with these rules must then be authenticated by an AAA server or Telnet password.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Secure Shell** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > Secure Shell** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 606: Secure Shell Page

Element	Description
SSH Version	Specify the SSH version(s) accepted by the device: choose **1**, **2**, or **1 and 2**. By default, SSH Version 1 and SSH Version 2 connections are accepted.
Timeout	Enter the number of minutes, 1 to 60, the Secure Shell session can remain idle before the device closes it. The default value is 5 minutes.
Allowed Hosts table	Use the Add Row, Edit Row, and Delete Row buttons below this table to manage the hosts allowed to connect to the security device via SSH. Add Row opens the Add Host dialog box, while Edit Row opens the Edit Host dialog box. See Add and Edit SSH Host Dialog Boxes , on page 1935 for information about these dialog boxes.
Enable Secure Copy	Check this box to enable the secure copy (SCP) server on the security appliance. This allows the appliance to function as an SCP server for transferring files from/to the device. Only clients that are allowed to access the security appliance using SSH can establish a secure copy connection. This implementation of the secure copy server has the following limitations: • The server can accept and terminate connections for secure copy, but cannot initiate them. • The server does not have directory support. The lack of directory support limits remote client access to the security appliance internal files. • The server does not support banners. • The server does not support wildcards. • The security appliance license must have the VPN-3DES-AES feature to support SSH version 2 connections.

Add and Edit SSH Host Dialog Boxes

Use the Add Host dialog box to add an SSH access rule.

Note The Edit Host dialog box is virtually identical to the Add Host dialog box, and is used to modify existing SSH access rules. The following descriptions apply to both dialog boxes.

Navigation Path

You can access the Add and Edit Host dialog boxes from the Configuring Secure Shell Access , on page 1934.

Field Reference

Table 607: Add and Edit Host Dialog Boxes

Element	Description
Interface	Enter or Select the name of the device interface on which SSH connections are permitted. **Note** Beginning with Cisco Security Manager version 4.17, you can configure BVI interface for SSH connections on ASA 9.9.2 devices and above. However, in multi-context, “Transparent” mode security context only supports BVI interface.
IP Addresses	Enter the name or IP address for each host or network that is permitted to establish an SSH connection with the security device on the specified interface; use commas to separate multiple entries. You also can click Select to select Networks/Hosts objects from a list. **Note** Beginning with version 4.13, Cisco Security Manager supports policies—Groups, Hosts, Address Range, and Network for IPv6 devices.

Configuring SSL - Basic and Advanced tabs

Beginning from version 4.8, Security Manager provides enhanced security features using Secure Sockets Layer (SSL).

To configure SSL under device access, ensure you enable SSL under **CSM Admin > Policy Management**

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > SSL** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > SSL** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 608: SSL Page Basic Tab

Element	Description
Certificate Authentication	
FCA Timeout	Enter a value in the range of 1 to 120. **Note** FCA Timeout is applicable for devices running the ASA software version 9.1(2) or later.
Interface	Use the Add Row, Edit Row, and Delete Row buttons below the Interface table to manage the interfaces and their port numbers allowed to connect to the security device via SSL. Add Row opens the Add Interface and Port dialog box, while Edit Row opens the Edit Interface and Port dialog box. You can select the interface from the available entries in the Interface Selector dialog box. Enter a value in the range of 1 to 65535 for the port number.
Client Version SSL/TLS Protocol Version	The Client Version is the SSL/TLS protocol version to use when the device acts as a client. Select any one of the following: • Any—Select this keyword to transmit SSLV3 ClientHellos and negotiate SSLV3 or greater. This is the default keyword. • SSLV3—Enter this keyword to transmit SSLv3 ClientHellos and negotiate SSLV3 or greater. • TLSV1—Enter this keyword to transmit TLSv1 ClientHellos and negotiate TLSV1 or greater. • TLSV1.1—Enter this keyword to transmit TLSV1.1 ClientHellos and negotiate TLSV1.1 or greater. • TLSV1.2—Enter this keyword to transmit TLSV1.2 ClientHellos and negotiate TLSV1.2 or greater. **Note** TLSV1.1 and TLSV1.2 protocol versions are applicable for devices running the ASA software version 9.3(2) or later.

Element	Description
Server Version SSL/TLS Protocol Version	The Server Version is the minimum SSL/TLS protocol version to use when the device acts as a server. Select any one of the following: • Any—Select this keyword to accept SSLV2 ClientHellos and negotiate the highest common version. This is the default keyword. • SSLV3—Enter this keyword to accept SSLV2 ClientHellos and negotiate SSLV3 or greater. • SSLV3-Only—Enter this keyword to accept SSLV2 ClientHellos and negotiate SSLV3 or greater. • TLSV1—Enter this keyword to accept SSLV2 ClientHellos and negotiate TLSV1 or greater. • TLSV1-Only—Enter this keyword to accept SSLV2 ClientHellos and negotiate TLSV1 or greater. • TLSV1.1—Enter this keyword to accept SSLV2 ClientHellos and negotiate TLSV1.1 or greater. • TLSV1.2—Enter this keyword to accept SSLV2 ClientHellos and negotiate TLSV1.2 or greater. **NOTES:** • The **Any** keyword is the default for both Server Version and Client Version and means that the device will negotiate the highest common supported version of TLS. • TLSV1.1 and TLSV1.2 protocol versions are applicable for devices running the ASA software version 9.3(2) or later. • SSLV3-Only and TLSV1-Only protocol versions are applicable for devices running the ASA software version older than 9.3(2).

Table 609: SSL Page Advanced Tab

Element	Description
Advanced SSL Settings for devices running the ASA software version older than 9.3(2)	

Element	Description
Encryption	Choose the encryption algorithms from the available list. To add an encryption algorithm, select the item in the Available Members list and then click >>. The item is moved from the Available Members list to the Selected Members list. You can add multiple encryption algorithms. The available encryption algorithms are as follows: • 3DES-SHA1 • AES128-SHA1 • AES256-SHA1 • DES-SHA1 • RC4-MD5 • RC4-SHA1 • NULL-SHA1 • DHE-AES128-SHA1 • DHE-AES256-SHA1 **Note** Beginning from 4.19, Cisco Security Manager does not support configuring TLS proxy with NULL SHA1 in SSL ciphers in ASA 9.12(1) and later devices. To remove an encryption algorithm, select the item in the Selected Members list and then click <<. The item is moved from the Selected Members list to the Available Members list. Click Save to save your settings.
Advanced SSL Settings for devices running the ASA software version 9.3(2) or later	
SSL Cipher	Use the Add Row, Edit Row, and Delete Row buttons below the SSL Cipher table to manage the SSL cipher version and level. On the Add Cipher dialog select a combination of the version and level.

Element	Description
Version	Select one of the following versions: • DEFAULT • DTLSV1 • DTLSV1.2 • SSLV3 • TLSV1 • TLSV1.1 • TLSV1.2 **Note** The DEFAULT keyword is used to configure outbound connections when the device is acting as a client and establishing a connection to a server. All the other keywords are used when the device is acting as a server and accepting connections from a client. **Note** The SSLV3 version has been deprecated from ASA version 9.4(1). Therefore, beginning with version 4.9, Security Manager performs a validation to check if SSLV3 option has been configured for any ASA devices running the version 9.4(1) or later.
Level	Select one of the following versions: • ALL - It includes all ciphers including NULL-SHA. • LOW - It includes all ciphers except NULL-SHA. • MEDIUM - It includes all ciphers except NULL-SHA:DES-CBC-SHA:RC4-SHA:RC4-MD5. • FIPS - It includes all FIPS-compliant ciphers (that is, not NULL-SHA:DES-CBC-SHA:RC4-MD5:RC4-SHA:DES-CBC3-SHA) • HIGH - It includes only AES-256 with SHA-2 ciphers, so it only applies to TLSV1.2.

Element	Description
Custom String	Use the CUSTOM keyword for Security Manager to exercise full control over the cipher suite using OpenSSL cipher definition strings. **Note** Beginning with version 4.9, Security Manager provides support for the following new TLSV1.2 ciphers for devices running the ASA software version 9.4(1) or later. • ECDHE_RSA_AES128_SHA256 • ECDHE_RSA_AES256_SHA384 • ECDHE_ECDSA_AES128_SHA256 • ECDHE_ECDSA_AES256_SHA384 **Note** Beginning with version 4.16, Security Manager provides support for the following new TLSV1.2 ciphers in addition to the above mentioned ciphers for devices running the ASA software version 9.4(1) or later. • ECDHE-ECDSA-AES256-GCM-SHA384 • ECDHE-RSA-AES256-GCM-SHA384 • DHE-RSA-AES256-GCM-SHA384 • AES256-GCM-SHA384 • ECDHE-ECDSA-AES128-GCM-SHA256 • ECDHE-RSA-AES128-GCM-SHA256 • DHE-RSA-AES128-GCM-SHA256 • AES128-GCM-SHA256
ECDH Configuration	Select from one of the options (19,20,21,none) in the ECDH Group. This feature is available from Security Manager version 4.9 onwards for ASA devices version 9.4(1) or later.
SSL DH Group Configuration	Select from one of the options (2, 5, 14, 15 and 24) in the SSL DH Group, DH group 14 is used by default. You can now use DH group 15 in SSL DH Group, for ASA 9.16(1) and later devices. **Note** Beginning with Cisco Security Manager 4.23, DH groups 2, 5, and 24 is unsupported in the SSL DH Group on ASA 9.16(1) and later devices.

Note Due to import regulations in some countries the Oracle implementation provides a default cryptographic jurisdiction policy file that limits the strength of cryptographic algorithms. If stronger algorithms need to be configured or are already configured on the device (for example, AES with 256-bit keys, DH group with 5,14,24), follow these steps:

1. Download the Java 7 unlimited strength cryptography policy .jar files from http://www.oracle.com. Cisco recommends to search for the following on the Oracle website:

Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files Java 7

(Click the download button to download the files by accepting the license agreement.)

1. Replace local_policy.jar and US_export_policy.jar on your Security Manager server in the folder CSCOpx\MDC\vms\jre\lib\security.
2. Restart your Security Manager server.

Reference Identities

Beginning with version 4.12, Security Manager enables you to configure Reference Identity policy objects for Secure Syslog Server connections on devices running the ASA software version 9.6(2) or later. This object enables support for Common Criteria requirements.

Reference identities are configured as one or more identifiers to be compared to the presented identifiers in the server certificate. Identifiers are specific instances of the four identifier types specified in RFC 6125.

Add/Edit Reference Identity Dialog Box

Use the Add/Edit Reference Identity Dialog Box to create a new Reference Identity policy object or to edit existing policy objects.

Navigation Path

Select **Manage > Policy Objects**, then select **Reference Identity** from the Object Type Selector. Right-click inside the work area, then select **New Object** or click the **+** button to add a new object, or right-click a row, then select **Edit Object.**

Field Reference

Table 610: Add/Edit Reference Identity Dialog Box

Element	Description
Name	Name of the Reference Identity policy object. Note that each Reference Identifier can have multi line values.
Description	Description of the Reference Identity policy object.
Common Name ID	A Relative Distinguished Name (RDN) in a certificate subject field that contains only one attribute-type-and-value pair of type Common Name (CN), where the value matches the overall form of a domain name. The CN value can be free text. A CN-ID reference identifier does not identify an application service.
Domain Name ID	A subjectAltName entry of type dNSName. This is a DNS domain name. A DNS-ID reference identifier does not identify an application service.
Service Name ID	A subjectAltName entry of type otherName whose name form is SRVName as defined in RFC 4985. A SRV-ID identifier may contain both a domain name and an application service type. For example, a SRV-ID of "_imaps.example.net" would be split into a DNS domain name portion of "example.net" and an application service type portion of "imaps."

Element	Description
Uniform Resource Identifier ID	A subjectAltName entry of type uniformResourceIdentifier whose value includes both (i) a “scheme” and (ii) a “host” component (or its equivalent) that matches the “reg-name” rule specified in RFC 3986. A URI-ID identifier must contain the DNS domain name, not the IP address, and not just the hostname. For example, a URI-ID of “sip:voice.example.edu” would be split into a DNS domain name portion of “voice.example.edu” and an application service type of “sip.”
Category	(Optional) Select a category between CAT-A and CAT-J.
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the Edit button to create, edit, and view the overrides. The Overrides field indicates the number of devices that have overrides for this object.

Note A reference identity is created when configuring one with a previously unused name. Once a reference identity has been created, the four identifier types and their associated values can be added or deleted from the reference identity. The reference identifiers MAY contain information identifying the application service and MUST contain information identifying the DNS domain name.

Configuring SNMP

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

The Simple Network Management Protocol (SNMP) enables monitoring of network devices from a central location. Cisco security appliances support network monitoring using SNMP versions 1, 2c, and 3, as well as traps and SNMP read access; SNMP write access is not supported.

You can configure a security appliance to send “traps” (event notifications) to a network management station (NMS), or you can use the NMS to browse the management information bases (MIBs) on the security appliance. Use CiscoWorks for Windows or any other SNMP MIB-II-compliant browser to receive SNMP traps and browse a MIB.

The security appliance has an SNMP agent that notifies designated management stations if specified events occur, for example, when a link in the network goes up or down. The notification includes an SNMP system object ID (OID), identifying the device to the management stations. The security appliance SNMP agent also replies when a management station asks for information.

SNMP MIBs and OIDs

An SNMP trap reports significant events occurring on a network device, most often errors or failures. SNMP traps are defined in Management Information Bases (MIBs), which can be either standard or enterprise-specific.

Standard traps and MIBs are created by the Internet Engineering Task Force (IETF) and documented in various RFCs. Standard traps are compiled into the security appliance software. If needed, you can also download RFCs, standard MIBS, and standard traps from the IETF website: http://www.ietf.org/ .

For Cisco MIB files and OIDs, refer to: http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml . OIDs may be downloaded from this FTP site: ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz.

This section contains the following topics:

SNMP Terminology

Here are definitions for some common SNMP terms:

- **Agent** – The SNMP server running on the security appliance. The agent responds to requests for information and action from the management station. The agent also controls access to its management information base (MIB), the collection of data objects that can be viewed or changed by the SNMP manager.
- **Management stations** – The PCs or workstations set up to monitor SNMP events and manage devices such as the security appliance. Management stations can also receive messages about events which require attention, such as hardware failures.
- **MIBs** – The agent maintains standardized data structures called Management Information Bases (MIBs), used to collect information, such as packet, connection and error counters, and buffer usage and failover status. A number of MIBs are defined for specific products, and for the common protocols and hardware standards used by most network devices. SNMP management stations can browse MIBs, or request only specific fields. In some applications, MIB data can be modified for administrative purposes.
- **OID** – The SNMP standard assigns a system object ID (OID) so that a management station can uniquely identify network devices with SNMP agents, and indicate to users the source of information monitored and displayed.
- **Traps** – Specified events that generate a message from the SNMP agent to the management station. Events include alarm conditions such as linkup, linkdown, coldstart, warmstart, authentication, or syslog events.

SNMP Version 3

SNMP Version 3 provides security enhancements that are not available in SNMP Version 1 or SNMP Version 2c. SNMP Versions 1 and 2c transmit data between the SNMP server and SNMP agent in clear text. SNMP Version 3 adds authentication and privacy options to secure protocol operations. In addition, this version controls access to the SNMP agent and MIB objects through the User-based Security Model (USM) and View-based Access Control Model (VACM). The ASA and ASASM also support the creation of SNMP groups and users, as well as hosts, which is required to enable transport authentication and encryption for secure SNMP communications.

Note SNMP Version 3 is supported on ASA devices running 8.2(1) or later and on ASASM devices running 8.5(1) or later.

Security Models

For configuration purposes, the authentication and privacy options are grouped together into security models. Security models apply to users and groups, which are divided into the following three types:

- NoAuth—No Authentication and No Privacy, which means that no security is applied to messages.
- Auth—Authentication but No Privacy, which means that messages are authenticated.
- Priv—Authentication and Privacy, which means that messages are authenticated and encrypted.

SNMP Groups

An SNMP group is an access control policy to which users can be added. Each SNMP group is configured with a security model, and is associated with an SNMP view. A user within an SNMP group must match the security model of the SNMP group. These parameters specify what type of authentication and privacy a user within an SNMP group uses. Each SNMP group name and security model pair must be unique.

SNMP Users

SNMP users have a specified username, a group to which the user belongs, authentication password, encryption password, and authentication and encryption algorithms to use. The authentication algorithm options are MD5 and SHA. The encryption algorithm options are DES, 3DES, and AES (which is available in 128, 192, and 256 versions). When you create a user, you must associate it with an SNMP group. The user then inherits the security model of the group.

SNMP Hosts

An SNMP host is an IP address to which SNMP notifications and traps are sent. To configure SNMP Version 3 hosts, along with the target IP address, you must configure a username, because traps are only sent to a configured user. SNMP target IP addresses and target parameter names must be unique on the ASA and ASA Services Module. Each SNMP host can have only one username associated with it. To receive SNMP traps, configure the SNMP NMS, and make sure that you configure the user credentials on the NMS to match the credentials for the ASA and ASASM.

Implementation Differences Between the ASA, ASA Services Module, and the Cisco IOS Software

The SNMP Version 3 implementation in the ASA and ASASM differs from the SNMP Version 3 implementation in the Cisco IOS software in the following ways:

- The local-engine and remote-engine IDs are not configurable. The local engine ID is generated when the ASA or ASASM starts or when a context is created.
- No support exists for view-based access control, which results in unrestricted MIB browsing.
- Support is restricted to the following MIBs: USM, VACM, FRAMEWORK, and TARGET.
- You must create users and groups with the correct security model.

- You must remove users, groups, and hosts in the correct sequence.
- Use of the **snmp-server host** command creates an ASA or ASASM rule to allow incoming SNMP traffic.

SNMP Page

Use the SNMP page to configure the security appliance for monitoring by Simple Network Management Protocol (SNMP) management stations.

Note For SNMP Version 3, configuration must occur in the following order: group, user, host.

Navigation Path

- (Device view) Select **Platform** > **Device Admin** > **Device Access** > **SNMP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Device Admin** > **Device Access** > **SNMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 611: SNMP Page

Element	Description
Enable SNMP Servers	When this option is selected, the security device provides SNMP information on the specified interface(s). You can deselect this option to disable SNMP monitoring while retaining the configuration information.

Element	Description
Read Community String Confirm	Enter the password used by a SNMP management station when sending requests to this device. The SNMP community string is a shared secret among the SNMP management stations and the network nodes being managed. The security device uses the password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces are not permitted. Repeat the password in the **Confirm** field to ensure it was entered correctly.
System Administrator Name	Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
Location	Describe the location of this security device (for example, **Building 42, Sector 54**). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
Port (PIX 7.x, ASA and FWSM 3.x only)	Specify the port on which incoming requests will be accepted. The default is 161.
Configure SNMP Traps	Click this button to configure SNMP traps in the SNMP Trap Configuration Dialog Box , on page 1947.
SNMP Engine ID	Shows the ID of the SNMP engine configured on the device. Click **Get SNMP Engine ID** to retrieve the engine ID from the device.
SNMP Hosts table	This table lists the SNMP management stations that can access the security appliance. This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, as described in Using Tables , on page 50. The Add Row and Edit Row buttons open the Add/Edit SNMP Host Access Entry Dialog Box , on page 1950, used to add and edit management station host entries. **Note** For ASA devices running 9.1(5) or later, you can configure up to 129 SNMP hosts. For other devices and earlier ASA versions, you can only configure up to 32 SNMP hosts.
SNMP Host Group table	Beginning with version 4.12, Security Manager enables you to add and edit the Host Group entries for SNMP Users. See Add/Edit SNMP Host Group Entry Dialog Box, on page 1951 for more information.
SNMPv3 Configuration	
SNMP Group tab	Lists the SNMP groups that have been configured. This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, as described in Using Tables , on page 50. The Add Row and Edit Row buttons open the Add/Edit SNMP Group Entry Dialog Box , on page 1952, used to add and edit SNMP groups.

Element	Description
SNMP User tab	Lists the SNMP users that have been configured. This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, as described in Using Tables , on page 50. The Add Row and Edit Row buttons open the Add/Edit SNMP User Entry Dialog Box , on page 1954, used to add and edit SNMP users.
SNMP User List tab	Beginning with version 4.12, Security Manager enables you to add a user list containing multiple SNMP users. See Add/Edit SNMP User List Entry Dialog Box , on page 1956 for more information.

SNMP Trap Configuration Dialog Box

Use the SNMP Trap Configuration dialog box to configure SNMP traps (event notifications) for the selected security device.

Traps are different than browsing; they are unsolicited "comments" from the managed device to the management station for certain events, such as **linkup**, **linkdown**, and **syslog event generated**.

An SNMP object ID (OID) for the device appears in SNMP event traps sent from the device. The SNMP service running on a security device performs two functions:

- Replies to SNMP requests from management stations.
- Sends traps to management stations or other devices that are registered to receive them from the security appliance.

Cisco security devices support three types of traps:

- firewall
- generic
- syslog

In the SNMP Trap Configuration dialog box, available traps are presented on four tabbed panels: Standard, Entity MIB, Resource, and Other.

Navigation Path

You can access the SNMP Trap Configuration dialog box from the SNMP Page , on page 1945.

Related Topics

- Configuring SNMP , on page 1942
- Add/Edit SNMP Host Access Entry Dialog Box , on page 1950

Field Reference

Table 612: SNMP Trap Configuration Dialog Box

Element	Description
Enable All SNMP Traps	Check this box to quickly select all traps on all four tabbed panels.
Enable Syslog Traps	Check this box to enable transmission of trap-related syslog messages. The severity level for syslog messages trapped is set on the Logging Filters Page , on page 2043.
Select the desired event-notification traps on the following four tabbed panels. Note that only the traps applicable to the selected device are displayed in the dialog box.	
Standard	• **Authentication** – Unauthorized SNMP access. This authentication failure occurs for packets with an incorrect community string. • **Link Up** – One of the device's communication links has become available (it has "come up"), as indicated in the notification. • **Link Down** – One of the device's communication links has failed, as indicated in the notification. • **Cold Start** – The device is reinitializing itself such that its configuration or the protocol entity implementation may be altered. • **Warm Start** – The device is reinitializing itself such that its configuration and the protocol entity implementation is unaltered.
Entity MIB	• **Field Replaceable Unit Insert** – A Field Replaceable Unit (FRU) has been inserted, as indicated. (FRUs include assemblies such as power supplies, fans, processor modules, interface modules, etc.) • **Field Replaceable Unit Delete** – A Field Replaceable Unit (FRU) has been removed, as indicated in the notification. • **Configuration Change** – There has been a hardware change, as indicated in the notification. • **Fan Failure** – A device cooling fan has failed, as indicated in the notification. • **CPU Temperature** – Temperature of the central processing unit has reached the configured limit. • **Power-Supply Failure** – A device power supply has failed, as indicated in the notification. • **Redundancy Switchover** – Switchover occurred for redundant component, as indicated in the notification. • **Alarm Asserted** – The condition described by the alarm exists. • **Alarm Cleared** – The condition described by the alarm does not exist.

Element	Description
Resource	• **Connection Limit Reached** – This trap indicates that a connection attempt was rejected because the configured connections limit has been reached. • **Resource Limit Reached** – This notification is generated when the configured resource limit is reached, as described in the notification. • **Resource Rate Limit Reached** – This notification is generated when the configured resource rate limit is reached, as described in the notification
Other	• **IKEv2 Start** – Internet Key Exchange version 2 (IKEv2) exchange initiated. • **IKEv2 Stop** – Internet Key Exchange version 2 (IKEv2) exchange terminated. • **Memory Threshold** – Available free memory has fallen below configured threshold, as indicated in the notification. • **ASA CPU Rising Threshold** – This notification is triggered when utilization of CPU resources exceeds the specified Percentage for a specified Period of time: **Percentage** – Enter the desired upper limit of CPU resource usage as a percentage of total available. Valid values range from 10 to 94; default is 70%. **Period** – Specify the length of time, in minutes, that the specified Percentage can be exceeded before notification is triggered. Valid values range from 1 to 60. • **Interface Threshold** – This notification is triggered when utilization of a physical interface exceeds the specified Percentage of total bandwidth: **Percentage** – Enter the desired upper limit on interface usage as a percentage of total available bandwidth. Valid values range from 30 to 99; default is 70%. • **IPSec Start** – IPsec has started, as indicated in the notification. • **IPSec Stop** – IPsec has stopped, as indicated in the notification. • **Remote Access Session Threshold Exceeded** – The number of remote access sessions has reach the defined limit, as indicated in the notification. • **NAT Packet Discard** – This notification is generated when IP packets are discarded by the NAT function. Available Network Address Translation addresses or ports have fallen below configured threshold. • **CPU Rising Threshold** – This notification is triggered when utilization of CPU resources exceeds the specified Percentage for a specified Period of time: **Percentage** – Enter the desired upper limit of CPU resource usage as a percentage of total available. Valid values range from 10 to 100; default is 70%. **Period** – Specify the length of time, in seconds, that the specified Percentage can be exceeded before notification is triggered. Valid values range from 60 to 3600.

Add/Edit SNMP Host Access Entry Dialog Box

Use the Add/Edit SNMP Host Access Entry dialog box to add and edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the security device.

For ASA devices running any software version between 9.1(5) and 9.3(2), you can configure 129 SNMP hosts. For ASA devices running the software version lower than 9.1(5) you can configure only 32 SNMP hosts.

Beginning with version 4.9, Security Manager enables you to configure up to 4096 SNMP hosts for ASA devices running the software version 9.4(1) or later. However, only 129 of this number can be for traps. You cannot configure more than 129 trap configured SNMP hosts.

Navigation Path

You can access the Add/Edit SNMP Host Access Entry dialog box from the SNMP Page , on page 1945.

Related Topics

- Add/Edit SNMP Group Entry Dialog Box , on page 1952
- Add/Edit SNMP User Entry Dialog Box , on page 1954

Field Reference

Table 613: Add/Edit SNMP Host Access Entry Dialog Box

Element	Description
Interface Name	Enter or Select the interface on which this SNMP management station contacts the device.
IP Address	Enter the IP address, or Select a Networks/Hosts object, representing the SNMP management station. **Note** Beginning with Cisco Security Manager version 4.17, IPv6 Address for SNMP policy is supported on ASA 9.9.2 devices and above. **Note** You can now configure network or range of the IPv6 address.
UDP Port	(Optional) Enter a UDP port for requests from the SNMP host. You can use this field to override the global value specified on the SNMP page.
Community String Confirm	Enter the password used by the SNMP management station when sending requests to the security device. The SNMP community string is a shared secret among the SNMP management stations and the network nodes being managed. Thus, the password is used to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces are not permitted. Repeat the password in the **Confirm** field.

Element	Description
SNMP Version	Choose the version of SNMP used by this management station: **1**, **2c**, or **3**.
SNMP User Name	If SNMP version 3 is selected, select the SNMP user. For information on SNMP users, see Add/Edit SNMP User Entry Dialog Box , on page 1954.
Server Poll/Trap Specification	Specify the type(s) of communication with this management station: poll only, trap only, or both trap and poll. Check either or both: • Poll – The security device waits for periodic requests from the management station. • Trap – The device sends trap events when they occur.

Add/Edit SNMP Host Group Entry Dialog Box

Beginning with Security Manager version 4.12, you can use the Add/Edit SNMP Host Group Entry dialog box to add and edit entries in the SNMP Host Group table on the SNMP page. These entries represent SNMP management stations allowed to access the security device.

For ASA devices running any software version between 9.1(5) and 9.4, you can configure 129 SNMP hosts. For ASA devices running the software version lower than 9.1(5) you can configure only 32 SNMP hosts.

Beginning with version 4.9, Security Manager enables you to configure up to 4096 SNMP hosts for ASA devices running the software version 9.4(1) or later. However, only 129 of this number can be for traps. You cannot configure more than 129 trap configured SNMP hosts.

Note If you edit a used Address Range or Network object in the Networks/Host Policy Object Manager after adding or editing SNMP Host or Host Group entries in the Add/ Edit SNMP Host Group entry page, Cisco Security Manager will not validate for the total number of SNMP traps. Thus, if the trap entries exceed 129, it will result in a deployment failure.

Navigation Path

You can access the Add/Edit SNMP Host Access Entry dialog box from the SNMP Page , on page 1945.

Related Topics

- Configuring SNMP , on page 1942

- Add/Edit SNMP User Entry Dialog Box , on page 1954

Field Reference

Table 614: Add/Edit SNMP Host Access Entry Dialog Box

Element	Description
Interface Name	Enter or Select the interface on which this SNMP management station contacts the device.
IP Address	Enter the IP address, or Select a Networks/Hosts object, representing the SNMP management station. **Note** SNMP Host Group Entry supports IPV6 grouping for the ASA 9.17(1) and above devices. You can configure the IPV6 network or range in the Add/Edit SNMP Host Access Entry Dialog Box .
UDP Port	(Optional) Enter a UDP port for requests from the SNMP host. You can use this field to override the global value specified on the SNMP page.
Community String Confirm	Enter the password used by the SNMP management station when sending requests to the security device. The SNMP community string is a shared secret among the SNMP management stations and the network nodes being managed. Thus, the password is used to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces are not permitted. Repeat the password in the **Confirm** field.
SNMP Version	Choose the version of SNMP used by this management station: **1**, **2c**, or **3**.
Server Poll/Trap Specification	Specify the type(s) of communication with this management station: poll only, trap only, or both trap and poll. Check either or both: • Poll – The security device waits for periodic requests from the management station. • Trap – The device sends trap events when they occur. **Note** You cannot enable both traps and polling for the same SNMP Host Group. If you need to enable this, Cisco recommends that you use the snmp-server host command for the relevant hosts.

Add/Edit SNMP Group Entry Dialog Box

Use the Add/Edit SNMP Group Entry dialog box to add and edit entries in the SNMP Groups table on the SNMP page. An SNMP group is an access control policy to which users can be added. Each SNMP group is configured with a security model, and is associated with an SNMP view. A user within an SNMP group must match the security model of the SNMP group. These parameters specify what type of authentication and privacy a user within an SNMP group uses. Each SNMP group name and security model pair must be unique.

For configuration purposes, the authentication and privacy options are grouped together into security models. Security models apply to users and groups, which are divided into the following three types:

- NoAuth—No Authentication and No Privacy, which means that no security is applied to messages.

- Auth—Authentication but No Privacy, which means that messages are authenticated.
- Priv—Authentication and Privacy, which means that messages are authenticated and encrypted.

Notes

- Before a group can be deleted, you must ensure that all users associated with that group are deleted. If any hosts are associated with a user that needs to be deleted, you must delete those hosts before you can delete the user.
- If users have been configured to belong to a particular group with a certain security model, you must do the following to change the security level of that group:
  1. Remove all host entries associated with any users belonging to the group.
  2. Remove the users from the group.
  3. Deploy the changes to the device.
  4. Change the group security level.
  5. Add users that belong to the group.
  6. Add hosts belonging to the users that were added for the group.
  7. Deploy the changes to the device.

Navigation Path

You can access the Add/Edit SNMP Group Entry dialog box from the SNMP Page , on page 1945.

Related Topics

- Configuring SNMP , on page 1942

- Add/Edit SNMP Host Access Entry Dialog Box , on page 1950
- Add/Edit SNMP User Entry Dialog Box , on page 1954

Field Reference

Table 615: Add/Edit SNMP Group Entry Dialog Box

Element	Description
Group Name	Enter the name of the SNMP group. Group names must be 32 characters or less.

Element	Description
Security Level	Specify the security level for the group: • NoAuth—No Authentication and No Privacy, which means that no security is applied to messages. • Auth—Authentication but No Privacy, which means that messages are authenticated. • Priv—Authentication and Privacy, which means that messages are authenticated and encrypted.

Add/Edit SNMP User Entry Dialog Box

Use the Add/Edit SNMP User Entry dialog box to add a user to an SNMP group or to edit entries in the SNMP User table on the SNMP page. SNMP users inherit the security model of the group to which they are assigned.

Notes

- After a user has been created, you cannot change the group to which the user belongs.
- Before a user can be deleted, you must ensure that no hosts are configured that are associated with that username.

Navigation Path

You can access the Add/Edit SNMP User Entry dialog box from the SNMP Page , on page 1945.

Related Topics

- Configuring SNMP , on page 1942
- SNMP Trap Configuration Dialog Box , on page 1947
- Add/Edit SNMP Host Access Entry Dialog Box , on page 1950
- Add/Edit SNMP Group Entry Dialog Box , on page 1952

Field Reference

Table 616: Add/Edit SNMP User Entry Dialog Box

Element	Description
Group Name	Select the SNMP group to which this user belongs. For information on SNMP groups, see Add/Edit SNMP Group Entry Dialog Box , on page 1952.

Element	Description
Security Level	Shows the security level for the selected group: • NoAuth—No Authentication and No Privacy, which means that no security is applied to messages. • Auth—Authentication but No Privacy, which means that messages are authenticated. • Priv—Authentication and Privacy, which means that messages are authenticated and encrypted.
User Name	Enter the name of the SNMP user. Usernames must be 32 characters or less and must be unique for the SNMP server group selected.
Engine ID (SNMP version v3 only)	The SNMP EngineID identifier used for authentication in v3. You can enter comma separated multiple Engine IDs. The Engine ID identifier must be valid, and each Engine Id must be within the range of 1 to 257 characters. • If you configure EngineID for an SNMP user with MD5 algorithm, the EngineID must be a valid one. If the EngineID is not valid, the preview config would fail with an error "failed to generate raw config". For example, the preview config fails if the EngineID entered is 111. • For an SNMP group with a security level of NoAuth, do not provide an EngineID identifier because on deployment, the ASA will ignore this engine ID and take the default local engine ID. • The following dynamic behaviors of the device cannot be handled in Security Manager: • If you upgrade a failover ASA device from version 8.x or 9.x to version 9.6(2), the device will automatically create multiple SNMP User commands for multiple SNMP Engine IDs. You must copy the Engine ID by retrieving it from the device into this Engine ID text box. For information about retrieving Engine ID from the device see SNMP Page , on page 1945. • If you add or remove an ASA device to or from a failover configuration, you must manually enter the Engine ID because the ASA device automatically removes or creates new SNMP User commands for the existing Engine IDs.
Encrypt Password Type	Specify the type of password you want to use: Clear Text or Encrypted. If the password type is Clear Text, Security Manager will encrypt the password when deploying to the device. If the password type is Encrypted, Security Manager will directly deploy the encrypted password. Security Manager will never directly deploy the clear text password to device.
Auth Algorithm Type	Specify the type of authentication you want to use: MD5, SHA, or SHA256. **Note** Beginning with version 4.21, Cisco Security Manager supports SHA256 authentication type for ASA 9.14(1) and higher devices. The MD5 authentication type will be deprecated in the upcoming ASA versions.

Element	Description
Authentication Password Confirm	Enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as *xx:xx:xx...* , where *xx* are hexadecimal values. **Note** The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less. If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.
Encryption Type	Specify the type of encryption you want to use: AES128, AES192, AES256, 3DES, DES. **Note** To use AES or 3DES encryption, you must have the appropriate license installed on the device.
Encryption Password Confirm	Enter the password to use for encryption. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as *xx:xx:xx...* , where *xx* are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows (where each *xx* is one octal): • AES 128 requires 16 octals • AES 192 requires 24 octals • AES 256 requires 32 octals • 3DES requires 32 octals • DES can be any size **Note** For all passwords, the length must be 256 characters or less. If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

Add/Edit SNMP User List Entry Dialog Box

Beginning with version 4.12, Security Manager enables you to use the Add/Edit SNMP User List Entry dialog box to add a user list containing multiple SNMP users.

Notes

- You cannot delete a user list if the list is used by a particular host group.
- You cannot delete an SNMP user if that user is referred to in a particular user list..

Navigation Path

You can access the Add/Edit SNMP User List Entry dialog box from the SNMP Page , on page 1945.

Field Reference

Table 617: Add/Edit SNMP User List Entry Dialog Box

Element	Description
User List Name	Enter the name of the User List. User List names must be 1-33 characters in length.
User Names	Select the user names from the drop-down list.

Telnet Page

Use the Telnet page to configure rules that permit only specific hosts or networks to connect to the firewall device using the Telnet protocol.

The rules restrict administrative Telnet access through a firewall device interface to a specific IP address and netmask. Connection attempts that comply with the rules must then be authenticated by a preconfigured AAA server or the Telnet password. You can monitor Telnet sessions using Monitoring > Telnet Sessions.

Note Only five Telnet sessions can be active at the same time in single-context mode. In multiple-context mode on ASAs, there can be only five Telnet sessions active per context, 100 Telnet sessions active per blade. With resource class, the administrator can further tune this parameter.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Telnet** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Device Access > Telnet** from the Policy Type selector. Right-click **Telnet** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Telnet Configuration Dialog Box , on page 1958

Field Reference

Table 618: Telnet Page

Element	Description
Timeout	Number of minutes a Telnet session can remain idle before the firewall device closes it. Values can range from 1 to 1440 minutes.
Telnet Access Table	
Interface	Interface that receives Telnet packets from the client.
IP Addresses	The IP address and network mask of each host or network that can access the Telnet console through the specified interface.

Telnet Configuration Dialog Box

Use the Telnet Configuration dialog box to configure Telnet options for an interface.

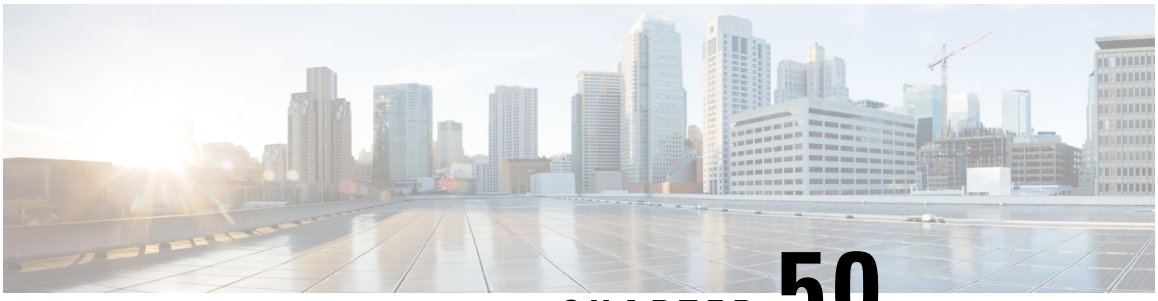
Navigation Path

You can access the Telnet Configuration dialog box from the Telnet Page , on page 1957.

Field Reference

Table 619: Telnet Configuration Dialog Box

Element	Description
Interface Name	Enter or Select an interface that can receive Telnet packets from a client. **Note** Beginning with Cisco Security Manager version 4.17, you can configure BVI interface for Telnet on ASA 9.9.2 devices and above. However, in multi-context, “Transparent” mode security context only supports BVI interface.
IP Addresses/Netmask	Enter or Select the IP address and netmask, separated by a “/”, of each host or network permitted to access the firewall device’s Telnet console through the specified interface. Use commas to separate multiple entries. **Note** To limit access to a single IP address, use 255.255.255.255 or 32 as the netmask. Do not use the subnetwork mask of the internal network. **Note** Beginning with version 4.13, Cisco Security Manager supports policies—Groups, Hosts, Address Range, and Network for IPv6 devices.



CHAPTER 50

Configuring Failover

The Failover page provides access to failover settings for the selected security appliance. The available settings and the overall appearance of the Failover page may change slightly, depending upon the type of device selected, its mode of operation (routed or transparent), and its context mode (single or multiple).

In other words, how you configure failover depends upon both the operating mode and the security context of the security appliance.

Please note the following caveats when assigning an interface as a failover link:

- You can define the interface in the Add/Edit Interface dialog box, but do not configure it. In particular, do not specify an interface Name, as this parameter disqualifies the interface from being used as the failover link. See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for more information.
- IPv6 addresses are not supported for failover links.
- On an ASA 5505, an interface assigned as the backup for another interface cannot be used as a failover link (although no checking is performed to prevent this).
- Do not assign a PPPoE-enabled interface as a failover link. PPPoE and Failover should not be configured on the same device interface (although no checking is performed to prevent this).
- A failover interface cannot use the same IP address as another interface, especially the Management IP address (although no checking is performed to prevent this).

Note also that after you assign an interface as a failover link, the interface is listed on the Interfaces page, but you cannot edit or delete the interface from that page. The only exception is if you set a physical interface to be the stateful failover link—you can configure its speed and duplex.

This chapter contains the following topics:

Understanding Failover

Failover lets you configure two identical security appliances such that one will take over firewall operations if the other fails. Using a pair of security appliances, you can provide high system availability without operator intervention.

The linked security appliances communicate failover information over a dedicated link. This failover link can be either a LAN-based connection or, on PIX security appliances, a dedicated serial failover cable. The following information is communicated over the failover link:

- Current failover state (active or standby)
- "Hello" messages (also called "keep-alives")
- Network link status
- MAC address exchange
- Configuration replication
- Per-connection state information, in the case of Stateful failover

Caution All information sent over the failover link is sent in clear text unless you secure the communication with a failover key. If the security appliance is used to terminate VPN tunnels, this information includes any user names, passwords, and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing failover communications with a failover key, particularly if you are using the security appliance to terminate VPN tunnels.

Cisco security appliances support two types of failover:

- **Active/Standby** – The *active* security appliance inspects all network traffic, while the *standby* security appliance remains idle until a failure occurs on the active appliance. Changes to the configuration of the active security appliance are transmitted over the failover link to the standby security appliance.

When failover occurs, the standby security appliance becomes the active unit, and it assumes the IP and MAC addresses of the previously active unit. Because other devices on the network do not see any changes in the IP or MAC addresses, ARP entries do not change or time-out anywhere on the network.

Active/Standby failover is available to security appliances operating in single- or multiple-context mode. In single-context mode, only Active/Standby failover is available, and all failover configuration is by means of the Failover page.

Note When using Active/Standby failover, you must make all configuration changes on the active unit. The active unit automatically replicates the changes to the standby unit. The standby unit should not be imported or added to the Security Manager device list. Also, you must manually copy the authentication certificate from the active device to the standby device. See Additional Steps for an Active/Standby Failover Configuration, on page 1967 for additional information.

- **Active/Active** – Both security appliances inspect network traffic by alternating their roles—such that one is active and one is standby—on a per context basis. This means Active/Active failover is available only on security appliances operating in multiple-context mode.

However, Active/Active failover is not required in multiple-context mode. That is, on a device operating in multiple-context mode, you can configure Active/Standby or Active/Active failover. In either case, you provide system-level failover settings in the system context, and context-level failover settings in the individual security contexts.

See Active/Active Failover , on page 1961 for additional information about this topic.

In addition, failover can be stateless or stateful:

- **Stateless** – Also referred to as "regular" failover. With stateless failover, all active connections are dropped when failover occurs. Clients need to re-establish connections when the new active unit takes over.
- **Stateful** – The active unit in the failover pair continually passes per-connection state information to the standby unit. When failover occurs, the same connection information is available on the new active unit. Supported end-user applications are not required to reconnect to maintain the current communication session.

See Stateful Failover , on page 1963 for more information.

- Basic Failover Configuration , on page 1963
- Failover Policies , on page 1968

Active/Active Failover

Active/Active failover is available only on security appliances operating in multiple-context mode. In an Active/Active failover configuration, both security appliances inspect network traffic, on a per-context basis. That is, for each context, one of the appliances is the active device, while the other is the standby device.

The active and standby roles are assigned over the complete set of security contexts, more or less arbitrarily.

To enable Active/Active failover on the security appliance, you must assign the security contexts to one of two failover groups. A failover group is a simply a logical group of one or more security contexts. You should specify failover group assignments on the unit that will have failover group 1 in the active state. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default.

As in Active/Standby failover, each unit in an Active/Active failover pair is given a primary or secondary designation. Unlike Active/Standby failover, this designation does not indicate which unit is active when both units start simultaneously. Each failover group in the configuration is given a primary or secondary role preference. This preference determines the unit on which the contexts in the failover group appear in the active state when both units start simultaneously. You can have both failover groups be in the active state on a single unit in the pair, with the other unit containing the failover groups in the standby state. However, a more typical configuration is to assign each failover group a different role preference to make each one active on a different unit, balancing the traffic across the devices.

Note To reliably manage security contexts in Active/Active failover mode, Cisco Security Manager requires an IP address for the management interface of each context so that it can communicate directly with the active security context of a failover pair.

Initial configuration synchronization occurs when one or both units start. This synchronization occurs as follows:

- When both units start simultaneously, the configuration is synchronized from the primary unit to the secondary unit.
- When one unit starts while the other unit is already active, the unit that is starting up receives the configuration from the already active unit.

After both units are running, commands are replicated from one unit to the other as follows:

- Commands entered within a security context are replicated from the unit on which the security context is in the active state to the peer unit.

Note A context is considered in the active state on a unit if the failover group to which it belongs is in the active state on that unit.

- Commands entered in the system execution space are replicated from the unit on which failover group 1 is in the active state to the unit on which failover group 1 is in the standby state.
- Commands entered in the admin context are replicated from the unit on which failover group 1 is in the active state to the unit on which failover group 1 is in the standby state.

Failure to enter the commands on the appropriate unit for command replication to occur will cause the configurations to be out of synchronization. Those changes may be lost the next time the initial configuration synchronization occurs.

Note When bootstrapping the peer devices in an Active/Active Failover configuration, the bootstrap configurations are only applied to the system contexts of the respective failover peer devices.

In an Active/Active failover configuration, failover occurs on a failover group basis, not a system basis. For example, if you designate both failover groups as active on the primary unit, and failover group 1 fails, failover group 2 remains active on the primary unit, while failover group 1 becomes active on the secondary unit.

Note When configuring Active/Active failover, make sure that the combined traffic for both units is within the capacity of each unit.

Stateful Failover

Note Stateful failover is not supported on the ASA 5505 appliance.

When stateful failover is enabled, the active unit in the failover pair continually updates the current connection-state information on the standby unit. When failover occurs, supported end-user applications are not required to reconnect to maintain the current communication session.

Note The IP and MAC addresses for the state and LAN failover links do not change at failover.

To employ stateful failover, you must configure a link to pass all state information to the standby unit. If you are using a LAN failover connection rather than the serial failover interface (which is available only on the PIX platform), you can use the same interface for the state link and the failover link. However, we recommend that you use a dedicated interface for passing state information to the standby unit.

The following information is passed to the standby unit when stateful failover is enabled:

- NAT translation table
- TCP connection table (except for HTTP), including the timeout connection
- HTTP connection states (if HTTP replication is enabled)
- H.323, SIP and MGCP UDP media connections
- The system clock
- The ISAKMP and IPsec SA table

The following information is not copied to the standby unit when stateful failover is enabled:

- HTTP connection table (unless HTTP replication is enabled)
- The user authentication (UAUTH) table
- The ARP table
- Routing tables

Basic Failover Configuration

The following steps describe basic failover configuration. Please note the following caveats when assigning an interface as a failover link:

- You can define the interface in the Add/Edit Interface dialog box, but do not configure it. In particular, **do not specify an interface Name**, as this parameter disqualifies the interface from being used as the failover link.
- On an ASA 5505, an interface assigned as the backup for another interface cannot be used as a failover link (although no checking is performed to prevent this).

- Do not assign a PPPoE-enabled interface as a failover link. PPPoE and Failover should not be configured on the same device interface (although no checking is performed to prevent this).
- A Failover interface cannot use the same IP address as another interface, especially the Management IP address (although no checking is performed to prevent this).

Note When you save a failover configuration, it is applied to both the security appliance and the failover peer.

Before You Begin

Licenses installed on the device must allow failover configurations. On ASA 5505 and 5510 devices, this failover license is an optional license. You must install the failover license outside of Security Manager, using ASDM or the device CLI, and ensure that the **License Supports Failover** option is selected in the General page of the device properties (right-click the device and select **Device Properties**). If the license is installed when you add the device to the inventory, or you install the license and then rediscover device policies, Security Manager can identify the license and set this option appropriately.

If the option is selected and the license is not in fact installed, you will see deployment failures. If the option is not selected, Security Manager will not deploy the failover policy to the device even if you configure the policy.

Related Topics

- Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835
- Understanding Failover , on page 1960
- Additional Steps for an Active/Standby Failover Configuration, on page 1967
- Failover Policies , on page 1968

Step 1 Ensure Device View is your present application view; if necessary, click the **Device View** button on the toolbar.

Note For more information on using the Device View to configure device policies, see Managing Policies in Device View and the Site-to-Site VPN Manager , on page 196.

Step 2 Select the appliance you want to configure.

Step 3 Expand the **Platform** entry in the Device Policy selector, then expand **Device Admin** and select **Failover**.

The Failover page is displayed.

Step 4 (PIX only) Choose the **Failover Method**: **Serial Cable** or **LAN Based**. If you choose Serial Cable, the LAN Failover settings are disabled; be sure the cable connecting the two devices is in place.

Step 5 Select **Enable Failover** to enable failover on this appliance.

Step 6 (Optional) Click the Settings button to open the Settings dialog box for the selected device. The contents of the Settings dialog box depend on the type of device, and whether it is operating in single or multiple mode—some options may not be available. Refer to the following sections:

- Settings Dialog Box , on page 1980 (ASA/PIX 7+)
- Advanced Settings Dialog Box , on page 1974 (FWSM)

Step 7 Click the **Bootstrap** button to open the Bootstrap configuration for LAN failover dialog box, which provides bootstrap configurations that can be applied to the primary and secondary devices in a LAN failover configuration. See Bootstrap Configuration for LAN Failover Dialog Box , on page 1986 for more information.

Step 8 (Multiple-context devices only) In the Configuration section, select the failover mode: **Active/Active** or **Active/Standby**.

Step 9 (Optional) Follow these steps to configure an interface for **LAN Failover** communications between the two devices:

a) Assign a device **Interface** for LAN-based communications, and then press the Tab key on your keyboard to update the page.

On PIX and ASA devices, this drop-down list displays the interfaces defined on the device. You can type in a port ID (e.g., *gigabitethernet1*), or you can choose the port if you have already defined the interface.

On an FWSM, the Interface list is not populated with VLAN IDs; you must enter the numeric ID of the VLAN you wish to use.

Note In both cases, this cannot be a Named interface, nor can the interface be configured for PPPoE.

b) Provide a **Logical Name** for this failover interface.
c) Enter the **Active IP** address for failover communications.
d) Enter a **Standby IP** address for failover communications. The Standby IP address is used on the security appliance that is currently the standby unit.
e) Enter the **Subnet Mask** for both IP addresses. Both must be on the same subnet.

Step 10 (Optional) Follow these steps to enable and configure an interface for **Stateful Failover** communications between the two devices:

a) Assign a device **Interface** for update communications, and then press the Tab key on your keyboard to update the page.

You can type in a port ID (e.g., *gigabitethernet1*), or you can choose the port if you have already defined the interface; note that this cannot be a Named interface.

Note On an FWSM, this is a **VLAN** interface.

b) Provide a **Logical Name** for this interface.
c) Enter the **Active IP** address for connection updates.
d) Enter a **Standby IP** address for update communications.
e) Enter the **Subnet Mask** for both IP addresses. Both must be on the same subnet.
f) Select **Enable HTTP Replication** to preserve HTTP connection information.

Connection information is communicated to the standby unit for all TCP protocols except HTTP, because HTTP connections are generally short-lived. Select this option to maintain HTTP connections during failover.

Step 11 Provide a communications-encryption key: enter a **Shared Key** and then repeat it in the **Confirm** field. Be sure to enter the same key on both devices. (Not available on FWSM versions prior to 3.1)

The Shared Key can be any arbitrary string of up to 63 alphanumeric characters. If **HEX** is checked, the Shared Key is an arbitrary string of exactly 32 hexadecimal characters. (The HEX option is available only on PIX/ASA version 7.0.5 and later, and FWSM versions 3.1.3 and later.)

Note This step is optional, but we strongly recommend encrypting failover communications.

Step 12 To specify a failover reconnect timeout value for asymmetrically routed sessions, enter a length of time in the **Timeout** field, in the form hh:mm:ss (the minutes and seconds values are optional). If the field is blank (the default), or contains a zero, reconnections are prevented. Setting this value to -1 disables the timeout, allowing connections to reconnect after any amount of time.

Step 13 (Optional) You can configure Bidirectional Forwarding Detection (BFD), to communicate with a failover pair and this can be used to monitor the health of the failover unit. Create or select a BFD template from the Health-Check Monitoring section.

Note This is applicable only for Firepower failover devices running ASA 9.7.1 and above.

Tip BFD failover commands are supported only in the Active/Standby mode.In a multi-context device, BFD failover commands are supported only in the system context.BFD Failover commands are not supported in the transparent mode.

Step 14 (FWSM only) – Configured interfaces are listed in the Interface Configuration table. To edit the failover configuration for a listed interface, select it and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box , on page 1983.

Adding A Security Context to Failover Group 2

To add a new security context to an existing failover group 2, you must save the new context configuration to a deployment file and then manually add it to the appropriate device. Otherwise, until the first successful deployment, Security Manager will attempt to communicate with the new context through the device's Admin context. This will fail since group 2 cannot be reached through the Admin context (unless both group 1 and 2 are active on the same device).

The following steps outline creating a new security context and adding it to failover group 2.

1. Create the new security context.

   Be sure to define: context Name, Configuration URL, assign an Interface, choose Failover Group 2, and provide a Management IP Address. See Managing Security Contexts , on page 2290 for more information.

2. Save and submit these changes.

3. Provide the following context-configuration information, saving each change as you go:

   - On the Credentials page of the Device Properties window for the new context, provide Username and Password. See Viewing or Changing Device Properties , on page 109 for additional information.
   - On the context's Interfaces page, edit the assigned interface, providing a Name, IP address and Subnet Mask. See Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835 for additional information.
   - On the context's Failover Page (ASA/PIX 7.0+) , on page 1976, edit the interface configuration to provide a Standby IP Address.
   - On the HTTP Page , on page 1928, check Enable HTTP Server and then define HTTP access.
   - On the Credentials page, provide the Username and Password to be used when contacting the context. See Configuring Device Credentials , on page 1921 for additional information.

4. Choose **Deploy** from the Configuration Manager's File menu. Submit your changes, and then in the Deploy Saved Changes dialog box, be sure only this new context is selected, and then click Edit Deploy method. In the Edit Deploy Method dialog box, change the Method to File and then specify the Destination and a file name. Click OK to close the Edit Deploy Method dialog box, and then click Deploy the Deploy Saved Changes dialog box.

5. After uploading the configuration file to the device, use the CLI to enable HTTP access for the context. For example:
6. The context configuration is saved to the specified file. See Deploying to a File , on page 391 for more information about this step.

```
ciscoasa/group2(config-if)#  int g3/0
ciscoasa/group2(config-if)# nameif man
ciscoasa/group2(config-if)# security-level 100
ciscoasa/group2(config-if)# ip add 203.0.113.176 255.255.254.0 st 203.0.113.177
ciscoasa/group2(config-if)# exit
ciscoasa/group2(config)# http serv ena
ciscoasa/group2(config)# http 0.0.0.0 0.0.0.0 man
ciscoasa/group2(config)# username cisco pass cisco
ciscoasa/group2(config)#wr
```

Following this process, any new changes to the context can be successfully deployed to the context with Security Manager (attempts to reach the context will not go through the Admin context's management IP address).

Alternative

Another approach to this issue is to add the new context to failover group 1 first, and then perform the configuration via Security Manager. However, in order to then move this context to failover group 2, both groups (1 and 2) must be active on the same device. Otherwise, this error will be reported:

```
"join-failover-group 2
ERROR: Command requires failover-group 2 and 1 to be in the same state or no nameif comand
 for all interfaces in this context"
```

Additional Steps for an Active/Standby Failover Configuration

Cisco Security Manager lets you authenticate a PIX/ASA/FWSM device by validating the certificate installed on the device. When configuring firewalls in an active/standby failover configuration, you must manually copy the certificate from the active device to the standby device so that Security Manager can communicate with the standby device after a failover occurs.

The following procedures describe how to export or display the identity certificate, CA certificate, and keys for a security appliances in your network using ASDM, and then import that information onto a standby device using ASDM.

- Exporting the Certificate to a File or PKCS12 data, on page 1967
- Importing the Certificate onto the Standby Device, on page 1968

Exporting the Certificate to a File or PKCS12 data

To export a trustpoint configuration, follow these steps using ASDM:

Step 1 **Go to Configuration > Features > Device Administration > Certificate > Trustpoint > Export**.

Step 2 Fill in the Trustpoint Name, Encryption Passphrase, and Confirm Passphrase fields. For information on these fields, click Help.

Step 3 Select a method for exporting the trustpoint configuration.

- Export to a File—Type the filename or browse for the file.
- Display the trustpoint configuration in PKCS12 format—Display the entire trustpoint configuration in a text box and then copy it for importing. For more information, click Help.

Step 4 Click **Export**.

Importing the Certificate onto the Standby Device

To import a trustpoint configuration, follow these steps using ASDM:

Step 1 **Go to Configuration > Features > Device Administration > Certificate > Trustpoint > Import**.

Step 2 Fill in the Trustpoint Name, Decryption Passphrase, and Confirm Passphrase fields. For information on these fields, click Help. The decryption passphrase is the same as the encryption passphrase used when the trustpoint configuration was exported.

Step 3 Select a method for importing the trustpoint configuration.

- Import from a File—Type the filename or browse for the file.
- Enter the trustpoint configuration in PKCS12 format—Paste the entire trustpoint configuration from the exported source into a text box. For more information, click Help.

Failover Policies

This section lists the pages that describe configuring failover on various types of security appliances; the pages are organized by device type.

PIX 6.x Firewalls

- Failover Page (PIX 6.3) , on page 1969
  - Edit Failover Interface Configuration Dialog Box (PIX 6.3) , on page 1970
  - Bootstrap Configuration for LAN Failover Dialog Box , on page 1986

Firewall Services Modules

- Failover Page (FWSM) , on page 1972
  - Advanced Settings Dialog Box , on page 1974
  - Add/Edit Interface MAC Address Dialog Box , on page 1982
  - Edit Failover Interface Configuration Dialog Box , on page 1983
  - Bootstrap Configuration for LAN Failover Dialog Box , on page 1986

Adaptive Security Appliances and PIX 7.0 Firewalls

- Failover Page (ASA/PIX 7.0+) , on page 1976
  - Settings Dialog Box , on page 1980
  - Edit Failover Group Dialog Box , on page 1984
  - Edit Failover Interface Configuration Dialog Box , on page 1983
  - Add/Edit Interface MAC Address Dialog Box , on page 1982
  - Bootstrap Configuration for LAN Failover Dialog Box , on page 1986

Failover Page (PIX 6.3)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

Use the Failover page to configure failover settings for a PIX 6.3.x Firewall.

Navigation Path

Select a PIX 6.3.x device in Device View and then select **Platform** > **Device Admin** > **Failover** from the Device Policy selector.

Related Topics

- Understanding Failover , on page 1960
- Failover Policies , on page 1968

Field Reference

Table 620: Failover Page (PIX 6.3)

Element	Description
Failover	
Failover Method	Choose the type of failover link: **Serial Cable** or **LAN Based**. If you choose Serial Cable, ensure the physical cable is connected to both devices.
Enable Failover	Check this box to enable failover on this device. Ensure that both devices have the same software version, activation key type, flash memory, and RAM. On PIX devices with LAN Based chosen as the Failover Method, you must next configure the logical LAN Failover interface and, optionally, the stateful failover interface.

Element	Description
Bootstrap button	Click to display the Bootstrap Configuration for LAN Failover dialog box. See Bootstrap Configuration for LAN Failover Dialog Box , on page 1986 for more information.
Failover Poll Time	Specify the amount of time between hello messages among units. Values can range from 3 to 15 seconds; default is 15.
LAN-Based Failover These fields are available when LAN Based is the chosen Failover Method.	
Interface	Choose the interface to be used for LAN-based failover. If "Not Selected" is chosen, LAN-based failover is disabled.
Shared Key Confirm	Used to encrypt communications between the primary and standby devices. Value can be any alphanumeric string. Re-enter the Shared Key in the Confirm field.
Stateful Failover (Optional) To configure Stateful Failover , on page 1963, provide the following parameters.	
Interface	Choose the interface to be used for Stateful Failover. If "Not Selected" is chosen, Stateful Failover is disabled. **Note** You must choose a fast LAN link from the list (for example, 100full, 1000full, or 1000sxfull).
Enable HTTP Replication	When selected, active HTTP sessions are copied to the standby firewall. Otherwise, HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link.
Interface Configuration The table lists all available named interfaces. To define a Standby IP address and Active and Standby MAC addresses for an interface, select it in the list and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box (PIX 6.3) , on page 1970.	

Edit Failover Interface Configuration Dialog Box (PIX 6.3)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

Use the Edit Failover Interface Configuration dialog box to configure failover interfaces for the selected PIX 6.3.x device.

Note The failover interface cannot be configured for PPPoE.

Navigation Path

You can access the Edit Failover Interface Configuration dialog box from the Interface Configuration table on the Failover Page (PIX 6.3) , on page 1969.

Related Topics

- Failover Policies , on page 1968

Field Reference

Table 621: Edit Failover Interface Configuration Dialog Box (PIX 6.3)

Element	Description
Interface	The name of the interface; read-only.
Active IP Address	Displays the IP address of the active interface. This address is used by the standby device to communicate with the active device. The address must be on the same network as the system IP address. The active IP address of this interface; read-only. This address is used by the standby device to communicate with the active device. This field is blank if an IP address has not been assigned to the interface. **Tip** You can use this IP address with the ping tool to check the status of the active device.
Netmask	The subnet mask for the active IP address; read-only. This field is blank if an IP address has not been assigned to the interface.
Standby IP Address	Specify the IP address of the corresponding interface on the standby failover unit. This address is used by the active device to communicate with the standby device. The address must be on the same network as the system IP address. This field does not appear if an IP address has not been assigned to the interface. **Tip** You can use this IP address with the ping tool to check the status of the standby device.
Failover MAC Addresses These parameters let you define virtual MAC addresses for a physical interface that is configured for failover; these addresses are optional.	
Active MAC Address	Specify a MAC address for the active interface in hexadecimal format (for example, 0123.4567.89ab).
Standby MAC Address	Specify a MAC address for the standby interface in hexadecimal format (for example, 0123.4567.89ab).

Failover Page (FWSM)

Note From version 4.17, though Cisco Security Manager continues to support FWSM features/functionality, it does not support any bug fixes or enhancements.

Use the Failover page to configure basic failover settings for the selected Firewall Services Module (FWSM).

Navigation Path

To access this feature, select a FWSM in Device View and then select **Platform > Device Admin > Failover** from the Device Policy selector.

Related Topics

- Additional Steps for an Active/Standby Failover Configuration, on page 1967
- Bootstrap Configuration for LAN Failover Dialog Box , on page 1986

Field Reference

Table 622: Failover Page (FWSM)

Element	Description
Enable Failover	Check this box to enable failover on this device. Ensure that both devices have the same software version, activation key, flash memory, and RAM. You must next configure the logical LAN Failover interface and, optionally, the stateful failover interface.
Settings button	Click to display the Advanced Settings Dialog Box , on page 1974, used to define when failover should occur.
Configuration This section is presented only for FWSM 3.1.1+ devices operating in multiple-context mode.	
Active/Active	In an Active/Active failover configuration, both security appliances inspect network traffic, on a per-context basis. That is, for each context, one of the appliances is the active device, while the other is the standby device. To enable Active/Active failover on the device, you must assign the security contexts to one of two failover groups. A failover group is a simply a logical group of one or more security contexts. You should specify failover group assignments on the unit that will have failover group 1 in the active state. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default. See Add/Edit Security Context Dialog Box (FWSM) , on page 2291 for information about assigning a context to a failover group.

Element	Description
Active/Standby	In an Active/Standby configuration, the active security appliance handles all network traffic passing through the failover pair. The standby security appliance does not handle network traffic until a failure occurs on the active security appliance. Whenever the configuration of the active security appliance changes, it sends configuration information over the failover link to the standby security appliance. When a failover occurs, the standby security appliance becomes the active unit. It assumes the IP and MAC addresses of the previously active unit. Because the other devices on the network do not see any changes in the IP or MAC addresses, ARP entries do not change or time out.
LAN Failover	
VLAN	Enter the numeric ID of the VLAN interface you are using for the failover link; for example, 11. This list is not automatically populated with VLAN IDs—you must highlight "Not Selected" and type the desired VLAN ID number; press your keyboard's Tab key to activate the related fields. When configured for failover, the interface is directly connected to the standby device.
Logical Name	Enter a logical name for the failover VLAN interface.
Active IP Address	Specify the active IP address for this interface.
Standby IP Address	Specify a standby IP address for this interface. To receive packets from both units in a failover pair, standby IP addresses need to be configured on all interfaces. The Standby IP address is used on the security appliance that is currently the standby unit, and it must be in the same subnet as the active IP address.
Subnet Mask	Enter the Subnet Netmask for the Active and Standby IP addresses.
Bootstrap button	Click to display the Bootstrap Configuration for LAN Failover dialog box. See Bootstrap Configuration for LAN Failover Dialog Box , on page 1986 for more information.
Stateful Failover (Optional) To configure Stateful Failover , on page 1963, provide the following parameters.	
VLAN	Enter the numeric ID of the VLAN interface you are using for the failover link; for example, 12. This list is not automatically populated with VLAN IDs—you must highlight "Not Selected" and type the desired VLAN ID number; press your keyboard's Tab key to activate the related fields. When configured for failover, the interface is directly connected to the standby device.
Logical Name	Enter a logical name for the Stateful failover VLAN interface.
Active IP Address	Specify the active IP address for this interface.

Element	Description
Standby IP Address	Specify a standby IP address for this interface. To receive packets from both units in a failover pair, standby IP addresses need to be configured on all interfaces. The Standby IP address is used on the security appliance that is currently the standby unit, and it must be in the same subnet as the active IP address.
Subnet Mask	Enter the Subnet Netmask for the Active and Standby IP addresses.
Enable HTTP Replication	When selected, allows stateful failover to copy active HTTP sessions to the standby firewall. Otherwise, HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link.
Shared Key (FWSM 3.1.1+ only) The options in this section let you encrypt the communications between the active and standby devices by providing a shared encryption key. **Caution** All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If this device is used to terminate VPN tunnels, this information includes any user names, passwords and shared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communications with a shared key.	
Shared Key Confirm	Enter any string of characters up to 63 numbers, letters and punctuation characters. This string is used to generate the encryption key. Re-enter this string the **Confirm** field. If you select **HEX**, the entry in the Shared Key and Confirm fields must be exactly 32 hexadecimal characters (0-9, a-f).
Interface Configuration This table is presented on the Failover page for devices operating in single-context mode, or for individual security contexts only. The table lists all available named interfaces. To enable or disable monitoring of an interface, select it in the list and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box , on page 1983. Select or deselect **Monitor this interface for failure**.	

Advanced Settings Dialog Box

The Advanced Settings dialog box lets you configure additional failover settings for the selected FWSM.

Note The following reference table describes all fields that can be presented in the Advanced Settings dialog box. The fields actually presented depend on operating mode (routed or transparent) and whether the device is hosting single or multiple contexts.

Navigation Path

You can access the Advanced Settings dialog box by clicking the Settings button on the Failover Page (FWSM) , on page 1972.

Table 623: Advanced Settings Dialog Box

Element	Description
Interface Policy Select a failed-interfaces option and provide an appropriate value.	
Number of failed interfaces	When the number of failed monitored interfaces exceeds this value, the security appliance fails over. Valid values range from 1 to 250.
Percentage of failed interfaces	When the number of failed monitored interfaces exceeds this percentage, the security appliance fails over.
Failover Poll Time These fields define how often hello messages are sent on the failover link, and how long to wait before testing the peer for failure if no hello messages are received.	
Unit Failover	The amount of time between hello messages between failover units. Enter a value between 1 and 15 seconds, or if **msec** is checked, between 500 and 999 milliseconds.
Unit Hold Time	The amount of time to wait for a hello message on the failover link, after which the unit begins testing for peer failure. Enter a value between 3 and 45 seconds. This value must be at least three times the Unit Failover value.
Monitored Interface	The amount of time between polls among interfaces. Enter a value between 3 and 15 seconds.
MAC Address Mapping In Active/Standby mode, this table lists interface-virtual MAC address mappings. This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, which are described in Using Tables , on page 50. To add or edit interface mappings, click the Add Row or Edit Row button to open the Add/Edit Interface MAC Address Dialog Box , on page 1982.	
Failover Groups In Active/Active mode, this table lists both failover groups. To edit failover parameters for either group, select it in the list and click the Edit Row button to open the Edit Failover Group Dialog Box , on page 1984.	

Element	Description
Bridge Group Configuration	
In single-context transparent mode, this table lists all currently defined bridge groups (see Managing Device Interfaces, Hardware Ports, and Bridge Groups , on page 1835). To add a standby IP address to a bridge group, select it in the list and click the Edit Row button to open the Edit Failover Bridge Group Configuration Dialog Box , on page 1976.	

Edit Failover Bridge Group Configuration Dialog Box

Use this dialog box to add a standby IP address to a failover bridge group.

Navigation Path

You can access the Edit Failover Bridge Group Configuration dialog box as follows:

- On the Failover page presented for an individual security context in transparent mode on an ASA.
- From the Bridge Group Configuration table in the Advanced Settings Dialog Box , on page 1974 presented by an FWSM in transparent mode.

Related Topics

Field Reference

Table 624: Edit Failover Bridge Group Configuration Dialog Box

Element	Description
Name	Identifies the bridge group; not editable.
IP Address	Identifies the IP address assigned to the bridge group; not editable.
Network Mask	Identifies the subnet mask for the IP Address; not editable.
Standby Address	Enter the IP address of the standby bridge group; this address must be on the same subnet as the primary address.

Failover Page (ASA/PIX 7.0+)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

Use the Failover page to configure basic failover settings for ASA and PIX 7.0+ security devices

Note The features and options presented on the Failover page vary according to type of device selected, operating system version, firewall mode (routed or transparent), and security contexts (single or multiple). Thus, some of the elements described in the following table may not appear on the Failover page for your currently selected device.

Navigation Path

Select an ASA or PIX 7.0+ in Device View and then select **Platform > Device Admin > Failover** from the Device Policy selector.

Field Reference

Table 625: Failover Page (ASA/PIX 7.0+)

Element	Description
Failover Method	Choose the type of failover link: **Serial Cable** or **LAN Based**. If you choose Serial Cable, ensure the physical cable is connected to both devices. **Note** This option is available only on PIX devices.
Enable Failover	Check this box to enable failover on this device. Ensure that both devices have the same software version, activation key type, flash memory, and RAM. On PIX devices with LAN Based chosen as the Failover Method, and on all ASAs, you must next configure the logical LAN Failover interface and, optionally, the stateful failover interface.
Bootstrap button	Click to display the Bootstrap Configuration for LAN Failover dialog box. See Bootstrap Configuration for LAN Failover Dialog Box , on page 1986 for more information.
Settings button	Click to display the Settings Dialog Box , on page 1980, used to define when failover should occur.

Element	Description
Timeout	The failover Timeout specifies the amount of time after a system boots or becomes active that "nailed" sessions are accepted; used in conjunction with static translation rules (see Static Rules Tab , on page 1044 for more information). Enter a value in this field to specify the failover reconnect timeout value for asymmetrically routed sessions. The value is in the form hh:mm:ss (hours:minutes:seconds); both minutes and seconds are optional. Valid values for the number of hours are -1 to 1193; the default value is 0, which means connections cannot be re-established. Setting this value to -1 disables the timeout, allowing reconnections after any amount of time.
Configuration This section is presented only for devices operating in multiple-context mode.	
Active/Active	In an Active/Active failover configuration, both security appliances inspect network traffic, on a per-context basis. That is, for each context, one of the appliances is the active device, while the other is the standby device. To enable Active/Active failover on the security appliance, you must assign the security contexts to one of two failover groups. A failover group is a simply a logical group of one or more security contexts. You should specify failover group assignments on the unit that will have failover group 1 in the active state. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default. See Add/Edit Security Context Dialog Box (PIX/ASA) , on page 2293 for information about assigning a context to a failover group.
Active/Standby	In an Active/Standby configuration, the active security appliance handles all network traffic passing through the failover pair. The standby security appliance does not handle network traffic until a failure occurs on the active security appliance. Whenever the configuration of the active security appliance changes, it sends configuration information over the failover link to the standby security appliance. When a failover occurs, the standby security appliance becomes the active unit. It assumes the IP and MAC addresses of the previously active unit. Because the other devices on the network do not see any changes in the IP or MAC addresses, ARP entries do not change or time out.
LAN Failover	

Element	Description
Interface	Choose the interface to use as the failover link; all interfaces available on the device are listed. When configured for failover, the interface is directly connected to the standby device. **Note** You can choose an EtherChannel interface as the failover link. As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named, and none of the EtherChannel's member interfaces can be named. Further, while being used as an active failover link, changes to the interface configuration are not allowed. Refer to Configuring EtherChannels , on page 1812 for more information.
Logical Name	Enter a logical name for the failover interface.
Active IP Address	Specify the active IP address for this interface.
Standby IP Address	Specify a standby IP address for this interface. To receive packets from both units in a failover pair, standby IP addresses need to be configured on all interfaces. The Standby IP address is used on the security appliance that is currently the standby unit, and it must be in the same subnet as the active IP address.
Subnet Mask	Enter the Subnet Netmask for the active and standby IP addresses.
Stateful Failover (Optional) To configure Stateful Failover , on page 1963, provide the following parameters.	
Interface	Choose the interface to use for the stateful failover link; all interfaces available on the device are listed. **Note** You can choose an EtherChannel interface as the stateful failover link. As with any other type of interface assigned as a failover link, the EtherChannel interface cannot be named, and none of the EtherChannel's member interfaces can be named. Further, while being used as an active failover link, changes to the interface configuration are not allowed. Refer to Configuring EtherChannels , on page 1812 for more information.
Logical Name	Enter the logical name of the interface on the active firewall device to communicate with standby device for failover. When configured for stateful failover, the interface is directly connected to the standby device.
Active IP Address	Specify the IP address of the active interface.
Standby IP Address	Specify the IP address of the standby interface.
Subnet Mask	Enter the Subnet Netmask for the active and standby IP addresses.

Element	Description
Enable HTTP Replication	When selected, active HTTP sessions are copied to the standby firewall. Otherwise, HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link.
Key The options in this section let you encrypt the communications between the active and standby devices. Select the type and provide a string of characters to produce the shared encryption key. **Caution** All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If this device is used to terminate VPN tunnels, this information includes any user names, passwords and shared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communications with a shared key.	
Any string HEX	If you select **Any string**, the entry in the Shared Key field can be any combination of up to 63 numbers, letters and punctuation characters. This string is used to generate the encryption key. If you select **HEX**, the entry in the Shared Key and Confirm fields must be exactly 32 hexadecimal characters (0-9, a-f). This string is used as the encryption key.
Shared Key Confirm	Enter any string of characters appropriate to the selected key type: Any string or HEX. Re-enter the string the **Confirm** field.
Interface Configuration(in some instances, labeled Monitor Interface Configuration) This table is presented on the Failover page for ASA 8.4.1+ devices operating in single-context, transparent mode, and for individual contexts on PIX/ASA devices. Otherwise, it appears in the Settings Dialog Box , on page 1980. The table lists all available named interfaces. To enable or disable monitoring of an interface, select it in the list and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box , on page 1983. Select or deselect **Monitor this interface for failure**.	

Settings Dialog Box

The Settings dialog box lets you define criteria for when failover should occur on the selected ASA or PIX 7.x appliance.

Navigation Path

You can access the Settings dialog box by clicking the Settings button on the Failover Page (ASA/PIX 7.0+) , on page 1976.

Note The following reference table presents all fields that can be presented in the Settings dialog box. The fields actually presented depend on operating mode (routed or transparent) and whether the device is hosting single or multiple contexts.

Field Reference

Table 626: Settings Dialog Box

Element	Description
Interface Policy	
Number of failed interfaces	When the number of failed monitored interfaces exceeds this value, the security appliance fails over. The range is between 1 and 250 failures.
Percentage of failed interfaces	When the number of failed monitored interfaces exceeds this percentage, the security appliance fails over.
Failover Poll Time	
Unit Failover	The amount of time between hello messages among units. The range is between 1 and 15 seconds, or between 200 and 999 milliseconds if the **Change units to msec** option is checked.
Unit Hold Time	Sets the time during which a unit must receive a hello message on the failover link, or the unit begins the testing process for peer failure. The range is between 3 and 45 seconds, or between 800 and 999 milliseconds if the **msec** option is checked. You cannot enter a value that is less than three times the Unit Failover value.
Monitored Interface	The amount of time between polls among interfaces. The range is between 3 and 15 seconds, or between 500 and 999 milliseconds if the msec option is checked.
Interface Hold Time	Sets the time during which a data interface must receive a hello message, after which the peer is declared failed. Valid values are from 5 to 75 seconds. This value must be at least five times the Unit Failover value.
Link State Interval	Sets the interval after which each ASA in a failover pair checks the link state of its interfaces. By default the link state interval value is 500msec. You can customize the polltime; for example, if you set the polltime to 300 msec, the ASA can detect an interface failure and trigger failover faster. Valid range is between 300 and 799 milliseconds. **Note** The Link State Interval is available for ASA 9.7.1 and later.

Element	Description
Failover Groups In Active/Active mode, this table lists both failover groups. To edit failover parameters for either group, select it in the list and click the Edit Row button to open the Edit Failover Group Dialog Box , on page 1984.	
MAC Address Mapping In Active/Standby mode, this table lists interface-virtual MAC address mappings. This is a standard Security Manager table, with Add Row, Edit Row and Delete Row buttons, which are described in Using Tables , on page 50. To add or edit interface mappings, click the Add Row or Edit Row button to open the Add/Edit Interface MAC Address Dialog Box , on page 1982.	
Monitor Interface Configuration In single-context mode, this table lists all available named interfaces. To define a Standby IP address for, and enable or disable monitoring of an interface, select it in the list and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box , on page 1983.	
Management IP Address In single-context transparent mode, this section presents the management IP address and netmask defined for the device (on the Management IP Page , on page 1899); you cannot change these values.	
Standby	Enter the management IP address of the standby unit; this address must be on the same subnet as the primary address.

Add/Edit Interface MAC Address Dialog Box

The Add/Edit Interface MAC Address dialog box lets you define virtual MAC addresses for a physical interface on ASA, FWSM 3.x and PIX 7.x security appliances that are configured for failover (not available on ASA 5505 devices).

In Active/Standby failover, the MAC addresses for the primary unit are always associated with the active IP addresses. If the secondary unit boots first and becomes active, it uses the burned-in MAC address for its interfaces. When the primary unit comes online, the secondary unit obtains the MAC addresses from the primary unit. This change can disrupt network traffic. You can configure virtual MAC addresses for each interface to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not specify virtual MAC addresses, the failover pair uses the burned-in MAC addresses.

Note You cannot configure a virtual MAC address for the failover or Stateful Failover links. The MAC and IP addresses for those links do not change during failover.

Navigation Path

You can open the Add/Edit Interface MAC Address dialog box from the Settings Dialog Box , on page 1980.

Field Reference

Table 627: Add/Edit Interface MAC Address Dialog Box

Element	Description
Physical Interface	Choose the physical interface on which failover virtual MAC addresses are to be configured.
MAC Address	
Active Interface	Enter a virtual MAC address for the active interface in hexadecimal format (for example, 0023.4567.89ab).
Standby Interface	Enter a virtual MAC address for the standby interface in hexadecimal format (for example, 0023.4567.89ab).

Edit Failover Interface Configuration Dialog Box

Use the Edit Failover Interface Configuration dialog box to define a standby IP address for an interface, and to specify whether the status of the interface should be monitored.

Note A failover interface cannot be configured for PPPoE.

Navigation Path

You can access the Edit Failover Interface Configuration dialog box from the Settings Dialog Box , on page 1980 (ASA/PIX 7.0+), Advanced Settings Dialog Box , on page 1974 (FWSM), and from the Failover page itself for ASA 8.4.1+ devices operating in single-context transparent mode, and for individual ASA/PIX security contexts.

Related Topics

Field Reference

Table 628: Edit Failover Interface Configuration Dialog Box

Element	Description
Interface Name	The name of the interface; read-only.
Active IP Address	The active IP address of this interface; read-only. This field is blank if an IP address has not been assigned to the interface; for example if DHCP is enabled on the interface.
Mask	The subnet mask for the active IP address; read-only. This field is blank if an IP address has not been assigned to the interface; for example, if DHCP is enabled on the interface.
Standby IP Address	Specify the IP address of the corresponding interface on the standby failover unit. This field does not appear if an IP address has not been assigned to the interface.
Monitor this interface for failure	Specifies whether this interface is monitored for failure: check this box to enable monitoring. The number of interfaces that can be monitored for the security appliance is 250. Hello messages are exchanged between the security appliance failover pair during every interface poll time period. The failover interface poll time is 3 to 15 seconds. For example, if the poll time is set to 5 seconds, testing begins on an interface if 5 consecutive hellos are not heard on that interface (25 seconds). Monitored failover interfaces can have the following status: • Unknown—Initial status. This status can also mean the status cannot be determined. • Normal—The interface is receiving traffic. • Testing—Hello messages are not heard on the interface for five poll times. • Link Down—The interface is administratively down. • No Link—The physical link for the interface is down. • Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.
ASR Group Number	If this interface is part of an asymmetric routing group, provide its ASR group number. Valid values for ASR group numbers are 1 through 32. Stateful failover must be enabled for asymmetric routing support to function properly between units in failover configurations.

Edit Failover Group Dialog Box

Use the Edit Failover Group dialog box to configure failover parameters for groups of security contexts in an Active/Active failover configuration. See Add/Edit Security Context Dialog Box (PIX/ASA) , on page 2293, or Add/Edit Security Context Dialog Box (FWSM) , on page 2291, for information about assigning a context to a failover group.

Navigation Path

You can access the Add Failover Group dialog box from the PIX/ASA Settings Dialog Box , on page 1980, or the FWSM Advanced Settings Dialog Box , on page 1974.

Related Topics

- Failover Policies , on page 1968
- Failover Page (ASA/PIX 7.0+) , on page 1976
- Failover Page (FWSM) , on page 1972

Field Reference

Table 629: Edit Failover Group Dialog Box

Element	Description
Preferred Role	Specifies the unit in the failover pair, primary or secondary, on which this failover group appears in the active state when both units start up simultaneously, or when the Preempt option is selected. Choose **Primary** or **Secondary**. You can have both failover groups in the active state on a single unit in the pair; however, a more typical configuration is to assign each failover group a different role to make each one active on a different unit, balancing the traffic across the devices.
Poll time interval for monitored interfaces	Specify the amount of time between polling of monitored interfaces. Valid values are from 3 to 15 seconds (or 500 to 999 milliseconds if **msec** is checked).
Hold Time	Specify the time period within which the group must receive a hello message, after which the other group is declared failed. Valid values are from 5 to 75 seconds.
Preempt after Reboot	Specifies the number of seconds that the preferred failover device should wait after rebooting before taking over as the active unit for this failover group. Valid values are from 0 to 1200 seconds.
Enable HTTP Replication	Indicates whether active HTTP sessions are copied to the standby device for this failover group as part of Stateful failover. If you do not allow HTTP replication, HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link. This setting overrides the HTTP replication setting on the Failover page.
Failover Criteria	Select a failed-interfaces criterion for this group and specify the appropriate value: • **Number of failed interfaces** – When this number of interfaces have failed, failover is triggered. Valid values are 1 to 250. • **Percentage of failed interfaces** – When this percentage of the total number of interfaces have failed, failover is triggered. Valid values are 1 to 100.

Element	Description
MAC Address Mapping This table displays interfaces to which active and standby MAC addresses are mapped.	

Failover Page (Security Context)

The Failover page for individual ASA and PIX 7.0+ security contexts presents the **Interface Configuration** table, which lists all available named interfaces.

You can select an interface in the table and click the Edit Row button to open the Edit Failover Interface Configuration Dialog Box , on page 1983, where you can specify a standby IP address and an ASR group number, and enable or disable monitoring of the interface.

For individual transparent-mode contexts on ASA 8.4.1+ devices, the Failover page also presents the **Bridge Group Configuration** table, which lists all currently defined failover bridge groups.

You can select an entry in the table and click the Edit Row button to open the Edit Failover Bridge Group Configuration Dialog Box , on page 1976, where you can specify a standby IP address for the selected bridge group.

Navigation Path

Select a security context in Device View and then select **Platform** > **Device Admin** > **Failover** from the Device Policy selector.

Bootstrap Configuration for LAN Failover Dialog Box

The Bootstrap Configuration for LAN Failover dialog box provides you with bootstrap configuration that can be applied to the primary and secondary devices in a LAN failover configuration.

Navigation Path

You can access the Bootstrap Configuration for LAN Failover dialog box from the Failover page. For more information about the Failover page, see:

- Failover Page (PIX 6.3) , on page 1969
- Failover Page (FWSM) , on page 1972
- Failover Page (ASA/PIX 7.0+) , on page 1976

Related Topics

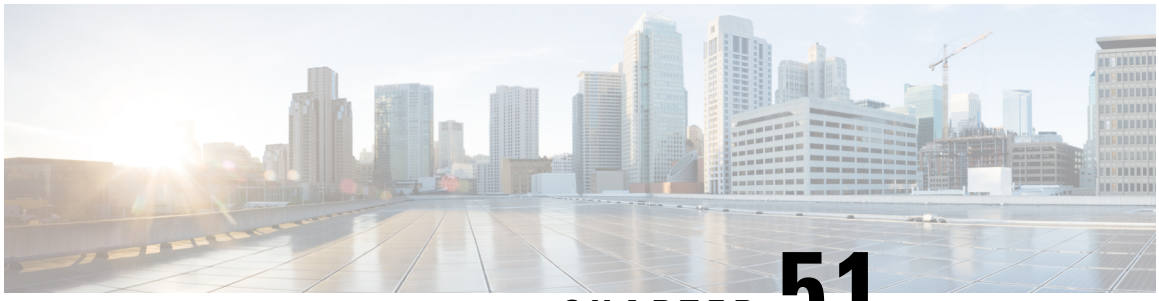
- Failover Policies , on page 1968
- Additional Steps for an Active/Standby Failover Configuration, on page 1967

Field Reference

Table 630: Bootstrap Configuration for LAN Failover Dialog Box

Element	Description
Primary	Contains the bootstrap configuration for the primary device. Open a console connection to the primary device and then paste this configuration to activate failover on the device.
Secondary	Contains the bootstrap configuration for the secondary device. After the primary device becomes active, open a console connection to the secondary device and then paste this configuration to activate failover on the device.

Note For Active/Active Failover, the bootstrap configurations are only applied to the system contexts of the respective failover peer devices.



CHAPTER 51

Configuring Hostname, Resources, User Accounts, and SLAs

The following topics describe configuring the host name on a security appliance, defining and managing Resource classes on Firewall Services Modules (FWSMs) in multiple-context mode, managing user accounts in the Local user database, and monitoring service level agreements (SLAs) to perform route tracking.

This chapter contains the following topics:

Hostname Page

You can use the Hostname page to specify a host name for your security device, and to specify a default domain. After the configuration file is deployed, the device uses this domain name when you do not enter a fully-qualified domain name in other commands. It also uses this domain name in RSA key generation.

The device appends this domain name to unqualified names. For example, if you set the domain name to "example.com," and specify a syslog server by the unqualified name "jupiter," the security appliance completes the name to "jupiter.example.com."

When you set a host name for the security appliance, that name appears in the command line prompt. If you establish sessions to multiple devices, the host name helps you keep track of where you enter commands. The default host name depends on your platform.

In multiple-context mode, you can specify a domain name for each context, as well as the system execution space. The host name you specify in the system execution space appears in the command line prompt for all contexts. The host name that you optionally set within a context does not appear in the command line, but can be used by the banner command $(hostname) token.

Navigation Path

In Device View, select a security device and then select **Platform** > **Device Admin** > **Hostname** from the Device Policy selector.

Field Reference

Table 631: Hostname Page

Element	Description
Host Name	Enter a unique device name to help you differentiate among devices; for example, *PIX-510-A* . **Note** We recommend that you use a unique host name for each device you manage. The device name can be up to 63 alphanumeric (U.S. English) characters and can include any of the following special characters: ` ( ) + - , . / : =.
Domain Name	Optionally, enter a valid Domain Name System (DNS) domain name for the device; for example, *cisco.com* .

Resource Management on Multi-context FWSMs

Note From version 4.17, though Cisco Security Manager continues to support FWSM features/functionality, it does not support any bug fixes or enhancements.

By default, all security contexts on a multiple-context Firewall Services Module (FWSM) have unlimited access to the resources of the FWSM, except where maximum limits per context are enforced. However, if you find that one or more contexts use too many resources, and they cause other contexts to be denied connections, for example, then you can configure resource management to limit the use of resources per context.

Note The FWSM does not limit the bandwidth per context; however, the switch containing the FWSM can limit bandwidth per VLAN. See the switch documentation for more information.

The FWSM manages resources by assigning contexts to resource classes. Each context uses the resource limits set by its class. When you create a class, the FWSM does not set aside a portion of the resources for each context assigned to the class; rather, the FWSM sets the maximum limit for a context. If you oversubscribe resources, or allow some resources to be unlimited, a few contexts can “use up” those resources, potentially affecting service to other contexts.

You can set the limit for all resources together as a percentage of the total available for the device. Also, you can set the limit for individual resources as a percentage or as an absolute value.

You can oversubscribe the FWSM by assigning more than 100 percent of the resources across all contexts. For example, you can set up a class to limit connections to 20 percent per context, and then assign 10 contexts to the class for a total of 200 percent. If contexts concurrently use more than the system limit, then each context gets less than the 20 percent you intended.

The FWSM also lets you assign unlimited access to one or more resources in a class, instead of a percentage or absolute number. When a resource is unlimited, contexts can use as much of the resource as the system has available. For example, contexts A, B, and C are assigned to class “Onepercent,” which limits each class member to one percent of the system inspections per second, for a total of three percent; but the three contexts

are currently only using two percent combined. On the other hand, class “Nolimit” has unlimited access to inspections. The contexts in Nolimit can use more than the 97 percent of “unassigned” inspections; they can also use the one percent of inspections not currently in use by contexts A, B, and C, even if that means that contexts A, B, and C are unable to reach their three percent combined limit. Setting unlimited access is similar to oversubscribing the FWSM, except that you have less control over how much you oversubscribe the system.

Default Class

All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to the default class.

If a context belongs to a class other than the default class, those class settings always override the default class settings. However, if the other class has any settings that are not defined, then the member context uses the default class for those limits. For example, if you create a class with a two percent limit for all concurrent connections, but no other limits, then all other limits are inherited from the default class. Conversely, if you create a class with a two percent limit for all resources, the class uses no settings from the default class.

As initially configured, the default class provides unlimited access to resources for all contexts, except for the following limits, which are by default set to the maximum allowed per context:

- Telnet sessions – 5 sessions
- SSH sessions – 5 sessions
- IPSec sessions – 5 sessions
- MAC addresses – 65,535 entries

Note that you can edit the default class.

- Add/Edit Security Context Dialog Box (FWSM) , on page 2291

Resources Page

Use the Resources page to configure and manage resource-management classes.

The table on this page lists all currently defined resource classes. Use the buttons below the table to manage this list:

- Add Row – Opens the Add Resource dialog box, where you can define a new class, and assign it to security contexts. See Add and Edit Resource Dialog Boxes , on page 1992 for more information.
- Edit Row – For the currently selected row, opens the Edit Resource dialog box, so you can edit that class and its context assignments. See Add and Edit Resource Dialog Boxes , on page 1992 for more information.
- Delete Row – Deletes the currently selected row(s); confirmation may be required.

Navigation Path

In Device View, select the system context of an ASA or FWSM in multiple-context mode, and then select **Platform > Device Admin > Resources** from the Device Policy selector.

Related Topics

- Resource Management on Multi-context FWSMs , on page 1990

Add and Edit Resource Dialog Boxes

Use the Add Resource and Edit Resource dialog boxes to add or edit resource classes and assignments for FWSM and ASA security contexts.

Except for their titles, both dialog boxes are identical; the following descriptions apply to both.

Navigation Path

You can access the Add Resource and Edit Resource dialog boxes from the Resources Page , on page 1991.

Related Topics

- Resource Management on Multi-context FWSMs , on page 1990

Field Reference

Table 632: Add and Edit Resource Dialog Boxes

Element	Description
Class Name	Enter a name for this class; can be a string of up to 20 alphanumeric characters, and may include any of the following special characters: ` ( ) + - , . / : =.
Limits Tab	
Note For the following Limits, if you do not specify a value for a particular limit, the limit is inherited from the default class. If the default class does not set that limit, the limit inherits the system limit. Also, any value you enter is considered to be that rate *per second* , unless you also check the related **percent** box, in which case the value is that percentage of the total resource.	
TCP or UDP Connections	Sets a Rate Limit for TCP or UDP connections between any two hosts, including connections between one host and multiple other hosts. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 102400, or you can assign more than 100 percent if you want to oversubscribe the device.
Inspections (Fixups)	Sets a Rate Limit for application inspections. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 10000 per second, or you can assign more than 100 percent if you want to oversubscribe the device.
Syslog Messages	Sets a Rate Limit for system log messages. You can set the limit as an absolute value, or you can assign more than 100 percent if you want to oversubscribe the device. The FWSM can support 30,000 messages per second for messages sent to the FWSM terminal or buffer. If you send messages to a syslog server, the FWSM supports 25,000 per second.

Element	Description
Connections	Sets the Absolute Limit for concurrent TCP or UDP connections. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 999900, or you can assign more than 100 percent if you want to oversubscribe the device. **Note** For concurrent connections, the FWSM allocates half of the limit to each of two network processors (NPs) that accept connections. Typically, the connections are divided evenly between the NPs. However, in some circumstances, the connections are not evenly divided, and the maximum connection limit could be reached on one NP before reaching the maximum on the other. In this case, the maximum connections allowed is less than the limit you set. The NP distribution is controlled by the switch, based on a distribution algorithm. You can adjust this algorithm on the switch, or you can adjust the connection limit upward to account for the inequity.
Hosts	Sets the limit for concurrent hosts that can connect through the FWSM. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 262144, or you can assign more than 100 percent if you want to oversubscribe the device.
IPsec Sessions	Sets the limit for IPsec sessions. You can set the limit as an absolute value by entering an integer between 1 and 5, or you can assign more than 100 percent if you want to oversubscribe the device. The system allows a maximum of 10 concurrent sessions divided between all contexts.
SSH Sessions	Sets the limit for SSH sessions. You can set the limit as an absolute value by entering an integer between 1 and 5, or you can assign more than 100 percent if you want to oversubscribe the device. The system allows a maximum of 100 concurrent sessions divided between all contexts.
Telnet Sessions	Sets the limit for concurrent Telnet sessions. You can set the limit as an absolute value by entering an integer between 1 and 5, or you can assign more than 100 percent if you want to oversubscribe the device. The system allows a maximum of 100 concurrent sessions divided between all contexts.
NAT Translations	Sets the limit for concurrent address translations. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 266144, or you can assign more than 100 percent if you want to oversubscribe the device.
MAC Address	(Transparent mode only) Sets the limit for concurrent MAC address entries allowed in the MAC address table. You can set the limit as an absolute value by entering an integer between 0 (system limit) and 65535, or you can assign more than 100 percent if you want to oversubscribe the device.

Element	Description
ASDM	Sets the limit for ASDM management sessions (the default is 5). You can set the limit as an absolute value by entering an integer between 1 and 5, or you can enter a percentage between 3.0 and 15.0. The system allows a maximum of 80 concurrent sessions divided between all contexts. ASDM sessions use two HTTPS connections: one for monitoring that is always present, and one for making configuration changes that is present only when you make changes. For example, the system limit of 80 ASDM sessions represents a limit of 160 HTTPS sessions, divided between all contexts.
Other VPN	Sets the limit for Site-to-site VPN sessions. You cannot oversubscribe this resource; all context assignments combined cannot exceed the model limit. The sessions you assign for this resource are guaranteed to the context.
Other VPN Burst	Sets the limit for the number of site-to-site VPN sessions allowed beyond the amount assigned to a context with vpn other. For example, if your model supports 5000 sessions, and you assign 4000 sessions across all contexts with vpn other, then the remaining 1000 sessions are available for other vpn burst. Unlike other vpn, which guarantees the sessions to the context, other vpn burst can be oversubscribed; the burst pool is available to all contexts on a first-come, first-served basis.
Note The maximum value for Anyconnect VPN and Anyconnect VPN Burst depends on ASA licenses. Cisco Security Manager cannot validate the values entered for Anyconnect VPN and Anyconnect VPN Burst. Therefore, the user should make sure that the values for Anyconnect VPN and Anyconnect VPN Burst are within the maximum values; else it results in a deployment error. To find the maximum value, telnet into ASA and execute the show version command. The Total VPN Peers value corresponds to the maximum value.	
Anyconnect VPN	Secure Client peers. You cannot oversubscribe this resource; all context assignments combined cannot exceed the model limit. The peers you assign for this resource are guaranteed to the context.
Anyconnect VPN Burst	The number of Secure Client sessions allowed beyond the amount assigned to a context with Secure Client. For example, if your model supports 5000 peers, and you assign 4000 peers across all contexts with Secure Client, then the remaining 1000 sessions are available for AnyConnect Burst. Unlike Secure Client, which guarantees the sessions to the context, AnyConnect Burst can be oversubscribed; the burst pool is available to all contexts on a first-come, first-served basis.
Storage	Beginning with version 4.12, Security Manager enables you to enter the storage size or select Default. This feature is available for ASA version 9.6(2) or later. The limit is set in MB. The default limit is 100% of the disk configured since this storage cannot span multiple disks.
All Resources Limit	Sets a limit for all resources. If you also set the limit for a specific resource, then that limit overrides the limit you set here for all resources. You can set the limit as a percentage, or as unlimited by setting the value to **0** (when **percent** is not checked). You cannot set any other absolute value. You can assign more than 100 percent if you want to oversubscribe the device.

Element	Description
Contexts Tab	
Available Contexts	Lists all contexts available for class assignments; contexts which already have class assignments are not displayed. Select one or more contexts and click the >> button to add the contexts to the Selected Contexts list.
Selected Contexts	Lists all contexts assigned to this class. Select one or more contexts and click the << button to return the contexts to the Available Contexts list.

Configuring User Accounts

The User Accounts page lets you manage the Local user database. User accounts in the Local database can be used in conjunction with the Authentication, Authorization, Accounting (AAA) functions to determine "who is allowed to do what" on a device. Refer to About AAA on Security Devices , on page 1903 for more information.

The table on this page lists all currently defined Local user accounts, showing for each, the name of the user and the assigned privilege level. For a detailed explanation of these fields, see Add/Edit User Account Dialog Boxes , on page 1996.

Important For a Cisco Security Manager-managed device, when you intend to change the password in the **Device Properties** page, make sure you update the same in the **User Accounts** page also. When you fail to do so, although the initial phase of communication between Security Manager and the device is successful and even the **Test Connectivity** gets verified successfully, the deployment still fails, because the password configured in the **User Accounts** page gets updated in the **Device Properties** page. It is therefore recommended to ensure that credential updates are made *parallelly* in **Device Properties** and the **User Accounts** pages.

- To add a user account, click the Add Row button.
- To edit the settings for an account, select it and click the Edit Row button.
- To delete a user account, select it and click the Delete Row button.

Navigation Path

- (Device view) Select **Platform > Device Admin > User Accounts** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > User Accounts** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Local Database , on page 1905

- Preparing for AAA , on page 1904

Add/Edit User Account Dialog Boxes

Use the Add and Edit User Account dialog boxes to add a local user account or to modify an existing user account.

Navigation Path

You can access the Add and Edit User Account dialog boxes from the User Accounts page, as described in Configuring User Accounts , on page 1995.

Field Reference

Table 633: Add/Edit User Account Dialog Boxes

Element	Description
Username	Enter a name for this user account: must be at least four characters; the maximum is 64 characters. Entries are case-sensitive.
Password	
Password as encrypted	Select Plain Text or Encrypted.
Password encrypt type	Select MD5 or PBKDF2.
Password	Enter a unique password for this user account. Entries are case-sensitive. **Note** To protect security, we recommend a password length of at least 8 characters. **Note** For Plain Text passwords: • The length of MD5 password should be three to 32 characters. • The length of PBKDF2 password should be 33 to 127 characters. Ensure PBKDF2 password has correct `sha` key values to avoid deployment failure.
Confirm	Re-enter the user password to confirm it.
Privilege Level	Choose a privilege level for this user; defines local command authorization. The range is 0 (lowest) to 15 (highest). The default privilege level is 2.

Monitoring Service Level Agreements (SLAs) To Maintain Connectivity

You can configure ASA or PIX devices that run version 7.2 or later to perform route tracking by monitoring service level agreements. By monitoring the connectivity to a device on another network, you can track the availability of a primary route and install a backup route if the primary route fails. For example, you can define a default route to an Internet service provider (ISP) gateway and a backup default route to a secondary ISP

in case the primary ISP becomes unavailable. This technique, called Dual ISP, provides security appliances with a form of high availability, which is a vital part of providing customers with the services to which they are entitled.

Without route tracking, there is no inherent mechanism for determining if the route is up or down. A static route remains in the routing table even if the next hop gateway becomes unavailable, and is removed only if the associated interface on the security appliance goes down.

The security appliance performs route tracking by associating a route with a monitoring target that you define in an SLA monitor policy object. It monitors the target using ICMP echo requests, according to the parameters configured in the object. If an echo reply is not received within a specified time period, the SLA monitor is considered down and the associated route is removed from the routing table. A previously configured backup route is used in place of the removed route.

SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration (that is, they do not age out).

Related Topics

- Configuring Static Routes , on page 2223

This section contains the following topics:

- Creating Service Level Agreements , on page 1997

Creating Service Level Agreements

The following procedure explains how to configure SLA monitor objects and associate them with routes and interfaces in an ASA or PIX configuration.

Related Topics

- Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996
- Configuring Static Routes , on page 2223
- Configuring Firewall Device Interfaces , on page 1805
- Creating Policy Objects , on page 237

Step 1 Create the SLA monitor policy object:

a) Select **Manage > Policy Objects** to open the Policy Object Manager (see Policy Object Manager , on page 232) and select **SLA Monitors** from the table of contents.

Tip You can also create SLA monitor objects when defining policies that use this object type. For more information, see Selecting Objects for Policies , on page 230.

b) Right-click in the work area and select **New Object** to open the Add SLA Monitor dialog box. For more information, see Configuring SLA Monitor Objects , on page 1998.

c) The monitoring options are appropriate for most connections, so you need only configure the following:

- Name—The name of the object.
- SLA Monitor ID—An identifying number for the monitoring process. The number must be unique within a device configuration.
- Monitored Address—The address that you are monitoring. When you select a monitoring target, make sure that it can respond to ICMP echo requests (pings). The target can be any network address that you choose, but consider the use of:
- The ISP gateway address.
- The next hop gateway address (if you are concerned about the availability of the ISP gateway).
- A server on the target network, such as an AAA server, with which the security appliance needs to communicate.
- A persistent network device on the destination network. (A desktop or notebook computer that gets shut down at night is not a good choice.)
- Interface—The interface name, or interface role that identifies an interface, that will be the source of the ICMP messages. The device pings the monitored address from this interface's IP address.

d) Click **OK** to save the object.

Step 2 Configure ASA/PIX policies to use the object to monitor routes. You can configure the following policies to monitor SLAs:

- **Platform > Routing > Static Route**—When you define a static route, you can select an SLA monitor object to do route tracking for the route. For more information, see Configuring Static Routes , on page 2223 and Add/Edit Static Route Dialog Box , on page 2224.
- **Interfaces**—When you define an interface that uses DHCP or PPPoE, you can configure the DHCP or PPPoE learned default routes to be tracked. For more information, see Device Interface: IP Type (PIX/ASA 7.0+) , on page 1870.

Configuring SLA Monitor Objects

Use the Add or Edit SLA (Service Level Agreement) Monitor dialog box to create, edit, and copy SLA monitor objects. Each SLA monitor defines a connectivity policy to a monitored address and tracks the availability of a route to the address. The route is periodically checked for availability by sending ICMP echo requests and waiting for the response. If the requests time out, the route is removed from the routing table and replaced with a backup route.

You can configure SLA monitors only for security appliances running PIX/ASA version 7.2 or later. SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration (that is, they do not age out).

For more information about configuring and using SLA monitor objects, see Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996.

Navigation Path

Select **Manage > Policy Objects**, then select **SLA Monitors** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Related Topics

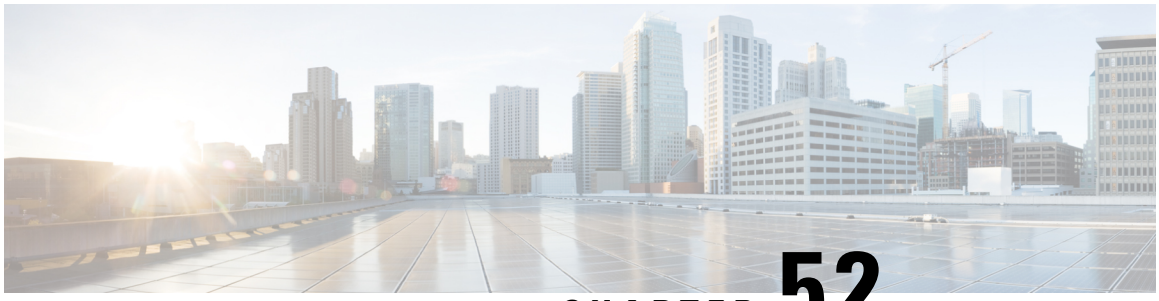
- Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996
- Policy Object Manager , on page 232

Field Reference

Table 634: SLA Monitor Dialog Box

Element	Description
Name	The object name, which can be up to 128 characters. Object names are not case-sensitive. For more information, see Creating Policy Objects , on page 237.
Description	An optional description of the object.
SLA Monitor ID	The ID number of the SLA operation. Values range from 1 to 2147483647. You can create a maximum of 2000 SLA operations on a device. Each ID number must be unique to the policy and the device configuration.
Monitored Address	The IP address that is being monitored for availability by the SLA operation. For recommendations on selecting an address to monitor, see Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996.
Interface	The source interface for all ICMP echo requests sent to the monitored address to test its availability. Enter the name of an interface or interface role, or click **Select** to select an it from a list or to create a new interface role.
Frequency	The frequency of ICMP echo request transmissions, in seconds. Values range from 1 to 604800 seconds (7 days). The default is 60 seconds. **Note** The frequency cannot be less than the timeout value; you must convert frequency to milliseconds to compare the values.
Threshold	The amount of time that must pass after an ICMP echo request before a rising threshold is declared, in milliseconds. Values range from 0 to 2147483647 milliseconds. The default is 5000 milliseconds. The threshold value is used only to indicate events that exceed the defined value. You can use these events to evaluate the proper timeout value. It is not a direct indicator of the reachability of the monitored address. **Note** The threshold value should not exceed the timeout value.
Time out	The amount of time that the SLA operation waits for a response to the ICMP echo requests, in milliseconds. Values range from 0 to 604800000 milliseconds (7 days). The default is 5000 milliseconds. If a response is not received from the monitored address within the amount of time defined in this field, the static route is removed from the routing table and replaced by the backup route. **Note** The timeout value cannot exceed the frequency value (adjust the frequency value to milliseconds to compare the numbers).

Element	Description
Request Data Size	The size of the ICMP request packet payload, in bytes. Values range from 0 to 16384 bytes. The default is 28 bytes, which creates a total ICMP packet of 64 bytes. Do not set this value higher than the maximum allowed by the protocol or the Path Maximum Transmission Unit (PMTU). For purposes of reachability, you might need to increase the default data size to detect PMTU changes between the source and the target. A low PMTU can affect session performance and, if detected, might indicate that the secondary path should be used.
ToS	The type of service (ToS) defined in the IP header of the ICMP request packet. Values range from 0 to 255. The default is 0. This field contains information such as delay, precedence, reliability, and so on. It can be used by other devices on the network for policy routing and features such as committed access rate.
Number of Packets	The number of packets that are sent. Values range from 1 to 100. The default is 1 packet. **Tip** Increase the default number of packets if you are concerned that packet loss might falsely cause the security appliance to believe that the monitored address cannot be reached.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.



CHAPTER 52

Configuring Server Access Settings on Firewall Devices

The Server Access section contains pages for configuring server access on firewall devices; Server Access is under Device Admin in the Device or Policy selector.

This chapter contains the following topics:

AUS Page

The AUS page lets you configure remote updating of a security appliance from a server that supports the Auto Update specification. Auto Update applies configuration changes and software updates to the appliance automatically from the remote server.

Note The server you identify on this page must be the same server you identify in the Auto Update section of the Device Properties (from the Tools menu, choose Device Properties). The Device Properties information identifies the AUS server to which Security Manager sends configuration updates, whereas the information on this page defines for the server the device will contact for updates. Also, the Device Identity you provide in the Device Properties must match the Device ID on this page.

If you change AUS servers, note that the device will continue to use the AUS server defined in its current configuration until it receives a new configuration. Thus, you should change the AUS policy but deploy the configuration using the previous AUS server. After deployment is successful, change the Device Properties to point to the new server. For more information on deploying to AUS, see Deploying Configurations Using an Auto Update Server or CNS Configuration Engine , on page 422.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > AUS** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > AUS** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Add and Edit Auto Update Server Dialog Boxes , on page 2003

Field Reference

Table 635: AUS Page

Element	Description
Auto Update Servers table	This table lists currently configured Auto Update servers. Use the buttons below the table to manage these entries. The entries are listed in order of precedence for contacting AUS servers. Use the Up and Down arrow buttons to change the ordering of the list by moving the selected entry up or down. Use the Add Row, Edit Row, and Delete Row buttons to add, edit or delete entries. Add Row opens the Add Auto Update Server dialog box, while Edit Row opens the Edit Auto Update Server dialog box for the selected row. See Add and Edit Auto Update Server Dialog Boxes , on page 2003 for information about these dialog boxes. **Note** The URL for contacting this AUS server is produced by concatenating the *Protocol* ://*Username* :*Password* @*IP IP Address* (:*Port*)/*Path* provided in the Add/Edit Auto Update Server dialog boxes. The Port is included only if you entered a port number other than the default 443.
Device ID Type	Choose the method used for identifying this device to the AUS server: • **Host Name** – The host name of this device, as provided in the Device Properties window (Tools > Device Properties). • **Serial Number** – The serial number of this device. • **IP Address** – The IP address of the specified interface. When you choose this option, an Interface field appears; enter or Select the desired device interface. • **MAC Address** – The MAC address of the specified interface. When you choose this option, an Interface field appears; enter or Select the desired device interface. • **User Defined** – A unique user-specified ID is used. When you choose this option, a User Defined field appears; enter any alphanumeric string. Note that this string must also appear in the Device Identity field in the Device Properties window (Tools > Device Properties).

Element	Description

Poll Type	Choose the method defining how often the AUS server is polled for updates:
	• **At Specified Frequency** – If you choose this option, the Poll Period field is displayed:
	  • **Poll Period** – Specify the number of minutes the device waits between polls of the AUS server; valid values are 1 to 35791.
	• **At Scheduled Time** – If you choose this option, the following fields are displayed (available only on ASA/PIX devices running version 7.2 or later):
	  • **Days of the week** – Select one or more days on which the device is to poll the AUS server.
	  • **Polling Start Time in Hours** – The hour at which polling is to begin on the selected days; based on a 24-hour clock.
	  • **Polling Start Time in Mins** – The minute within the chosen hour when polling is to begin.
	  • **Enable Randomization of the Start Time** – Select this option to specify a random polling window; the Randomization Window field is enabled.
	Randomization Window – The maximum number of minutes the device can use to randomize the specified polling time; valid values are 1 to 1439.

Retry Count	The number of times the device will try to poll the AUS server for new information. Optional; if you enter zero or leave this field blank, the device will not retry after a failed poll attempt.
Retry Period	If Retry Count is not zero or blank, the number of minutes the device will wait to re-poll the AUS server if the previous attempt failed; valid values are 1 to 35791. If Retry Count is not zero or blank and you leave this field blank, the value defaults to five minutes.
Disable Device After:	Selecting this option ensures that if no response is received from the AUS server within the specified Timeout period, the security appliance will stop passing traffic. • **Timeout** – The number of minutes the firewall device will wait to timeout if no response is received from the AUS server.

Add and Edit Auto Update Server Dialog Boxes

Use the Add Auto Update Server dialog box to configure a new AUS server definition. The security appliance will automatically poll this server for image and configuration updates.

The Auto Update specification allows the Auto Update server to either push configuration information and send requests for information to the security appliance, or to pull configuration information by causing the security appliance to periodically poll the Auto Update server. The Auto Update server can also send a command to the security appliance to send an immediate polling request at any time. Communication between the Auto Update server and the security appliance requires a communications path and local CLI configuration on each security appliance.

Note The URL for contacting this AUS server is produced by concatenating the *Protocol* ://*Username* :*Password* @*IP IP Address* (:*Port*)/*Path* provided in these dialog boxes. The Port is included only if you entered a port number other than the default 443.

With the exception of the title, the Edit Auto Update Server dialog box is identical to the Add Auto Update Server dialog box. The following descriptions apply to both.

Navigation Path

You can access the Add and Edit Auto Update Server dialog boxes from the AUS Page , on page 2001.

Field Reference

Table 636: Add and Edit Auto Update Server Dialog Boxes

Element	Description
Protocol	The protocol used to communicate with the AUS server; choose **http** or **https**. **Note** If https is selected as the protocol to communicate with the Auto Update server, the security appliance will use SSL. This requires the security appliance to have a DES, 3DES, or AES license.
IP Address	Enter the IP address or Select a Networks/Hosts object representing this AUS server.
Port	Enter the number of the port on which communications with the AUS server take place. Defaults to 80 if http is chosen as the Protocol, and to 443 if https is chosen. If you enter an arbitrary port number, be sure the AUS server is configured to use the same port.
Path	The path to AUS services on the server. The standard path is autoupdate/AutoUpdateServlet ; change this to admin/auto-update only if the AUS server host is an ASA.
AUS Interface	Enter or Select the interface to use when polling the Auto Update server.
Verify Certificate	Select this option to require SSL verification from the AUS server. The certificate returned by the server will be checked against Certification Authority (CA) root certificates. This requires that the AUS Server and this device use the same Certification Authority.
Username	Enter a user name to be used for AUS authentication (optional).
Password	Enter the password to be used for AUS authentication (optional).
Confirm	Re-enter the password (optional).

DHCP Relay Page

Use the DHCP Relay page to configure DHCP relay services for security devices. Dynamic Host Configuration Protocol (DHCP) relay passes DHCP requests received on one interface to an external DHCP server located behind a different interface. To configure DHCP relay, you need to specify at least one DHCP relay server and then enable a DHCP relay agent on the interface receiving DHCP requests.

Note You cannot enable a DHCP relay agent on an interface where a DHCP relay server is configured. The DHCP relay agent works only with external DHCP servers; it will not forward DHCP requests to a security appliance interface configured as a DHCP server.

Beginning with Security Manager version 4.9, DHCP Relay IPv4 is supported for ASA cluster devices running the software version 9.4.0 or later.

For ASA-SM 9.1.2+ devices, you can configure DHCP relay servers per-interface, so requests that enter a given interface are relayed only to servers specified for that interface. When a DHCP request enters an interface that does not have interface-specific servers configured, the ASA relays the request to all global servers. If the interface has interface-specific servers, then the global servers are not used. IPv6 is not supported for per-interface DHCP relay. For more information, see Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+) , on page 1850.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > DHCP Relay** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > DHCP Relay** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 637: DHCP Relay Page

Element	Description
DHCP Relay Agent table	This table lists the interfaces on which DHCP relay is configured. Use the Add Row, Edit Row, and Delete Row buttons to manage these entries. The Add Row button opens the Add DHCP Relay Agent Configuration dialog box, while Edit Row opens the Edit DHCP Relay Agent Configuration dialog box. See Add and Edit DHCP Relay Agent Configuration Dialog Boxes , on page 2006 for more information.
DHCP Servers table	This table lists the global DHCP servers to which DHCP requests are relayed. Use the Add Row, Edit Row, and Delete Row buttons to manage these entries. The Add Row button opens the Add DHCP Relay Server Configuration dialog box, while Edit Row opens the Edit DHCP Relay Server Configuration dialog box. See Add and Edit DHCP Relay Server Configuration Dialog Boxes , on page 2007 for more information.
Timeout (seconds)	Specify the amount of time, in seconds, allowed for DHCP address negotiation. Valid values range from 1 to 3600 seconds; the default value is 60 seconds.

Element	Description
Trust Info (Option 82)	Specifies that you want to trust all DHCP client interfaces. You can configure interfaces as trusted interfaces to preserve DHCP Option 82. **Note** You can also specify interfaces to trust individually. For more information, see Add/Edit Interface Dialog Box: Advanced Tab (ASA/PIX 7.0+) , on page 1850. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the ASA DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then the ASA will drop that packet by default. You can now preserve Option 82 and forward the packet by identifying an interface as a trusted interface.

Add and Edit DHCP Relay Agent Configuration Dialog Boxes

Use the Add DHCP Relay Agent Configuration dialog box to configure and enable a DHCP relay agent on an interface. Use the Edit DHCP Relay Agent Configuration dialog box to update an existing interface relay agent.

Note You cannot enable a DHCP relay agent on an interface where a DHCP relay server is configured. The DHCP relay agent works only with external DHCP servers; it will not forward DHCP requests to a security appliance interface configured as a DHCP server.

The Add DHCP Relay Agent Configuration dialog box and the Edit DHCP Relay Agent Configuration dialog box are virtually identical; the following descriptions apply to both.

Navigation Path

You can access the Add and Edit DHCP Relay Agent Configuration dialog boxes from the DHCP Relay Page , on page 2004.

Related Topics

- Add and Edit DHCP Relay Server Configuration Dialog Boxes , on page 2007

Field Reference

Table 638: Add and Edit DHCP Relay Agent Configuration Dialog Boxes

Element	Description
Interface	Enter or Select the name of the interface on which you want to configure a DHCP relay agent.
Enable DHCP Relay	When checked, the DHCP relay is enabled on the specified interface.

Element	Description
Set Route	Check this box to configure the DHCP relay agent to modify the default router address in the information returned from the DHCP server. When this option is selected, the DHCP relay agent substitutes the address of the selected interface for the default router address in the information returned from the DHCP server.

Add and Edit DHCP Relay Server Configuration Dialog Boxes

Use the Add DHCP Relay Server Configuration dialog box to define a new DHCP relay server; use the Edit DHCP Relay Server Configuration dialog box to update existing server information. You can configure a maximum of 10 DHCPv4 relay servers in single mode and per context, global and interface-specific servers combined, with a maximum of 4 servers per interface.

Note PIX Firewalls running an OS earlier than 7.2 only support 4 DHCP relay servers.

The Add DHCP Relay Server Configuration dialog box and the Edit DHCP Relay Server Configuration dialog box are virtually identical; the following descriptions apply to both.

Navigation Path

You can access the Add and Edit DHCP Relay Server Configuration dialog boxes from the DHCP Relay Page , on page 2004.

Related Topics

- Add and Edit DHCP Relay Agent Configuration Dialog Boxes , on page 2006

Field Reference

Table 639: Add and Edit DHCP Relay Server Configuration Dialog Boxes

Element	Description
Server	Enter the IP address or Select a Networks/Hosts object representing the external DHCP server to which DHCP requests are forwarded.
Interface	Enter or Select the interface through which DHCP requests are forwarded to the external DHCP server.

DHCP Relay IPv6 Page

Use the DHCP Relay IPv6 page to configure DHCPv6 relay services for security devices. Dynamic Host Configuration Protocol v6 (DHCPv6) relay passes DHCPv6 requests received on one interface to an external DHCPv6 server located behind a different interface. To configure DHCPv6 relay, you need to specify at least one DHCPv6 relay server and then enable a DHCPv6 relay agent on the interface receiving DHCPv6 requests.

Note You cannot enable a DHCPv6 relay agent on an interface where a DHCPv6 relay server is configured. The DHCPv6 relay agent works only with external DHCPv6 servers; it will not forward DHCPv6 requests to a security appliance interface configured as a DHCPv6 server. Beginning with Security Manager version 4.9, DHCP Relay IPv6 is supported for ASA cluster devices running the software version 9.4.0 or later.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > DHCP Relay IPv6** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > DHCP Relay IPv6** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Note Two new interface settings have been introduced for DHCPv6: "managed-config-flag" and "other-config-flag." For more information, refer to Configuring IPv6 Interfaces (ASA/FWSM) , on page 1860.

Field Reference

Table 640: DHCP Relay IPv6 Page

Element	Description
DHCP Relay IPv6 Agent table	This table lists the interfaces on which DHCP relay IPv6 is configured. Use the Add Row, Edit Row, and Delete Row buttons to manage these entries. The Add Row button opens the Add DHCP Relay IPv6 Agent Configuration dialog box, while Edit Row opens the Edit DHCP Relay IPv6 Agent Configuration dialog box. See Add and Edit DHCP Relay IPv6 Agent Configuration Dialog Boxes , on page 2009 for more information.
DHCP Servers table	This table lists the interfaces on which DHCP relay IPv6 is configured. Use the Add Row, Edit Row, and Delete Row buttons to manage these entries. The Add Row button opens the Add DHCP Relay IPv6 Server Configuration dialog box, while Edit Row opens the Edit DHCP Relay IPv6 Server Configuration dialog box. See Add and Edit DHCP Relay IPv6 Server Configuration Dialog Boxes , on page 2009 for more information.
Timeout (seconds)	Specify the amount of time, in seconds, allowed for DHCPv6 address negotiation. Valid values range from 1 to 3600 seconds; the default value is 60 seconds.

Add and Edit DHCP Relay IPv6 Agent Configuration Dialog Boxes

Use the Add DHCP Relay IPv6 Agent Configuration dialog box to configure and enable a DHCPv6 relay agent on an interface. Use the Edit DHCP Relay IPv6 Agent Configuration dialog box to update an existing interface relay agent.

Note You cannot enable a DHCPv6 relay agent on an interface where a DHCPv6 relay server is configured. The DHCPv6 relay agent works only with external DHCPv6 servers; it will not forward DHCPv6 requests to a security appliance interface configured as a DHCPv6 server.

The Add DHCP Relay IPv6 Agent Configuration dialog box and the Edit DHCP Relay IPv6 Agent Configuration dialog box are virtually identical; the following descriptions apply to both.

Navigation Path

You can access the Add and Edit DHCP Relay IPv6 Agent Configuration dialog boxes from the DHCP Relay IPv6 Page , on page 2007.

Related Topics

- Add and Edit DHCP Relay IPv6 Server Configuration Dialog Boxes , on page 2009

Field Reference

Table 641: Add and Edit DHCP Relay IPv6 Agent Configuration Dialog Boxes

Element	Description
Interface	Enter or Select the name of the interface on which you want to configure a DHCPv6 relay agent.
Enable DHCPv6 Relay	When checked, the DHCPv6 relay is enabled on the specified interface.
Set Route	Check this box to configure the DHCPv6 relay agent to modify the default router address in the information returned from the DHCPv6 server. When this option is selected, the DHCPv6 relay agent substitutes the address of the selected interface for the default router address in the information returned from the DHCPv6 server.

Add and Edit DHCP Relay IPv6 Server Configuration Dialog Boxes

Use the Add DHCP Relay IPv6 Server Configuration dialog box to define a new DHCPv6 relay server; use the Edit DHCP Relay IPv6 Server Configuration dialog box to update existing server information. You can define up to ten DHCPv6 relay servers.

Note The Add DHCP Relay IPv6 Server Configuration dialog box and the Edit DHCP Relay IPv6 Server Configuration dialog box are virtually identical; the following descriptions apply to both.

Navigation Path

You can access the Add and Edit DHCP Relay IPv6 Server Configuration dialog boxes from the DHCP Relay IPv6 Page , on page 2007.

Field Reference

Table 642: Add and Edit DHCP Relay IPv6 Server Configuration Dialog Boxes

Element	Description
Server	Enter the IP address or Select a Networks/Hosts object representing the external DHCPv6 server to which DHCPv6 requests are forwarded.
Interface	Enter or Select the interface through which DHCPv6 requests are forwarded to the external DHCPv6 server.

Configuring DHCP Servers

A Dynamic Host Configuration Protocol (DHCP) server provides network configuration parameters, such as IP addresses, to DHCP clients. The security appliance can provide DHCP server or DHCP relay services to DHCP clients attached to the security appliance interfaces. The DHCP server provides network configuration parameters directly to DHCP clients: DHCP relay passes DHCP requests received on one interface to an external DHCP server located behind a different interface. For more information about DHCP relay, see DHCP Relay Page , on page 2004.

Note The security appliance DHCP server does not support BOOTP requests.In multiple-context mode, you cannot enable a DHCP server or DHCP relay on an interface that is used by more than one context.

You can configure a DHCP server on each interface of the security appliance, and each interface can have its own pool of addresses to draw from. However, the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.

You cannot configure a DHCP client or DHCP relay services on an interface on which the DHCP server is enabled. Additionally, DHCP clients must be directly connected to the interface on which the server is enabled.

If your firewall is also acting as a DHCP client on the outside interface, you can enable auto-negotiated IP configuration. This allows the firewall to pass the DNS, WINS and domain name parameters it gets from the outside interface (as a DHCP client) to hosts on its inside network. Alternatively, you can manually specify the DNS, WINS and domain name parameters. If you specify those parameters manually and auto-configuration is on, your values take precedence over auto-configuration.

Use the DHCP Server Page , on page 2011 to manage DHCP server definitions.

DHCP Server Page

Use the DHCP Server page to configure global DHCP server and dynamic DNS (DDNS) update options, to set up a DHCP server on one or more device interfaces, and to configure advanced server options.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > DHCP Server** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > DHCP Server** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

- Configuring DHCP Servers , on page 2010

Field Reference

Table 643: DHCP Server Page

Element	Description
Ping Timeout	Specify the amount of time, in milliseconds, that the firewall device waits to time out a DHCP ping attempt. To avoid address conflicts, firewall devices send two ICMP ping packets to an address before assigning that address to a DHCP client. Valid values range from 10 to 10000 milliseconds.
Lease Length	Specify the amount of time, in seconds, that the client can use its allocated IP address before the lease expires. Valid values range from 300 to 1048575 seconds. The default value is 3600 seconds (1 hour).
Enable auto-configuration (PIX and ASA only)	Select this option to enable DHCP auto configuration. DHCP auto configuration causes the DHCP server to provide DHCP clients with DNS server, domain name, and WINS server information obtained from a DHCP client running on the specified interface. If any of the information obtained through auto configuration is also specified manually, the manually specified information takes precedence over the discovered information.
Interface	If Enable auto-configuration is checked, this field is available. Enter or Select the interface running the DHCP client that supplies the DNS, WINS, and domain name parameters.
Define settings (optional)	
Domain Name	Specify the DNS domain name for DHCP clients. Enter a valid DNS domain name; for example, example.com .
Primary DNS Server	Enter the IP address or Select a Networks/Hosts object representing the primary DNS server for a DHCP client.

Element	Description
Primary WINS Server	Enter the IP address or Select a Networks/Hosts object representing the primary WINS server for a DHCP client.
Secondary DNS Server	Enter the IP address or Select a Networks/Hosts object representing the alternate DNS server for a DHCP client.
Secondary WINS Server	Enter the IP address or Select a Networks/Hosts object representing the alternate WINS server for a DHCP client.
Dynamic DNS Update	
Enable Dynamic DNS Update	Check this box to define global DDNS update options: • Select the type of resource-record updating: **PTR Record** only, or **A Record and PTR Record**. • You also can select Override DHCP Client Request. If selected, DHCP server updates override any updates requested by DHCP clients. These options are available only on ASA/PIX 7.2 and later.
DHCP Server Interface Configuration table	
Interface table	This table lists device interfaces on which a DHCP server, DDNS updating, or both are configured. Use the Add Row, Edit Row, and Delete Row buttons to manage these entries. The Add Row button opens the Add DHCP Server Interface Configuration dialog box, while Edit Row opens the Edit DHCP Server Interface Configuration dialog box. See Add and Edit DHCP Server Interface Configuration Dialog Boxes , on page 2012 for more information.
Advanced Options	
Advanced button	Opens the Add/Edit DHCP Server Advanced Configuration Dialog Box , on page 2013.

Add and Edit DHCP Server Interface Configuration Dialog Boxes

Use these dialog boxes to enable DHCP and specify a DHCP address pool for a specified interface, and to enable dynamic DNS (DDNS) updating on the interface.

Note Other than the titles, the two dialog boxes are identical.

Navigation Path

You can access the Add DHCP Server Interface Configuration and Edit DHCP Server Interface Configuration dialog boxes from the DHCP Server Page , on page 2011.

Related Topics

- Configuring DHCP Servers , on page 2010

Field Reference

Table 644: Add/Edit DHCP Server Interface Configuration Dialog Boxes

Element	Description
Interface	Identifies the interface on which you are configuring a DHCP server. Enter an interface name, or select an interface object.
DHCP Address Pool	Enter an IP address or a range of addresses, separated by a hyphen, that the DHCP server will use when assigning IP addresses. The beginning and ending addresses in the range must be in the same subnet, and the beginning address cannot be greater than the ending address.
Enable DHCP Server	Check this box to enable a DHCP server on this interface.
Enable Dynamic DNS Update	Check this box to enable DDNS updating by this DHCP server. Specify the record(s) to be updated: • **PTR Record** only • **A Record and PTR Record** You also can select **Override DHCP Client Request**. If selected, DHCP server updates override any updates requested by DHCP clients.

Add/Edit DHCP Server Advanced Configuration Dialog Box

The Add/Edit DHCP Server Advanced Configuration dialog box lets you manage DHCP options configured for the DHCP server. These options provide additional information to DHCP clients. For example, DHCP option 150 and DHCP option 66 provide TFTP server information to Cisco IP Phones and Cisco IOS routers.

Navigation Path

You can access the Add/Edit DHCP Server Advanced Configuration dialog box by clicking the Advanced button on the DHCP Server Page , on page 2011.

Related Topics

- Configuring DHCP Servers , on page 2010

Field Reference

Table 646: Add/Edit DHCP Server Option Dialog Box

Element	Description
Option Code	Choose an option from the list of available option codes. All DHCP options (options 1 through 255) are supported except 1, 12, 50-54, 58-59, 61, 67, and 82. Detailed information about DHCP option codes is available on cisco.com: DHCP Options Reference.
Type	Choose the type of information the option returns to the DHCP client: • **IP** – Choosing this type specifies that one or two IP addresses are returned to the DHCP client. Provide up to two IP addresses. • **ASCII** – Choosing this type specifies that an ASCII value is returned to the DHCP client. Provide the ASCII character string, which cannot include spaces. • **HEX** – Choosing this type specifies that an hexadecimal value is returned to the DHCP client. Provide the HEX string with an even number of digits and no spaces; you do not need to use a 0x prefix.

DNS Page

Use the DNS page to configure DNS server groups. The firewall device uses these DNS servers to resolve fully-qualified domain names (host names) to IP addresses for SSL VPN, certificates, and FQDN network/host objects used in identity-aware firewall policies. Other features that define server names (such as AAA) do not support DNS resolution—you must enter the IP address or manually resolve the name to an IP address.

Tip The DefaultDNS server group is predefined on the ASA and is used for FQDN network/host object resolution. If you use FQDN objects, ensure that you configure DNS servers for this group; otherwise, the names cannot be resolved. To enhance security, ensure that you specify DNS servers that are trusted and that are preferably inside your network. For more information, see Requirements for Identity-Aware Firewall Policies , on page 641.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > DNS** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > DNS** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Add DNS Server Dialog Box , on page 2017

Field Reference

Table 647: DNS Page

Element	Description
DNS Server Groups table	This table lists the currently defined DNS server groups. Use the Add Row, Edit Row and Delete Row buttons below the table to manage these group entries. The Add Row button opens the Add DNS Server Group dialog box, and the Edit Row button opens the Edit DNS Server Group dialog box; except for the titles these dialog boxes are identical. See Add DNS Server Group Dialog Box , on page 2016 for more information.
DNS Group Map	**Enable DNS To Domain**—Check this option to enable mapping of DNS Server Group Name to DNS Group Map domain name. If this option is unchecked, then the DNS Group Map table will be empty. The DNS Group Map table lists the currently defined DNS Group Map. Use the Add Row, Edit Row, and Delete Row buttons below the table to manage these group entries. For more information, see Add DNS Group Map Dialog Box .
DNS Lookup Interfaces	Lists the interfaces on which you want to enable DNS lookup. Enter or Select one or more interfaces or interface roles.

Element	Description
Enable DNS Guard (ASA/PIX 7.0(5), 7.2(x) and 8.x only)	Check this box to enable DNS Guard for the selected device or shared policy. DNS Guard tears down the DNS session associated with a DNS query as soon as the DNS reply is forwarded by the security appliance. DNS Guard also monitors the message exchange to ensure that the ID of the DNS reply matches the ID of the DNS query. This command is effective only on interfaces for which DNS inspection is disabled. When DNS inspection is enabled, the DNS Guard function is always performed. **Note** In releases prior to 7.0(5), the DNS Guard functions are always enabled regardless of the configuration of DNS inspection.
DefaultDNS Server Group (ASA 8.4(2)+)	Additional settings that apply to the DefaultDNS server group only. These settings are used when resolving FQDN network/host objects to IP addresses. • **Poll Timer**—The time, in minutes, of the polling cycle used to resolve FQDN network/host objects to IP addresses. FQDN objects are resolved only if they are used in a firewall policy. The timer determines the maximum time between resolutions; the DNS entry's time-to-live (TTL) value is also used to determine when to update to IP address resolution, so individual FQDNs might be resolved more frequently than the polling cycle. The default is 240 (four hours). The range is 1 to 65535 minutes. • **Expire Entry Timer**—The number of minutes after a DNS entry expires (that is, the TTL has passed) that the entry is removed from the DNS lookup table. Removing an entry requires that the table be recompiled, so frequent removals can increase the processing load on the device. Because some DNS entries can have very short TTL (as short as three seconds), you can use this setting to virtually extend the TTL. The default is 1 minute (that is, the entry is removed one minute after the TTL has passed). The range is 1 to 65535 minutes.

Add DNS Server Group Dialog Box

Use the Add DNS Server Group dialog box to define the DNS servers and settings for a DNS server group, used by security devices to resolve server names to IP addresses in policies that support name resolution.

Note With the exception of its title, the Edit DNS Server Group dialog box is identical to this one, and the following descriptions apply to both.

Navigation Path

You can access the Add DNS Server Group and Edit DNS Server Group dialog boxes from the DNS Page , on page 2015.

Field Reference

Table 648: Add/Edit DNS Server Group Dialog Boxes

Element	Description
Name	Provide a name for the group of DNS servers. **Tip** The name DefaultDNS is predefined on the ASA and includes the servers used for policies that do not allow the selection of a specific group, such as for FQDN network/host object resolution.
DNS Servers	Lists the DNS servers in this group. You can specify up to six servers to which DNS requests can be forwarded. The security appliance tries each DNS server in top-to-bottom order until it receives a response. **Note** You also must specify at least one interface on which DNS is enabled in the DNS Lookup section of the DNS Page , on page 2015. Use the buttons next to this list to manage the entries; from the top down, they are: • Add a DNS server to the list; opens the Add DNS Server Dialog Box , on page 2017. • Delete the currently selected DNS server entry from the list. • Move the currently selected entry up one row. • Move the currently selected entry down one row.
Timeout	Specify the number of seconds, from 1 to 30, to wait before trying the next DNS server; the default is 2 seconds. Each time the security device retries the list of servers, this timeout doubles.
Retries	Specify the number of times, from 0 to 10, to retry the list of DNS servers when the security device does not receive a response.
Domain Name	Optionally, specify a valid DNS domain name for the server; for example, **dnsexample.com**.

Add DNS Server Dialog Box

Use the Add DNS Server dialog box to add a DNS server to the DNS servers list in the Add DNS Server Group or Edit DNS Server Group dialog boxes.

Navigation Path

You can access the Add DNS Server dialog box from the Add DNS Server Group or Edit DNS Server Group dialog boxes. For more information about these dialog boxes, see Add DNS Server Group Dialog Box , on page 2016.

Related Topics

Field Reference

Table 649: Add DNS Server Dialog Box

Element	Description
DNS Server	The IP address, or the host network/host object that defines the address, of the DNS server. Enter the address or click **Select** to select the network/host object from a list or to create a new object.
Interface (ASA 9.5(1) or later)	Click select to choose an interface. The Interface selector dialog box lists only Interface Roles and not Physical Interfaces. Therefore you must add a Physical Interface to the Interface Role before selecting the Source Interface. There is no default value for the interface. This feature is available in Security Manager version 4.9 and later for devices running ASA version 9.5(1) or later.

Add DNS Group Map Dialog Box

Use the Add DNS Group Map dialog box to define the DNS Group Map name and domain.

Note To edit the Group Map entries, use the Edit DNS Group Map dialog box.

Navigation Path

You can access the Add DNS Group Map and Edit DNS Group Map dialog boxes from the DNS Page .

Field Reference

Table 650: Add/Edit DNS Group Map Dialog Boxes

Element	Description
Name	Provide a name for the DNS Group Map.
Domain Name	Specify a valid DNS domain name for the group map; for example, **dnsexample.com**. **Note** Enter a unique domain value for each DNS Group Map name.

Configuring DDNS

Dynamic DNS (DDNS) provides IP-address and domain-name mapping updates so hosts can find each other even though their DHCP-assigned IP addresses may change frequently. Also, beginning with the version 7.2(3), Cisco security appliances can generate DDNS updates. The DDNS page is where you configure this feature.

The DDNS mappings are maintained on the DHCP server in two types of resource records (RRs): the address or *A* records contain the name-to-IP-address mappings, while the pointer or *PTR* records map addresses to host names.

By automatically recording the association between assigned addresses and host names at defined intervals, DDNS allows frequently changing address-host name associations to be updated frequently. Mobile hosts, for example, can then move freely on a network without user or administrator intervention.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > DDNS** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > DDNS** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 651: DDNS Page

Element	Description
Dynamic DNS Interface Settings	This table lists currently defined DDNS interface-update methods. Use the Add Row, Edit Row, and Delete Row buttons below the table to manage these methods; the Add Row and Edit Row buttons open the Add/Edit DDNS Interface Rule Dialog Box , on page 2019.
DHCP Client requests DHCP Server to update records	The global setting on the appliance for DHCP client update requests. This option enables the client to send DDNS updates via the DHCP server, and specifies what is updated: the PTR resource record, both the A and PTR resource records, or neither. Choose **Not Selected**, **Only PTR Record**, **Both A and PTR Record**, or **No Update**.
DHCP Client ID Interface	Specify the interface(s) for global DHCP client update requests: enter an interface name or IP address, or Select an interface object.
Enable DHCP Client Broadcast	Select this option to allow DHCP clients on the device to broadcast DDNS updates. Available on ASA/PIX 7.2(3)+ devices only.

Add/Edit DDNS Interface Rule Dialog Box

Use the Add/Edit DDNS Interface Rule dialog box to manage rules for dynamic DNS updates. These rules are defined on a per-interface basis.

Navigation Path

You access the Add/Edit DDNS Interface Rule dialog box from the Configuring DDNS , on page 2018.

Table 654: Add/Edit DDNS Update Methods Dialog Box

Element	Description
Method Name	Provide an identifier for this method.
Update Interval	Specify how often records are to be updated for this method: provide a number of days, hours, minutes, and seconds. Note that while zero is the default value for hours, minutes and seconds, there is no default Day value: you must enter a number for Day.
Update Records	Specify the resource record(s) to be updated: select **Not Defined**, **A Records**, or **Both A and PTR Records**. Selecting A Records or Both A and PTR Records overrides the setting in the Add/Edit DDNS Interface Rule Dialog Box , on page 2019.

NTP Page

Network Time Protocol (NTP) is used to implement a hierarchical system of servers that provide precisely synchronized timing for network systems. This kind of accuracy is required for time-sensitive operations, such as validating Certificate Revocation Lists (CRLs), which include a precise time stamp. You can configure multiple NTP servers. The security device chooses the server with the lowest stratum—a measure of how reliable the data is.

Note This page is not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

Use the NTP page to enable NTP and manage the NTP servers used to dynamically set the time on a security device.

Note Time derived from an NTP server overrides any time set manually on the Clock page.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > NTP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > NTP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 655: NTP Page

Element	Description
Enable NTP Authentication	Enables or disables authentication with an NTP server. Disabling authentication does not alter the list of configured servers. If you enable authentication, the security appliance only communicates with an NTP server if it uses the correct trusted key in the packets. The security appliance also uses an authentication key to synchronize with the NTP server.
NTP Server Table	Lists the currently configured NTP servers. Use the Add Row, Edit Row and Delete Row buttons to manage this list; the Add Row and Edit Row buttons open the NTP Server Configuration Dialog Box , on page 2022.

NTP Server Configuration Dialog Box

Use the NTP Server Configuration dialog box to add or edit an NTP server definition.

Navigation Path

You can access the NTP Server Configuration dialog box from the NTP Page , on page 2021.

Note The NTP page is not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

Field Reference

Table 656: NTP Server Configuration Dialog Box

Element	Description
IP Address	Enter or Select the IP address of the NTP server.

Element	Description
Preferred	If checked, this NTP server is the preferred server when multiple servers are similarly accurate. NTP uses an algorithm to determine which server is the most accurate and synchronizes to that one. If multiple servers are of similar accuracy, then this option specifies which of those servers to use. However, if a server is significantly more accurate than the preferred one, the security appliance uses the more accurate server. For example, the security appliance uses a server of stratum 2 over a server of stratum 3 that is preferred. We recommend that you configure an NTP server as preferred only when multiple servers are likely to have the same stratum.
Interface	Enter or Select the interface used for NTP traffic, if you want to override the default interface in to the routing table.
Authentication Type	Adding to MD5, the following authentication types are also supported in Cisco Security Manager starting from version 4.20 for ASA 9.13(1) and higher devices: • sha1 • sha256 • sha512 • cmac
Key Number	Enter the ID for this authentication key. The NTP server packets must also use this key ID. If you previously configured a key ID for another server, you can select it in the list; otherwise, type a number between 1 and 4294967295.
Trusted	Sets this key as a trusted key. You must select this option for authentication to work.
Key Value	Enter the authentication key as a string up to 32 characters in length.
Confirm	Re-enter the authentication key to verify it is correct.

SMTP Server Page

Use the SMTP Server page to specify the IP address of an SMTP server and optionally, the IP address of a backup server, to which e-mail alerts and notifications are sent in response to specific events.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > SMTP Server** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > SMTP Server** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 657: SMTP Server Page

Element	Description
Primary Server IP Address	Enter or Select the IP address of the SMTP server.
Secondary Server IP Address	Enter or Select the IP address of a back-up SMTP server.

TFTP Server Page

The Trivial File Transfer Protocol (TFTP) is a simple client/server file transfer protocol described in RFC783 and RFC1350 Rev. 2. You can use the TFTP Server page to configure the security appliance as a TFTP client so it can transfer a copy of its running configuration file to a TFTP server. In this way, you can back up and propagate configuration files to multiple security appliances. Only one server is supported.

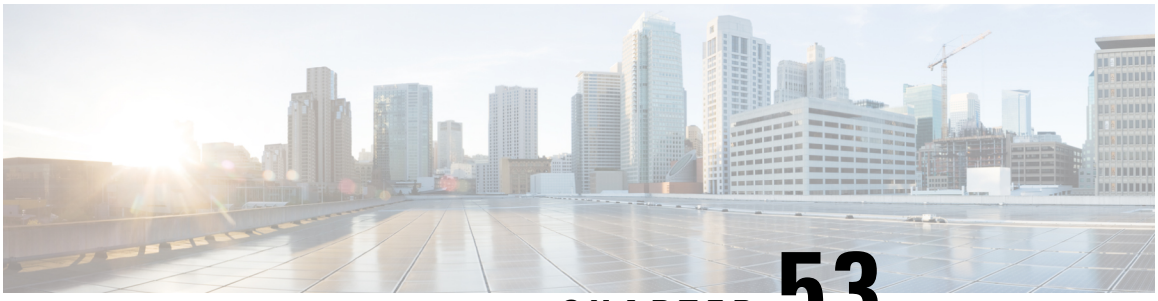
Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > TFTP Server** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > Server Access > TFTP Server** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 658: TFTP Server Page

Element	Description
Interface	Enter or Select the name of interface on which the TFTP server is accessed.
IP Address	Enter or Select the IP address of the TFTP server.
Directory	Enter the path on the TFTP server, beginning with a forward slash (/) and ending in the file name, to which the configuration files will be written (for example, **/tftpboot/asa/config3**). **Note** The path must begin with a forward slash (/).



CHAPTER 53

Configuring FXOS Server Access Settings on Firepower 2100 Series Devices

The FXOS Server Access section contains pages for configuring FXOS server access on Firepower 2100 Series devices; FXOS Server Access is under Device Admin in the Device or Policy selector.

The Firepower 2100 Series devices supported by ASA and Cisco Security Manager are:

- Cisco FPR-2110 Adaptive Security Appliance
- Cisco FPR-2120 Adaptive Security Appliance
- Cisco FPR-2130 Adaptive Security Appliance
- Cisco FPR-2140 Adaptive Security Appliance

This chapter contains the following topics:

HTTPS Page

The HTTPS page allows you to configure the device to access the FXOS server through HTTPS. When you deploy configurations with this protocol, Cisco Security Manager encrypts the configuration file before sending it to the device.

Navigation Path

- (Device view) Select **Platform > Device Admin > FXOS Server Access > HTTPS** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > FXOS Server Access > HTTPS** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Add and Edit HTTPS Dialog Boxes , on page 2026

Field Reference

Table 659: HTTPS Page

Element	Description
Action	The permit action allows configuring the Firepower 2100 Series device with IP address and port. It supports IPv4 and IPv6 addresses.
Interface	The name of the device interface for which the HTTPS is configured. HTTPS cannot be configured on a Bridge Groups (BG) interface.
IP Address	The IP address of the device. It can be an IPv4 or an IPv6 address.
Port	The port on which communications with the FXOS server take place.

Add and Edit HTTPS Dialog Boxes

Use the Add HTTPS Configuration dialog box to create the HTTPS rules. The security appliance will automatically poll this server for image and configuration updates.

The Edit HTTPS Configuration dialog box is identical to the Add HTTPS Configuration dialog box. The following descriptions apply to both.

Navigation Path

You can access the Add and Edit HTTPS Configuration dialog boxes from the HTTPS Page, on page 2025.

Field Reference

Table 660: Add and Edit HTTPS Configuration Dialog Boxes

Element	Description
Action	Select Permit.
Interface	Click Select and choose the interface. The Bridge Groups (BG) interface cannot be configured with HTTPS.
IP Address	Click Select and choose the IP address of the device that can access the FXOS server. It can be an IPv4 or an IPv6 address.
Port	This value defaults to 3443 when you save the page. You can also enter the port on which communications with the FXOS server should take place.

SSH Page

Use the Secure Shell page to configure port that permit FXOS server access to a Firepower 2100 Series device using the SSH protocol. The rules permit SSH access to a specific IP address and netmask.

Navigation Path

- (Device view) Select **Platform > Device Admin > FXOS Server Access > SSH** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > FXOS Server Access > SSH** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Add and Edit HTTPS Dialog Boxes , on page 2026

Field Reference

Table 661: SSH Page

Element	Description
Action	The permit action allows configuring the Firepower 2100 Series device with IP address and port to access the FXOS server. It supports IPv4 and IPv6 addresses.
Interface	The name of the device interface for which the SSH is configured. SSH cannot be configured on a Bridge Groups (BG) interface.
IP Address	The IP address of the device. It can be an IPv4 or an IPv6 address.
Port	The port on which communications with the FXOS server take place.

Add and Edit SSH Dialog Boxes

Use the Add SSH Configuration dialog box to create the SSH rules. The security appliance will automatically poll this server for image and configuration updates.

The Edit SSH Configuration dialog box is identical to the Add SSH Configuration dialog box. The following descriptions apply to both.

Navigation Path

You can access the Add and Edit SSH Configuration dialog boxes from the HTTPS Page, on page 2025.

Field Reference

Table 662: Add and Edit SSH Configuration Dialog Boxes

Element	Description
Action	Select Permit.
Interface	Click Select and choose the interface. The Bridge Groups (BG) interface cannot be configured with SSH.

Element	Description
IP Address	Click Select and choose the IP address of the device that can access the FXOS server. It can be an IPv4 or an IPv6 address.
Port	This value defaults to 3022 when you save the page. You can also enter the port on which communications with the FXOS server should take place.

SNMP Page

SNMP is an application layer protocol that facilitates the exchange of management information between network devices. You can use the SNMP page to configure the Firepower 2100 Series devices for monitoring by SNMP.

Navigation Path

- (Device view) Select **Platform > Device Admin > FXOS Server Access > SNMP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Device Admin > FXOS Server Access > SNMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

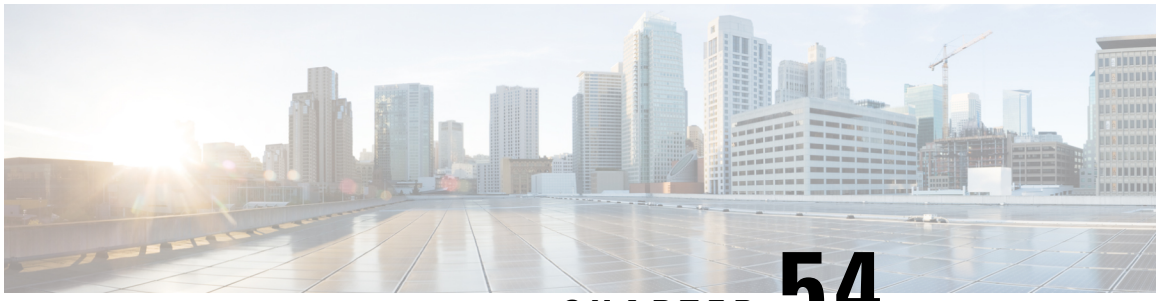
IP Address	Click Select and choose the IP address of the device that can access the FXOS server. It can be an IPv4 or an IPv6 address.
Port	This value defaults to 3161 when you save the page. You can also enter the port on which communications with the FXOS server should take place.



CHAPTER 54

Configuring Logging Policies on Firewall Devices

The Logging feature lets you enable and manage NetFlow "collectors," and enable system logging, set up logging parameters, configure event lists (syslog filters), apply the filters to a destination, set up syslog messages, configure syslog servers, and specify e-mail notification parameters.

After you enable logging and set up the logging parameters using the Logging Setup page, the Event Lists page lets you configure filters (for a set of syslogs) which can be sent to a logging destination. The Logging Filters page lets you specify a logging destination for the syslogs to be sent. Finally, the Syslog and E-Mail pages configure syslog and e-mail setup.

This chapter contains the following topics:

NetFlow Page

A device configured for NetFlow data export captures flow-based traffic statistics on the device. This information is periodically transmitted from the device to a NetFlow collection server, in the form of User Datagram Protocol (UDP) datagrams.

The NetFlow page lets you enable NetFlow export on the selected device, and define and manage NetFlow "collectors" to which collected flow information is transmitted.

Navigation Path

- (Device view) Select **Platform > Logging > NetFlow** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > NetFlow** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Using Rules Tables , on page 604
- Filtering Tables , on page 50
- Table Columns and Column Heading Features , on page 51

Field Reference

Table 665: NetFlow Page

Element	Description
Enable Flow Export	If checked, NetFlow data export is enabled.
Template Export Interval	Interval (in minutes) between transmissions of flow information to the collectors. The value can be from one to 3600 minutes; the default is 30.
Active Refresh Interval	For active connections, specifies the time interval between flow-update events in minutes. Valid values are from 1 to 60 minutes. The default value is 1 minute.
Delay Flow Create	Delays the sending of a flow-create event by the specified number of seconds. The value can be from one to 180 seconds. If no value is entered, there is no delay, and the flow-create event is exported as soon as the flow is created. If the flow is torn down before the configured delay, the flow-create event is not sent; an extended flow teardown event is sent instead.
Collectors table	Lists the currently defined NetFlow collectors. Use the Add Row, Edit Row and Delete Row buttons below the table to manage these entries. The Add Row and Edit Row buttons open the Add and Edit Collector Dialog Boxes (NetFlow) , on page 2032. **Note** Cisco Security Manager does not allow duplicate netflow collectors for ASA 9.6(4) to 9.7.0, and 9.8(2) and above devices. Change the current configuration or remove the duplicate or overlapping configuration (**Platform> Logging > Netflow**) for the device.

Add and Edit Collector Dialog Boxes (NetFlow)

Use the Add Collector and Edit Collector dialog boxes to define and edit NetFlow “collectors.” Except for the title, the two dialog boxes are identical; the following information applies to both.

Navigation Path

You can open the Add and Edit Collector dialog boxes from the NetFlow Page , on page 2031.

Field Reference

Table 666: Add and Edit Collector Dialog Boxes

Element	Description
Interface	Enter or Select the name of the device interface through which the collector is contacted.
Collector	Enter the IP address or the network name of the server to which NetFlow packets will be sent. You also can Select a Networks/Hosts object.
UDP Port	Specify the UDP port on the specified Collector to which NetFlow packets will be sent. Values can range from 1 to 65535; the default is 2055.

Embedded Event Manager

The Embedded Event Manager (EEM) enables you to debug problems and provides general purpose logging for troubleshooting. There are two components: events to which the EEM responds or listens, and event manager applets that define actions as well as the events to which the EEM responds. You may configure multiple event manager applets to respond to different events and perform different actions.

Note Embedded Event Manager is supported on ASA 9.2(1)+ only.

Supported Events

The EEM supports the following events:

- Syslog—The ASA uses syslog message IDs to identify syslog messages that trigger an event manager applet. You may configure multiple syslog events, but the syslog message IDs may not overlap within a single event manager applet.
- Timers—You may use timers to trigger events. You may configure each timer only once for each event manager applet. Each event manager applet may have up to three timers. The three types of timers are the following:
  - Watchdog (periodic) timers trigger an event manager applet after the specified time period following the completion of the applet's actions and restart automatically.
  - Countdown (one-shot) timers trigger an event manager applet once after the specified time period and do not restart unless they are removed, then re-added.
  - Absolute (once-a-day) timers cause an event to occur once a day at a specified time, and restart automatically. The time-of-day format is in hh:mm:ss.

You may configure only one timer event of each type for each event manager applet.

- None—The none event is triggered when you run an event manager applet manually.
- Crash—The crash event is triggered when the ASA crashes. Regardless of the value of the output command, the action commands are directed to the crashinfo file. The output is generated before the show tech command.

Note Be careful when using a range of Syslog IDs and when using timers. Incorrect configuration can cause an ASA loop and prevent the applet from executing normally.

Configuring Actions

When an event manager applet is triggered, the actions on the event manager applet are performed. Each action has a number that is used to specify the sequence of the actions. The sequence number must be unique within an event manager applet. You may configure multiple actions for an event manager applet. The commands are typical CLI commands, such as **show blocks**.

Configuring Output Destinations

You may send the output of the action CLI commands to one of three locations:

- None, which is the default and discards the output
- Console, which sends the output to the ASA console
- File, which sends the output to a file. The following four file options are available:
  - new—creates a new, uniquely named file each time that an event manager applet is invoked.
  - overwrite—overwrites a specified file each time that an event manager applet is invoked.
  - append—appends to a specified file each time that an event manager applet is invoked. If the file does not yet exist, it is created.
  - rotate—creates a set of uniquely named files that are rotated each time that an event manager applet is invoked.

Guidelines and Limitations

- Supported in single mode only. Not supported in multiple context mode.
- Supported in routed and transparent firewall modes.
- EEM will be enabled irrespective of whether logging functionality is enabled on the device or not.
- The EEM functionality on the ASA only contains a subset of the EEM functionality found on Cisco routers.
- During a crash, the state of the ASA is generally unknown. Some commands may not be safe to run during this condition.
- The name of an event manager applet may not contain spaces.
- You cannot modify the None event and Crashinfo event parameters.
- Performance may be affected because syslog messages are sent to the EEM for processing.
- The default output is none for each event manager applet. To change this setting, you must enter a different output value.
- You may have only one output option defined for each event manager applet.

The Embedded Event Manager table lists the currently defined event manager applets. Use the Add Row, Edit Row and Delete Row buttons below the table to manage these entries. The Add Row and Edit Row buttons open the Add and Edit Applet Dialog Boxes , on page 2035.

Navigation Path

- (Device view) Select **Platform > Logging > Embedded Event Manager** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Embedded Event Manager** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

Add and Edit Applet Dialog Boxes

Use the Add Applet and Edit Applet dialog boxes to define and edit event manager applets. Except for the title, the two dialog boxes are identical; the following information applies to both.

Navigation Path

You can open the Add and Edit Applet dialog boxes from the Embedded Event Manager , on page 2033.

Field Reference

Table 667: Add and Edit Applet Dialog Boxes

Element	Description
Name	Enter a unique name for the event manager applet. The name cannot contain spaces and must be less than 32 characters.
Description	Enter a description for the event manager applet. The description may be up to 256 characters long.
Configuration Tab	
Crashinfo	When selected, the event manager applet is triggered when the ASA crashes. Regardless of the value of the Output field, the action commands are directed to the crashinfo file. The output is generated before the show tech command. **Note** The state of the ASA is generally unknown when it crashes. Some CLI commands may not be safe to run during this condition.
None	When selected, you can trigger the event manager applet manually. **Note** Manual triggering of the EEM applet is not supported in Cisco Security Manager. To manually trigger an applet, you must use a FlexConfig. See Managing Flexconfigs, on page 341 for more information.

Element	Description
Syslog table	The Syslog table lists the currently defined syslog message IDs for the selected applet. Use the Add Row, Edit Row and Delete Row buttons below the table to manage these entries. The Add Row and Edit Row buttons open the Add and Edit Syslog Configuration Dialog Boxes , on page 2037.
Absolute	Configure an absolute (once-a-day) timer event Absolute timers cause an event to occur once a day at a specified time, and restart automatically. Use the fields provided to enter the time of day in hours, minutes, and seconds. The time range is from 00:00:00 (midnight) to 23:59:59.
Countdown	Configures a countdown (one-shot) timer event. Countdown timers trigger an event manager applet once after the specified time period and do not restart unless they are removed, then re-added. Enter the time period in seconds. The number of seconds may range from 1- 604800.
Watchdog	Configures a watchdog (periodic) timer event. Watchdog timers trigger an event manager applet after the specified time period following the completion of the applet's actions and restart automatically. Enter the time period in seconds. The number of seconds may range from 1- 604800.
Output	To configure specific destinations for sending output from an action, choose one of the available output destination options: • none—(default) discards the output. • console—sends the output to the ASA console. • file—sends the output to a file. Select the file option in the Action list.
Action	The following four file options are available: • new—creates a new, uniquely named file each time that an event manager applet is invoked. The filename has the format of eem-applet-timestamp.log, in which applet is the name of the event manager applet and timestamp is a dated timestamp in the format of YYYYMMDD-hhmmss. • overwrite—overwrites a specified file each time that an event manager applet is invoked. Specify the file details using the File Location and File Name fields. • append—appends to a specified file each time that an event manager applet is invoked. If the file does not yet exist, it is created. Specify the file details using the File Location and File Name fields. • rotate—creates a set of uniquely named files that are rotated each time that an event manager applet is invoked. Specify the number of files to be rotated in the File Count field (valid values range from 2 - 100). When a new file is to be written, the oldest file is deleted, and all subsequent files are renumbered before the first file is written. The newest file is indicated by 0, and the oldest file is indicated by the highest number. The filename format is eem-applet-x.log, in which applet is the name of the applet, and x is the file number.

Element	Description
File Location	Specifies the location of the output file. The location may also use FTP, TFTP, and SMB targeted files.
File Name	Specifies the filename of the output file.
File Count	Specify the number of files to be rotated when "rotate" is the selected Action. When a new file is to be written, the oldest file is deleted, and all subsequent files are renumbered before the first file is written. The newest file is indicated by 0, and the oldest file is indicated by the highest number. Valid values for the rotate value range from 2 - 100. The filename format is eem-applet-x.log, in which applet is the name of the applet, and x is the file number.
Action Tab	
Action table	The Action table lists the currently defined actions for the selected applet. Use the Add Row, Edit Row and Delete Row buttons below the table to manage these entries. The Add Row and Edit Row buttons open the Add and Edit Action Configuration Dialog Boxes , on page 2038.

Add and Edit Syslog Configuration Dialog Boxes

Use the Add Syslog Configuration and Edit Syslog Configuration dialog boxes to configure the syslog message IDs for an event manager applet. Except for the title, the two dialog boxes are identical; the following information applies to both.

Navigation Path

You can open the Add and Edit Syslog Configuration dialog boxes from the Add and Edit Applet Dialog Boxes , on page 2035.

Field Reference

Table 668: Add and Edit Syslog Configuration Dialog Boxes

Element	Description
ID	Enter a single syslog message or a range of syslog messages. If a syslog message occurs that matches the specified individual syslog message or range of syslog messages, an event manager applet is triggered. **Note** Syslog message IDs may not be entered twice or overlap within a single event manager applet.
Occurs	(Optional) In the occurrences field, enter the number of times that the syslog message must occur for an event manager applet to be invoked. The default is 1 occurrence every 0 seconds. Valid values are from 1 - 4294967295.
Period	(Optional) In the period field, enter the number of seconds within which the syslog messages must occur to invoke the action. This value limits how frequently an event manager applet is invoked to at most once in the configured period. Valid values are from 0 - 604800. A value of 0 means that no period is defined.

Add and Edit Action Configuration Dialog Boxes

Use the Add Action Configuration and Edit Action Configuration dialog boxes to configure the actions for an event manager applet. Except for the title, the two dialog boxes are identical; the following information applies to both.

Navigation Path

You can open the Add and Edit Action Configuration dialog boxes from the Add and Edit Applet Dialog Boxes , on page 2035.

Field Reference

Table 669: Add and Edit Action Configuration Dialog Boxes

Element	Description
Ordinal ID	Enter the unique sequence number in the Ordinal ID field. Valid sequence numbers range from 0 - 4294967295. When adding an action configuration, the Ordinal ID will default to one greater than the highest Ordinal ID used.
CLI	Enter the CLI command in the CLI field. The command runs in global configuration mode as a user with privilege level 15 (the highest). The command may not accept any input, because it is disabled.

E-Mail Setup Page

The E-Mail Setup page (PIX 7.0/ASA Only) lets you set up a source e-mail address, as well as a list of recipients for specified syslog messages to be sent as e-mails. You can filter the syslog messages sent to a destination e-mail address by severity. The table shows which entries have been set up.

The syslog severity filter used for the destination e-mail address will be the higher of the severity selected in this section and the global filter set for all e-mail recipients in the Logging Filters page.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog > E-Mail Setup** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > E-Mail Setup** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 670: E-Mail Setup Page

Element	Description
Source Email Address	Enter the email address to be used as the source address when syslogs are sent as emails.

Element	Description
Destination Address table	Lists the currently defined email recipients of syslog messages. Use the Add Row, Edit Row and Delete Row buttons below the table to manage this list; the Add Row and Edit Row buttons open the Add/Edit Email Recipient Dialog Box , on page 2039.

Add/Edit Email Recipient Dialog Box

The Add/Edit Email Recipient dialog box lets you configure a destination address to be sent emails containing syslog messages; you can limit the messages sent according to severity.

The syslog severity filter used for the destination email address will be the higher of the severity selected in this section and the global filter set for all email recipients on the Logging Filters Page , on page 2043.

Navigation Path

You can access the Add/Edit Email Recipient dialog box from the E-Mail Setup Page , on page 2038.

Field Reference

Table 671: Add/Edit Email Recipient Dialog Box

Element	Description
Destination Email Address	Enter the recipient email address for the chosen type of syslog messages.
Syslog Severity list	Choose the severity of the syslogs to be emailed to this recipient; messages of the chosen severity and higher are sent. Message severity levels are described in Logging Levels , on page 2055.

Event Lists Page

The Event Lists page (PIX 7.0+/ASA only) lets you define a set of syslog message filters for logging. After you enable logging and set up global logging parameters on the Logging Setup page, use this page to configure event lists used to filter syslog messages sent to different logging destinations. (The Logging Filters Page , on page 2043 lets you specify logging destinations for event lists.)

Use the Add Row, Edit Row and Delete Row buttons below the Event Lists table to manage the entries. Add Row and Edit Row open the Add/Edit Event List Dialog Box , on page 2041.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog > Event Lists** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Event Lists** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

vpnlb	VPN Load Balancing	718

Class	Definition	Message ID Numbers
webvpn	Web-based VPN	716

Add/Edit Event List Dialog Box

The Add/Edit Event List dialog box lets you create or edit an event list, and specify which syslog messages to include in the event list filter.

You can use the following criteria to define an event list:

- Class and Severity
- Message ID

Class represents specific types of related syslog messages. For example, the class auth represents all syslog messages related to user authentication.

Severity classifies syslogs based on the relative importance of the event in the normal functioning of the network. The highest severity is Emergency, which means the resource is no longer available. The lowest severity is Debugging, which provides detailed information about every network event.

The message ID is a numeric value that uniquely identifies each individual message. You can specify a single message ID, or a range of IDs, in an event list.

Navigation Path

You can access the Add/Edit Event List dialog box from the Event Lists Page , on page 2039.

Field Reference

Table 673: Add/Edit Event List Dialog Box

Element	Description
Event List Name	Enter a name that uniquely identifies this event list.
Event Class/Severity Filters	This table lists the event class and severity level filters defined for this event list. Use the Add Row, Edit Row and Delete Row buttons below this table to manage the entries. Add Row and Edit Row open the Add/Edit Syslog Class Dialog Box , on page 2041.
Message ID Filters	This table list the message ID filters defined for this event list. Use the Add Row, Edit Row and Delete Row buttons below this table to manage the entries. Add Row and Edit Row open the Add/Edit Syslog Message ID Filter Dialog Box , on page 2042.

Add/Edit Syslog Class Dialog Box

The Add/Edit Syslog Class dialog box lets you specify an event class and a related severity level as an event list filter.

Class represents specific types of related syslog messages, so you do not have to select the syslogs individually. For example, the class auth represents all syslog messages related to user authentication.

Severity classifies syslogs based on the relative importance of the event in the normal functioning of the network. The highest severity is Emergency, which means the resource is no longer available. The lowest severity is Debugging, which provides detailed information about every network event.

Navigation Path

You access the Add/Edit Syslog Class dialog box from the Add/Edit Event List Dialog Box , on page 2041.

Related Topics

Field Reference

Message IDs – Enter a syslog message ID, or a range of IDs. Use a hyphen to specify a range; for example, 101001-101010 . Message IDs must be between 100000 and 999999.

Message IDs and their corresponding messages are listed in the System Log Message guides for the appropriate product. You can access these guides from cisco.com:

PIX Firewall

- http://www.cisco.com/en/US/products/sw/secursw/ps2120/products_system_message_guides_list.html

ASA

- http://www.cisco.com/en/US/products/ps6120/products_system_message_guides_list.html

FWSM

- http://www.cisco.com/en/US/products/hw/modules/ps2706/ps4452/tsd_products_support_model_home.html

Logging Filters Page

The Logging Filters page lets you configure a logging destination for event lists (syslog filters) that have been configured using the Event Lists page, or for only the syslog messages that you specify using the Edit Logging Filters page. Syslog messages from specific or all event classes can be selected using the Edit Logging Filters page.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog > Logging Filters** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Logging Filters** from the Policy Type selector. Right-click **Logging Filters** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

Field Reference

Table 675: Logging Filters Page

Element	Description
Logging Destination	Lists the name of the logging destination to which messages matching this filter are sent. Logging destinations are as follows: • **Internal Buffer**. Messages matching this filter are published to the internal buffer of the security appliance. • **Console**. Messages matching this filter are published to any console port connections. • **Telnet Sessions**. Messages matching this filter are published to any Telnet sessions connected to the security appliance. • **Syslog Servers**. Messages matching this filter are published to any syslog servers specified on the **Platform > Logging > Syslog Servers page**. • **E-Mail**. Messages matching this filter are published to any recipients specified on the **Platform > Logging > E-mail Setup (PIX7.0/ASA Only)** page. • **SNMP Trap**. Messages matching this filter are published to any SNMP management stations specified on the **Platform > Device Admin > Device Access > SNMP** page. • **ASDM**. Messages matching this filter are published to any ASDM sessions.
Syslogs From All Event Classes	Lists the severity on which to filter, the event list to use, or whether logging is disabled from all event classes. Event classes are described in Message Classes and Associated Message ID Numbers , on page 2040.
Syslogs From Specific Event Classes	Lists event class and severity set up as the filter. Event classes are described in Message Classes and Associated Message ID Numbers , on page 2040. Severity levels are described in Logging Levels , on page 2055.

Edit Logging Filters Dialog Box

The Edit Logging Filters dialog box lets you edit filters for a logging destination. Syslogs can be configured from all or specific event classes, or disabled for a specific logging destination.

Navigation Path

You can access the Edit Logging Filters dialog box from the Logging Filters page. For more information about the Logging Filters page, see Logging Filters Page , on page 2043.

Logging Destination list	Specifies the logging destination for this filter: • **Internal Buffer**. Messages matching this filter are published to the internal buffer of the security appliance. • **Console**. Messages matching this filter are published to any console port connections. • **Telnet Sessions**. Messages matching this filter are published to any Telnet sessions connected to the security appliance. • **Syslog Servers**. Messages matching this filter are published to any syslog servers specified on the **Platform > Logging > Syslog Servers page**. • **E-Mail**. Messages matching this filter are published to any recipients specified on the **Platform > Logging > E-mail Setup (PIX7.0/ASA Only)** page. • **SNMP Trap**. Messages matching this filter are published to any SNMP management stations specified on the **Platform > Device Admin > Device Access > SNMP** page. • **ASDM**. Messages matching this filter are published to any ASDM sessions.
Syslog from All Event Classes	
Filter on severity option	Filters on the severity of the logging messages.
Filter on severity list	Specifies the level of logging messages on which to filter.
Use event list option	Specifies to use an event list.
Use event list	Specifies the event list to use. Event lists are defined on the Event Lists Page , on page 2039.
Disable logging option	Disables all logging to the selected destination.
Syslog from Specific Event Classes (PIX7.0)	
Event Class	Specifies the event class and severity. Event classes include one or all available items. Event classes are described in Message Classes and Associated Message ID Numbers , on page 2040.
Severity	Specifies the level of logging messages. Severity levels are described in Logging Levels , on page 2055.

Configuring Logging Setup

The Logging Setup page lets you enable system logging on the security appliance and configure other logging options. These options include enabling logging on the security appliance and failover unit, specifying the base log format and detail, and logging to longer-term storage devices, FTP server or Flash, before purging the internal buffer.

Related Topics

- Logging Setup Page , on page 2046

Step 1 Select **Platform** > **Logging** > **Syslog** > **Logging Setup** to display the Logging Setup page.

Step 2 Check **Enable Logging**.

This option enables logging on the security appliance.

Step 3 To enable logging on the failover unit paired with this security appliance, select the **Enable logging on the standby failover unit** check box.

Step 4 To enable EMBLEM format, or to send debug messages as part of the syslog messages, select the corresponding check boxes.

If you enable EMBLEM, you must use the UDP protocol to publish syslog messages. It is not compatible with TCP.

Step 5 To write the internal buffer data to an FTP server for future processing prior to clearing the buffer, do the following:

a) Check **FTP Server Buffer wrap**.
b) Enter the IP address of the FTP server in the **IP Address** field.
c) Enter the user name of the account used to log into the FTP server in the **User Name** field.
d) Enter the path in the **Path** field, relative to the FTP root, where the file should be stored.
e) Enter and confirm the password used to authenticate the user name.

Step 6 To write the internal buffer data to Flash for future processing prior to clearing the buffer, do the following:

a) Check **Flash**.
b) Specify the maximum amount of memory to allocate to the storage of internal buffer data.
c) Specify the minimum memory that should remain free on the Flash drive. If this minimum value cannot be retained while writing out the data from the internal buffer, the messages will be pruned to meet the space requirements.

Step 7 To specify the maximum queue size maintained on the appliance for viewing by an ASDM client, enter that value in the **Message Queue Size (Messages)** field.

Logging Setup Page

The Logging Setup page lets you enable system logging on the security appliance and configure other logging options.

Navigation Path

- (Device view) Select **Platform** > **Logging** > **Syslog** > **Logging Setup** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Logging Setup** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 677: Logging Setup Page

Element	Description
Enable Logging	Turns on logging for the main security appliance.
Enable Logging on the Failover Standby Unit	Turns on logging for the standby security appliance, if available.
Send syslogs in EMBLEM format (PIX7.x+, ASA, FWSM 3.x+)	Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages; EMBLEM is not compatible with TCP. **Note** This setting is not compatible with CS-MARS.
Send debug messages as syslogs (PIX7.x+, ASA, FWSM 3.x+)	Redirects all the debug trace output to the syslog. The syslog message does not appear in the console if this option is enabled. Therefore, to see debug messages, you must enable logging at the console and configure it as the destination for the debug syslog message number and logging level. The syslog message number used is *711011* . Default logging level for this syslog is *debug* .
Memory Size of Internal Buffer (bytes)	Specify the size of the internal buffer to which syslogs is saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 1048576.
Specify FTP Server Information (PIX7.x+, ASA, FWSM 3.x+)	
FTP Server Buffer Wrap	To save the buffer contents to the FTP server before it is overwritten, check this box and enter the necessary destination information in the following fields. To remove the FTP configuration, deselect this option.
IP Address	Enter the IP address of the FTP server.
User Name	Enter the user name to use when connecting to the FTP server.
Path	Enter the path, relative to the FTP root, where the buffer contents should be saved.
Password/Confirm	Enter and confirm the password used to authenticate the user name to the FTP server.
Specify flash size	
Flash	To save the buffer contents to the flash memory before it is overwritten, check this box. This option is only available in routed or transparent single mode.

Element	Description
Maximum flash to be used by logging (KB)	Specify the maximum space to be used in the flash memory for logging (in KB). This option is available only in routed or transparent single mode.
Minimum free space to be preserved (KB)	Specifies the minimum free space to be preserved in flash memory (in KB). This option is available only in routed or transparent single mode.
ASDM Logging (PIX7.x+, ASA, FWSM 3.x+)	
Message Queue Size	Specify the queue size for syslogs intended for viewing in ASDM.

Configuring Rate Limit Levels

The Rate Limit page lets you specify the maximum number of log messages of specific types (e.g., “alert” or “critical”), and messages with specific Syslog IDs, that can be generated within given periods of time. You can specify individual limits for each logging level, and each Syslog message ID. If the settings conflict, the Syslog message ID limits take precedence.

The Add/Edit Rate Limited Syslog Message Dialog Box , on page 2050 is used to specify the maximum number of messages that can be generated for a particular Syslog message ID within a given period of time.

The Add/Edit Rate Limit for Syslog Logging Levels Dialog Box , on page 2050 is used to specify the maximum number of messages that can be generated for a particular Syslog logging level within a given period of time.

Related Topics

- Rate Limit Page , on page 2049

Follow these steps to manage rate limits for message logging:

Step 1 Access the Rate Limit page by doing one of the following:

- (Device view) Select **Platform > Logging > Syslog > Rate Limit** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Rate Limit** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new policy.

Step 2 Add, edit and delete rate limits for Syslog logging levels:

- To specify the maximum number of messages that can be generated within a given period of time for particular logging level, click the **Add Row** button under the Rate Limits for Syslog Logging Levels table to open the Add/Edit Rate Limit for Syslog Logging Levels Dialog Box , on page 2050. Choose a logging level and define a rate limit.
- To edit the rate limit for a particular logging level, select the appropriate entry in the Rate Limits for Syslog Logging Levels table, and then click the **Edit Row** button under the table to open the Add/Edit Rate Limit for Syslog Logging Levels Dialog Box , on page 2050. Alter the rate limit as necessary.
- To delete a rate limit entry from the Rate Limits for Syslog Logging Levels table, select it and then click the **Delete Row** button under the table. A confirmation dialog box may be displayed; click OK to delete the entry.

Step 3 Add, edit and delete limits for log messages according to message IDs:

- To specify the maximum number of messages that can be generated within a given period of time for particular message ID, click the **Add Row** button under the Individually Rate Limited Syslog Messages table to open the Add/Edit Rate Limited Syslog Message Dialog Box , on page 2050. Choose a Syslog message ID and define a rate limit.
- To edit the rate limit for a particular Syslog message ID, select the appropriate entry in the Individually Rate Limited Syslog Messages table, and then click the **Edit Row** button under the table to open the Add/Edit Rate Limited Syslog Message Dialog Box , on page 2050. Alter the rate limit as necessary.
- To delete a message limit entry from the Individually Rate Limited Syslog Messages table, select it and then click the **Delete Row** button under the table. A confirmation dialog box may be displayed; click OK to delete the entry.

Rate Limit Page

The Rate Limit page allows you to specify the maximum number of log messages of a particular type (for example, alert or critical) that should be generated within a given period of time. You can specify a limit for each logging level and Syslog message ID. If the settings differ, Syslog message ID limits take precedence.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog > Rate Limit** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Rate Limit** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new policy.

Field Reference

Table 678: Rate Limit Page

Element	Description
Rate Limits for Syslog Logging Levels Table	
Logging Level	The Syslog logging level for which you are specifying a rate limit.
No. of Messages	Maximum number of messages of the specified type allowed in the specified time period.
Interval (seconds)	Number of seconds before the rate limit counter resets.
Individually Rate Limited Syslog Messages Table	

Element	Description
Syslog ID	Identification number of the Syslog message for which you are specifying a rate limit.
No. of Messages	Maximum number of messages with the specified ID allowed in the specified time period.
Interval (seconds)	Number of seconds before the rate limit counter resets.

Add/Edit Rate Limit for Syslog Logging Levels Dialog Box

Using the Add/Edit Rate Limit for Syslog Logging Levels dialog box, you can specify the maximum number of log messages for particular log level that should be generated within a given period of time. You can specify a limit for each logging level or syslog message ID (see Add/Edit Rate Limited Syslog Message Dialog Box , on page 2050). If the settings differ, the rate limited syslog message-level settings override rate limit logging level settings.

Navigation Path

You can access the Add/Edit Rate Limit for Syslog Logging Levels dialog box from the Rate Limit page. For more information, see Rate Limit Page , on page 2049.

Field Reference

Table 680: Add/Edit Rate Limited Syslog Message Dialog Box

Element	Description
Syslog ID	Identification number of the syslog message for which you are specifying a rate limit.
Number of Messages	Maximum number of messages with the specified ID allowed in the specified time period.
Interval (Seconds)	Number of seconds before the rate limit counter resets.

Configuring Syslog Server Setup

You can configure general syslog server settings to set the facility code to be included in syslog messages that are sent to syslog servers, specify whether a timestamp is included in each message, specify the device ID to include in messages, view and modify the severity levels for messages, and disable the generation of specific messages.

Related Topics

- Defining Syslog Servers , on page 2057

Step 1 Do one of the following:

- (Device view) Select **Platform > Logging > Syslog > Server Setup** to open the Server Setup Page , on page 2053.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Server Setup** from the Policy Type selector. Select an existing policy or create a new one.

Step 2 Change the basic message configuration as required:

- If your syslog server expects a different facility than the default, select the required facility in the **Facility** list.
- If you want to include the date and time a message was generated in the message, select **Enable Timestamp on Each Syslog Message**.
  - If you want to configure logging timestamp in the rfc5424 format, select Enable Timestamp Format(rfc5424). This option is applicable for ASA 9.12.1 devices and later. Example output of the timestamp:

Example:

```
2003-08-24T05:14:15.000003-07:00
```

- If you want to add a device identifier to syslog messages (which is placed at the beginning of the message), select **Enable Syslog Device ID** and then select the type of ID:

Note For an ASA cluster, each unit in the cluster generates its own syslog messages. You can configure logging so that each unit uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all units in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all units look as if they come from a single unit. If you configure logging to use the local-unit name that is assigned in the cluster bootstrap configuration as the device ID (Cluster ID option), syslog messages look as if they come from different units. You can also specify whether or not the interface IP address of the Control unit should be used for all cluster devices.

- **Interface**—To use the IP address of the specified interface, regardless of the interface through which the appliance sends the message. Click **Select** to select the interface or the interface role that identifies the interface. Interface roles must map to a single interface.

For ASA clusters, to specify that the interface IP address of the Control unit should be used for all cluster devices, select the corresponding option under the Interface Name field.

- **User Defined ID**—To use a text string (up to 16 characters) of your choosing.
- **Host Name**—To use the hostname of the device.
- **Cluster ID**—To use the unique name in the boot configuration of an individual ASA unit in the cluster as the device ID.

Step 3 Use the Syslog Message table to alter the default settings for specific syslog messages. You need to configure rules in this table only if you want to change the default settings. You can change the severity assigned to a message, or you can suppress (disable) the generation of a message.

- To add a rule, click the **Add Row** button and fill in the Add/Edit Syslog Message Dialog Box , on page 2056.

You select the message number whose configuration you want to change, and then select the new severity level, or select **Suppressed** to disable the generation of the message. Typically, you would not change the severity level and disable the message, but you can make changes to both fields if desired. Click **OK** to add the rule to the table.

For a description of message severity levels, see Logging Levels , on page 2055.

- To edit a rule, select it and click the **Edit Row** button, make the desired changes, and click **OK**.
- To delete a rule, select it and click the **Delete Row** button.
- If you are using NetFlow, you can easily disable the generation of syslog messages that have NetFlow equivalents by clicking the **Disable NetFlow Equivalent Syslogs** button. This adds the messages to the table as suppressed messages. Note that if any of these syslog equivalents are already in the table, your existing rules are not overwritten.

Syslog Relay Configuration

In addition to events being received by the Cisco Security Manager server, they can be forwarded to a maximum of two external/remote controllers (syslog hosts). Syslog relay will forward the received messages to another syslog host using the UDP syslog protocol.

If you want the syslog messages that are forwarded from the Cisco Security Manager server to have the Cisco Security Manager server's IP address as the source IP address of the syslog message, you must enable it through CLI command:

1. Navigate to CSCOpx\MDC\logrelay and open the logrelay.properties file.
2. Set the values of ext1 and ext2 to false like this:

```
## Source Preservation
#logrelay.dp.txring.ext0.preserve.source=true logrelay.dp.txring.ext1.preserve.source=false
logrelay.dp.txring.ext2.preserve.source=false
```

Note By default the value is true for all collectors, by setting ext1 and ext2 as false, Cisco Security Manager will send the sylog messages with Cisco Security Manager IP. This modification can be done only for remote collectors and not for the local collector (ext0).

Server Setup Page

The Server Setup page allows you to set the facility code to be included in syslog messages that are sent to syslog servers, specify whether a timestamp is included in each message, specify the device ID to include in messages, view and modify the severity levels for messages, and disable the generation of specific messages.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog > Server Setup** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Server Setup** from the Policy Type selector. Select an existing policy or create a new one.

Related Topics

- Configuring Syslog Server Setup , on page 2051
- Defining Syslog Servers , on page 2057
- Configuring Logging Setup , on page 2046
- Logging Levels , on page 2055

Field Reference

Table 681: Server Setup Page

Element	Description
Facility	The syslog facility code that the appliance includes in messages destined for syslog servers. The default is LOCAL4(20), which is what most UNIX systems expect. You can select a facility between LOCAL0(16) and LOCAL7(23). Syslog facility is useful when you have a central syslog monitoring system that needs to distinguish among the various network devices that generate syslog data streams. Because your network devices share the eight available facilities, you might need to change this value.
Enable Timestamp on Each Syslog Message	Whether to include the date and time a message was generated in syslog messages. The default is to not include time stamps.
Enable Syslog Device ID	Whether to configure a device ID in non-EMBLEM-format syslog messages. If you select this option, select one of the following to use as the device ID, which is place at the start of all syslog messages: **Note** For an ASA cluster, each unit in the cluster generates its own syslog messages. You can configure logging so that each unit uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all units in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all units look as if they come from a single unit. If you configure logging to use the local-unit name that is assigned in the cluster bootstrap configuration as the device ID (Cluster ID option), syslog messages look as if they come from different units. You can also specify whether or not the interface IP address of the Control unit should be used for all cluster devices. • Interface—The IP address of the selected interface. Enter the name of the interface or click **Select** to select it from a list (or to select an interface role that specifies the interface). Messages include the IP address of the interface specified, regardless of which interface the adaptive security appliance uses to send the log data to the external server. If you select an interface role, that role must map to a single interface on the device. For ASA clusters, to specify that the interface IP address of the Control unit should be used for all cluster devices, select the corresponding option under the Interface Name field. • User Defined ID—A text string you define as the device ID. This string can be up to 16 characters, but cannot contain any of the following special characters: & ’ " < > ? • Host Name—The hostname of the security appliance. • Cluster ID—Use the unique name in the boot configuration of an individual ASA unit in the cluster as the device ID.

Element	Description
Syslog Message table	Use this table to enable or disable the generation of specific syslog messages, or to change the severity level of a message. If you do not want to constrict which message types are generated, or change any message severity levels, you do not need to configure anything in this table. The table shows the messages you have configured with the message level and whether generation is suppressed ("true" in the table). • To add a rule, click the **Add Row** button and fill in the Add/Edit Syslog Message Dialog Box , on page 2056. • To edit a rule, select it and click the **Edit Row** button. • To delete a rule, select it and click the **Delete Row** button.
Disable/Enable NetFlow Equivalent Syslogs	If you are using NetFlow logging, you might want to disable the generation of syslog messages that duplicate NetFlow messages. If you click the Disable button, these duplicate syslog messages are added to the Syslog Message table as suppressed messages, and the button is renamed Enable NetFlow Equivalent Syslogs. Clicking the Enable button removes the duplicate syslog messages from the table, meaning that they will no longer be suppressed, and the device will start sending them again. However, if you manually edited any message that was added to the list by the Disable button, the Enable button does not remove them.

Logging Levels

The following table describes logging levels.

Table 682: Logging Levels

Logging Level	Type	Description
0	Emergency	System unusable. Generates messages that identify system instabilities.
1	Alerts	Immediate action needed. Generates messages that identify system integrity issues that require immediate administrative action.
2	Critical	Critical condition. Generates messages that identify critical system issues.
3	Errors	Error condition. Generates messages that identify system errors during operation.
4	Warnings	Warning condition. Generates messages that identify system warnings. For example, device might be configured incorrectly.
5	Notifications	Normal but significant condition. Generates messages that identify normal operations that are typically considered significant events.
6	Information	Informational only. Generates messages that identify system information that is typical of day-to-day activity, such as network session records.

Logging Level	Type	Description
7	Debugging	Generates syslog messages that assist you in debugging. Also generates logs that identify the commands issued during FTP sessions and the URLs requested during HTTP sessions. Includes all emergency, alert, critical, error, warning, notification, and information messages.
-	Disabled	No logging.

Add/Edit Syslog Message Dialog Box

The Add/Edit Syslog Message dialog box lets you modify the logging level or suppression setting for a syslog message.

Navigation Path

You can access the Add/Edit Syslog Message dialog box from the Server Setup Page , on page 2053.

Field Reference

Table 683: Add/Edit Syslog Message Dialog Box

Element	Description
Syslog ID list	The message log ID of the message whose severity level or suppression setting you want to alter. These values and their corresponding messages are identified in the System Log Message guides for the appropriate product: **PIX Firewall** http://www.cisco.com/en/US/products/sw/secursw/ps2120/products_system_message_guides_list.html **ASA** http://www.cisco.com/en/US/products/ps6120/products_system_message_guides_list.html **FWSM** http://www.cisco.com/en/US/products/hw/modules/ps2706/ps4452/tsd_products_support_model_home.html **Note** Starting from Cisco Security Manager 4.10, you can enter a syslog message in the Syslog ID field. Make sure that you enter a valid syslog ID corresponding to the device; else the deployment may fail.
Logging Level list	The logging level that you want to assign to the message. For logging levels and descriptions, see Logging Levels , on page 2055. Select (default) to use the default level assigned to the message.
Suppressed	Whether to suppress the generation of the syslog message. Suppressing a message disables its generation, so you will not see it in syslogs.

Element	Description
Disable Syslogs on Standby	Whether to block specific syslog messages from being generated on standby ASA devices. This feature is available from ASA version 9.4(1) and Security Manager supports this feature starting from version 4.9.

Defining Syslog Servers

The Syslog Servers page lets you specify the syslog servers to which the security appliance will send syslog messages. To make use of the syslog servers you define, you must enable logging using the Logging Setup page and set up the appropriate filters for destinations using the Logging Filters page.

Tip If you want to view events from an ASA device using Security Manager Event Viewer, ensure that you define the Security Manager server as a syslog server. Also, if you use CS-MARS or other applications to manage syslog events, include those servers in this policy.

By directing syslog records generated by a security appliance to a syslog server, you can process and study the records.

Before You Begin

Enable logging. See Configuring Logging Setup , on page 2046.

Related Topics

- Syslog Servers Page , on page 2058
- Add/Edit Syslog Server Dialog Box , on page 2059

Step 1 Select **Platform** > **Logging** > **Syslog** > **Syslog Servers** to display the Syslog Servers page.

Step 2 Do one of the following:

- To add a new syslog target, click the **Add Row** button.
- To edit an existing syslog target, select the check box for the row, then click the **Edit Row** button.

Step 3 Enter or select the interface name in the **Interface** field.

The list displays all interfaces defined at the current scope.

Step 4 Enter or select the IP address of the syslog server in the **IP Address** field.

Step 5 Determine whether to use UDP or TCP, then click the appropriate radio button under Protocol.

Step 6 Enter the port from which the security appliance sends either UDP or TCP syslog messages. The port must be the same port on which the syslog server listens.

- TCP—1470 (Default). TCP ports work only with a security appliance syslog server.
- UDP—514 (Default).

Step 7 To generate syslog messages using the EMBLEM format, select the **Log messages in Cisco EMBLEM format** check box.

To enable this option, you must select UDP protocol to publish messages to this syslog server.

Step 8 Click **OK**.

The definition appears in the Syslog Servers table.

Syslog Servers Page

The Syslog Servers page lets you specify the syslog servers to which the security appliance sends syslog messages. To make use of the syslog servers you define, you must enable logging using the Logging Setup page and set up the appropriate filters for destinations using the Logging Filters page.

Tip If you want to view events from an ASA device using Security Manager Event Viewer, ensure that you define the Security Manager server as a syslog server. Also, if you use CS-MARS or other applications to manage syslog events, include those servers in this policy.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog > Syslog Servers** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Logging > Syslog > Syslog Servers** from the Policy Type selector. Select an existing policy or create a new one.

Related Topics

- Defining Syslog Servers , on page 2057
- Configuring Logging Setup , on page 2046

Field Reference

Table 684: Syslog Servers Page

Element	Description
Syslog Servers table	The syslog servers to which this device sends syslog messages. The table shows the device interface that publishes messages to the server, the server's IP address, syslog protocol and port number, and whether the messages are in Cisco EMBLEM syslog format. There is a limit of four syslog servers that can be set up per context. • To add a server, click the **Add Row** button and fill in the Add/Edit Syslog Server Dialog Box , on page 2059. • To edit a server, select it and click the **Edit Row** button. • To delete a server, select it and click the **Delete Row** button.
Queue Size	Specifies the size of the queue for storing syslog messages on the security appliance when syslog server is busy. Minimum is 1 message. Default is 512. Specify 0 to allow an unlimited number of messages to be queued (subject to available block memory).
Allow user traffic to pass when TCP syslog server is down	Whether to restrict all traffic if any syslog server that is using the TCP protocol is down.

Add/Edit Syslog Server Dialog Box

The Add/Edit Syslog Servers dialog box lets you add or edit the syslog servers to which the security appliance will send syslog messages. To make use of the syslog servers you define, you must enable logging using the Logging Setup page and set up the appropriate filters for destinations using the Logging Filters page.

Note There is a limit of four syslog servers that can be set up per context.

Navigation Path

You can access the Add Syslog Servers dialog box from the Syslog Servers page. For more information about the Syslog Servers page, see Syslog Servers Page , on page 2058.

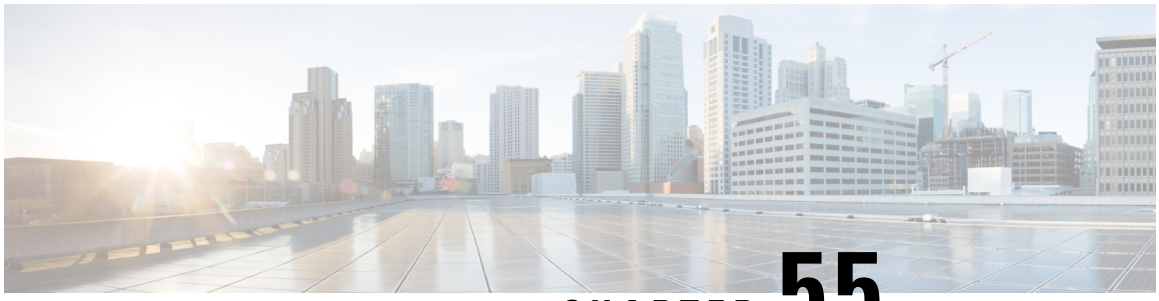
Related Topics

- Defining Syslog Servers , on page 2057
- Configuring Logging Setup , on page 2046

Field Reference

Table 685: Add/Edit Syslog Server Dialog Box

Element	Description
Interface	The interface used to communicate with the syslog server. Enter the name of the interface or interface role object, or click **Select** to select it from a list or to create a new object.
IP Address	The IP address of syslog server. Enter the IP address or the name of the network/host policy object that defines the address, or click **Select** to select the network/host object. **Note** Starting with Cisco Security Manager 4.13, IPv6 addresses are supported for the syslog server.
Protocol	The protocol used by syslog server, either TCP or UDP. UDP is the default. TCP ports work only with a security appliance syslog server. **Note** You must select UDP if you intend to use the EMBLEM format.
Port	The TCP or UDP port from which the security appliance sends syslog messages and on which the syslog server receives them. The default ports for each protocol are: • TCP—1470. • UDP—514. **Tip** If you are defining the Security Manager server as a syslog server, you can find the port number on the Security Manager Administration Event Management Page , on page 538. **Note** During the installation or upgrade of Security Manager, the Common Services syslog service port is changed from 514 to 49514. Later, if Security Manager is uninstalled, the port is not reverted to 514.
Log messages in Cisco EMBLEM format (UDP only)	Whether to log messages in Cisco EMBLEM format. The syslog server must use UDP. **Note** If the syslog server is a Cisco Security MARS appliance, do not select this option. Cisco Security MARS does not process the EMBLEM format.
Reference Identity	Beginning with version 4.12, Security Manager enables you to select Reference Identity policy object name from the Policy Objects Selector. Reference Identity is enabled only if the Port is TCP and is disabled if the Port is UDP. For more information, see Reference Identities , on page 1941.



CHAPTER 55

Configuring Multicast Policies on Firewall Devices

The Multicast section contains pages for defining IP multicast routing on security devices. Multicast routing is supported in single-context, routed mode only.

Enabling multicast routing enables IGMP and PIM on all interfaces by default. Internet Group Management Protocol (IGMP) is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. Protocol Independent Multicast (PIM) is used to maintain forwarding tables for multicast datagrams.

Note Only the UDP transport layer is supported for multicast routing.

This chapter contains the following topics:

Enabling PIM and IGMP

The Enable PIM and IGMP page lets you enable or disable Internet Group Management Protocol (IGMP) and Protocol Independent Multicast (PIM) on all interfaces on the security appliance. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

When **Enable PIM and IGMP** is checked on this page, PIM and IGMP are enabled on all interfaces on the security appliance. Deselect the option to disable PIM and IGMP on all interfaces.

Note You can disable PIM and IGMP on a per-interface basis; see IGMP Page - Protocol Tab , on page 2063 and PIM Page - Protocol Tab , on page 2072 for more information.

Navigation Path

- (Device view) Select **Platform > Multicast > Enable PIM and IGMP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Multicast > Enable PIM and IGMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Configuring IGMP

Internet Protocol hosts use IGMP to report their group memberships to directly connected multicast routers. Internet Group Management Protocol (IGMP) uses group-address (Class D) IP addresses.

Host group addresses can be in the range 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

The IGMP page provides four tabbed panels, used to configure and manage IGMP in Security Manager:

- IGMP Page - Protocol Tab , on page 2063 – This panel displays interface-specific IGMP parameters; you can disable IGMP and change IGMP parameters.
- IGMP Page - Access Group Tab , on page 2065 – Lets you manage access groups that restrict the multicast sources allowed on an interface.
- IGMP Page - Static Group Tab , on page 2066 – Sometimes, hosts on a network may have a configuration that prevents them from answering IGMP queries; however, you still want multicast traffic to be forwarded to that network segment. There are two methods to pull multicast traffic down to a network segment:
  - Use the Join Group tab to configure the interface as a member of the multicast group. With this method, the security appliance accepts the multicast packets in addition to forwarding them to the specified interface.
  - Use the Static Group tab to configure the security appliance to be a statically connected member of a group. With this method, the security appliance does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but itself is not a member of the multicast group.

Use this tab to statically assign a multicast group to an interface, or change existing static group assignments.

- IGMP Page - Join Group Tab , on page 2067 – Use this tab to manage the multicast groups to which the security appliance belongs.

Note If you simply want to forward multicast packets for a specific group to an interface without the security appliance accepting those packets as part of the group, see IGMP Page - Static Group Tab , on page 2066.

Navigation Path

- (Device view) Select **Platform** > **Multicast** > **IGMP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Multicast** > **IGMP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

IGMP Page - Protocol Tab

Use the Protocol tab to configure IGMP parameters for an interface on the security appliance.

Navigation Path

You can access the Protocol tab from the IGMP page. For more information about the IGMP page, see Configuring IGMP , on page 2062.

Field Reference

Table 686: Protocol Tab

Element	Description
Protocol Table	
Interface	The name of the interface to which the IGMP settings apply.
Enabled	Indicates whether IGMP is enabled on the interface.
Version	The version of IGMP enabled on the interface.
Query Interval	The interval, in seconds, at which the designated router sends IGMP host-query messages. Valid values range from 1 to 3600 seconds. The default value is 125 seconds.

Element	Description
Query Timeout	The period of time, in seconds, before the security appliance takes over querying the interface, after the previous appliance has stopped doing so. Valid values range from 60 to 300 seconds. The default value is 255 seconds.
Response Time	The maximum response time, in seconds, advertised in IGMP queries. If the security appliance does not receive any host reports within the designated response time, the IGMP group is pruned. Decreasing this value lets the security appliance prune groups faster. Valid values range from 1 to 12 seconds. The default value is 10 seconds. Changing this value is only valid only for IGMP Version 2.
Group Limit	The maximum number of hosts that can join on an interface. Valid values range from 1 to 500. The default value is 500.
Maximum Groups (PIX 6.3)	The maximum number of groups enabled for multicast. Valid values range from 0 to 2000.
Forward Interface	The name of the interface to which the selected interface forwards IGMP host reports if IGMP forwarding is enabled.

Configure IGMP Parameters Dialog Box

Use the Configure IGMP Parameters dialog box to configure IGMP parameters for an interface on the security appliance.

Navigation Path

You can access the Configure IGMP Parameters dialog box from the IGMP Page - Protocol tab. For more information, see IGMP Page - Protocol Tab , on page 2063.

Related Topics

Field Reference

Table 687: Configure IGMP Parameters Dialog Box

Element	Description
Interface	The name of the interface to which the IGMP settings apply.
Forward Interface	The name of the interface to which IGMP host reports are forwarded if IGMP forwarding is enabled.
Version	The version of IGMP to enable on the interface. Choose 1 to enable IGMP Version 1, or 2 to enable IGMP Version 2. Some features require IGMP Version 2. By default, the security appliance uses IGMP Version 2.

Element	Description
Query Interval	The interval, in seconds, at which the designated router sends IGMP host-query messages. Valid values range from 1 to 3600 seconds. The default value is 125 seconds.
Response Time	The maximum response time, in seconds, advertised in IGMP queries. If the security appliance does not receive any host reports within the designated response time, the IGMP group is pruned. Decreasing this value lets the security appliance prune groups faster. Valid values range from 1 to 12 seconds. The default value is 10 seconds. Changing this value is valid only for IGMP Version 2.
Maximum Groups (PIX 6.3)	The maximum number of groups enabled for multicast. Valid values range from 0 to 2000.
PIX 7.x and ASA Only	
Enable IGMP	When selected, IGMP is enabled on the specified interface.
Group Limit	The maximum number of hosts that can join on an interface. Valid values range from 1 to 500. The default value is 500.
Query Timeout	The period of time, in seconds, before the security appliance takes over querying the interface, after the previous appliance has stopped doing so. Valid values range from 60 to 300 seconds. The default value is 255 seconds.

IGMP Page - Access Group Tab

Use the Access Group tab to control the multicast groups that are allowed on an interface.

The table on this page lists all currently defined multicast access groups, showing for each, the name of the interface or interface role for which the group is defined, the group network(s), and whether this group is permitted or denied. For a detailed explanation of these fields, see Configure IGMP Access Group Parameters Dialog Box , on page 2066.

- To add a multicast access group to the table, click the Add Row button.
- To edit the settings for a group, select it and click the Edit Row button.
- To delete a group, select it and click the Delete Row button.

Navigation Path

You can access the Access Group tab from the Configuring IGMP , on page 2062.

Element	Description
Interface	The name of the interface for which you are configuring multicast group membership.
Join Group	The multicast group address to which this rule applies. The group address must be from 224.0.0.0 to 239.255.255.255.

Configuring Multicast Routes

Static multicast routes let you separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them, sending the multicast packets over the tunnel.

Static multicast routes are local to the security appliance and are not advertised or redistributed.

Use the Multicast Routes page to manage static multicast routes—currently defined routes are listed, and you can add, edit and delete static multicast routes.

See Add/Edit MRoute Configuration Dialog Box , on page 2069 for more information about the fields displayed in the table on this page.

Navigation Path

- (Device view) Select **Platform** > **Multicast** > **Multicast Routes** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Multicast** > **Multicast Routes** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Add/Edit MRoute Configuration Dialog Box

Use the Add/Edit MRoute Configuration dialog box to add a static multicast route to the security appliance, or to change an existing route.

Navigation Path

You can access the Add/Edit MRoute Configuration dialog box from the Multicast Routing page. See Configuring Multicast Routes , on page 2068 for more information.

Field Reference

Table 693: Add/Edit MRoute Configuration Dialog Box

Element	Description
Source Interface	Enter or Select the incoming interface for the multicast route.
Source Network	Enter the IP address and mask of the multicast source, or select a Networks/Hosts object.
Output Interface/Dense	(Optional) Enter or Select the outgoing interface for the multicast route. If you specify the destination interface, the route is forwarded through the selected interface. If you do not specify a destination interface, then RPF is used to forward the route. You can specify the interface, or the RPF neighbor, but not both at the same time.
Multicast Network (PIX 6.3)	Enter or Select the group that is to receive the multicast packets. This must be a multicast IP address in the range of 224.0.1.0 to 239.255.255.255.
Distance (PIX 7.x, ASA and FWSM)	Enter an administrative distance for the static multicast route. If the static multicast route has the same administrative distance as the unicast route, the static multicast route takes precedence.

Configuring Multicast Boundary Filters

On an ASA running version 7.2(1) or later, you can use the Multicast Boundary Filter page to configure the appliance to act as a boundary between multicast domains. The ASA compares multicast group addresses to an access list, blocking all multicast traffic except that specifically permitted by the list.

The Multicast Boundary Filter page lists all currently defined per-interface boundary filter lists; you can add, edit and delete filter lists from this page.

Refer to Add/Edit MBoundary Configuration Dialog Box , on page 2070 for a description of the fields on this page.

Navigation Path

- (Device view) Select **Platform > Multicast > Multicast Boundary Filter** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Multicast > Multicast Boundary Filter** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 695: Add/Edit MBoundary Interface Configuration Dialog Box

Element	Description
Action	Choose **permit** or **deny** to specify the action taken for this multicast group.
Multicast Group	Enter a single multicast address, or a multicast group address, to which this action applies. The address must be 0.0.0.0, or from 224.0.0.0 to 239.255.255.255. A group address range can be entered using either a standard subnet mask (e.g., 239.0.0.0 255.0.0.0), or using CIDR prefix notation (e.g., 239.0.0.0/8). You also can Select a named network/host object.

Configuring PIM

Protocol independent multicast (PIM) provides a scalable method for determining the best paths in a network for distributing a specific multicast transmission to each host that has registered using IGMP to receive the transmission. Routers and security devices use PIM to maintain tables for forwarding multicast datagrams.

With PIM sparse mode (PIM SM), which is the default for Cisco routers, when the source of a multicast transmission begins broadcasting, the traffic is forwarded from one multicast router to the next until the packets reach every registered host. If a more direct path to the traffic source exists, the last-hop router sends a join message to the source that causes the traffic to be rerouted along the better path.

Note PIM is not supported with PAT—the PIM protocol does not use ports and PAT only works with protocols that use ports.

When you enable multicast routing on a security appliance, PIM and IGMP are enabled on all interfaces by default. You can disable PIM on a per-interface basis.

The PIM page provides up to six tabbed panels:

- PIM Page - Protocol Tab , on page 2072– Lets you manage interface-specific PIM properties.
- PIM Page - Neighbor Filter Tab , on page 2073 – Lets you manage neighbor filters for individual interfaces; available only on ASA 7.2(1)+ devices.
- PIM Page - Bidirectional Neighbor Filter Tab , on page 2074 – Lets you manage bidirectional neighbor filters for individual interfaces; available only on ASA 7.2(1)+ devices.
- PIM Page - Rendezvous Points Tab , on page 2076 – When you configure PIM, you must choose one or more devices to operate as the rendezvous point (RP). An RP is a single, common root of a shared distribution tree and is statically configured on each device. First-hop routers use the RP to send registration packets on behalf of the source multicast hosts.
- PIM Page - Route Tree Tab , on page 2078 – By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This reduces delay, but requires more memory than shared tree. You can configure whether the security appliance should join shortest-path tree, or use a shared tree, either for all multicast groups or only for specific multicast addresses.
- PIM Page - Request Filter Tab , on page 2079 – When the security appliance is acting as an RP, you can restrict specific multicast sources from registering. This prevents unauthorized sources from registering with the RP. The Request Filter panel lets you define the multicast sources from which the security appliance will accept PIM registration messages.

PIM Page - Protocol Tab

Use the Protocol tab to configure PIM properties for the interfaces on a security appliance (not available on PIX 6.3 devices). All currently configured interfaces are listed; you can add, edit and delete entries on this panel.

Refer to Add/Edit PIM Protocol Dialog Box , on page 2072 for a description of the fields on this panel.

Navigation Path

You access the Protocol tab from the PIM page. For more information, see Configuring PIM , on page 2071.

Related Topics

Add/Edit PIM Protocol Dialog Box

Use the Add/Edit PIM Protocol dialog box to configure PIM properties for an interface on a security appliance running PIX 7.x or later.

About the Designated Router

The DR is responsible for sending PIM register, join, and prune messaged to the Rendezvous Point (RP). When there is more than one multicast routing device on a network segment, there is an election process to select the Designated Router based on DR priority. If multiple devices have the same DR priority, then the device with the highest IP address becomes the DR. By default, security appliances have a DR priority of 1.

Navigation Path

You can access the Add/Edit PIM Protocol dialog box from the PIM Page - Protocol Tab , on page 2072.

Field Reference

Table 696: Add/Edit PIM Protocol Dialog Box

Element	Description
Interface	Enter or Select the interface on which you are configuring PIM.
Enable PIM	When checked, PIM is enabled on the selected interface. You can deselect this option to disable PIM on the interface without deleting this PIM Protocol entry from the table.
DR Priority	The designated router (DR) priority for this interface. The router with the highest DR priority on subnet becomes the designated router. Valid values range from 0 to 4294967294. The default DR priority is 1. Setting this value to zero makes the security appliance interface ineligible to become the default router.
Hello Interval (seconds)	The frequency, in seconds, at which the interface sends PIM hello messages. Valid values range from 1 to 3600 seconds; the default value is 30 seconds.
Join-Prune Interval (seconds)	The frequency, in seconds, at which the interface sends PIM join and prune advertisements. Valid values range from 10 to 600 seconds; the default value is 60 seconds.

PIM Page - Neighbor Filter Tab

A PIM neighbor filter is an access control list (ACL) that defines the neighbor devices that can participate in PIM. If a neighbor filter is not configured for an interface, then there are no restrictions. If a PIM neighbor filter is configured, only those neighbors permitted by the filter list can participate in PIM with the security appliance.

On an ASA running version 7.2(1) or later, you can use the Neighbor Filter tab to control the devices that can become PIM neighbors. This panel is used to define and manage the per-interface neighbor filter list. Refer to Add/Edit PIM Neighbor Filter Dialog Box , on page 2074 for a description of the fields on this panel.

Navigation Path

You access the Protocol tab from the PIM page. For more information, see Configuring PIM , on page 2071.

Add/Edit PIM Neighbor Filter Dialog Box

Use the Add/Edit PIM Neighbor Filter dialog box to add and edit entries in the PIM neighbor filter ACL displayed on the Neighbor Filter panel of the PIM page.

Navigation Path

You can access the Add/Edit PIM Neighbor Filter dialog box from the PIM Page - Neighbor Filter Tab , on page 2073.

Field Reference

Table 697: Add/Edit PIM Neighbor Filter Dialog Box

Element	Description
Interface	Enter or Select the interface to which this PIM Neighbor filter entry will be applied.
Neighbor Filter Group	Enter a single multicast address, or a multicast group address, to which the chosen Action applies. A group address range can be entered using either a standard subnet mask (e.g., 239.0.0.0 255.0.0.0), or using CIDR prefix notation (e.g., 239.0.0.0/8). You also can Select a named network/host object.
Action	Choose **permit** to allow the specified neighbors to participate in PIM, or **deny** to prevent the specified neighbors from participating in PIM.

PIM Page - Bidirectional Neighbor Filter Tab

A PIM bidirectional neighbor filter is an access control list (ACL) that defines the neighbor devices that can participate in the bidirectional trees and designated forwarder (DF) election. If a PIM bidirectional neighbor filter is not configured for an interface, then there are no restrictions. If a PIM bidirectional neighbor filter is configured, only those neighbors permitted by the ACL can participate in DF election process.

The PIM bidirectional neighbor filters enable the transition from a sparse-mode-only network to a “bidir” network by letting you specify the devices that should participate in DF election, while still allowing all devices to participate in the sparse-mode domain. The bidir-enabled devices can elect a DF from among themselves, even when there are non-bidir devices on the segment. Multicast boundaries on the non-bidir devices prevent PIM messages and data from the bidir groups from leaking in or out of the bidir subset cloud.

Bidirectional PIM allows multicast devices to maintain reduced state information. All of the multicast devices in a segment must be bidirectionally enabled for bidir to elect a DF.

When a PIM bidirectional neighbor filter is enabled, the routers and other devices that are permitted by the ACL are considered to be bidir-capable. Therefore:

- If a permitted neighbor does not support bidir, the DF election does not occur.
- If a denied neighbor supports bidir, then DF election does not occur.
- If a denied neighbor does not support bidir, the DF election can occur.

Managing the Bidirectional Neighbor Filter List

On an ASA running version 7.2(1) or later, you can use this panel to define and manage the per-interface bidirectional neighbor filter list, permitting or denying multicast source addresses for specific interfaces. Refer to Add/Edit PIM Bidirectional Neighbor Filter Dialog Box , on page 2075 for a description of the fields on this panel.

Navigation Path

You access the Bidirectional Neighbor Filter tab from the PIM page. For more information, see Configuring PIM , on page 2071.

Add/Edit PIM Bidirectional Neighbor Filter Dialog Box

Use the Add/Edit PIM Bidirectional Neighbor Filter dialog box to add or edit an entry in the bidirectional neighbor access control list displayed on the PIM Page - Bidirectional Neighbor Filter Tab , on page 2074.

Navigation Path

You can access the Add/Edit PIM Bidirectional Neighbor Filter dialog box from the PIM Page - Bidirectional Neighbor Filter Tab , on page 2074.

Field Reference

Table 698: Add/Edit PIM Bidirectional Neighbor Filter Dialog Box

Element	Description
Interface	Enter or Select the interface to which this PIM Bidirectional Neighbor filter entry will be applied.
Neighbor Filter Group	Enter a single multicast address, or a multicast group address, to which the chosen Action applies. A group address range can be entered using either a standard subnet mask (e.g., 239.0.0.0 255.0.0.0), or using CIDR prefix notation (e.g., 239.0.0.0/8). You also can Select a named network/host object.

Element	Description
Action	Choose **permit** to allow the specified neighbors to participate in the DF election process, or **deny** to prevent the specified neighbors from participating in the process.

PIM Page - Rendezvous Points Tab

When you configure PIM, you must choose one or more routers or routing devices to operate as the RP. An RP is a single, common root of a shared distribution tree and is statically configured on each device. First hop routers use the RP to send register packets on behalf of the source multicast hosts.

You can configure a single RP to serve more than one group. If a specific group is not specified, the RP for the group is applied to the entire IP multicast group range (224.0.0.0/4).

Use the Rendezvous Points panel to define rendezvous points. You can configure more than one RP, but you cannot have more than one entry with the same RP.

Navigation Path

You access the Rendezvous Points tab from the PIM page. For more information, see Configuring PIM , on page 2071.

Related Topics

- PIM Page - Protocol Tab , on page 2072

Field Reference

Table 699: Rendezvous Points Tab

Element	Description
Generate older IOS compatible register messages	Check this box if your rendezvous point is a Cisco IOS router. The security appliance software accepts register messages with the checksum calculated on the PIM header and only the next 4 bytes, while Cisco IOS software accepts register messages with the checksum calculated on the entire PIM message for all PIM message types.
Rendezvous Points table	Lists the rendezvous points currently configured on the security appliance. Use the Add Row, Edit Row and Delete Row buttons to manage this list; the Add Row and Edit Row buttons open the Add/Edit Rendezvous Point Dialog Box , on page 2076.

Add/Edit Rendezvous Point Dialog Box

Use the Add/Edit Rendezvous Point dialog box to add an entry to the Rendezvous Points table, or to edit an existing rendezvous point entry. Please note the following:

- You cannot use the same rendezvous point address twice.
- You cannot specify “All Groups” for more than one rendezvous point.

Navigation Path

You can access the Add/Edit Rendezvous Point dialog box from the PIM Page - Rendezvous Points Tab , on page 2076.

Field Reference

Table 700: Add/Edit Rendezvous Point Dialog Box

Element	Description
Rendezvous Point IP Address	Enter the IP address of the rendezvous point. This is a unicast address. You also can click Select to select a Networks/Hosts object. When editing a rendezvous point entry, you cannot change this value.
Use bi-directional forwarding	Check this box if you want the specified Multicast Groups to operate in bidirectional mode. In bidirectional mode, if the security appliance receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a Prune message back to the source. Deselect this option if you want the specified Multicast Groups to operate in Sparse Mode. **Note** The security appliance always advertises bidirectional capability in PIM hello messages regardless of the actual bidir configuration.
Use this RP for All Multicast Groups	Select this option to use the specified Rendezvous Point for all multicast groups on the interface.
Use this RP for the Multicast Groups as specified below	Select this option to define the multicast groups that are to use the specified Rendezvous Point; the Multicast Groups table is activated.
Multicast Groups table	The multicast groups currently associated with the specified Rendezvous Point are listed. Table entries are processed from the top down. For example, you can create an entry that includes a range of multicast groups, and then exclude specific groups within that range by placing deny rules for those specific groups at the top of the table. That is, the permit rule for the range of multicast groups follows the individual deny statements. Use the buttons at the bottom of the table to open the Add/Edit Multicast Group Rules Dialog Box , on page 2077 to add or edit an entry; to delete an entry; and to move entries up or down in the table.

Add/Edit Multicast Group Rules Dialog Box

Use the Add/Edit Multicast Group Rules dialog box to create a multicast group rule, or modify a multicast group rule, for the Multicast Groups table in the Add/Edit Rendezvous Point dialog box. This dialog box is also used to specify individual multicast groups that use Shared Tree route filtering on the Route Tree tab

Navigation Path

When defining Rendezvous Points, you access the Add/Edit Multicast Group Rules dialog box from the Add/Edit Rendezvous Point Dialog Box , on page 2076. See PIM Page - Rendezvous Points Tab , on page 2076 for more information.

When specifying how PIM register messages are filtered, you open this dialog box by clicking Add Row or Edit row buttons below the Multicast Groups table on the PIM Page - Route Tree Tab , on page 2078.

Field Reference

Table 701: Add/Edit Multicast Group Rules Dialog Box

Element	Description
Action	Choose **permit** to create a group rule that allows the specified multicast addresses; choose **deny** to create a group rule that denies the specified multicast addresses.
Multicast Group Network	Enter the multicast address and network mask associated with the group, or Select the desired Networks/Hosts object.

PIM Page - Route Tree Tab

If the security appliance is acting as a Rendezvous Point, use the Route Tree tab to specify how the PIM register messages from various sources are filtered: shortest-path tree or shared tree, either for all multicast groups or only for specific multicast addresses.

Navigation Path

You can access the Route Tree tab from the PIM page. For more information, see Configuring PIM , on page 2071.

Related Topics

- PIM Page - Protocol Tab , on page 2072
- PIM Page - Rendezvous Points Tab , on page 2076
- PIM Page - Request Filter Tab , on page 2079

Field Reference

Table 702: Route Tree Tab

Element	Description
If.., specify how the PIM register messages from various sources are filtered	Select a tree/groups option: • **Use Shortest Path Tree for All Groups** – The security appliance uses shortest-path tree for all multicast groups. • **Use Shared Tree for All Groups** – The security appliance uses shared tree for all multicast groups. • **Use Shared Tree for the Groups specified below** – The security appliance uses shared tree for those groups specified below in the Multicast Groups table. Shortest-path tree is used for any group not listed in the Multicast Groups table.
Multicast Groups table	The multicast groups using Shared Tree are listed. Table entries are processed from the top down. For example, you can create an entry that includes a range of multicast groups, and then exclude specific groups within that range by placing deny rules for those specific groups at the top of the table. That is, the permit rule for the range of multicast groups follows the individual deny statements. Use the buttons at the bottom of the table to open the Add/Edit Multicast Group Rules Dialog Box , on page 2077 to add or edit an entry; to delete an entry; and to move entries up or down in the table.

PIM Page - Request Filter Tab

When the security appliance acts as a rendezvous point, you can restrict specific multicast sources from registering with it. This prevents unauthorized sources from registering with the rendezvous point. You can use the Request Filter tab to define the multicast sources from which the security appliance accepts and denies PIM register messages.

Navigation Path

You can access the Request Filter tab from the PIM page. For more information, see Configuring PIM , on page 2071.

Related Topics

- PIM Page - Protocol Tab , on page 2072

- PIM Page - Route Tree Tab , on page 2078

Field Reference

Table 703: Request Filter Tab

Element	Description
Filter PIM register messages using	Choose how PIM register messages are filtered for different multicast groups: • **None** – Do not filter PIM register messages. • **route-map** – Filter PIM register messages using a specified route map; the Route Map field is activated. Only PIM register messages that are permitted by the route map are allowed to reach the rendezvous point. • **access-list** – Filter PIM register messages using an access list; the Multicast Groups table is activated. Only PIM register messages that are permitted by the access list are allowed to reach the rendezvous point.
Route Map	When **route-map** is the chosen filter, enter a route-map name. Use standard host ACLs in the referenced route map; extended ACLs are not supported. **Note** This field contains only the Route Map name. The Route Map is created and contained within a FlexConfig.
Multicast Groups table	Lists the currently defined multicast group Request Filter rules. Table entries are processed from the top down. For example, you can create an entry that includes a range of multicast groups, and then exclude specific groups within that range by placing deny rules for those specific groups at the top of the table. That is, the permit rule for the range of multicast groups follows the individual deny statements. Use the buttons at the bottom of the table to open the Add/Edit Multicast Group Rules Dialog Box , on page 2077 to add or edit an entry; to delete an entry; and to move entries up or down in the table.

Add/Edit Multicast Group Rules Dialog Box

Use the Add/Edit Multicast Group Rules dialog box to define the multicast sources that are denied or permitted to register with the security appliance when the appliance acts as a rendezvous point. You create the filter rules based on the source IP address and the destination multicast address.

Navigation Path

You can access the Add/Edit Multicast Group Rules dialog box from the PIM Page - Request Filter Tab , on page 2079.

Field Reference

Table 704: Add/Edit Multicast Group Rules Dialog Box

Element	Description
Action	Choose **permit** to create a rule that allows the specified Source of the specified Destination multicast traffic to register with the security appliance; choose **deny** to create a rule that denies registration to the specified Source/Destination multicast traffic.
Source Network	Enter the IP address and network mask for the source of the register message, or Select the appropriate Networks/Hosts object.
Destination Network	Enter the IP address and network mask for the multicast destination, or Select the appropriate Networks/Hosts object.

PIM Page - Bootstrap Router Tab

PIM Bootstrap Router (BSR) is a dynamic Rendezvous Point (RP) selection model that uses candidate routers for Rendezvous Point function and for relaying the Rendezvous Point information for a group.The Rendezvous Point function includes RP discovery and provides a default route to the RP. It does this by configuring a set of devices as candidate BSRs (C-BSR) which participate in a BSR election process to choose a BSR amongst themselves. Once the BSR is chosen, devices that are configured as candidate Rendezvous Points (C-RP) will start sending their group mapping to the elected BSR. The BSR then distributes the group-to-RP mapping information to all the other devices down the multicast tree, through BSR messages that travel from PIM router to PIM router on a per-hop basis.

You can use the Boot Strap Router tab to configure a device as a PIM Bootstrap Router.

Navigation Path

You can access the Bootstrap Router tab from the PIM page. For more information, see Configuring PIM , on page 2071.

Related Topics

- PIM Page - Protocol Tab , on page 2072
- PIM Page - Rendezvous Points Tab , on page 2076
- PIM Page - Route Tree Tab , on page 2078

Field Reference

Table 705: Bootstrap Router Tab

Element	Description
Interface	Select the interface from which the BSR address is derived, to make it a candidate BSR.

Element	Description
Hash Mask Length	Enter the length of a mask that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash (correspond) to the same Rendezvous Point (RP). For example, if this value is 24, only the first 24 bits of the group addresses matter. This fact allows you to get one RP for multiple groups.
Priority	Enter the priority of the candidate BSR. The BSR with the larger priority is preferred. If the priority values are the same, the router with the larger IP address is the BSR.

Add/Edit Bootstrap Router Dialog Box

Use the Add/Edit Bootstrap Router dialog box to configure a Bootstrap Router as a Border BSR. BSR messages should not be exchanged between different domains, because routers in one domain may elect rendezvous points (RPs) in the other domain, resulting in protocol malfunction or loss of isolation between the domains

A border interface in a PIM sparse mode (PIM-SM) domain is configured to avoid exchange of certain traffic with a neighboring domain reachable through that interface, especially if that domain is also running PIM-SM. Thus to prevent BSR messages from being sent or received through such an interface configure the interface as a border BSR.

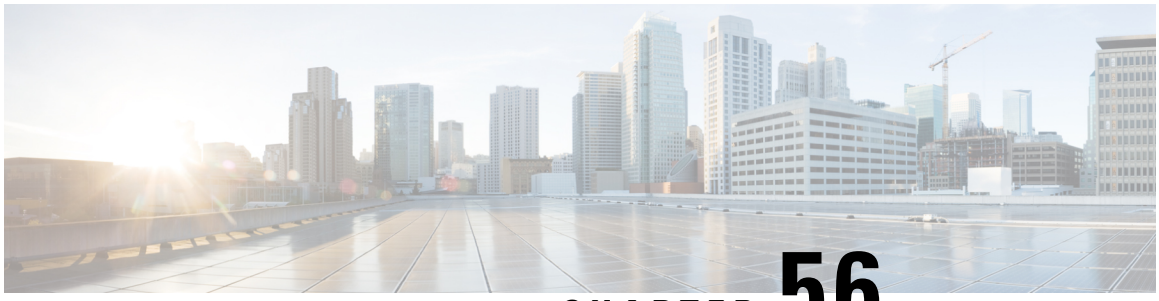
Navigation Path

You can access the Add/Edit Bootstrap Router dialog box from the PIM Page - Bootstrap Router Tab , on page 2081

Field Reference

Table 706: Add/Edit Bootstrap Router Dialog Box

Element	Description
(Optional) BSR Border table Add	Add an interface and configure it as a border BSR. No PIM BSR messages will be sent or received, when an interface is configured as a Border BSR.



CHAPTER 56

Configuring Routing Policies on Firewall Devices

The Routing section in Security Manager contains pages for defining and managing routing settings for security appliances.

This chapter contains the following topics:

Configuring No Proxy ARP

When a host sends IP traffic to another device on the same Ethernet network, the host needs to know the MAC address of the device. Address Resolution Protocol (ARP) is a Layer 2 protocol that resolves an IP address to a MAC address: a host sends an ARP request asking “Who is this IP address?” The device owning the IP address replies, “I own that IP address; here is my MAC address.”

With Proxy ARP, a device responds to an ARP request with its own MAC address, even though the device does not own the IP address. Serving as an ARP Proxy for another host effectively directs network traffic to the proxy, in this case your security appliance. Traffic that passes through the appliance is then routed to the appropriate destination.

For example, the security appliance uses proxy ARP when you configure NAT and specify a global address that is on the same network as the appliance interface. The only way traffic can reach the destination hosts is if the appliance claims and subsequently routes traffic to the destination global addresses.

By default, proxy ARP is enabled for all interfaces. Use the No Proxy ARP page to disable proxy ARP for global addresses:

- To disable proxy ARP for one or more interfaces, enter their names in the Interfaces field. Separate multiple interfaces with commas. You can click Select to choose the interfaces from a list of interfaces defined on the device, and interface roles defined in Security Manager.

Note On ASA 8.4.2 and later devices operating in routed mode, you can disable Proxy ARP on the egress interface for a Manual NAT rule. See *Do not proxy ARP on Destination Interface in Table 24-15* for more information.

Navigation Path

- (Device view) Select **Platform > Routing > No Proxy ARP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > No Proxy ARP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

Configuring BGP

Border Gateway Protocol (BGP) is an inter autonomous system routing protocol. An autonomous system is a network or group of networks under a common administration and with common routing policies. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP).

Note BGP configuration is supported on ASA 9.2(1)+ only. Also, beginning with ASA 9.3(1), BGP is supported in L2 (EtherChannel Type) and L3 (Individual Interface Type) clustering modes.

Navigation Path

- (Device view) Select **Platform > Routing > BGP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > BGP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

The BGP page provides two tabbed panels for configuring BGP routing on a firewall device. This is the basic procedure for configuring the BGP process:

1. Enable the BGP routing process by checking the Enable BGP check box on the BGP page.

2. In the AS Number field, enter the autonomous system (AS) number for the BGP process. The AS number internally includes multiple autonomous numbers. The AS number can be from 1 to 4294967295 or from 1.0 to 65535.65535.
3. On the General Tab , on page 2087:
   - (Optional) Check the Limit the number of AS numbers in AS_PATH attribute of received routes check box to restrict the number of AS numbers in AS_PATH attribute to a specific number. Valid values are from 1 to 254.
   - (Optional) Check the Log Neighbor Changes check box to enable logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability.
   - (Optional) Check the Use TCP path MTU Discovery check box to use the Path MTU Discovery technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation.
   - (Optional) Check the Enable fast external failover check box to reset the external BGP session immediately upon link failure.
   - (Optional) Check the Enforce that the first AS is peer's AS for EBGP routes check box to discard incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH attribute. This prevents a mis-configured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system.
   - (Optional) Check the Use dot notation for AS numbers check box to split the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 0-65553 are represented as decimal numbers and AS numbers larger than 65535 are represented using the dot notation.
   - Define the configuration related to the best path selection process for BGP routing (see General Tab , on page 2087).
   - Specify the timer information in the Neighbor timers area (see General Tab , on page 2087).
   - (Optional) Configure Graceful Restart (see General Tab , on page 2087).
4. On the IPv4 Family tab, select the Enable IPv4 Family check box and then use the tabs provided to configure IPv4 Address Family settings. For more information, see IPv4 Family Tab , on page 2089.
5. On the IPv6 Family tab, select the Enable IPv6 Family check box and then use the tabs provided to configure IPv6 Address Family settings. For more information, see IPv6 Family Tab , on page 2103.

- About BGP , on page 2085

About BGP

BGP is an inter autonomous system routing protocol. An autonomous system is a network or group of networks under a common administration and with common routing policies. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP).

When to Use BGP

Customer networks, such as universities and corporations, usually employ an Interior Gateway Protocol (IGP) such as OSPF for the exchange of routing information within their networks. Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

Routing Table Changes

BGP neighbors exchange full routing information when the TCP connection between neighbors is first established. When changes to the routing table are detected, the BGP routers send to their neighbors only those routes that have changed. BGP routers do not send periodic routing updates, and BGP routing updates advertise only the optimal path to a destination network.

Routes learned via BGP have properties that are used to determine the best route to a destination, when multiple paths exist to a particular destination. These properties are referred to as BGP attributes and are used in the route selection process:

- Weight -- This is a Cisco-defined attribute that is local to a router. The weight attribute is not advertised to neighboring routers. If the router learns about more than one route to the same destination, the route with the highest weight is preferred.
- Local preference -- The local preference attribute is used to select an exit point from the local AS. Unlike the weight attribute, the local preference attribute is propagated throughout the local AS. If there are multiple exit points from the AS, the exit point with the highest local preference attribute is used as an exit point for a specific route.
- Multi-exit discriminator -- The multi-exit discriminator (MED) or metric attribute is used as a suggestion to an external AS regarding the preferred route into the AS that is advertising the metric. It is referred to as a suggestion because the external AS that is receiving the MEDs may also be using other BGP attributes for route selection. The route with the lower MED metric is preferred.
- Origin -- The origin attribute indicates how BGP learned about a particular route. The origin attribute can have one of three possible values and is used in route selection.
  - IGP- The route is interior to the originating AS. This value is set when the network router configuration command is used to inject the route into BGP.
  - EGP-The route is learned via the Exterior Border Gateway Protocol (EBGP).
  - Incomplete- The origin of the route is unknown or learned in some other way. An origin of incomplete occurs when a route is redistributed into BGP.
- AS_path -- When a route advertisement passes through an autonomous system, the AS number is added to an ordered list of AS numbers that the route advertisement has traversed. Only the route with the shortest AS_path list is installed in the IP routing table.
- Next hop -- The EBGP next-hop attribute is the IP address that is used to reach the advertising router. For EBGP peers, the next-hop address is the IP address of the connection between the peers. For IBGP, the EBGP next-hop address is carried into the local AS.
- Community -- The community attribute provides a way of grouping destinations, called communities, to which routing decisions (such as acceptance, preference, and redistribution) can be applied. Route maps are used to set the community attribute. The predefined community attributes are as follows:
  - no-export- Do not advertise this route to EBGP peers.

- no-advertise- Do not advertise this route to any peer.
- internet- Advertise this route to the Internet community; all routers in the network belong to it.

BGP Path Selection

BGP may receive multiple advertisements for the same route from different sources. BGP selects only one path as the best path. When this path is selected, BGP puts the selected path in the IP routing table and propagates the path to its neighbors. BGP uses the following criteria, in the order presented, to select a path for a destination:

- If the path specifies a next hop that is inaccessible, drop the update.
- Prefer the path with the largest weight.
- If the weights are the same, prefer the path with the largest local preference.
- If the local preferences are the same, prefer the path that was originated by BGP running on this router.
- If no route was originated, prefer the route that has the shortest AS_path.
- If all paths have the same AS_path length, prefer the path with the lowest origin type (where IGP is lower than EGP, and EGP is lower than incomplete).
- If the origin codes are the same, prefer the path with the lowest MED attribute.
- If the paths have the same MED, prefer the external path over the internal path.
- If the paths are still the same, prefer the path through the closest IGP neighbor.
- If both paths are external, prefer the path that was received first (the oldest one).
- Prefer the path with the lowest IP address, as specified by the BGP router ID.
- If the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster list length.
- Prefer the path that comes from the lowest neighbor address.

General Tab

Use the General tab to configure BGP settings such as Best Path Selection, Neighbor Timers, and Graceful Restart.

Navigation Path

You can access the Neighbors tab from the BGP page (see Configuring BGP , on page 2084).

Related Topics

- IPv4 Family Tab , on page 2089

Field Reference

Table 707: General Tab

Element	Description
Limit the number of AS numbers in AS_PATH attribute of received routes	Restricts the number of AS numbers in AS_PATH attribute to a specific number. Valid values are from 1 to 254.
Log Neighbor Changes	Enables logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability.
Use TCP path MTU Discovery	Enables the use of the Path MTU Discovery technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation.
Enable fast external failover	Resets the external BGP session immediately upon link failure.
Enforce that the first AS is peer's AS for EBGP routes	Discards incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH attribute. This prevents a mis-configured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system.
Use dot notation for AS numbers	Splits the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 0-65553 are represented as decimal numbers and AS numbers larger than 65535 are represented using the dot notation.
Best Path Selection	
Default local preference	Specify a value between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.
Allow comparing MED from different neighbors	Allows the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems.
Compare Router-id for identical EBGP paths	Compares similar paths received from external BGP peers during the best path selection process and switches the best path to the route with the lowest router ID.
Pick the best MED path among paths advertised from the neighboring AS	Enables MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path.
Treat missing MED as the least preferred one	Considers the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred.
Neighbor Timers	

Element	Description
Keepalive Interval	Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.
Hold Time	Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured. The default values is 180 seconds.
Min Hold Time	(Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured. Specify a value from 0 to 65535.
Graceful Restart (Use in failover or spanned cluster mode) (ASA 9.3.1+ only)	
Enable Graceful Restart	Enables ASA peers to avoid a routing flap following a switchover.
Restart Time	Specify the time duration that ASA peers will wait to delete stale routes before a BGP open message is received. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.
Stalepath Time	Enter the time duration that the ASA will wait before deleting stale routes after an end of record (EOR) message is received from the restarting ASA. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.

IPv4 Family Tab

Use the IPv4 Family tab on the BGP page to enable and configure IPv4 settings for BGP.

Navigation Path

You can access the IPv4 Family tab from the BGP page. For more information about the BGP page, see Configuring BGP , on page 2084.

Related Topics

- About BGP , on page 2085
- General Tab , on page 2087

Field Reference

Table 708: IPv4 Family - Aggregate Address Tab

Element	Description
Enable IPv4 Family	Enables configuration of routing sessions that use standard IPv4 address prefixes.

Element	Description
General	Use this panel to configure general IPv4 settings such as Best Path Selection, Neighbor Timers, and Graceful Restart. See IPv4 Family - General Tab , on page 2090 for more about these definitions.
Aggregate Address	Use this panel to define the aggregation of specific routes into one route. Specify a value for the aggregate timer (in seconds) in the Aggregate Timer field. Valid values are 0 or any value between 6 and 60. The default value is 30. See Add/Edit Aggregate Address Dialog Box , on page 2106 for more about these definitions.
Filtering	Use this panel to filter routes or networks received in incoming BGP updates. See Add/Edit Filter Dialog Box , on page 2093 for more about these definitions.
Neighbor	Use this panel to define BGP neighbors and neighbor settings. See Add/Edit Neighbor Dialog Box , on page 2094 for more about these definitions.
Networks	Use this panel to define the networks to be advertised by the BGP routing process. See Add/Edit Network Dialog Box , on page 2100 for more about these definitions.
Redistribution	Use this panel to define the conditions for redistributing routes from another routing domain into BGP. See Add/Edit Redistribution Dialog Box , on page 2101 for more about these definitions.
Route Injection	Use this panel to define the routes to be conditionally injected into the BGP routing table. See Add/Edit Route Injection Dialog Box , on page 2102 for more about these definitions.

IPv4 Family - General Tab

Use the IPv4 Family - General tab to configure the general IPv4 settings.

Navigation Path

You can access the General tab from the IPv4 Family Tab on the BGP page. For more information about the IPv4 Family tab, see IPv4 Family Tab , on page 2089.

Related Topics

- Configuring BGP , on page 2084
- About BGP , on page 2085

Field Reference

Table 709: IPv4 Family - General Tab

Element	Description
Router ID	On a single device, choose **Automatic** or **IP Address**. (An address field appears when you choose IP Address.) If you choose Automatic, the highest-level IP address on the security appliance is used as the router ID. To use a fixed router ID, choose IP Address and enter an IPv4 address in the Router ID field. On a device cluster, choose **Automatic** or **Cluster Pool**. (An IPv4 Pool object ID field appears when you choose Cluster Pool.) If you choose Cluster Pool, enter or Select the name of the IPv4 Pool object that is to supply the Router ID address. For more information, see Add or Edit IPv4 Pool Dialog Box , on page 323.
Learned Route Map	Enter or Select the name of a route map object. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Scanning Interval	Enter a scanning interval (in seconds) for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60.
Routes and Synchronization	
Generate Default Route	(Optional) Configures a BGP routing process to distribute a default route (network 0.0.0.0).
Summarize subnet routes into network-level routes	(Optional) Configures automatic summarization of subnet routes into network-level routes.
Advertise inactive routes	(Optional) Advertises routes that are not installed in the routing information base (RIB).
Synchronize between BGP and the Interior Gateway Protocol (IGP) system	Enables synchronization between BGP and your Interior Gateway Protocol (IGP) system. To enable the Cisco IOS software to advertise a network route without waiting for the IGP, deselect this option. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. By default, synchronization between BGP and the IGP is turned off to allow the Cisco IOS software to advertise a network route without waiting for route validation from the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems. Use synchronization if routers in the autonomous system do not speak BGP.
Redistribute iBGP into an IGP	(Optional) Configures iBGP redistribution into an interior gateway protocol (IGP), such as IS-IS or OSPF.

Element	Description
Administrative Route Distances	
External	Specifies the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.
Internal	Specifies administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.
Local	Specifies administrative distance for local BGP routes. Local routes are those networks listed with a network router configuration command, often as back doors, for the router or for the networks that is being redistributed from another process. The range of values for this argument are from 1 to 255. The default value is 200.
Next Hop	
Enable address tracking	(Optional) Enables BGP next hop address tracking.
Delay Interval	Specify the delay interval between checks on updated next-hop routes installed in the routing table.
Forward packets over Multiple Paths	
Number of Paths	(Optional) Specify the maximum number of external BGP routes that can be installed to the routing table.
IBGP Number of Paths	(Optional) Specify the maximum number of internal BGP routes that can be installed to the routing table.

Add/Edit Aggregate Address Dialog Box

Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

Navigation Path

You can access the Add/Edit Aggregate Address dialog box from the IPv4 Family Tab , on page 2089.

Field Reference

Table 711: Add/Edit Filter Dialog Box

Element	Description
ACL	Select an Access Control List that defines which networks are to be received and which are to be suppressed in routing updates.
Direction	Choose a direction from the Direction drop-down list. The direction will specify if the filter should be applied to inbound updates or outbound updates.
Protocol	Select the routing process for which you want to filter: None, BGP, Connected, EIGRP, OSPF, RIP, or Static.
AS Number	Shows the autonomous system number of the BGP routing process. This value is specified on the BGP page (see Configuring BGP , on page 2084).
Process ID	Enter the identifier for the routing process. Applies to EIGRP and OSPF routing protocols.

Add/Edit Neighbor Dialog Box

Use the Add/Edit Neighbor dialog box to define BGP neighbors and neighbor settings.

Navigation Path

You can access the Add/Edit Neighbor dialog box from the IPv4 Family Tab , on page 2089.

Field Reference

Table 712: Add/Edit Neighbor Dialog Box

Element	Description
General	
IP Address	Enter the BGP neighbor IP address. This IP address is added to the BGP neighbor table.
Remote AS	Enter the autonomous system to which the BGP neighbor belongs.
Enable Address Family	(Optional) Enables communication with the BGP neighbor.
Shutdown neighbor administratively	(Optional) Disable a neighbor or peer group.
Configure Graceful Restart per neighbor (ASA 9.3.1+ only)	(Optional) Enables configuration of the Border Gateway Protocol (BGP) graceful restart capability for this neighbor. After selecting this option, you must use the Graceful Restart (Use in failover or spanned cluster mode) option to specify whether graceful restart should be enabled or disabled for this neighbor.
Graceful Restart (Use in failover or spanned cluster mode) (ASA 9.3.1+ only)	(Optional) Enables the Border Gateway Protocol (BGP) graceful restart capability for this neighbor.
Description	(Optional) Enter a description for the BGP neighbor.
fall-over BFD	(Optional) Enables BFD support for fall-over for the BGP neighbor.
BFD-Hop	(Optional) Specify if there is a single IP hop or multiple IP hops between a BFD source and destination.
Filtering	
Filter routes using an access list	(Optional) Enter or Select the appropriate incoming or outgoing access control list to distribute BGP neighbor information.
Filter routes using route map	(Optional) Enter or Select the appropriate incoming or outgoing route maps to apply a route map to incoming or outgoing routes. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Filter routes using a Prefix list	(Optional) Enter or Select the appropriate incoming or outgoing prefix list to distribute BGP neighbor information. **Tip** Click **Select** to open the Prefix List Object Selector from which you can select a prefix list object. You can also create new objects from the object Prefix List Object selector. For more information, see Add or Edit Prefix List Object Dialog Box , on page 2241.

Element	Description
Filter routes using AS Path filter	(Optional) Enter or Select the appropriate incoming or outgoing AS path filter to distribute BGP neighbor information. **Tip** Click **Select** to open the AS Path Object Selector from which you can select an AS path object. You can also create new AS path objects from the AS Path Object Selector. For more information, see Add or Edit As Path Object Dialog Boxes , on page 2246.

Limit the number of prefixes allowed from the neighbor	(Optional) Select to control the number of prefixes that can be received from a neighbor.
	• Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.
	• Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.
	• (Optional) Check the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following:
	  • Select **Terminate peering when prefix limit is exceeded** to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the Restart interval field.
	  • Select **Give only warning message when prefix limit is exceeded** to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.

Routes	
Advertisement Interval	Enter the minimum interval (in seconds) between the sending of BGP routing updates. Valid values are between 1 and 600.
Remove private AS numbers from outbound routing updates	(Optional) Excludes the private AS numbers from being advertised on outbound routes.
Generate Default route	(Optional) Select to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the Route map field. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.

Element	Description

Conditionally Advertised Routes	(Optional) To add or edit conditionally advertised routes, click the **Add Row (+)**button, or select a row in the table and click the **Edit Row(pencil)**button.
	In the Add/Edit Advertised Route dialog box, do the following:
	• Click **Select** to open the Route Map Object Selector from which you can select a route map that will be advertised if the conditions of the exist map or the non-exist map are met. For more information about route maps, see Understanding Route Map Objects , on page 2227.
	• Do one of the following:
	  • Select Set Exist Map and choose a route map from the Route Map Object Selector. This route map will be compared with the routes in the BGP table, to determine whether or not the advertise map route is advertised.
	  • Select Non-Exist Map and choose a route map from the Route Map Object Selector. This route map will be compared with the routes in the BGP table, to determine whether or not the advertise map route is advertised.

Timers	
Set timers for the BGP peer	(Optional) Select to set the keepalive frequency, hold time and minimum hold time.
Keepalive Interval	Enter the frequency (in seconds) with which the ASA sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.
Hold Time	Enter the interval (in seconds) after not receiving a keepalive message that the ASA declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.
Min Hold Time	(Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that the ASA declares a peer dead. Valid values are between 0 and 65535. The default value is 0 seconds.
Advanced	

Element	Description
Enable Authentication	(Optional) Select to enable MD5 authentication on a TCP connection between two BGP peers. • Choose an encryption type from the Enable Encryption drop-down list. • Enter a password in the Password field. Reenter the password in the Confirm field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The first character cannot be a number. The string can contain any alphanumeric characters, including spaces. **Note** You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.
Send Community attribute to this neighbor	(Optional) Specifies that communities attributes should be sent to the BGP neighbor.
Use ASA as next hop for neighbor	(Optional) Select to configure the router as the next-hop for a BGP speaking neighbor or peer group.
Disable connection verification	(Optional) Select to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. This command is required only when the neighbor ebgp-multihop command is configured with a TTL value of 1. The address of the single-hop eBGP peer must be reachable. The neighbor update-source command must be configured to allow the BGP routing process to use the loopback interface for the peering session. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly connected to same network segment, connection verification will prevent the peering session from being established.
Allow connections with neighbor that is not directly connected	Select to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the TTL hops field. Valid values are between 1 and 255. **Note** This feature should be used only under the guidance of Cisco technical support staff. To prevent the creation of loops through oscillating routes, the multihop will not be established if the only route to the multihop peer is the default route (0.0.0.0).

Element	Description
Limit number of TTL hops to neighbor	Select this option to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the TTL hops field. Valid values are between 1 and 254. This feature provides a lightweight security mechanism to protect BGP peering sessions from CPU utilization-based attacks. These types of attacks are typically brute force Denial of Service (DoS) attacks that attempt to disable the network by flooding the network with IP packets that contain forged source and destination IP addresses in the packet headers. This feature leverages designed behavior of IP packets by accepting only IP packets with a TTL count that is equal to or greater than the locally configured value. Accurately forging the TTL count in an IP packet is generally considered to be impossible. Accurately forging a packet to match the TTL count from a trusted peer is not possible without internal access to the source or destination network. This feature should be configured on each participating router. It secures the BGP session in the incoming direction only and has no effect on outgoing IP packets or the remote router. When this feature is enabled, BGP will establish or maintain a session only if the TTL value in the IP packet header is equal to or greater than the TTL value configured for the peering session. This feature has no effect on the BGP peering session, and the peering session can still expire if keepalive packets are not received. If the TTL value in a received packet is less than the locally configured value, the packet is silently discarded and no Internet Control Message Protocol (ICMP) message is generated. This is designed behavior; a response to a forged packet is not necessary. To maximize the effectiveness of this feature, the hop-count value should be strictly configured to match the number of hops between the local and external network. However, you should also take path variation into account when configuring this feature for a multihop peering session. The following restrictions apply to the configuration of this command: • This feature is not supported for internal BGP (iBGP) peers. • The effectiveness of this feature is reduced in large-diameter multihop peerings. In the event of a CPU utilization-based attack against a BGP router that is configured for large-diameter peering, you may still need to shut down the affected peering sessions to handle the attack. • This feature is not effective against attacks from a peer that has been compromised inside of your network. This restriction also includes peers that are on the network segment between the source and destination network.
Use TCP Path MTU Discovery	(Optional) Select to enable a TCP transport session for a BGP session.
TCP transport mode	Choose the TCP connection mode from the drop-down list. Options are Default, Active, or Passive.

Element	Description
Weight	(Optional) Enter a weight for the BGP neighbor connection.
BGP Version	Choose the BGP version that the ASA will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.
Migration **Note** This customization should only be used for AS migration, and should be removed after the transition has been completed. The procedure should be attempted only by an experienced network operator. Routing loops can be created through improper configuration.	
Customize the AS number for routes received from the neighbor	(Optional) Select to customize the AS_PATH attribute for routes received from an eBGP neighbor.
Local AS Number	Enter the local autonomous system number. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.
Do not prepend local AS number to routes received from neighbor	(Optional) Select to prevent the local AS number from being prepended to any routes received from eBGP peer.
Replace real AS number with local AS number in routes received from neighbor	(Optional) Select to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.
Accept either real AS number or local AS number in routes received from neighbor	(Optional) Configures the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

Add/Edit Network Dialog Box

Use the Add/Edit Network dialog box to define the networks to be advertised by the BGP routing process.

Navigation Path

You can access the Add/Edit Network dialog box from the IPv4 Family Tab , on page 2089.

Field Reference

Table 713: Add/Edit Network Dialog Box

Element	Description
Network	Specifies the network to be advertised by the BGP routing processes.
Route Map	(Optional) Enter or Select a route map that should be examined to filter the networks to be advertised. If not specified, all networks are redistributed. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.

Add/Edit Redistribution Dialog Box

Use the Add/Edit Redistribution dialog box to define the conditions for redistributing routes from another routing domain into BGP.

Navigation Path

You can access the Add/Edit Redistribution dialog box from the IPv4 Family Tab , on page 2089.

Field Reference

Table 714: Add/Edit Redistribution Dialog Box

Element	Description
Source Protocol	Choose the protocol from which you want to redistribute routes into the BGP domain from the Source Protocol drop-down list.
Process ID	Enter the identifier for the routing process. Applies to EIGRP and OSPF routing protocols.
Metric	(Optional) Enter a metric for the redistributed route.
Route Map	Enter or Select a route map that should be examined to filter the networks to be redistributed. If not specified, all networks are redistributed. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Match	The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions. These options are enabled only when OSPF is chosen as the Source Protocol. • Internal • External 1 • External 2 • NSSA External 1 • NSSA External 2

Add/Edit Route Injection Dialog Box

Use the Add/Edit Route Injection dialog box to define the routes to be conditionally injected into the BGP routing table.

Navigation Path

You can access the Add/Edit Route Injection dialog box from the IPv4 Family Tab , on page 2089.

Field Reference

Table 716: IPv6 Family - Aggregate Address Tab

Element	Description
Enable IPv6 Family	Enables configuration of routing sessions that use standard IPv6 address prefixes.
General	Use this panel to configure general IPv6 settings. See IPv6 Family - General Tab , on page 2104 for more about these definitions.
Aggregate Address	Use this panel to define the aggregation of specific routes into one route. Specify a value for the aggregate timer (in seconds) in the Aggregate Timer field. Valid values are 0 or any value between 6 and 60. The default value is 30. See Add/Edit Aggregate Address Dialog Box , on page 2106 for more about these definitions.
Neighbor	Use this panel to define BGP neighbors and neighbor settings. See Add/Edit Neighbor Dialog Box , on page 2107 for more about these definitions.
Networks	Use this panel to define the networks to be advertised by the BGP routing process. See Add/Edit Network Dialog Box , on page 2113 for more about these definitions.
Redistribution	Use this panel to define the conditions for redistributing routes from another routing domain into BGP. See Add/Edit Redistribution Dialog Box , on page 2114 for more about these definitions.
Route Injection	Use this panel to define the routes to be conditionally injected into the BGP routing table. See Add/Edit Route Injection Dialog Box , on page 2115 for more about these definitions.

IPv6 Family - General Tab

Use the IPv6 Family - General tab to configure the general IPv6 settings.

Navigation Path

You can access the General tab from the IPv6 Family Tab on the BGP page. For more information about the IPv6 Family tab, see IPv6 Family Tab , on page 2103.

Related Topics

- Configuring BGP , on page 2084

Field Reference

Table 717: IPv6 Family - General Tab

Element	Description
Scanning Interval	Enter a scanning interval (in seconds) for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60.
Routes and Synchronization	
Generate Default Routes	(Optional) Configures a BGP routing process to distribute a default route (network 0.0.0.0).
Advertise inactive routes	(Optional) Advertises routes that are not installed in the routing information base (RIB).
Synchronize between BGP and the Interior Gateway Protocol (IGP) system	Enables synchronization between BGP and your Interior Gateway Protocol (IGP) system. To enable the Cisco IOS software to advertise a network route without waiting for the IGP, deselect this option. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. By default, synchronization between BGP and the IGP is turned off to allow the Cisco IOS software to advertise a network route without waiting for route validation from the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems. Use synchronization if routers in the autonomous system do not speak BGP.
Redistribute iBGP into an IGP (use filtering to limit the number of prefixes that are redistributed)	(Optional) Configures iBGP redistribution into an interior gateway protocol (IGP), such as IS-IS or OSPF.
Administrative Route Distances	
External	Specifies the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.
Internal	Specifies administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.
Local	Specifies administrative distance for local BGP routes. Local routes are those networks listed with a network router configuration command, often as back doors, for the router or for the networks that is being redistributed from another process. The range of values for this argument are from 1 to 255. The default value is 200.
Forward packets over Multiple Paths	
Number of Paths	(Optional) Specify the maximum number of Border Gateway Protocol routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

Element	Description
IBGP Number of Paths	(Optional) Specify the maximum number of parallel internal Border Gateway Protocol (iBGP) routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

Add/Edit Aggregate Address Dialog Box

Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

Navigation Path

You can access the Add/Edit Aggregate Address dialog box from the IPv6 Family Tab , on page 2103. Click the **Add Row (+)** button, or select a row in the table and click the **Edit Row(pencil)** button.

Table 719: Add/Edit Neighbor Dialog Box

Element	Description
General	
IP Address	Enter the BGP neighbor IP address. This IP address is added to the BGP neighbor table.
Remote AS	Enter the autonomous system to which the BGP neighbor belongs.
Enable Address Family	(Optional) Enables communication with the BGP neighbor.

Element	Description
Shutdown neighbor administratively	(Optional) Disable a neighbor or peer group.
Configure Graceful Restart per neighbor (ASA 9.3.1+ only)	(Optional) Enables configuration of the Border Gateway Protocol (BGP) graceful restart capability for this neighbor. After selecting this option, you must use the Graceful Restart (Use in failover or spanned cluster mode) option to specify whether graceful restart should be enabled or disabled for this neighbor.
Graceful Restart (Use in failover or spanned cluster mode) (ASA 9.3.1+ only)	(Optional) Enables the Border Gateway Protocol (BGP) graceful restart capability for this neighbor.
Description	(Optional) Enter a description for the BGP neighbor.
fall-over BFD	(Optional) Enables BFD support for fall-over for the BGP neighbor.
BFD-Hop	(Optional) Specify if there is a single IP hop or multiple IP hops between a BFD source and destination.
Filtering	
Filter routes using an access list	(Optional) Enter or Select the appropriate incoming or outgoing access control list to distribute BGP neighbor information.
Filter routes using route map	(Optional) Enter or Select the appropriate incoming or outgoing route maps to apply a route map to incoming or outgoing routes. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Filter routes using a Prefix list	(Optional) Enter or Select the appropriate incoming or outgoing prefix list to distribute BGP neighbor information. **Tip** Click **Select** to open the Prefix List Object Selector from which you can select a prefix list object. You can also create new objects from the object Prefix List Object selector. For more information, see Add or Edit Prefix List Object Dialog Box , on page 2241.
Filter routes using AS Path filter	(Optional) Enter or Select the appropriate incoming or outgoing AS path filter to distribute BGP neighbor information. **Tip** Click **Select** to open the AS Path Object Selector from which you can select an AS path object. You can also create new AS path objects from the AS Path Object Selector. For more information, see Add or Edit As Path Object Dialog Boxes , on page 2246.

Element	Description

Limit the number of prefixes allowed from the neighbor	(Optional) Select to control the number of prefixes that can be received from a neighbor.
	• Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.
	• Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.
	• (Optional) Check the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following:
	  • Select **Terminate peering when prefix limit is exceeded** to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the Restart interval field.
	  • Select **Give only warning message when prefix limit is exceeded** to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.

Routes	
Advertisement Interval	Enter the minimum interval (in seconds) between the sending of BGP routing updates. Valid values are between 1 and 600.
Remove private AS numbers from outbound routing updates	(Optional) Excludes the private AS numbers from being advertised on outbound routes.
Generate Default route	(Optional) Select to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the Route map field. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.

Element	Description

Conditionally Advertised Routes	(Optional) To add or edit conditionally advertised routes, click the **Add Row (+)**button, or select a row in the table and click the **Edit Row(pencil)**button.
	In the Add/Edit Advertised Route dialog box, do the following:
	• Click **Select** to open the Route Map Object Selector from which you can select a route map that will be advertised if the conditions of the exist map or the non-exist map are met. For more information about route maps, see Understanding Route Map Objects , on page 2227.
	• Do one of the following:
	  • Select Set Exist Map and choose a route map from the Route Map Object Selector. This route map will be compared with the routes in the BGP table, to determine whether or not the advertise map route is advertised.
	  • Select Non-Exist Map and choose a route map from the Route Map Object Selector. This route map will be compared with the routes in the BGP table, to determine whether or not the advertise map route is advertised.

Timers	
Set timers for the BGP peer	(Optional) Select to set the keepalive frequency, hold time and minimum hold time.
Keepalive Interval	Enter the frequency (in seconds) with which the ASA sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.
Hold Time	Enter the interval (in seconds) after not receiving a keepalive message that the ASA declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.
Min Hold Time	(Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that the ASA declares a peer dead. Valid values are between 0 and 65535. The default value is 0 seconds.
Advanced	

Element	Description
Enable Authentication	(Optional) Select to enable MD5 authentication on a TCP connection between two BGP peers. • Choose an encryption type from the Enable Encryption drop-down list. • Enter a password in the Password field. Reenter the password in the Confirm field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The first character cannot be a number. The string can contain any alphanumeric characters, including spaces. **Note** You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.
Send Community attribute to this neighbor	(Optional) Specifies that communities attributes should be sent to the BGP neighbor.
Use ASA as next hop for neighbor	(Optional) Select to configure the router as the next-hop for a BGP speaking neighbor or peer group.
Disable connection verification	(Optional) Select to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. This command is required only when the neighbor ebgp-multihop command is configured with a TTL value of 1. The address of the single-hop eBGP peer must be reachable. The neighbor update-source command must be configured to allow the BGP routing process to use the loopback interface for the peering session. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly connected to same network segment, connection verification will prevent the peering session from being established.
Allow connections with neighbor that is not directly connected	Select to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the TTL hops field. Valid values are between 1 and 255. **Note** This feature should be used only under the guidance of Cisco technical support staff. To prevent the creation of loops through oscillating routes, the multihop will not be established if the only route to the multihop peer is the default route (0.0.0.0).

Element	Description
Limit number of TTL hops to neighbor	Select this option to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the TTL hops field. Valid values are between 1 and 254. This feature provides a lightweight security mechanism to protect BGP peering sessions from CPU utilization-based attacks. These types of attacks are typically brute force Denial of Service (DoS) attacks that attempt to disable the network by flooding the network with IP packets that contain forged source and destination IP addresses in the packet headers. This feature leverages designed behavior of IP packets by accepting only IP packets with a TTL count that is equal to or greater than the locally configured value. Accurately forging the TTL count in an IP packet is generally considered to be impossible. Accurately forging a packet to match the TTL count from a trusted peer is not possible without internal access to the source or destination network. This feature should be configured on each participating router. It secures the BGP session in the incoming direction only and has no effect on outgoing IP packets or the remote router. When this feature is enabled, BGP will establish or maintain a session only if the TTL value in the IP packet header is equal to or greater than the TTL value configured for the peering session. This feature has no effect on the BGP peering session, and the peering session can still expire if keepalive packets are not received. If the TTL value in a received packet is less than the locally configured value, the packet is silently discarded and no Internet Control Message Protocol (ICMP) message is generated. This is designed behavior; a response to a forged packet is not necessary. To maximize the effectiveness of this feature, the hop-count value should be strictly configured to match the number of hops between the local and external network. However, you should also take path variation into account when configuring this feature for a multihop peering session. The following restrictions apply to the configuration of this command: • This feature is not supported for internal BGP (iBGP) peers. • The effectiveness of this feature is reduced in large-diameter multihop peerings. In the event of a CPU utilization-based attack against a BGP router that is configured for large-diameter peering, you may still need to shut down the affected peering sessions to handle the attack. • This feature is not effective against attacks from a peer that has been compromised inside of your network. This restriction also includes peers that are on the network segment between the source and destination network.
Use TCP Path MTU Discovery	(Optional) Select to enable a TCP transport session for a BGP session.
TCP transport mode	Choose the TCP connection mode from the drop-down list. Options are Default, Active, or Passive.

Element	Description
Weight	(Optional) Enter a weight for the BGP neighbor connection.
BGP Version	Choose the BGP version that the ASA will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.
Migration **Note** This customization should only be used for AS migration, and should be removed after the transition has been completed. The procedure should be attempted only by an experienced network operator. Routing loops can be created through improper configuration.	
Customize the AS number for routes received from the neighbor	(Optional) Select to customize the AS_PATH attribute for routes received from an eBGP neighbor.
Local AS Number	Enter the local autonomous system number. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.
Do not prepend local AS number to routes received from neighbor	(Optional) Select to prevent the local AS number from being prepended to any routes received from eBGP peer.
Replace real AS number with local AS number in routes received from neighbor	(Optional) Select to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.
Accept either real AS number or local AS number in routes received from neighbor	(Optional) Configures the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

Add/Edit Network Dialog Box

Use the Add/Edit Network dialog box to define the networks to be advertised by the BGP routing process.

Navigation Path

You can access the Add/Edit Network dialog box from the IPv6 Family Tab , on page 2103. Click the **Add Row (+)** button, or select a row in the table and click the **Edit Row(pencil)** button.

Element	Description
Inject Map	Enter or Select the route map that specifies the prefixes to inject into the local BGP routing table. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Exist Map	Enter or Select the route map containing the prefixes that the BGP speaker will track. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Injected routes will inherit the attributes of the aggregate route	Configures the injected route to inherit attributes of the aggregate route.

Configuring EIGRP

The EIGRP page provides six tabbed panels for configuring Enhanced Interior Gateway Routing Protocol (EIGRP) routing on a firewall device. The following topics provide detailed information about enabling and configuring EIGRP:

Navigation Path

- (Device view) Select **Platform** > **Routing** > **EIGRP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Routing** > **EIGRP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 723: EIGRP Page

Element	Description
Enable EIGRP	Check this box to enable the EIGRP routing process.
AS Number	Enter the autonomous system (AS) number for the EIGRP process. The AS number can be from 1 to 65535.
Advanced button	Opens the EIGRP Advanced Dialog Box , on page 2118, in which you can configure additional EIGRP process settings, such as the router ID, stub routing, and adjacency changes.
Setup tab	Use the Setup tab to configure the networks used by the EIGRP routing process, passive interfaces, default route information, administrative distances, and default metrics. For more information, see Setup Tab , on page 2120.
Filter Rules tab	Use the Filter Rules tab to define filter rules that let you control which routes are accepted or advertised by the EIGRP routing process. For more information, see Filter Rules Tab , on page 2123.
Neighbors tab	Use the Neighbors tab to manually define EIGRP neighbors. For more information, see Neighbors Tab , on page 2124.
Redistribution tab	Use the Redistribution tab to define the rules for redistributing routes from other routing protocols to the EIGRP routing process. For more information, see Redistribution Tab , on page 2126.
Summary Address tab	Use the Summary Address tab to create statically defined EIGRP summary addresses. For more information, see Summary Address Tab , on page 2129.
Interfaces tab	Use the Interfaces tab to configure interfaces for EIGRP. For more information, see Interfaces Tab , on page 2131.

About EIGRP

EIGRP is an enhanced version of IGRP developed by Cisco. Unlike IGRP and RIP, EIGRP does not send out periodic route updates. EIGRP updates are sent out only when the network topology changes. Key capabilities that distinguish EIGRP from other routing protocols include fast convergence, support for variable-length subnet mask, support for partial updates, and support for multiple network layer protocols.

A router running EIGRP stores all the neighbor routing tables so that it can quickly adapt to alternate routes. If no appropriate route exists, EIGRP queries its neighbors to discover an alternate route. These queries propagate until an alternate route is found. Its support for variable-length subnet masks permits routes to be automatically summarized on a network number boundary. In addition, EIGRP can be configured to summarize on any bit boundary at any interface. EIGRP does not make periodic updates. Instead, it sends partial updates only when the metric for a route changes. Propagation of partial updates is automatically bounded so that only

those routers that need the information are updated. As a result of these two capabilities, EIGRP consumes significantly less bandwidth than IGRP.

Neighbor discovery is the process that the ASA uses to dynamically learn of other routers on directly attached networks. EIGRP routers send out multicast hello packets to announce their presence on the network. When the ASA receives a hello packet from a new neighbor, it sends its topology table to the neighbor with an initialization bit set. When the neighbor receives the topology update with the initialization bit set, the neighbor sends its topology table back to the ASA.

The hello packets are sent out as multicast messages. No response is expected to a hello message. The exception to this is for statically defined neighbors. If you manually configure a neighbor, the hello messages sent to that neighbor are sent as unicast messages. Routing updates and acknowledgments are sent out as unicast messages.

Once this neighbor relationship is established, routing updates are not exchanged unless there is a change in the network topology. The neighbor relationship is maintained through the hello packets. Each hello packet received from a neighbor includes a hold time. This is the time in which the ASA can expect to receive a hello packet from that neighbor. If the ASA does not receive a hello packet from that neighbor within the hold time advertised by that neighbor, the ASA considers that neighbor to be unavailable.

The EIGRP protocol uses four key algorithm technologies, four key technologies, including neighbor discovery/recovery, Reliable Transport Protocol (RTP), and DUAL, which is important for route computations. DUAL saves all routes to a destination in the topology table, not just the least-cost route. The least-cost route is inserted into the routing table. The other routes remain in the topology table. If the main route fails, another route is chosen from the feasible successors. A successor is a neighboring router used for packet forwarding that has a least-cost path to a destination. The feasibility calculation guarantees that the path is not part of a routing loop.

If a feasible successor is not found in the topology table, a route recomputation must occur. During route recomputation, DUAL queries the EIGRP neighbors for a route, who in turn query their neighbors. Routers that do no have a feasible successor for the route return an unreachable message.

During route recomputation, DUAL marks the route as active. By default, the ASA waits for three minutes to receive a response from its neighbors. If the ASA does not receive a response from a neighbor, the route is marked as stuck-in-active. All routes in the topology table that point to the unresponsive neighbor as a feasibility successor are removed.

Note EIGRP neighbor relationships are not supported through the IPsec tunnel without a GRE tunnel.

EIGRP Advanced Dialog Box

Use the EIGRP Advanced dialog box to configure settings such as the router ID, stub routing, and adjacency changes.

Navigation Path

You can access the EIGRP Advanced dialog box from the EIGRP page (see Configuring EIGRP , on page 2116).

Related Topics

- Configuring EIGRP , on page 2116

Field Reference

Table 724: EIGRP Advanced Dialog Box

Element	Description
Router ID	The router ID is used to identify the originating router for external routes. If an external route is received with the local router ID, the route is discarded. To prevent this, specify a global address for the router ID. A unique value should be configured for each EIGRP router. On a single device, choose **Automatic** or **IP Address**. (An address field appears when you choose IP Address.) If you choose Automatic, the highest-level IP address on the security appliance is used as the router ID. To use a fixed router ID, choose IP Address and enter an IPv4 address in the Router ID field. On a device cluster, choose **Automatic** or **Cluster Pool**. (An IPv4 Pool object ID field appears when you choose Cluster Pool.) If you choose Cluster Pool, enter or Select the name of the IPv4 Pool object that is to supply the Router ID address. For more information, see .

Element	Description
Stub	You can enable, and configure the ASA as an EIGRP stub router. Stub routing decreases memory and processing Add or Edit IPv4 Pool Dialog Box , on page 323 requirements on the ASA. As a stub router, the ASA does not need to maintain a complete EIGRP routing table because it forwards all nonlocal traffic to a distribution router. Generally, the distribution router need not send anything more than a default route to the stub router. Only specified routes are propagated from the stub router to the distribution router. As a stub router, the ASA responds to all queries for summaries, connected routes, redistributed static routes, external routes, and internal routes with the message "inaccessible." When the ASA is configured as a stub, it sends a special peer information packet to all neighboring routers to report its status as a stub router. Any neighbor that receives a packet informing it of the stub status will not query the stub router for any routes, and a router that has a stub peer will not query that peer. The stub router depends on the distribution router to send the correct updates to all peers. To enable the ASA as an EIGRP stub routing process, choose one or more of the following EIGRP stub routing processes: • Receive only—Configures the EIGRP stub routing process to receive route information from the neighbor routers but does not send route information to the neighbors. If this option is selected, you cannot select any of the other stub routing options. • Connected—Advertises connected routes. • Redistributed—Advertises redistributed routes. • Static—Advertises static routes. • Summary—Advertises summary routes.
Adjacency Changes	These options specify the syslog messages sent when adjacency changes occur. • Log Neighbor Changes – enables the logging of EIGRP neighbor adjacency changes. This option is selected by default. • Log Neighbor Warnings – enables the logging of EIGRP neighbor warning messages. This option is selected by default. (Optional) The time interval (in seconds) between repeated neighbor warning messages. Valid values are from 1 to 65535. Repeated warnings are not logged if they occur during this interval.

Setup Tab

Use the Setup tab on the EIGRP page to configure the networks used by the EIGRP routing process, passive interfaces, default route information, administrative distances, and default metrics.

Navigation Path

You can access the Setup tab from the EIGRP Page; see Configuring EIGRP , on page 2116 for more information.

- Interfaces Tab , on page 2131

Field Reference

Table 725: EIGRP - Setup Tab

Element	Description
Auto Summary	Check this box to enable automatic route summarization. Auto summary is enabled by default for ASA versions earlier than 9.2.1 and is disabled by default for ASA 9.2(1) and later. When enabled, the EIGRP routing process summarizes on network number boundaries. This can cause routing problems if you have noncontiguous networks. For example, if you have a router with the networks 192.168.1.0, 192.168.2.0, and 192.168.3.0 connected to it, and those networks all participate in EIGRP, the EIGRP routing process creates the summary address 192.168.0.0 for those routes. If an additional router is added to the network with the networks 192.168.10.0 and 192.168.11.0, and those networks participate in EIGRP, they will also be summarized as 192.168.0.0. To prevent the possibility of traffic being routed to the wrong location, you should disable automatic route summarization on the routers creating the conflicting summary addresses.
Networks	Enter the IP addresses of the networks to participate in the EIGRP routing process. **Tip** You can click **Select** to select the networks from a list of network/host objects.
Passive Interface	You can configure one or more interfaces as passive interfaces. In EIGRP, a passive interface does not send or receive routing updates. By deafult, all interfaces are enabled for active routing (sending and receiving routing updates) when routing is enabled for that interface. To configure passive interfaces, do one of the following: • To enable all interfaces for active routing (sending and receiving routing updates) when routing is enabled for that interface, select **None**. • To configure all interfaces as passive, select **All Interfaces**. • To configure specific interfaces as passive, select **Specified Interfaces** and then enter or select the interfaces that you want to make passive.

Element	Description
Default Route Information	You can control the sending and receiving of default route information in EIGRP updates. By default, default routes are sent and accepted. Configuring the ASA to disallow default information to be received causes the candidate default route bit to be blocked on received routes. Configuring the ASA to disallow default information to be sent disables the setting of the default route bit in advertised routes. • Accept Default Route Info—configures EIGRP to accept exterior default routing information. Optionally, you can specify a standard access list that define which networks are allowed and which are not when receiving default route information. • Send Default Route Info—configures EIGRP to advertise external routing information. Optionally, you can specify a standard access list that defines which networks are allowed and which are not when sending default route information.
Administrative Distance	Because every routing protocol has metrics based on algorithms that are different from the other routing protocols, it is not always possible to determine the “best path” for two routes to the same destination that were generated by different routing protocols. Administrative distance is a route parameter that the ASA uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. If you have more than one routing protocol running on the ASA, you can use the distance eigrp command to adjust the default administrative distances of routes discovered by the EIGRP routing protocol in relation to the other routing protocols.: Internal Distance—Administrative distance for EIGRP internal routes. Internal routes are those that are learned from another entity within the same autonomous system. Valid values are from 1 to 255. The default value is 90. External Distance—Administrative distance for EIGRP external routes. External routes are those for which the best path is learned from a neighbor external to the autonomous system. Valid values are from 1 to 255.The default value is 170.
Default Metrics	You can define the default metrics for routes redistributed into the EIGRP routing process: • Bandwidth—the minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295. • Delay Time—the route delay in tens of microseconds. Valid values range from 0 to 4294967295. • Reliability—the likelihood of successful packet transmission expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability. • Loading—the effective bandwidth of the route. Valid values range from 1 to 255; 255 indicates 100 percent loaded. • MTU—the smallest allowed value for the maximum transmission unit of the path. Valid values range from 1 to 65535.

Filter Rules Tab

The Filter Rules tab contains the Filter Rules table which displays the route filtering rules configured for the EIGRP routing process. Filter rules let you control which routes are accepted or advertised by the EIGRP routing process.

Navigation Path

You can access the Filter Rules tab from the EIGRP Page; see Configuring EIGRP , on page 2116 for more information.

Table 727: Add/Edit EIGRP Filter Rule Dialog Box

Element	Description
EIGRP Filter Direction	Specify the direction for the filter rule: • Inbound—The rule filters default route information from incoming EIGRP routing updates. • Outbound—The rule filters default route information from outgoing EIGRP routing updates.
Type	Specify the type of filter rule: • (Optional) Interface—Specify the interface on which to apply the routing updates. Specifying an interface causes the access list to be applied only to routing updates for that interface. If no interface is specified, the access list will be applied to all updates. • (Optional) Routing Protocol—For outbound EIGRP routing updates, select the routing protocol for which you want to filter: BGP, Connected, OSPF, RIP, or Static. Routing Protocol ID—Enter the identifier for the routing process. Applies to BGP and OSPF routing protocols.
ACL	Select an Access Control List that defines which networks are to be received and which are to be suppressed in routing updates.

Neighbors Tab

The Neighbors tab contains the Neighbors table, through which you can define static neighbors. When you manually define an EIGRP neighbor, hello packets are sent to that neighbor as unicast messages.

Navigation Path

You can access the Neighbors tab from the EIGRP Page; see Configuring EIGRP , on page 2116 for more information.

Table 730: EIGRP - Redistribution Tab

Element	Description
Protocol	The source protocol from which the routes are being redistributed: • BGP—Redistribute routes discovered by the BGP routing process to EIGRP. • RIP—Redistributes routes discovered by the RIP routing process to EIGRP. • Static—Redistributes static routes to the EIGRP routing process. Static routes that fall within the scope of a network statement are automatically redistributed into EIGRP; you do not need to define a redistribution rule for them. • Connected—Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the EIGRP routing process. Connected routes that fall within the scope of a network statement are automatically redistributed into EIGRP; you do not need to define a redistribution rule for them. • OSPF—Redistributes routes discovered by the OSPF routing process to EIGRP. If you choose this protocol, the Match options on this dialog box become visible. These options are not available when redistributing static, connected, RIP, or BGP routes.
ID	The autonomous system (AS) number for the BGP or OSPF routing process.
Bandwidth	The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
Delay Time	The route delay in tens of microseconds. Valid values range from 0 to 4294967295.
Reliability	The likelihood of successful packet transmission expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
Loading	The effective bandwidth of the route. Valid values range from 1 to 255; 255 indicates 100 percent loaded.
MTU	The smallest allowed value for the maximum transmission unit of the path. Valid values range from 1 to 65535.
Route Map	The name of the route map object to apply to the redistribution entry.

Add/Edit EIGRP Redistribution Dialog Box

Use the Add/Edit Redistribution dialog box to add a redistribution rule or to edit an existing redistribution rule in the Redistribution table.

Navigation Path

You can access the Add/Edit EIGRP Redistribution dialog box from the Redistribution Tab , on page 2126.

Field Reference

Table 731: Add/Edit EIGRP Redistribution Dialog Box

Element	Description
Protocol	Select the source protocol from which the routes are being redistributed. You can choose one of the following options: • BGP—Redistribute routes discovered by the BGP routing process to EIGRP. • RIP—Redistributes routes discovered by the RIP routing process to EIGRP. • Static—Redistributes static routes to the EIGRP routing process. Static routes that fall within the scope of a network statement are automatically redistributed into EIGRP; you do not need to define a redistribution rule for them. • Connected—Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the EIGRP routing process. Connected routes that fall within the scope of a network statement are automatically redistributed into EIGRP; you do not need to define a redistribution rule for them. • OSPF—Redistributes routes discovered by the OSPF routing process to EIGRP. If you choose this protocol, the Match options on this dialog box become visible. These options are not available when redistributing static, connected, RIP, or BGP routes.
Routing Process ID	The autonomous system (AS) number for the BGP or OSPF routing process.
Optional Metrics	You can define the following metrics for routes redistributed into the EIGRP routing process: • Bandwidth—the minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295. • Delay Time—the route delay in tens of microseconds. Valid values range from 0 to 4294967295. • Reliability—the likelihood of successful packet transmission expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability. • Loading—the effective bandwidth of the route. Valid values range from 1 to 255; 255 indicates 100 percent loaded. • MTU—the smallest allowed value for the maximum transmission unit of the path. Valid values range from 1 to 65535.

Element	Description
Route Map	Enter or Select a route map object to define which routes are redistributed into the EIGRP routing process. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Optional OSPF Redistribution	If you have chosen OSPF as the Route Type, choose the conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions: • Internal—The route is internal to a specific AS. • External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 external routes. • External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 external routes. • NSSA External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes. • NSSA External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes.

Summary Address Tab

Use the Summary Address tab to configure a summary for EIGRP on a specific interface. You can configure summary addresses on a per-interface basis. You need to manually define summary addresses if you want to create summary addresses that do not occur at a network number boundary or if you want to use summary addresses on an ASA with automatic route summarization disabled. If any more specific routes are in the routing table, EIGRP will advertise the summary address out the interface with a metric equal to the minimum of all more specific routes.

Navigation Path

You can access the Summary Address tab from the EIGRP Page; see Configuring EIGRP , on page 2116 for more information.

Table 734: EIGRP - Interfaces Tab

Element	Description
Interface	The name of the interface to which the configuration applies.
Hello Interval	The interval, in seconds, between EIGRP hello packets sent on an interface. Valid values range from 1 to 65535 seconds. The default value is 5 seconds.
Hold Time	The hold time advertised by the ASA in EIGRP hello packets. Valid values range from 1 to 65535 seconds. The default value is 15 seconds.
Split Horizon	Whether EIGRP split-horizon is enabled (true) or disabled (false) on an interface.
Delay	The delay time in tens of microseconds. Valid values are from 1 to 16777215. This option is not supported for devices in multi-context mode.
Key ID	The ID of the key used to authenticate EIGRP updates.

Add/Edit EIGRP Interface Dialog Box

Use the Add/Edit EIGRP Interface dialog box to configure interface-specific EIGRP routing parameters.

Navigation Path

You can access the Add/Edit EIGRP Interface dialog box from the Interfaces Tab , on page 2131.

Table 735: Add/Edit EIGRP Interface Dialog Box

Element	Description
Interface	The name of the interface to which the configuration applies.
Hello Interval	The interval, in seconds, between EIGRP hello packets sent on an interface. Valid values range from 1 to 65535 seconds. The default value is 5 seconds.
Hold Time	The hold time advertised by the ASA in EIGRP hello packets. Valid values range from 1 to 65535 seconds. The default value is 15 seconds.
Split Horizon	Enable/disable EIGRP split-horizon on an interface.
Delay Time	The delay time in tens of microseconds. Valid values are from 1 to 16777215. This option is not supported for devices in multi-context mode and will be disabled.
Enable MD5 Authentication	Enables MD5 authentication of EIGRP packets.
Key Type	Select Clear Text to indicate that the key you will be entering is in clear text. Select Encrypted to indicate that the key you will be entering is already encrypted.
Key ID and Key	Specify the key to authenticate EIGRP updates: • Key ID—Enter a numerical key identifier. Valid values range from 0to 255. • Key—An alphanumeric character string of up to 16 bytes. • Confirm—Re-enter the key.

Configuring ISIS

The ISIS page provides nine tabbed panels for configuring ISIS (Intermediate System-to-Intermediate System) routing on a firewall device. ISIS routing protocol is supported from Security Manager version 4.11 for ASA devices running the software version 9.6(1) or later. The following topics provide detailed information about enabling and configuring ISIS:

Navigation Path

- (Device view) Select **Platform** > **Routing** > **ISIS** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > ISIS** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Select Enable ISIS to enable Intermediate System-to-Intermediate System routing protocol on the selected ASA device.

About ISIS

Intermediate System-to-Intermediate System (ISIS) routing protocol is a link-state Interior Gateway Protocol (IGP). Link-state protocols are characterized by the propagation of the information required to build a complete network connectivity map on each participating router. That map is then used to calculate the shortest path to destinations. The IOS ISIS implementation supports CLNP, IPv4, and IPv6.

A routing domain may be divided into one or more sub-domains. Each sub-domain is referred to as an area and is assigned an area address. Routing within an area is referred to as Level-1 routing. Routing between Level-1 areas is referred to as Level-2 routing. A router in OSI terminology is referred to as an Intermediate System (IS). An IS may operate at Level 1, Level 2, or both. ISs that operate at Level 1 exchange routing information with other Level-1 ISs in the same area. ISs that operate at Level 2 exchange routing information with other Level-2 routers regardless of whether they are in the same Level-1 area. The set of Level-2 routers and the links that interconnect them form the Level-2 sub-domain, which must not be partitioned in order for routing to work properly.

General Tab

Use the General tab to configure BGP settings such as Best Path Selection, Neighbor Timers, and Graceful Restart.

Navigation Path

You can access the Neighbors tab from the BGP page (see Configuring BGP , on page 2084).

Related Topics

- Configuring BGP , on page 2084
- About BGP , on page 2085
- IPv4 Family Tab , on page 2089

Field Reference

Table 736: General Tab

Element	Description
Limit the number of AS numbers in AS_PATH attribute of received routes	Restricts the number of AS numbers in AS_PATH attribute to a specific number. Valid values are from 1 to 254.
Log Neighbor Changes	Enables logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability.

Element	Description
Use TCP path MTU Discovery	Enables the use of the Path MTU Discovery technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation.
Enable fast external failover	Resets the external BGP session immediately upon link failure.
Enforce that the first AS is peer's AS for EBGP routes	Discards incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH attribute. This prevents a mis-configured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system.
Use dot notation for AS numbers	Splits the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 0-65553 are represented as decimal numbers and AS numbers larger than 65535 are represented using the dot notation.
Best Path Selection	
Default local preference	Specify a value between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.
Allow comparing MED from different neighbors	Allows the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems.
Compare Router-id for identical EBGP paths	Compares similar paths received from external BGP peers during the best path selection process and switches the best path to the route with the lowest router ID.
Pick the best MED path among paths advertised from the neighboring AS	Enables MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path.
Treat missing MED as the least preferred one	Considers the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred.
Neighbor Timers	
Keepalive Interval	Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.
Hold Time	Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured. The default values is 180 seconds.
Min Hold Time	(Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured. Specify a value from 0 to 65535.

Element	Description
Graceful Restart (Use in failover or spanned cluster mode) (ASA 9.3.1+ only)	
Enable Graceful Restart	Enables ASA peers to avoid a routing flap following a switchover.
Restart Time	Specify the time duration that ASA peers will wait to delete stale routes before a BGP open message is received. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.
Stalepath Time	Enter the time duration that the ASA will wait before deleting stale routes after an end of record (EOR) message is received from the restarting ASA. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.

IPv4 Family Tab

Use the IPv4 Family tab on the BGP page to enable and configure IPv4 settings for BGP.

Navigation Path

You can access the IPv4 Family tab from the BGP page. For more information about the BGP page, see Configuring BGP , on page 2084.

Related Topics

Field Reference

Table 737: IPv4 Family - Aggregate Address Tab

Element	Description
Enable IPv4 Family	Enables configuration of routing sessions that use standard IPv4 address prefixes.
General	Use this panel to configure general IPv4 settings such as Best Path Selection, Neighbor Timers, and Graceful Restart. See IPv4 Family - General Tab , on page 2090 for more about these definitions.
Aggregate Address	Use this panel to define the aggregation of specific routes into one route. Specify a value for the aggregate timer (in seconds) in the Aggregate Timer field. Valid values are 0 or any value between 6 and 60. The default value is 30. See Add/Edit Aggregate Address Dialog Box , on page 2106 for more about these definitions.

Element	Description
Filtering	Use this panel to filter routes or networks received in incoming BGP updates. See Add/Edit Filter Dialog Box , on page 2093 for more about these definitions.
Neighbor	Use this panel to define BGP neighbors and neighbor settings. See Add/Edit Neighbor Dialog Box , on page 2094 for more about these definitions.
Networks	Use this panel to define the networks to be advertised by the BGP routing process. See Add/Edit Network Dialog Box , on page 2100 for more about these definitions.
Redistribution	Use this panel to define the conditions for redistributing routes from another routing domain into BGP. See Add/Edit Redistribution Dialog Box , on page 2101 for more about these definitions.
Route Injection	Use this panel to define the routes to be conditionally injected into the BGP routing table. See Add/Edit Route Injection Dialog Box , on page 2102 for more about these definitions.

IPv4 Family Tab—General Tab

Field Reference

Table 738: ISIS IPv4 Family Tab—General Tab

Element	Description
Perform Adjacency Check	Check the 'Perform adjacency check' check box for the router to check on nearby IS routers.
Distance	
Administrative Distance	In the Administrative Distance field, enter a distance assigned to routes discovered by IS-IS protocol. Administrative distance is a parameter used to compare routes among different routing protocols. In general, the higher the value, the lower the trust rating. And administrative distance of 255 means that the routing information source cannot be trusted at all and should be ignored. The range is 1 to 255. The default is 115.
Maximum No. of Forward Paths	Enter the maximum number of IS routes that can be installed in a routing table. The range is 1 to 8, the default is 4.
Distribute Default Route	Check the Distribute default route check box to configure an IS routing process to distribute a default route, and then choose the default route from the Route Map Object selector.
ISIS Metrics	

Element	Description
Global ISIS Metric Level 1	Enter a number specifying the metric. The range depends on the TLV Style that you select. The default is 10. • If you select Use old style of TLVs with narrow metric, the range is 1 to 63. • If you select Use new style of TLVs to carry wider metric, the range is 1 to 16777214. • If you select Send and accept both styles of TLVs during transition, the range is 1 to 16777214.
Global ISIS Metric Level 2	Enter a number specifying the metric. The range depends on the TLV Style that you select. The default is 10. • If you select Use old style of TLVs with narrow metric, the range is 1 to 63. • If you select Use new style of TLVs to carry wider metric, the range is 1 to 16777214. • If you select Send and accept both styles of TLVs during transition, the range is 1 to 16777214.
TLV Style	Select one of the following Type, Length, and Values: • Use old style of TLVs with narrow metric • Use new style of TLVs to carry wider metric • Send and accept both styles of TLVs during transition
Accept both styles of TLVs during transition	If you selected one of the first two options in TLV Style, you can select this option,
Apply metric style to	Select one of the following: • Level 1 • Level 2 • Both The default is Level 1.

IPv4 Family Tab—SPF Tab

Field Reference

Table 739: ISIS IPv4 FamilyTab—SPF Tab

Element	Description
Shortest Path First	
Honour external metrics during SPF calculations	Check this check box to have the SPF calculations include external metrics.
Signal other routers to not use this router as an intermediate hop in their SPF calculations	Check this check box if you want to exclude this device, and configure the following:
Specify on-startup behavior	If you select this element you must choose one of the following options: • Advertise overself as overloaded until BGP has converged • Specify time to advertise overself as overloaded after reboot—Specify the time in the range of 5 to 86400 seconds.
Don’t advertise IP prefixes learned from other protocols when overload bit is set	Check this check box to exclude IP prefixes.
Don’t advertise IP prefixes learned from another ISIS level when overload bit is set	Check this check box to exclude IP prefixes.
Minimum interval between partial route calculations	
PRC Interval	Enter an amount of time for the router to wait between partial route calculations (PRCs). The range is 1 to 120 seconds. The default is 5 seconds.
Initial wait for PRC	Enter the initial PRC calculation delay (in milliseconds) after a topology change. The range is 1 to 120.000 milliseconds. The default is 2000 milliseconds.
Minimum wait between first and second PRC	Enter the amount of time in milliseconds that you want the router to wait between PRCs. The range is 1 to 120,000 milliseconds. The default is 5000 milliseconds.
Minimum interval between SPF calculations	
Configure parameters for level 1	
SPF calculation interval	Enter an amount of time for the router to wait between SPF calculations. The range is 1 to 120 seconds. The default is 10 seconds.

Element	Description
Initial wait for SPF calculation	Enter the amount of time for the router to wait for an SPF calculation. The range is 1 to 120.000 milliseconds. The default is 5500 milliseconds.
Minimum wait between first and second SPF calculation	Enter the amount of time in milliseconds that you want the router to wait between SPF calculations. The range is 1 to 120,000 milliseconds. The default is 5500 milliseconds.
Configure parameters for level 2	
SPF calculation interval	Enter an amount of time for the router to wait between SPF calculations. The range is 1 to 120 seconds. The default is 10 seconds.
Initial wait for SPF calculation	Enter the amount of time for the router to wait for an SPF calculation. The range is 1 to 120.000 milliseconds. The default is 5500 milliseconds.
Minimum wait between first and second SPF calculation	Enter the amount of time in milliseconds that you want the router to wait between SPF calculations. The range is 1 to 120,000 milliseconds. The default is 5500 milliseconds.

IPv4 Family Tab—Redistribution Tab

Use the Add/Edit button to add a new Redistribution route or edit an existing row.

Field Reference

Table 740: ISIS IPv4 Family Tab—Redistribution Tab

Element	Description
Source Protocol	From the Source Protocol drop-down list, choose the protocol (BGP, Connected, EIGRP, OSPF, RIP, or Static) from which you want to redistribute routes into the ISIS domain.
Process ID	Enter the Process ID for the source protocol.
Route Level	From the Route Level drop-down list, choose Level-1, Level- 2, or Level 1-2.
Metric	In the Metric field, enter a metric for the redistributed route. The range is 1 to 4294967295.
Metric Type	For the Metric Type, click the internal or external radio button.
ISIS Inter Area Route Levels	
Source ISIS Level	Select Level 1 or Level 2. The default is Level 1.
Destination ISIS Level	Select Level 1 or Level 2. The default is Level 1.
Distribution List	Select from the available Access Control List or add new.

Element	Description
Route Map	Choose a route map from the Route Map Object selector that should be examined to filter the networks to be redistributed, or click Add to add a new route map or edit an existing route map.
Match	Check one or more of the Match check boxes -Internal, External 1, External 2, NSSA External 1, and NSSA External 2 check boxes to redistribute routes from an OSPF network.

IPv6 Family Tab

Use the IPv6 Family tab on the BGP page to enable and configure IPv6 settings for BGP.

Navigation Path

You can access the IPv6 Family tab from the BGP page. For more information about the BGP page, see Configuring BGP , on page 2084.

Initial wait for SPF calculation	Enter the amount of time for the router to wait for an SPF calculation. The range is 1 to 120.000 milliseconds. The default is 5500 milliseconds.
Minimum wait between first and second SPF calculation	Enter the amount of time in milliseconds that you want the router to wait between SPF calculations. The range is 1 to 120,000 milliseconds. The default is 5500 milliseconds.

IPv6 Family Tab—Redistribution Tab

Use the Add/Edit button to add or edit Redistribution routes.

Field Reference

Table 744: ISIS IPv6 Family Tab—Redistribution Tab

Element	Description
Source Protocol	From the Source Protocol drop-down list, choose the protocol (BGP, Connected, EIGRP, OSPF, RIP, or Static) from which you want to redistribute routes into the ISIS domain.
Process ID	Enter the Process ID for the source protocol.
Route Level	From the Route Level drop-down list, choose Level-1, Level- 2, or Level 1-2.
Metric	In the Metric field, enter a metric for the redistributed route. The range is 1 to 4294967295.
Metric Type	For the Metric Type, click the internal or external radio button.
ISIS Inter Area Route Levels	
Source ISIS Level	Select Level 1 or Level 2. The default is Level 1.
Destination ISIS Level	Select Level 1 or Level 2. The default is Level 1.
Distribution List	Select from the available Access Control List or add new.
Route Map	Choose a route map from the Route Map Object selector that should be examined to filter the networks to be redistributed, or click Add to add a new route map or edit an existing route map.
Match	Check one or more of the Match check boxes -Internal, External 1, External 2, NSSA External 1, and NSSA External 2 check boxes to redistribute routes from an OSPF network.

IPv6 Family Tab—Summary Prefix

You must configure at least one Network Entity Title entry to proceed.

See Network Entity Title Tab , on page 2147 for more information.

Use the Add/Edit button to add or edit Summary Prefix.

Field Reference

Table 745: ISIS IPv6 Family Tab—Summary Prefix Tab

Element	Description
IPv6 Summary Prefix	IPv6 prefix in the form X.X.X.X.::X/0-128
Apply Summary Prefix into	Select Level 1, Level 2, or Both. Level 1: Only routes redistributed into Level 1 are summarized with the configured address and mask value. Level 2: Routes learned by Level 1 routing are summarized into the Level 2 backbone with the configured address and mask value. Redistributed routes into Level 2 ISIS are also summarized. Both: Summary routes are applied when redistributing routes into Level 1 and Level2 ISIS and when Level 2 ISIS advertises Level 1 routes as reachable in it area.

Authentication Tab

Field Reference

Table 746: ISIS Authentication Tab

Element	Description
Configure authentication parameter for level 1	
Type	Select a Type from the drop-down list.
Key	Enter the key to authenticate ISIS updates. The key can include up to 16 characters.
Confirm	Confirm the key.
Send only	Click Enable or Disable depending on whether you want Send Only enabled.
Mode	Choose the authentication mode by clicking either the Disabled, MD5, or Clear Text radio buttons.
Area password	Enter the Area password and confirm the same in the next textbox.
Configure authentication parameter for level 2	
Type	Select a Type from the drop-down list.
Key	Enter the key to authenticate ISIS updates. The key can include up to 16 characters.

Element	Description
Confirm	Confirm the key.
Send only	Click Enable or Disable depending on whether you want Send Only enabled.
Mode	Choose the authentication mode by clicking either the Disabled, MD5, or Clear Text radio buttons.
Domain password	Enter the Domain password and confirm the same.

Link State Packet Tab

Field Reference

Table 747: ISIS Link State Packet Tab

Element	Description
Ignore LSP Errors	Check the Ignore LSP Errors check box to allow the ASA to ignore LSP packets that are received with internal checksum errors rather than purging the LSPs.
Flood LSPs before running SPF	Check this box to fast-flood and fill LSPs before running SPF. If you select this option, enter the number of LSPs to be flooded in the range of 1 to 15. This parameter sends a specified number of LSPs from the ASA. If no LSP number is specified, the default of 5 is used. The LSPs invoke SPF before running SPF. Cisco recommends that you enable fast flooding, because then you speed up the LSP flooding process, which improves overall network convergence time.The default value is 5.
Suppress IP prefixes	To suppress IP prefixes, check the Suppress IP prefixes check box, and then check one of the following. In networks where there is no limit placed on the number of redistributed routes into IS-IS, it is possible that the LSP can become full and routes will be dropped. Use these options to control which routes are suppressed when the PDU becomes full.
Don’t advertise IP prefixes learned from another ISIS level when ran out of LSP fragments	Suppresses any routes coming from another level. For example, if the Level-2 LSP becomes full, routes from Level 1 are suppressed.
Don’t advertise IP prefixes learned from other protocols when ran out of LSP fragments	Suppresses any redistributed routes on the ASA.
LSP General Interval	
LSP Interval Parameters for level 1	

Element	Description
LSP Calculation Interval	Enter the interval of time in seconds between transmission of each LSP. The range is 1-120 seconds. The default is 5. The number should be greater than the expected round-trip delay between any two ASAs on the attached network. The number should be conservative or needless transmission results. Retransmissions occur only when LSPs are dropped. So setting the number to a higher value has little effect on reconvergence. The more neighbors the ASAs have, and the more paths over which LSPs can be flooded, the higher you can make this value.
Initial wait for LSP calculation	Enter the time in milliseconds specifying the initial wait time before the first LSP is generated. The range is 1 to 120,000. The default is 50.
Minimum wait between first and second	Enter the time in milliseconds between the first and second LSP generation. The range is 1 to 120,000. The default is 5000.
LSP Interval Parameters for level 2	
Use level 1 parameter also for level 2	If you want the values you configured for Level 1 to also apply to Level 2, check the Use level 1 parameters also for level 2 check box.
LSP Calculation Interval	Enter the interval of time in seconds between transmission of each LSP. The range is 1-120 seconds. The default is 5. The number should be greater than the expected round-trip delay between any two ASAs on the attached network. The number should be conservative or needless transmission results. Retransmissions occur only when LSPs are dropped. So setting the number to a higher value has little effect on reconvergence. The more neighbors the ASAs have, and the more paths over which LSPs can be flooded, the higher you can make this value.
Initial wait for LSP calculation	Enter the time in milliseconds specifying the initial wait time before the first LSP is generated. The range is 1 to 120,000. The default is 50.
Minimum wait between first and second	Enter the time in milliseconds between the first and second LSP generation. The range is 1 to 120,000. The default is 5000.
Maximum LSP size	In the Maximum LSP size field, enter the number of seconds. The range is 128 to 4352. The default is 1492.
LSP refresh interval	In the LSP refresh interval field, enter the number of seconds at which LSPs are refreshed. The range is 1 to 655535. The default is 900. The refresh interval determines the rate at which the software periodically transmits in LSPs the route topology information that it originates. This is done to keep the database information from becoming too old. Reducing the refresh interval reduces the amount of time that undetected link state database corruption can persist at the cost of increased link utilization. (This is an extremely unlikely event, however, because there are other safeguards against corruption.) Increasing the interval reduces the link utilization caused by the flooding of refreshed packets (although this utilization is very small).

Element	Description
Maximum LSP lifetime	In the Maximum LSP lifetime field, enter the maximum number of seconds that LSPs can remain in a router's database without being refreshed. The range is 1 to 65535. The default is 1200 (20 minutes). You might need to adjust this parameter if you change the LSP refresh interval. LSPs must be periodically refreshed before their lifetimes expire. The value set for LSP refresh interval should be less that the value set for the maximum LSP lifetime; otherwise LSPs will time out before they are refreshed. If you make the LSP lifetime too low compared to the LSP refresh interval, the LSP refresh interval is automatically reduced to prevent the LSPs from timing out.

Summary Address Tab

Use the Add/Edit button to add or edit Summary Addresses.

Field Reference

Table 748: ISIS Summary Address Tab

Element	Description
IP address	Enter the IP address of the summary route.
Net Mask	Choose or enter the network mask to apply to the IP address.
Select level	Select the Level 1, Level 2, or Level 1 and 2 radio button depending on which levels you want to receive summary addresses.
Tag	In the Tag field, enter a number for the tag. The range is from 1 to 4294967295.
Metric	In the Metric field. enter the metric that will be applied to the summary route. The range is from 1 to 4294967295. The default value is 10.

Network Entity Title Tab

Use the Add/Edit button to add to edit Network Entity Title.

Field Reference

Table 749: ISIS Network Entity Title Tab

Element	Description
Network Entity Title (NET)	Enter a value in the address format 48.0000.1111.2222.00. The total length of NET address must be between 16 and 40 characters.

Element	Description
NET Pool	Click Select to open the NET Pool Object Selector dialog box. You can add and edit NET Pool Objects using this dialog box. For more information about how to add or edit NET Pool Objects, see Add or Edit NET Pool Object Dialog Box, on page 326. The NET Pool is applicable only for cluster devices in individual mode. Network Entity Title (NET) is not applicable for cluster devices in individual mode.
Maximum allowed NET	Enter a NET value in the range of 3 to 254. The default value is 3.

Interface Tab

Use the Interface tab to configure interface-specific OSPF authentication routing properties.

Navigation Path

You can access the Interface tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit Interface Dialog Box , on page 2188

Field Reference

Table 750: Interface Tab

Element	Description
Interface	The name of the interface to which the configuration applies.
Authentication	The type of OSPF authentication enabled on the interface. The authentication type can be one of the following values: • None—OSPF authentication is disabled. • Password—Clear text password authentication is enabled. • MD5—MD5 authentication is enabled. • Area—The authentication type specified for the area is enabled on the interface. Area authentication is the default value for interfaces. However, area authentication is disabled by default. So, unless you previously specified an area authentication type, interfaces showing Area authentication have authentication disabled. • Key Chain—Key chain authentication is enabled.
Point-to-Point	Displays “true” if the interface is set to non-broadcast (point-to-point). Displays “false” if the interface is set to broadcast.

Element	Description
Cost	The cost of sending a packet through the interface.
Priority	The OSPF priority assigned to the interface.
MTU Ignore	Displays “false” if MTU mismatch detection is enabled. Displays “true” if the MTU mismatch detection is disabled.
Database Filter	Displays “true” if outgoing LSAs are filtered during synchronization and flooding. Displays “false” if filtering is not enabled.
Hello Interval	The interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected but the more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. Valid values range from 1 to 65535 seconds. The default value is 10 seconds.
Transmit Delay	The estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 65535 seconds. The default value is 1 second.
Retransmit Interval	The time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 65535 seconds. The default value is 5 seconds.
Dead Interval	The interval, in seconds, in which no hello packets are received, causing neighbors to declare a router down. Valid values range from 1 to 65535. The default value of this setting is four times the interval set by the Hello Interval field.
Hello Multiplier (ASA 9.2(1)+ only)	The number of hello packets to be sent per second. Valid values are between 3 and 20.

Interface Tab—General Tab

Field Reference

Table 751: ISIS Interfaces Tab—General Tab

Element	Description
Interface	Select the interface from available interfaces.

Element	Description
Shutdown ISIS on this interface	Shutdown ISIS on this interface—Lets you disable the IS-IS protocol for this interface without removing the configuration parameters. The IS-IS protocol will not form any adjacencies on this interface and the IP address of this interface will be put into the LSP that is generated by the ASA.
Enable ISIS on this interface	Enables IS-IS protocol on the selected interface.
Enable IPv6 ISIS on this interface	Enables IPv6 IS-IS routing on the selected interface.
Priority for level 1	Lets you set a priority for Level 1. The priority is used to determine which router on a LAN will be the designated router or Designated Intermediate System (DIS). The priorities are advertised in the hello packets. The router with the highest priority becomes the DIS. The range is 0 to 127. The default is 64.
Priority for level 2	Lets you set a priority for Level 2. The priority is used to determine which router on a LAN will be the designated router or Designated Intermediate System (DIS). The priorities are advertised in the hello packets. The router with the highest priority becomes the DIS. The range is 0 to 127. The default is 64.
Tag	Sets a tag on the IP address configured for an interface when this IP prefix is put into an ISIS LSP.
CSNP Interval for level 1	Sets the Complete Sequence Number PDUs (CSNPs) interval in seconds between transmission of CSNPs on multiaccess networks for Level 1. This interval only applies for the designated router. The range is from 0 to 65535. The default is 10 seconds.
CSNP Interval for level 2	Sets the Complete Sequence Number PDUs (CSNPs) interval in seconds between transmission of CSNPs on multiaccess networks for Level 2. This interval only applies for the designated router. The range is from 0 to 65535. The default is 10 seconds.
Adjacency filter	Filters the establishment of IS-IS adjacencies.
Match all area addresses	All NSAP addresses must match the filter to accept the adjacency. If not specified (the default), only one address must match the filter for the adjacency to be accepted.

Interface Tab—Authentication Tab

Field Reference

Table 752: ISIS Interfaces Tab—Authentication Tab

Element	Description
Level 1 parameters	

Element	Description
Key Type	Select Clear Text or Encrypted.
Key	Enter the key to authenticate IS-IS updates. The range is 0 to 8 characters. If no password is configured with the Key option, no key authentication is performed. **Note** If you selected Key Type as Clear Text, you can enter a maximum of 17 characters in the Key field. If you selected Key Type as Encrypted, you can enter a maximum of 50 characters in the Key field.
Send only	For Send only click the Enable or Disable radio button. Choosing Send only causes the system only to insert the password into the SNPs, but not check the password in SNPs that it receives. Use this keyword during a software upgrade to ease the transition. The default is disabled.
Mode	Choose the authentication mode by checking the Mode check box and then choosing MD5 or Text from the drop-down list.
Password	Enter a password. **Note** You can select either Mode or enter a password value.
Level 2 parameters	
Key Type	Select Clear Text or Encrypted.
Key	Enter the key to authenticate IS-IS updates. The range is 0 to 8 characters. If no password is configured with the Key option, no key authentication is performed. **Note** If you selected Key Type as Clear Text, you can enter a maximum of 17 characters in the Key field. If you selected Key Type as Encrypted, you can enter a maximum of 50 characters in the Key field.
Send only	For Send only click the Enable or Disable radio button. Choosing Send only causes the system only to insert the password into the SNPs, but not check the password in SNPs that it receives. Use this keyword during a software upgrade to ease the transition. The default is disabled.
Mode	Choose the authentication mode by checking the Mode check box and then choosing MD5 or Text from the drop-down list.
Password	Enter a password. **Note** You can select either Mode or enter a password value.

Interface Tab—Hello Padding Tab

Field Reference

Table 753: ISIS Interfaces Tab—Hello Padding Tab

Element	Description
Hello Padding	Enables Hello Padding. IS-IS hellos are padded to the full maximum transmission unit (MTU) size. Padding IS-IS hellos to the full MTU allows for early detection of errors that result from transmission problems with large frames or errors that result from mismatched MTUs on adjacent interfaces.
Minimal holdtime 1 second for level 1	Enables the holdtime (in seconds) that the LSP remains valid for Level 1.
Hello interval for level 1	Specifies the length of time in seconds between hello packets for Level 1. The range is 1 to 65535. The default is 10.
Minimal holdtime 1 second for level 2	Enables the holdtime (in seconds) that the LSP remains valid for Level 2.
Hello interval for level 2	Specifies the length of time in seconds between hello packets for Level 2. The range is 1 to 65535. The default is 10.
Hello multiplier for level 1	Specifies the number of IS-IS hello packets a neighbor must miss before the ASA declares the adjacency is down for Level 1. The advertised hold time in IS-IS hello packets will be set to the hello multiplier times the hello interval. Neighbors will declare an adjacency to this router down after not having received any IS-IS hello packets during the advertised hold time. The hold time (and thus the hello multiplier and the hello interval) can be set on a per-interface basis, and can be different between different routers in one area. The range is 3 to 1000. The default is 3.
Hello multiplier for level 2	Specifies the number of IS-IS hello packets a neighbor must miss before the ASA declares the adjacency is down for Level 2. The advertised hold time in IS-IS hello packets will be set to the hello multiplier times the hello interval. Neighbors will declare an adjacency to this router down after not having received any IS-IS hello packets during the advertised hold time. The hold time (and thus the hello multiplier and the hello interval) can be set on a per-interface basis, and can be different between different routers in one area. The range is 3 to 1000. The default is 3.
Configure Circuit Type	Specifies whether the interface is configured for local routing (level 1), area routing (Level 2), or both local and area routing (Level 1-2).

Interface Tab—LSP Settings Tab

Field Reference

Table 754: ISIS Interfaces Tab—LSP Settings Tab

Element	Description
Advertise ISIS Prefix	Allows the advertising of IP prefixes of connected networks in the LSP advertisements per IS-IS interface. Disabling this option is an IS-IS mechanism to exclude IP prefixed of connected network from LSP advertisements thereby reducing IS-IS convergence time.
Retransmit Interval	Specifies the amount of time in seconds between retransmission of each IS-IS LSP on a point-to-point link. The number should be greater than the expected round-trip delay between any two routers on the attached network. The range is 0 to 65535. The default is 5.
Retransmit Throttle Interval	Specifies the amount of time in milliseconds between retransmissions on each IS-IS LSP on a point-to-point interface. This option may be useful in very large networks with many LSPs and many interfaces as a way of controlling LSP retransmission traffic. This option controls the rate at which LSPs can be re-sent on the interface. The range is 0 to 65535. The default is 33.
LSP Interval	Specifies the time delay in millisecond between successive IS-IS LSP transmissions. In topologies with a large number of IS-IS neighbors and interfaces, a router may have difficulty with the CPU load imposed by LSP transmission and reception. This option allows the LSP transmission rate (and by implication the reception rate of other systems) to be reduced. The range is 1 to 4294967295. The default is 33.

Interface Tab—Metrics Tab

Field Reference

Table 755: ISIS Interfaces Tab—Metrics Tab

Element	Description
Metrics for level 1	
Use maximum metric value	Specifies the metric assigned to the link and used to calculate the cost from each other router via the links in the network to other destinations. This is enabled by default.
Default metric	Enter the number for the metric. The range is 1 to 16777214.
Metrics for level 2	

Element	Description
Use maximum metric value	Specifies the metric assigned to the link and used to calculate the cost from each other router via the links in the network to other destinations. This is enabled by default.
Default metric	Enter the number for the metric. The range is 1 to 16777214.

Passive Interfaces Tab

The Passive Interfaces tab enables you to allow or suppress routing updates on an interface. Only interfaces configured with a name can be suppressed from sending routing updates.

Field Reference

Table 756: ISIS Network Entity Title Tab

Element	Description
Passive Interface	Select from the following options: • None—No Interface is selected. • Default—Open the Interfaces Selector dialog to select interfaces that you want to exclude. By default all interfaces are selected. • Specified Interfaces—Open the Interfaces Selector dialog to select interfaces that you want to select and include.

Configuring BFD Routing

The BFD page provides two tabs for configuring BFD (Bidirectional Forwarding Detection) routing on a firewall device. The following topics provide detailed information on configuring BFD.

Navigation Path

- (Device view) Select **Platform > Routing > BFD** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > BFD** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- About BFD, on page 2155
- Create BFD Template, on page 2158
- Add/Edit BFD Map Dialog Box, on page 2160
- Add/ Edit BFD Interface Dialog Box, on page 2161

About BFD

Bidirectional Forwarding Detection (BFD) is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols. BFD operates in a unicast, point-to-point mode on top of any data protocol being forwarded between two systems. Packets are carried in the payload of the encapsulating protocol appropriate for the media and the network.

BFD provides a consistent failure detection method for network administrators in addition to fast forwarding path failure detection. Because the network administrator can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms, network profiling and planning are easier and reconvergence time is consistent and predictable.

BFD Asynchronous Mode and Echo Function

BFD can operate in asynchronous mode with or without the echo function enabled.

Asynchronous Mode

In asynchronous mode, the systems periodically send BFD control packets to one another, and if a number of those packets in a row are not received by the other system, the session is declared to be down. Pure asynchronous mode (without the Echo function) is useful because it requires half as many packets to achieve a particular detection time as the Echo function requires.

BFD Echo Function

The BFD echo function sends echo packets from the forwarding engine to the directly-connected single-hop BFD neighbor. The echo packets are sent by the forwarding engine and forwarded back along the same path to perform detection. The BFD session at the other end does not participate in the actual forwarding of the echo packets. Because the echo function and the forwarding engine are responsible for the detection process, the number of BFD control packets that are sent out betweenBFD neighbors is reduced. And also because the forwarding engine is testing the forwarding path on the remote neighbor system without involving the remote system, the inter-packet delay variance is improved. This results in quicker failure detection times.

When the echo function is enabled, BFD can use the slow timer to slow down the asynchronous session and reduce the number of BFD control packets that are sent between BFD neighbors, which reduces processing overhead while at the same time delivering faster failure detection.

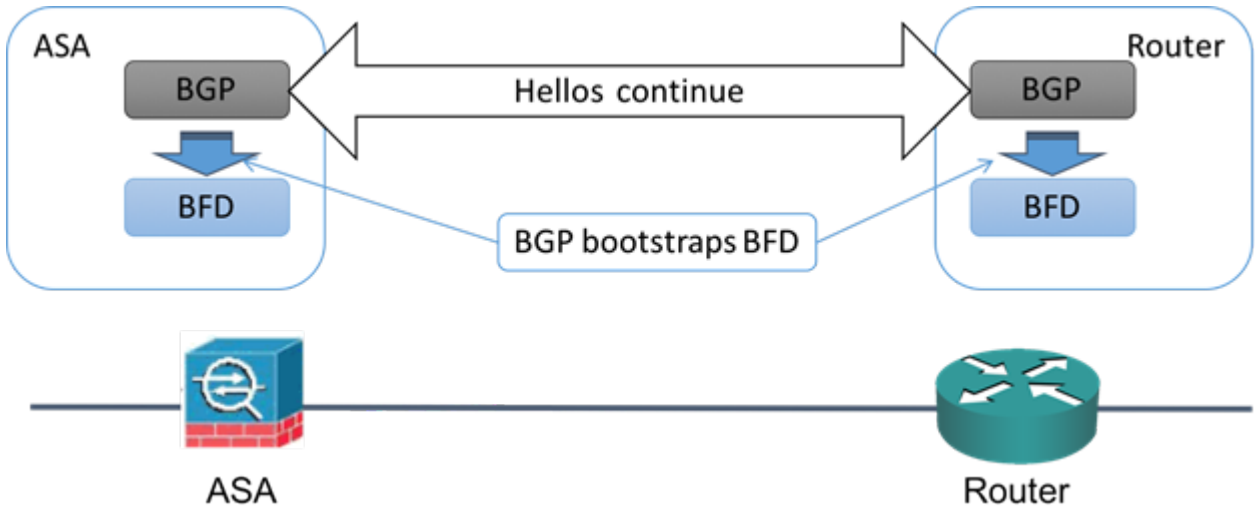
Note The echo function is not supported for IPv4 multi-hop or IPv6 single-hop BFD neighbors.

You can enable BFD at the interface and routing protocol levels. You must configure BFD on both systems (BFD peers). After you enable BFD on the interfaces and at the router level for the appropriate routing protocols, a BFD session is created, BFD timers are negotiated, and the BFD peers begin to send BFD control packets to each other at the negotiated level.

BFD Session Establishment

The following example shows the ASA and a neighboring router running Border Gateway Protocol (BGP).At the time when both devices come up, there is no BFD session established between them.

Figure 44: BFD Session Initiated



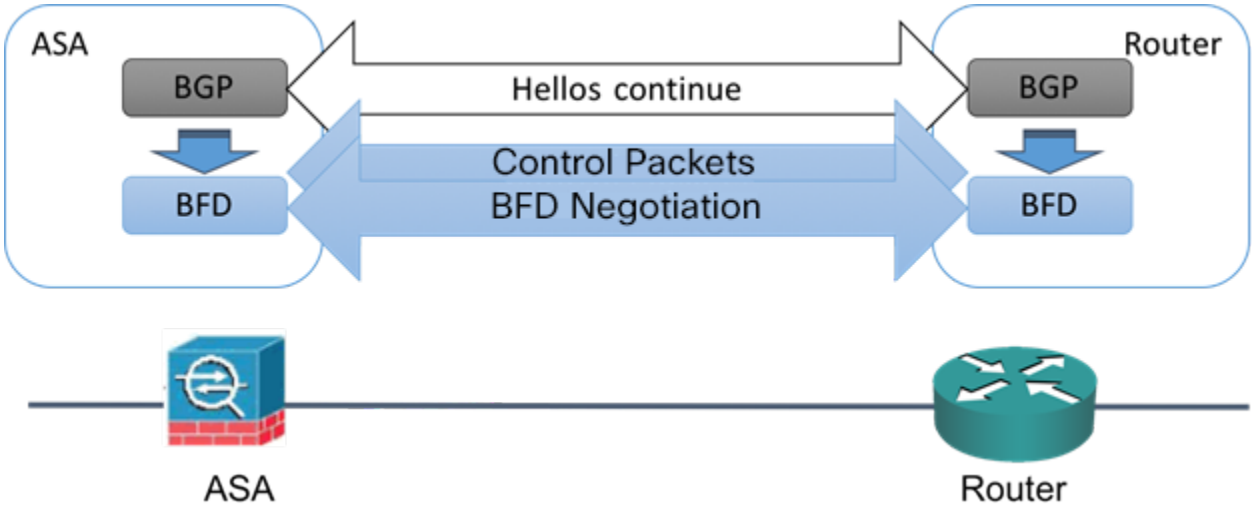
After BGP identifies its BGP neighbor, it bootstraps the BFD process with the IP address of the neighbor. BFD does not discover its peers dynamically. It relies on the configured routing protocols to tell it which IP addresses to use and which peer relationships to form.

The BFD on the router and the BFD on the ASA form a BFD control packet and start sending the packets to each other at a one-second interval until the BFD session is established. The initial control packets from either system are very similar, for example, the Vers, Diag, H, D, P, and F bits are all set to zero, and the State is set to Down. The My Discriminator field is set to a value that is unique on the transmitting device. The Your Discriminator field is set to zero because the BFD session has not yet been established. The TX and RX timers are set to the values found in the configuration of the device.

After the remote BFD device receives a BFD control packet during the session initiation phase, it copies the value of the My Discriminator field into its own Your Discriminator field and the transition from Down state to Init state and then eventually to Up state occurs. Once both systems see their own Discriminators in each other's control packets, the session is officially established.

The following illustration shows the established BFD connection.

Figure 45: BFD Session Established



BFD Timer Negotiation

BFD devices must negotiate the BFD timers to control and synchronize the send rate of BFD control packets.

A device needs to ensure the following before it can negotiate a BFD timer:

- That its peer device saw the packet containing the proposed timers of the local device
- That it never sends BFD control packets faster than the peer is configured to receive them
- That the peer never sends BFD control packets faster than the local system is configured to receive them

The setting of the Your Discriminator field and the H bit are sufficient to let the local device that the remote device has seen its packets during the initial timer exchange. After receiving a BFD control packet, each system takes the Required Min RX Interval and compares it to its own Desired Min TX Interval, and then takes the greater (slower) of the two values and uses it as the transmission rate for its BFD packets. The slower of the two systems determines the transmission rate.

When these timers have been negotiated, they can be renegotiated at any time during the session without causing a session reset. The device that changes its timers sets the P bit on all subsequent BFD control packets until it receives a BFD control packet with the F bit set from the remote system. This exchange of bits guards against packets that might otherwise be lost in transit.

Note The setting of the F bit by the remote system does not mean that it accepts the newly proposed timers. It indicates that the remote system has seen the packets in which the timers were changed.

BFD Failure Detection

When the BFD session and timers have been negotiated, the BFD peers send BFD control packets to each other at the negotiated interval. These control packets act as a heartbeat that is very similar to IGP Hello protocol except that the rate is more accelerated.

As long as each BFD peer receives a BFD control packet within the configured detection interval (Required Minimum RX Interval), the BFD session stays up and any routing protocol associated with BFD maintains its adjacencies. If a BFD peer does not receive a control packet within this interval, it informs any clients participating in that BFD session about the failure. The routing protocol determines the appropriate response to that information. The typical response is to terminate the routing protocol peering session and reconverge and thus bypass a failed peer.

Each time a BFD peer successfully receives a BFD control packet in a BFD session, the detection timer for that session is reset to zero. Thus the failure detection is dependent on received packets and NOT when the receiver last transmitted a packet.

BFD Deployment Scenarios

The following describes how BFD operates in these specific scenarios.

Failover

In a failover scenario, BFD sessions are established and maintained between the active unit and the neighbor unit. Standby units do not maintain any BFD sessions with the neighbors. When a failover happens, the new active unit must initiate session establishment with the neighbor because session information is not synched between active and standby units.

For a graceful restart/NSF scenario, the client (BGP IPv4/IPv6) is responsible for notifying its neighbor about the event. When the neighbor receives the information, it keeps the RIB table until failover is complete. During failover, the BFD and the BGP sessions go down on the device. When the failover is complete, a new BFD session between the neighbors is established when the BGP session comes up.

Spanned EtherChannel and L2 Cluster

In a Spanned EtherChannel cluster scenario, the BFD session is established and maintained between the primary unit and its neighbor. Subordinate units do not maintain any BFD sessions with the neighbors.If a BFD packet is routed to the subordinate unit because of load balancing on the switch, the subordinate unit must forward this packet to the primary unit through the cluster link. When a cluster switchover happens, the new primary unit must initiate session establishment with the neighbor because session information is not synched between primary and subordinate units.

Individual Interface Mode and L3 Cluster

In an individual interface mode cluster scenario, individual units maintain their BFD sessions with their neighbors.

Create BFD Template

This section describes the steps required to create a BFD template policy object. The BFD template specifies a set of BFD interval values. BFD interval values as configured in the BFD template are not specific to a single interface. You can also configure authentication for single-hop and multi-hop sessions. You can enable Echo on single-hop only.

Navigation Path

Select **Manage > Policy Objects**, then select **BFD Template** from the Object Type selector. Right-click inside the work area, then select **New Object** or right-click a row and select **Edit Object**.

Field Reference

Table 757: Add/Edit BFD Template

Element	Description
Name	The object name, which can be up to 128 characters. Object names are not case-sensitive. For more information, see Creating Policy Objects , on page 237.
Description	An optional description of the object.
Config Mode	Specify if there is a single IP hop or multiple IP hops between a BFD source and destination associated with an interface.
Enable Echo	(Optional) Select to enable echo. When enabled, echo packets are sent by the forwarding engine and forwarded back along the same path in order to perform detection. **Note** This is applicable only for single hop configuration mode.
Interval tab (Optional)	
Interval Type	Specify if you want to define the interval type in microseconds or milliseconds.The default interval type is None.
Transmit and Receive Values Interval Values in Microseconds	This section is enabled, if the Interval type is microseconds. Valid values are between 50000 and 999000 microseconds. Minimum Transmit Value - Enter the minimum transmit interval capability in microseconds. Minimum Receive Value - Enter the minimum receive interval capability microseconds.
Transmit and Receive Values Interval Values in Milliseconds	This section is enabled, if the Interval type is milliseconds. Valid values are between 50 and 999 milliseconds. Minimum Transmit Value - Enter the minimum transmit interval capability in milliseconds. Minimum Receive Value - Enter the minimum receive interval capability milliseconds.
Multiplier Value	Enter the number of consecutive BFD control packets that must be missed before BFD declares that a peer is unavailable.The default value is 3. Valid values are between 3 to 50.
Authentication tab (Optional)	
Authentication Type	Select to configure authentication for the BFD template and specify if you want to use an encrypted password or an unencrypted password,for the authentication.

Element	Description
Key Value	Enter a BFD password and confirm it. • For encrypted BFD templates, the length of the Key value is between 17 and 66 characters. • For unencrypted BFD templates of sha-1 or meticulous- sha-1authentication type the length of the Key Value must be less than 29 characters. • For unencrypted BFD templates of md5 or meticulous-md5 authentication type the length of the Key Value must be less than 25 characters.
Key ID	Enter an authentication key ID. This is a shared key ID, that matches the key string.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the **Edit** button to create, edit, and view the overrides. The **Overrides** field indicates the number of devices that have overrides for this object.

Add/Edit BFD Map Dialog Box

The Add/ Edit BFD Map dialog box lets you create a BFD map containing destinations that you can associate with a multi-hop template. You must have a multi-hop BFD template already configured. For more information see, Create BFD Template, on page 2158.

Navigation Path

You can access the Add/ Edit BFD Map dialog box from the Maps tab on the BFD page. Click the Add Row button to add a new BFD map; select an existing BFD map and click the Edit Row button to edit that map.

Related Topics

- Create BFD Template, on page 2158

Field Reference

Table 758: BFD Maps Tab

Element	Description
BFD Template	Select a multi-hop BFD template or add a multi-hop BFD template. For more information see, Create BFD Template, on page 2158.

Element	Description
IP version	Select the appropriate address format for the source and destination - IPv4 or IPv6.
IPv4 Destination/Prefix, IPv4 Source/Prefix	Enter the IPv4 address for the destination and source in the appropriate fields in the x.x.x.x/prefix format.
IPv6 Destination/ Prefix, IPv6 Source/prefix	Enter the IPv6 address for the destination and source in the appropriate fields in the x:x:x:x:x:x:x:x/prefix format.
Slow Timers	This reduces the number of BFD control packets, that are sent between BFD neighbors. This slows down the asynchronous session, reduces the processing overhead and results in faster failure detection. The default value for slow timers is 1000 and valid values are between 1000 - 30000.

Add/ Edit BFD Interface Dialog Box

The Add/ Edit BFD Interfaces dialog box lets you bind a BFD template to an interface, configure the baseline BFD session parameters per interface, and enable echo mode per interface.

Navigation Path

You can access the Add/ Edit BFD Interface dialog box from the Interface tab on the BFD page. Click the Add Row button to add a new BFD interface; select an existing BFD interface and click the Edit Row button to edit that map.

Related Topics

- Create BFD Template, on page 2158

Field Reference

Table 759: BFD Interface Tab

Element	Description
Interface	Enter an interface name, select an interface or add an interface role.
BFD Configuration	Select BFD template to select an existing single-hop BFD template or add a single-hop BFD template. Alternately, select BFD interval. For more information see, Create BFD Template, on page 2158.
BFD Interval	
Minimum Transmit Value	Enter the minimum transmit interval capability in milliseconds.Valid values are between 50 and 999 milliseconds
Minimum Receive Value	Enter the minimum receive interval capability milliseconds. Valid values are between 50 and 999 milliseconds

Element	Description
Multiplier	Enter the number of consecutive BFD control packets that must be missed before BFD declares that a peer is unavailable.The default value is 3. Valid values are between 3 to 50.
Echo	(Optional) Select to enable echo. When enabled, echo packets are sent by the forwarding engine and forwarded back along the same path in order to perform detection.

Configuring OSPF

The OSPF page provides ten tabbed panels for configuring OSPF (Open Shortest Path First) routing on a firewall device. The following topics provide detailed information about enabling and configuring OSPF:

Note Depending on the device version that you are configuring, some tabs might not be available.

Note Beginning with ASA version 9.2(1), certain OSPF settings have changed. If you configure a shared policy that uses settings specific to ASA 9.2(1)+, you will receive a validation error if that policy is assigned to a device whose version is earlier than 9.2(1). Likewise, if you configure a shared policy that uses settings that no longer apply to ASA 9.2(1)+, you will receive a validation error if that policy is assigned to an 9.2(1)+ device.

- Area Tab , on page 2170
- Range Tab , on page 2173
- Neighbors Tab , on page 2124
- Redistribution Tab , on page 2126
- Virtual Link Tab , on page 2178
- Filtering Tab , on page 2181
- Filter Rule Tab , on page 2183
- Summary Address Tab , on page 2129
- Interface Tab , on page 2148
- Configuring Key Chain , on page 2190

Navigation Path

- (Device view) Select **Platform** > **Routing** > **OSPF** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Routing** > **OSPF** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

About OSPF

Open Shortest Path First (OSPF) is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. OSPF propagates link-state advertisements (LSAs) rather than routing table updates. Because only LSAs are exchanged, rather than entire routing tables, OSPF networks converge more quickly than RIP networks.

OSPF supports MD5 and clear-text neighbor authentication. Authentication should be used with all routing protocols whenever possible, because route redistribution between OSPF and other protocols (like RIP) can potentially be used by attackers to subvert routing information.

If NAT is used when OSPF is operating on public and private areas, and if address filtering is required, you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR type 3 LSA filtering, you can have separate private and public areas with the security appliance acting as an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other. This lets you use NAT and OSPF together without advertising private networks.

Note Only type 3 LSAs can be filtered. If you configure the security appliance as an ASBR in a private network, it will send type 5 LSAs describing private networks, which will be broadcast to the entire autonomous system (AS) including public areas.

If NAT is employed but OSPF is only running in public areas, routes to public networks can be redistributed inside the private network, either as default or type 5 AS External LSAs. However, you need to configure static routes for the private networks protected by the security appliance. Also, you should not mix public and private networks on the same security appliance interface.

Related Topics

- Configuring OSPF , on page 2162

General Tab

Use the General panel on the OSPF page to enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks.

Note You cannot enable OSPF if you have RIP enabled.

Navigation Path

You can access the General tab from the OSPF page; see Configuring OSPF , on page 2162 for more information.

Field Reference

Table 760: OSPF General Tab

Element	Description
The General tab provides two identical sections; each is used to enable one OSPF process. The following options are available in each section.	
Enable this OSPF Process	Check this box to enable an OSPF process. You cannot enable an OSPF process if you have RIP enabled on the security appliance. Deselect this option to remove the OSPF process.
OSPF Process ID	Enter a unique numeric identifier for the OSPF process. This process ID is used internally and does not need to match the OSPF process ID on any other OSPF devices. Valid values are from 1 to 65535.
Advanced button	Opens the OSPF Advanced Dialog Box , on page 2164, in which you can configure additional process-related parameters, such as Router ID, Adjacency Changes, Administrative Route Distances, Timers, and Default Information Originate settings.

OSPF Advanced Dialog Box

Use the OSPF Advanced dialog box to configure settings such as the Router ID, Adjacency Changes, Administrative Route Distances, Timers, and Default Information Originate settings for an OSPF process.

Note Beginning with ASA version 9.2(1), certain OSPF settings have changed. If you configure a shared policy that uses settings specific to ASA 9.2(1)+, you will receive a validation error if that policy is assigned to a device whose version is earlier than 9.2(1). Likewise, if you configure a shared policy that uses settings that no longer apply to ASA 9.2(1)+, you will receive a validation error if that policy is assigned to an 9.2(1)+ device.

Navigation Path

You can access the OSPF Advanced dialog box from the General Tab , on page 2163.

Related Topics

- Configuring OSPF , on page 2162

Field Reference

Table 761: OSPF Advanced Dialog Box

Element	Description
OSPF Process	Displays the ID of the OSPF process you are configuring. You cannot change this value in this dialog box.
General Tab	
Router ID	To use a fixed router ID, select **IP Address** and then enter a router ID in IP address format in the Router ID field. To have the router ID automatically generated (the highest-level IP address on the security appliance is used as the router ID), select **Automatic**.
Ignore LSA MOSPF	Select this option to suppress transmission of syslog messages when the security appliance receives Type 6 (MOSPF) LSA packets.
RFC 1583 Compatible	Select this option to calculate summary route costs per RFC 1583. Deselect this option to calculate summary route costs per RFC 2328. To minimize the chance of routing loops, all OSPF devices in an OSPF routing domain should have RFC compatibility set identically. This option is selected by default.
Adjacency Changes	These options specify the syslog messages sent when adjacency changes occur. • Log Adjacency Changes – When selected, the security appliance sends a syslog message whenever an OSPF neighbor goes up or down. This option is selected by default. • Log Adjacency Changes Detail – When selected, the security appliance sends a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This option is not selected by default.

Element	Description
Administrative Route Distances	Settings for the administrative route distances, according to the route type. • Inter Area – The administrative distance for all routes from one area to another. Valid values range from 1 to 255; the default value is 110. • Intra Area – The administrative distance for all routes within an area. Valid values range from 1 to 255; the default value is 110. • External – The administrative distance for all routes from other routing domains that are learned through redistribution. Valid values range from 1 to 255; the default value is 110.

Element	Description
Timers	

Element	Description

	Settings used to configure LSA arrival, LSA pacing, and throttling for ASA 9.2(1)+ devices:
	• LSA Arrival – The minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 600,000 milliseconds. The default is 1000 milliseconds.
	• LSA Flood Pacing – The time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.
	• LSA Group Pacing – The interval at which LSAs are collected into a group and refreshed, checksummed, or aged. Valid values range from 10 to 1800; the default value is 240 seconds.
	• LSA Retransmission Pacing - The time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.
	• LSA Throttle – The delay in milliseconds to generate the first occurrence of the LSA. Valid values range from 0 to 600000 milliseconds. When you enter a value in this field, the Min and Max fields are enabled:
	  • Min – The minimum delay for originating the same LSA. Valid values range from 1 to 600000 milliseconds.
	  • Max – The maximum delay for originating the same LSA. Valid values range from 1 to 600000 milliseconds.
	Note For LSA throttling, the first occurrence value must be equal to or less than the minimum value and the minimum value must be equal to or less than the maximum value.
	• SPF Throttle – The delay to receive a change to the SPF calculation. Valid values range from 1 to 600000 milliseconds. When you enter a value in this field, the Min and Max fields are enabled:
	  • Min – The delay between the first and second SPF calculations. Valid values range from 1 to 600000 milliseconds.
	  • Max – The maximum wait time for SPF calculations. Valid values range from 1 to 600000 milliseconds.
	Note For SPF throttling, the first occurrence value must be equal to or less than the minimum value and the minimum value must be equal to or less than the maximum value.
	Settings used to configure LSA pacing and SPF calculation timers for device versions earlier than 9.2(1):
	• SPF Delay – The time between receipt of a topology change and the start of shortest path first (SPF) calculations. Valid values range from 0 to 65535; the default value is 5 seconds.

Element	Description
	• SPF Hold – The hold time between consecutive SPF calculations. Valid values range from 1 to 65534; the default value is 10 seconds. • LSA Group Pacing – The interval at which LSAs are collected into a group and refreshed, checksummed, or aged. Valid values range from 10 to 1800; the default value is 240 seconds.

Default Information Originate	Settings used by an ASBR to generate a default external route into an OSPF routing domain.
	• Enable Default Information Originate – Check this box to enable generation of a default route into the OSPF routing domain; the following options become available:
	  • Always advertise the default route – Check this box to always advertise the default route.
	  • Metric Value – Enter the OSPF metric for the default route. Valid values range from 0 to 16777214; the default value is 1.
	  • Metric Type – Choose the external link type associated with the default route advertised into the OSPF routing domain. The choices are **1** or **2**, indicating a Type 1 or a Type 2 external route. The default value is 2.
	  • Route Map – (Optional) Enter or Select a route map object to apply. The routing process generates the default route if the route map is satisfied.
	Tip Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.

Non Stop Forwarding Tab **Note** Non Stop Forwarding (NSF) is supported on ASA 9.3(1)+ devices in Spanned Cluster mode or Failover mode only.	
Enable Cisco Non Stop Forwarding Capability	Enables configuration of Cisco nonstop forwarding (NSF) operations.
Enable Cisco Non Stop Forwarding Helper mode	Enables Cisco nonstop forwarding (NSF) helper mode. When an ASA has NSF enabled, it is said to be NSF-capable and will operate in graceful restart mode--the OSPF router process performs nonstop forwarding recovery due to a Route Processor (RP) switchover. By default, the neighboring ASAs of the NSF-capable ASA will be NSF-aware and will operate in NSF helper mode. When the NSF-capable ASA is performing graceful restart, the helper ASAs assist in the nonstop forwarding recovery process. If you do not want the ASA to help the restarting neighbor with nonstop forwarding recovery, clear the Enable Cisco Non Stop Forwarding Helper mode option.

Element	Description
Enable Cisco Non Stop Forwarding	Enables Cisco nonstop forwarding (NSF).
Cancel NSF restart when non-NSF-aware neighboring networking devices are detected (Enforce Global)	If neighbors that are not NSF-aware are detected on a network interface during an NSF graceful restart, restart is aborted on that interface only and graceful restart will continue on other interfaces. To cancel restart for the entire OSPF process when neighbors that are not NSF-aware are detected during restart, select the Cancel NSF restart when non-NSF-aware neighboring networking devices are detected (Enforce Global) option. **Note** The NSF graceful restart will also be canceled for the entire process when a neighbor adjacency reset is detected on any interface or when an OSPF interface goes down.
Enable IETF Non Stop Forwarding Capability	Enables configuration of Internet Engineering Task Force (IETF) NSF operations.
Enable IETF Non Stop Forwarding Helper mode	Enables IETF nonstop forwarding (NSF) helper mode. When an ASA has NSF enabled, it is said to be NSF-capable and will operate in graceful restart mode--the OSPF router process performs nonstop forwarding recovery due to a Route Processor (RP) switchover. By default, the neighboring ASAs of the NSF-capable ASA will be NSF-aware and will operate in NSF helper mode. When the NSF-capable ASA is performing graceful restart, the helper ASAs assist in the nonstop forwarding recovery process. If you do not want the ASA to help the restarting neighbor with nonstop forwarding recovery, clear the Enable IETF Non Stop Forwarding Helper mode option.
Enable Strict Link State advertisement checking	Enables strict link-state advertisement (LSA) checking for IETF NSF helper mode.
Enable IETF Non Stop Forwarding	Enables IETF nonstop forwarding (NSF).
Length of graceful restart interval	(Optional) Specifies the length of the graceful restart interval, in seconds. The range is from 1 to 1800. The default is 120. **Note** For a restart interval below 30 seconds, graceful restart will be terminated.

Area Tab

Use the Area tab on the OSPF page to configure OSPF areas and networks.

Navigation Path

You can access the Area tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Field Reference

Table 762: Area Tab

Element	Description
OSPF Process	The OSPF process the area applies to.
Area ID	The area ID.
Area Type	The area type (Normal, Stub, or NSSA).
Networks	The area networks.
Options	The options, if any, set for the area type.
Authentication	The type of authentication set for the area (None, Password, or MD5).
Cost	The default cost for the area.

Add/Edit Area/Area Networks Dialog Box

Use the Add/Edit Area/Area Networks dialog box to define area parameters, the networks contained by the area, and the OSPF process associated with the area.

Navigation Path

You can access the Add/Edit Area/Area Networks dialog box from the Area Tab , on page 2170.

Related Topics

- Configuring OSPF , on page 2162

Field Reference

Table 763: Add/Edit Area/Area Networks Dialog Box

Element	Description
OSPF Process	When adding a new area, choose the OSPF process ID for the OSPF process for which the area is being added. If there is only one OSPF process enabled on the security appliance, that process is selected by default. When editing an existing area, you cannot change the OSPF process ID.
Area ID	When adding a new area, enter the area ID. You can specify the area ID as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295. You cannot change the area ID when editing an existing area.
Area Type	
Normal	Choose this option to make the area a standard OSPF area. This option is selected by default when you first create an area.
Stub	Choosing this option makes the area a stub area. Stub areas do not have any routers or areas beyond it. Stub areas prevent AS External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you can prevent summary LSAs (Type 3 and 4) from being flooded into the area by deselecting the Summary check box.
Summary (allows sending LSAs into the stub area)	When the area being defined is a stub area, deselecting this check box prevents LSAs from being sent into the stub area. This check box is selected by default for stub areas.
NSSA	Choose this option to make the area a not-so-stubby area. NSSAs accept Type 7 LSAs. When you create a NSSA, you can prevent summary LSAs from being flooded into the area by deselecting the Summary check box. You can also disable route redistribution by deselecting the Redistribute check box and enabling Default Information Originate.
Redistribute (imports routes to normal and NSSA areas)	Deselect this check box to prevent routes from being imported into the NSSA. This check box is selected by default.
Summary (allows sending LSAs into the NSSA area)	When the area being defined is a NSSA, deselecting this check box prevents LSAs from being sent into the stub area. This check box is selected by default for NSSAs.
Default Information Originate (generate a Type 7 default)	Select this check box to generate a Type 7 default into the NSSA. This check box is deselected by default.
Metric Value	Specifies the OSPF metric value for the default route. Valid values range from 0 to 16777214. The default value is 1.
Metric Type	The OSPF metric type for the default route. The choices are 1 (Type 1) or 2 (Type 2). The default value is 2.

Element	Description
Network	The IP address and network mask of the network or host to be added to the area. Use 0.0.0.0 with a netmask of 0.0.0.0 to create the default area. You can only use 0.0.0.0 in one area. **Tip** You can click **Select** to select the interfaces from a list of interface objects.
Authentication	Contains the settings for OSPF area authentication. • None—Choose this option to disable OSPF area authentication. This is the default setting. • Password—Choose this option to use a clear text password for area authentication. This option is not recommended where security is a concern. • MD5—Choose this option to use MD5 authentication.
Default Cost	Specify a default cost for the area. Valid values range from 0 to 65535 for ASA devices earlier than 9.2(1) and from 0 to 16777214 for ASA 9.2(1)+. The default value is 1.

Range Tab

Use the Range tab to summarize routes between areas.

Navigation Path

You can access the Range tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit Area Range Network Dialog Box , on page 2174

Field Reference

Table 764: Range Tab

Element	Description
Process ID	The ID of the OSPF process associated with the route summary.
Area ID	The ID of the area associated with the route summary.
Network	The summary IP address and network mask.
Advertise	Displays “true” if the route summaries are advertised when they match the address/mask pair or “false” if the route summaries are suppressed when they match the address/mask pair.

Add/Edit Area Range Network Dialog Box

Use the Add/Edit Area Range Network dialog box to add a new entry to the Route Summarization table or to change an existing entry.

Navigation Path

You can access the Add/Edit Area Range Network dialog box from the Range Tab , on page 2173.

Related Topics

- Configuring OSPF , on page 2162

Field Reference

Table 765: Add/Edit Area Range Network Dialog Box

Element	Description
OSPF Process	Select the OSPF process to which the route summary applies. You cannot change this value when editing an existing route summary entry.
Area	Select the area ID of the area to which the route summary applies. You cannot change this value when editing an existing route summary entry.
Network	The IP address and mask of the network for the routes being summarized. **Tip** You can click **Select** to select the networks from a list of network objects.
Advertise	Select this check box to set the address range status to “advertise”. This causes Type 3 summary LSAs to be generated. Deselect this check box to suppress the Type 3 summary LSA for the specified networks.

Neighbors Tab

Use the Neighbors tab to define static neighbors. You need to define a static neighbor for each point-to-point, non-broadcast interface. You also need to define a static route for each static neighbor in the Neighbors table.

Navigation Path

You can access the Neighbors tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit Static Neighbor Dialog Box , on page 2175

Interface	The interface associated with the static neighbor. **Tip** You can click **Select** to select the interface from a list of interface objects.

Redistribution Tab

Use the Redistribution tab to define the rules for redistributing routes from one routing domain to another.

Navigation Path

You can access the Redistribution tab from the OSPF Page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Redistribution Dialog Box , on page 2176

Field Reference

Table 768: Redistribution Tab

Element	Description
OSPF Process	The OSPF process associated with the route redistribution entry.
Route Type	The source protocol the routes are being redistributed from. Valid entries are the following: • BGP—Redistribute routes from the BGP routing process. • Connected—Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed as external to the AS. • EIGRP—Redistributes routes from the EIGRP routing process. Choose the autonomous system number of the EIGRP routing process from the list. • OSPF—Redistributes routes from another OSPF routing process. • RIP—Redistributes routes from the RIP routing process. • Static—Redistributes static routes to the OSPF routing process.
Match	The conditions used for redistributing routes from one routing protocol to another. These options are not available when redistributing static, connected, RIP, BGP, or EIGRP routes.
Subnets	Displays “true” if subnetted routes are redistributed. Does not display anything if only routes that are not subnetted are redistributed.
Metric Value	The metric that is used for the route. This column is blank for redistribution entries if the default metric is used.
Metric Type	Displays “1” if the metric is a Type 1 external route, “2” if the metric is Type 2 external route.
Tag Value	A 32-bit decimal value attached to each external route. This value is not used by OSPF itself. It may be used to communicate information between ASBRs. Valid values range from 0 to 4294967295.
Route Map	The name of the route map object to apply to the redistribution entry.

Redistribution Dialog Box

Use the Redistribution dialog box to add a redistribution rule or to edit an existing redistribution rule in the Redistribution table.

Navigation Path

You can access the Redistribution dialog box from the Redistribution Tab , on page 2175.

Related Topics

- Configuring OSPF , on page 2162

Field Reference

Table 769: OSPF Redistribution Settings Dialog Box

Element	Description
OSPF Process	Select the OSPF process associated with the route redistribution entry.
Route Type	Select the source protocol from which the routes are being redistributed. You can choose one of the following options: • BGP—Redistribute routes from the BGP routing process. • Connected—Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed as external to the AS. • EIGRP—Redistributes routes from the EIGRP routing process. Choose the autonomous system number of the EIGRP routing process from the list. • OSPF—Redistributes routes from another OSPF routing process. If you choose this protocol, the Match options on this dialog box become visible. These options are not available when redistributing static, connected, RIP, BGP, or EIGRP routes. • RIP—Redistributes routes from the RIP routing process. • Static—Redistributes static routes to the OSPF routing process.
Routing Process ID	The autonomous system (AS) number for the BGP or EIGRP routing process.
Match	If you have chosen OSPF as the Route Type, choose the conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions: • Internal—The route is internal to a specific AS. • External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 external routes. • External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 external routes. • NSSA External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes. • NSSA External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes.

Element	Description
Metric Value	The metric value for the routes being redistributed. Valid values range from 1 to 16777214. When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.
Metric Type	Select "1" if the metric is a Type 1 external route, "2" if the metric is a Type 2 external route.
Tag Value	The tag value is a 32-bit decimal value attached to each external route. This is not used by OSPF itself. It may be used to communicate information between ASBRs. Valid values range from 0 to 4294967295.
Use Subnets	When selected, redistribution of subnetted routes is enabled. Deselect this check box to cause only routes that are not subnetted to be redistributed.
Route Map	Enter or Select a route map object to apply to the redistribution entry. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.

Virtual Link Tab

Use the Virtual Link tab to create virtual links. If you add an area to an OSPF network, and it is not possible to connect the area directly to the backbone area, you need to create a virtual link. A virtual link connects two OSPF devices that have a common area, called the transit area. One of the OSPF devices must be connected to the backbone area.

Navigation Path

You can access the Virtual Link tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit OSPF Virtual Link Configuration Dialog Box , on page 2179

Field Reference

Table 770: Virtual Link Tab

Element	Description
OSPF Process	The OSPF process associated with the virtual link.
Area ID	The ID of the transit area.
Peer Router	The IP address of the virtual link neighbor.

Element	Description
Authentication	Displays the type of authentication used by the virtual link: • None—No authentication is used. • Password—Clear text password authentication is used. • MD5—MD5 authentication is used. • Key Chain—Key chain authentication is enabled.

Add/Edit OSPF Virtual Link Configuration Dialog Box

Use the Add/Edit OSPF Virtual Link Configuration dialog box to define virtual links or change the properties of existing virtual links.

Navigation Path

You can access the Add/Edit OSPF Virtual Link Configuration dialog box from the Virtual Link Tab , on page 2178.

Related Topics

- Add/Edit OSPF Virtual Link MD5 Configuration Dialog Box , on page 2181
- Configuring OSPF , on page 2162

Field Reference

Table 771: Add/Edit OSPF Virtual Link Configuration Dialog Box

Element	Description
OSPF Process	Select the OSPF process associated with the virtual link.
Area ID	Select the area shared by the neighbor OSPF devices. The selected area cannot be an NSSA or a stub area.
Peer Router	Enter the IP address of the virtual link neighbor.
Hello Interval	The interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected but the more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. Valid values range from 1 to 65535 seconds for ASA devices earlier than 9.2(1) and from 1 to 8192 seconds for ASA 9.2(1)+. The default value is 10 seconds.

Element	Description
Retransmit Interval	The time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it will resend the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 65535 seconds for ASA devices earlier than 9.2(1) and from 1 to 8192 seconds for ASA 9.2(1)+. The default value is 5 seconds.
Transmit Delay	The estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 65535 seconds for ASA devices earlier than 9.2(1) and from 1 to 8192 seconds for ASA 9.2(1)+. The default value is 1 second.
Dead Interval	The interval, in seconds, in which no hello packets are received, causing neighbors to declare a router down. Valid values range from 1 to 65535 seconds for ASA devices earlier than 9.2(1) and from 1 to 8192 seconds for ASA 9.2(1)+. The default value of this field is four times the interval set by the Hello Interval field.
Authentication	Contains the OSPF authentication options. • None—Choose this option to disable OSPF authentication. • Area—Choose this option to use the authentication type specified for the area. See Add/Edit Area/Area Networks Dialog Box , on page 2171 for information about configuring area authentication. Area authentication is disabled by default. Therefore, unless you have previously specified an area authentication type, interfaces set to area authentication have authentication disabled until you configure this setting. • Password—Choose this option to use clear text password authentication. This is not recommended where security is a concern. • MD5—Choose this option to use MD5 authentication (recommended). • Key Chain—Choose this option to use key chain authentication.
Key Chain	This field appears when Key Chain authentication is enabled. Click Select and choose the configured key chain. To know the configuration steps, refer Configuring Key Chain , on page 2190. **Note** Use the same authentication type and key ID for the peers to establish a successful adjacency.
Authentication Password	Contains the settings for entering the password when password authentication is enabled. • Password—Enter a text string of up to 8 characters. • Confirm—Re-enter the password.

Element	Description
MD5 IDs and Keys	Contains the settings for entering the MD5 keys and parameters when MD5 authentication is enabled. All devices on the interface using OSPF authentication must use the same MD5 key and ID. • MD5 Key ID and MD5 Key Table • MD5 Key ID—A numerical key identifier. Valid values range from 1 to 255. • MD5 Key—An alphanumeric character string of up to 16 bytes.

Add/Edit OSPF Virtual Link MD5 Configuration Dialog Box

Use the Add/Edit OSPF Virtual Link MD5 Configuration dialog box to define MD5 keys for authentication of virtual links.

Navigation Path

You can access the Add/Edit OSPF Virtual Link MD5 Configuration dialog box from the Add/Edit OSPF Virtual Link Configuration Dialog Box , on page 2179.

Related Topics

- Add/Edit OSPF Virtual Link Configuration Dialog Box , on page 2179
- Virtual Link Tab , on page 2178
- Configuring OSPF , on page 2162

Field Reference

Table 772: Add/Edit OSPF Virtual Link MD5 Configuration Dialog Box

Element	Description
MD5 Key ID	A numerical key identifier. Valid values range from 1 to 255.
MD5 Key	An alphanumeric character string of up to 16 bytes.
Confirm	Re-enter the MD5 key.

Filtering Tab

Use the Filtering tab to configure the ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restricts all other prefixes. This type of area filtering can be applied out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF areas at the same time.

Benefits

OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

Restrictions

Only type-3 LSAs that originate from an ABR are filtered.

Navigation Path

You can access the Filtering tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit Filtering Dialog Box , on page 2182

Field Reference

Table 773: Filtering Tab

Element	Description
OSPF Process	The OSPF process associated with the filter entry.
Area ID	The ID of the area associated with the filter entry.
Prefix List Name	The name of the prefix list.
Filtered Network	The IP address and mask of the network being filtered.
Traffic Direction	Displays “Inbound” if the filter entry applies to LSAs coming in to an OSPF area or “Outbound” if it applies to LSAs going out of an OSPF area.
Sequence #	The sequence number for the filter entry. When multiple filters apply to an LSA, the filter with the lowest sequence number is used.
Action	Displays “Permit” if LSAs matching the filter are allowed or “Deny” if LSAs matching the filter are denied.
Lower Range	The minimum prefix length to be matched.
Upper Range	The maximum prefix length to be matched.

Add/Edit Filtering Dialog Box

Use the Add/Edit Filtering dialog box to add new filters to the Filter table or to modify an existing filter.

Navigation Path

You can access the Add/Edit Filtering dialog box from the Filtering Tab , on page 2181.

Related Topics

- Configuring OSPF , on page 2162

Field Reference

Table 774: Add/Edit Filtering Dialog Box

Element	Description
OSPF Process	Select the OSPF process associated with the filter entry.
Area ID	Select the ID of the area associated with the filter entry.
Prefix List Name	Enter or Select the appropriate prefix list object. **Tip** Click **Select** to open the Prefix List Object Selector from which you can select a prefix list object. You can also create new objects from the object Prefix List Object selector. For more information, see Add or Edit Prefix List Object Dialog Box , on page 2241.
Filtered Network	Enter the IP address and mask of the network being filtered.
Traffic Direction	Select the traffic direction to filter. Choose “Inbound” to filter LSAs coming into an OSPF area or “Outbound” to filter LSAs going out of an OSPF area.
Sequence Number	Enter a sequence number for the filter. Valid values range from 1 to 4294967294. When multiple filters apply to an LSA, the filter with the lowest sequence number is used.
Action	Select “Permit” to allow the LSA traffic or “Deny” to block the LSA traffic.
Lower Range	Specify the minimum prefix length to be matched. The value of this setting must be greater than the length of the network mask entered in the Filtered Network field and less than or equal to the value, if present, entered in the Upper Range field.
Upper Range	Enter the maximum prefix length to be matched. The value of this setting must be greater than or equal to the value, if present, entered in the Lower Range field, or, if the Lower Range field is left blank, greater than the length of the network mask length entered in the Filtered Network field.

Filter Rule Tab

Use the Filter Rule tab to configure rules to filter networks received or transmitted in Open Shortest Path First (OSPF) updates.

Note Filter rules are supported on ASA 9.2(1)+ only.

Navigation Path

You can access the Filter Rule tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit Filter Rule Dialog Box , on page 2184

Field Reference

Table 775: Filter Rule Tab

Element	Description
Process ID	The OSPF process associated with the filter rule.
ACL	Standard IP access list name. The list defines which networks are to be received and which are to be suppressed in routing updates.
Direction	The direction for the filter rule: • in—The rule filters default route information from incoming routing updates. • out—The rule filters default route information from outgoing routing updates.
Interface	(Optional) The interface to which the filter rule applies.
Routing Process	The routing process: None, BGP, Connected, EIGRP, OSPF, RIP, or Static.
Routing Process ID	The identifier for the routing process.

Add/Edit Filter Rule Dialog Box

Use the Add/Edit Filter Rule dialog box to add new filter rules to the Filter Rules table or to modify an existing filter rule.

Note Filter rules are supported on ASA 9.2(1)+ only.

Navigation Path

You can access the Add/Edit Filter Rule dialog box from the Filter Rule Tab , on page 2183.

Related Topics

- Configuring OSPF , on page 2162

Field Reference

Table 776: Add/Edit Filter Rule Dialog Box

Element	Description
OSPF Process	Select the OSPF process associated with the filter rule.
ACL	Select an Access Control List that defines which networks are to be received and which are to be suppressed in routing updates.
Direction	Specify the direction for the filter rule: • in—The rule filters default route information from incoming routing updates. • out—The rule filters default route information from outgoing routing updates.
Interface	(Optional) Specify the interface on which to apply the routing updates. Specifying an interface causes the access list to be applied only to routing updates received on that interface.
Routing Process	Select the routing process for which you want to filter: None, BGP, Connected, EIGRP, OSPF, RIP, or Static.
Routing Process ID	Enter the identifier for the routing process. Applies to BGP, EIGRP, and OSPF routing protocols.

Summary Address Tab

Use the Summary Address tab to configure summary addresses for each OSPF routing process.

Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

Navigation Path

You can access the Summary Address tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit Summary Address Dialog Box , on page 2186

Element	Description
OSPF Process	Choose the OSPF process associated with the summary address. You cannot change this information when editing an existing entry.
Network	The IP address and network mask of the summary address.
Tag	The tag value is a 32-bit decimal value attached to each external route. This is not used by OSPF itself. It may be used to communicate information between ASBRs. Valid values range from 0 to 4294967295.
Advertise	When selected, summary routes are advertised. Deselect this check box to suppress routes that fall under the summary address. By default, this check box is selected.

Interface Tab

Use the Interface tab to configure interface-specific OSPF authentication routing properties.

Navigation Path

You can access the Interface tab from the OSPF page. For more information about the OSPF page, see Configuring OSPF , on page 2162.

Related Topics

- Add/Edit Interface Dialog Box , on page 2188

Field Reference

Table 779: Interface Tab

Element	Description
Interface	The name of the interface to which the configuration applies.
Authentication	The type of OSPF authentication enabled on the interface. The authentication type can be one of the following values: • None—OSPF authentication is disabled. • Password—Clear text password authentication is enabled. • MD5—MD5 authentication is enabled. • Area—The authentication type specified for the area is enabled on the interface. Area authentication is the default value for interfaces. However, area authentication is disabled by default. So, unless you previously specified an area authentication type, interfaces showing Area authentication have authentication disabled. • Key Chain—Key chain authentication is enabled.
Point-to-Point	Displays “true” if the interface is set to non-broadcast (point-to-point). Displays “false” if the interface is set to broadcast.
Cost	The cost of sending a packet through the interface.
Priority	The OSPF priority assigned to the interface.
MTU Ignore	Displays “false” if MTU mismatch detection is enabled. Displays “true” if the MTU mismatch detection is disabled.
Database Filter	Displays “true” if outgoing LSAs are filtered during synchronization and flooding. Displays “false” if filtering is not enabled.
Hello Interval	The interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected but the more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. Valid values range from 1 to 65535 seconds. The default value is 10 seconds.

Element	Description
Transmit Delay	The estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 65535 seconds. The default value is 1 second.
Retransmit Interval	The time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 65535 seconds. The default value is 5 seconds.
Dead Interval	The interval, in seconds, in which no hello packets are received, causing neighbors to declare a router down. Valid values range from 1 to 65535. The default value of this setting is four times the interval set by the Hello Interval field.
Hello Multiplier (ASA 9.2(1)+ only)	The number of hello packets to be sent per second. Valid values are between 3 and 20.

Add/Edit Interface Dialog Box

Use the Add/Edit Interface dialog box to add OSPF authentication routing properties for an interface or to change an existing entry.

Note Beginning with ASA version 9.2(1), the upper limit for acceptable entries for Hello Interval, Transmit Delay, Retransmit Interval, and Dead Interval has been reduced from 65535 seconds to 8192 seconds. If you configure a shared policy that uses a value over 8192, you will receive a validation error if that policy is assigned to an 9.2(1)+ device.

Navigation Path

You can access the Add/Edit Interface dialog box from the Interface Tab , on page 2148.

Related Topics

- Configuring OSPF , on page 2162

Field Reference

Table 780: Add/Edit Interface Dialog Box

Element	Description
Interface	The name of the interface to which the configuration applies.

Element	Description
Authentication	The type of OSPF authentication enabled on the interface. The authentication type can be one of the following values: • No Authentication—OSPF authentication is disabled. • Area Authentication—The authentication type specified for the area is enabled on the interface. Area authentication is the default value for interfaces. However, area authentication is disabled by default. So, unless you previously specified an area authentication type, interfaces showing Area authentication have authentication disabled. • Password Authentication—Clear text password authentication is enabled. • MD5 Authentication—MD5 authentication is enabled. • Key Chain—Key chain authentication is enabled.
Key Chain	Click Select and choose the configured key chain. To know the configuration steps, refer Configuring Key Chain , on page 2190. **Note** Use the same authentication type and key ID for the peers to establish a successful adjacency.
Authentication Password	Contains the settings for entering the password when password authentication is enabled. • Enter Password—Enter a text string of up to 8 characters. • Confirm—Re-enter the password.
MD5 Key IDs and Keys	Contains the settings for entering the MD5 keys and parameters when MD5 authentication is enabled. All devices on the interface using OSPF authentication must use the same MD5 key and ID. • Key ID—Enter a numerical key identifier. Valid values range from 1 to 255. • Key—An alphanumeric character string of up to 16 bytes. • Confirm—Re-enter the MD5 key. Enter the above values, then click >> to add the key information to the Keys table. Select a key entry and then click << to remove it from the Keys table.
Cost	The cost of sending a packet through the interface.
Priority	The OSPF priority assigned to the interface.
MTU Ignore	When selected, MTU mismatch detection is disabled. Clear this check box to enable MTU mismatch detection.
Database Filter All Out	When selected, outgoing LSAs are filtered during synchronization and flooding. Deselect this check box to disable filtering.

Element	Description
Hello Interval (sec)	The interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected but the more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. For ASA 9.2(1)+ devices, valid values range from 1 to 8192 seconds. For all other devices, valid values range from 1 to 65535 seconds. The default value is 10 seconds.
Transmit Delay (sec)	The estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. For ASA 9.2(1)+ devices, valid values range from 1 to 8192 seconds. For all other devices, valid values range from 1 to 65535 seconds. The default value is 1 second.
Retransmit Interval (sec)	The time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it will resend the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. For ASA 9.2(1)+ devices, valid values range from 1 to 8192 seconds. For all other devices, valid values range from 1 to 65535 seconds. The default value is 5 seconds.
Dead Interval (sec)	The interval, in seconds, in which no hello packets are received, causing neighbors to declare a router down. For ASA 9.2(1)+ devices, valid values range from 1 to 8192 seconds. For all other devices, valid values range from 1 to 65535 seconds. The default value of this setting is four times the interval set by the Hello Interval field.
Hello Multiplier (Hello/Sec) (ASA 9.2(1)+ only)	The number of hello packets to be sent per second. Valid values are between 3 and 20. **Note** If you specify a Hello Multiplier, the Hello Interval and Dead Interval values will be ignored. If you entered a value for Hello Interval or Dead Interval, you will be asked to confirm that you want to use the Hello Multiplier instead of the Hello Interval and Dead Interval settings.
Point-to-Point	Displays “true” if the interface is set to non-broadcast (point-to-point). Displays “false” if the interface is set to broadcast.

Configuring Key Chain

To enhanced data security and protection on the networking devices, the devices are configured with rotating keys for authenticating IGP peers that have a duration of 180 days or less. The rotating keys prevent any malicious user from guessing the keys used for routing protocol authentication and thereby protecting the network from advertising incorrect routes and redirecting traffic. Changing the keys frequently reduces the

risk of them eventually being guessed. When configuring authentication for routing protocols that provide key chains, configure the keys in a key chain to have overlapping lifetimes. This configuration helps to prevent loss of key-secured communication due to absence of an active key. If the key lifetime expires and no active keys are found, OSPF uses the last valid key to maintain the adjacency with peers.

The two limitations of key chain configuration in Cisco Security Manager are:

- The configured Key ID will be displayed in unencrypted format in the OOB (Out of Band) Changes Dialog Box , on page 429.
- The option to copy provision is not available for key chains.

Related Topics

- Lifetime of a Key, on page 2191
- Add/Edit Key Chain , on page 2192

Lifetime of a Key

To maintain stable communications, each device stores key chain authentication keys and uses more than one key for a feature at the same time. Based on the send and accept lifetimes of a key, keychain management provides a secured mechanism to handle key rollover. The device uses the lifetimes of keys to determine which keys in a key chain are active.

Each key in a key chain has two lifetimes:

- Accept lifetime—The time interval within which the device accepts the key during key exchange with another device.
- Send lifetime—The time interval within which the device sends the key during key exchange with another device.

During a key send lifetime, the device sends routing update packets with the key. The device does not accept communication from other devices when the key sent is not within the accept lifetime of the key on the device.

If lifetimes are not configured then it is equivalent to configuring MD5 authentication key without timelines.

Key Selection

- When key chain has more than one valid key, OSPF selects the key that has the maximum life time.
- Key having an infinite lifetime is preferred.
- If keys have the same lifetime, then key with the higher key ID is preferred.

Related Topics

- Configuring Key Chain , on page 2190
- Add/Edit Key Chain , on page 2192

Add/Edit Key Chain

Use the Add/Edit KeyChain dialog box to add new entries or to modify existing entries in the KeyChain table.

Navigation Path

- You can access the Key Chain page tab from the Interface tab of OSPF page. For more information about the Interface tab, see Interface Tab , on page 2148.
- You can directly access the Add Key Chain page from **Manage > Policy Objects > Key Chain**.

Step 1 Create a key chain policy object that includes the key chains for authentication.

a) Select **Manage > Policy Objects** to open the Policy Object Manager window (see Policy Object Manager , on page 232).
b) Select **Key Chain** from the table of contents.
c) Right-click and choose **New Object**.
d) In the Add Key Chain dialog box, enter a name for the object, for example, Chain 1.
e) Click the **Add button** to add the key chain entry to the Key Chain list.

Step 2 Enter the relevant values in the **Add Key Chain Entry dialog box:**

Field Reference

Table 781: Add Key Chain Entry page

Element	Description
Algorithm	MD5 is the default cryptographic algorithm used for authentication.
Key ID	Enter a value between 0 and 255. **Note** The Key ID does not get displayed in encrypted format in the OOB (Out of Band) Changes Dialog Box , on page 429.
Authentication Type	Select the relevant option: • Clear Text—To have the authentication key in text format. • Encryption —To have the authentication key in encrypted format.
Key String	Enter the key string.
Confirm Key String	Re-enter the same key string.
Accept Lifetime Settings— Provide the interval within which the device accepts the key during key exchange with another device.	
Timezone	Select either UTC or Local.
Start Date/Time	Provide the start date and the time in hh:mm:ss format.

Element	Description
End Time Type	Select the relevant option: • Date Time—The absolute time that the lifetime ends. • Duration—The number of seconds after the start time that the lifetime ends. • Infinite—Infinite lifetime (no end-time).
End Date	Provide the absolute date and the time. This option is not available if you choose Duration or Infinite as the End Time Type.
Duration	Provide the value in seconds after the start time that the lifetime ends. The permissible range is 1 and 2147483646. This option is not available if you choose Date Time or Infinite as the End Time Type.
Send Lifetime Settings—The time interval within which the device sends the key during key exchange with another device.	
Timezone	Select either UTC or Local.
Start Date/Time	Provide the start date and the time in hh:mm:ss format.
End Time Type	Select the relevant option: • Date Time—The absolute time that the lifetime ends. • Duration—The number of seconds after the start time that the lifetime ends. • Infinite—Infinite lifetime (no end-time).
End Date	Provide the absolute date and the time. This option is not available if you choose Duration or Infinite as the End Time Type.
Duration	Provide the value in seconds after the start time that the lifetime ends. The permissible range is 1 and 2147483646. This option is not available if you choose Date Time or Infinite as the End Time Type.

Step 3 Click Ok. Remember to submit your changes to the databases.

What to do next

- Lifetime of a Key, on page 2191

Configuring OSPFv3

The OSPFv3 page provides two tabbed panels for configuring OSPF (Open Shortest Path First) version 3 routing on a firewall device.

Navigation Path

- (Device view) Select **Platform > Routing > OSPFv3** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > OSPFv3** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

This is the basic procedure for configuring an OSPFv3 process and assigning it to an interface on the OSPFv3 page:

1. On the Process Tab , on page 2196:
   - Specify which of the two processes you are configuring by choosing **Process 1** or **Process 2** from the OSPFv3 Process drop-down list.
   - Check **Enable OSPFv3 Process**.
   - Assign a **Process ID**; any positive integer between 1 and 65535.
   - Use the following features as needed to define the process:
   - **Advanced** button, opening the OSPFv3 Advanced Properties Dialog Box , on page 2197.
   - Area Tab (OSPFv3) , on page 2201, for managing area, range, and virtual-link definitions, by means of the Add/Edit Area Dialog Box (OSPFv3) , on page 2201, Add/Edit Range Dialog Box (OSPFv3) , on page 2203, and Add/Edit Virtual Link Dialog Box (OSPFv3) , on page 2204.
   - **Redistribution** panel, for managing route redistribution definitions by means of the Add/Edit Redistribution Dialog Box (OSPFv3) , on page 2205.
   - **Summary Prefix** panel, for managing summary-prefix definitions by means of the Add/Edit Summary Prefix Dialog Box (OSPFv3) , on page 2206.
2. On the OSPFv3 Interface Tab , on page 2207:
   a. Use the Interface and Neighbor panels to assign the process to a specific interface, using the Add/Edit Interface Dialog Box (OSPFv3) , on page 2208 and the Add/Edit Neighbor Dialog Box (OSPFv3) , on page 2211.

Related Topics

- About OSPFv3 , on page 2194

About OSPFv3

Open Shortest Path First (OSPF) is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. Version 3 is basically OSPFv2 enhanced for IPv6. It is similar to OSPFv2 (see

About OSPF , on page 2163), but it is not backward compatible. To use OSPF to route both IPv4 and IPv6v packets, it will be necessary to run both OSPFv2 and OSPFv3 concurrently. They co-exist with each other, but do not interact.

Note OSPFv3 is supported on ASA 9.0+ devices operating in single-context, routed mode only. That is, multiple contexts and transparent mode are not supported.

Think of a link as being an interface on a networking device. A link-state protocol makes its routing decisions based on the states of the links that connect source and destination devices. The state of a link is a description of that interface and its relationship to its neighboring networking devices. This interface information includes the IPv6 prefix/length of the interface, the type of network it is connected to, the devices connected to that network, and so on. This information is propagated in various type of link-state advertisements (LSAs). Because only LSAs are exchanged, rather than entire routing tables, OSPF networks converge more quickly than RIP networks.

The ASA can run two processes of the OSPFv3 protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these interfaces to co-exist, but OSPFv3 does not allow overlapping addresses). Or you might want to run one process on the inside interface and another on the outside, redistributing a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPFv3 routing process from another OSPFv3 routing process, a RIP routing process, or from static and connected routes configured on OSPFv3-enabled interfaces.

If NAT is employed but OSPFv3 is only running in public areas, routes to public networks can be redistributed inside the private network, either as default or type 5 AS External LSAs. However, you need to configure static routes for the private networks protected by the security appliance. Also, you should not mix public and private networks on the same security appliance interface.

Differences Between OSPFv2 and OSPFv3

The additional features provided by OSPFv3 over OSPFv2 include the following:

- Use of the IPv6 link-local address for neighbor discovery and other features.
- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Authentication support using the IPSec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

Configuration Restrictions

The following are ASA OSPFv3 configuration restrictions:

- To enable OSPFv3 on a specific interface, IPv6 should be enabled on the interface and it must be named.
- Only one OSPFv3 process, with one area and one instance, can be assigned to an interface.
- The Interface neighbor entries take effect only when the OSPFv3 is enabled, and network type should be point-to-point on the specified interface.
- Interface neighbor address must be a link-local address.
- Range value in area Range table should be unique across the area.
- If the area is set to NSSA or stub, the same area cannot be set for virtual-link.
- OSPFv3 redistribution not applicable on the same OSPFv3 process.
- If used in an ASA cluster, OSPFv3 encryption should be disabled.
- The Layer 3 cluster pool is not shared between OSPFv3 and the interface.

Related Topics

- Configuring OSPFv3 , on page 2194
- Process Tab , on page 2196
- OSPFv3 Interface Tab , on page 2207

Process Tab

Use the Process tab on the OSPFv3 page to enable and configure up to two OSPFv3 routing processes. Each OSPF process has its own associated areas and networks. For each, at minimum, create an area for OSPFv3, enable an interface for OSPFv3, then redistribute the route into the targeted OSPFv3 routing processes. Note that only single-context mode is supported.

Navigation Path

The Process tab is on the OSPFv3 page.

- (Device view) Select **Platform > Routing > OSPFv3** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > OSPFv3** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Table 782: Process Tab

Element	Description
OSPFv3 Process	Identify which OSPFv3 process you are configuring: choose **Process 1** or **Process 2**. You can enable one or both.
Enable OSPFv3 Process	Check this box to enable the chosen OSPFv3 process. Deselect this option to disable the OSPFv3 process; the process configuration information is retained should you wish to re-enable it later.
Process ID	Enter a unique numeric identifier for this process. The ID can be any positive integer between 1 and 65535. This process ID is used internally and does not need to match the OSPFv3 process ID on any other OSPFv3 devices.
Advanced	Opens the OSPFv3 Advanced Properties Dialog Box , on page 2197, in which you can configure additional process-related parameters, such Router ID, Adjacency Changes, Administrative Route Distances, Timers, Default Information Originate, and Passive Interface settings.
Area	Use the tabs and tables in this panel to manage area, range and virtual-link definitions. See Area Tab (OSPFv3) , on page 2201 for more about these definitions.
Redistribution	Use this panel to manage redistribution definitions. See Add/Edit Redistribution Dialog Box (OSPFv3) , on page 2205 for more about these definitions.
Summary Prefix	Use this panel to manage summary prefix definitions. See Add/Edit Summary Prefix Dialog Box (OSPFv3) , on page 2206 for more about these definitions.

OSPFv3 Advanced Properties Dialog Box

Use the OSPF Advanced dialog box to configure settings such as the Router ID, Adjacency Changes, Administrative Route Distances, Timers, and Default Information Originate settings for an OSPF process.

Navigation Path

You can access the OSPF Advanced dialog box from the Process Tab , on page 2196.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194

Field Reference

Table 783: OSPF Advanced Dialog Box

Element	Description
OSPF Process	This read-only field displays the ID of the OSPF process you are configuring.
Router ID	On a single device, choose **Automatic** or **IP Address**. (An address field appears when you choose IP Address.) If you choose Automatic, the highest-level IP address on the security appliance is used as the router ID. To use a fixed router ID, choose IP Address and enter an IPv4 address in the Router ID field. On a device cluster, choose **Automatic** or **Cluster Pool**. (An IPv4 Pool object ID field appears when you choose Cluster Pool.) If you choose Cluster Pool, enter or Select the name of the IPv4 Pool object that is to supply the Router ID address. For more information, see Add or Edit IPv4 Pool Dialog Box , on page 323.
Ignore LSA MOSPF	Select this option to suppress transmission of syslog messages when the security appliance receives Type 6 (MOSPF) LSA packets.
Adjacency Changes	These options specify the syslog messages sent when adjacency changes occur: • Log Adjacency Changes – When selected, the security appliance sends a syslog message whenever an OSPF neighbor goes up or down. Checking this box enables the Include Details option. • Include Details – When selected, the security appliance sends a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This option is available only when Log Adjacency Changes is checked.
Administrative Route Distances	Settings for the administrative route distances, according to the route type. • Inter Area – The administrative distance for all routes from one area to another. Valid values range from 1 to 254; the default value is 110. • Intra Area – The administrative distance for all routes within an area. Valid values range from 1 to 254; the default value is 110. • External – The administrative distance for all routes from other routing domains that are learned through redistribution. Valid values range from 1 to 254; the default value is 110.

Element	Description

Timers (in milliseconds)	LSA and SPF throttling provide a dynamic mechanism to slow LSA updates in OSPFv3 during times of network instability, and allow faster OSPFv3 convergence by providing LSA rate limiting. The settings used to configure LSA pacing and SPF calculation timers are:
	• LSA Arrival – The minimum delay between acceptance of the same LSA arriving from neighbors. Valid values range from 0 to 600000 milliseconds. The default is 1000.
	• LSA Flood Pacing – The amount of time LSAs in the flooding queue are paced in between updates. Valid values range from 5 to 100 milliseconds. The default value is 33.
	• LSA Group Pacing – The interval at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800; the default value is 240 milliseconds.
	• LSA Retransmission Pacing – The length of time at which LSAs in the retransmission queue are paced. Valid values range from 5 to 200 milliseconds. The default value is 66.
	• LSA Throttle – The delay in milliseconds to generate the first occurrence of the LSA. Valid values range from 0 to 600000 milliseconds. When you enter a value in this field, the min and max fields are enabled:
	  • min – The minimum delay for originating the same LSA. Valid values range from 1 to 600000 milliseconds.
	  • max – The maximum delay for originating the same LSA. Valid values range from 1 to 600000 milliseconds.
	• SPF Throttle – The delay to receive a change to the SPF calculation. Valid values range from 1 to 600000 milliseconds. When you enter a value in this field, the min and max fields are enabled:
	  • min – The delay between the first and second SPF calculations. Valid values range from 1 to 600000 milliseconds.
	  • max – The maximum wait time for SPF calculations. Valid values range from 1 to 600000 milliseconds.
	Note For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

Element	Description

Default Information Originate	Settings used by an ASBR to generate a default external route into an OSPFv3 routing domain:
	• Enable Default Information Originate – Check this box to enable generation of a default route into the OSPFv3 routing domain; the following options become available:
	  • Always advertise the default route – Check this box to always advertise the default route.
	  • Metric Value – The OSPFv3 metric used to generate the default route. Valid values range from 0 to 16777214.
	  • Metric Type – The external link type associated with the default route advertised into the OSPFv3 routing domain. Choose **1** or **2**, indicating a Type 1 or a Type 2 external route. The default value is 1.
	  • Route Map – (Optional) Enter or Select the name of a route map object to apply. The routing process generates the default route if the route map is satisfied.
	Tip Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.

Passive Interface	Passive routing helps control the advertisement of OSPFv3 routing information, and disables sending and receiving OSPFv3 routing updates on an interface. Enter or Select one or more interfaces, or interface objects, to enable passive OSPFv3 routing on those interfaces. IPv4 and IPv6 addresses are supported.
Non Stop Forwarding Tab **Note** Non Stop Forwarding (NSF) is supported on ASA 9.3(1)+ only.	
Enable graceful-restart helper	Enables graceful restart helper mode. When an ASA has NSF enabled, it is said to be NSF-capable and will operate in graceful restart mode. By default, the neighboring ASAs of the NSF-capable ASA will be NSF-aware and will operate in NSF helper mode. When the NSF-capable ASA is performing graceful restart, the helper ASAs assist in the nonstop forwarding recovery process. If you do not want the ASA to help the restarting neighbor with nonstop forwarding recovery, clear the Enable graceful-restart helper option.
Enable Link State Advertisement	Enables strict link-state advertisement (LSA) checking. **Note** When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.

Element	Description
Enable graceful-restart (Use when Spanned Cluster or Failover configured)	Enables graceful restart on the ASA.
Length of graceful restart interval	(Optional) Specifies the length of the graceful restart interval, in seconds. The range is from 1 to 1800. The default is 120. **Note** For a restart interval below 30 seconds, graceful restart will be terminated.

Area Tab (OSPFv3)

Use the Area panel on the Process Tab , on page 2196 of the OSPFv3 page to configure OSPFv3 areas, ranges and virtual links. The Area panel consists of three definition tables—Area, Range, and Virtual Link:

- Refer to Add/Edit Area Dialog Box (OSPFv3) , on page 2201 for information about adding and editing Area table entries.
- Refer to Add/Edit Range Dialog Box (OSPFv3) , on page 2203 for information about adding and editing Range table entries.
- Refer to Add/Edit Virtual Link Dialog Box (OSPFv3) , on page 2204 for information about adding and editing Virtual Link table entries.

Refer to Using Tables , on page 50 for basic information about working with Security Manager tables.

Navigation Path

You can access the Area tab from the Process Tab , on page 2196 of the OSPFv3 page. For more information about the OSPFv3 page, see Configuring OSPFv3 , on page 2194.

Related Topics

- About OSPFv3 , on page 2194
- OSPFv3 Interface Tab , on page 2207

Add/Edit Area Dialog Box (OSPFv3)

Use the Add/Edit Area dialog box to define parameters for the area.

Navigation Path

You can access the Add/Edit Area dialog box from the Area Tab (OSPFv3) , on page 2201.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194
- Process Tab , on page 2196

Field Reference

Table 784: Add/Edit Area Dialog Box

Element	Description
Area ID	Enter an identifier for the area as either a decimal number or an IP address. Valid decimal values range from 0 to 4294967295.
Cost	The cost of sending a packet on an interface. Valid values are 0 to 65535. Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The ASA calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.
Type	Define the area type by choosing one of the following: • Normal – Make the area a standard OSPFv3 area. This option is selected by default when you first create an area. • NSSA – Make the area a "not-so-stubby area." NSSAs accept Type 7 LSAs. When you choose this option, the Default Information Originate options are enabled. When you create a NSSA, you can prevent summary LSAs from being flooded into the area by deselecting *Allow sending summary LSA into this area* . You can also disable route redistribution by deselecting *Redistribute* , and enabling *Default information originate* . • Stub – Make the area a stub area. Stub areas do not have any routers or areas beyond it. Stub areas prevent AS External LSAs (Type 5 LSAs) from being flooded into the stub area. When you choose this option, *Allow sending summary LSA into this area* is enabled. When you create a stub area, you can prevent summary LSAs (Type 3 and 4) from being flooded into the area by deselecting *Allow sending summary LSA into this area* .
Default Information Originate These options are enabled when you choose NSSA as the area Type. The first option is enabled when you choose Stub as the area Type.	
Allow sending summary LSA into this area	Select to allow flooding of summary LSAs into the area.
Redistribute (imports routes to normal and NSSA areas)	Select to allow route redistribution.

Element	Description
Default information originate	Check this box to generate a Type 7 default into the NSSA. Selecting this option enables the following metric options: • Metric – The OSPF metric value for the default route. Valid values range from 1 to 16777214. The default is 1. • Metric Type – The OSPF metric type for the default route. Choose 1 (Type 1) or 2 (Type 2). The default is 1.

Add/Edit Range Dialog Box (OSPFv3)

Use the Add/Edit Area Range Network dialog box to add a new range to the area selected in the Area table, or to change an existing entry.

Navigation Path

You can access the Add/Edit Range dialog box from the Range panel under the Area Tab (OSPFv3) , on page 2201.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194
- Process Tab , on page 2196

Field Reference

Table 785: Add/Edit Range Dialog Box

Element	Description
Area ID	This read-only entry is the ID of the area to which this range applies.
IPv6 Prefix/Length	The IPv6 address(es) for the routes being summarized. **Tip** You can click **Select** to select the networks from a list of network objects.
Cost	The cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values are 0 to 16777215. Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The ASA calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.
Advertise	Select this option to set the address range status to advertise. This causes Type 3 summary LSAs to be generated (this is the default). Deselect this optionn to suppress the Type 3 summary LSAs for the specified networks.

Add/Edit Virtual Link Dialog Box (OSPFv3)

Use the Add/Edit Virtual Link dialog box to define virtual links for the area selected in the Area table, or change the properties of existing virtual links.

Navigation Path

You can access the Add/Edit Virtual Link dialog box from the Virtual Link panel under the Area Tab (OSPFv3) , on page 2201.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194
- Process Tab , on page 2196

Field Reference

Table 786: Add/Edit Virtual Link Dialog Box

Element	Description
Area ID	This read-only entry is the ID of the area to which this virtual link applies.
Peer Router ID	Enter the IP address of the virtual link neighbor. **Tip** You can click **Select** to select from a list of network objects.
TTL Security	The time-to-live (TTL) security hop count on a virtual link. The hop count value can range from 1 to 254.
Dead Interval	The interval, in seconds, if no hello packets are received, neighbors declare the device down. Valid values range from 1 to 8192. The default value of this field is four times the Hello Interval.
Hello Interval	The interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected but the more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. Valid values range from 1 to 8192 seconds. The default value is 10 seconds.
Transmit Interval	The time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a device sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the device does not receive an acknowledgment, it will resend the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 8192 seconds. The default value is 5 seconds.

Element	Description
Transmit Delay	The estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 8192 seconds. The default value is 1 second.

Add/Edit Redistribution Dialog Box (OSPFv3)

Use the Add/Edit Redistribution dialog box to add a redistribution rule to this process, or to edit an existing redistribution rule.

Navigation Path

You can access the Redistribution dialog box from the Redistribution panel under the Process Tab , on page 2196.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194

Field Reference

Table 787: Add/Edit Redistribution Dialog Box

Element	Description
Source Protocol	Choose the source protocol for route redistribution: • Connected – Redistributes connected routes (routes established automatically by virtue of having an IP address enabled on the interface) to the OSPFv3 routing process. Connected routes are redistributed as external to the autonomous system. • OSPF – Redistributes routes from another OSPF routing process. The Routing PID and the Match options are enabled when you choose this option. • Static – Redistributes static routes to the OSPFv3 routing process.
Metric	The metric value for the routes being redistributed. Valid values range from 1 to 16777214; the default is 20. When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified.

Element	Description
Metric Type	The metric type is the external link type associated with the default route that is advertised into the OSPFv3 routing domain. Choose None, 1, or 2, where None indicates there is no default route, 1 indicates the metric is a Type 1 external route, and 2 is a Type 2 external route.
Tag (optional)	The tag is a 32-bit decimal value attached to each external route. This is not used by OSPF itself. It may be used to communicate information between other border devices. Valid values range from 0 to 4294967295.
Route Map	Enter or Select the name of the route map object to apply to the redistribution entry. **Tip** Click **Select** to open the Route Map Object Selector from which you can select a route map object. You can also create new route map objects from the Route Map Object Selector. For more information, see Understanding Route Map Objects , on page 2227.
Routing PID	The ID of the process to which redistribution is directed. (The Process ID is defined on the Process Tab , on page 2196.) This option is enabled only when OSPF is chosen as the Source Protocol.
Include Connected	Check this box to include connected routes in the redistribution.
Match The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions. These options are enabled only when OSPF is chosen as the Source Protocol.	
Internal	The route is internal to a specific autonomous system.
External 1	Routes that are external to the autonomous system, but are imported into OSPF as Type 1 external routes.
External 2	Routes that are external to the autonomous system, but are imported into OSPF as Type 2 external routes.
NSSA External 1	Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes.
NSSA External 2	Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes.

Add/Edit Summary Prefix Dialog Box (OSPFv3)

Use the Add/Edit Summary Prefix dialog box to add new route-summarization entries to the selected process, or to modify existing entries.

Navigation Path

You can access the Add/Edit Summary Prefix dialog box from the Summary Prefix panel under the Process Tab , on page 2196.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194

Field Reference

Table 788: Add/Edit Summary Prefix Dialog Box

Element	Description
Process ID	This read-only value identifies the process to which this rule applies.
IPv6 Prefix/Length	Enter an IPv6 prefix/length for external route summarization. **Tip** You can click **Select** to select from a list of network objects.
Advertise	When selected, summary routes that match the specified prefix and mask pair are advertised. When deselected, routes that match the specified prefix and mask pair are suppressed. By default, this check box is selected.
Tag (optional)	The tag is a 32-bit decimal value attached to each external route. This is not used by OSPF itself. It may be used to communicate information between border devices. Valid values range from 0 to 4294967295. This field is enabled when you check Advertise.

OSPFv3 Interface Tab

Use the Interface panel to configure interface-and neighbor-specific OSPFv3 routing properties. The Interface panel consists of two definition tables, Interface and Neighbor:

- Refer to Add/Edit Interface Dialog Box (OSPFv3) , on page 2208 for information about adding and editing Interface table entries.
- Refer to Add/Edit Neighbor Dialog Box (OSPFv3) , on page 2211 for information about adding and editing Neighbor table entries.

Refer to Using Tables , on page 50 for basic information about working with Security Manager tables.

Navigation Path

Click the Interface tab on the OSPFv3 page to display this panel. For more information about the OSPFv3 page, see Configuring OSPFv3 , on page 2194.

Related Topics

- About OSPFv3 , on page 2194

Add/Edit Interface Dialog Box (OSPFv3)

Use the Add/Edit Interface dialog box to define OSPFv3 routing properties for an individual interface, or to change an existing entry.

Navigation Path

You can access the Add/Edit Interface dialog box from the Interface panel under the OSPFv3 Interface Tab , on page 2207.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194
- Process Tab , on page 2196

Field Reference

Table 789: Add/Edit Interface Dialog Box

Element	Description
Interface	The name of the interface to which this routing configuration applies. **Tip** You can click **Select** to select from a list of interface objects.
Enable OSPFv3 on this interface	Check this box to enable OSPFv3 on the specified interface, and activate the following fields: • Process ID – Choose the process to apply to this interface; defined on the OSPFv3 Process Tab , on page 2196. • Area ID – Identify the area to be assigned; areas are also defined on the OSPFv3 Process Tab , on page 2196. • Instance ID – (Optional) Specify an ID for this process instance. Valid values for this setting range from 0 to 255. This feature lets you have multiple OSPFv3 processes on a single link. Received packets with other instance IDs are then ignored by this process.
Properties	
Filter outgoing link-state advertisements	Check this box to filter outgoing LSAs. All outgoing LSAs are flooded to the interface by default.
Disable MTU mismatch detection	Check this box to disable the OSPFv3 MTU mismatch detection when database description (DBD) packets are received.
Flood Reduction	Check this box to suppress unnecessary flooding of LSAs in stable topologies.

Element	Description
Point-to-point Network	Check this box to define this as a link to a point-to-point network; that is, a network between two routing devices. All neighbors on a point-to-point network establish adjacency and there is no designated router. This option is unavailable when the Broadcast option is selected.
Broadcast	Check this box to define this as a link to a network with multiple routing devices. Such networks establish a designated router (DR), as well as a backup designated router (BDR), that controls LSA flooding on the network. This option is unavailable when the Point-to-point Network option is selected.
Cost	The cost of sending a packet through the interface. Link cost is an arbitrary number used in shortest path first calculations. If you do not assign a value, the configured reference bandwidth divided by the interface port speed is used. (The default reference bandwidth is 40 Gb/sec.)
Priority	Assign an OSPFv3 priority to this interface. Valid values for this setting range from 0 to 255. Entering 0 for this setting makes the device ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, non-broadcast interfaces. When two routing devices connect to a network, both attempt to become the designated router. The device with the higher priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.
Dead Interval	If no hello packets are received from a neighbor within this interval, that device is designated as inactive. Valid values range from 1 to 65535. The default value for this setting is four times the hello interval.
Poll Interval	If a neighboring device is inactive, it may be necessary to continue sending hello packets to that neighbor. The hello packets are sent at this reduced interval, which should be larger than the hello interval.
Retransmit Interval	The time, in seconds, between LSA retransmissions for adjacent neighbors. When a router sends an LSA to a neighbor, it keeps the LSA until it receives an acknowledgment. If an acknowledgment is not received within this interval, it will resend the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 65535 seconds.
Transmit Delay	The estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 65535 seconds.
Authentication	

Element	Description
Type	The type of authentication enabled on this interface. Choose one of the following: • Area – OSPFv3 does not provide "built-in" authentication, instead relying on IPv6/IPSec protocols. Choose this option to use those protocols to authenticate OSPFv3 traffic on all interfaces in the area; this means all routing devices in the area must use this option. This is the default. • Interface – Choose this option to secure this interface and protect OSPFv3 virtual links. The additional parameters in this section are enabled when you choose this option. • None – OSPFv3 authentication is disabled.
Security Parameter Index	Enter an IPSec identification tag used to distinguish this particular OSPFv3 interface; used in conjunction with the specified authentication and encryption rules. Valid values range from 256 to 4294967295.
Authentication Algorithm	Choose the type of authentication algorithm to use: • md5 – Message Digest 5; produces a 128-bit hash value. • sha1 – Secure Hash Algorithm version 1; produces a 160-bit hash value.
Authentication Key	Enter an authentication key. The length of the key entered depends on the type of authentication chosen as the Authentication Algorithm, and whether the key is to be encrypted (when you check the Encrypt Authentication Key box): • md5 – 32 characters. • md5 (encrypted) – 66 characters. • sha1 – 40 characters. • sha1 (encrypted) – 82 characters.
Encrypt Authentication Key	Check this box to require encryption of the specified Authentication Key for transmission.
Include Encryption	Check this box to require encryption of OSPFv3 packets. The following options are enabled.

Element	Description
Encryption Algorithm	Choose the type of encryption to use: • 3des – Triple DES; the Data Encryption Standard cipher algorithm is applied three times to each packet. • aes-cbc – Encryption is based on the Advanced Encryption Standard with Cipher Block Chaining, to produce a key of the size chosen with the Key Type parameter. The Key Type list is enabled only when you choose this encryption option. Choose one of these options: • 128 – For 128-bit keys. • 192 – For 192-bit keys. • 256 – For 256-bit keys. • des – Encryption is based on the Data Encryption Standard, using 56-bit keys.
Encryption Key	Enter an encryption key. The length of the key entered depends on the type of encryption chosen as the Encryption Algorithm, and whether the key is to be encrypted (when you check the Encrypt Key box): • 3des – 48 characters (192 bits). • 3des (encrypted) – 98 characters (192 bits). • aes-cbc/128 – 32 characters (128 bits). • aes-cbc/128 (encrypted) – 66 characters (128 bits). • aes-cbc/192 – 48 characters (192 bits). • aes-cbc/192 (encrypted) – 98 characters (192 bits). • aes-cbc/256 – 64 characters (256 bits). • aes-cbc/256 (encrypted) – 130 characters (256 bits). • des – 16 characters (64 bits). • des (encrypted) – 34 characters (64 bits).
Encrypt Key	Check this box to require encryption of the specified Encryption Key for transmission.

Add/Edit Neighbor Dialog Box (OSPFv3)

You must define a static neighbor for each point-to-point, non-broadcast interface. This feature lets you broadcast OSPFv3 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel. Note the following restrictions:

- You cannot define the same static neighbor for two different OSPFv3 processes.
- You must define a static route for each static neighbor.

Use the Add/Edit Neighbor dialog box to define a static neighbor for the interface selected in the Interface table, or to change information for an existing static neighbor.

Navigation Path

You can access the Add/Edit Neighbor dialog box from the Neighbor panel under the OSPFv3 Interface Tab , on page 2207.

Related Topics

- Configuring OSPFv3 , on page 2194
- About OSPFv3 , on page 2194

Field Reference

Table 790: Add/Edit Neighbor Dialog Box

Element	Description
Interface	The interface associated with this neighbor definition (read-only).
Link-local Address	Enter the IPv6 address of the static neighbor.
Cost and Database Filter	Check this box to enable filtering of the outgoing LSAs on the interface during synchronization and flooding. The following options are enabled: • Cost – Use this field to assign an arbitrary cost to this neighbor. If a value is not assigned, the cost of the interface is used (this value is based on the port speed of the interface, and is calculated as reference bandwith divided by interface speed). Valid values range from 1 to 65535. • Filter outgoing link-state advertisements – Check this box to disable forwarding of outgoing LSAs to this neighbor. **Note** The Cost and Database Filter options and the Poll-Interval options are mutually exclusive.

Element	Description
Poll-Interval	Check this box to enable the following options: • Poll Interval – Time interval in seconds between transmission of hello packets to a "dead" neighbor. The default is 120. If a neighboring device becomes inactive (hello packets have not been received for the dead interval period), it may be necessary to continue sending hello packets to the dead neighbor at a reduced rate. Thus this value should be larger than the interface hello interval. • Priority – The router priority value of this neighbor. The default is 0; valid values range from 1 to 255. The priority value helps determine the designated router for an OSPFv3 link. A value of zero means the device is ineligible to become the designated router, or backup designated router. **Note** The Poll-Interval options and the Cost and Database Filter options are mutually exclusive. Also, these values do not apply to point-to-multipoint interfaces.

Configuring RIP

Routing Information Protocol (RIP) is a dynamic routing protocol, or more precisely, an interior gateway protocol that is based on distance vectors. RIP uses hop count as the metric for path selection. When RIP is enabled on an interface, the interface exchanges RIP broadcast packets with neighboring devices to dynamically learn about and advertise routes. These RIP packets contain information about the destination networks that the gateways can reach, and the number of gateways that a packet must travel through to reach those destinations.

Cisco Security Manager supports both RIP version 1 and RIP version 2. Version 1 does not send the subnet mask with the routing update; RIP version 2 sends the subnet mask with the routing update, and supports variable-length subnet masks. Additionally, RIP version 2 supports neighbor authentication when routing updates are exchanged. This authentication ensures that the security appliance receives reliable routing information from a trusted source.

Note You cannot enable RIP if you have OSPF processes running.

Limitations

RIP has the following limitations:

- Cisco Security Manager cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.

RIP Version 2 Notes

The following information applies to RIP Version 2 only:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP version 2 updates to the interface.
- With RIP version 2, the security appliance transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP version 2 configuration is removed from an interface, that multicast address is unregistered.

Using Security Manager to Configure RIP on Security Appliances

Use the RIP page to enable the Routing Information Protocol on an interface. The settings and features available when configuring RIP depend on the type of device and OS version that you are configuring:

- To configure RIP on a PIX Firewall or ASA running an OS version earlier than 7.2, or on any FWSM, see RIP Page for PIX/ASA 6.3–7.1 and FWSM , on page 2214.
- To configure RIP on a PIX Firewall or ASA running OS version 7.2 or later, see RIP Page for PIX/ASA 7.2 and Later , on page 2216.

RIP Page for PIX/ASA 6.3–7.1 and FWSM

Note From version 4.17, though Cisco Security Manager continues to support PIX and FWSM features/functionality, it does not support any bug fixes or enhancements.

Use this RIP page to enable the Routing Information Protocol (RIP) on an interface in any FWSM, or in a PIX/ASA running a pre-7.2 version operating system.

The RIP table on this page lists all interfaces on which RIP is currently defined. Use the Add RIP Configuration and Edit RIP Configuration dialog boxes to create and maintain these entries. See RIP Page for PIX/ASA 6.3–7.1 and FWSM , on page 2214 for more information.

Navigation Path

- (Device view) Select **Platform** > **Routing** > **RIP** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > RIP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

When creating a shared RIP policy, you must choose a Version in the Create a Policy dialog box, as follows:

- **PIX/ASA 6.3-7.1 and FWSM**
- **PIX/ASA 7.2 and Later**

When assigning a shared RIP policy, be sure to assign the appropriate RIP policy for the device. For example, you cannot assign a PIX/ASA 7.2+ RIP policy to an FWSM.

Add/Edit RIP Configuration (PIX/ASA 6.3–7.1 and FWSM) Dialog Boxes

Note From version 4.17, though Cisco Security Manager continues to support PIX and FWSM features/functionality, it does not support any bug fixes or enhancements.

Use the Add RIP Configuration and Edit RIP Configuration dialog boxes to add a RIP configuration to the security appliance, or to make changes to an existing RIP configuration. By adding a RIP configuration, you enable RIP on the specified interface. Except for their titles, the two dialog boxes are identical.

Navigation Path

You can access the Add and Edit RIP Configuration dialog boxes from the RIP Page for PIX/ASA 6.3–7.1 and FWSM , on page 2214.

Field Reference

Table 791: Add/Edit RIP Configuration (PIX/ASA 6.3-7.1 and FWSM) Dialog Boxes

Element	Description
Interface	Enter or Select the interface for the RIP configuration. You cannot configure two different RIP configurations on the same interface.

Element	Description
Mode	Select the interface behavior regarding RIP updates: • **Send default routes** – The interface will transmit RIP routing updates only. • **Receive routes** – The interface will listen for RIP routing broadcasts and use that information to populate its routing table, but it will not send RIP routing updates. • **Send default routes and receive routes** – The interface will send and receive RIP routing updates.
Version	Select the RIP version to enable on the interface: • **RIP Version 1** – Enables RIP Version 1 on the interface. • **RIP Version 2** – Enables RIP Version 2 on the interface. Configuring RIP Version 2 registers the multicast address 224.0.0.9 on the interface.
Version 2 Authentication	These options let you enable and select the type of authentication used with RIP Version 2. • **Enable Authentication** – This option is available when you select RIP Version 2 above. When this box is checked, RIP neighbor authentication is enabled and the following options become available: • **Type** – Select **MD5** to use the MD5 hash algorithm for authentication (recommended), or select **Clear text** to use clear text for authentication. • **Key ID** – The identification number of the authentication key. This number must be shared with all other devices sending updates to and receiving updates from the security appliance. Valid values range from 1 to 255. • **Key** – The shared key used for authentication. This key must be shared with all other devices sending updates to and receiving updates from the security appliance. The key can be up to 16 characters.

RIP Page for PIX/ASA 7.2 and Later

Note From version 4.17, though Cisco Security Manager continues to support PIX and FWSM features/functionality, it does not support any bug fixes or enhancements.

Use this RIP page to enable and configure the Routing Information Protocol (RIP) on PIX and ASA devices running operating system 7.2 or later. The RIP page consists of these tabbed panels:

• RIP - Setup Tab , on page 2217
• RIP - Redistribution Tab , on page 2219
• RIP - Filtering Tab , on page 2220
• RIP - Interface Tab , on page 2221

Navigation Path

- (Device view) Select **Platform > Routing > RIP** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > RIP** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

When creating a shared RIP policy, you must choose a Version in the Create a Policy dialog box, as follows:

- **PIX/ASA 6.3-7.1 and FWSM**
- **PIX/ASA 7.2 and Later**

When assigning a shared RIP policy, be sure to assign the appropriate RIP policy for the device. For example, you cannot assign a PIX/ASA 7.2+ RIP policy to an FWSM.

RIP - Setup Tab

Use the Setup panel to define RIP on the security appliance, and to configure global RIP protocol parameters. You can only enable a single RIP process on the security appliance.

Navigation Path

You can access the Setup tab from the RIP Page for PIX/ASA 7.2 and Later , on page 2216.

Related Topics

- RIP - Redistribution Tab , on page 2219
- RIP - Filtering Tab , on page 2220
- RIP - Interface Tab , on page 2221

Field Reference

Table 792: Setup Tab

Element	Description
Networks	Define one or more networks for RIP routing. Enter IP address(es), or enter or Select the desired Network/Hosts objects (see Understanding Networks/Hosts Objects , on page 310); IP addresses must not contain any subnet information. There is no limit to the number of networks you can add to the security appliance configuration. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.
Passive Interface	Use this option to specify passive interfaces on the security appliance, and by extension the active interfaces. The device listens for RIP routing broadcasts on passive interfaces, using that information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive, receive and send updates. Choose one of these options: 1. **None** – No interfaces are designated as passive. 2. **All Interfaces** – All interfaces on the device are designated as passive, except those entered the Excluded Interfaces field below. 3. **Specified Interfaces** – Only those interfaces explicitly specified in the Interfaces field below are designated as passive.
Interfaces/Excluded Interfaces	Use this field to specify the interfaces excluded from the passive list, or those explicitly designated as passive, depending on your choice from the Passive Interface list above: • If you chose All Interfaces, this field is labeled **Excluded Interfaces**: enter or Select only those interfaces to be excluded (that is, those that are to be active not passive). • If you chose Specified Interfaces in the Passive Interface list, enter or Select those interfaces that are to be designated as passive. **Note** You cannot specify two different RIP configurations for the same interface.
RIP Version	Choose the RIP versions for sending and receiving RIP updates: • Receive Version 1 and 2, Send Version 1 • Send and Receive Version 1 • Send and Receive Version 2
Generate Default Route	When selected, a default route is generated for distribution, based on the Route Map you specify.

Element	Description
Route Map	Specify the route map to use for generating default routes. **Note** This field contains only the Route Map name. The Route Map is created and contained within a FlexConfig; see Understanding FlexConfig Policies and Policy Objects , on page 342 for more information.
Enable Auto-Summary	When Send and Receive Version 2 is the chosen RIP Version, this option is available. When checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised. **Note** RIP Version 1 always uses automatic summarization—you cannot disable it.

RIP - Redistribution Tab

Use the Redistribution panel to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process. See Add/Edit Redistribution Dialog Box , on page 2114 for more information.

Navigation Path

You can access the Redistribution tab from the RIP Page for PIX/ASA 7.2 and Later , on page 2216.

Related Topics

- RIP - Setup Tab , on page 2217

Add/Edit Redistribution Dialog Box

Use the Add Redistribution and Edit Redistribution dialog boxes to add and edit redistribution routes on the RIP - Redistribution Tab , on page 2219. These are the routes that are being redistributed from other routing processes into the RIP routing process. Except for their titles, these two dialog boxes are identical.

Navigation Path

You can access the Add and Edit Redistribution dialog boxes from the Redistribution tab on the RIP Page for PIX/ASA 7.2 and Later , on page 2216.

Field Reference

Table 793: Add/Edit Redistribution Dialog Box

Element	Description
Protocol to Redistribute	Choose the routing protocol to redistribute into the RIP routing process: • **Static** - Static routes • **Connected** – Directly connected networks. • **OSPF** – Routes discovered by the OSPF routing process. If you choose OSPF, you must also enter the OSPF Process ID and, optionally, Match criteria.
Process ID	Enter the process ID when the OSPF protocol is chosen.
Match	If you are redistributing OSPF routes into the RIP routing process, you can select specific types of OSPF routes to redistribute. Ctrl-click to select multiple types: • Internal – Routes internal to the autonomous system (AS) are redistributed. • External 1 – Type 1 routes external to the AS are redistributed. • External 2 – Type 2 routes external to the AS are redistributed. • NSSA External 1 – Type 1 routes external to a not-so-stubby area (NSSA) are redistributed. • NSSA External 2 – Type 2 routes external to an NSSA are redistributed. Match criteria are optional. The default is match Internal, External 1, and External 2.
Metric	The RIP metric type to apply to the redistributed routes. The two choices are: • **Transparent** – Use the current route metric. • **Specified Value** – Assign a specific metric value.
Route Map	The name of a route map that must be satisfied before the route can be redistributed into the RIP routing process. **Note** This field contains only the route Map name. The contents of the route map are created and contained within a FlexConfig. See Understanding FlexConfig Policies and Policy Objects , on page 342 for more information.

RIP - Filtering Tab

Use the Filtering panel to manage filters for the RIP policy. Filters are used to limit network information in incoming and outgoing RIP advertisements. See Add/Edit Filter Dialog Box , on page 2221 for more information.

Navigation Path

You can access the Filtering tab from the RIP Page for PIX/ASA 7.2 and Later , on page 2216.

Related Topics

- RIP - Setup Tab , on page 2217

Add/Edit Filter Dialog Box

Use the Add Filter and Edit Filter dialog boxes to add and edit RIP filters on the RIP - Filtering Tab , on page 2220. Filters are used to limit network information in incoming and outgoing RIP advertisements. Except for their titles, these two dialog boxes are identical.

Navigation Path

You can access the Add and Edit Filter dialog boxes from the Filtering tab on the RIP Page for PIX/ASA 7.2 and Later , on page 2216.

Field Reference

Table 794: Add/Edit Filter Dialog Box

Element	Description
Traffic Direction	Choose the type of traffic to be filtered: **Inbound** or **Outbound**. **Note** If Traffic Direction is Inbound, you can define an Interface filter only.
Filter On	Specify whether the filter is based on an **Interface** or a **Route**. If you select Interface, enter or Select the name of the interface on which routing updates are to be filtered. If you select Route, choose the route type: • **Static** – Only static routes are filtered. • **Connected** – Only connected routes are filtered. • **OSPF** – Only OSPF routes discovered by the specified OSPF process are filtered. Enter the Process ID of the OSPF process to be filtered.
Filter ACLs	Enter or Select the name of one or more access control lists (ACLs) that define the networks to be allowed or removed from RIP route advertisements.

RIP - Interface Tab

Use the Interface panel to manage the interfaces configured to send and receive RIP broadcasts. See Add/Edit Interface Dialog Box , on page 2222 for more information.

Navigation Path

You can access the Interface tab from the RIP Page for PIX/ASA 7.2 and Later , on page 2216.

Related Topics

- RIP - Setup Tab , on page 2217

Add/Edit Interface Dialog Box

Use the Add Interface and Edit Interface dialog boxes to add and edit RIP interface configurations on the RIP - Interface Tab , on page 2221. Except for their titles, these two dialog boxes are identical.

Navigation Path

You can access the Add and Edit Interface dialog boxes from the Interface tab on the RIP Page for PIX/ASA 7.2 and Later , on page 2216.

Field Reference

Table 795: Add/Edit Interface Dialog Box

Element	Description
Interface	Enter or Select an interface defined on this appliance.
Send (Version)	These options let you override, for this interface, the global Send versions specified on the RIP - Setup Tab , on page 2217. Select the appropriate boxes to specify sending updates using RIP Version 1, Version 2, or both.
Receive (Version)	These options let you override the global Receive versions. Select the appropriate boxes to specify accepting updates using RIP Version 1 only, Version 2 only, or both.
Authentication Type	Choose the authentication used on this interface for RIP broadcasts: • **None** – No authentication. • **MD5** – Employ MD5. • **Clear Text** – Employ clear-text authentication. If you choose MD5 or Clear Text, you must also provide the following authentication parameters: • **Key ID** – The ID of the authentication key. Valid values are from 0 to 255. • **Key** – The key used by the chosen authentication method. Can contain up to 16 characters. • **Confirm** – Enter the authentication key again, to confirm.

Configuring Static Routes

A static route is a specific path to a particular destination network that is manually defined on the current device. Static routes are used in a variety of situations, and can be a quick and effective way to route data from one network to another when there is no dynamic route to the destination, or when use of a dynamic routing protocol is not feasible.

All routes have a value or “metric” that represents its priority of use. (This metric is also referred to as “administrative distance.”) When two or more routes to the same destination are available, devices use administrative distance to decide which route to use.

For static routes, the default metric value is one, which gives them precedence over routes from dynamic routing protocols. If you increase the metric to a value greater than that of a dynamic route, the static route operates as a back-up in the event that dynamic routing fails. For example, Open Shortest Path First (OSPF)-derived routes have a default administrative distance of 100. To configure a back-up static route that is overridden by an OSPF route, specify a metric value for the static route that is greater than 100. This is referred to as a “floating” static route.

There is a special kind of static route known as a default route, or a “zero-zero” route because all zeroes are used for both the destination address and subnet mask. The default static route serves as a catch-all gateway: if there are no matches for a particular destination in the device’s routing table, the default route is used. The default route generally includes a next-hop IP address or local exit interface.

Use the Static Route page to maintain manually defined static routes. The Static Route table on this page lists all currently defined static routes, showing for each, the name of the interface or interface role for which the route is defined, the destination network(s), the next hop gateway, the route metric, whether the route is tunneled, and whether there is service-level agreement tracking for the route. For a detailed explanation of these fields, see Add/Edit Static Route Dialog Box , on page 2224 or Add/Edit IPv6 Static Route Dialog Box , on page 2225.

Static null0 Route Configuration

Typically ACLs are used for traffic filtering and they enable you to filter packets based on the information contained in their headers. In packet filtering, the ASA firewall examines packet headers to make a filtering decision, thus adding some overhead to the processing of the packets and affecting performance.

Static null 0 routing is a complementary solution to filtering. A static null0 route is used to forward unwanted or undesirable traffic into a black hole. The null interface null0, is used to create the black hole. Static routes are created for destinations that are not desirable, and the static route configuration points to the null interface. Any traffic that has a destination address that has a best match of the black hole static route is automatically dropped. Unlike with ACLs, static null0 routes do not cause any performance degradation.

The static null0 route configuration is used to prevent routing loops. BGP leverages the static null0 configuration for Remotely Triggered Black Hole routing.

Navigation Path

- (Device view) Select **Platform > Routing > Static Route** or **Platform > Routing > IPv6 Static Route** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > Routing > Static Route** or **PIX/ASA/FWSM Platform > Routing > IPv6 Static Route** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Add/Edit Static Route Dialog Box

The Add/Edit Static Route dialog box lets you add or edit a static route.

Navigation Path

You can access the Add/Edit Static Route dialog box from the Static Routes page. Click the Add Row button to add a new static route; select an existing static route and click the Edit Row button to edit that route.

Related Topics

- Configuring Static Routes , on page 2223

Field Reference

Table 796: Add/Edit Static Route Dialog Box

Element	Description
Interface	Enter or Select the interface to which this static route applies. Sending traffic to a Null0 interface results in dropping the packets destined to the specified network. This feature is useful in configuring Remotely Triggered Black Hole (RTBH) for BGP. For more information, see Configuring Static Routes , on page 2223. **Note** If Null0 is selected as the interface, the Gateway and Tunneled options are disabled.
Network	Enter or Select the destination network(s). You can provide one or more IP address/netmask entries, one or more Networks/Hosts objects, or a combination of both; separate the entries with commas. Enter “0.0.0.0/0” or “any” to specify a default route.
Gateway	Enter or Select the gateway router which is the next hop for this route. You can provide an IP address, or a Networks/Hosts object. **Note** If an IP address from one of the security appliance’s interfaces is used as the Gateway IP address, the security appliance will resolve the designated IP address in the packet instead of resolving the Gateway IP address.

Element	Description
Metric	The Metric is a measurement of the "expense" of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. Because the hop count includes the destination network, all directly connected networks have a metric of 1. Enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1. The maximum number of equal-cost (equal-metric) routes that can be defined per interface is three. You cannot add a route with the same metric on different interfaces that are on the same network.
Tunneled	Select this option to make this a tunnel route; can be used only for a default route. You can configure only one default tunneled gateway per device. The Tunneled option is not supported in transparent mode. Available only on PIX/ASA 7.0+ devices.
Route Tracking	To monitor route availability, enter or Select name of an SLA (service level agreement) object that defines the monitoring policy. Available only on PIX/ASA 7.2+ devices. For more information on route tracking, see Monitoring Service Level Agreements (SLAs) To Maintain Connectivity , on page 1996.

Add/Edit IPv6 Static Route Dialog Box

The Add/Edit IPv6 Static Route dialog box lets you add or edit an IPv6 static route. IPv6 static routes are only supported on the following devices:

- ASA 7.0 and later (Routed mode)
- ASA 8.2 and later (Transparent mode)
- FWSM 3.1 and later (Routed mode)

Navigation Path

You can access the Add/Edit IPv6 Static Route dialog box from the IPv6 Static Route page. Click the **Add Row** button to add a new static route; select an existing static route and click the **Edit Row** button to edit that route.

Related Topics

- Configuring Static Routes , on page 2223

Table 797: Add/Edit IPv6 Static Route Dialog Box

Element	Description
Interface	Enter or Select the interface to which this static route applies.

Element	Description
IPv6 Network	Enter or Select the destination network(s). You can provide one or more IP address entries, one or more Networks/Hosts objects, or a combination of both; separate the entries with commas. Enter two colons (::) to specify a default route.
IPv6 Gateway	Enter or Select the gateway router which is the next hop for this route. You can provide an IP address, or a Networks/Hosts object. **Note** If an IP address from one of the security appliance's interfaces is used as the Gateway IP address, the security appliance will resolve the designated IP address in the packet instead of resolving the Gateway IP address.
Metric	The Metric is a measurement of the "expense" of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. Because the hop count includes the destination network, all directly connected networks have a metric of 1. Enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1. The maximum number of equal-cost (equal-metric) routes that can be defined per interface is three. You cannot add a route with the same metric on different interfaces that are on the same network.
Tunneled	Select this option to specify the route as the default tunnel gateway for VPN traffic. You can configure only one default tunneled gateway per device. Available only on ASA 7.0+ devices in routed mode.

Configuring Policy Objects for ASA Routing Policies

There are several policy objects that you use with ASA routing policies. This reference explains the configuration of these policy objects.

This section contains the following topics:

Understanding Route Map Objects

You can use route maps to define the conditions for redistributing routes from one routing protocol into another, or to enable policy routing.

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, each has a permit or deny result. Evaluation of ACL or route maps consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms—Criteria matches and match interpretation are dictated by the way that they are applied. The same route map applied to different tasks might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps frequently use ACLs as matching criteria.

Note Route maps do not support ACLs that include a user, user group, security group tag, or fully qualified domain name objects.

- The main result from the evaluation of an ACL is a yes or no answer—An ACL either permits or denies input data. Applied to redistribution, an ACL determines if a particular route can (route matches ACLs permit statement) or can not (matches deny statement) be redistributed. Typical route maps not only permit (some) redistributed routes but also modify information associated with the route, when it is redistributed into another protocol.
- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.
- Each ACL ends with an implicit deny statement, by design convention; there is no similar convention for route maps. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Fortunately, route maps that are applied to redistribution behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained deny statement at the end.

Route maps are preferred if you intend to either modify route information during redistribution or if you need more powerful matching capability than an ACL can provide. If you simply need to selectively permit some routes based on their prefix or mask, we recommend that you use a route map to map to an ACL (or equivalent prefix list).

Note You must use a standard ACL as the match criterion for your route map. Using an extended ACL will not work, and your routes will never be redistributed. We recommend that you number clauses in intervals of 10 to reserve numbering space in case you need to insert clauses in the future.

Permit and Deny Clauses

Route maps can have permit and deny clauses. If the match criteria are met for this route map, and the permit keyword is specified, the route is redistributed as controlled by the set actions. If the match criteria are not met, and the permit keyword is specified, the next route map with the same map tag is tested. If a route passes none of the match criteria for the set of route maps sharing the same name, it is not redistributed by that set. If the match criteria are met for the route map and the deny keyword is specified, the route is not redistributed.

The following rules apply:

- If you use an ACL in a route map using a permit clause, routes that are permitted by the ACL are redistributed.
- If you use an ACL in a route map deny clause, routes that are permitted by the ACL are not redistributed.
- If you use an ACL in a route map permit or deny clause, and the ACL denies a route, then the route map clause match is not found and the next route-map clause is evaluated.

Match and Set Clause Values

Each entry in a route map statement contains a combination of match and set clauses. The match clause defines the criteria for whether appropriate packets meet the particular policy (that is, the conditions to be met). The set clause explains how the packets should be routed once they have met the match criteria.

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeed, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified as defined by the set clause. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found whose match clause matches the route or until the end of the route map is reached.

A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several Match Clause values are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a Match Clause value refers to several objects in one command, any of the objects should match (the logical OR algorithm is applied).
- If a Match Clause value is not present, all routes match the clause.
- If a Set Value is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

Note Do not configure a Set Value in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a Match or Set value performs an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).

BGP Match and BGP Set Clauses

In addition to the match and set values described above, BGP provides additional match and set capabilities to route maps.

The following route-map match clauses are supported with BGP:

- match AS path access list
- match community
- match policy list

The following route-map set clauses are supported with BGP:

- set AS path
- set community
- set automatic tag
- set local preference
- set weight
- set origin
- set next hop
- set IP prefix list

Creating and Using Route Map Objects

When configuring a policy that requires that you identify a route map, you can select or create route map objects by clicking the **Select** button next to the Route Map field. To create a new route map from the Route Map Object Selector dialog box, click the **Create** button beneath the route map list. You can also create route map objects from the Policy Object Manager , on page 232 by selecting **Route Map** from the Object Type Selector and then clicking the **New Object** button. For information on the specific fields available when creating a route map object, see Add or Edit Route Map Object Dialog Boxes , on page 2230.

Note about the use of Route Map Objects in BGP Policies

Some of the match and set criteria used in route maps are not supported in all BGP subcommands. For example:

The following route map match criteria:

- Match Clause tab > Match first hop interface of route, Match Next Hop (IPv4 and IPv6), Match Route Source (IPv4 and IPv6), Match Metric Route Value, and Match Tag
- BGP Match Clause tab > Match AS path access lists

and the following route map set criteria:

- Set Clause tab > Metric Values (all fields) and Metric Type
- BGP Set Clause tab > Set AS path, Prepend AS path, and Prepend last AS to the AS path

are not supported in the following places:

- BGP policy > IPv4 Address Family:
  - Aggregate Address tab > Attribute Map, Advertise Map, and Suppress Map
  - Neighbor tab > Filtering tab
  - Route Injection tab > Inject Map and Exist Map

Security Manager allows you to use route maps in your BGP configuration even if the route map contains unsupported match or set criteria and you will not receive a warning or error during validation. In such cases, deployment will fail and you will receive an error from the device in the following format: ...%"My-Route-map" used as BGP inbound route-map, nexthop match not supported... .

Please refer to the ASA documentation for guidelines on the match/set criteria supported in route maps used in BGP configuration.

Add or Edit Route Map Object Dialog Boxes

Use the Add/Edit Route Map Object dialog box to create, copy and edit route map policy objects. You can use route maps to define the conditions for redistributing routes from one routing protocol into another, or to enable policy routing.

Navigation Path

Select **Manage > Policy Objects**, then select **Route Map** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Field Reference

Table 798: Add/Edit Route Map Object Dialog Box

Element	Description
Name	Enter a meaningful name for the route map object. The route map object name cannot be more than 58 characters. **Caution** Security Manager allows you to rename these objects even though you cannot rename them on the device. When you rename these objects in Security Manager, the name change is accomplished by negating the existing CLI, and then issuing new CLI to create and assign the object using the new name. This initial negation may cause routing/network issues in your environment. Security Manager will not provide a warning message about these consequences when you rename the object.
Description	An optional description of the object.
Route Map table	The Route Map entries that are defined in the object. • To add a Route Map entry, click the **Add** button to open the Add or Edit Route Map Entry Dialog Box , on page 2231. • To edit a Route Map entry, select it and click the **Edit** button. • To delete a Route Map entry, select it and click the **Delete** button.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the **Edit** button to create, edit, and view the overrides. The **Overrides** field indicates the number of devices that have overrides for this object.

Add or Edit Route Map Entry Dialog Box

Use the Add/Edit Route Map Entry dialog box to create a new route map entry for a Route Map object or to edit an existing one.

Navigation Path

From the Add or Edit Route Map Object Dialog Boxes , on page 2230, click the **Add** button beneath the Route Map table or select an entry in the table and click the **Edit** button.

Field Reference

Table 799: Add/Edit Route Map Entry Dialog Box

Element	Description
Sequence Number	A number, between 0 and 65535, that indicates the position a new route map entry will have in the list of route maps entries already configured for this route map object. **Tip** We recommend that you number clauses in intervals of at least 10 to reserve numbering space in case you need to insert clauses in the future.
Redistribution	Whether to redistribute a route or not. To allow redistribution for route matches, click **Permit**. To reject route matches from redistribution, select **Deny**. If you use an ACL in a route map Permit clause, routes that are permitted by the ACL are redistributed. If you use an ACL in a route map Deny clause, routes that are permitted by the ACL are not redistributed. In addition, if you use an ACL in a route map Permit or Deny clause, and the ACL denies a route, then the route map clause match is not found and the next route map clause is evaluated.
Match Clause Tab Select the Match Clause tab to choose routes to which this clause should be applied, and set the following parameters:	

Element	Description
Match first hop interface of route	Enable or disable matching routes that have their next hop out one of the interfaces specified. Enter or select the interfaces to match. Separate multiple entries with a comma. If you specify more than one interface, then the route can match either interface. Use the ellipsis to open the Interfaces Selector from which you can select one or more interfaces. You can also create new interface roles from the Interfaces Selector. For more information, see Understanding Interface Role Objects , on page 303.
IPv4	
Match Address	Enable or disable matching of any routes that have a route address or match packet that is passed by one of the access lists specified. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290 or Add or Edit Prefix List Object Dialog Box , on page 2241.
Match Next Hop	Enable or disable matching of the next hop address of a route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290 or Add or Edit Prefix List Object Dialog Box , on page 2241.
Match Route Source	Enable or disable matching of the advertising source address of the route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290 or Add or Edit Prefix List Object Dialog Box , on page 2241.
IPv6	

Element	Description
Match Address	Enable or disable matching of any routes that have a route address or match packet that is passed by one of the access lists specified. For IPv6 addresses, choose whether to use an access list or IPv6 Prefix list for matching from the drop-down list and then enter or select the ACL objects or IPv6 Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or IPv6 Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290or Add or Edit Prefix List IPv6 Object Dialog Box , on page 2243.
Match Next Hop	Enable or disable matching of the next hop address of a route. For IPv6 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or IPv6 Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or IPv6 Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290or Add or Edit Prefix List IPv6 Object Dialog Box , on page 2243.
Match Route Source	Enable or disable matching of the advertising source address of the route. For IPv6 addresses, choose whether to use an access list or IPv6 Prefix list for matching from the drop-down list and then enter or select the ACL objects or IPv6 Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or IPv6 Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290or Add or Edit Prefix List IPv6 Object Dialog Box , on page 2243.
Match Metric Route Value	Enable or disable matching the metric of a route. Type the metric values to use for matching in the Match Metric Route Value field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.
Match Tag	Enable or disable matching the security group tag of a route. Type the tag values to use for matching in the Match Tag field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.
Match Route Type	Enable or disable matching of the route type. Valid route types are External1, External2, Internal, Local, NSSA-External1, and NSSA-External2. When enabled, you can choose more than one route type from the list.

Element	Description
Set Clause Tab Select the Set Clause tab to modify the following information, which will be redistributed to the target protocol: **Note** You can specify just the Bandwidth value, all of the values, or none of the values.	
Bandwidth	Metric value or Bandwidth in Kbits per second; an integer value from 0 to 4294967295.
EIGRP Delay	EIGRP route delay, in tens of microseconds. Valid values range from 1 to 4294967295.
EIGRP Reliability	Likelihood of successful packet transmission for EIGRP expressed as a number from 0 to 255. The value 255 means 100 percent reliability; 0 means no reliability.
EIGRP Effective	Effective EIGRP bandwidth of a route expressed as a number from 1 to 255. The value 255 means 100 percent loading.
EIGRP MTU	Minimum MTU size of a route for EIGRP, in bytes. Valid values range from 1 to 4294967295.
Set Metric Type	Select to specify the type of metric for the destination routing protocol, and choose the metric type from the drop-down list: internal, type-1, or type-2.
BGP Match Clause Tab	
Match AS path access lists	Select to enable matching the BGP autonomous system path access list with the specified path access list. If you specify more than one path access list, then the route can match either path access list. Use the ellipsis to open the AS Path Object Selector from which you can select one or more AS path objects. You can also create new AS path objects from the AS Path Object Selector. For more information, see Add or Edit As Path Object Dialog Boxes , on page 2246.
Match community	Select to enable matching the BGP community with the specified community. If you specify more than one community, then the route can match either community. Any route that does not match at least one Match community will not be advertised for outbound route maps. Use the ellipsis to open the Community List Object Selector from which you can select one or more Community List objects. You can also create new Community List objects from the Community List Object Selector. For more information, see Add or Edit Community List Object Dialog Box , on page 2247. To enable matching the BGP community exactly with the specified community, check the **Match the specified community exactly** check box.

Element	Description
Match policy list	Select to configure a route map to evaluate and process a BGP policy. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only. Use the ellipsis to open the Policy List Object Selector from which you can select one or more Policy List objects. You can also create new Policy List objects from the Policy List Object Selector. For more information, see Add or Edit Policy List Object Dialog Box , on page 2238.
BGP Set Clause Tab Select the BGP Set Clause tab to modify the following information, which will be redistributed to the BGP protocol:	
Set AS path	Select to modify an autonomous system path for BGP routes. • Select **Prepend AS path** to prepend an arbitrary autonomous system path string to BGP routes. Usually the local AS number is prepended multiple times, increasing the autonomous system path length. If you specify more than one AS path number then the route can prepend either AS number. • Select **Prepend last AS to the AS path** to prepend the AS path with the last AS number. Enter a value for the AS number from 1 to 10. • Select **Convert route tag into AS path** to convert the tag of a route into an autonomous system path.
Set community	Select to set the BGP communities attributes. • Select **None** to remove the community attribute from the prefixes that pass the route map. • Select **Specify community** to enter a community number, if applicable. Valid values are from 1 to 4294967295. Select **Add to the existing communities** to add the community to the already existing communities. • Select **Internet**, **no-advertise** or **no-export** to use one of the well-known communities.
Set Automatic-tag	Select to automatically compute the tag value.
Set local preference	Select to specify a preference value for the autonomous system path. Enter a value between 0 and 4294967295.
Set weight	Select to specify the BGP weight for the routing table. Enter a value between 0 and 65535.
Set origin	Select to specify the BGP origin code. Valid values are Local IGP and Incomplete.
Next hop IPv4	

Element	Description
Set next hop	Select to specify the output address of packets that fulfill the match clause of a route map: • Select **Specify IPv4 address** to enter the IPv4 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv4 address then the packets can output at either IP address. • Select **Use peer address** to set the next hop to be the BGP peer address.
Next hop IPv6	
Set next hop	Select to specify the output address of packets that fulfill the match clause of a route map: • Select **Specify IPv6 address** to enter the IPv6 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv6 address then the packets can output at either IP address. You can enter multiple values separated by commas. • Select **Use peer address** to set the next hop to be the BGP peer address.
Prefix List	
Set IPv4 prefix list	Select to set an IPv4 prefix list. Use the ellipsis to open the Prefix List Object Selector from which you can select one or more Prefix List objects. You can also create new Prefix List objects from the Prefix List Object Selector. For more information, see Add or Edit Prefix List Object Dialog Box , on page 2241.
Set IPv6 prefix list	Select to set an IPv6 prefix list. Use the ellipsis to open the Prefix List Object IPv6 Selector from which you can select one or more IPv6 Prefix List objects. You can also create new IPv6 Prefix List objects from the Prefix List Object Selector. For more information, see Add or Edit Prefix List IPv6 Object Dialog Box , on page 2243.
Policy Based Routing (PBR) Tab Click the Policy Based Routing tab to define policy for traffic flows, and lessening reliance on routes derived from routing protocols. PBR gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols. PBR allows you to set the IP precedence. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link.	
Set Default Next-Hop IPv4 Address	Check the Set default next-hop IPv4 address check box to indicate where to output packets that pass a match clause of a route map for policy routing. In the IPv4 Address enter the destination address.
Set Default Next-Hop IPv6 Address	Check the Set default next-hop IPv6 address check box to indicate where to output packets that pass a match clause of a route map for policy routing. In the IPv6 Address enter the destination address.

Element	Description
Recursively find and set Next-Hop IPv4 Address	Check the Recursively find and set next-hop IP address check box and specify an IP address in the IPv4 Address field. In this case, the next-hop IP address need not be on a directly connected subnet.
Set Interfaces	Check the Set interfaces check box and select a destination interface from the Interfaces Selector dialog box.
Set Null0 Interfaces as Default Interface	Check the Set null0 interface as the default interface check box, if there is a need to completely black hole or drop some traffic.
Set do-not-fragment bit to either 0 or 1	Check the Set do-not-fragment bit to either 1or 0 and then select the appropriate radio button.
Set Differential Service Code point (DSCP) value in Q...	Check the Set differential service code point (DSCP) value in QoS bits for IPv4 packets check box and either enter a value between 0 and 63 or select a value from the Select Value drop-down list.
Set Differential Service Code point (DSCP) value in QOS bits for IPv6 packets	Check the Set differential service code point (DSCP) value in QoS bits for IPv6 packets check box and either enter a value between 0 and 63 or select a value from the Select Value drop-down list.
Set Adaptive Interface	Check the **Set adaptive Interface** box, select the metrics from the drop-down list, and specify the interface in the Set Adaptive Interface dialog box to determine the best path for routing PBR traffic. Following are the adaptive interface metrics: • **cost**—Traffic is forwarded based on the priority of the interfaces. • **jitter**—Traffic is forwarded to the interface that has the lowest jitter value. **lost**—Traffic is forwarded to the interface that has the the minimal packet loss. • **mos**—Traffic is forwarded to the interface that has the maximum mean opinion score (MOS) • **rtt**—Traffic is forwarded to the interface that has the the minimal round trip time (RTT)

Add or Edit Policy List Object Dialog Box

Use the Add/Edit Policy List Object dialog box to create, copy, and edit policy list policy objects. You can create policy list objects to use when you are configuring route maps (see Understanding Route Map Objects , on page 2227).

When a policy list is referenced within a route map, all of the match statements within the policy list are evaluated and processed. Two or more policy lists can be configured with a route map. A policy list can also coexist with any other preexisting match and set statements that are configured within the same route map but outside of the policy list. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only.

Navigation Path

Select **Manage** > **Policy Objects**, then select **Policy List** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Field Reference

Table 800: Add/Edit Policy List Object Dialog Box

Element	Description
Name	The name of the object. Object names are not case-sensitive. For more information, see Creating Policy Objects , on page 237. **Caution** Security Manager allows you to rename these objects even though you cannot rename them on the device. When you rename these objects in Security Manager, the name change is accomplished by negating the existing CLI, and then issuing new CLI to create and assign the object using the new name. This initial negation may cause routing/network issues in your environment. Security Manager will not provide a warning message about these consequences when you rename the object.
Description	An optional description of the object.
Basic Tab	
Action	Whether to permit access for matching conditions or not. **Note** The Action for a policy list object cannot be changed after the initial creation of the policy list object.
Match Interface	Select to distribute routes that have their next hop out of one of the interfaces specified. Enter or select the interfaces to match. Separate multiple entries with a comma. If you specify more than one interface, then the route can match either interface. Use the ellipsis to open the Interfaces Selector from which you can select one or more interfaces. You can also create new interface roles from the Interfaces Selector. For more information, see Understanding Interface Role Objects , on page 303.

Element	Description
Match Address	Select to redistribute any routes that have a destination address that is permitted by a standard access list or prefix list. Choose whether to use an Access List or Prefix List for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290 or Add or Edit Prefix List Object Dialog Box , on page 2241.
Match Next-Hop	Select to redistribute any routes that have a next hop router address passed by one of the access lists or prefix lists specified. Choose whether to use an Access List or Prefix List for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290 or Add or Edit Prefix List Object Dialog Box , on page 2241.
Match Route Source	Select to redistribute routes that have been advertised by routers and access servers at the address specified by the access lists or prefix list. Choose whether to use an Access List or Prefix List for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching. Use the ellipsis to open the Access Control List Object Selector or Prefix List Object Selector from which you can select one or more objects. You can also create new objects from the object selector. For more information, see Add or Edit Access List Dialog Boxes , on page 290 or Add or Edit Prefix List Object Dialog Box , on page 2241.
Advanced Tab	
Match AS Path	Select to match a BGP autonomous system path. If you specify more than one AS path, then the route can match either AS path. Use the ellipsis to open the AS Path Object Selector from which you can select one or more AS path objects. You can also create new AS path objects from the AS Path Object Selector. For more information, see Add or Edit As Path Object Dialog Boxes , on page 2246.
Match Community Rules	Select to enable matching the BGP community with the specified community. If you specify more than one community, then the route can match either community. Use the ellipsis to open the Community List Object Selector from which you can select one or more Community List objects. You can also create new Community List objects from the Community List Object Selector. For more information, see Add or Edit Community List Object Dialog Box , on page 2247. To enable matching the BGP community exactly with the specified community, check the **exact-match** check box.

Element	Description
Match Metric	Enable or disable matching the metric of a route. Type the metric values to use for matching in the Match Metric field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.
Match Tag	Enable or disable matching the security group tag of a route. Type the tag values to use for matching in the Match Tag field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the **Edit** button to create, edit, and view the overrides. The **Overrides** field indicates the number of devices that have overrides for this object.

Add or Edit Prefix List Object Dialog Box

Use the Add/Edit Prefix List Object dialog box to create, copy and edit prefix list policy objects. You can create prefix list objects to use when you are configuring route maps (see Understanding Route Map Objects , on page 2227), policy maps (see Add or Edit Policy List Object Dialog Box , on page 2238), OSPF Filtering (see Add/Edit Filtering Dialog Box , on page 2182), or BGP Neighbor Filtering (see Add/Edit Neighbor Dialog Box , on page 2094).

Area Border Router (ABR) type 3 link-state advertisement (LSA) filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number.

Navigation Path

Select **Manage > Policy Objects**, then select **Prefix List** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Field Reference

Table 801: Add/Edit Prefix List Object Dialog Box

Element	Description
Name	The object name, which can be up to 128 characters. Object names are not case-sensitive. For more information, see Creating Policy Objects , on page 237. **Caution** Security Manager allows you to rename these objects even though you cannot rename them on the device. When you rename these objects in Security Manager, the name change is accomplished by negating the existing CLI, and then issuing new CLI to create and assign the object using the new name. This initial negation may cause routing/network issues in your environment. Security Manager will not provide a warning message about these consequences when you rename the object.
Description	An optional description of the object.
Prefix List table	The prefix list entries that are defined in the object. • To add a prefix list entry, click the **Add** button to open the Add or Edit Prefix List Entry Dialog Box , on page 2243. • To edit a prefix list entry, select it and click the **Edit** button. • To delete a prefix list entry, select it and click the **Delete** button.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the **Edit** button to create, edit, and view the overrides. The **Overrides** field indicates the number of devices that have overrides for this object.

Add or Edit Prefix List Entry Dialog Box

Use the Add/Edit Prefix List Entry dialog box to create a new prefix list entry or edit an existing one.

Navigation Path

From the Add or Edit Prefix List Object Dialog Box , on page 2241, click the **Add** button beneath the Prefix List table or select an entry in the table and click the **Edit** button.

Field Reference

Table 802: Add/Edit Prefix List Entry Dialog Box

Element	Description
Action	Select the Permit or Deny radio button to indicate the redistribution access.
Sequence No	(Optional) Unique number that indicates the position a new prefix list entry will have in the list of prefix list entries already configured for this object. If left blank, the sequence number will default to five more than the largest sequence number currently in use.
IP Address	Specify the prefix number in the format of IP address/mask length.
Minimum Prefix Length	(Optional) Enter the minimum prefix length. The value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.
Maximum Prefix Length	(Optional) Enter the maximum prefix length. The value must be greater than or equal to the Minimum Prefix Length, if present, or greater than the mask length if the Minimum Prefix Length is not specified.

Add or Edit Prefix List IPv6 Object Dialog Box

Use the Add/Edit Prefix List IPv6 Object dialog box to create, copy and edit IPv6 prefix list policy objects. You can create IPv6 prefix list objects to use when you are configuring route maps (see Understanding Route Map Objects , on page 2227), policy maps (see Add or Edit Policy List Object Dialog Box , on page 2238), OSPF Filtering (see Add/Edit Filtering Dialog Box , on page 2182), or BGP Neighbor Filtering (see Add/Edit Neighbor Dialog Box , on page 2107).

Area Border Router (ABR) type 3 link-state advertisement (LSA) filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number.

Navigation Path

Select **Manage** > **Policy Objects**, then select **Prefix ListIPv6** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Table 803: Add/Edit IPv6 Prefix List Object Dialog Box

Element	Description
Name	The IPv6 Prefix List object name, which can be up to 128 characters. Object names are not case-sensitive. For more information, see Creating Policy Objects , on page 237. **Caution** Security Manager allows you to rename these objects even though you cannot rename them on the device. When you rename these objects in Security Manager, the name change is accomplished by negating the existing CLI, and then issuing new CLI to create and assign the object using the new name. This initial negation may cause routing/network issues in your environment. Security Manager will not provide a warning message about these consequences when you rename the object.
Description	An optional description of the object.
IPv6 Prefix List table	The IPv6 prefix list entries that are defined in the object. • To add an IPv6 prefix list entry, click the **Add** button to open the Add or Edit IPv6 Prefix List Entry Dialog Box , on page 2245. • To edit an IPv6 prefix list entry, select it and click the **Edit** button. • To delete an IPv6 prefix list entry, select it and click the **Delete** button.

Element	Description
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the **Edit** button to create, edit, and view the overrides. The **Overrides** field indicates the number of devices that have overrides for this object.

Add or Edit IPv6 Prefix List Entry Dialog Box

Use the Add/Edit IPv6 Prefix List Entry dialog box to create a new IPv6 prefix list entry or edit an existing one.

Navigation Path

From the Add or Edit IPv6 Prefix List Entry Dialog Box , on page 2245, click the **Add** button beneath the Prefix List table or select an entry in the table and click the **Edit** button.

Field Reference

Table 804: Add/Edit Prefix List Entry Dialog Box

Element	Description
Action	Select the Permit or Deny radio button to indicate the redistribution access.
Sequence No	(Optional) Unique number that indicates the position a new IPv6 prefix list entry will have in the list of IPv6 prefix list entries already configured for this object. If left blank, the sequence number will default to five more than the largest sequence number currently in use. **Note** Sequence Number must be in the range of 1 to 4294967295
IPv6 Address	Specify the prefix number in the format: IPv6 address/mask length where mask length is less than or equal to 128.
Minimum Prefix Length	(Optional) Enter the minimum prefix length in the range of 1 to 128. The value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.
Maximum Prefix Length	(Optional) Enter the maximum prefix length in the range of 1 to 128. The value must be greater than or equal to the Minimum Prefix Length, if present, or greater than the mask length if the Minimum Prefix Length is not specified.

Add or Edit As Path Object Dialog Boxes

Use the Add/Edit As Path Object dialog box to create, copy and edit autonomous system (AS) path policy objects. You can create AS path objects to use when you are configuring route maps (see Understanding Route Map Objects , on page 2227), policy maps (see Add or Edit Policy List Object Dialog Box , on page 2238), or BGP Neighbor Filtering (see Add/Edit Neighbor Dialog Box , on page 2094).

An AS path filter allows you to filter the routing update message by using access lists and look at the individual prefixes within an update message. If a prefix within the update message matches the filter criteria then that individual prefix is filtered out or accepted depending on what action the filter entry has been configured to carry out.

Note AS path object names must be a unique integer from 1-500. If an AS path object is discovered from a device or configuration file that uses the same name as an existing AS path object, the AS path object on Security Manager will be overwritten regardless of the Allow Device Override for Discovered Policy Objects setting on the Security Manager Administration - Discovery page.

Navigation Path

Select **Manage > Policy Objects**, then select **As Path** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Table 805: Add/Edit As Path Object Dialog Box

Element	Description
Name	Enter a name for the AS Path Filter. Specify a unique value between 1 and 500.
Description	An optional description of the object.

Element	Description
AS Path table	The AS path entries that are defined in the object. • To add an AS path entry, click the **Add** button to open the Add or Edit As Path Entry Dialog Box , on page 2247. • To edit an AS path entry, select it and click the **Edit** button. • To delete an AS path entry, select it and click the **Delete** button. • To rearrange the entries, select an entry and then click the **Move Up** or **Move Down** button.
Category	The category assigned to the object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.
Allow Value Override per Device Overrides Edit button	Whether to allow the object definition to be changed at the device level. For more information, see Allowing a Policy Object to Be Overridden , on page 247 and Understanding Policy Object Overrides for Individual Devices , on page 246. If you allow device overrides, you can click the **Edit** button to create, edit, and view the overrides. The **Overrides** field indicates the number of devices that have overrides for this object.

Add or Edit As Path Entry Dialog Box

Use the Add/Edit As Path Entry dialog box to create a new autonomous system (AS) path entry or edit an existing one.

Navigation Path

From the Add or Edit As Path Object Dialog Boxes , on page 2246, click the **Add Row** button beneath the As Path table or select an entry and click the **Edit Row** button.

Field Reference

Table 806: Add/Edit As Path Entry Dialog Box

Element	Description
Action	Select the **Permit** or **Deny** radio button to indicate the redistribution access.
Reg Exp	Specify the regular expression that defines the AS path filter. For information on the metacharacters you can use to build regular expressions, see Metacharacters Used to Build Regular Expressions , on page 880.

Add or Edit Community List Object Dialog Box

Use the Add/Edit Community List Object dialog box to create, copy and edit community list policy objects. You can create community list objects to use when you are configuring route maps (see Understanding Route Map Objects , on page 2227) or policy maps (see Add or Edit Policy List Object Dialog Box , on page 2238).

A community is a group of destinations that share some common attribute. You can use community lists to create groups of communities to use in a match clause of a route map. Just like an access list, a series of community lists can be created. Statements are checked until a match is found. As soon as one statement is satisfied, the test is concluded.

Navigation Path

Select **Manage > Policy Objects**, then select **Community List** from the Object Type Selector. Right-click inside the work area and select **New Object** or right-click a row and select **Edit Object**.

Add or Edit Community List Entry Dialog Box

Use the Add/Edit Community List Entry dialog box to create a new community list entry or edit an existing one.

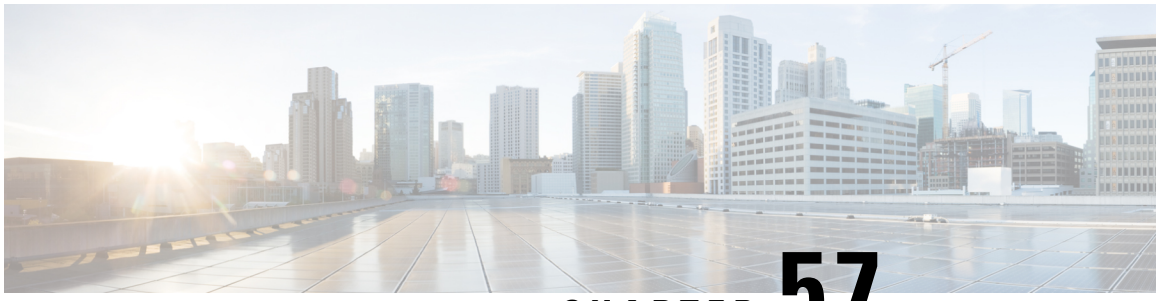
Navigation Path

From the Add or Edit Community List Object Dialog Box , on page 2247, click the **Add** button beneath the Community List table or select an entry in the table and click the **Edit** button.

Field Reference

Table 808: Add/Edit Community List Entry Dialog Box

Element	Description
Type	Select the **Standard** or **Expanded** radio button to indicate the community rule type. **Note** You cannot have entries using Standard and entries using Expanded community rule types in the same Community List object.
Action	Select the **Permit** or **Deny** radio button to indicate the redistribution access.
Communities	Specify a community number. Valid values can be from 1 to 4294967295 or from 0:1 to 65534:65535.
internet	Select to specify the Internet well-known community. Routes with this community are advertised to all peers (internal and external).
no-advertise	Select to specify the no-advertise well-known community. Routes with this community are not advertised to any peer (internal or external).
no-export	Select to specify the no-export well-known community. Routes with this community are advertised to only peers in the same autonomous system or to only other sub-autonomous systems within a confederation. These routes are not advertised to external peers.
Expressions	For an expanded community list, specify the regular expression. For information on the metacharacters you can use to build regular expressions, see Metacharacters Used to Build Regular Expressions , on page 880.



CHAPTER 57

Configuring Security Policies on Firewall Devices

You can configure general security settings for the device using the General page and the Timeouts page under Platform > Security. You can enable anti-spoofing on interfaces, configure IP fragment settings, and configure a variety of timeout values for the device.

This chapter contains the following topics:

General Page

Use the General page to configure security settings that help protect against malformed packets, spoofed packets, fragmented packets, and denial of service attacks. See Configuring Floodguard, Anti-Spoofing and Fragment Settings , on page 2252 for more information about the settings on this page.

Navigation Path

- (Device view) Select **Platform** > **Security** > **General** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Security** > **General** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Related Topics

- Add/Edit General Security Configuration Dialog Box , on page 2254
- Configuring Timeouts , on page 2254

Field Reference

Table 809: General Page

Element	Description
Disable Floodguard (PIX 6.3 and FWSM 2.x only)	Check this box to disable Floodguard on the firewall device. This option is available only on PIX 6.3 and FWSM 2.x devices. See Configuring Floodguard, Anti-Spoofing and Fragment Settings , on page 2252 for more information about the Floodguard feature.
Global Fragment Settings Use these options to configure global fragment settings for the device. You can override these settings for individual interfaces; see Add/Edit General Security Configuration Dialog Box , on page 2254 for more information.	
Enable Default Settings	Check this box to enable the default fragment settings fields.
Size	Specify the maximum number of fragments that can be in the IP re-assembly database waiting for re-assembly. The default is 200.
Chain	Specify the maximum number of fragments into which a full IP packet can be fragmented. The default is 24 packets.
Timeout	Specify the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.
Interface Configuration Table This table lists all interfaces on which individual anti-spoofing and fragment settings have been defined. Refer to Configuring Floodguard, Anti-Spoofing and Fragment Settings , on page 2252 for more information about these settings. Refer to Add/Edit General Security Configuration Dialog Box , on page 2254 for more information about configuring these settings on individual interfaces.	

Configuring Floodguard, Anti-Spoofing and Fragment Settings

Use the General page under Platform > Security to enable or disable Floodguard (on a PIX 6.3 or FWSM 2.x device), to enable Unicast Reverse Path Forwarding (anti-spoofing) on individual interfaces, and to configure IP fragment settings for the device, and for each interface of the device.

Floodguard

Floodguard lets you reclaim firewall resources if the user authentication subsystem runs out of resources. If an inbound or outbound uauth connection is being attacked or overused, the firewall will actively reclaim TCP user resources.

If the user authentication subsystem is depleted, TCP user resources in different states are reclaimed in the following order, depending on urgency:

1. Timewait

2. LastAck
3. FinWait
4. Embryonic
5. Idle

Floodguard is enabled by default. This option applies only to PIX 6.3 or FWSM 2.x devices.

Anti-spoofing

Unicast Reverse Path Forwarding (RPF) guards against IP spoofing—a packet using an incorrect source IP address to obscure its true source—by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the security appliance looks only at the destination address when determining where to forward the packet. Unicast RPF instructs the security appliance to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the security appliance, the security appliance routing table must include a route back to the source address. See RFC 2267 for more information.

With outside traffic, for example, the security appliance can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the security appliance uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, the security appliance drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the security appliance drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route look-up. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

Fragment Settings

Fragment settings provide management of packet fragmentation and improve compatibility with the Network File System (NFS). By default, the security appliance allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to allow fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the security appliance, as fragmented packets are often used as DoS attacks.

Related Topics

- General Page , on page 2251
- Add/Edit General Security Configuration Dialog Box , on page 2254

Add/Edit General Security Configuration Dialog Box

Use the Add/Edit General Security Configuration dialog box to enable or disable anti-spoofing, and to configure override fragment settings, for an interface.

Navigation Path

You can access the Add/Edit General Security Configuration dialog box from the Anti-Spoofing and Fragment Interface Configuration table on the Platform > Security > General Page , on page 2251.

Related Topics

- Configuring Floodguard, Anti-Spoofing and Fragment Settings , on page 2252

Field Reference

Table 810: Add/Edit General Security Configuration Dialog Box

Element	Description
Interface	Enter or Select the name of the interface for which you want to configure anti-spoofing or fragment settings.
Enable Anti-Spoofing	Check this box to enable Unicast RPF (anti-spoofing) on the specified interface.
Override Default Fragment Settings	To override the default fragment settings on the specified interface, check this box to enable the following fields, and then enter the new values. See the General Page , on page 2251 for the default global fragment settings on the device.
Size	Specify the maximum number of fragments that can be in the IP re-assembly database waiting for re-assembly for the specified interface. The default is 200.
Chain	Specify the maximum number of fragments into which a full IP packet can be fragmented for the specified interface. The default is 24 packets.
Timeout	Specify the maximum number of seconds to wait for an entire fragmented packet to arrive on the specified interface. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.

Configuring Timeouts

The Timeouts page lets you set a variety of timeout values on the security appliance. All times are in the format **hh:mm:ss**.

These values represent idle timeouts for the connection and translation slots for various protocols. If a slot has not been used for the idle time specified, the resource is returned to the free pool. TCP connection slots are freed approximately 60 seconds after a normal connection close sequence.

Danger We recommend that you do not change these values unless advised to do so by Customer Support.

Navigation Path

- (Device view) Select **Platform** > **Security** > **Timeouts** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Security** > **Timeouts** from the Policy Types selector. Select an existing policy from the Policies selector, or create a new one.

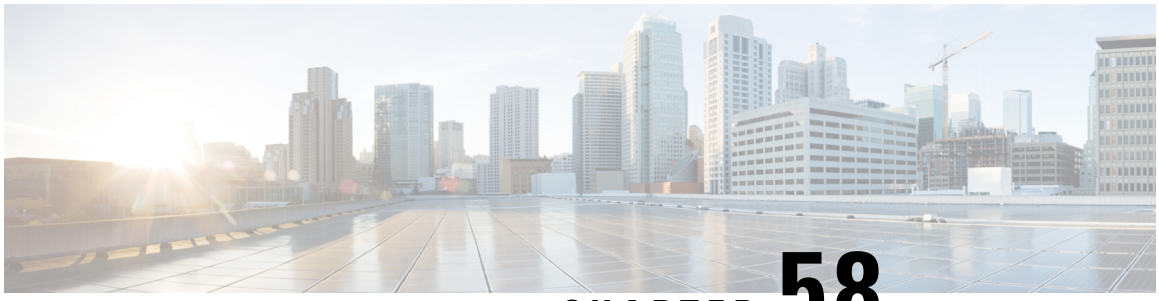
Field Reference

Table 811: Timeouts Page

Element	Description
To change the timeout value for a parameter, click the radio button to the left of the parameter entry to activate it, and then enter the new value in the parameter field. To reset any value to its default, click the related Default button. Clicking the Disable button, where provided, disables the timeout by setting its value to 0:00:00. Follow either of the procedures in the previous paragraph to re-enable a disabled value.	
Translation Slot (xlate)	Length of time idle until a translation slot is freed. This value must be at least 1 minute; the default is 3 hours. Enter 0:00:00 to disable this timeout.
Connection (conn)	Length of time idle until a connection slot is freed. This value must be at least 5 minutes; the default is 1 hour. Click Disable or enter 0:00:00 to disable this timeout.
Half-Closed	Length of time idle until a half-closed TCP connection is closed. For ASA 9.1.2 and later devices, the minimum is 30 seconds. For all other devices, the minimum is 5 minutes. The default is 10 minutes. Click Disable or enter 0:00:00 to disable this timeout.
UDP	Length of time idle until a UDP protocol connection is closed. This value must be at least 1 minute; the default is 2 minutes. Click Disable or enter 0:00:00 to disable this timeout.
SCTP	Length of time idle until a SCTP protocol connection is closed. This value must be at least 1 minute; the default is 2 minutes. Click Disable or enter 0:00:00 to disable this timeout.
Connection Holddown	Length of time idle until traffic is forwarded. This is the time for which the ASA waits before forwarding traffic, to avoid route flapping.This value must be at least 1 second; the default is 15 seconds. Click Disable or enter 0:00:00 to disable this timeout.
ICMP (PIX 7.x+, ASA, FWSM 3.x+)	Length of time idle after which general ICMP states are closed.

Element	Description
RPC/Sun RPC	Length of time idle until a SunRPC slot is freed. This value must be at least 1 minute; the default is 10 minutes. Click Disable or enter 0:00:00 to disable this timeout.
H.225	Length of time idle until an H.225 signaling connection is closed. The H.225 default timeout is 1 hour (01:00:00). Setting the value to 00:00:00 means never close the connection. To close a connection immediately after all calls are cleared, enter 1 second (0:00:01).
H.323	Length of time idle until an H.323 media connection is closed. The default is 5 minutes. Click Disable or enter 0:00:00 to disable this timeout.
MGCP	Length of time idle after which MGCP media ports are closed. The default is 5 minutes (0:05:00). Click Disable or enter 0:00:00 to disable this timeout.
MGCP PAT (PIX 7.x+, ASA, FWSM 3.x+)	Length of time idle after which an MGCP PAT translation is removed. The minimum time is 30 seconds; the default is 5 minutes (0:05:00). Click Disable or enter 0:00:00 to disable this timeout.
SIP	Length of time idle until an SIP signaling port connection is closed. This value must be at least 5 minutes; the default is 30 minutes. Click Disable or enter 0:00:00 to disable this timeout.
SIP Media	Length of time idle until an SIP media port connection is closed. This value must be at least 1 minute; the default is 2 minutes. Click Disable or enter 0:00:00 to disable this timeout.
SIP Disconnect (PIX 6.3(5), PIX/ASA 7.2+, FWSM 3.2+)	Length of time idle after which a SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message. The minimum value is 0:00:01; the maximum value is 0:10:00. The default value is 0:02:00.
SIP Invite (PIX 6.3(5), PIX/ASA 7.2+, FWSM 3.2+)	Length of time idle after which pinholes for PROVISIONAL responses and media xlates will be closed. The minimum value is 0:01:00; the maximum value is 0:30:00. The default value is 0:03:00.
SIP Provisional Media (PIX/ASA 7.2(3)+)	The timeout value for SIP provisional media connections; must be a value between 0:01:00 and 1193:00:00. The default is 2 minutes.

Element	Description
Auth. (uath) Absolute	Length of time until the authentication cache times out and new connections must be re-authenticated. The system waits until a user starts a new connection to prompt for re-authentication. This time must be shorter than the Translation Slot value. Click Disable or enter 0:00:00 to disable caching and require re-re-authentication on every new connection. **Note** Do not set this value to 0:00:00 if passive FTP is used on the connections. **Note** If you set this value to 0:00:00; HTTPS authentication may not work. If a browser initiates multiple TCP connections to load a Web page after HTTPS authentication, the first connection is permitted through, but subsequent connections trigger authentication. As a result, users are continuously presented with an authentication page, even after successful authentication. To work around this, set the authentication absolute timeout to 1 second. However, this workaround opens a one-second window of opportunity that might allow non-authenticated users through the firewall if they are coming from the same source IP address.
Auth. (uath) Inactivity	Length of time idle until the authentication cache times out and users have to re-authenticate new connections. This duration must be shorter than the Translation Slot value.
IGP	The Cisco ASA supports Non-Stop Forwarding from software Version 9.3.1 and later for dynamic routing protocols— Border Gateway Protocol (BGP) and Open Shortest Path First (OSPF). The length of convergence time of Open Shortest Path First (OSPF) is 70 seconds by default. Using this field, you can change the length of the convergence time. This value must be within the range of 10 seconds to 1 hour and 40 seconds. The default value for IGP is 0:01:10.



CHAPTER 58

Configuring Service Policy Rules on Firewall Devices

This section describes configuring service policy rules. Service policies provide a consistent and flexible way to configure certain security appliance features, including priority queuing, application inspection, and QoS (quality of service). For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications.

About Service Policy Rules

Service policy rules encompass these features:

- TCP and general connection settings (including TCP State Bypass; see About TCP State Bypass , on page 2260)
- Content security control (CSC)
- Application inspection
- Intrusion Prevention Services
- QoS queuing and policing
- ASA CX redirection (see About the ASA CX , on page 2276)
- ASA FirePOWER redirection
- User statistics for identity-based firewall policies

The configuration options for these features are presented on two pages in Security Manager—**Priority Queues** and **Rules**—accessed by navigating to Platform > Service Policy.

Priority Queuing

Priority queuing establishes two queues on an interface, a Low Latency Queuing (LLQ) priority queue and a "best effort" queue. This lets you prioritize latency-sensitive traffic like voice and video, so it is transmitted ahead of other traffic. Packets in the priority queue are always transmitted before packets in the best effort queue.

Because queues are not of infinite size, they can fill and overflow. When a queue is full, additional packets cannot get into the queue and are dropped. This is called "tail drop." To minimize tail drop, you can increase the queue buffer size. You can also fine-tune the maximum number of packets allowed into the transmit queue. These options let you control the latency and robustness of priority queuing.

Priority queuing is a Quality of Service (QoS) feature. In Security Manager, priority queue size and transmit queue size are managed on the Priority Queues Page , on page 2262, while establishment of priority queuing for a traffic class is an option on the QoS tab of the Service Policy (MPC) Rule Wizard, which is accessed from the Service Policy Rules Page , on page 2263.

Application Inspection and QoS

Some applications require special handling by the security appliance, and specific application inspection engines are provided for this purpose. Specifically, applications that embed IP addressing information in the user data packet, or open secondary channels on dynamically assigned ports require special inspection.

Application inspection is enabled by default for many protocols, while it is disabled for others. In many cases, you can change the port which the application inspection engine monitors for traffic.

Application inspection engines work with network address translation (NAT) to help identify the location of embedded addressing information. This allows NAT to translate these embedded addresses, and to update any checksum or other fields that are affected by the translation.

Service policy rules define how specific types of application inspection are applied to different types of traffic processed by the security appliance. You can apply rules to specific interfaces, or globally to every interface.

These rules provide a means to configure security appliance features in a manner similar to the Cisco IOS software quality-of-service (QoS) CLI. For example, with service policy rules you can include IP Precedence as one of the criteria to identify traffic for rate-limiting. You can also create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications.

Traffic match criteria are used to define the types of traffic to which you want to apply application inspection. For example, TCP traffic on port 23 might be classified as the Telnet traffic class. You then might use the traffic class to apply connection limits.

Multiple traffic match criteria can be assigned to a single interface, but a packet will only match the first criteria within a specific service policy rule.

About TCP State Bypass

By default, all traffic that enters an ASA or FWSM is inspected using the Adaptive Security Algorithm, and is either allowed through or dropped based on the security policy. The device maximizes its firewall performance by checking the state of each packet—to determine whether this a new connection, or an established connection—and assigning it to the session management path (if it is a new connection SYN packet), the fast path (if it is an established connection), or the control-plane path (for advanced inspection).

Note TCP State Bypass is available on FWSM 3.2+ and ASA 8.2+ devices only.

TCP packets that match existing connections in the fast path can pass through the appliance without every aspect of the security policy being rechecked. This feature maximizes performance. However, the method of establishing the session in the fast path using the SYN packet, and the checks that occur in the fast path (such as TCP sequence number), require that both outbound and inbound flows for a connection pass through the same device, which is not the case in asymmetric routing environments.

For example, assume a new connection is assigned to security device 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through device 1, then the packets match the entry in the fast path, and are passed through. But if subsequent packets go to device 2, where a SYN packet did not go through the session management path, there is no entry in the fast path for the connection, and the packets are dropped.

Thus, if you have asymmetric routing configured on upstream routers, and traffic alternates between two security devices, enable TCP state bypass for those specific traffic flows. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. TCP traffic is then treated much as a UDP connection is treated: when a non-SYN packet matching the specified networks enters the security device, and there is not a fast path entry, then the packet goes through the session management path to establish a connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.

Unsupported Features

The following features are not supported when you enable TCP state bypass:

- Application inspection – Application inspection requires both inbound and outbound traffic to go through the same security device, so application inspection is not supported with TCP state bypass.
- AAA authenticated sessions – When a user authenticates with one security device, traffic returning via the other security device will be denied because the user did not authenticate with that device.
- TCP Intercept, Maximum Embryonic Connections limit, TCP sequence number randomization – If TCP state bypass is enabled, the device does not keep track of the state of the connection, so these features are not applicable.
- Cisco CSC SSM (Content Security and Control Security Services Module) – SSM and SSC functionality cannot be used with TCP state bypass.

Compatibility with NAT

Because the translation session is established separately for each security device, be sure to configure static NAT on both devices for TCP state bypass traffic; if you use dynamic NAT, the address chosen for the session on device 1 will differ from the address chosen for the session on device 2.

Related Topics

- About Service Policy Rules, on page 2259

Priority Queues Page

Priority queues let you define how traffic is prioritized in the network. You can define a series of filters based on packet characteristics to cause traffic to be placed in a higher or lower priority queue. The queue with the highest priority is serviced first until it is empty, then the lower queues are serviced in sequence.

In Security Manager, priority queue size and transmit queue size are managed on this page, while establishment of priority queuing for a traffic class is an option on the QoS tab of the Service Policy (MPC) Rule Wizard, which is accessed from the Service Policy Rules Page , on page 2263.

The Priority Queue Configuration dialog box is used to add and edit these queues. Refer to Priority Queue Configuration Dialog Box , on page 2262 for descriptions of the fields displayed in the Priority Queues table on this page.

Note Priority queuing is are not available on Catalyst 6500 service modules (the Firewall Services Module and the Adaptive Security Appliance Service Module).

Navigation Path

- (Device view) Select **Platform** > **Service Policy** > **Priority Queues** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform** > **Service Policy** > **Priority Queues** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

Field Reference

Table 812: Priority Queue Configuration Dialog Box

Element	Description
Interface Name	Specify the interface to which this rule applies; you can enter the interface name, or click Select to choose an available interface.
Queue Limit	Enter the maximum number of packets that can be queued in a priority queue before it drops data. This limit must be in the range of 0 through 2048 packets.
Transmission Ring Limit	Enter the maximum number of packets allowed into the transmit queue. This fine-tuning of the transmit queue can reduce latency and offer better performance through the transmit driver. On PIX devices, this value can range from 3 through 128 packets. On ASAs prior to version 7.2, this limit can be in the range 3 through 256 packets, while on ASAs running version 7.2 and later, the value can be in the range 3 through 512 packets.

Service Policy Rules Page

Use the Service Policy Rules page to define new service policy rules, and to edit or delete existing service policy rules.

Configuring Service Policy Rules consists of three tasks:

1. **Configure a service policy**. Create a service policy and determine the interfaces to which the service policy applies. For more information, see Step 1. Configure a Service Policy , on page 2265.
2. **Configure the traffic class**. Specify the criteria you want to use to identify the traffic to which the service policy applies. For more information, see Step 2. Configure the traffic class , on page 2265.
3. **Configure the actions**. Specify the actions that should be taken to protect information or resources, or to perform QoS functions for the traffic specified in this service policy. For more information, see Step 3. Configure the MPC actions , on page 2266.

The three tasks are performed using the Insert/Edit Service Policy (MPC) Rule Wizard , on page 2264. Refer to the individual task topics for descriptions of the fields displayed in the Service Policy Rules table on this page.

Navigation Path

- (Device view) Select **Platform** > **Service Policy** > **Rules** from the Device Policy selector.

- (Policy view) Select **PIX/ASA/FWSM Platform > Service Policy > Rules** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or create a new one.

ASA CX Auth Proxy Configuration

The CXSC Auth Proxy button below the Service Policy Rules table opens the Add/Edit CXSC Auth Proxy Configuration dialog box, which is described in ASA CX Auth Proxy Configuration , on page 2276.

The CXSC Auth Proxy button is available below the Service Policy Rules table only in Device view; it is not visible in Policy view.

Note Security Manager uses “CXSC” in some places to refer to an ASA CX Security Services Processor (SSP).

Insert/Edit Service Policy (MPC) Rule Wizard

Use the Insert/Edit Service Policy (MPC) Rule wizard to add and edit service policy rules on the Service Policy Rules page. The Insert/Edit Service Policy (MPC) Rule wizard presents the following steps:

- Step 1. Configure a Service Policy , on page 2265
- Step 2. Configure the traffic class , on page 2265
- Step 3. Configure the MPC actions , on page 2266

Note “MPC” refers to what is now called the Modular Policy Framework. Refer to Using Modular Policy Framework for additional information.

Navigation Path

Open the Insert/Edit Service Policy (MPC) Rule wizard by clicking the Add Row or Edit Row button on the Service Policy Rules Page , on page 2263.

Step 1. Configure a Service Policy

The first step in using the Insert/Edit Service Policy (MPC) Rule Wizard to configure a Service Policy Rule involves enabling the rule and specifying the interface(s) to which it is applied.

Navigation Path

Open the Insert/Edit Service Policy (MPC) Rule wizard by clicking the Add Row or Edit Row button on the Service Policy Rules Page , on page 2263.

Related Topics

- Step 2. Configure the traffic class , on page 2265
- Step 3. Configure the MPC actions , on page 2266

Table 813: Insert/Edit Service Policy (MPC) Rule Wizard—Step 1. Configure a Service Policy.

Element	Description
Enable The Current MPC Rule	Check this box to enable this service policy rule. You can deselect this option if you want to define the rule now, but not deploy it to the device until later.
Category	To assign the rule to a category, choose the category from the list. Categories can help you organize and identify rules and objects. For more information, see Using Category Objects , on page 241.
Description	Optionally, enter a description for the service policy rule.
Global - Applies to All Interfaces	Select this option to apply the rule globally to all interfaces. This option is not compatible with matching traffic based on the source or destination IP address using an access list.
Interfaces	Select this option to apply the rule to a specific interface or group of interfaces (or interface roles), and then enter or Select the name of an interface or interface object. This selection is required if you want to match traffic based on the source or destination IP address using an access list. **Note** Interface-specific rules take precedence over the global service policy for a given feature. For example, if you have a global policy with FTP inspection, and an interface policy with TCP connection limits, then both FTP inspection and TCP connection limits are applied to the interface. However, if you have a global policy with FTP inspection, and an interface policy with FTP inspection, then only the interface policy FTP inspection is applied to that interface.

Step 2. Configure the traffic class

The second step in using the Insert/Edit Service Policy (MPC) Rule Wizard to configure a Service Policy Rule involves specifying the traffic class to which the rule is applied.

Specify the class to use to match traffic for this rule:

- **Use class-default As The Traffic Class**—Select this option to use the traffic class class-default for this service policy. The class-default traffic class matches all traffic.
- **Traffic Class**—Select this option to apply this rule to a specific traffic class. Enter the name of the previously defined traffic class, or click **Select** to select it from the Traffic Flows Selector.

You also can define or edit a traffic flow "on the fly" by clicking the either Create or Edit buttons in the Traffic Flows Selector. (Traffic flows are also created and edited on the Traffic Flows page of the Policy Object Manager.) See Configuring Traffic Flow Objects , on page 2277 for more information.

Related Topics

- Step 1. Configure a Service Policy , on page 2265
- Step 3. Configure the MPC actions , on page 2266

Step 3. Configure the MPC actions

The third step in the Insert/Edit Service Policy (MPC) Rule Wizard involves specifying IPS, CXSC, FirePOWER, Connection Setting, QoS, CSC, User Statistics, ScanSafe Web Security, and NetFlow parameters for the rule; each set of parameters is presented on a separate tabbed panel.

Related Topics

- Step 1. Configure a Service Policy , on page 2265
- Step 2. Configure the traffic class , on page 2265

Field Reference

Table 814: Insert/Edit Service Policy (MPC) Rule Wizard—Step 3. Configure the actions.

Element	Description
Intrusion Prevention tab	
Enable IPS for this Traffic	Enables or disables intrusion prevention for this traffic flow. When this box is checked, the other parameters on this panel are available. **Note** These parameters are applicable only on ASA 7.0+ devices that have an IPS module installed. See About IPS Modules on ASA Devices , on page 2274 for more information.

Element	Description
IPS Mode	Select the operating mode for intrusion prevention: • **Inline**—This mode places the IPS module directly in the traffic flow. No traffic that you identified for IPS inspection can continue through the ASA without first passing through, and being inspected by, the IPS module. This mode is the most secure because every packet identified for inspection is analyzed before being allowed through. Also, the IPS module can implement a blocking policy on a packet-by-packet basis. However, this mode can affect throughput. • **Promiscuous**—This mode sends a duplicate stream of traffic to the IPS module. This is less secure than Inline mode, but has little impact on traffic throughput. Unlike Inline mode, in Promiscuous mode the IPS module cannot drop the original packets, it can only block traffic by instructing the ASA to shun the traffic, or by resetting the connection on the appliance. Also, while the IPS module is analyzing the traffic, a small amount of traffic may pass through the ASA before the IPS module can shun it.
On IPS Card Failure	Specify the action to be taken if the IPS module becomes inoperable. Select either: • **Open**—Permits traffic if the module or card fails. • **Close**—Blocks traffic if the module or card fails.
Virtual Sensor	Text box in which you can view, edit, or remove the virtual sensor in the service policy that you are adding or editing
CXSC tab **Note** Security Manager uses "CXSC" in places to refer to an ASA CX Security Services Processor (SSP).	
Enable CXSC For This Traffic	Check this box to enable redirection of this traffic flow to an ASA CX installed in the ASA. When this box is checked, the other parameters on this panel are available. **Note** These parameters are applicable only on ASA 5585-X devices running version 8.4(4)+ and ASA 55xx-X devices running version 9.1(1)+ that have an ASA CX SSP installed.
On Context Security Card Failure	Specify the action to be taken if the ASA CX becomes inoperable. Select either: • **Open** – If the ASA CX fails for any reason, the ASA will continue to pass traffic that would otherwise be redirected to the ASA CX. • **Close** – If the ASA CX fails, the ASA will drop any traffic that would otherwise be redirected to the ASA CX.

Element	Description
Enable Auth Proxy	Check this box to enable the authentication proxy, which is required if you want to use active authentication in the identity policies on the ASA CX. If not checked, no authentication is performed. **Note** You can change the port used for authentication proxy; see ASA CX Auth Proxy Configuration , on page 2276 for more information.
FirePOWER tab	
Enable FirePOWER Card For This Traffic	Check this box to enable redirection of this traffic flow to an ASA FirePOWER module installed in the ASA. When this box is checked, the other parameters on this panel are available. **Note** These parameters are applicable only on ASA 55xx-X devices running version 9.2(1)+.
On FirePOWER Card Failure	Specify the action to be taken if the ASA FirePOWER module becomes inoperable. Select either: • **Open** – If the ASA FirePOWER module fails for any reason, the ASA will continue to pass traffic that would otherwise be redirected to the ASA FirePOWER module. • **Close** – If the ASA FirePOWER module fails, the ASA will drop any traffic that would otherwise be redirected to the ASA FirePOWER module.
Enable Monitor Only	Sets the module to monitor-only mode. In monitor-only mode, the module can process traffic for demonstration purposes, but then drops the traffic. You cannot use the traffic-forwarding interface or the device for production purposes.
Connection Settings tab	
Enable Connection Settings For This Traffic	Enables or disables connection settings for this traffic flow. When this box is checked, the other parameters on this panel become active. From the Connection Settings tab you can configure maximum connections, embryonic connections, timeouts, and TCP parameters.

Element	Description
Maximum Connections	You can specify the maximum number of TCP and UDP connections, and the maximum number of embryonic connections for this traffic flow: • **Maximum TCP & UDP Connections** – Specify the maximum number of simultaneous TCP and UDP connections for the entire subnet, up to 65,535, for ASA versions earlier than 8.4(5); for ASA 8.4(5) and later, the maximum number is 2,000,000. The default is zero for both protocols, which means the maximum possible connections are allowed. • **Maximum TCP & UDP Connections Per Client** – For ASA/PIX 7.1+ only; specify the maximum number of simultaneous TCP and UDP connections on a per client basis. For ASA 8.4(5) and later, the maximum number is 2,000,000. • **Maximum Embryonic Connections** – For ASA/PIX 7.0+ only; specify the maximum number of embryonic connections per host, up to 65,535, for ASA versions earlier than 8.4(5); for ASA 8.4(5) and later, the maximum number is 2,000,000. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. This limit enables the TCP Intercept feature. The default is zero, which means the maximum embryonic connections. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server. This feature is not applicable if TCP State Bypass is enabled. • **Maximum Embryonic Connections Per Client** – For ASA/PIX 7.1+ only; specify the maximum number of embryonic connections on a per client basis. For ASA 8.4(5) and later, the maximum number is 2,000,000. This feature is not applicable if TCP State Bypass is enabled.

Element	Description
Connection Timeouts	You can specify the following connection timeout settings for this traffic flow: • **Embryonic Connection Timeout** – Specify the idle time until an embryonic connection slot is freed. Enter 0:00:00 to disable timeout for the connection. The default is 20 seconds for FWSMs, and 30 seconds for ASA/PIX devices. • **Half Closed Connection Timeout** – Specify the idle time until a half-closed connection slot is freed. Enter 0:00:00 to disable timeout for the connection. For FWSMs, the default value is 20 seconds; the maximum value is 255 seconds (four minutes, 15 seconds). For ASA 9.1.2 and later devices, the minimum is 30 seconds. For all other ASA/PIX devices, the minimum is 5 minutes. The default is 10 minutes for all ASA/PIX devices. • **Idle Connection Timeout** – Specify the idle time until a connection slot is freed. Enter 0:00:00 to disable timeout for the connection. This duration must be at least 5 minutes. The default is 1 hour.
Reset Connection Upon Timeout	If selected, connections are reset after a timeout occurs. Available for ASA/PIX 7.0(4)+ only.
Detect Dead Connections	Enables the Dead Connection Detection feature; available for ASA/PIX 7.2+ devices. Selecting this option enables these two fields: • **Dead Connection Detection Timeout** – Specify the period of time between retries when a dead connection is detected. The default is 15 seconds. • **Dead Connection Detection Retries** – Specify the number of retries to be performed after a dead connection is detected. The default is five.
Traffic Flow Idle Timeout	Specify the period of time between a traffic flow becoming idle and the flow's disconnection. Applicable to FWSM 3.2+ only. The default is 1 hour.
Enable TCP Normalization	Enables TCP normalization, and activates the TCP Map selection option. Applies to ASA/PIX 7.0+ only; not applicable if TCP State Bypass is enabled.
TCP map	Specify the TCP map to use for TCP normalization: enter or Select the name of a TCP map. For more information, see Configuring TCP Maps , on page 2281.
Randomize TCP Sequence Number	Enables the Randomize Sequence Number feature. Disable this feature only if another inline security appliance is also randomizing sequence numbers and the result is scrambling the data. Each TCP connection has two Initial Sequence Numbers: one generated by the client and one generated by the server. The security appliance randomizes the ISN that is generated by the host/server on the higher security interface. At least one ISN must be randomly generated so that attackers cannot predict the next ISN and potentially hijack the session. Not applicable if TCP State Bypass is enabled.

Element	Description
Enable TCP State Bypass	Enables TCP state bypass for this traffic flow. This is allows specific traffic flows in asymmetric routing environments when both the outbound and inbound flow for a connection do not pass through the same device. Applicable to FWSM 3.2+ and ASA 8.2+ only. See About TCP State Bypass , on page 2260 for more information.
Enable SCTP State Bypass (ASA 9.5.2 + only)	You can bypass Stream Control Transmission Protocol (SCTP) stateful inspection if you do not want SCTP protocol validation.
Enable Decrement TTL	Select this option to turn on decrementing of the time-to-live (TTL) value in packets passed by the security appliance. Applicable to PIX/ASA 7.2.2+ only.
Configure Flow Offload (For Firepower 9000/4000 series ASA 9.6(1) and above)	**Note** You must enable flow offload manually on the ASA and restart the device, before configuring flow offload in the Service Policy Wizard in Cisco Security Manager. Flow offload and flow offload statistics are supported on the ASA only in the single context and system context modes. It is not supported in the admin or user context.ASA supports flow offload starting from version 9.5.2(1); however Cisco Security Manager supports flow offload from ASA 9.6(1). Select this option to offload specific traffic to a super-fast path; traffic is switched and processed in the NIC instead of the ASA. Offloading can help you improve performance for data-intensive applications such as large file transfers. **Tip** You can configure flow offload only when TCP State Bypass and SCTP State bypass are not enabled on your device.
QoS tab	
Enable QoS For This Traffic	Enables Quality of Service (QoS) options for this traffic flow. When selected, the Enable Priority For This Flow and the Traffic Policing options become active. **Note** The options on this tab are applicable to PIX/ASA 7.0+ devices only.
Enable Priority For This Flow	Enables strict scheduling priority for this flow. The priority queues must be defined on the Priority Queues Page , on page 2262.
Traffic Policing	Enables output and input traffic policing. Traffic policing lets you control the maximum rate of traffic transmitted or received on an interface.

Element	Description
Output (Traffic Policing)	Enables policing of traffic flowing out of the device. If you enable policing, you can specify the following values: • **Committed Rate** – The rate limit for this traffic flow; this is a value in the range 8,000 to 2,000,000,000, specifying the maximum speed (bits per second) allowed. • **Burst Rate** – A value in the range 1,000 to 512,000,000 that specifies the maximum number of instantaneous bytes allowed in a sustained burst before throttling to the conforming rate value. • **Conform Action** – The action to take when the rate is less than the conform-burst value. Choices are Transmit or Drop. • **Exceed Action** – Take this action when the rate is between the conform-rate value and the conform-burst value. Choices are Transmit or Drop.
Input (Traffic Policing)	Enables policing of traffic flowing into the device; these options apply to ASA/PIX 7.2+ devices only. If you enable policing, you can specify the following values: • **Committed Rate** – The rate limit for this traffic flow; this is a value in the range 8,000 to 2,000,000,000, specifying the maximum speed (bits per second) allowed. • **Burst Rate** – A value in the range 1,000 to 512,000,000 that specifies the maximum number of instantaneous bytes allowed in a sustained burst before throttling to the conforming rate value. • **Conform Action** – The action to take when the rate is less than the conform-burst value. Choices are Transmit or Drop. • **Exceed Action** – Take this action when the rate is between the conform-rate value and the conform-burst value. Choices are Transmit or Drop.
CSC tab	
Enable Content Security Control For This Traffic	Enables or disables the use of the Cisco CSC SSM (Content Security and Control Security Services Module) for this traffic flow. When this box is checked, the On CSC SSM Failure options become available. These options are applicable on ASA 7.1+ devices only; they are not applicable if TCP State Bypass is enabled. The CSC SSM provides protection against viruses, spyware, spam, and other unwanted traffic by scanning the FTP, HTTP, POP3, and SMTP packets.
On CSC SSM Failure	Specifies the action to take if the CSC SSM becomes inoperable: • **Open** – Permits traffic if the CSC SSM fails. • **Close** – Blocks traffic if the CSC SSM fails.
User Statistics tab	

Element	Description
Enable user statistics accounting (ASA 8.4(2)+ only)	Whether to collect user statistics accounting information for identity-based firewall policies. These statistics are kept for users to which a firewall policy is applied based on user name or user group membership. Select the type of information you want to collect: • **Account for sent drop count** • **Account for sent packet, sent drop and received packet count**
Protocol Inspection tab	
Enable Scansafe Web Security for this traffic (ASA 9.0+ only)	Enables or disables the use of ScanSafe Web Security for this traffic flow. When this box is checked, two options become available: These options are applicable on ASA 9.0+ devices only. • **ScanSafe Policy Map**– enables policy map selection. • **On ScanSafe Tower Communication Failure**– specifies action the system should take if ScanSafe Tower communication fails.
Enable SCTP for this traffic (ASA 9.5.2 + only	Enables or disables the use of SCTP for this traffic flow. • **SCTP Policy Map**– enables policy map selection
Enable Diameter Inspection for this traffic (ASA 9.5.2 + only)	Enables or disables the use of Diameter inspection for this traffic flow. • **Diameter Policy Map**– enables policy map selection When Diameter Inspection is enabled, you can further enable inspection of encrypted traffic by selecting the Enable encrypted traffic inspection check box. You must select the TLS Proxy to be used for this inspection.
Enable LISP for this traffic (ASA 9.5.2 + only)	Enables or disables the use of LISP Inspection for this traffic flow. • **LISP Policy Map**– enables policy map selection
Enable Flow LISP mobility for devices (ASA 9.5.2 + only)	Enables flow mobility in clustering.
Enable STUN Inspection support for devices (ASA 9.6.2 + only)	Enables or disables the use of STUN inspection for this traffic flow. It is supported on ASA 9.6.2 and above in the single and multi-context mode. **Note** When you enable STUN inspection on the default inspection class, TCP/UDP port 3478 is watched for STUN traffic. The inspection supports IPv4 addresses and TCP/UDP only.STUN inspection is supported in failover and cluster modes, as pinholes are replicated. However, as the transaction ID is not replicated among units, when a unit fails after receiving a STUN Request and another unit received the STUN Response, the STUN Response will be dropped.

Element	Description
Enable M3UA for this traffic (ASA 9.6.2 + only)	Enables or disables the use of M3UA for this traffic flow. • **M3UA Policy Map**– enables policy map selection
NetFlow tab	
Enable NetFlow for this traffic	Enables or disables the use of NetFlow for this traffic flow. When this box is checked, the NetFlow options become available.
Collectors	Specify the collectors that should be used when sending NetFlow events of a specific event type: **Note** Only use collectors that have been configured on the NetFlow page at Platform > Logging > NetFlow. • Flow Create Event • Flow Deny Event • Flow Tear Event • All Event Types **Note** Cisco Security Manager does not allow duplicate netflow collectors for ASA 9.6(4) to 9.7.0, and 9.8(2) and above devices. Ensure that you remove the duplicate collectors.

About IPS Modules on ASA Devices

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

You can install a variety of IPS modules, such as the Advanced Inspection and Prevention Security Services Module (AIP-SSM), in some ASA device models. The IPS modules supported by each ASA model differ. The IPS modules run advanced IPS software that provides proactive, full-featured intrusion prevention services to stop malicious traffic, including worms and network viruses, before they can affect your network.

The ASA IPS module runs separately from the adaptive security appliance, and you need to add it to the device inventory as a separate device. It is, however, integrated into the ASA traffic flow.

When you configure the ASA IPS module, you need to configure the service policy rules on the host ASA as well as the IPS policies on the IPS module. The service policy rules determine which traffic is inspected by the IPS module. For an overview of IPS policy configuration, see Overview of IPS Configuration , on page 1617.

When you identify traffic for IPS inspection, the traffic flows through the ASA and the IPS module as follows:

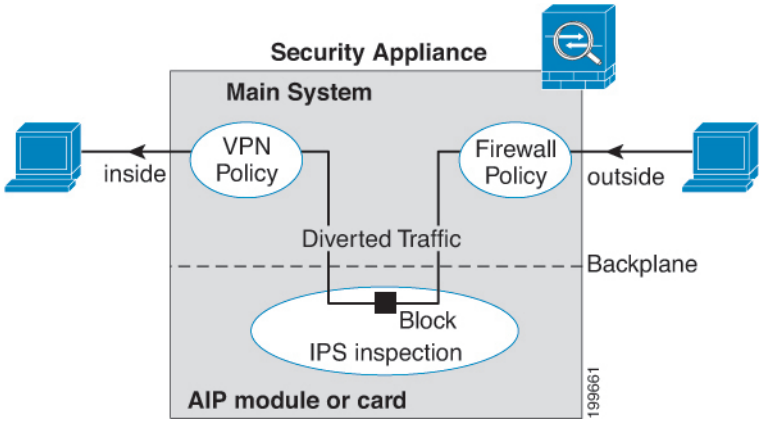
1. Traffic enters the ASA.
2. Firewall policies, such as interface access rules, are applied.

3. Traffic is sent to the IPS module over the backplane when you operate in inline mode. If you configure the system to use promiscuous mode, a copy of the traffic is sent to the IPS module.

   See **IPS Mode** in the Intrusion Prevention section of the Insert/Edit Service Policy (MPC) Rule wizard (Step 3. Configure the MPC actions , on page 2266) for more information about Inline and Promiscuous modes.

4. The IPS module applies its security policy to the traffic and takes appropriate actions.
5. Allowed traffic is sent back to the adaptive security appliance over the backplane. In Inline mode, the IPS module may block some traffic according to its security policy; in other words, that traffic is not passed back.
6. VPN policies are applied (if configured).
7. Traffic exits the ASA.

The following illustration depicts traffic flow when running the IPS module in Inline mode. In this example, the IPS module automatically blocks traffic that it identifies as an attack. All other traffic is returned to the ASA.



The next illustration depicts traffic flow when the IPS module is running in Promiscuous mode. In this example, the IPS module sends a shun message to the ASA for traffic it has identified as a threat.

About the ASA CX

The ASA CX is a Security Services Processor (SSP) that can be installed in the Cisco ASA-5585-X series Adaptive Security Appliance. You configure the parent ASA to redirect traffic to the ASA CX, which then applies its security policies and either drops the traffic, or returns it to the ASA for further processing and routing to the next destination.

There are two basic policies that may need adjustment in the ASA when you add a ASA CX: access rules and inspection rules:

- Access rules, whether global rules or those applied to specific interfaces, are always applied before traffic is redirected to the ASA CX. Thus, the security card sees only the traffic already permitted, and does not process traffic that was dropped at entry to the ASA. Consider adjusting the rules to ensure that all traffic that you want the ASA CX to process is permitted.
- Inspection rules determine which traffic is inspected. The ASA CX does not inspect traffic that has already been inspected by the ASA. Therefore, you must ensure that you do not inspect traffic that you intend the ASA CX to inspect. Specifically, do not inspect HTTP traffic, because HTTP inspection is one of the core functions of the ASA CX. The default inspection rules on the ASA do not include HTTP inspection, so you must alter your inspection rules only if you added HTTP rules.

Determine if you need to create access rules for an interface, or global access rules that apply to all interfaces. Use the ASA access rules to filter traffic before it is redirected to the ASA CX. If you know there are classes of traffic that you never want to pass, it is more efficient to drop them immediately upon entry to the ASA.

If you have already established access rules, there is no requirement to change them. However, you should evaluate whether they need to be relaxed in order to have the ASA CX process certain types of traffic that you are now dropping by means of access rules.

Enabling traffic redirection to an installed ASA CX is described in Step 3. Configure the MPC actions , on page 2266 of the Insert/Edit Service Policy (MPC) Rule Wizard , on page 2264.

Related Topics

- About Service Policy Rules, on page 2259

ASA CX Auth Proxy Configuration

If you enabled ASA CX authentication proxy—on the **CXSC** tab during Step 3 of the Insert/Edit Service Policy (MPC) Rule Wizard; see Step 3. Configure the MPC actions , on page 2266—and you want to use a non-default port for active authentication, use the Add/Edit CXSC Auth Proxy Configuration dialog box to change the ASA CX Auth Proxy Port number.

If users must be prompted for authentication credentials, the prompting is done through this port.

Note Security Manager uses “CXSC” in some places to refer to an ASA CX Security Services Processor (SSP).

Navigation Path

Open the Add/Edit CXSC Auth Proxy Configuration dialog box by clicking the **CXSC Auth Proxy** button below the rules table on the Service Policy Rules Page , on page 2263.

Note The CXSC Auth Proxy button is available below the IPS, QoS, and Connection Rules table only in Device view; it is not visible in Policy view.

Related Topics

- Service Policy Rules Page , on page 2263

Field Reference

Table 815: Add/Edit CXSC Auth Proxy Configuration Dialog Box

Element	Description
CXSC Auth Proxy Port	The default authentication proxy TCP port is 885; however, if you change it, you must enter a port number between 1024 and 65535.

Configuring Traffic Flow Objects

Use the Add and Edit Traffic Flow dialog boxes to configure traffic-match definitions. These traffic-flow definitions correspond to class maps (the **class map** command) in the IPS, QoS and Connection Rules service policy for devices running the PIX 7.0+, ASA 7.0+, and FWSM 3.2+ operating systems. For more information on configuring these rules, see About Service Policy Rules, on page 2259.

Navigation Path

Select **Manage > Policy Objects**, then select **Traffic Flows** from the Object Type selector. Right-click inside the work area and choose New Object, or right-click a row and choose Edit Object.

These dialog boxes also can be opened by clicking the Create or Edit buttons in the Traffic Flows Selector while defining a Service Policy rule. See for Step 2. Configure the traffic class , on page 2265 more information about selecting a Traffic Flow class.

Related Topics

- Creating Access Control List Objects , on page 283

Field Reference

Table 816: Add and Edit Traffic Flow Dialog Boxes

Element	Description
Name	The name of the Traffic Flow object. A maximum of 40 characters is allowed. The name space for class maps is local to a security context. Therefore, the same name may be used in multiple security contexts. The maximum number of class maps per security context is 255.
Description	A description of the Traffic Flow (optional). A maximum of 1024 characters is allowed.
Traffic Match Type	The type of traffic to match. The option you choose may change the fields in the dialog box; all possible fields are explained later in this table. The Traffic Match Type options are: • Any Traffic – Matches all traffic. • Source and Destination IP Address (access-list) – Matches the source and destination IP addresses in a packet based on the access control list that you specify. For ASA 8.4(2+) devices, the ACL can include FQDN objects and user specifications to perform identity-based traffic matching. • Default Inspection Traffic – Matches default inspection traffic. For a list of default settings, see Default Inspection Traffic , on page 2279. • Default Inspection Traffic with access list – Matches default inspection traffic limited by the access control list that you specify. • TCP or UDP or SCTP Destination Port – Matches traffic to the TCP or UDP or SCTP destination port or port range that you specify. Valid port numbers here are 0 to 65535. • RTP Range – Matches traffic to the range of UDP destination ports that you specify. Valid port numbers here are 2000 to 65535. • Tunnel Group – Matches the destination address based on flows in VPN tunnels belonging to a specified tunnel group. • IP Precedence Bits – Matches precedence values assigned to the traffic packets. You can select a maximum of four values. • IP DiffServe Code Points (DSCP) Values – Matches DSCP values associated with the traffic packets. You can select a maximum of eight values.
Variable Fields The following fields may appear in the Add and Edit Traffic Flow dialog boxes, depending on your choice in the Traffic Match Type field. This list is the complete set of possible fields.	

Element	Description
Available ACLs	A list of the access control list (ACL) objects that you can select for the map. Select the ACL that defines the target traffic, or click the Create button to add a new object. You can also select an object and click Edit to change its definition. If the list of objects is large, use the Filter field to limit the display (see Filtering Items in Selectors , on page 47).
TCP or UDP or SCTP TCP/UDP/SCTP Port or Port Range	Radio buttons used to specify a protocol (either TCP, UDP, or SCTP), and a text field used to specify a destination port number or range of numbers to use when matching traffic based on the specified protocol/ports. You can specify a single port value, or a range of port numbers (for example, 0-2000). Valid port numbers are 0 to 65535.
RTP Port Range	The range of RTP destination ports associated with the traffic flow. You must enter a port range within the valid range of 2000 to 65535. **Note** When you close the dialog box, the port range you entered is converted to port-span values by subtracting the start value from the end value. For example, if you enter the range 2001-3000 in the dialog box, "RTP port 2001 range 999" appears in the Match Value column of the Traffic Flows policy object table. Port-span values are expected by the device.
Tunnel group name Match Flow IP Destination Address	Lists available VPN tunnel groups. Choose one or enter the name of a group. You can also select Match Flow IP Destination Address to recognize the destination address as the match type. **Tip** You can use FlexConfig objects and policies to define a VPN tunnel group on a PIX 7.0+ device. For more information, see Understanding FlexConfig Policies and Policy Objects , on page 342.
Available IP Precedence Match on IP Precedence	The IP precedence numbers. Select the values you want to match and click >> to add them to the Match table. Ctrl-click to select multiple values. You can select a maximum of four values. To remove a value from the Match table, select it and click <<.
Available DSCP Values Match on DSCP	The IP DiffServe Code Points (DSCP) numbers. Select the values you want to match and click >> to add them to the Match table. Ctrl-click to select multiple values. You can select a maximum of eight values. To remove a value from the Match table, select it and click <<.
Category	The category assigned to the traffic-flow object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.

Default Inspection Traffic

When you create a Traffic Flow policy object, you can choose to match the default inspection traffic. For more information, see Configuring Traffic Flow Objects , on page 2277. The following table lists the types of traffic included in the Default Inspection Traffic category.

Table 817: Default Inspection Traffic

Value	Port	NAT Limitations	Comments
CTIQBE	TCP/2748		
CuSeeMe	UDP/7648		
DNS over UDP	UDP/53	No NAT support for name resolution through WINS.	No PTR records are changed.
FTP	TCP/21		
GTP	UDP/2123, 3386		
H.323, H.225	TCP/1720, 1718	No NAT on same security interfaces. No static PAT.	
RAS	UDP/1718, 1719	No NAT on same security interfaces. No static PAT.	
HTTP	TCP/80		
ICMP	—		All ICMP traffic is matched in the default class map.
ILS (LDAP)	TCP/389	No PAT.	
IP Options	—		All IP Options traffic is matched in the default class map.
MGCP	UDP/2427, 2727		
NETBIOS Name Server	UDP/137, 138 (Source ports)		NetBIOS is supported by performing NAT of the packets for NBNS UDP port 137 and NBDS UDP port 138.
RSH	TCP/514	No PAT.	
RTSP	TCP/554	No PAT. No outside NAT.	No handling for HTTP cloaking.
SIP	TCP/5060; UDP/5060	No outside NAT. No NAT on same security interfaces.	
Skinny Client Control Protocol (SCCP)	TCP/2000	No outside NAT. No NAT on same security interfaces.	
SMTP and ESMTP	TCP/25		
SQL*Net	TCP/1521		Versions 1 and 2.

Value	Port	NAT Limitations	Comments
Sun RPC over UDP	UDP/111	No NAT or PAT.	The default rule includes UDP port 111; if you want to enable Sun RPC inspection for TCP port 111, you need to create a new rule that matches TCP port 111 and performs Sun RPC inspection.
TFTP	UDP/69		Payload IP addresses are not translated.
XDMCP	UDP/177	No NAT or PAT.	

Configuring TCP Maps

Use the Add and Edit TCP Map dialog boxes to define TCP normalization maps for use with IPS, QoS, and Connection Rules service policies. The TCP normalization feature lets you specify criteria that identify abnormal packets, which the security appliance drops when they are detected. The map is used for TCP traffic that passes through the device or that is going to the device.

These TCP maps can be applied to TCP flows on PIX 7.x+ and ASA devices. For more information on configuring IPS, QoS, and Connection Rules, see About Service Policy Rules, on page 2259.

Navigation Path

Select **Manage > Policy Objects**, then select **Maps > TCP Maps** from the Object Type selector. Right-click inside the work area and choose New Object, or right-click a row and choose Edit Object.

These dialog boxes also can be opened by clicking the Create or Edit buttons in the TCP Maps Selector while defining a Service Policy rule. See the “Connection Settings” section of Step 3. Configure the MPC actions , on page 2266 for more information about enabling TCP normalization and selecting a TCP map.

Related Topics

- Understanding Map Objects , on page 308

Field Reference

Table 818: Add and Edit TCP Map Dialog Boxes

Element	Description
Name	The name of the TCP normalization map. A maximum of 128 characters is allowed.
Description	A description of the map object. A maximum of 1024 characters is allowed.

Element	Description
Queue Limit (ASA devices only)	The maximum number of out-of-order packets that can be buffered and put in order for a TCP connection; enter a value between 1 and 250. Enter 0 to disable this setting and use the default system queue limit, which depends on the type of traffic: • Connections for application inspection, IPS, and TCP check-retransmission have a queue limit of 3 packets. If the security appliance receives a TCP packet with a different window size, then the queue limit is dynamically changed to match the advertised setting. • For other TCP connections, out-of-order packets are passed through untouched. However, if you set the Queue Limit to 1 or higher, the number of out-of-order packets allowed for all TCP traffic matches the specified value. For application inspection, IPS, and TCP check-retransmission traffic, any advertised settings are ignored. For other TCP traffic, out-of-order packets are now buffered and put in order instead of passed through untouched.
Time Out (ASA 7.2(4)+ devices only)	The maximum amount of time that out-of-order packets can remain in the buffer before they are dropped; enter a value between 1 and 20 seconds. The default is 4 seconds. This setting is ignored if you entered 0 for the Queue Limit.
Verify TCP Checksum	If checked, checksum verification is enabled.
Drop SYN Packets with Data	If checked, TCP SYN packets that include data are dropped.
Drop Connection on Window Variation	If checked, connections that change window size unexpectedly are dropped.
Drop Packets that Exceed Maximum Segment Size	If checked, packets that exceed the maximum segment size (MSS) set by a peer are dropped.
Check if Transmitted Data is the Same as Original	If checked, retransmit data checking is enabled.
Clear Urgent Flag	If checked, the URG (urgent) flag is cleared through the security appliance. The URG flag is used to indicate that the packet contains information that is of higher priority than other data within the stream. The TCP RFC is vague about the exact interpretation of the URG flag; therefore end systems handle urgent offsets in different ways, which may make the end system vulnerable.

Element	Description
Enable TTL Evasion Protection	Enables the TTL evasion protection offered by the security appliance. Do not enable this option if you want to prevent attacks that attempt to evade security policy. For example, an attacker can send a packet that passes policy with a very short TTL. When the TTL goes to zero, a router between the security appliance and the endpoint drops the packet. It is at this point that the attacker can send a malicious packet with a long TTL that appears to the security appliance to be a retransmission and is passed. To the endpoint host, however, it is the first packet that has been received. In this case, an attacker is able to succeed without security preventing the attack.
Selective Acknowledgment	
Clear Selective Ack	When checked, clears window selective acknowledgment mechanism option and allows packet. When unchecked, allows packets with single selective acknowledgment option.
Selective Ack Allow Multiple	Whether or not packets with multiple selective acknowledgment mechanism (SACK) are allowed.
Note If the selective acknowledgment options are not configured, by default, packets with a single selective acknowledgment option are allowed and packets with multiple selective acknowledgment options are dropped.	
TCP Timestamp	
Clear TCP Timestamp	When checked, clears TCP timestamp option and allows packet. When unchecked, allows packets with single TCP timestamp option. **Note** When the Clear TCP timestamp option is enabled, PAWS and RTT are disabled.
TCP Timestamp Allow multiple	Whether or not packets with multiple TCP timestamp option are allowed.
Note If the TCP timestamp options are not configured, by default, packets with a single TCP timestamp option are allowed and packets with multiple TCP timestamp options are dropped.	
Window Scale	
Clear Window Scale	When checked, clears window scale timestamp option and allows packet. When unchecked, allows packet with single window scale option.
Window Scale Allow Multiple	Whether or not the packets with multiple window scale timestamp option are allowed.
Note If the window scale options are not configured, by default, packets with a single window scale option are allowed and packets with multiple window scale options are dropped.	
Maximum Segment Size (MSS)	
Clear MSS	When checked, clears MSS option and allows packet. When unchecked, allows packet with a single MSS option.

Element	Description
MSS Allow Multiple	Whether or not the packets with multiple MSS options are allowed.
Max. MSS	Enter a value for the TCP MSS limit in bytes. Valid values are between 68- 65535.
Note If the MSS options are not configured, by default, packets with a single MSS option are allowed and packets with multiple MSS options are dropped.	
Allow packets with MD5 option	Whether or not to allow packets with the MD5 option. The Allow, Allow Multiple and Clear checkboxes are available when packets with MD5 option are allowed. Allow: This allows a packet with a single MD5 option. Allow Multiple: This allows a packet with multiple MD5 options. Clear: This clears the MD5 option and allows a packet.
Note If the MD5 options are not configured, by default, packets with a single MD5 option are allowed and packets with multiple MD5 options are dropped.	
Reserved Bits	Specify how to handle TCP packets with the reserved bits set in the TCP header. The six reserved bits in the TCP header are for future use and usually have a value of 0. • Clear and Allow—Clears the reserved bits in the TCP header and allows the packet. • Allow only—Permits packets with the reserved bits set in the TCP header. • Drop—Drops packets with the reserved bits set in the TCP header.
TCP Range Options table	The TCP Range Options table lists TCP options ranges defined for the TCP map, and the action to take for those options. The typical range numbers are 6-7, 9-18 and 20-255; the lower bound must be less than or equal to the upper bound. • To add a range, click the Add button to open the Add TCP Option Range dialog box (see Add and Edit TCP Option Range Dialog Boxes , on page 2285). • To edit a range, select it and click the Edit button. • To delete a range, select it and click the Delete button. **Note** Prior to ASA 9.6(2), the TCP values are in the range of 6-7 and 9-255.
Category	The category assigned to the map object. Categories help you organize and identify rules and objects. See Using Category Objects , on page 241.

Add and Edit TCP Option Range Dialog Boxes

Use the Add and Edit TCP Option Range dialog boxes to define or edit a range of TCP options for use with a TCP normalization map; these are TCP options not explicitly supported on the device. This feature lets you allow or discard packets with the specified TCP options set. The typical range numbers are 6-7, 9-18 and 20-255.

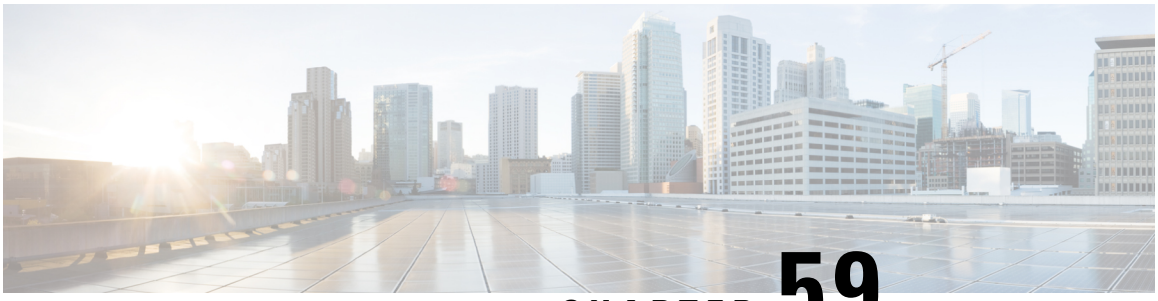
Navigation Path

In the Add and Edit TCP Map dialog boxes, right-click inside the TCP Range Options table and choose Add Row, or right-click an existing row and choose Edit Row. See Configuring TCP Maps , on page 2281.

Field Reference

Table 819: Add and Edit TCP Option Range Dialog Boxes

Element	Description
Note Prior to ASA 9.6(2), specify either 6 or 7 or an integer from 9-255 for the lower and upper bounds of the range, respectively. For all devices, the Lower bound must be less than or equal to the Upper bound.	
Lower	The lower bound of the range; enter either 6 or 7, or an integer from 9 to 18 or an integer from 20-255.
Upper	The upper bound of the range; enter either 6 or 7, or an integer from 9 to 18 or an integer from 20-255.
Action	Choose the action to take for packets with the specified options set: • Allow – Allows any packet with a specified option set. • Clear – Clears the specified option from any packet that has it set and allows the packet. • Drop – Discards any packet with a specified option set.



CHAPTER 59

Configuring Security Contexts on Firewall Devices

You can define multiple security "contexts" on a single security appliance. Each context operates as an independent virtual device, with its own security policy, interfaces and administrators. Multiple contexts are similar to having multiple stand-alone devices. Many features are supported in multiple-context mode, including routing tables, firewall features, IPS, and management. Some features are not supported; for example, VPN, multicast, and dynamic routing protocols; security contexts support only static routes; and you cannot enable OSPF or RIP in multiple-context mode. Also, some features are not directly managed by Cisco Security Manager, such as the IPS feature set for ASA and PIX devices.

In multiple-context mode, the security appliance includes a configuration for each context that identifies the security policy, interfaces, and most of the options you can configure on a stand-alone device. The system administrator adds and manages contexts by configuring them in the system configuration, which, like a single-mode configuration, is the start-up configuration. The system configuration identifies basic settings for the security appliance, but it does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses the context that is designated as the Admin context. The system configuration is used to add, delete and edit basic context settings, including allocating network interfaces to the various contexts.

The Admin context is just like any other context, except that when a user logs in to the Admin context, that user has system administrator rights and can access the system configuration and all other contexts.

This chapter contains the following topics:

Enabling and Disabling Multiple-Context Mode

Cisco Security Manager does not support switching to multiple-context mode on an existing device. To perform this task, you must delete the device from Security Manager, enable multiple-context mode using a device manager or CLI input, and then add the device again to Security Manager. After the device is added in multiple-context mode, you can add, edit and delete security contexts.

Note When manually defining a multiple-context device, choose **Multi** from the Contexts list in the Operating System section of the New Device - Device Information dialog box.

Similarly, Cisco Security Manager does not support restoring an existing device to single-context mode. To perform this task, you must delete the device and any of its child contexts from Security Manager, restore single-context operation using a device manager or CLI input, and then add the device again to Security Manager.

Note When manually defining a single-context device, choose **Single** from the Contexts list in the Operating System section of the New Device - Device Information dialog box.

Checklist for Configuring Multiple Security Contexts

Security contexts allow a single physical device to act as multiple independent firewalls. Each security context defines a single virtual firewall, complete with its own configuration—and just as with physical devices, each security context must be correctly configured, or overall security can be compromised. Thus, defining and configuring multiple firewalls on the same physical appliance requires special care.

The following checklist outlines the basic steps necessary to configure a firewall device with multiple security contexts. Each of these steps may involve multiple substeps; all steps should be performed in the order presented. For example, you must define interfaces before configuring the various contexts.

Step	Task
Step 1	**Define interfaces and subinterfaces, or VLANs, on the physical appliance.** In this task, you define the interfaces and subinterfaces, or VLANs on FWSMs, that will be allocated to the various security contexts when you create them later. Provide physical interface parameters, such as connection type (Ethernet, GigabitEthernet, etc.), hardware Port ID, speed, and duplex mode, as well as VLAN ID if defining a subinterface. **Result**: All interfaces and subinterfaces are defined. For more information, see Configuring Firewall Device Interfaces , on page 1805.

Step	Task
Step 2	**Define an Admin context for administering the base security appliance.** This task is called out separately to ensure you define a context and IP address specifically for administration of the security appliance. The process is the same as defining a security context; however, during the process, be sure to check **Admin Context** to designate this as the administration context. In addition to being used to administer the appliance, the Admin context is used to publish syslog and SNMP messages to monitoring devices, such as the Cisco Security Monitoring, Analysis and Response System (CS-MARS), for further processing. Until you associate a specific management IP address with the Admin context, the IP address used to manage the security appliance is the one you specified when defining the device. When you specify a Management IP Address with the Admin context, it takes precedence over the one on the Device Properties page. **Result**: The Admin context is defined and associated with a physical interface. For more information, see: • Add/Edit Security Context Dialog Box (PIX/ASA) , on page 2293 • Add/Edit Security Context Dialog Box (FWSM) , on page 2291
Step 3	**Define each security context, or virtual firewall, on the base appliance.** In this task, you define individual security contexts, naming each, assigning a location for its configuration files, and allocating interfaces. Each security context represents a virtual firewall, and its definition includes the interfaces and range of associated VLAN IDs that are under its control. **Note** While the Admin context can operate as a firewall device, it is typically used as such only in single-context mode. Therefore, security contexts are treated as separate entities in this checklist. You cannot add new interfaces or modify the hardware Port value when defining a security context—you simply select previously defined interfaces for allocation to the context. **Result**: Each security context is defined and associated with a physical interface; the VLANs on which the security context will inspect traffic are also specified. For more information, see: • Add/Edit Security Context Dialog Box (PIX/ASA) , on page 2293 • Add/Edit Security Context Dialog Box (FWSM) , on page 2291

Step	Task
Step 4	**Submit/deploy to generate the virtual firewalls as children of the base appliance.** You must create the desired contexts on the security appliance before you can begin defining the individual settings of each context. To create contexts on the appliance, you must define them, and then either submit changes in Workflow mode, or deploy the changes to the security appliance in non-Workflow mode. When you create a security context, a "virtual firewall device" appears beneath the original security appliance in the Device View. Each virtual device is indicated by a related device icon with a dotted outline, and its name is the base security appliance name, underscore (_), context name. For example, the virtual device *asaMultiRouted_admin* would represent the Admin context (named "admin") on the security appliance named "asaMultiRouted." Similarly, *asaMultiRouted_security1* would represent the security context "security1" on the same base appliance. **Result**: Your changes are submitted or deployed (depending on the Workflow mode), which in turn creates the Admin and security contexts as children of the base security appliance. For more information, see: • Workflow and Activities Overview , on page 20 • Submitting an Activity for Approval (Workflow Mode with Activity Approver) , on page 161 • Working with Deployment and the Configuration Archive , on page 405
Step 5	**Define additional settings for each security context.** You can now complete the definition of each security context by selecting a virtual firewall device in the Device Selector and editing available policies, such as access rules, translation options and so on. **Result**: Each security context is fully defined, ready to operate as a virtual firewall.

Managing Security Contexts

The Security Contexts page lists security contexts configured for the selected device. You can add, edit and delete security contexts for an ASA, PIX 7.0+, or FWSM device running in multiple-context mode from this page.

Tip Deleting a security context from an FWSM device removes the security context from the running configuration of the device, but it does not delete the associated configuration file. This can cause problems if you later add another security context with the same name as the one previously deleted. This is a known issue for FWSM and is not connected to the behavior of Security Manager. A work-around is to use the CLI to delete the configuration file from the device.

Remember, the security appliance must be in multiple-context mode in order for you to configure contexts using Security Manager. See Enabling and Disabling Multiple-Context Mode , on page 2287 for more information.

Follow these steps to manage security contexts:

Step 1 Ensure Device View is your present application view; if necessary, click the **Device View** button on the toolbar.

For more information on using the Device View to configure device policies, see Managing Policies in Device View and the Site-to-Site VPN Manager , on page 196.

Step 2 Select the appliance you want to configure.

Step 3 Select **Security Contexts** in the Device Policy selector to display the Security Contexts page.

Note The child contexts of a multiple-mode device are represented using a different icon than firewall devices in single mode.

Step 4 Add, edit and delete contexts, as necessary:

- To define a new context, click the **Add Row** button at the bottom of the page to open the Add Security Context box.
- To edit an existing context, select the desired entry in the Security Contexts list and then click the **Edit Row** button at the bottom of the page to open the Edit Security Context dialog box.
- To delete an existing context, select the desired entry in the list and then click the **Delete Row** button.

Note Deleting a security context here will also cause the security context device to be removed from device inventory.

Confirm the deletion of the security context and corresponding security context device.

Note Except for the titles, the Add Security Context dialog box and the Edit Security Context dialog box are identical. For PIX/ASA devices, see Add/Edit Security Context Dialog Box (PIX/ASA) , on page 2293 for more information; for FWSMs, see Add/Edit Security Context Dialog Box (FWSM) , on page 2291 for more information.

Add/Edit Security Context Dialog Box (FWSM)

Note From version 4.17, though Cisco Security Manager continues to support FWSM features/functionality, it does not support any bug fixes or enhancements.

The Add Security Context and Edit Security Context dialog boxes let you define and maintain contexts for the currently selected Firewall Service Module. (Except for their titles, the two dialog boxes are identical.)

Note that at least one security context must be designated as the Admin context.

Caution Security Manager does not support mapped (that is, “named” or “aliased”) interfaces for FWSMs. If you discover an FWSM with named interfaces and then change the related configuration, redeployment will fail. Replace any interface aliases with the appropriate VLAN IDs.

Navigation Path

You can access the Add Security Context and Edit Security Context dialog boxes from the Security Contexts page, as described in Managing Security Contexts , on page 2290.

Field Reference

Table 820: Add/Edit Security Context Dialog Box (FWSM)

Element	Description
Name	Enter a name of up to 32 characters for the context. The names System and Null (in any combination of upper- and lower-case letters) are reserved, and cannot be used. **Note** While context names are case-sensitive on the device, they are not in Security Manager. That is, you cannot have two contexts with the same name but different capitalization in Security Manager.
Mode (FWSM 3.1+)	Choose the mode, Router or Transparent, for this security context. **Note** You cannot change the chosen mode in the Edit Security Context dialog box.
Admin Context	Check this box if this context is to be the Admin context for this device. **Note** The name of the Admin context for the device is displayed below the Security Contexts table.
VLAN IDs	Enter the VLANs assigned to this context. Use commas to separate multiple VLAN entries.
Config URL	Specify the context configuration location, as a URL-type address, by choosing a file-system protocol and then entering the path and name of the file to access for the context configuration. That is, choose a protocol type from the drop-down list, and then type the server name (for remote file systems), path, and file name in the related text field. For example, the combined URL for FTP has the following format: ftp://server.example.com/configs/admin.cfg . Available protocols are: • disk:/ • ftp:// • http:// • https:// • tftp://
Failover Group	If this context is part of an active/active failover configuration, choose the failover group to which this context belongs.
Description	Enter an optional description for the context.

Add/Edit Security Context Dialog Box (PIX/ASA)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

The Add Security Context and Edit Security Context dialog boxes let you define and maintain contexts for the currently selected PIX/ASA security appliance. (Except for their titles, the two dialog boxes are identical.)

Note that at least one security context must be designated as the Admin context.

Navigation Path

You can access the Add Security Context and Edit Security Context dialog boxes from the Security Contexts page, as described in Managing Security Contexts , on page 2290.

Field Reference

Table 821: Add/Edit Security Context Dialog Box (PIX/ASA)

Element	Description
Name	Enter a name of up to 32 characters for the context. The names System and Null (in any combination of upper- and lower-case letters) are reserved, and cannot be used. **Note** While context names are case-sensitive on the device, they are not in Security Manager. That is, you cannot have two contexts with the same name but different capitalization in Security Manager.
Description	Enter an optional description for the context.
Mode (ASA 9.0+)	Choose the mode, Router or Transparent, for this security context. **Note** You cannot change the chosen mode in the Edit Security Context dialog box.
Admin Context	Check this box if this context is to be the Admin context for this device. **Note** The name of the Admin context for the device is displayed below the Security Contexts table. **Note** If this box is checked, the IPv4 Address Pool field is disabled.

Element	Description
Config URL	Specify the context configuration location, as a URL-type address, by choosing a file-system protocol and then entering the path and name of the file to access for the context configuration. That is, choose a protocol type from the drop-down list, and then type the server name (for remote file systems), path, and file name in the related text field. For example, the combined URL for FTP has the following format: ftp://server.example.com/configs/admin.cfg . Available protocols are: • disk0:/ • disk1:/ • flash:/ • ftp:// • http:// • https:// • tftp://
VPN in multiple context mode—Beginning with Security Manager version 4.12 for ASA version 9.6(2) devices, remote access VPN on multi-context supports flash virtualization. Within a multi-context structure, each created user context can have a private storage space and a shared storage place based on the total flash that is available.	
Storage URL - Private	Click the Private check box to store files associated only with that user and specific to the content that you want for that user. From the drop-down menu, choose the private directory that you created and map it to what you designated in Config URL. Select one of the following options for Private Storage URL for multi-context ASA 9.6(2) or later devices. • disk0:/ • flash:/ The default value of Storage URL - Private is **disk0:/**. You can modify this value. This context label name is used as a directory while performing any file deploy activity for ASA 9.6(2) Multi Context devices.

Element	Description
Storage URL - Shared	Click the Shared check box to upload files to the shared storage space and have it accessible to any user context for read/write access. From the drop-down menu. choose the shared directory that you created and map it to what you designated in Config URL. Select one of the following options for Shared Storage URL for multi-context ASA 9.6(2) or later devices. • disk0:/ • flash:/ The default value of Storage URL - Shared is **shared**. You can modify this value. This context label name is used as a directory while performing any file deploy activity for ASA 9.6(2) Multi Context devices.
ScanSafe Settings	To enable ScanSafe inspection in this context, select Enable ScanSafe Web Security. To override the license specified in the system configuration, enter a license ID in the License field; must be 32 hexadecimal characters.
Interfaces	This table lists the interfaces and subinterfaces allocated to this context, and their associated settings. These are the interfaces and subinterfaces for which the security context will inspect traffic. To add interfaces and subinterfaces to this context, click the Add Row button below the table to open the Allocate Interfaces Dialog Box (PIX/ASA only) , on page 2295. You can allocate one or more interfaces, and optionally with each interface, one or a range of subinterfaces. To edit an allocation entry, select it and then click the Edit Row button below the table to open the Edit Interface dialog box. Note that you can edit only the Alias Name and the Show hardware properties option; you cannot change the interface/subinterface assignments. Refer to Allocate Interfaces Dialog Box (PIX/ASA only) , on page 2295 for more information about these options. To remove an interface/subinterface allocation, select the appropriate row in this table and then click the Delete Row button below the table.
Failover Group	If this context is part of an active/active failover configuration, choose the failover group to which this context belongs.

Allocate Interfaces Dialog Box (PIX/ASA only)

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

The Allocate Interfaces dialog box lets you assign an interface, and optionally one or a range of related subinterfaces, to a context, and set name-aliasing options.

Navigation Path

You access the Allocate Interfaces dialog box from the Add Security Context and Edit Security Context dialog boxes. See for more information.

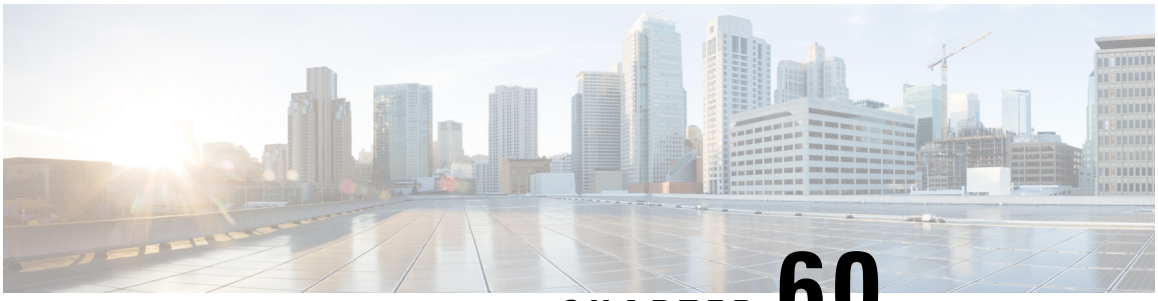
Related Topics

- Managing Security Contexts , on page 2290

Field Reference

Table 822: Allocate Interfaces Dialog Box

Element	Description
Physical Interface	Choose a physical interface to assign to this context. In transparent firewall mode, you can assign only an interface that has not been allocated to another context. If you choose an interface already assigned to another context, you must also specify an subinterface.
Sub Interface ID From/To	Use these drop-down lists to specify a subinterface, or a range of subinterfaces; both lists present the subinterface IDs associated with the chosen Physical Interface. To specify a single subinterface, choose the desired ID from the first list. To specify a range, if available, choose the ending ID from the second list. (In transparent firewall mode, only subinterfaces that have not been allocated to other contexts are shown.)
View Allocation button	Click this button to open the View Interface Allocation dialog box, which presents a read-only list of all physical interfaces defined on this device and the security contexts and failover groups associated with each. You can use this to quickly determine current allocations without closing the Allocate Interfaces dialog box.
Use aliased name in context	To enable name aliasing for this interface/subinterface, check **Use aliased names in the security context** and then enter an alias in the Alias Name field. The specified alias replaces the name of this physical interface or subinterface anywhere it would be displayed for this context—for example, the Hardware Port column on the Interfaces Page.
Alias Name	Enter the desired alias. An alias must start with a letter, end with a letter or digit, and have as interior characters only letters, digits, and underscores.
Suffix Range From/To	If you specified a range of subinterfaces, these fields are available to let you specify numeric suffixes for their aliased name. The aliased name for each subinterface consists of its sequence number from this range appended to the Alias Name you provided in the previous field. These values default to the beginning and ending subinterface ID numbers, but you can enter any valid range of numbers.
Show hardware properties in context	Select this option to allow the **show interface** CLI command to display of physical interface properties for the context even if you defined an alias. If not selected, the show interface output includes the aliased name.



CHAPTER 60

User Preferences

The User Preferences section consists of the Deployment page and the Transactional Commit page. The Deployment page provides access to the Clear XLATE on deployment option. The Transactional Commit page allows you to enable or disable the transactional commit model for access rules or NAT rules.

Configuring Deployment Preferences on Firewall Devices

Use the User Preferences Deployment page to specify deployment options for specific firewall devices. You can create a policy with the deployment options you want to use and then apply that policy to all devices that you want using those deployment settings.

Step 1 Do one of the following:

- (Device view) Select **Platform > User Preferences > Deployment** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > User Preferences > Deployment** from the Policy Types selector. Right-click **Deployment** and choose **New Deployment Policy** to create a policy, or select an existing policy from the Policies selector

.

The Deployment page is displayed.

Step 2 Check **Clear XLATE on deployment** if you want the translation table cleared when a configuration is deployed to this device.

Select this option to send a **clear xlate** command to the firewall before changes to access lists are made. This command clears all NAT translations. By default this option is not selected.

Note This option is necessary for certain commands to take effect. If these commands are changed, you should make sure this option is enabled for the device. However, clearing the translation table disconnects all current connections that use translations.

Step 3 Click **Save** at the bottom of the page.

Configuring Transactional Commit Preferences on Firewall Devices

By default, when you change a rule-based policy (such as access rules), the changes become effective immediately. However, this immediacy comes at a slight cost in performance. The performance cost is more noticeable for very large rule lists in a high connections-per-second environment, for example, when you change a policy with 25,000 rules while the ASA is handling 18,000 connections per second.

The performance is affected because the rule engine compiles rules to enable faster rule lookup. By default, the system will also search uncompiled rules when evaluating a connection attempt so that new rules can be applied; since the rules are not compiled, the search takes longer.

Beginning with ASA 9.1(5), you can change this behavior so that the rule engine uses a transactional model when implementing rule changes, continuing to use the old rules until the new rules are compiled and ready for use. Using the transactional model, performance should not drop during the rule compilation. The following table clarifies the behavioral difference.

Model	Before Compilation	During Compilation	After Compilation
Default	Match old rules	Match new rules. (Connections per second rate will decrease.)	Match new rules.
Transactional	Match old rules	Match old rules. (Connections per second rate will be unaffected.)	Match new rules.

An additional benefit of the transactional model is that, when replacing an ACL on an interface, there is no gap between deleting the old ACL and applying the new one. This reduces the chances that acceptable connections will be dropped during the operation.

Tip If you enable the transactional model for a rule type, there are syslog messages to mark the beginning and the end of the compilation. These messages are numbered 780001 and following.

Step 1 Do one of the following:

- (Device view) Select **Platform** > **User Preferences** > **Transactional Commit** from the Device Policy selector.
- (Policy view) Select **PIX/ASA/FWSM Platform > User Preferences > Transactional Commit** from the Policy Types selector. Right-click **Transactional Commit** and choose **New Transactional Commit Policy** to create a policy, or select an existing policy from the Policies selector.

The Transactional Commit page is displayed.

Step 2 Enable the transactional commit model for the desired features. Options include:

- Access Group

- NAT

Step 3 Click **Save** at the bottom of the page.

PART VI

Router and Switch Device Configuration

CHAPTER 61

Managing Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Cisco Security Manager supports the management and configuration of security features and other platform-specific features on Cisco IOS access security routers. You configure these features in the form of policies, each of which defines a different aspect of the configuration of the router. For a detailed explanation of the policy paradigm used by Security Manager, Understanding Policies , on page 167

You can discover the configurations that are already defined on Cisco IOS routers. The discovery process imports the device configuration into Security Manager as policies and policy objects that you can then manage as required. For more information, see Discovering Router Policies , on page 2305

Note Security Manager supports Cisco IOS Software Releases 12.3 and later. However, a limited number of policies are supported for routers running Cisco IOS Software Release 12.1 or 12.2. See Configuring Routers Running IOS Software Releases 12.1 and 12.2 , on page 2305

By right-clicking a policy type in one of the policy selectors, you can assign a policy to a single router, share the policy among multiple routers, or unassign the policy from the device.

The following topics describe how to configure platform policies and interface policies on Cisco IOS routers:

- Interface polices:
  - Basic Interface Settings on Cisco IOS Routers , on page 2307
  - Advanced Interface Settings on Cisco IOS Routers , on page 2318
  - IPS Module Interface Settings Page , on page 2327
  - CEF Interface Settings on Cisco IOS Routers , on page 2330
  - Dialer Interfaces on Cisco IOS Routers , on page 2333
  - ADSL on Cisco IOS Routers , on page 2339
  - SHDSL on Cisco IOS Routers , on page 2346
  - PVCs on Cisco IOS Routers , on page 2352

- PPP on Cisco IOS Routers , on page 2376

- Device administration policies:
  - AAA on Cisco IOS Routers , on page 2390
  - User Accounts and Device Credentials on Cisco IOS Routers , on page 2402
  - Bridging on Cisco IOS Routers , on page 2407
  - Time Zone Settings on Cisco IOS Routers , on page 2411
  - CPU Utilization Settings on Cisco IOS Routers , on page 2414
  - HTTP and HTTPS on Cisco IOS Routers , on page 2417
  - Line Access on Cisco IOS Routers , on page 2424
  - Optional SSH Settings on Cisco IOS Routers , on page 2452
  - SNMP on Cisco IOS Routers , on page 2456
  - DNS on Cisco IOS Routers , on page 2464
  - Hostnames and Domain Names on Cisco IOS Routers , on page 2467
  - Memory Settings on Cisco IOS Routers , on page 2468
  - Secure Device Provisioning on Cisco IOS Routers , on page 2471
  - DHCP Policy Page , on page 2482
  - NTP on Cisco IOS Routers , on page 2487

- Identity policies:
  - 802.1x on Cisco IOS Routers , on page 2493
  - 802.1x on Cisco IOS Routers , on page 2493
  - Network Admission Control on Cisco IOS Routers , on page 2500

- Logging policies:
  - Logging on Cisco IOS Routers , on page 2515

- Quality of Service:
  - Quality of Service on Cisco IOS Routers , on page 2531

- Routing policies:
  - BGP Routing on Cisco IOS Routers , on page 2565
  - EIGRP Routing on Cisco IOS Routers , on page 2573
  - OSPF Routing on Cisco IOS Routers , on page 2585

- RIP Routing on Cisco IOS Routers , on page 2608
- Static Routing on Cisco IOS Routers , on page 2617

Note The settings on the Policy Management page of the Security Manager Administration window determine which router platform policies can be managed with Security Manager. Any policy type that you do not select in this window does not appear on the configuration pages of Security Manager.

- Configuring Routers Running IOS Software Releases 12.1 and 12.2 , on page 2305
- Discovering Router Policies , on page 2305

Configuring Routers Running IOS Software Releases 12.1 and 12.2

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Security Manager provides limited support for routers running Cisco IOS Software Releases 12.1 and 12.2 (with the exception of the ASR 1000 Series, which supports more features). You can configure the following policies on these routers:

- Access Rules (Layer 3 only). See Understanding Access Rules , on page 717.
- Access Rule Settings. See Understanding Access Rules , on page 717.
- Interfaces. See Basic Interface Settings on Cisco IOS Routers , on page 2307.
- FlexConfigs. See Understanding FlexConfig Policies and Policy Objects , on page 342.

All other policies require Cisco IOS Software Release 12.3 or later. For more information about supported devices, see Supported Devices and Software Versions for Cisco Security Manager .

Discovering Router Policies

You can discover the configurations of your Cisco IOS routers and import these configurations as policies into Security Manager. This makes it possible to add existing devices and manage them with Security Manager without having to manually configure each device policy by policy. For more information, see Adding Devices to the Device Inventory , on page 77.

You can discover all Cisco IOS commands that can be configured with Security Manager. Discovery ignores unsupported commands, which means that they are left intact on the device even after subsequent deployments. Additionally, in cases where Security Manager can discover the command, but not all the subcommands and keywords related to that command, the unsupported elements are ignored and left intact on the device.

You can also rediscover the configurations of devices that you are already managing with Security Manager at any time. Be aware, however, that performing rediscovery overwrites the policies that you have defined in

Security Manager, and is therefore not generally recommended. For more information, see Discovering Policies on Devices Already in Security Manager , on page 181.

Note We recommend that you perform deployment immediately after you discover the policies on a Cisco IOS router, *before* you make any changes to policies or unassign policies from the device. Otherwise, the changes that you configure in Security Manager might not be deployed to the device.

Note If a policy that is not configured in Security Manager was configured on the device using an out-of-band method (such as the CLI) between the time of the first discovery and rediscovery, we recommend that you perform deployment immediately after rediscovery.

CHAPTER 62

Configuring Router Interfaces

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

This chapter contains the following topics:

Basic Interface Settings on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

You typically add interfaces to Security Manager by performing discovery, as described in Discovering Policies , on page 178. After you have discovered the interfaces, you can modify the properties of each interface.

You can also use Security Manager to configure physical and virtual interfaces manually. This is useful when you modify interface configurations of existing devices, and makes it possible for you to configure all the interfaces of a device before you physically add the device to the network.

Related Topics

- Defining Basic Router Interface Settings , on page 2310
- Deleting a Cisco IOS Router Interface , on page 2312

Available Interface Types

Table 823: Router Interface Types , on page 2308 describes the types of interfaces that can be configured on Cisco IOS routers.

Table 823: Router Interface Types

Type	Description
Null	Null interface.
Analysis-module	A Fast Ethernet interface that connects to the internal interface on the Network Analysis Module (NAM). **Note** You cannot configure parameters such as speed and duplex mode for this type of interface.
Async	Port line used as an asynchronous interface.
ATM	ATM interface.
BRI	ISDN BRI interface. This interface configuration propagates to each B channel. B channels cannot be configured individually. **Note** You must configure a dialer interface policy for calls to be placed on a BRI interface. For more information, see Dialer Interfaces on Cisco IOS Routers , on page 2333.
BVI	Bridge-group virtual interface. BVI interfaces are used to route traffic at Layer 3 to the interfaces in a bridge group.
Content-engine	Content engine (CE) network module interface. **Note** You cannot configure parameters such as speed and duplex mode for this type of interface. You cannot create subinterfaces for this type of interface.
Dialer	Dialer interface.
Ethernet	Ethernet IEEE 802.3 interface.

Type	Description
Fast Ethernet	100-Mbps Ethernet interface.
FDDI	Fiber Distributed Data Interface.
Gigabit Ethernet	1000-Mbps Ethernet interface.
Group-Async	Main asynchronous interface. This interface type creates a single asynchronous interfaces to which other interfaces are associated. This one-to-many configuration enables you to configure all associated member interfaces by configuring the main interface.
HSSI	High-Speed Serial Interface.
Loopback	A logical interface that emulates an interface that is always up. For example, having a loopback interface on the router prevents a loss of adjacency with neighboring OSPF routers if the physical interfaces on the router go down. The name of a loopback interface must end with a number ranging from 0-2147483647. **Note** This interface type is supported on all platforms. You can create an unlimited number of loopback interfaces.
Multilink	Multilink interface. A logical interface used for multilink PPP (MLP).
Port channel	Port channel interface. This interface type enables you to bundle multiple point-to-point Fast Ethernet links into one logical link. It provides bidirectional bandwidth of up to 800 Mbps.
POS	Packet OC-3 interface on the Packet-over-SONET (POS) interface processor.
PRI	ISDN PRI interface. Includes 23/30 B-channels and one D-channel.
Serial	Serial interface.
Switch	Switch interface.
Ten Gigabit Ethernet	10000-Mbps Ethernet interface.
Token Ring	Token Ring interface.
Tunnel	Tunnel interface. **Note** You can create an unlimited number of virtual, tunnel interfaces. Valid values range from 0-2147483647.
VG-AnyLAN	100VG-AnyLAN port adapter.
VLAN	Virtual LAN subinterface.
Virtual Template	Virtual template interface. When a user dials in, a predefined configuration template is used to configure a virtual access interface; when the user is done, the virtual access interface goes down and the resources are freed for other dial-in uses.

Related Topics

- Defining Basic Router Interface Settings , on page 2310
- Deleting a Cisco IOS Router Interface , on page 2312
- Basic Interface Settings on Cisco IOS Routers , on page 2307

Defining Basic Router Interface Settings

When you define an interface or subinterface for a Cisco IOS router, you name it, specify how it is assigned an IP address, and optionally define other properties, such as the speed, maximum transmission unit (MTU), and the encapsulation type.

Note Basic interface settings are always local to the device on which they are configured. You cannot share this policy with other devices. You can, however, share advanced interface settings. For more information, see Advanced Interface Settings on Cisco IOS Routers , on page 2318.

Related Topics

- Deleting a Cisco IOS Router Interface , on page 2312

Step 1 In Device view, select **Interfaces > Interfaces** from the Policy selector.

The Router Interfaces Page , on page 2313 is displayed.

Step 2 To add a new interface or subinterface, click the Add Row button to open the Create Router Interface dialog box.

To edit an existing interface or subinterface, select it in the Interfaces table, and then click the Edit Row button to open the Edit Router Interface dialog box. Refer to Create Router Interface Dialog Box , on page 2314 for descriptions of the fields in these dialog boxes.

Step 3 Select **Enabled** to have Security Manager actively manage this interface or subinterface. If this option is deselected, the interface/subinterface definition is retained, but the interface/subinterface itself is disabled (or "shutdown").

Step 4 Choose **Interface** or **Subinterface** from the Type list.

Step 5 If you are creating an interface, enter a name for the interface. You can click **Select** to open a dialog box that will help you generate a standard name based on interface type and details about the interface's location, such as card, slot, and subinterface. For more information on using the dialog box to generate an interface name, see Interface Auto Name Generator Dialog Box , on page 2318.

Note When naming a BVI interface, use the bridge group number as the card number. Deployment will fail if you configure a BVI interface without configuring a corresponding bridge group.

Step 6 If you are creating a subinterface, provide the following:

a) **Parent**—Choose the parent interface for this subinterface.
b) **Subinterface ID**—Enter a number to identify the subinterface.

Note Security Manager configures serial subinterfaces as point-to-point, not multipoint.

Step 7 To specify a **Layer Type**, choose a Level 2 (data link) or Level 3 (network) option from this list.

Step 8 Choose a method of **IP** address assignment for this interface/subinterface, then provide additional information, as required:

- **Static IP**—Provide an **IP Address** and **Subnet Mask**.
- **DHCP**—No additional information is required.
- **PPPoE**—No additional information is required.
- **Unnumbered**—Provide the name of the interface from which an IP address is to be "borrowed."

Note Layer 2 interfaces do not support IP addresses.

Step 9 Define additional properties of the interface/subinterface:

- Use the **Negotiation** check box to enable and disable auto-negotiation for the interface.

Auto-negotiation detects the capabilities of remote devices and negotiates the best possible performance between the two devices. When Negotiation is enabled, the Fast Ethernet Duplex and Speed options are disabled.

Note Auto-negotiation is available only for Fast Ethernet and Gigabit Ethernet interfaces on ASR devices.

- Choose a transmission mode from the **Duplex** list. If you choose Auto, be sure the network device to which this interface is connected is set to automatically detect the transmission mode. (Auto is not available on ASRs; use auto-negotiation instead.)

Note You must configure a fixed speed to define the duplex value. Tunnel and loopback interfaces do not support this setting.

- Choose a transmission speed from the **Speed** list. If you choose Auto, be sure the network device to which this interface is connected is set to automatically detect the transmission speed. (Auto is not available on ASRs; use auto-negotiation instead.)
- Enter the maximum transmission unit (**MTU**), which defines the largest packet size, in bytes, that this interface can support.

Note Certain interface properties are set automatically, or are unavailable, depending on the interface type and the underlying port type. For example, the Speed options are available for Fast Ethernet and Gigabit Ethernet interfaces only.

Step 10 Choose an encapsulation method from the **Encapsulation** list:

- **None**—No encapsulation; no additional parameters are required.
- (Ethernet subinterfaces only) **DOT1Q**—VLAN encapsulation, as defined by the IEEE 802.1Q standard. Provide the following VLAN parameters for this subinterface:
  - Enter a VLAN ID to associate with this subinterface.

Note All VLAN IDs must be unique among all subinterfaces configured on the same physical interface.

- If you are defining the 802.1Q trunk interface, select Native VLAN.

Tip To configure DOT1Q encapsulation on an Ethernet interface without associating a VLAN with the subinterface, enter the **vlan-id dot1q**command using CLI commands or FlexConfigs. See Understanding FlexConfig Policies and Policy Objects , on page 342. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the router.

- (Serial interfaces only) **Frame Relay**—IETF Frame Relay encapsulation. Provide a data-link connection identifier (DLCI) for the subinterface.

Note Frame relay must be configured on the parent interface.

Note IETF Frame Relay encapsulation provides interoperability between a Cisco IOS router and equipment from other vendors. To configure Cisco Frame Relay encapsulation, use CLI commands or FlexConfigs.

Step 11 (Optional) Enter a description of up to 1024 characters for the interface.

Step 12 Click **OK** to save the interface/subinterface definition and close the dialog box. The new interface is displayed on the Router Interfaces page. Subinterfaces are displayed beneath the parent interface.

Deleting a Cisco IOS Router Interface

Although you can delete the definition of a virtual interface at any time, use this option with great care. If the interface is included in any policy definitions that exist for this router, deleting the interface causes these policy definitions to fail when they are deployed to the device.

Note Deleting the basic interface definition does not delete any advanced settings that are configured under **Interface** > **Settings** > **Advanced Settings**. You must delete these advanced settings separately. If you fail to do so, deployment fails.

Note Deleting the definition of a physical interface from the Router Interfaces page does not remove the interface from the device. If you perform this operation by mistake, you can perform rediscovery to restore the definition to Security Manager. For more information, see Discovering Policies on Devices Already in Security Manager , on page 181.

Related Topics

- Defining Basic Router Interface Settings , on page 2310
- Basic Interface Settings on Cisco IOS Routers , on page 2307

Step 1 Click the **Device View** button on the toolbar.

Step 2 Select a router from the Device selector.

Step 3 Select **Interfaces** > **Interfaces** from the Policy selector. The Router Interfaces page is displayed. See Table 824: Router Interfaces Page , on page 2313 for an explanation of the fields on this page.

Step 4 Select an interface from the table, then click the **Delete** button. The interface is deleted.

Router Interfaces Page

Use the Router Interfaces page to view, create, edit, and delete interface definitions (physical and virtual) on a selected Cisco IOS router. The Router Interfaces page displays interfaces that were discovered by Security Manager as well as interfaces added manually after you added the device to the system.

Note Unlike other router policies, the Interfaces policy cannot be shared among multiple devices. The Advanced Settings policy, however, may be shared. See Local Policies vs. Shared Policies , on page 169.

For more information, see Basic Interface Settings on Cisco IOS Routers , on page 2307.

Navigation Path

Select a Cisco IOS router from the Device selector, then select **Interfaces > Interfaces** from the Policy selector.

- Deleting a Cisco IOS Router Interface , on page 2312
- Table Columns and Column Heading Features , on page 51
- Filtering Tables , on page 50

Field Reference

Table 824: Router Interfaces Page

Element	Description
Interface Type	The interface type. Subinterfaces are displayed indented beneath their parent interface.
Interface Name	The name of the interface.
Enabled	Indicates whether the interface is currently enabled (managed by Security Manager) or disabled (shutdown state).
IP Address	The IP address of interfaces defined with a static address.
IP Address Type	The type of IP address assigned to the interface—static, DHCP, PPPoE, or unnumbered. (IP address is defined by a selected interface role.)
Interface Role	The interface roles that are assigned to the selected interface.
Add button	Opens the Create Router Interface Dialog Box , on page 2314. From here you can create an interface on the selected router.
Edit button	Opens the Create Router Interface Dialog Box , on page 2314. From here you can edit the selected interface.

Element	Description
Delete button	Deletes the selected interfaces from the table. Ensure that the interface is not being used in any other policy before deleting it.

Create Router Interface Dialog Box

Use the Create Router Interface dialog box to create and edit physical and virtual interfaces on the selected Cisco IOS router.

Tip Interface configuration is specific to the type of device. Many of the options on this page might be greyed out for specific device or interface types because they do not apply or they are not configurable.

Navigation Path

Go to the Router Interfaces Page , on page 2313, then click the **Add** or **Edit** button beneath the table.

- Deleting a Cisco IOS Router Interface , on page 2312
- Advanced Interface Settings on Cisco IOS Routers , on page 2318

Field Reference

Table 825: Create Router Interface Dialog Box

Element	Description
Enabled	Whether the interface is enabled (no shutdown). If you deselect this option, the interface is created in the configuration but it is shut down.
Type	Specifies whether you are defining an interface or subinterface.
Name	Applies only to interfaces. The name of the interface. Enter a name manually, or click **Select** to display a dialog box for generating a name automatically. See Interface Auto Name Generator Dialog Box , on page 2318. Logical interfaces require a number after the name: • The range for dialer interfaces is 0-799. • The range for loopback interfaces is 0-2147483647. • The range for BVI interfaces is 1-255. • The only allowed value for null interfaces is 0.

Element	Description
Parent	Applies only to subinterfaces. The parent interface of the subinterface. Choose the parent interface from this list.
Subinterface ID	Applies only to subinterfaces. The ID number of the subinterface.
IP	The method of IP address assignment for the interface: • Static IP—Defines a static IP address and subnet mask for the interface. Enter this information in the fields that appear below the option. **Note** You can define the mask using either dotted decimal (for example, 255.255.255.255) or CIDR notation (/32). See Contiguous and Discontiguous Network Masks for IPv4 Addresses , on page 311. • DHCP—The interface obtains its IP address dynamically from a DHCP server. • PPPoE—The router automatically negotiates its own registered IP address from a central server (via PPP/IPCP). The following interface types support PPPoE: • Async • Serial • High-Speed Serial Interface (HSSI) • Dialer • BRI, PRI (ISDN) • Virtual template • Multilink • Unnumbered—The interface obtains its IP address from a different interface on the device. Choose an interface from the Interface list. This option can be used with point-to-point interfaces only. **Note** Layer 2 interfaces do not support IP addresses. Deployment fails if you define an IP address on a Layer 2 interface.
Layer Type	The OSI layer at which the interface is defined: • Unknown—The layer is unknown. • Layer 2—The data link layer, which contains the protocols that control the physical layer (Layer 1) and how data is framed before being transmitted on the medium. Layer 2 is used for bridging and switching. Layer 2 interfaces do not have IP addresses. • Layer 3—The network layer, which is primarily responsible for the routing of data in packets across logical internetwork paths. This routing is accomplished through the use of IP addresses.

Element	Description
Negotiation	Available on ASRs; applies to Fast Ethernet and Gigabit Ethernet interfaces only. Auto-negotiation detects the capabilities of remote devices and negotiates the best possible performance between the two devices. When Negotiation is enabled, the Duplex and Speed options are disabled.
Duplex	The interface transmission mode: • None—The transmission mode is returned to its device-specific default setting. • Full—The interface transmits and receives at the same time (full duplex). • Half—The interface can transmit or receive, but not at the same time (half duplex). This is the default. • Auto—The router automatically detects and sets the appropriate transmission mode, either full or half duplex. Not available on ASRs; use auto-negotiation instead. **Note** When using Auto mode, be sure that the port on the active network device to which you connect this interface is also set to automatically negotiate the transmission mode. Otherwise, select the appropriate fixed mode. **Note** You can configure a duplex value only if you set the Speed to a fixed speed, not Auto. **Note** This setting does not apply to serial, HSSI, ATM, PRI, DSL, tunnel, or loopback interfaces.
Speed	Applies only to Fast Ethernet and Gigabit Ethernet interfaces. The speed of the interface: • None—The setting is not configurable on the device. • 10—10 megabits per second (10Base-T networks). • 100—100 megabits per second (100Base-T networks). This is the default for Fast Ethernet interfaces. • 1000—1000 megabits per second (Gigabit Ethernet networks). This is the default for Gigabit Ethernet interfaces. • Auto—The router automatically detects and sets appropriate interface speed. Not available on ASRs; use auto-negotiation. **Note** When using Auto mode, be sure that the port on the active network device to which you connect this interface is also set to automatically negotiate the transmission speed. Otherwise, select the appropriate fixed speed.
MTU	The maximum transmission unit, which refers to the maximum packet size, in bytes, that this interface can handle. Valid values for serial, Ethernet, and Fast Ethernet interfaces range from 64 to 17940 bytes. Valid values for Gigabit Ethernet interfaces range from 1500 to 9216 bytes.

Element	Description
Encapsulation	The type of encapsulation performed by the interface: • None—No encapsulation. • DOT1Q—VLAN encapsulation, as defined by the IEEE 802.1Q standard. Applies only to Ethernet subinterfaces. • Frame Relay—IETF Frame Relay encapsulation. Applies only to serial interfaces (not serial subinterfaces). **Note** IETF Frame Relay encapsulation provides interoperability between a Cisco IOS router and equipment from other vendors. To configure Cisco Frame Relay encapsulation, use CLI commands or FlexConfigs.
VLAN ID	Applies only to subinterfaces with encapsulation type DOT1Q. The VLAN ID associated with this subinterface. The VLAN ID specifies where 802.1Q tagged packets are sent and received on this subinterface; without a VLAN ID, the subinterface cannot send or receive traffic. Valid values range from 1 to 4094. **Note** All VLAN IDs must be unique among all subinterfaces configured on the same physical interface. **Tip** To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the **vlan-id dot1q** command using CLI commands or FlexConfigs. See Understanding FlexConfig Policies and Policy Objects , on page 342. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the router.
Native VLAN	Applies only when the encapsulation type is DOT1Q and you are configuring a physical interface that is meant to serve as an 802.1Q trunk interface. Trunking is a way to carry traffic from several VLANs over a point-to-point link between two devices. When selected, the Native VLAN is associated with this interface, using the ID specified in the VLAN ID field. (If no VLAN ID is specified for the Native VLAN, the default is 1.) The native VLAN is the VLAN to which all untagged VLAN packets are logically assigned by default. This includes the management traffic associated with the VLAN. If no VLAN ID is defined, the default is 1. For example, if the VLAN ID of this interface is 1, all incoming untagged packets and packets with VLAN ID 1 are received on the main interface and not on a subinterface. Packets sent from the main interface are transmitted without an 802.1Q tag. When deselected, the Native VLAN is not associated with this interface. **Note** The Native VLAN cannot be configured on a subinterface of the trunk interface. Be sure to configure the same Native VLAN value at both ends of the link; otherwise, traffic may be lost or sent to the wrong VLAN.
DLCI	Applies only to serial subinterfaces with Frame Relay encapsulation. Enter the data-link connection identifier to associate with the subinterface. Valid values range from 16 to 1007. **Note** Security Manager configures serial subinterfaces as point-to-point not multipoint.

Element	Description
Description	Additional information about the interface (up to 1024 characters).
Roles	The interface roles assigned to this interface. A message is displayed if no roles have yet been assigned.

Interface Auto Name Generator Dialog Box

Use the Interface Auto Name Generator dialog box to have Security Manager generate a name for the interface based on the interface type and its location in the router or switch.

Navigation Path

Go to the Create Router Interface Dialog Box , on page 2314, select **Interface** from the Type list, then click **Select** in the Name field.

Field Reference

Table 826: Interface Auto Name Generator Dialog Box

Element	Description
Type	The type of interface. Your selection from this list forms the first part of the generated name, as displayed in the Result field. For more information, see Available Interface Types , on page 2308.
Card	The card related to the interface. **Note** When defining a BVI interface, enter the number of the corresponding bridge group.
Slot	The slot related to the interface.
Port	The port related to the interface. **Note** The information you enter in these fields forms the remainder of the generated name, as displayed in the Result field.
Result	The name generated by Security Manager from the information you entered for the interface type and location. The name displayed in this field is read-only. **Tip** After closing this dialog box, you can edit the generated name in the Create Router Interface dialog box, if required.

Advanced Interface Settings on Cisco IOS Routers

In addition to the basic interface definitions that you can define on the Interfaces page, Security Manager provides a method for defining selected advanced settings on interfaces that support those settings.

Unlike the basic interface settings defined on the Interface page, you can share an advanced settings policy with multiple devices. This provides a convenient method for configuring multiple devices with identical settings. See Working with Shared Policies in Device View or the Site-to-Site VPN Manager , on page 203.

You can define a variety of advanced settings on a selected interface, subinterface, or interface role, including:

- Cisco Discovery Protocol (CDP) settings.
- Internet Control Message Protocol (ICMP) settings.
- Directed broadcast settings.
- Load interval for determining the average load.
- Throughput delay for use by routing protocols.
- Configuring TCP maximum segment size.
- Helper addresses for forwarding UDP broadcasts. For more information on helper addresses, see Understanding Helper Addresses , on page 2320.
- Enabling Maintenance Operation Protocol (MOP).
- Enabling virtual fragmentation reassembly (VFR).
- Enabling proxy ARP.
- Enabling NBAR protocol discovery.
- Enabling and configuring unicast reverse path forwarding (RFP).

Tip You can define these settings for multiple interfaces on a device at once by choosing an interface role instead of a specific interface. For example, if you have defined an All-Ethernets interface role, you can define identical advanced settings for every Ethernet interface on the device with a single definition. See Understanding Interface Role Objects , on page 303.

Before You Begin

- Define basic interface settings. See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Step 1 Do one of the following:

- (Device view) Select **Interfaces > Settings > Advanced Settings** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > Advanced Settings** from the Policy Type selector. Select an existing policy or create a new one.

The Advanced Interface Settings page is displayed (see Advanced Interface Settings Dialog Box , on page 2322).

Step 2 Do one of the following:

- Click the **Add** button to add an interface or interface role to the table. In the Advanced Interface Settings dialog box, enter the name of the interface or interface role, or click **Select** to select an existing role or to create a new role.
- Select an existing entry in the table and click the **Edit** button to change its settings.

Step 3 Configure the advanced settings required for the selected interface. For details about each setting, see Advanced Interface Settings Dialog Box , on page 2322.

Step 4 Click **OK** to save your definitions. Your definitions are displayed in the Advanced Interface Settings table.

Understanding Helper Addresses

Network hosts occasionally use User Datagram Protocol (UDP) broadcasts to determine address, configuration, and name information. This presents a problem if the host is on a network segment that does not include the required server, as by default, routers do not forward UDP broadcasts beyond their subnet. You can remedy this situation by configuring the interface to forward certain classes of broadcasts to a helper address.

One common use of helper addresses is when the router acts as a relay agent for DHCP clients who need to contact a DHCP server located on a different subnet. The helper address can either represent a specific DHCP server or a network address for a segment containing multiple DHCP servers. You can also configure a helper address for each DHCP server.

In Figure 46: Helper Addresses, on page 2320, hosts located on network 192.168.1.0 can use 10.44.23.7 as a helper address to forward UDP broadcasts to the other network, while hosts located on network 10.44.0.0 can use 192.168.1.19 as their helper address.

Figure 46: Helper Addresses

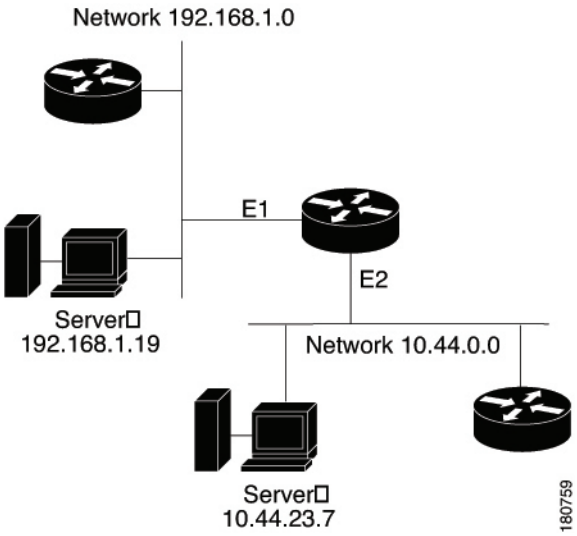

Table 827: Default UDP Services Forwarded to Helper Addresses , on page 2320 lists the default UDP services that can be forwarded to helper addresses.

Table 827: Default UDP Services Forwarded to Helper Addresses

Service	Port
BOOTP/DHCP Client	68
BOOTP/DHCP Server	67
DNS	53
NetBIOS datagram service	138

Service	Port
NetBIOS name service	137
TACACS	49
TFTP	69
Time	37

Tip To forward additional UDP services, use the CLI or FlexConfigs to configure the ip forward-protocol command. Use the no form of this command to prevent the forwarding of any of the default services listed in Table 827: Default UDP Services Forwarded to Helper Addresses , on page 2320.

All of the following conditions must be met in order for a UDP or IP packet to use helper addresses:

- The MAC address of the received frame must be an all-ones broadcast address (ffff.ffff.ffff).
- The IP destination address must be one of the following: all-ones broadcast (255.255.255.255), subnet broadcast for the receiving interface, or major-net broadcast for the receiving interface if the no ip classless command is also configured.
- The IP time-to-live (TTL) value must be at least 2.
- The IP protocol must be UDP (17).

Related Topics

Advanced Interface Settings Page

Use the Advanced Interface Settings page to configure advanced interface definitions (physical and virtual) on a router. Examples of advanced settings include Cisco Discovery Protocol (CDP) settings, ICMP message settings, and virtual fragment reassembly settings. You can configure settings for specific interfaces or for interface roles. The columns in the table summarize the advanced settings for an entry and are explained in Advanced Interface Settings Dialog Box , on page 2322.

To configure advanced settings:

- Click the **Add** button to add an interface or interface role to the table, and fill in the Advanced Interface Settings dialog box.
- Select an entry and click the **Edit** button to edit an existing entry.
- Select an entry and click the **Delete** button to delete it.

For more information, see Advanced Interface Settings on Cisco IOS Routers , on page 2318.

Navigation Path

- (Device view) Select **Interfaces > Settings > Advanced Settings** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > Advanced Settings** from the Policy Type selector. Right-click **Advanced Settings** to create a policy, or select an existing policy from the Shared Policy selector.

- Available Interface Types , on page 2308

Field Reference

Table 828: Advanced Interface Settings Dialog Box

Element	Description
Interface	The interface on which the advanced settings are defined. Enter the name of an interface or interface role, or click **Select** to select it. If the you want is not listed, click the **Create** button to create it. **Note** The only advanced settings supported on Layer 2 interfaces are Max. Bandwidth, Load Interval, and CDP.

Element	Description
Max Bandwidth	The bandwidth value to communicate to higher-level protocols in kilobits per second (kbps). The value you define in this field is an informational parameter only; it does not affect the physical interface.
Load Interval	The length of time, in seconds, used to calculate the average load on the interface. Valid values range from 30 to 600 seconds, in multiples of 30 seconds. The default is 300 seconds (5 minutes). Load interval is not supported on subinterfaces. Modify the default to shorten the length of time over which load averages are computed. You can do this if you want load computations to be more reactive to short bursts of traffic. Load data is gathered every 5 seconds. This data is used to compute load statistics, including input/output rate in bits and packets per second, load, and reliability. Load data is computed using a weighted-average calculation in which recent load data has more weight in the computation than older load data. **Tip** You can use this option to increase or decrease the likelihood of activating a backup interface; for example, a backup dial interface may be triggered by a sudden spike in the load on an active interface.
TCP Maximum Segment Size	The maximum segment size (MSS) of TCP SYN packets that pass through this interface. Valid values range from 500 to 1460 bytes. If you do not specify a value, the MSS is determined by the originating host. This option helps prevent TCP sessions from being dropped as they pass through the router. Use this option when the ICMP messages that perform auto-negotiation of TCP frame size are blocked (for example, by a firewall). We highly recommend using this option on the tunnel interfaces of DMVPN networks. **Note** Typically, the optimum MSS is 1452 bytes. This value plus the 20-byte IP header, the 20-byte TCP header, and the 8-byte PPPoE header add up to a 1500-byte packet that matches the MTU size for the Ethernet link.
Helper Addresses	The helper addresses that are used to forward User Datagram Protocol (UDP) broadcasts that are received on this interface. Enter one or more addresses or the names of the network/host objects, or click **Select** to select an object from a list or to create a new object. By default, routers do not forward broadcasts outside of their subnet. Helper addresses provide a solution by enabling the router to forward certain types of UDP broadcasts as a unicast to an address on the destination subnet. For more information, see Understanding Helper Addresses , on page 2320.
Interface Throughput Delay	The expected delay for the interface in tens of microseconds (for example, 3000 translates to 30,000 microseconds). You can enter a value between 1 and 16777215, and the default varies by the type of interface. Higher-level protocols might use delay information to make operating decisions. For example, IGRP can use delay information to differentiate between a satellite link and a land link. This setting is for informational purposes only and does not affect the actual delay on the interface.

Element	Description
Cisco Discovery Protocol settings	Settings related to the Cisco Discovery Protocol (CDP). CDP is a media- and protocol-independent device-discovery protocol that runs on all Cisco-manufactured equipment including routers, access servers, bridges, and switches. It is primarily used to obtain protocol addresses of neighboring devices and to discover the platform of those devices. The options are: • Enable CDP—Whether to enable the Cisco Discovery Protocol (CDP) on this interface. You cannot enable CDP on ATM interfaces. • Log CDP Messages—On Ethernet interfaces, whether to log duplex mismatches for this interface.
ICMP Messages Settings	
Enable Redirect Messages	Whether to enable the sending of Internet Control Message Protocol (ICMP) redirect messages if the device is forced to resend a packet through the same interface on which it was received to another device on the same subnet. Redirect messages are sent when the device wants to instruct the originator of the packet to remove it from the route and substitute a different device that offers a more direct path to the destination.
Enable Unreachable Messages	Whether to enable the sending of ICMP unreachable messages. Unreachable messages are sent in two circumstances: • If the interface receives a nonbroadcast packet destined for itself that uses an unknown protocol, the interface sends an ICMP unreachable message to the source. • If the device receives a packet that it cannot deliver to its ultimate destination because it knows of no route to the destination address, it sends an ICMP host unreachable message to the originator of the packet. **Note** This is the only advanced setting supported by the null0 interface.
Enable Mask Reply Messages	Whether to enable the sending of ICMP mask reply messages. Mask reply messages are sent in response to mask request messages, which are sent when a device needs to know the subnet mask for a particular subnetwork.
Additional Settings	
Enable Maintenance Operation Protocol (MOP)	Whether to enable MOP on the interface. You can use MOP for utility services such as uploading and downloading system software, remote testing, and problem diagnosis.
Enable Virtual Fragment Reassembly (VFR)	Whether to enable virtual fragmentation reassembly (VFR) on this interface. VFR is a feature that enables the Cisco IOS Firewall to create dynamic ACLs that can protect the network from various fragmentation attacks.

Element	Description
Enable Proxy ARP	Whether to enable proxy Address Resolution Protocol (ARP) on the interface. Proxy ARP, defined in RFC 1027, is the technique in which one host, usually a router, answers ARP requests intended for another machine, thereby accepting responsibility for routing packets to the real destination. Proxy ARP can help machines on a subnet reach remote subnets without configuring routing or a default gateway.
Enable NBAR Protocol Discovery	Whether to enable network-based application recognition (NBAR) on this interface to discover traffic and keep traffic statistics for all protocols known to NBAR. Protocol discovery provides a method to discover application protocols traversing an interface so that QoS policies can be developed and applied to them. For more information, go to: http://www.cisco.com/en/US/products/ps6616/products_qanda_item09186a00800a3ded.shtml
Enable Directed Broadcasts ACL	Whether to have directed broadcast packets "exploded" as a link-layer broadcast when this interface is directly connected to the destination subnet. When deselected, directed broadcast packets that are intended for the subnet to which this interface is directly connected are dropped rather than being broadcast. This is the default. An IP directed broadcast is an IP packet whose destination address is a valid broadcast address on a different subnet from the node on which it originated. In such cases, the packet is forwarded as if it was a unicast packet until it reaches its destination subnet. This option affects only the final transmission of the directed broadcast on its destination subnet; it does not affect the transit unicast routing of IP directed broadcasts. If you enable directed broadcasts, you can apply an ACL to determine which directed broadcasts are permitted to be broadcast on the destination subnet. All other directed broadcasts destined for the subnet to which this interface is directly connected are dropped. Enter the name of a standard or extended ACL object, or click **Select** to select an object from a list or to create a new object. **Tip** Because directed broadcasts, and particularly ICMP directed broadcasts, have been abused by malicious persons, we recommend deselecting this option on interfaces where directed broadcasts are not needed. When you enable directed broadcasts, apply an ACL to restrict their use.
Unicast Reverse Path Forwarding (RFP) Settings	
Enable Unicast RFP	Whether to enable unicast reverse path forwarding (RFP) on the interface. When you enable Unicast RPF on an interface, the router examines all packets that are received on that interface. The router checks to make sure that the source address appears in the FIB, and takes action based on your unicast RFP settings. Use unicast RFP to mitigate problems caused by malformed or forged (spoofed) IP source addresses that pass through a router. Malformed or forged source addresses can indicate DoS attacks based on source IP address spoofing. For more information on unicast RFP, see the description of the **ip verify unicast source reachable-via** command in the *Cisco IOS Interface and Hardware Component Command Reference* . To enable unicast RFP, you must also globally enable Cisco Express Forwarding (CEF). For more information on CEF, see CEF Interface Settings on Cisco IOS Routers , on page 2330.

Element	Description
Mode	How strict to make unicast RFP: • Loose Mode—The default. Examines incoming packets to determine whether the source address is in the Forwarding Information Base (FIB) and permits the packet if the source is reachable through any interface on the router. Use loose mode on interfaces where asymmetric paths allow packets from valid source networks (networks contained in the FIB). For example, routers that are in the core of an ISP network have no guarantee that the best forwarding path out of the router will be the path selected for packets returning to the router. • Strict Mode—Examines incoming packets to determine whether the source address is in the FIB and permits the packet only if the source is reachable through the interface on which the packet was received. Use strict mode on interfaces where only one path allows packets from valid source networks (networks contained in the FIB). Also, use strict mode when a router has multiple paths to a given network as long as the valid networks are switched through the incoming interfaces. Packets for invalid networks are dropped. For example, routers at the edge of the network of an ISP are likely to have symmetrical reverse paths. Strict mode is also applicable in certain multihomed situations, provided that optional Border Gateway Protocol (BGP) attributes, such as weight and local preference, are used to achieve symmetric routing.
Allow Use Of Default Route for RFP Verification	Whether to permit Unicast RPF to successfully match on prefixes that are known through the default route when determining whether to pass packets. Normally, sources found in the FIB but only by way of the default route are dropped.
Allow Self Ping	Whether to allow the router to ping its own interfaces. By default, when you enable Unicast RPF, packets that are generated by the router and destined to the router are dropped, thereby making certain troubleshooting and management tasks difficult to accomplish. **Caution** Allowing self-ping opens a potential denial of service (DoS) hole.
ACL (For Unicast RFP)	If you enable unicast RFP, you can apply an ACL to refine how packets are handled when a reverse path is not found. If you specify an ACL, when (and only when) a packet fails the Unicast RPF check, the ACL is checked to determine whether the packet should be dropped (using a deny statement in the ACL) or forwarded (using a permit statement in the ACL). Enter the name of a standard or extended ACL object, or click **Select** to select an object from a list or to create a new object.

IPS Module Interface Settings on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IPS and IOS features/functionality, it does not support any bug fixes or enhancements.

On some routers, you can install IPS modules such as the Cisco Intrusion Prevention System Advanced Integration Module or Network Module. When installed and active, you must configure the IPS Module interface settings policy to define the following:

- The name of the interface between the module and the router.
- The failure mode of the module. If the module fails, you can configure it to allow all traffic or to deny all traffic.
- The router interfaces to monitor. You can name specific interfaces or use interface roles to cover more than one interface at a time. For example, if you have defined an All-Ethernets interface role, you can define identical monitoring settings for every Ethernet interface on the device with a single definition. See Understanding Interface Role Objects , on page 303.

Tip After you have defined an IPS Module interface settings policy, you can share the policy and assign it to other devices. This provides a convenient method for configuring multiple devices with identical settings. See Working with Shared Policies in Device View or the Site-to-Site VPN Manager , on page 203.

Before You Begin

Define basic interface settings. See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Step 1 Do one of the following:

- (Device view) Select **Interfaces > Settings > IPS Module** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > IPS Module** from the Policy Type selector. Select an existing policy or create a new one.

The IPS Module Interface Settings page is displayed. See IPS Module Interface Settings Page , on page 2327 for an explanation of the fields on this page.

Step 2 In the IPS Module Interface Settings fields, enter the name of the IPS interface (such as IDS-Sensor1/0) or click Select to select it from a list. Also determine whether you want to allow all traffic if the module fails (fail open) or to deny all traffic (fail closed).

Step 3 Identify the router interfaces that the module should monitor. Click the **Add** button below the IPS Module Service Module Monitoring Settings table to add interfaces to the list, or select an interface and click the **Edit** button to change the settings for an existing interface. Use the IPS Monitoring Information dialog box to define the interface name or role, monitoring mode, and access list (if any). For more information, see IPS Monitoring Information Dialog Box , on page 2329.

IPS Module Interface Settings Page

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

Use the IPS Module Interface Settings page to define the settings on the Cisco Intrusion Prevention System Advanced Integration Module or Network Module. The module must be running IPS 6.0 or later. You can define the fail mode for the IPS interface, and the interfaces that the module should monitor. Configure this policy only if the router hosts an IPS module.

Caution Cisco IOS IPS and the Cisco IPS module cannot be used together. Cisco IOS IPS must be disabled when the IPS module is installed.

Navigation Path

- (Device view) Select **Interfaces > Settings > IPS Module** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > IPS Module** from the Policy Type selector. Create a new policy or select an existing policy from the Shared Policy selector.

Related Topics

- IPS Module Interface Settings on Cisco IOS Routers , on page 2326

- Filtering Tables , on page 50

Field Reference

Table 829: IPS Module Interface Settings Page

Element	Description
Interface Name	The name of the IPS module interface. Enter the name or click **Select** to select the interface or interface role. If the object that you want is not listed, click the **Create** button to create it.
Fail Over Mode	How the module should handle traffic inspection during a module failure, either to fail open (passing all traffic without inspection) or fail closed (dropping all traffic). The default is fail open.

Element	Description
IPS Module Service Module Monitoring Settings table	The list of interfaces on the router that the IPS module should monitor. The table shows the name of the interface or interface role, whether monitoring is inline or promiscuous, and whether an ACL is used to filter traffic for inspection on the interface. Inline mode puts the IPS module directly into the traffic flow, allowing it to stop attacks by dropping malicious traffic before it reaches the intended target. In promiscuous mode, packets do not flow through the sensor; the sensor analyzes a copy of the monitored traffic rather than the actual forwarded packet. If the ACL is matched, the matched traffic is not inspected. • To add an interface to the table, click the Add button and fill in the IPS Monitoring Information Dialog Box , on page 2329. • To edit the settings for an interface, select it and click the Edit button. • To delete an interface, select it and click the Delete button.

IPS Monitoring Information Dialog Box

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

Use the IPS Monitoring Information dialog box to add or edit the properties of interfaces to be monitored by the IPS module.

Navigation Path

Go to the IPS Module Interface Settings Page , on page 2327, then click the **Add** or **Edit** button beneath the IPS Module Service Module Monitoring Settings table.

Related Topics

- IPS Module Interface Settings on Cisco IOS Routers , on page 2326

Field Reference

Table 830: IPS Monitoring Information Dialog Box

Element	Description
Interface Name	A name of the interface or interface role that the module should monitor. Enter the name or click **Select** to select the interface or interface role. If the object that you want is not listed, click the **Create** button to create it.

Element	Description
Monitoring Mode	How the interface should be monitored: • Inline mode—The IPS module is directly in the traffic flow, allowing it to stop attacks by dropping malicious traffic before it reaches the intended target. • Promiscuous mode—Packets do not flow through the sensor; the sensor analyzes a copy of the monitored traffic rather than the actual forwarded packet.
Access List	The name of the standard or extended access list policy object to use to filter traffic on this interface for inspection, if you want to apply one. A matched ACL causes traffic not to be inspected for that ACL. Click **Select** to select the ACL or to create a new one.

CEF Interface Settings on Cisco IOS Routers

Cisco Express Forwarding (CEF) is an advanced Layer 3 IP switching technology that optimizes network performance and scalability for all kinds of networks, from those that carry small amounts of traffic to those that carry large amounts of traffic in complex patterns, such as the Internet and networks characterized by intensive web-based applications or interactive sessions. CEF is enabled by default on most Cisco IOS routers.

Typically, you do not need to configure a CEF policy unless you want to enable CEF accounting so that you can view statistics with the **show ip cef** command on the router. You would also configure the policy if you want to disable CEF, or to configure non-default CEF behavior on specific interfaces, for example, to have CEF load balance based on packets rather than source-destination packet streams.

When configuring alternate CEF settings for interfaces, you can name specific interfaces or use interface roles to cover more than one interface at a time. For example, if you have defined an All-Ethernets interface role, you can define identical CEF settings for every Ethernet interface on the device with a single definition. See Understanding Interface Role Objects , on page 303.

Tip After you have defined a CEF interface settings policy, you can share the policy and assign it to other devices. This provides a convenient method for configuring multiple devices with identical settings. See Working with Shared Policies in Device View or the Site-to-Site VPN Manager , on page 203.

Before You Begin

Define basic interface settings. See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Step 1 Do one of the following:

- (Device view) Select **Interfaces > Settings > CEF** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > CEF** from the Policy Type selector. Select an existing policy or create a new one.

The CEF Interface Settings page is displayed. See CEF Interface Settings Page , on page 2331 for an explanation of the fields on this page.

Step 2 If you are enabling CEF, select the accounting options you desire.

Step 3 If you want to configure non-default behavior for certain interfaces, add them to the CEF Interface Settings table. Click the **Add** button below the table to add interfaces to the list, or select an interface and click the **Edit** button to change the settings for an existing interface. For more information about the options, see CEF Interface Settings Dialog Box , on page 2332.

CEF Interface Settings Page

Use the CEF Interface Settings page to define the settings for Cisco Express Forwarding. CEF is an advanced Layer 3 IP switching technology that optimizes network performance and scalability for all kinds of networks, from those that carry small amounts of traffic to those that carry large amounts of traffic in complex patterns, such as the Internet and networks characterized by intensive web-based applications or interactive sessions. CEF is enabled by default on most Cisco IOS routers.

Navigation Path

- (Device view) Select **Interfaces > Settings > CEF** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > CEF** from the Policy Type selector. Create a new policy or select an existing policy from the Shared Policy selector.

Related Topics

- CEF Interface Settings on Cisco IOS Routers , on page 2330

- Filtering Tables , on page 50

Field Reference

Table 831: CEF Interface Settings Page

Element	Description
Enable Cisco Express Forwarding	Whether to enable CEF globally on the device. The option is greyed out if you cannot disable CEF on the device. You can configure other settings on the page only if you enable CEF globally.

Element	Description
CEF Network Accounting	These options are for configuring CEF accounting globally. If you collect accounting statistics, you can view them using the **show ip cef** command on the router. You can select the following options to enable different types of accounting: • Enable Accounting for Traffic Through Non-Recursive Prefixes—For network prefixes with directly connected next hops, non-recursive accounting enables express forwarding of the collection of packets through a prefix. • Enable Per-Prefix Accounting—Accounting statistics based on the packet's network prefix. • Enable Prefix Length Accounting—Accounting statistics based on the network prefix length. • Enable Load Balance Hash Accounting—When you use per-destination load balancing (the default), CEF uses a series of 16 hash buckets to distribute the available paths based on the source and destination addresses. Enabling load balance hash accounting provides per-hash-bucket counters.
CEF Interface Settings table	The interfaces on the router for which you are defining special CEF configurations. When you enable CEF globally, by default, all interfaces on the router enable CEF and use per-destination load balancing. Add interfaces to this table only if you want to configure different behavior for the interfaces. The table shows the name of the interface or interface role, whether CEF is enabled or disabled, and whether the interface is load balancing based on destination or on a per-packet basis. For a detailed explanation of the fields, see CEF Interface Settings Dialog Box , on page 2332. • To add an interface to the table, click the Add button. • To edit the settings for an interface, select it and click the Edit button. • To delete an interface, select it and click the Delete button.

CEF Interface Settings Dialog Box

Use the CEF Interface Settings dialog box to add or edit the CEF properties of interfaces when you want to configure something different than the global default.

Navigation Path

Go to the CEF Interface Settings Page , on page 2331, and then click the **Add** or **Edit** button beneath the CEF Interface Settings table.

Related Topics

- CEF Interface Settings on Cisco IOS Routers , on page 2330
- Basic Interface Settings on Cisco IOS Routers , on page 2307

Field Reference

Table 832: CEF Interface Settings Dialog Box

Element	Description
Interface Name	The name of the interface or interface role for which you are configuring CEF. Enter the name or click **Select** to select the interface or interface role. If the object that you want is not listed, click the **Create** button to create it.
Enable CEF on Interface	Whether to enable CEF on the interface. CEF is enabled by default.
Load Balancing	How the interface should balance traffic, either per-destination or per-packet. In per-destination load balancing, all packets for a given source-destination pair take the same path. In per-packet load balancing, packets for a given source-destination pair can take different equal-cost routes, and thus reach their destination out of order. The default is to balance the load based on the destination of the traffic.

Dialer Interfaces on Cisco IOS Routers

Before you can configure a dial backup policy for a site-to-site VPN (see Configuring Dial Backup , on page 1115), you must configure a dialer interface policy on the appropriate Cisco IOS router. The dialer interface policy uses dialer pools to associate the dialer interface used by dial backup with a physical BRI interface on the router. Each dialer interface is associated with a single dialer pool, which can contain one or more physical interfaces. Multiple dialer interfaces can reference the same dialer pool.

The following topics describe how to create dialer interfaces policies on Cisco IOS routers:

- Defining Dialer Profiles , on page 2333
- Defining BRI Interface Properties , on page 2335

Defining Dialer Profiles

When you configure a dialer profile, you must select the interface or interface role representing the dialer interface and specify the number to be dialed. You must also assign a pool ID, which you use to reference this dialer interface when configuring the physical dialer interface. Additionally, you can modify the default timeout settings for the line.

Note IP is the only protocol supported for dialer profiles by Security Manager.

Note Authentication parameters for the dialer profile are defined in the PPP policy.

Before You Begin

Define the virtual and physical dialer interfaces on the router. See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Note In addition, you can optionally define interface roles for the virtual and physical dialer interfaces. See Defining Dialer Profiles , on page 2333.

Related Topics

- Defining BRI Interface Properties , on page 2335
- Dialer Interfaces on Cisco IOS Routers , on page 2333

Step 1 Do one of the following:

- (Device view) Select **Interfaces > Settings > Dialer** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > Dialer** from the Policy Type selector. Select an existing policy or create a new one.

The Dialer page is displayed. See Table 833: Dialer Page , on page 2336 for a description of the fields on this page.

Step 2 Select a dialer profile from the upper table on the Dialer Interfaces page, then click **Edit**, or click **Add** to create a profile. The Dialer Profile dialog box appears. See Table 834: Dialer Profile Dialog Box , on page 2337 for a description of the fields in this dialog box.

Step 3 Enter the name of the interface or interface role that represents the virtual dialer interface, or click **Select** to select an interface role object or to create a new one. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Step 4 Enter a name for the dialer profile. Having a name makes it easier for you to assign the correct dialer pool to the physical interface. See Defining BRI Interface Properties , on page 2335.

Tip We recommend that you define a name that is logically associated with the site to which the dialer interface serves as a backup. For example, if the dialer interface is serving as a backup connection to the London site, define the name London for the dialer profile.

Step 5 Enter an ID number for the dialer pool to associate with this dialer interface. Each dialer interface is associated with a single pool. Multiple interfaces may, however, be associated with the same dialer pool.

Step 6 Enter the number of the dialer group to assign to the dialer interface.

Step 7 (Optional) In the Interesting Traffic ACL field, enter the name of the extended ACL object that defines which packets are permitted to initiate calls using this dialer profile, or click **Select** to select the object from a list or to create a new one. Use this option to limit the IP traffic that can make use of the dialer.

Step 8 Enter the dialer string, which is the phone number of the remote side of the dialer interface connection.

Step 9 (Optional) Modify the default timeout values (Idle Timeout and Fast Idle Timeout), if required.

Step 10 Click **OK** to save your definitions locally on the client and close the dialog box. The dialer profile appears in the Dialer Profile table on the Dialer page.

Defining BRI Interface Properties

You configure the properties of the physical BRI interfaces used for dialer interface policies by selecting the appropriate interface or interface role, defining the dialer pools to which the interface belongs, and defining the ISDN switch type. It is the dialer pool that connects the physical interface with the virtual dialer interface.

Note To define other types of physical dialer interfaces, such as ATM and Ethernet, use FlexConfigs. For more information, see Understanding FlexConfig Policies and Policy Objects , on page 342.

Before You Begin

Define the virtual and physical dialer interfaces on the router. See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Note In addition, you can optionally define interface roles for the virtual and physical dialer interfaces. See Creating Interface Role Objects , on page 304.

Related Topics

- Defining Dialer Profiles , on page 2333
- Dialer Interfaces on Cisco IOS Routers , on page 2333

Step 1 Do one of the following:

- (Device view) Select **Interfaces > Settings > Dialer** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > Dialer** from the Policy Type selector. Select an existing policy or create a new one.

The Dialer Interfaces page is displayed. See Table 833: Dialer Page , on page 2336 for a description of the fields on this page.

Step 2 Select a physical BRI interface from the Dialer Physical Interfaces table, then click **Edit**, or click **Add** to add an interface. The Dialer Physical Interface dialog box appears. See Table 835: Dialer Physical Interface Dialog Box , on page 2338 for a description of the fields in this dialog box.

Step 3 Enter the name of the interface or interface role that represents the physical dialer interface, or click **Select** to select an interface role object from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Step 4 Enter the names of the dialer pools to associate with the physical interface, or click **Select** to display a selector. Separate multiple entries with commas.

Step 5 Select the ISDN switch type used by the physical interface. <Table> describes the available switch types.

Step 6 (Optional) If you selected the Basic-DMS-100, Basic-NI, or Basic-5ess switch type, enter up to two service provider identifiers (SPIDs).

Note We recommend that you do not enter SPIDs for the Basic-5ess switch type, even though SPIDs are supported.

Step 7 Click **OK** to save your definitions locally on the client and close the dialog box. The interface definition appears in the Dialer Physical Interfaces table on the Dialer Interface page.

Dialer Policy Page

Use the Dialer page to define the relationship between physical Basic Rate Interface (BRI) and virtual dialer interfaces. You use these dialer interfaces when you configure the dial backup feature for site-to-site VPNs.

For more information, see Dialer Interfaces on Cisco IOS Routers , on page 2333.

Navigation Path

- (Device view) Select **Interfaces > Settings > Dialer** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > Dialer** from the Policy Type selector. Right-click **Dialer** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 833: Dialer Page

Element	Description
Dialer Profiles table	The dialer profiles that define the dialer pools. You must add profiles before you can add physical BRI interfaces. The table shows the name of the interface or interface role that the dialer interface uses, the profile name, pool, group, the ACL that defines which traffic can use this profile, the dial string, and idle times. • To add a profile, click the **Add Row** button and fill in the Dialer Profile Dialog Box , on page 2337. • To edit a profile, select it and click the **Edit Row** button. • To delete a profile, select it and click the **Delete Row** button.
Dialer Physical Interfaces (BRI) table	The physical interfaces that use the dialer profiles. The table shows the name of the interface or interface role, the dial pools, ISDN switch type, and first and second service provider identifiers (SPID) related to the interface. • To add an interface, click the **Add Row** button and fill in the Dialer Physical Interface Dialog Box , on page 2338. • To edit an interface, select it and click the **Edit Row** button. • To delete an interface, select it and click the **Delete Row** button.

Dialer Profile Dialog Box

Use the Dialer Profile dialog box to add or edit dialer profiles.

Navigation Path

Go to the Dialer Policy Page , on page 2336, then click the **Add** or **Edit** button beneath the Dialer Profile table.

- Creating Interface Role Objects , on page 304

Field Reference

Table 834: Dialer Profile Dialog Box

Element	Description
Name	A descriptive name for the dialer profile. This name enables you to assign the correct dialer pool to the physical interface. You can also use the profile name as a reference to the site to which this dialer interface serves as a backup.
Interface	The virtual dialer interface to associate with the dialer profile. Enter the name of an interface or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.
Pool ID	The dialer pool ID. Each pool can contain multiple physical interfaces and can be associated with multiple dialer interfaces. Each dialer interface, however, is associated with only one pool.
Group	The group ID, which identifies the dialer group that this dialer interface uses.
Interesting Traffic ACL	The extended, numbered ACL that defines which packets are permitted to initiate calls using this dialer profile. The valid ACL number range is 100 to 199. Enter the name of the ACL object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.
Dialer String (Remote Phone Number)	The phone number of the destination that the dialer contacts.
Idle Timeout	The default amount of idle time before an uncontested line is disconnected. The default is 120 seconds.

Element	Description
Fast Idle Timeout	The default amount of idle time before a contested line is disconnected. The default is 20 seconds. Line contention occurs when a busy line is requested to send another packet to a different destination.

Dialer Physical Interface Dialog Box

Use the Dialer Physical Interface dialog box to add or edit the properties that associate physical BRI interfaces with dialer interfaces.

Note Use FlexConfigs to define other types of physical dialer interfaces, such as ATM and Ethernet. For more information, see Understanding FlexConfig Policies and Policy Objects , on page 342.

Navigation Path

Go to the Dialer Policy Page , on page 2336, then click the **Add** or **Edit** button beneath the Dialer Physical Interfaces table.

Related Topics

- Dialer Profile Dialog Box , on page 2337

Field Reference

Table 835: Dialer Physical Interface Dialog Box

Element	Description
ISDN BRI	The physical BRI interface associated with the dialer interface. Enter the name of an interface or interface role object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.
Pools	Associates dialer pools with a physical interface. Enter the names of one or more pools (as defined in the Dialer Profile Dialog Box , on page 2337), or click **Select** to display a selector. Use commas to separate multiple entries.

Element	Description
Switch Type	The ISDN switch type. Options for North America are: • basic-5ess—Lucent (AT&T) basic rate 5ESS switch • basic-dms100—Northern Telecom DMS-100 basic rate switch • basic-ni—National ISDN switches Options for Australia, Europe, and the UK are: • basic-1tr6—German 1TR6 ISDN switch • basic-net3—NET3 ISDN BRI for Norway NET3, Australia NET3, and New Zealand NET3 switch types; ETSI-compliant switch types for Euro-ISDN E-DSS1 signaling system • vn3—French VN3 and VN4 ISDN BRI switches Option for Japan is: • ntt—Japanese NTT ISDN switches Option for Voice/PBX system is: • basic-qsig—PINX (PBX) switches with QSIG signaling per Q.931 ()
SPID1	Applies only when you select Basic-DMS-100, Basic-NI, or Basic-5ess as the switch type. The service provider identifier (SPID) for the ISDN service to which the interface subscribes. Some service providers in North America assign SPIDs to ISDN devices when you first subscribe to an ISDN service. If you are using a service provider that requires SPIDs, your ISDN device cannot place or receive calls until it sends a valid assigned SPID to the service provider when accessing the switch to initialize the connection. Valid SPIDs can contain up to 20 characters, including spaces and special characters. **Note** We recommend that you do not enter a SPID for interfaces using the AT&T 5ESS switch type, even though they are supported.
SPID2	Applies only when you select DMS-100 or NI as the switch type. The service provider identifier (SPID) for a second ISDN service to which the interface subscribes. Valid SPIDs can contain up to 20 alphanumeric characters (no spaces are permitted).

ADSL on Cisco IOS Routers

Digital Subscriber Line (DSL) is a family of technologies that transports data over existing twisted-pair copper wire. DSL uses frequencies that are beyond the upper list used by POTS (plain old telephone service) to deliver broadband applications, such as multimedia and video, over the local loop (or *last mile*) that connects the telephone company's central office to customer sites.

Asymmetric Digital Subscriber Line (ADSL) is a form of DSL where the data flow downstream to customer sites is much greater than the data flow upstream to the central office (CO). This asymmetric setup is well-suited

for applications where users typically download far more information than they send, such as web surfing, video-on-demand, and remote LAN access. With ADSL, the connection speed is related to the distance between the customer site and the digital subscriber line-access multiplexer (DSLAM) that aggregates the connections from multiple customer sites onto a high-speed line.

ADSL downstream rates range from 1.5 to 9 Mbps, whereas upstream bandwidth ranges from 16 to 640 kbps. ADSL transmissions work at distances up to 18,000 feet (5,488 meters) over a single copper twisted pair. Newer versions of ADSL technology, such as ADSL2 and ADSL2+, offer even higher data rates for short distances, as well as power management and realtime performance monitoring.

ATM is used in many ADSL implementations due to its small, fixed-length cell size, which makes it suitable for carrying time-critical traffic, such as voice and video, in conjunction with other traffic. You can use Security Manager to configure ATM over DSL on a Cisco IOS router. For more information about configuring ADSL policies in Security Manager, see Defining ADSL Settings , on page 2341.

To configure ADSL in Security Manager, you must do the following:

1. Configure an ATM interface or subinterface. See Defining Basic Router Interface Settings , on page 2310.
2. Configure ADSL settings on the ATM interface or subinterface. See Defining ADSL Settings , on page 2341.
3. Configure PVCs on the ATM interface or subinterface. See Defining ATM PVCs , on page 2357.

Note If you perform discovery on the device, Security Manager populates the Interfaces policy with the ATM interface and subinterface and the ADSL policy with the ADSL settings for that interface. Any discovered PVCs are added to the PVC policy.

Defining ADSL Settings

When you configure an ADSL definition in Security Manager, you must select the ATM interface on which ADSL is being defined. In addition, we highly recommend that you specify the router type or the type of WIC (WAN interface card) installed in the router. The validity of DSL policy definitions is highly dependent on the hardware. By specifying the hardware used by this policy, you enable Security Manager to properly validate the values you define and avoid deployment failures.

You can optionally specify the following parameters:

- The DSL operating mode.
- Whether to enable dynamic VC bandwidth adjustments when using Inverse Multiplexing over ATM (IMA).
- Whether certain interface cards should use a particular set of carrier tones.

Modular Cisco IOS routers may contain multiple interface cards, each of which contains a single ATM interface. You may define only one ADSL definition per interface.

Before You Begin

- Make sure that the device contains an ADSL ATM interface. See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Related Topics

- Supported ADSL Operating Modes , on page 2340

- ADSL on Cisco IOS Routers , on page 2339
- PVCs on Cisco IOS Routers , on page 2352

Step 1 Do one of the following:

- (Device view) Select **Interfaces** > **Settings** > **DSL** > **ADSL** from the Policy selector.
- (Policy view) Select **Router Interfaces** > **Settings** > **DSL** > **ADSL** from the Policy Type selector. Select an existing policy or create a new one.

The ADSL page is displayed. See Table 838: ADSL Page , on page 2343 for a description of the fields on this page.

Step 2 Click the **Add** button beneath the table to display the ADSL Settings dialog box. See Table 839: ADSL Settings Dialog Box , on page 2344 for a description of the fields in this dialog box.

Step 3 In the ATM Interface field, enter the name of the ATM interface or interface role on which you want to define ADSL settings, or click **Select** to select an interface role or create a new one. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Note The interface that you select must be physically present on the device; otherwise, deployment fails.

Step 4 (Optional) Select the interface card type installed on the router.

Note When discovering from a live device, the correct interface card type is already displayed. If you did not perform discovery on a live device, or if Security Manager cannot detect the type of interface card installed on the device, this field displays “Unknown”.

Step 5 (Optional) When using IMA groups, select the **Allow bandwidth change on ATM PVCs** check box to enable dynamic adjustments to VC bandwidth in response to changes in group bandwidth. If this check box is left deselected, you must make these adjustments manually.

Step 6 (Optional) Specify the DSL operating mode for this ATM interface. See Table 836: ADSL Cards and Supported DSL Operating Modes , on page 2340 for a list of the operating modes supported for each card type.

Step 7 (Optional) Select the **Use low tone set** check box to have the interface card use carrier tones 29 through 48.

Step 8 Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the ADSL table.

Note To edit an ADSL definition, select it from the table, then click **Edit**. To remove an ADSL definition, select it, then click **Delete**.

Step 9 Repeat Step 2, on page 2342 through Step 8, on page 2342 to define ADSL settings on additional ATM interfaces. Only one ADSL definition may be defined on an interface.

ADSL Policy Page

Use the ADSL page to create, edit, and delete ADSL definitions on the ATM interfaces of the router. For more information, see Defining ADSL Settings , on page 2341.

Navigation Path

- (Device view) Select **Interfaces** > **Settings** > **DSL** > **ADSL** from the Policy selector.

- (Policy view) Select **Router Interfaces > Settings > DSL > ADSL** from the Policy Type selector. Right-click **ADSL** to create a policy, or select an existing policy from the Shared Policy selector.

- Table Columns and Column Heading Features , on page 51
- Filtering Tables , on page 50

Field Reference

Table 838: ADSL Page

Element	Description
ATM Interface	The ATM interface on which ADSL settings are defined.
Interface Card	The type of device or ADSL interface card on which the ATM interface resides.
Bandwidth Change	Indicates whether the router makes dynamic adjustments to VC bandwidth as overall bandwidth changes. (This is relevant only when IMA groups are configured on the ATM interface.)
DSL Operating Mode	The DSL operating mode for this interface.
Tone Low	Indicates whether the interface is using the low tone set (carrier tones 29 through 48).
Add button	Opens the ADSL Settings Dialog Box , on page 2343. From here you can define the ADSL settings for a selected ATM interface.
Edit button	Opens the ADSL Settings Dialog Box , on page 2343. From here you can edit the selected ADSL definition.
Delete button	Deletes the selected ADSL definition from the table.

ADSL Settings Dialog Box

Use the ADSL Settings dialog box to configure ADSL settings on a selected ATM interface.

Note When you configure ADSL settings, we highly recommend that you select the type of device or interface card on which the ATM interface is defined. ADSL settings are highly dependent on the hardware. Defining the hardware type in Security Manager enables proper validation of your configuration for a successful deployment to your devices.

Navigation Path

Go to the ADSL Policy Page , on page 2342, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Defining ADSL Settings , on page 2341
- PVC Policy Page , on page 2360

Field Reference

Table 839: ADSL Settings Dialog Box

Element	Description
ATM Interface	The ATM interface on which ADSL settings are defined. Enter the name of an interface or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. **Note** We recommend that you do not define an interface role that includes ATM interfaces from different interface cards. The different settings supported by each card type may cause deployment to fail. **Note** You can create only one ADSL definition per interface.
Interface Card	The device type or the type of interface card installed on the router: • [blank]—The interface card type is not defined. • WIC-1ADSL—A 1-port ADSL WAN interface card that provides ADSL over POTS (ordinary telephone lines). • WIC-1ADSL-I-DG—A 1-port ADSL WAN interface card that provides ADSL over ISDN with Dying Gasp support. (With Dying Gasp, the router warns the DSLAM of imminent line drops when the router is about to lose power.) • WIC-1ADSL-DG—A 1-port ADSL WAN interface card that provides ADSL over POTS with Dying Gasp support. • HWIC-1ADSL—A 1-port high-speed ADSL WAN interface card that provides ADSL over POTS. • HWIC-1ADSLI—A 1-port high-speed ADSL WAN interface card that provides ADSL over ISDN. • HWIC-ADSL-B/ST—A 2-port high-speed ADSL WAN interface card that provides ADSL over POTS with an ISDN BRI port for backup. • HWIC-ADSLI-B/ST—A 2-port high-speed ADSL WAN interface card that provides ADSL over ISDN with an ISDN BRI port for backup.

Element	Description
Interface Card (continued)	• 857 ADSL—Cisco 857 Integrated Service Router with an ADSL interface. • 876 ADSL—Cisco 876 Integrated Services Router with an ADSL interface. • 877 ADSL—Cisco 877 Integrated Services Router with an ADSL interface. • 1801 ADSLoPOTS—Cisco 1801 Integrated Services Router that provides ADSL over POTS. • 1802 ADSLoISDN—Cisco 1802 Integrated Services Router that provides ADSL over ISDN. **Note** When discovering from a live device, the correct interface card type will already be displayed. If you did not perform discovery on a live device, or if Security Manager cannot detect the type of interface card installed on the device, this field displays "Unknown".
Allow bandwidth change on ATM PVCs	When selected, the router makes dynamic adjustments to VC bandwidth in response to changes in the overall bandwidth of the Inverse Multiplexing over ATM (IMA) group defined on the ATM interface. When deselected, PVC bandwidth must be adjusted manually (using the CLI) whenever an individual physical link in the IMA group goes up or down.
DSL Operating Mode	The operating mode configured for this ADSL line: • auto—Performs automatic negotiation with the DSLAM located at the central office (CO). This is the default. • ansi-dmt—The line trains in ANSI T1.413 Issue 2 mode. • itu-dmt—The line trains in G.992.1 mode. • splitterless—The line trains in G.992.2 (G.Lite) mode. • etsi—The line trains in ETSI (European Telecommunications Standards Institute) mode. • adsl2—The line trains in G.992.3 (adsl2)mode. • adsl2+—The line trains in G.992.5 (adsl2+) mode. **Note** See Table 836: ADSL Cards and Supported DSL Operating Modes , on page 2340 for a description of the operating modes that are supported by each card type.
Use low tone set	When selected, the interface card uses carrier tones 29 through 48. When deselected, the interface card uses carrier tones 33 through 56. **Note** Leave this option deselected when the interface card is operating in accordance with Deutsche Telekom specification U-R2.

SHDSL on Cisco IOS Routers

Digital Subscriber Line (DSL) is a family of technologies that transports data over existing twisted-pair copper wire. DSL uses frequencies that are beyond the upper list used by POTS (plain old telephone service) to deliver broadband applications, such as multimedia and video, over the local loop (or *last mile*) that connects the telephone company's central office to customer sites.

Based on the International Telecommunications Union (ITU) G.991.2 global industry standard, symmetric high-speed digital subscriber line (SHDSL) delivers symmetrical data rates from 192 up to 2.3 Mbps on a single wire pair. It transports many types of signals, such as T1, E1, ISDN, ATM, and IP. In addition, the G.SHDSL signal has a greater distance reach from the central office than ADSL and proprietary SDSL connections.

To configure SHDSL in Security Manager, do the following:

1. Configure the SHDSL controller. See Defining SHDSL Controllers , on page 2346.
2. Deploy the SHDSL policy. If ATM mode is activated, the router creates an ATM interface that corresponds to the controller upon deployment. See Working with Deployment and the Configuration Archive , on page 405.
3. Rediscover the device to add the new ATM interface to Security Manager. See Discovering Policies on Devices Already in Security Manager , on page 181.
4. (Optional) Create one or more subinterfaces on the ATM interface. See Defining Basic Router Interface Settings , on page 2310.
5. Configure PVCs on the ATM interface or subinterface. See Defining ATM PVCs , on page 2357.

Note If you perform discovery on the device, Security Manager populates the SHDSL policy with the definition of the controller and the Interfaces policy with the ATM interface and subinterface. Any discovered PVCs are added to the PVC policy.

Related Topics

- PVCs on Cisco IOS Routers , on page 2352

Defining SHDSL Controllers

When you configure an SHDSL controller in Security Manager, you must enter the name of the controller that is installed in the Cisco IOS router. The following settings are then applied automatically:

- ATM mode is enabled.
- The line termination is set to CPE (customer premises equipment).
- The line mode is set to Auto.

You can optionally change the line termination to CO and specify the DSL mode and line mode. In addition, you can define signal-to-noise ratio margins to improve line stability.

A Cisco IOS router may contain multiple SHDSL controllers. You may define only one SHDSL definition per controller.

Note When you deploy an SHDSL policy with ATM mode enabled, an ATM interface is created automatically on the router. Perform rediscovery to add the interface into Security Manager. You can then define PVCs on the ATM interface as required. See Defining ATM PVCs , on page 2357.

Before You Begin

- Make sure that an SHDSL controller in installed on the device.

Related Topics

- SHDSL on Cisco IOS Routers , on page 2346

Step 1 Do one of the following:

- (Device view) Select **Interfaces > Settings > DSL > SHDSL** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > DSL > SHDSL** from the Policy Type selector. Select an existing policy or create a new one.

The SHDSL page is displayed. See SHDSL Policy Page , on page 2347 for a description of the fields on this page.

Step 2 Click the **Add** button beneath the table to display the SHDSL dialog box.

Step 3 Enter the name of the controller, or click **Select** to display the utility for generating the name. See Controller Auto Name Generator Dialog Box , on page 2351.

Note The controller that you select must be physically present on the device; otherwise, deployment fails.

Step 4 Define the SHDSL controller as required. For more information, see Table 841: SHDSL Dialog Box , on page 2349.

Step 5 Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the SHDSL table.

Note To edit an SHDSL controller, select it from the table, then click **Edit**. To remove an SHDSL controller, select it, then click **Delete**.

Step 6 Repeat Step 2, on page 2347 through Step 5, on page 2347 to define additional SHDSL controllers. Only one definition may be defined per controller.

SHDSL Policy Page

Use the SHDSL page to create, edit, and delete DSL controller definitions on the router. For more information, see Defining SHDSL Controllers , on page 2346.

Navigation Path

- (Device view) Select **Interfaces > Settings > DSL > SHDSL** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > DSL > SHDSL** from the Policy Type selector. Right-click **SHDSL** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 841: SHDSL Dialog Box

Element	Description
Name	The name of the controller. Enter a name manually, or click **Select** to display a dialog box for generating a name. See Controller Auto Name Generator Dialog Box , on page 2351.
Description	Additional information about the controller (up to 80 characters).
Shutdown	When selected, the DSL controller is in shutdown state. However, its definition is not deleted. When deselected, the DSL controller is enabled. This is the default.
Configure ATM mode	When selected, sets the controller into ATM mode and creates an ATM interface with the same ID as the controller. This is the default. You must enable ATM mode and then perform rediscovery to configure ATM or PVCs on the device. When deselected, ATM mode is disabled. No ATM interface is created on deployment. **Note** You cannot remove ATM mode from a controller after it has been saved in Security Manager.
Line Termination	The line termination that is set for the router: • CPE—Customer premises equipment. This is the default. • CO—Central office.

Element	Description
DSL Mode	The DSL operating mode, including regional operating parameters, used by the controller: • [blank]—The operating mode is not defined. (When deployed, the Annex A standard for North America is used.) • A—Supports Annex A of the G.991.2 standard for North America. • A-B—Supports Annex A or Annex B. Available only when the Line Term is set to CPE. The appropriate mode is selected when the line trains. • A-B-ANFP—Supports Annex A or Annex B-ANFP. Available only when the Line Term is set to CPE. The appropriate mode is selected when the line trains. • B—Supports Annex B of the G.991.2 standard for Europe. • B-ANFP—Supports Annex B-ANFP (Access Network Frequency Plan). **Note** The available DSL modes are dependent on the selected line termination.
Line Mode settings	
Line Mode	The line mode used by the controller: • auto—The controller operates in the same mode as the other line termination (2-wire line 0, 2-wire line 1, or 4-wire enhanced). This is the default for CPE line termination. • 2-wire—The controller operates in two-wire mode. This is the default for CO line termination. • 4-wire—The controller operates in four-wire mode. **Note** You can select Auto only when you configure the controller as the CPE.
Line	Applies only when the Line Mode is defined as 2-wire. The pair of wires to use: • line-zero—RJ-11 pin 1 and pin 2. This is the default for CO line termination. • line-one—RJ-11 pin 3 and pin 4.
Exchange Handshake	Applies only when the Line Mode is defined as 4-wire. The type of handshake mode to use: • [blank]—The handshake mode is not specified. (When deployed, the enhanced option is used.) This is the default. • enhanced—Exchanges handshake status on both wire pairs. • standard—Exchanges handshake status on the main wire pair only.

Element	Description
Line Rate	Does not apply when the Line Mode is defined as Auto. The DSL line rate (in kbps) available for the SHDSL port: • auto—The controller selects the line rate. This is available only in 2-wire mode. • Supported line rates: • For 2-wire mode: 192, 256, 320, 384, 448, 512, 576, 640, 704, 768, 832, 896, 960, 1024, 1088, 1152, 1216, 1280, 1344, 1408, 1472, 1536, 1600, 1664, 1728, 1792, 1856, 1920, 1984, 2048, 2112, 2176, 2240, and 2304. • For 4-wire mode: 384, 512, 640, 768, 896, 1024, 1152, 1280, 1408, 1536, 1664, 1792, 1920, 2048, 2176, 2304, 2432, 2560, 2688, 2816, 2944, 3072, 3200, 3328, 3456, 3584, 3712, 3840, 3968, 4096, 4224, 4352, 4480, and 4608. **Note** Third-party equipment may use a line rate that includes an additional SHDSL overhead of 8 kbps for 2-wire mode or 16 kbps for 4-wire mode.
SNR Margin settings	
Current	The current signal-to-noise (SNR) ratio on the controller, in decibels (dB). Valid values range from -10 to 10 dB. This option can create a more stable line by making the line train more than current noise margin plus SNR ratio threshold during training time. If any external noise is applied that is less than the set SNR margin, the line will be stable. **Note** Select **disable** to disable the current SNR.
Snext	The Self Near-End Crosstalk (SNEXT) signal-to-noise ratio on the controller, in decibels. Valid values range from -10 to 10 dB. This option can create a more stable line by making the line train more than SNEXT threshold during training time. If any external noise is applied that is less than the set SNEXT margin, the line will be stable. **Note** Select **disable** to disable the SNEXT SNR.

Controller Auto Name Generator Dialog Box

Use the Controller Auto Name Generator dialog box to have Security Manager generate a name for the DSL controller based on its location in the router.

Navigation Path

Go to the SHDSL Controller Dialog Box , on page 2349, then click **Select** in the Name field**.**

Field Reference

Table 842: Controller Auto Name Generator Dialog Box

Element	Description
Type	The type of interface. This field displays the value DSL and is read-only.
Card	The card related to the controller.
Slot	The slot related to the controller.
Port	The port related to the controller. **Note** The information you enter in these fields forms the remainder of the generated name, as displayed in the Result field.
Result	The name generated by Security Manager from the information you entered for the controller location. The name displayed in this field is read-only. **Tip** After closing this dialog box, you can edit the generated name in the SHDSL dialog box, if required.

PVCs on Cisco IOS Routers

Asynchronous Transfer Mode (ATM) is an International Telecommunication Union (ITU-T) standard designed for the high-speed transfer of voice, video, and data through public and private networks using cell relay technology. A cell switching and multiplexing technology, ATM combines the benefits of circuit switching (constant transmission delay, guaranteed capacity) with those of packet switching (flexibility, efficiency for intermittent traffic). An ATM network is made up of one or more ATM switches and ATM endpoints, such as a Cisco IOS router.

There are three general types of ATM services, permanent virtual connections (PVCs), switched virtual connections (SVCs), and connectionless service. PVCs allow direct and permanent connections between sites to provide a service that is similar to a leased line. Advantages of PVCs are the guaranteed availability of a connection and that no call setup procedures are required between switches. Each piece of equipment between the source and destination must be manually provisioned for the PVC.

For more information about ATM PVCs, see:

- Understanding Virtual Paths and Virtual Channels , on page 2353
- Understanding ATM Service Classes , on page 2354
- Understanding ATM Management Protocols , on page 2355

For more information about defining PVCs in Security Manager, see:

- Defining ATM PVCs , on page 2357
- SHDSL on Cisco IOS Routers , on page 2346

Related Topics

- ADSL on Cisco IOS Routers , on page 2339
- SHDSL on Cisco IOS Routers , on page 2346

Understanding Virtual Paths and Virtual Channels

ATM networks are fundamentally connection oriented. This means that a virtual connection needs to be established across the ATM network before any data transfer. Two types of ATM connections exist:

- Virtual path connections (VPCs), identified by a virtual path identifier (VPI).
- Virtual channel connections (VCCs), identified by the combination of a VPI and a VCI (virtual channel identifier). PVCs are a type of VCC where a permanent connection is defined between two sites.

As shown in Figure 47: ATM Virtual Path and Virtual Channel Connections, on page 2353, a virtual path is a bundle of virtual channels, all of which are switched transparently across the ATM network on the basis of the common VPI. A VPC can be thought of as a bundle of VCCs with the same VPI value.

Figure 47: ATM Virtual Path and Virtual Channel Connections

Every cell header contains a VPI field and a VCI field, which explicitly associate a cell with a given virtual channel on a physical link. It is important to remember the following attributes of VPIs and VCIs:

- VPIs and VCIs are not addresses, such as MAC addresses used in LAN switching.
- VPIs and VCIs are explicitly assigned at each segment of a connection and, as such, have only local significance across a particular link. They are remapped, as appropriate, at each switching point.

Using the VPI/VCI identifier, the ATM layer can multiplex (interleave), demultiplex, and switch cells from multiple connections. Certain VPI/VCI identifiers are reserved for particular uses, such as the Integrated Local Management Interface (ILMI).

Understanding ATM Service Classes

Version 4.0 of the Traffic Management Specification published by the ATM Forum defines five service classes that describe the user traffic transmitted on a network and the quality of service that a network needs to provide for that traffic. Security Manager supports the following ATM service classes:

- *Available Bit Rate (ABR)* This is a service class where ATM switches make no guarantee of cell delivery, but do guarantee a minimum bit rate and that cell loss is kept as low as possible with the use of a feedback mechanism. The ABR service category is designed for VCs that carry file transfers and other bursty, non-real-time traffic that requires a minimum amount of bandwidth. This bandwidth is specified via a minimum cell rate that must be available while the VC is configured and active. For more details, see *Understanding the Available Bit Rate (ABR) Service Category for ATM VCs* at: http://www.cisco.com/en/US/tech/tk39/tk51/technologies_tech_note09186a00800fbc76.shtml .
- *Constant Bit Rate (CBR)* This is a service class where cells are transmitted in a continuous bitstream to meet voice and video QoS needs. The CBR service class is designed for ATM virtual circuits (VCs) that need a static amount of bandwidth that is continuously available for the duration of the active connection. An ATM VC configured as CBR can send cells at peak cell rate (PCR) at any time and for any duration. It also can send cells at a rate less than the PCR or even emit no cells. The configuration on CBR may vary with different platforms. For more details, see *Understanding the CBR Service Category for ATM VCs* at: http://www.cisco.com/en/US/tech/tk39/tk51/technologies_tech_note09186a0080094e6a.shtml .
- *Unspecified Bit Rate (UBR)* This is a service class where the network management makes no Quality of Service (QoS) commitment. It models the best-effort service that the Internet normally provides and is suitable for applications tolerant to delay that do not require real-time responses. Examples include email, fax transmission, file transfers, Telnet, LAN and remote office interconnections. For more details, see *Understanding the UBR Service Category for ATM Virtual Circuits* at: http://www.cisco.com/en/US/tech/tk39/tk51/technologies_tech_note09186a00800a4837.shtml .
- *Unspecified Bit Rate (UBR+)* Cisco provides a variant of the UBR service class called UBR+. The main advantage of the UBR+ service class is that it allows an ATM end-system to signal a minimum cell rate to an ATM switch in a connection request, and the ATM network attempts to maintain this minimum as an end-to-end guarantee. For more details, see *Understanding the UBR+ Service Category for ATM VCs* at: http://www.cisco.com/en/US/tech/tk39/tk51/technologies_tech_note09186a0080094b40.shtml .
- *Variable Bit Rate - Non-Real Time (VBR-nrt)* This service class is used to transmit non-real-time applications that are bursty in nature. The traffic characteristics are defined in terms of the Peak Cell Rate (PCR), Sustained Cell Rate (SCR), and Minimum Burst Size (MBS). For more details, see *Understanding the VBR-nrt Service Category and Traffic Shaping for ATM VCs* at: http://www.cisco.com/en/US/tech/tk39/tk51/technologies_tech_note09186a0080102a42.shtml .
- *Variable Bit Rate - Real Time (VBR-rt)* This service class is used to transmit real-time data that is sensitive to time delays, like compressed voice over IP and video conferencing. As with VBR-nrt, VBR-rt traffic is defined in terms of a PCR, SCR, and MBS. For more details, see *Understanding the Variable Bit Rate Real Time (VBR-rt) Service Category for ATM VCs* at: http://www.cisco.com/en/US/tech/tk39/tk51/technologies_tech_note09186a0080094cd0.shtml .

You can use these service classes to define ATM quality of service (QoS) guarantees, such as traffic shaping. Traffic shaping is the use of queues to constrain data bursts, limit peak data rate, and smooth jitter so that traffic fits within the envelope defined by the traffic contract. ATM devices use traffic shaping to adhere to the terms of the traffic contract.

Related Topics

Understanding ATM Management Protocols

ATM uses two different types of signaling for tracking the status of PVCs:

- Integrated Local Management Interface (ILMI). For more information, see Understanding ILMI , on page 2355.
- Flow 4 (F4) and Flow 5 (F5) Operation, Administration, and Maintenance (OAM) cells. For more information, see Understanding OAM , on page 2356.

Security Manager can be used to enable and disable ILMI on specific PVCs and to configure F5 OAM functionality.

- PVCs on Cisco IOS Routers , on page 2352

Understanding ILMI

The Integrated Local Management Interface (ILMI) is a protocol defined by the ATM Forum for setting and capturing physical layer, ATM layer, virtual path, and virtual circuit parameters on ATM interfaces. ILMI facilitates network-wide autoconfiguration by enabling devices to determine the status of components at the other end of a physical link and to negotiate a common set of operational parameters to ensure interoperability. The ATM routing protocols, PNNI (Private Network to Network Interface) and IISP (Interim-Interswitch Signaling Protocol), use this information to discover and bring up a network of interconnected ATM switch routers.

When two ATM interfaces run the ILMI protocol, they exchange ILMI packets across the physical connection. These packets consist of SNMP messages as large as 484 octets. ATM interfaces encapsulate these messages in an ATM adaptation layer 5 (AAL5) trailer, segment the packet into cells, and schedule the cells for transmission. ATM interfaces use the SNMP object IDs in network functions such as permanent virtual circuit (PVC) autodiscovery, which is particularly useful in digital subscriber line (DSL) applications.

ILMI organizes managed objects into multiple information bases (MIBs), including one for link management. This MIB contains the following object groups for all ATM interfaces:

- Physical layer—ILMI 4.0 discontinues or "deprecates" earlier physical-layer ILMI values and specifies the use of the standard Interface MIB (RFC 1213).

- ATM layer—Indicates the number of available bits for VPI and VCI values in the ATM cell header, maximum number of virtual path connections (VPCs) and virtual channel connections (VCCs) allowed, number of configured PVCs, and so on.
- Virtual path connection—Indicates the up or down status of a VPC and its Quality of Service (QoS) parameters.
- Virtual channel connection—Indicates the up or down status of the VCC and its QoS parameters.

Administrators may enable or disable ILMI at will, but we highly recommend you enable it. Without ILMI, you must manually configure many of the parameters otherwise managed by ILMI for the ATM devices to operate correctly. ILMI operates over a reserved PVC of VPI=X, VCI=16.

Related Topics

- Understanding ATM Management Protocols , on page 2355
- PVCs on Cisco IOS Routers , on page 2352

Understanding OAM

The Operation, Administration, and Maintenance (OAM) feature provides fault management and performance management for ATM and is based on the standard defined in ITU recommendation I.610. OAM detects network connectivity failures on a PVC and reacts by bringing down the PVC. Without OAM, a PVC would remain up after network connectivity is lost. In such a situation, routing table entries would continue to point to the PVC, resulting in lost packets.

Security Manager enables the use of F5 OAM, which operates at the virtual circuit (VC) level. To detect a failure along the PVC path on an end-device, such as a Cisco IOS router, OAM uses the following cells:

- Loopback cells—At regular intervals, routers configured for OAM send loopback cells which must be looped in the network. This looping point can be the machine at the end of the PVC (end-to-end loopback cells) or a device on the path (segment loopback cells). A failure occurs when the loopback cell fails to return to its point of origin.
- Continuity Check (CC) cells—CC cells are sent regularly by routers configured for OAM to check the integrity of the link. CC cells can be sent either end-to-end or confined to a particular segment of the PVC. Activation and deactivation cells are used to initiate and suspend continuity checking. Any connectivity failures are reported in special SNMP notifications.
- Alarm Indication Signal (AIS) cells—In the event of a failure at the physical layer, AIS cells are sent to downstream devices to report a virtual connection failure at the ATM layer. The PVC moves to the down state after a defined number of AIS cells are received and does not come up again until a defined interval passes without additional AIS cells.
- Remote Detection Indication (RDI) cells—When AIS cells are sent to warn downstream devices of a connectivity failure, RDI cells are sent upstream in response as a control and feedback mechanism for the network.

AIS/RDI cells are sent using the same VPI/VCI as the user cells on the affected PVC until the failure is resolved.

- Defining OAM Management on ATM PVCs , on page 2359

Defining ATM PVCs

You define an ATM permanent virtual circuit (PVC) by selecting an ATM interface and then defining the following settings:

- The PVC ID.
- The type of encapsulation to use.
- Whether ILMI management is enabled on this PVC.
- Whether Inverse ARP (InARP) is used to learn the IP addresses of the destination devices.
- Options related to PPP over Ethernet (PPPoE) and PPP over ATM (PPPoA).
- Quality-of-service settings, such as traffic shaping.
- Static IP address mappings in place of InARP.

For information about defining F5 Operation, Administration, and Maintenance (OAM) management, such as loopbacks and continuity checks, on PVCs, see Defining OAM Management on ATM PVCs , on page 2359.

Before You Begin

- When configuring ATM over DSL, make sure that you have configured either an ADSL policy (see ADSL on Cisco IOS Routers , on page 2339) or an SHDSL policy (SHDSL on Cisco IOS Routers , on page 2346).
- Make sure that the device contains an ATM interface and subinterface. (PVCs are typically configured on ATM subinterfaces.) See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Note When configuring ATM for SHDSL, the ATM interface is created when you define the SHDSL controller and enable ATM mode. You must then rediscover the device to add the ATM interface to Security Manager. See Defining SHDSL Controllers , on page 2346.

Related Topics

- Defining OAM Management on ATM PVCs , on page 2359
- Understanding Policing and Shaping Parameters , on page 2537
- PVCs on Cisco IOS Routers , on page 2352

Step 1 Do one of the following:

- (Device view) Select **Interfaces** > **Settings** > **PVC** from the Policy selector.

- (Policy view) Select **Router Interfaces > Settings > PVC** from the Policy Type selector. Select an existing policy or create a new one.

The PVC page is displayed. See Table 843: PVC Page , on page 2361 for a description of the fields on this page.

Step 2 Click the **Add** button beneath the table to display the PVC dialog box. See Table 844: PVC Dialog Box , on page 2362 for a description of the fields in this dialog box.

Step 3 In the Interface field, enter the name of the ATM interface, ATM subinterface, or interface role on which you want to define the PVC, or click **Select** to select an interface role or to create a new one.

Step 4 Select the type of device or DSL WAN interface card that contains the ATM interface.

Note We highly recommend that you define this setting to ensure the proper validation of your PVC policy, as the settings in this policy are highly hardware-dependent.

Step 5 On the Settings tab of the PVC dialog box, define the basic settings of the PVC:

a) Enter the VPI/VCI identifier and an optional text handle. If you are defining the management PVC, select the **Management PVC (ILMI)** check box.

Note An error occurs if two users attempt to define PVCs with the same identifiers at the same time.

b) Select the type of ATM encapsulation to use. If you select aal5autoppp or aal5ciscoppp, you must define the virtual template to use for PPPoA, or click Select to display a selector. If you select aal5mux as the encapsulation type, you must select the protocol that is carried by the PVC.

Note Do not select an encapsulation type when defining the management PVC.

Note If you modify the virtual template settings on an existing PVC, you must enter the **shutdown** command followed by the **no shutdown** command on the ATM subinterface to restart the interface. This causes the newly configured parameters to take effect.

c) Select the Enable ILMI check box to enable the ILMI to manage this PVC. For more information, see Understanding ILMI , on page 2355.

Note You cannot configure the management PVC on a subinterface.

d) Select the Inverse ARP check box to enable the PVC to dynamically learn the Layer 3 addresses that are required to forward traffic to those devices.

Note Alternatively, you can create static address mappings, as described in Step 7, on page 2358.

e) In the PPPoE Max Sessions field, define the maximum number of PPPoE sessions allowed on the PVC.

f) In the VPN Service Name field, define the static domain name to use for PPPoA sessions on the PVC.

See Table 845: PVC Dialog Box—Settings Tab , on page 2364 for a description of the fields on the Settings tab.

Step 6 (Optional) On the QoS tab of the PVC dialog box, define the type of ATM traffic shaping to perform on the traffic carried by this PVC. Traffic shaping regulates the flow of traffic carried by the PVC by queuing traffic that exceeds the defined bit rates. See Table 846: PVC Dialog Box—QoS Tab , on page 2367 for a description of the fields on the QoS tab.

Step 7 (Optional) On the Protocol tab of the PVC dialog box, create static mappings for the IP addresses at the other end of the PVC:

a) Click **Add** to display the Define Mapping dialog box. See Table 848: Define Mapping Dialog Box , on page 2371 for a description of the fields in this dialog box.

b) Select IP Address, then enter the address or network/host object that you want to map, or click **Select** to select a network/host object from a list or to create a new one.

c) Click **OK**. The static mapping is displayed on the Protocol tab.
d) Repeat 7.a, on page 2358 through 7.c, on page 2359 to define additional static mappings.

Note You can also use the Protocol tab to change the type of InARP to use, broadcast or non-broadcast.

Step 8 Click **Advanced** to configure OAM management on the PVC. See Defining OAM Management on ATM PVCs , on page 2359.

Step 9 Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the PVC table.

Note To edit a PVC, select it from the table, then click **Edit**. To remove a PVC, select it, then click **Delete**.

Step 10 Repeat Step 2, on page 2358 through Step 9, on page 2359 to define additional PVCs.

Defining OAM Management on ATM PVCs

Security Manager enables you to configure the following F5 (VC level) Operation, Administration, and Maintenance (OAM) cells for detecting PVC failures in a Cisco IOS router:

- Loopback cells
- Continuity Check (CC) cells
- Alarm Indication Signal (AIS) cells
- Remote Detection Indication (RDI) cells

You can enable and disable each of these cell types and define settings that determine how each cell type affects the PVC when a failure is detected.

Before You Begin

- Select the ATM interface on which the PVC is defined.
- Define the general settings and the QoS settings of the PVC. See Defining ATM PVCs , on page 2357.

Related Topics

- Defining ATM PVCs , on page 2357
- PVCs on Cisco IOS Routers , on page 2352

Step 1 In the PVC dialog box, click **Advanced** to display the PVC Advanced Settings dialog box. See Table 849: PVC Advanced Settings Dialog Box , on page 2371 for a description of the fields in this dialog box.

Step 2 Enable OAM loopback cells on the selected PVC:

a) Click the **OAM-PVC** tab. See Table 851: PVC Advanced Settings Dialog Box—OAM-PVC Tab , on page 2374 for a description of the fields on this tab.
b) Select the **Enable OAM Management** check box.
c) Define the frequency of loopback cell transmissions.

Step 3 (Optional) Enable segment CC cells on the PVC:

a) Under Segment Continuity Check, select **Configure Continuity Check**.

b) Choose whether the router should act as the sink, source, or both. This determines the direction in which CC cells are sent.
c) Choose whether the PVC should remain up after segment or end-to-end failures are detected.

Note Select **Deny Activation Requests** to have the router reject CC activation requests received from peers.

Step 4 (Optional) Enable end-to-end CC cells on the PVC, using the procedure described in Step 3, on page 2359 for segment CC cells.

Step 5 (Optional) Configure additional loopback cell parameters:

a) Click the **OAM** tab.
b) Select the **Enable OAM Retry** check box, then define the down count, up count, and retry frequency. See Table 850: PVC Advanced Settings Dialog Box—OAM Tab , on page 2372 for a description of the available options.

Step 6 (Optional) Configure additional CC cell parameters:

a) Select the **Enable** check box for segment CC cells, then define the activation count, deactivation count, and retry frequency. These fields determine how many activation and deactivation requests are sent to peers and how often the router waits between each attempt. See Table 850: PVC Advanced Settings Dialog Box—OAM Tab , on page 2372 for a description of the available options.
b) Repeat 6.a, on page 2360 for end-to-end CC cells.

Step 7 (Optional) Configure AIS/RDI cells on the PVC:

a) On the OAM tab, select the **Enable AIS-RDI Detection** check box.
b) Define how many AIS/RDI cells are required to move the PVC to the down state.
c) Define how many seconds must elapse without receiving AIS/RDI cells before moving the PVC to the up state.

Step 8 Click **OK** to close the dialog box and return to PVC dialog box.

PVC Policy Page

Use the PVC page to create, edit, and delete permanent virtual connections (PVCs) on the router. PVCs allow direct and permanent connections between sites to provide a service that is similar to a leased line. These PVCs can be used in ADSL, SHDSL, or pure ATM environments. For more information, see Defining ATM PVCs , on page 2357.

Navigation Path

- (Device view) Select **Interfaces > Settings > PVC** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > PVC** from the Policy Type selector. Right-click **PVC** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 843: PVC Page

Element	Description
ATM Interface	The ATM interface on which the PVC is defined.
Interface Card	The type of device or WAN interface card on which the ATM interface resides.
PVC ID	The Virtual Path Identifier (VPI) and Virtual Channel Identifier (VCI) of the PVC.
Settings	Additional settings configured for the PVC, including encapsulation, the number of PPPoE sessions, and the VPN service name.
QoS	Quality-of-service settings defined for the PVC, such as traffic shaping.
Protocol	The IP protocol mappings (static maps or Inverse ARP) configured for the PVC.
OAM	The F5 Operation, Administration, and Maintenance (OAM) loopback, continuity check, and AIS/RDI definitions configured for the PVC.
OAM-PVC	The OAM management cells that are configured for the PVC.
Add button	Opens the PVC Dialog Box , on page 2361. From here you can define a PVC.
Edit button	Opens the PVC Dialog Box , on page 2361. From here you can edit the selected PVC.
Delete button	Deletes the selected PVC from the table.

PVC Dialog Box

Use the PVC dialog box to configure ATM permanent virtual circuits (PVCs).

You can configure the following types of interface cards:

- Unknown—The interface card type is not defined.
- WIC-1ADSL—A 1-port ADSL WAN interface card that provides ADSL over POTS (ordinary telephone lines).
- WIC-1ADSL-I-DG—A 1-port ADSL WAN interface card that provides ADSL over ISDN with Dying Gasp support. (With Dying Gasp, the router warns the DSLAM of imminent line drops when the router is about to lose power.)
- WIC-1ADSL-DG—A 1-port ADSL WAN interface card that provides ADSL over POTS with Dying Gasp support.
- HWIC-1ADSL—A 1-port high-speed ADSL WAN interface card that provides ADSL over POTS.
- HWIC-1ADSLI—A 1-port high-speed ADSL WAN interface card that provides ADSL over ISDN.

- HWIC-ADSL-B/ST—A 2-port high-speed ADSL WAN interface card that provides ADSL over POTS with an ISDN BRI port for backup.
- HWIC-ADSLI-B/ST—A 2-port high-speed ADSL WAN interface card that provides ADSL over ISDN with an ISDN BRI port for backup.
- WIC-1-SHDSL-V2—A 1-port multiline G.SHDSL WAN interface card with support for 2-wire mode and enhanced 4-wire mode.
- WIC-1-SHDSL-V3—A 1-port multiline G.SHDSL WAN interface card with support for 2-wire mode and 4-wire mode (standard & enhanced).
- NM-1A-T3—A 1-port ATM network module with a T3 link.
- NM-1A-OC3-POM—A 1-port ATM network module with an optical carrier level 3 (OC-3) link and three operating modes (multimode, single-mode intermediate reach (SMIR), and single-mode long-reach (SMLR)).
- NM-1A-E3—A 1-port ATM network module with an E3 link.
- 857 ADSL—Cisco 857 Integrated Service Router with an ADSL interface.
- 876 ADSL—Cisco 876 Integrated Services Router with an ADSL interface.
- 877 ADSL—Cisco 877 Integrated Services Router with an ADSL interface.
- 878 888 G.SHDSL—Cisco 878 Integrated Services Router with a G.SHDSL interface.
- 1801 ADSLoPOTS—Cisco 1801 Integrated Services Router that provides ADSL over POTS.
- 1802 ADSLoISDN—Cisco 1802 Integrated Services Router that provides ADSL over ISDN.
- 1803 G.SHDSL—Cisco 1803 Integrated Services Router that provides 4-wire G.SHDSL.

Navigation Path

Go to the PVC Policy Page , on page 2360, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Defining ATM PVCs , on page 2357

Field Reference

Table 844: PVC Dialog Box

Element	Description
ATM Interface	The ATM interface on which the PVC is defined. Enter the name of an interface, subinterface, or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. **Note** We strongly recommend not defining an interface role that includes ATM interfaces from different interface cards. The different settings supported by each card type may cause deployment to fail.

Element	Description
Interface Card	The type of WAN interface card installed on the router or the router type. Supported card types are listed above. **Note** To ensure proper policy validation, we highly recommend that you define a value in this field. When you discover a live device, the correct interface card type will already be displayed. If you did not perform discovery on a live device, or if Security Manager cannot detect the type of interface card installed on the device, this field displays "Unknown".
Settings tab	Defines basic PVC settings, such as the VPI/VCI and encapsulation. See PVC Dialog Box—Settings Tab , on page 2363.
QoS tab	Defines ATM traffic shaping and other quality-of-service settings for the PVC. See PVC Dialog Box—QoS Tab , on page 2366.
Protocol tab	Defines the IP protocol mappings configured for the PVC (static maps or Inverse ARP). See PVC Dialog Box—Protocol Tab , on page 2369.
Advanced button	Defines F5 Operation, Administration, and Maintenance (OAM) settings for the PVC. See PVC Advanced Settings Dialog Box—OAM Tab , on page 2372.

PVC Dialog Box—Settings Tab

Use the Settings tab of the PVC dialog box to configure the basic settings of the PVC, including:

- ID settings.
- Encapsulation settings.
- Whether ILMI and Inverse ARP are enabled.
- The maximum number of PPPoE sessions.
- The static domain (VPN service) name to use for PPPoA.

Navigation Path

Go to the PVC Dialog Box , on page 2361, then click the **Settings** tab.

Related Topics

- PVC Dialog Box—QoS Tab , on page 2366

- PVC Advanced Settings Dialog Box , on page 2371
- Defining ATM PVCs , on page 2357

Field Reference

Table 845: PVC Dialog Box—Settings Tab

Element	Description
PVC ID settings	
VPI	The virtual path identifier of the PVC. In conjunction with the VCI, identifies the next destination of a cell as it passes through a series of ATM switches on the way to its destination. Valid values for most platforms range from 0 to 255. For Cisco 2600 and 3600 Series routers using Inverse Multiplexing for ATM (IMA), valid values range from 0 to 15, 64 to 79, 128 to 143, and 192 to 207. **Note** VPI/VCI values must be unique for all the PVCs configured on a selected interface. VPI/VCI values are unique to a single link only and might change as cells traverse the ATM network.
VCI	The 16-bit virtual channel identifier of the PVC. In conjunction with the VPI, identifies the next destination of a cell as it passes through a series of ATM switches on the way to its destination. Valid values vary by platform. Typically, values up to 31 are reserved for special traffic (such as ILMI) and should not be used. 3 and 4 are invalid. **Note** VPI/VCI values must be unique for all the PVCs configured on a selected interface. VPI/VCI values are unique to a single link only and might change as cells traverse the ATM network.
Handle	An optional name to identify the PVC. The maximum length is 15 characters.
Management PVC (ILMI)	Does not apply when configuring the PVC on a subinterface. When selected, designates this PVC as the management PVC for this ATM interface by enabling communication with the Interim Local Management Interface (ILMI). ILMI is a protocol defined by the ATM Forum for setting and capturing physical layer, ATM layer, virtual path, and virtual circuit parameters on ATM interfaces. See Understanding ILMI , on page 2355. When deselected, this PVC does not act as the management PVC. This is the default. **Note** The VPI/VCI for the management PVC is typically set to 0/16.
Encapsulation settings	

Element	Description
Type	Does not apply when the Management PVC (ILMI) check box is enabled. The ATM adaptation layer (AAL) and encapsulation type to use on the PVC: • [blank]—The encapsulation type is not defined. (When deployed, aal5snap is applied.) • aal2—For PVCs dedicated to AAL2 Voice over ATM. AAL2 is used for variable bit rate (VBR) traffic, which can be either realtime (VBR-RT) or non-realtime (VBR-NRT). • aal5autoppp—Enables the router to distinguish between incoming PPP over ATM (PPPoA) and PPP over Ethernet (PPPoE) sessions and create virtual access for both PPP types based on demand. • aal5ciscoppp—For the proprietary Cisco version of PPP over ATM. • aal5mux—Enables you to dedicate the PVC to a single protocol, as defined in the Protocol field. • aal5nlpid—Enables ATM interfaces to work with High-Speed Serial Interfaces (HSSI) that are using an ATM data service unit (ADSU) and running ATM-Data Exchange Interface (DXI). • aal5snap—Supports Inverse ARP and incorporates the Logical Link Control/Subnetwork Access Protocol (LLC/SNAP) that precedes the protocol datagram. This allows multiple protocols to traverse the same PVC.
Virtual Template	The virtual template used for PPP over ATM on this PVC. Enter the name of a virtual template interface or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. When a user dials in, the virtual template is used to configure a virtual access interface. When the user is done, the virtual access interface goes down and the resources are freed for other dial-in users. **Note** If you modify the virtual template settings on an existing PVC, you must enter the shutdown command followed by the no shutdown command on the ATM subinterface to restart the interface. This causes the newly configured parameters to take effect.
Protocol	Applies only when aal5mux is the defined encapsulation type. The protocol carried by the MUX-encapsulated PVC: • frame-relay—Frame-Relay-ATM Network Interworking (FRF.5) on the Cisco MC3810. • fr-atm-srv—Frame-Relay-ATM Service Interworking (FRF.8) on the Cisco MC3810. • ip—IP protocol. • ppp—IETF-compliant PPP over ATM. You must specify a virtual template when using this protocol type. • voice—Voice over ATM.

Element	Description
Additional settings	
Enable ILMI	When selected, enables ILMI management on this PVC. When deselected, ILMI management on this PVC is disabled.
Inverse ARP	When selected, the Inverse Address Resolution Protocol (Inverse ARP) is enabled on the PVC. When deselected, Inverse ARP is disabled. This is the default. Inverse ARP is used to learn the Layer 3 addresses at the remote ends of established connections. These addresses must be learned before the virtual circuit can be used. **Note** Use the Protocol tab to define static mappings of IP addresses instead of dynamically learning the addresses using Inverse ARP. See PVC Dialog Box—Protocol Tab , on page 2369.
PPPoE Max Sessions	The maximum number of PPP over Ethernet sessions that are permitted on the PVC.
VPN Service Name	The static domain name to use on this PVC. The maximum length is 128 characters. Use this option when you want PPP over ATM (PPPoA) sessions in the PVC to be forwarded according to the domain name supplied, without starting PPP.

PVC Dialog Box—QoS Tab

Use the QoS tab of the PVC dialog box to configure the ATM traffic shaping and other quality-of-service settings of the PVC, including:

- The limit on packets placed on transmission rings.
- The QoS service.
- Whether random detection is enabled.

These settings regulate the flow of traffic over the PVC by queuing traffic that exceeds the defined allowable bit rates.

Note QoS values are highly hardware dependent. Please refer to your router documentation for additional details about the settings that can be configured on your device.

Navigation Path

Go to the PVC Dialog Box , on page 2361, then click the **QoS** tab.

Related Topics

- Quality of Service Policy Page , on page 2550
- Understanding Policing and Shaping Parameters , on page 2537

Field Reference

Table 846: PVC Dialog Box—QoS Tab

Element	Description
Tx Ring Limit	The maximum number of transmission packets that can be placed on a transmission ring on the WAN interface card (WIC) or interface. The range of valid values depends on the type of interface card selected in the Settings tab. See PVC Dialog Box—Settings Tab , on page 2363.
Traffic Shaping settings	
Traffic Shaping	The type of service to define on the PVC: • [null]—The bit rate is not defined. • ABR—Available Bit Rate. A best-effort service suitable for applications that do not require guarantees against cell loss or delays. • CBR—Constant Bit Rate service. Delay-sensitive data, such as voice or video, is sent at a fixed rate, providing a service similar to a leased line. • UBR—Unspecified Bit Rate service. A best-effort service suitable for applications that are tolerant to delay and do not require realtime responses. • UBR+—Unspecified Bit Rate service. Unlike UBR, UBR+ attempts to maintain a guaranteed minimum rate. • VBR-NRT—Variable Bit Rate - Non-Real Time service. A service suitable for non-realtime applications that are bursty in nature. VBR is more efficient than CBR and more reliable than UBR. • VBR-RT—Variable Bit Rate - Real Time service. A service suitable for realtime applications that are bursty in nature. For more information about each service class, see Understanding ATM Service Classes , on page 2354.

Element	Description
ABR	The following fields are displayed when ABR is selected as the Bit Rate: • PCR—The peak cell rate in kilobits per second (kbps). It specifies the maximum value of the ABR. • MCR—The minimum cell rate in kilobits per second (kbps). It specifies the minimum value of the ABR. The ABR varies between the MCR and the PCR. It is dynamically controlled using congestion control mechanisms.
CBR	The following field is displayed when CBR is selected as the Bit Rate: • Rate—The constant bit rate (also known as the average cell rate) for the PVC in kilobits per second (kbps). An ATM VC configured for CBR can send cells at this rate for as long as required.
UBR	The following field is displayed when UBR is selected as the Bit Rate: • PCR—The peak cell rate for output in kilobits per second (kbps). Cells in excess of the PCR may be discarded.
UBR+	The following fields are displayed when UBR+ is selected as the Bit Rate: • PCR—The peak cell rate for output in kilobits per second (kbps). Cells in excess of the PCR may be discarded. • MCR—The minimum guaranteed cell rate for output in kilobits per second (kbps). Traffic is always allowed to be sent at this rate. **Note** UBR+ requires Cisco IOS Software Release 12.4(2)XA or later, or version 12.4(6)T or later.
VBR-NRT	The following fields are displayed when VBR-NRT is selected as the Bit Rate: • PCR—The peak cell rate for output in kilobits per second (kbps). Cells in excess of the PCR may be discarded. • SCR—The sustained cell rate for output in kilobits per second (kbps). This value, which must be lower than or equal to the PCR, represents the maximum rate at which cells can be transmitted without incurring data loss. • MBS—The maximum burst cell size for output. This value represents the number of cells that can be transmitted above the SCR but below the PCR without penalty.

Element	Description
VBR-RT	The following fields are displayed when VBR-RT is selected as the Bit Rate: • Peak Rate—The peak information rate for realtime traffic in kilobits per second (kbps). • Average Rate—The average information rate for realtime traffic in kilobits per second (kbps). This value must be lower than or equal to the peak rate. • Burst—The burst size for realtime traffic, in number of cells. Configure this value if the PVC carries bursty traffic. These values configure traffic shaping between realtime traffic (such as voice and video) and data traffic to ensure that the carrier does not discard realtime traffic, for example, voice calls.
IP QoS settings	
Random Detect	When selected, enables Weighted Random Early Detection (WRED) or VIP-distributed WRED (DWRED) on the PVC. When deselected, WRED and DWRED are disabled. This is the default. WRED is a queue management method that selectively drops packets as the interface becomes congested. See Tail Drop vs. WRED , on page 2535.

PVC Dialog Box—Protocol Tab

Use the Protocol tab of the PVC dialog box to add, edit, or delete the protocol mappings configured for the PVC. You may configured static mappings or Inverse ARP (broadcast or nonbroadcast) for each PVC, but not both.

Note IP is the only protocol supported by Security Manager for protocol mapping on ATM networks. You cannot define protocol mappings on the Management PVC (ILMI).

Navigation Path

Go to the PVC Dialog Box , on page 2361, then click the **Protocol** tab.

Field Reference

Table 847: PVC Dialog Box—Protocol Tab

Element	Description
IP Protocol Mapping	Displays the IP protocol mappings configured for the PVC.
Add button	Opens the Define Mapping Dialog Box , on page 2370. From here you can define an IP protocol mapping.
Edit button	Opens the Define Mapping Dialog Box , on page 2370. From here you can edit the selected mapping.
Delete button	Deletes the selected mapping from the table.

Define Mapping Dialog Box

Use the Define Mapping dialog box to configure the IP protocol mappings to use on the ATM PVC. Mappings are required by the PVC to discover which IP address is reachable at the other end of a connection. Mappings can either be learned dynamically using Inverse ARP (InARP) or defined statically. Static mappings are best suited for simple networks that contain only a few nodes.

Note Inverse ARP is only supported for the aal5snap encapsulation type. See PVC Dialog Box—Settings Tab , on page 2363.

Tip Use the CLI or FlexConfigs to configure mappings for protocols other than IP.

Navigation Path

Go to the PVC Dialog Box—Protocol Tab , on page 2369, then click **Add** or **Edit**.

Related Topics

- PVC Dialog Box , on page 2361

Field Reference

Table 848: Define Mapping Dialog Box

Element	Description
IP Options	The type of IP protocol mapping to use: • IP Address—Select this option when using static mapping. Enter the address or the name of a network/host object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. • InARP—Inverse ARP. Select this option when using dynamic mapping. This allows the PVC to resolve its own network addresses without configuring a static map. Dynamic mappings age out and are refreshed periodically every 15 minutes by default. **Note** InARP can be used only when aal5snap is the defined encapsulation type for the PVC. See PVC Dialog Box—Settings Tab , on page 2363.
Broadcast Options	Indicates whether to use this map entry when sending IP broadcast packets (such as EIGRP updates): • Broadcast—The map entry is used for broadcast packets. • No Broadcast—The map entry is used only for unicast packets. • None—Broadcast options are disabled.

PVC Advanced Settings Dialog Box

Use the PVC Advanced Settings dialog box to configure F5 Operation, Administration, and Maintenance (OAM) functionality on an ATM PVC. OAM is used to detect connectivity failures at the ATM layer.

For more information, see Defining OAM Management on ATM PVCs , on page 2359.

Navigation Path

Go to the PVC Dialog Box , on page 2361, then click **Advanced**.

Related Topics

Table 849: PVC Advanced Settings Dialog Box

Element	Description
OAM tab	Defines loopback, connectivity check, and AIS/RDI settings. See PVC Advanced Settings Dialog Box—OAM Tab , on page 2372.

Element	Description
OAM-PVC tab	Enables OAM loopbacks and connectivity checks on the PVC. See PVC Advanced Settings Dialog Box—OAM-PVC Tab , on page 2374.

PVC Advanced Settings Dialog Box—OAM Tab

Use the OAM tab of the PVC Advanced Settings dialog box to define:

- The number of loopback cell responses that move the PVC to the down or up state.
- The number of alarm indication signal/remote defect indication (AIS/RDI) cells that move the PVC to the down or up state.
- The number and frequency of segment/end continuity check (CC) activation and deactivation requests that are sent on this PVC.

For more information, see Defining OAM Management on ATM PVCs , on page 2359.

Note The settings defined in this tab are dependent on the settings defined in the OAM-PVC tab. See PVC Advanced Settings Dialog Box—OAM-PVC Tab , on page 2374.

Navigation Path

Go to the PVC Advanced Settings Dialog Box , on page 2371, then click the **OAM** tab.

Related Topics

- PVC Dialog Box , on page 2361

Field Reference

Table 850: PVC Advanced Settings Dialog Box—OAM Tab

Element	Description
Retry settings	
Enable OAM Retry	When selected, OAM management settings can be defined. When deselected, OAM management settings cannot be defined. **Note** If Enable OAM Management is deselected in the OAM-PVC tab, these settings are saved in the device configuration but are not applied.
Down Count	The number of consecutive, unreceived, end-to-end loopback cell responses that cause the PVC to move to the down state. The default is 3.
Up Count	The number of consecutive end-to-end loopback cell responses that must be received in order to move the PVC to the up state. The default is 5.

Element	Description
Retry Frequency	The interval between loopback cell verification transmissions in seconds. The default is 1 second. If a PVC is up and a loopback cell response is not received within the specified interval (as defined in the Frequency field of the PVC-OAM tab), loopback cells are transmitted at the frequency defined here to verify whether the PVC is down. If the number of consecutive cells that do not receive a response matches the defined down count, the PVC is moved to the down state.
AIS-RDI settings	
Enable AIS-RDI Detection	When selected, alarm indication signal (AIS) cells and remote defect indication (RDI) cells are used to report connectivity failures at the ATM layer of the PVC. When deselected, AIS/RDI cells are disabled. AIS cells notify downstream devices of the connectivity failure. The last ATM switch then generates RDI cells in the upstream direction towards the device that sent the original failure notification.
Down Count	The number of consecutive AIS/RDI cells that cause the PVC to go down. Valid values range from 1 to 60. The default is 1.
Up Count	The number of seconds after which a PVC is brought up if no AIS/RDI cells are received. Valid values range from 3 to 60 seconds. The default is 3.
Segment Continuity Check settings	
Enable Segment Continuity Check	When selected, OAM F5 continuity check (CC) activation and deactivation requests are sent to a device at the other end of a segment. When deselected, segment CC activation and deactivation requests are disabled. **Note** If Configure Continuity Check is deselected in the OAM-PVC tab, these settings are saved in the device configuration but are not applied.
Activation Count	The maximum number of times that the activation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3.
Deactivation Count	The maximum number of times that the deactivation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3.
Retry Frequency	The interval between activation/deactivation retries, in seconds. The default is 30 seconds.
End-to-End Continuity Check settings	

Element	Description
Enable End-to-End Continuity Check	When selected, OAM F5 continuity check (CC) activation and deactivation requests are sent to a device at the other end of the PVC. When deselected, segment CC activation and deactivation requests are disabled. **Note** If Configure Continuity Check is deselected in the OAM-PVC tab, these settings are saved in the device configuration but are not applied.
Activation Count	The maximum number of times that the activation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3.
Deactivation Count	The maximum number of times that the deactivation request is sent before the receipt of an acknowledgement. Valid values range from 3 to 600. The default is 3.
Retry Frequency	The interval between activation/deactivation retries, in seconds. The default is 30 seconds.

PVC Advanced Settings Dialog Box—OAM-PVC Tab

Use the OAM-PVC tab of the PVC Advanced Settings dialog box to enable loopback cells and connectivity checks (CCs) on the PVC. These functions test the connectivity of the virtual connection.

For more information, see Defining OAM Management on ATM PVCs , on page 2359.

Note Use the OAM tab to define additional settings related to the settings on this tab. See PVC Advanced Settings Dialog Box—OAM Tab , on page 2372.

Navigation Path

Go to the PVC Advanced Settings Dialog Box , on page 2371, then click the **OAM-PVC** tab.

Related Topics

- PVC Dialog Box , on page 2361

Field Reference

Table 851: PVC Advanced Settings Dialog Box—OAM-PVC Tab

Element	Description
OAM settings	
Enable OAM Management	When selected, OAM loopback cell generation and OAM management are enabled on the PVC. When deselected, OAM loopback cells and OAM management are disabled. However, continuity checks can still be performed.

Element	Description
Frequency	The interval between loopback cell transmissions. Valid values range from 0 to 600 seconds.
Segment Continuity Check settings	
Segment Continuity Check	The current configuration of OAM F5 continuity checks performed on PVC segments: • None—Segment continuity checks (CC) are disabled. • Deny Activation Requests—The PVC rejects activation requests from peer devices, which prevents OAM F5 CC management from being activated on the PVC. • Configure Continuity Check—Segment CCs are enabled on the PVC. The router on which CC management is configured sends a CC activation request to the router at the other end of the segment, directing it to act as either a source or a sink. Segment CCs occur on a PVC segment between the router and a first-hop ATM switch.
Direction	Applies only when CC management is enabled. The direction in which CC cells are transmitted: • both—CC cells are transmitted in both directions. • sink—CC cells are transmitted toward the router that initiated the CC activation request. • source—CC cells are transmitted away from the router that initiated the CC activation request.
Keep VC up after segment failure	When selected, the PVC is kept in the up state when CC cells detect connectivity failure. When deselected, the PVC is brought down when CC cells detect connectivity failure.
Keep VC up after end-to-end failure	When selected, specifies that if AIS/RDI cells are received, the PVC is not brought down because of end CC failure or loopback failure. When deselected, the PVC is brought down because of end CC failure or loopback failure.
End-to-End Continuity Check settings	

Element	Description
End-to-End Continuity Check	The current configuration of OAM F5 end-to-end continuity checks on the PVC: • None—End-to-end continuity checks (CC) are disabled. • Deny Activation Requests—The PVC rejects activation requests from peer devices, which prevents OAM F5 CC management from being activated on the PVC. • Configure Continuity Check—End-to-end CCs are enabled on the PVC. The router on which CC management is configured sends a CC activation request to the router at the other end of the connection, directing it to act as either a source or a sink. End-to-end CC monitoring is performed on the entire PVC between two ATM end stations.
Direction	Applies only when CC management is enabled. The direction in which CC cells are transmitted: • both—CC cells are transmitted in both directions. • sink—CC cells are transmitted toward the router that initiated the CC activation request. • source—CC cells are transmitted away from the router that initiated the CC activation request.
Keep VC up after end-to-end failure	When selected, the PVC is kept in the up state when CC cells detect connectivity failure. When deselected, the PVC is brought down when CC cells detect connectivity failure.
Keep VC up after segment failure	When selected, specifies that if AIS/RDI cells are received, the PVC is not brought down because of a segment CC failure. When deselected, the PVC is brought down because of a segment CC failure.

PPP on Cisco IOS Routers

The Point-to-Point Protocol (PPP), as defined in RFC 1661, provides a method for transporting packets between two devices or hosts using physical or logical links. PPP is a Layer 2 data-link protocol that can work with multiple Layer 3 network-layer protocols, including IP, IPX, and AppleTalk.

PPP is used in many common scenarios, such as:

- Connecting remote users to a central network over dial-in connections.
- Connecting the gateway of an enterprise network to an ISP for internet access.
- Connecting two LANs (for example, a central office and a branch office) to exchange data between them.

PPP connectivity is established in stages:

1. First, a Link Control Protocol (LCP) establishes, configures, and tests the data-link connection.
2. (Optional) Authentication verifies the identity of the two parties.
3. A family of Network Control Protocols (NCPs) establishes and configures the necessary network-layer protocols.

The PPP policy in Security Manager provides a method for configuring selected parameters that are negotiated between the two nodes during the LCP stage, including authentication (typically CHAP or PAP) and Multilink PPP (MLP). For more information about MLP, see Defining Multilink PPP Bundles , on page 2380.

The following topics describe the tasks you perform to create PPP policies on Cisco IOS routers:

- Defining PPP Connections , on page 2378
- Defining Multilink PPP Bundles , on page 2380

Understanding Multilink PPP (MLP)

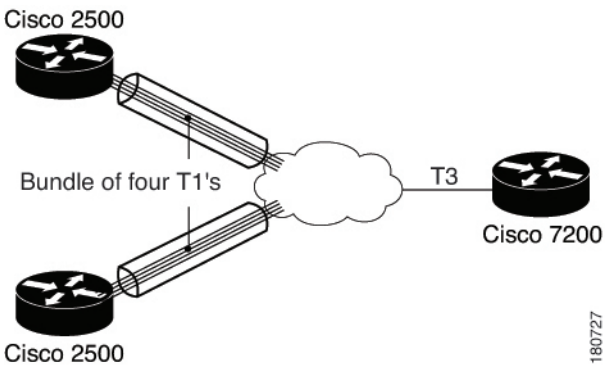
MLP, as defined in RFC 1990, is a method for splitting, recombining, and sequencing datagrams across multiple logical data links. MLP was originally designed to exploit multiple bearer channels in ISDN, but it can be used whenever multiple PPP links connect two systems, including asynchronous links.

MLP spreads inbound and outbound traffic across multiple physical WAN links (known collectively as a bundle) while providing the following benefits:

- Packet fragmentation and reassembly
- Proper sequencing
- Multivendor interoperability
- Load balancing

As shown in Figure 48: Multilink PPP, on page 2377, traffic routed across an MLP link is fragmented, with the fragments being sent across the different physical links. At the remote end of the link, the fragments are reassembled and forwarded to the next hop toward their ultimate destination. By using multiple physical links, MLP provides a way to temporarily use the additional bandwidth afforded by these links.

Figure 48: Multilink PPP



Every MLP bundle is controlled by a single interface, the bundle director, which is a virtual-access interface. This interface is created in the background when the bundle is first created. The physical interface becomes part of the bundle that is managed by the bundle director. Bundles are also used when you create a multilink group consisting of a multilink interface and its associated serial interfaces, which is a setup that is often found in static, leased-line environments.

MLP uses an endpoint discriminator to identify the system transmitting a packet. By default, this discriminator is based on the hostname of the router, but it can also be based on other criteria, such as the IP address or MAC address of the interface, a telephone number, or a user-defined string. If the endpoint discriminator matches the discriminator of an existing link, the new link is added to the matching bundle. If no match exists, a new bundle is created. When authentication is used, a new bundle is established whenever there is a mismatch in either the discriminator or the authentication information exchanged between the two nodes.

Related Topics

- Defining Multilink PPP Bundles , on page 2380
- PPP on Cisco IOS Routers , on page 2376

Defining PPP Connections

When you define a PPP connection, the first step is to select the interface on which PPP should be enabled. You must select one of the following interface types:

- Async
- Group-Async
- Serial
- High-Speed Serial Interface (HSSI)
- Dialer
- BRI, PRI (ISDN)
- Virtual template
- Multilink

You cannot define PPP connections on:

- Subinterfaces.
- Serial interfaces with Frame Relay encapsulation.
- Virtual template interfaces defined as Ethernet or tunnel types (serial is supported).

Note You cannot configure PPP on serial interfaces that are configured for Frame Relay encapsulation. See Defining Basic Router Interface Settings , on page 2310.

Note Deployment might fail if you define PPP on a virtual template that is also used in an 802.1x policy. See Defining 802.1x Policies , on page 2496.

You can select one or more authentication protocols and define when authentication should be performed.

In addition, you can configure the authentication and authorization methods to use when performing AAA on a remote security server. You can either define a default method list to use for all PPP connections on the device or define a customized method list that applies to a specific connection.

Before You Begin

- Make sure that the device contains an interface on which PPP can be configured. See Basic Interface Settings on Cisco IOS Routers , on page 2307.

Related Topics

- Defining Multilink PPP Bundles , on page 2380
- PPP on Cisco IOS Routers , on page 2376

Step 1 Do one of the following:

- (Device view) Select **Interfaces > Settings > PPP/MLP** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > PPP/MLP** from the Policy Type selector. Select an existing policy or create a new one.

The PPP/MLP page is displayed. See PPP/MLP Policy Page , on page 2381 for a description of the fields on this page.

Step 2 Click the **Add** button beneath the table to display the PPP dialog box.

Step 3 In the Interface field, enter the name of the interface or interface role on which you want to define the PPP connection, or click **Select** to select an interface role from a list or to create a new one.

Step 4 (Optional) On the PPP tab, define authentication for the PPP connection:

a) Select one or more authentication protocols.

b) Select one or more authentication options. These options determine when to perform authentication (callin, callout, and callback), whether to use one-time passwords, and whether to allow a mobile station in a PDSN configuration to receive Simple IP and Mobile IP services without using CHAP or PAP.

Note The Call Back option only enables authentication during callback. Use the CLI or FlexConfigs to configure the callback feature on the device.

c) See PPP Dialog Box—PPP Tab , on page 2383 for a description of the fields on this tab.

Step 5 (Optional) When using a remote AAA server to perform authentication, select Default List or Custom Method List in the Authenticate Using field, then define the methods to use in the Prioritized Method List field.

Note If you modify the default list, your changes affect all PPP connections on the devices that use this list. If you leave this field blank, authentication is performed using the local database on the device.

Step 6 (Optional) When using a remote AAA server to perform authorization, select AAA Policy Default List or Custom Method List, then define the methods to use in the Prioritized Method List field.

Note If you choose AAA Policy Default List, the device uses the default authorization methods defined in the AAA policy. See Defining AAA Services , on page 2392.

Step 7 (Optional) Define the username and password to send in response to PAP authentication requests.

Note If you entered the encrypted version of the password, select the **Encrypted** check box.

Step 8 (Optional) Define a different hostname to send in all CHAP challenges and responses in place of the router's own hostname.

Note If you entered the encrypted version of the password, select the **Encrypted** check box.

Step 9 (Optional) To enable Multilink PPP on this connection, click the **MLP** tab. See Defining Multilink PPP Bundles , on page 2380.

Step 10 Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the PPP table.

Note To edit a PPP connection, select it from the table, then click **Edit**. To remove a PPP connection, select it, then click **Delete**.

Step 11 Repeat Step 2, on page 2379 to Step 10, on page 2380 to define PPP connections on additional interfaces. Only one PPP connection may be defined on an interface.

Defining Multilink PPP Bundles

You enable Multilink PPP (MLP) on the selected interface by selecting the check box at the top of the Multilink tab in the PPP dialog box. You can optionally enable Multiclass Multilink PPP (MCMP), which prevents delay-sensitive traffic from fragmentation, and interleaving, which enables packets to be interspersed among the fragments of larger packets. If you want to restrict a serial interface to a specific bundle, you can select the multilink interface that represents that bundle.

In addition, you can optionally modify the following default settings:

- The maximum fragment delay.
- The endpoint discriminator that identifies the router when negotiating the use of MLP.
- The maximum receive reconstructed unit (MRRU) permitted by the router and its peers.
- The maximum queue depth for first-in, first-out (FIFO) and non-FIFO queues.

Before You Begin

- Select the interface on which the PPP connection should be enabled.

Related Topics

- Defining PPP Connections , on page 2378
- PPP on Cisco IOS Routers , on page 2376

Step 1 In the PPP dialog box, click the **MLP** tab. See PPP Dialog Box—MLP Tab , on page 2386 for a description of the fields on this tab.

Step 2 Select the **Enable Multilink Protocol (MLP)** check box.

Step 3 (Optional) Configure one or more of the following options:

a) Whether to enable the multiclass feature that prevents delay-sensitive traffic from being fragmented. This is achieved by placing delay-sensitive traffic in a separate class from regular traffic.

b) Whether to enable the interleaving of packets among the fragments of larger packets on the MLP bundle.

c) Whether to restrict the physical link to joining only a designated multilink-group (defined by selecting a multilink interface). If a peer at the other end of the link tries to join a different bundle, the connected is severed.

d) Whether to modify the default amount of time required to transmit a fragment on the MLP bundle. The default is 30 milliseconds.

Note If you enable interleaving without defining a fragment delay, the default delay of 30 seconds is configured. This value does not appear in Security Manager or in the device configuration.

Step 4 (Optional) Under Endpoint, modify the default endpoint discriminator used on the MLP bundle.

The endpoint discriminator is used to identify the router on the MLP bundle. The default endpoint discriminator is either the globally configured hostname, or the PAP username or CHAP hostname (depending on the authentication protocol being used), if you configured those values on the PPP tab. See Defining PPP Connections , on page 2378.

Step 5 (Optional) In the MRRU fields, modify the default maximum packet size that the router (local) or the peer (remote) is capable of receiving.

Step 6 (Optional) Modify the default maximum size of link transmit queues when using FIFO and non-FIFO (QoS) queuing.

Step 7 Click **OK** to close the dialog box. Your definitions are displayed on the PPP page.

PPP/MLP Policy Page

Use the PPP/MLP page to create, edit, and delete PPP connections on the router. For more information, see Defining PPP Connections , on page 2378.

Navigation Path

- (Device view) Select **Interfaces > Settings > PPP/MLP** from the Policy selector.
- (Policy view) Select **Router Interfaces > Settings > PPP/MLP** from the Policy Type selector. Right-click **PPP/MLP** to create a policy, or select an existing policy from the Shared Policies selector.

Field Reference

Table 852: PPP/MLP Page

Element	Description
Interface	The interface that is configured for PPP/MLP.
Authentication	The types of authentication used on the PPP connection.
Authorization	The method list used for AAA authorization on the PPP connection.
Multilink	Indicates whether Multilink PPP (MLP) is enabled on this PPP connection.
Endpoint	The type of default endpoint discriminator to use when negotiating the use of MLP with the peer.
Multiclass	Indicates whether the Multiclass Multilink PPP (MCMP) feature is enabled on this PPP connection.
Group	The number of the multilink-group interface to which the physical link is restricted.
Interleave	Indicates whether the PPP multilink interleave feature is enabled on this PPP connection.
Add button	Opens the PPP Dialog Box , on page 2382. From here you can define the authentication and multilink settings for the PPP connection.
Edit button	Opens the PPP Dialog Box , on page 2382. From here you can edit the selected PPP connection.
Delete button	Deletes the selected PPP connection from the table.

PPP Dialog Box

Use the PPP dialog box to configure PPP connections on the router. When you configure a PPP connection, you can define the type of authentication and authorization to perform and define multilink parameters.

Navigation Path

Go to the , then click the **Add** or **Edit** button beneath the table.

Table 853: PPP Dialog Box

Element	Description
Interface	The interface on which PPP encapsulation is enabled. Enter the name of an interface or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. The following interface types support PPP: • Async • Group-Async • Serial • High-Speed Serial Interface (HSSI) • Dialer • BRI, PRI (ISDN) • Virtual template • Multilink You cannot define PPP on: • Subinterfaces. • Serial interfaces with Frame Relay encapsulation. • Virtual template interfaces defined as Ethernet or tunnel types (serial is supported). **Note** You can define only one PPP connection per interface. **Note** Deployment might fail if you define PPP on a virtual template that is also used in an 802.1x policy. See .
PPP tab	Defines the type of authentication and authorization to perform on the PPP connection. See PPP Dialog Box—PPP Tab , on page 2383.
MLP tab	Defines how to split and recombine sequential datagrams across multiple logical data links using Multilink PPP (MLP). See . This tab is greyed out and cannot be opened for devices that do not support the configuration settings.

PPP Dialog Box—PPP Tab

Use the PPP tab of the PPP dialog box to define the types of authentication and authorization to perform on the PPP connection.

Navigation Path

Go to the PPP Dialog Box , on page 2382, then click the **PPP** tab.

Related Topics

- PPP Dialog Box—MLP Tab , on page 2386

Field Reference

Table 854: PPP Dialog Box—PPP Tab

Element	Description
Authentication settings	
PPP Encapsulation	When selected, indicates that PPP encapsulation is enabled for the selected interface. This field is read-only.
Protocol	The authentication protocols to use: • CHAP—Challenge-Handshake Authentication Protocol. • PAP—Password Authentication Protocol. • MS-CHAP—Version 1 of the Microsoft version of CHAP (RFC 2433). • MS-CHAP-2—Version 2 of the Microsoft version of CHAP (RFC 2759). • EAP—Extensible Authentication Protocol. You may select one or more authentication protocols, as required.
Options	The authentication options to use: • Call In—When selected, authentication is performed on incoming calls. • Call Out—When selected, authentication is performed on outgoing calls. • Call Back—When selected, authentication is performed on callback. • One Time—When selected, one-time passwords are used for authentication. One-time passwords are considered highly secure since each one is used only once. When deselected, one-time passwords are not used. **Note** AAA authentication must be enabled in order to use one-time passwords. See AAA Policy Page , on page 2394. One-time passwords cannot be used with CHAP. • Optional—When selected, allows a mobile station in a Packet Data Serving Node (PDSN) configuration to receive Simple IP and Mobile IP services without using CHAP or PAP. When deselected, mobile stations must use CHAP or PAP to receive Simple IP and Mobile IP services.

Element	Description
Authenticate Using	AAA authentication settings for the PPP connection: • PPP Default List—Defines a default list of methods to be queried when authenticating a user for PPP. Enter the names of one or more AAA server group objects (up to four) in the Prioritized Method List field, or click **Select** to select it. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Tip** After you create the default list for one PPP connection, you can use it for other PPP connections on this device. • Prioritized Method List—Defines a sequential list of methods to be queried when authenticating a user for this PPP connection only. **Note** Leave this field blank to perform authentication using the local database on the router.
PAP Authentication settings	
Username	The username to send in PAP authentication requests. The username is case sensitive.
Password	The password to send in PAP authentication requests. Enter the password again in the Confirm field. The password can contain 1 to 25 uppercase or lowercase alphanumeric characters. The password is case sensitive. The username and password are sent if the peer requests the router to authenticate itself using PAP.
Encrypted Password	When selected, this indicates that the password you entered is already encrypted. When deselected, this indicates that the password you entered is in clear text.
CHAP Authentication settings	
Hostname	By default, the router uses its hostname to identify itself to the peer. If required, you can enter a different hostname to use for all CHAP challenges and responses. For example, use this field to specify a common alias for all routers in a rotary group.
Secret	The secret used to compute the response value for any CHAP challenge from an unknown peer. Enter the secret again in the Confirm field.
Encrypted Secret	When selected, this indicates that the password you entered is already encrypted. When deselected, this indicates that the password you entered is in clear text.
Authorization settings	

Element	Description
Authorize Using	AAA authorization settings for the PPP connection: • AAA Policy Default List—Uses the default authorization method list that is defined in the device's AAA policy. See AAA Policy Page , on page 2394. • Prioritized Method List—Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select it. Use the up and down arrows to define the order in which selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** Leave this field blank to perform authorization using the local database on the router.

PPP Dialog Box—MLP Tab

Use the MLP tab of the PPP dialog box to define Multilink PPP (MLP) parameters for the selected PPP connection.

Navigation Path

Go to the PPP Dialog Box , on page 2382, then click the **MLP** tab.

Related Topics

- PPP Dialog Box , on page 2382

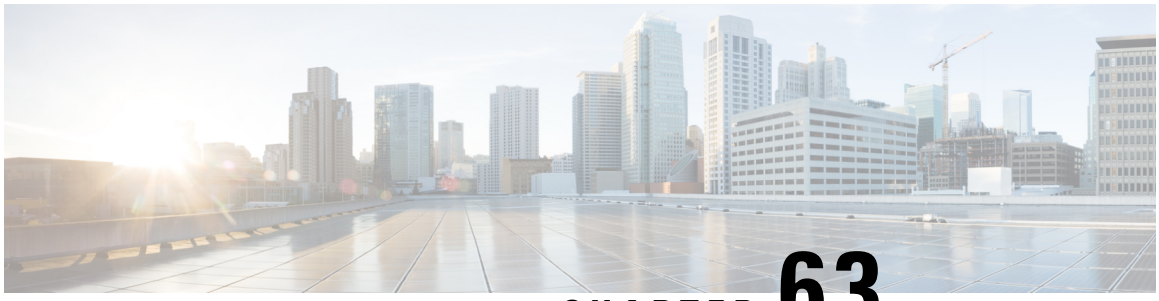
Field Reference

Table 855: PPP Dialog Box—MLP Tab

Element	Description
Enable Multilink PPP (MLP)	When selected, MLP is enabled on this PPP connection. When deselected, MLP is disabled.
Allow Multiple Data Classes	When selected, enables multiple data classes on the MLP bundle. Delay-sensitive traffic is placed into Class 1, where it can be interleaved but never fragmented. Normal data traffic is placed into Class 0, which is subject to fragmentation just as regular multilink packets are. When deselected, all traffic is subject to fragmentation.

Element	Description
Enable Interleaving of Packets Among Fragments of Larger Packets	When selected, enables the interleaving of packets among the fragments of larger packets on the MLP bundle. **Note** If you enable interleaving without defining a fragment delay, the default delay of 30 seconds is configured. This value does not appear in Security Manager or in the device configuration. When deselected, interleaving is disabled. **Note** Serial interfaces do not support interleaving.
Multilink Group	Applies only to serial, Group-Async, and multilink interfaces. Restricts the physical link to the selected multilink-group interface. Enter the name of a multilink interface or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. This option is typically used in static leased-line environments, where the remote systems to which the device's serial lines are connected are known in advance. In effect, this option dedicates a specific interfaces to a particular user, even when that user is not connected. If a peer at the other end of the link tries to join a different bundle, the connected is severed.
Maximum Fragment Delay	The maximum amount of time that should be required to transmit a fragment on the MLP bundle. Valid values range from 1 to 1000 milliseconds. Fragment size is determined by the defined fragment delay and the bandwidth of the links. **Note** Serial interfaces do not support this feature.

Element	Description
Endpoint Type	The identifier used by the router when transmitting packets on the MLP bundle: • [null]—Negotiation is conducted without using an endpoint discriminator. (No CLI command is generated.) • Hostname—The hostname of the router. This option is useful when multiple routers are using the same username to authenticate but have different hostnames. • IP—A defined IP address. Enter the address or the name of a network/host object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. • MAC—The MAC address of a specific interface. Enter the name of the interface or interface role, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. • None—Negotiation is conducted without using an endpoint discriminator. (The relevant CLI command is generated, but no endpoint discriminator is provided.) This option is useful when the router is connected to a malfunctioning peer that does not handle the endpoint discriminator properly. • Phone—An E.164-compliant telephone number. Enter the number in the field displayed. • String—A character string. Enter the string in the field displayed. The default endpoint discriminator is either the globally configured hostname, or the PAP username or CHAP hostname (depending on the authentication protocol being used), if you have configured those values on the PPP tab.
MRRU Local Peer	The maximum receive reconstructed unit (MRRU) value of the local peer. This value represents the maximum size packet that the local router is capable of receiving. Valid values range from 128 to 16384 bytes. The default is the maximum transmission unit (MTU) of the multilink group interface and 1524 bytes for all other interfaces.
MRRU Remote Peer	The maximum receive reconstructed unit (MRRU) value of the remote peer. This value represents the maximum size packet that the remote peer is capable of receiving. Valid values range from 128 to 16384 bytes. The default is 1524 bytes.
Maximum FIFO Queue Size	The maximum queue depth when the bundle uses first-in, first-out (FIFO) queuing. Valid values range from 2 to 255 packets. The default is 8.
Maximum QoS Queue Size	The maximum queue depth when the bundle uses non-FIFO queuing. Valid values range from 2 to 255 packets. The default is 2.



CHAPTER 63

Router Device Administration

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

This chapter contains the following topics:

• DHCP on Cisco IOS Routers , on page 2477
• DHCP Policy Page , on page 2482
• NTP on Cisco IOS Routers , on page 2487
• NTP Policy Page , on page 2489

AAA on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Authentication, authorization, and accounting (AAA) network security services provide the primary framework through which you set up access control on your Cisco IOS router. Use the AAA policy in Security Manager to enable AAA functionality on Cisco IOS routers and to configure default AAA settings. The default settings that you define in this policy can be used in other policies, such as HTTP and line access (console and VTY) policies. Enabling AAA functionality is a prerequisite for any device policy that makes use of AAA, including NAC, SDP, and 802.1x.

For more information about AAA, see:

• Supported Authorization Types , on page 2390
• Supported Accounting Types , on page 2391
• Understanding Method Lists , on page 2391

To configure a AAA policy, see:

• Defining AAA Services , on page 2392

Related Topics

• Understanding AAA Server and Server Group Objects , on page 256
• Line Access on Cisco IOS Routers , on page 2424

Supported Authorization Types

AAA authorization enables you to limit the services available to an authenticated user. Security Manager supports the following types of authorization:

- Network—Authorizes various types of network connections, such as PPP, SLIP, and ARAP.
- EXEC—Authorizes the launching of EXEC (CLI) sessions.
- Command—Authorizes the use of all EXEC mode commands that are associated with specific privilege levels.

When authorization is enabled, the router uses information retrieved from the user's profile to configure the user session. The profiles are located either in the local user database or on a security server. Users are granted access to a requested service only if the profile allows it.

Related Topics

- Supported Accounting Types , on page 2391
- Understanding Method Lists , on page 2391
- Defining AAA Services , on page 2392
- AAA on Cisco IOS Routers , on page 2390

Supported Accounting Types

AAA accounting enables you to track the services the users are accessing and the amount of network resources that they are consuming. Security Manager supports the following accounting types:

- Connection—Records information about all outbound connections made from this device, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin connections.

For example, a RADIUS connection accounting record for an outbound Telnet connection includes such information as the port and IP address of the network access server (NAS), the start and end times of the connection, the identity of the user, and the number of packets that were transmitted during the session.

- EXEC—Records information about user EXEC (CLI) sessions on the devices, including the username, date, start and stop times, and the IP address of the NAS. For dial-in users, the record includes the telephone number from which the call originated.
- Command—Records information about the EXEC commands executed on the device by users with specific privilege levels. Each command accounting record includes a list of the commands executed for that privilege level, the date and time each command was executed, and the name of the user who executed it.

For each accounting type, you can choose whether you want to generate an accounting record at the start and end of each user session or only at the end.

When AAA accounting is enabled, the router sends accounting records of user activity to the TACACS+ or RADIUS security server. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can later be analyzed for network management, client billing, and auditing purposes.

Related Topics

- Supported Accounting Types , on page 2391
- Understanding Method Lists , on page 2391
- Defining AAA Services , on page 2392
- AAA on Cisco IOS Routers , on page 2390

Understanding Method Lists

A method list is a sequential list describing the methods to use to perform a particular AAA function. In Security Manager, you define method lists by selecting AAA server groups, which are reusable objects that typically contain one or more AAA servers running the same protocol, such as RADIUS or TACACS+.

Method lists enable you to designate one or more security protocols to be used for each AAA function, thus ensuring a backup system if the initial method fails.

Note Security Manager also contains predefined AAA server group objects for using the enable password or a local database. See Predefined AAA Authentication Server Groups , on page 260.

For each AAA function, the device initially uses the first method defined in the list. If that method fails to respond, the device selects the next method in the list. This process continues until there is successful communication with a listed method, or all methods defined in the method list are exhausted.

Note The device attempts to communicate with the next listed method only when there is no response from the previous method. If the AAA service fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access or services—the process stops and no other methods are attempted.

Related Topics

- Supported Authorization Types , on page 2390
- Supported Accounting Types , on page 2391
- Defining AAA Services , on page 2392
- AAA on Cisco IOS Routers , on page 2390

Defining AAA Services

To define AAA services on a Cisco IOS router, you must first enable AAA functionality on the router. After you do this, you can define the kind of functionality (authentication, authorization, and accounting) that you want the device to implement. You must define a method list for each function, including lists for each type of authorization and accounting that you enable.

For example, if you want to configure EXEC authorization and command authorization, you must define one method list for EXEC authorization and other method lists for each privilege level on which command authorization is performed.

Note If you use RADIUS for authentication, you must use the same RADIUS server group for authorization as well.

Related Topics

- Understanding Method Lists , on page 2391
- AAA on Cisco IOS Routers , on page 2390
- Understanding AAA Server and Server Group Objects , on page 256

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > AAA** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > AAA** from the Policy Type selector. Select an existing policy or create a new one.

The AAA page is displayed. See AAA Policy Page , on page 2394 for a description of the fields on this page.

Step 2 Define which login authentication methods to use on users who access the device:

a) On the Authentication tab (see AAA Page—Authentication Tab , on page 2395), select the **Enable Device Login Authentication** check box.

b) Enter the names of one or more AAA server group objects (up to four) in the Prioritized Method List field, or click **Select** select the object from a list or to create a new one. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used.

Note If you select None as a method, it must appear as the last method in the list.

Step 3 (Optional) In the Maximum Number of Attempts field, define the maximum number of unsuccessful authentication attempts to allow before a user is locked out.

Step 4 (Optional) Define which authorization methods to use on users who have been successfully authenticated:

a) Click the **Authorization** tab on the AAA page. See Table 858: AAA Page—Authorization Tab , on page 2396 for a description of the fields on this tab.

b) Define method lists for one or more of the following types of authorization:

- Network
- EXEC
- Command—Click the **Add** button to display the Command Authorization dialog box (see Command Authorization Dialog Box , on page 2398). From here, you can select a privilege level and the method list to apply to it.

For more information about these authorization types, see Supported Authorization Types , on page 2390.

Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

Step 5 (Optional) Define which accounting methods to use on the activities performed by users:

a) Click the **Accounting** tab on the AAA page. See Table 860: AAA Page—Accounting Tab , on page 2399 for a description of the fields on this tab.

b) Define method lists for one or more of the following types of accounting:

- Connection
- EXEC
- Command—Click the **Add** button to display the Command Accounting dialog box (see Command Accounting Dialog Box , on page 2401). From here, you can select a privilege level and the method list to apply to it.

For more information about these accounting types, see Supported Accounting Types , on page 2391.

c) For each accounting type defined above, select a value from the Accounting Process Notices list. This defines when to create an accounting record, at the beginning and end of the user process or only at the end.

d) For each accounting type defined above, select the **Enable broadcast to multiple servers** check box if you want accounting information sent simultaneously to the first server in each AAA server group defined in the method list.

AAA Policy Page

Use the AAA page to define the default authentication, authorization, and accounting methods to use on the router. You do this by configuring method lists, which define which methods to use and the sequence in which to use them.

Note You can use the method lists defined in this policy as default settings when you configure AAA on the router's console port and VTY lines. See Console Policy Page , on page 2431 and VTY Policy Page , on page 2439.

Navigation Path

- (Device view) Select **Platform > Device Admin > AAA** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > AAA** from the Policy Type selector. Right-click **AAA** to create a policy, or select an existing policy from the Shared Policy selector.

- AAA Server Group Dialog Box , on page 280
- Predefined AAA Authentication Server Groups , on page 260

Field Reference

Table 857: AAA Page—Authentication Tab

Element	Description
Enable Device Login Authentication	When selected, enables the authentication of all users when they log in to the device, using the methods defined in the method list. When deselected, authentication is not performed.
Prioritized Method List	Defines a sequential list of methods to be queried when authenticating a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. Supported methods include Line, Local, Kerberos, LDAP, RADIUS, TACACS+, and None. **Note** If you select None as a method, it must appear as the last method in the list.

Element	Description
Maximum Number of Attempts	The maximum number of unsuccessful authentication attempts before a user is locked out. This feature is disabled by default. Valid values range from 1 to 65535. **Note** From the standpoint of the user, there is no distinction between a normal authentication failure and an authentication failure due to being locked out. The system administrator has to explicitly clear the status of a locked-out user using **clear** commands.

AAA Page—Authorization Tab

Use the Authorization tab of the AAA page to define the type of authorization services to enable on the device and the methods to use for each type. Security Manager supports the following types of authorization:

- Network—Authorizes various types of network connections, such as PPP.
- EXEC—Authorizes the launching of EXEC sessions.
- Command—Authorizes the use of all EXEC mode commands that are associated with specific privilege levels.

Note You can use the method lists defined in this policy on the console and VTY lines that are used to communicate with the device. See Console Policy Page , on page 2431 and VTY Line Dialog Box—Authentication Tab , on page 2444.

Navigation Path

Go to the AAA Policy Page , on page 2394, then click the **Authorization** tab.

Field Reference

Table 858: AAA Page—Authorization Tab

Element	Description
Network Authorization settings	

Element	Description
Enable Network Authorization	When selected, enables the authorization of network connections, such as PPP, SLIP, or ARAP connections, using the methods defined in the method list. When deselected, network authorization is not performed.
Prioritized Method List	Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. Supported methods include LDAP, RADIUS, TACACS+, Local, and None. **Note** RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization. **Note** If you select None as a method, it must appear as the last method in the list.
EXEC Authorization settings	
Enable CLI/EXEC Operations Authorization	When selected, this type of authorization determines whether the user is permitted to open an EXEC (CLI) session, using the methods defined in the method list. When deselected, EXEC authorization is not performed.
Prioritized Method List	Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received.
Command Authorization settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Authorization Dialog Box , on page 2398. From here you can configure a command authorization definition.
Edit button	Opens the Command Authorization Dialog Box , on page 2398. From here you can edit the command authorization definition.
Delete button	Deletes the selected command authorization definitions from the table.

Command Authorization Dialog Box

Use the Command Authorization dialog box to define which methods to use when authorizing the EXEC commands that are associated with a given privilege level. This enables you to authorize all commands associated with a specific privilege level, from 0 to 15.

Navigation Path

From the AAA Page—Authorization Tab , on page 2396, click the **Add** button beneath the Command Authorization table.

Related Topics

- Defining AAA Services , on page 2392

- Understanding Method Lists , on page 2391

Field Reference

Table 859: Command Authorization Dialog Box

Element	Description
Privilege Level	The privilege level for which you want to define a command accounting list. Valid values range from 0 to 15.
Prioritized Method List	Defines a sequential list of methods to be used when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. Supported methods include TACACS+, Local, and None. **Note** If you select None as a method, it must appear as the last method in the list.

AAA Page—Accounting Tab

Use the Accounting tab of the AAA page to define the type of accounting services to enable on the device and the methods to use for each type. Security Manager supports the following types of accounting:

- Connection—Records information about all outbound connections made from this device.
- EXEC—Records information about user EXEC sessions on the devices, including the username, date, start and stop times, and the IP address.
- Command—Records information about the EXEC commands executed on the device by users with specific privilege levels.

In addition, you use the Accounting page to determine when accounting records should be generated and whether they should be broadcast to more than one AAA server.

Note You can use the method lists defined in this policy on the console and VTY lines that are used to communicate with the device. See Console Policy Page , on page 2431 and VTY Line Dialog Box—Authentication Tab , on page 2444.

Navigation Path

Go to the AAA Policy Page , on page 2394, then click the **Accounting** tab.

Related Topics

- Defining AAA Services , on page 2392

Field Reference

Table 860: AAA Page—Accounting Tab

Element	Description
Connection Accounting settings	
Enable Connection Accounting	When selected, enables the recording of information about outbound connections (such as Telnet) made over this device, using the methods defined in the method list. When deselected, connection accounting is not performed.
Generate Accounting Records for	Defines when the device sends an accounting notice to the accounting server: • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the “start” accounting record. • Stop Only—Generates an accounting record at the end of the user process only. • None—Disables this type of accounting.

Element	Description
Prioritized Method List	Defines a sequential list of methods to be queried when creating connection accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. Supported methods include LDAP, RADIUS, and TACACS+.
Enable Broadcast to Multiple Servers	When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group. When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.
EXEC Accounting Settings	
Enable CLI/EXEC Operations Accounting	When selected, enables the recording of basic information about user EXEC sessions, using the methods defined in the method list. When deselected, EXEC accounting is not performed.
Generate Accounting Records for	See Table 547: Cat6k Block VLAN Dialog Box , on page 1775.
Prioritized Method List	Defines a sequential list of methods to be queried when creating connection accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it.
Enable Broadcast to Multiple Servers	When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group.
Command Accounting settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Generate Accounting Records for	The points in the process where the device sends an accounting notice to the accounting server.
Enable Broadcast	Whether accounting records are broadcast to multiple servers simultaneously.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Accounting Dialog Box , on page 2401. From here you can configure a command accounting definition.

Element	Description
Edit button	Opens the Command Accounting Dialog Box , on page 2401. From here you can edit the command accounting definition.
Delete button	Deletes the selected command accounting definitions from the table.

Command Accounting Dialog Box

Use the Command Accounting dialog box to define which methods to use when recording information about the EXEC commands that are executed for a given privilege level. Each accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the name of the user who executed it.

Navigation Path

From the AAA Page—Accounting Tab , on page 2398, click the **Add** button beneath the Command Accounting table.

Field Reference

Table 861: Command Accounting Dialog Box

Element	Description
Privilege Level	The privilege level for which you want to define a command accounting list. Valid values range from 0 to 15.
Generate Accounting Records for	Defines when the device sends an accounting notice to the accounting server: • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the "start" accounting record. • Stop Only—Generates an accounting record at the end of the user process only. • None—No accounting records are generated.

Element	Description
Prioritized Method List	Defines a sequential list of methods to be used when creating accounting records for a user. Enter the names of one or more AAA server group objects (up to 10 for IOS 12.4(22)T+, otherwise up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. TACACS+ is the only supported method, but you can select multiple AAA server groups configured with TACACS+. **Note** If you select None as a method, it must appear as the last method in the list.
Enable Broadcast to Multiple Servers	When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group. When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.

User Accounts and Device Credentials on Cisco IOS Routers

Accounts and credential policies define the contact information for accessing the router, including the privilege level provided to each user account. You can configure as many user accounts as required. However, the user account that Security Manager uses to connect to the router is always the one configured in the Device Properties page.

Additionally, you use device access policies to define the enable or enable secret password required to access privileged EXEC mode. This is the mode required to make any configuration changes on the router.

Note If you use this policy to define a password, be careful later not to unassign this policy without assigning a replacement policy before your next deployment. If you deploy a device access policy that removes this password and the device contains a different type of password not known to Security Manager, such as a line console password, you will not be able to configure this device in the future. This is because the device reverts to this unknown password if Security Manager removes the enable password that it had previously configured.

Related Topics

- Defining Accounts and Credential Policies , on page 2403

Defining Accounts and Credential Policies

This procedure describes how to define a device access policy on a Cisco IOS router. If the username that you configured on the Device Properties page to connect to the router (see Viewing or Changing Device Properties , on page 109) matches one of the user accounts you defined in this policy, Security Manager updates the device credentials according to your policy definition.

If you change the password for the user defined in the device properties, which Security Manager uses to deploy configurations to the device, or change the enable password, Security Manager uses the existing credentials defined in the device properties to log into the device and deploy changes. After successful deployment, the device properties are then changed to use your new settings. For more information on credentials in device properties, see Device Credentials Page , on page 114.

Note You can discover encrypted passwords, but any password you enter must be in clear text. If you discover an encrypted password and then modify it, the password is saved as clear text.

Related Topics

- User Accounts and Device Credentials on Cisco IOS Routers , on page 2402

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Accounts and Credentials** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Accounts and Credentials** from the Policy Type selector. Select an existing policy or create a new one.

The Accounts and Credentials page is displayed. See Table 862: Accounts and Credentials Page , on page 2405 for a description of the fields on this page.

Step 2 Enter the password for switching to privileged EXEC mode on the router:

a) Select **Enable Password** or **Enable Secret Password**. The Enable Secret Password option offers better security than the Enable Password option by storing the password using MD5 encryption. This option is useful in environments in which the password crosses the network or is stored on a TFTP server.

Note After you set an enable secret password, you can switch to an enable password only if the enable secret is disabled or an older version of Cisco IOS software is being used, such as when running an older rxboot image.

b) Enter a password, then enter it again in the Confirm field. The password that you enter must be in clear text. If you are configuring the enable secret password, the password is encrypted on deployment.

Step 3 (Optional) Select the **Enable Password Encryption Service** check box to encrypt all passwords on the device. This includes, for example, the enable password, username passwords, authentication key passwords, console and VTY line access passwords, and BGP neighbor passwords.

We recommend using this feature to help prevent unauthorized individuals from viewing the passwords in your configuration file.

Note This option does not provide a high level of security and should not be used as a substitute for additional network security measures.

Step 4 To define new user accounts for the router:

a) Click the **Add** button under the table to display the User Accounts dialog box.

b) Enter the details for the new user. See Table 863: User Account Dialog Box , on page 2406 for a description of the available fields.

c) Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the User Accounts table.

Note To edit a user account, select it from the User Accounts table, then click **Edit**. To remove a user account, select it, then click **Delete**.

Caution While deleting a user account, Cisco Security Manager times out and deployment fails. To avoid this, you can set up Security Manager to download despite an error. Enable **Allow Download** on **Error** in **Tools > Administrator > Deployments** in the Configuration Manager.

Accounts and Credentials Policy Page

Use the Accounts and Credentials page to define the enable password or enable secret password assigned to the router. In addition, you can define a list of usernames that can be used to access the router.

For more information, see Defining Accounts and Credential Policies , on page 2403.

Navigation Path

- (Device view) Select **Platform > Device Admin > Accounts and Credentials** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Accounts and Credentials** from the Policy Type selector. Right-click **Accounts and Credentials** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- User Accounts and Device Credentials on Cisco IOS Routers , on page 2402
- User Account Dialog Box , on page 2406
- Table Columns and Column Heading Features , on page 51
- Filtering Tables , on page 50

Field Reference

Table 862: Accounts and Credentials Page

Element	Description
Enable Secret Password	The enable secret password for entering privileged EXEC mode on the router. This option offers better security than the Enable Password option. The enable secret password can contain between 1-25 alphanumeric characters. The first character must be a letter. Spaces are allowed, but leading spaces are ignored. Question marks are also allowed. **Note** You can discover an encrypted password, but any password you enter must be in clear text. If you modify an encrypted password, it is saved as clear text. **Note** After you set an enable secret password, you can switch to an enable password only if the enable secret is disabled or an older version of Cisco IOS software is being used, such as when running an older rxboot image.
Enable Password	The enable password for entering privileged EXEC mode on the router. The enable password can contain between 1-25 alphanumeric characters. The first character must be a letter. Spaces are allowed, but leading spaces are ignored. Question marks are also allowed. **Note** You must enter the password in clear text.
Enable Password Encryption Service	When selected, encrypts all passwords on the device, including the enable password (which is otherwise saved in clear text). For example, use this option to encrypt username passwords, authentication key passwords, console and VTY line access passwords, and BGP neighbor passwords. This command is primarily used for keeping unauthorized individuals from viewing your passwords in your configuration file. When deselected, device passwords are stored unencrypted in the configuration file. **Note** This option does not provide a high level of network security. You should also take additional network security measures.
User Accounts Table	
Username	The username that can be used to access the router. The username must be a single word up to 64 characters in length. Spaces and quotation marks are not allowed.
Encryption	Indicates whether password information for the user is encrypted using MD5 encryption.
Privilege Level	The privilege level assigned to the user.
Add button	Opens the User Account Dialog Box , on page 2406. From here you can define a user account.
Edit button	Opens the User Account Dialog Box , on page 2406. From here you can edit the selected user.

Element	Description
Delete button	Deletes the selected user accounts from the table.

User Account Dialog Box

Employ the User Account dialog box to define a username and password combination that can be used by Security Manager to access the router. You can also define the privilege level of the user account, which determines whether you can configure all commands on this router or only a subset of them.

Note Remember—there may be additional user accounts defined on the router using other methods, such as the CLI.

Navigation Path

Go to the Accounts and Credentials Policy Page , on page 2404, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Understanding FlexConfig Policies and Policy Objects , on page 342

Field Reference

Table 863: User Account Dialog Box

Element	Description
Username	The username for accessing the router.
Password	The password for accessing the router with this user account. **Note** You can discover an encrypted password, but any password you enter must be in clear text.
Confirm	Confirms the password for this user account.
Encrypt password using MD5	When selected, uses MD5 encryption to encrypt the password for this user account. This is the default. When deselected, the password is sent to the router unencrypted.

Element	Description
Privilege Level	The privilege level assigned to the user account. Valid values range from 0 to 15: • 0—Grants access to these commands only: **disable**, **enable**, **exit**, **help**, and **logout**. • 1—Enables nonprivileged access to the router (normal EXEC-mode use privileges). • 15—Enables privileged access to the router (traditional enable privileges). **Note** Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig.

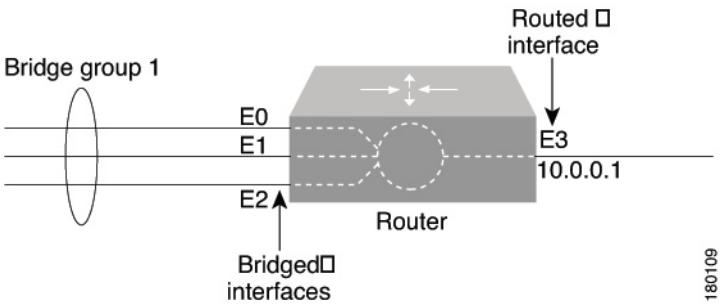
Bridging on Cisco IOS Routers

Bridging policies enable you to perform transparent bridging (as specified in RFC 1286) on selected interfaces that you have configured to function as a bridge group. Security Manager supports integrated routing and bridging, which makes it possible to route a specific protocol between routed interfaces and bridge groups, or route a specific protocol between bridge groups. Local or unroutable traffic can be bridged among the bridged interfaces in the same bridge group, while routable traffic can be routed to other routed interfaces or bridge groups, as shown in Figure 49: Transparent Bridging, on page 2407.

Using integrated routing and bridging, you can:

- Switch packets from a bridged interface to a routed interface.
- Switch packets from a routed interface to a bridged interface.
- Switch packets within the same bridge group.

Figure 49: Transparent Bridging



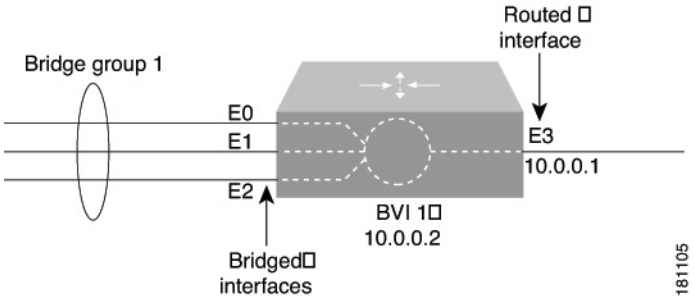
Related Topics

- Defining Bridge Groups , on page 2408
- Bridge-Group Virtual Interfaces , on page 2408

Bridge-Group Virtual Interfaces

Because bridging takes places at the data link layer and routing takes place at the network layer, they have different protocol configuration models. With IP, for example, bridge group interfaces belong to the same network and have a collective IP network address. In contrast, each routed interface represents a distinct network and has its own IP network address. Integrated routing and bridging uses the concept of a bridge-group virtual interface (BVI) to enable these interfaces to exchange packets for a given protocol. As shown in Figure 50: Bridge-Group Virtual Interface, on page 2408, the interface number assigned to the BVI corresponds to the bridge group that the BVI represents. This number serves as the link between the virtual interface and the bridge group.

Figure 50: Bridge-Group Virtual Interface



When you enable routing for a given protocol on the BVI, packets coming from a routed interface that are destined for a host in a bridged domain are routed to the BVI and then forwarded to the corresponding bridged interface. All traffic routed to the BVI is forwarded to the corresponding bridge group as bridged traffic. All routable traffic received on a bridged interface is routed to other routed interfaces as if it is coming directly from the BVI.

Note BVI interfaces are configured using the Interfaces policy. See Defining Basic Router Interface Settings , on page 2310. The BVI interface must have a corresponding bridge group with the same number; otherwise, deployment will fail.

Note When the bridge group contains more than two interfaces, add a BVI interface to the group to help prevent unicast flooding, which is a potential security issue.

Related Topics

- Defining Bridge Groups , on page 2408
- Bridging on Cisco IOS Routers , on page 2407

Defining Bridge Groups

You define a bridge group by selecting the L3 interfaces that are part of the bridge group and assigning the group a number. All bridge groups in Security Manager perform integrated routing and bridging on IP traffic only and use the standard Spanning Tree Protocol (IEEE 802.1D).

Note Use CLI commands or FlexConfigs to bridge other protocols, such as AppleTalk or IPX, and to use other spanning tree protocols, such as VLAN-Bridge. Concurrent routing and bridging is not supported.

Related Topics

- Bridging on Cisco IOS Routers , on page 2407
- Bridge-Group Virtual Interfaces , on page 2408

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Bridging** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Bridging** from the Policy Type selector. Select an existing policy or create a new one.

The Bridging page is displayed. See Table 864: Bridging Page , on page 2410 for a description of the fields on this page.

Step 2 Click the **Add** button under the table to display the Bridge Group dialog box. See Table 865: Bridge Group Dialog Box , on page 2411 for a description of the fields in this dialog box. From here you can define a bridge group.

Step 3 Enter a number to identify the bridge group.

Step 4 Enter the names of the interfaces and interface roles that are part of the bridge group, or click **Select** to select an interface role or to create a new one. For more information, see Specifying Interfaces During Policy Definition , on page 306.

You can select most Layer 3 interfaces, except X.25 and Integrated Services Digital Network (ISDN) bridged interfaces and certain types of logical interfaces (such as loopback, tunnel, null, and BVI). Each interface can be included in only one bridge group.

You can select a LAN subinterface only if the parent interface is configured with Inter-Switch Link (ISL) or 802.1Q encapsulation.

Step 5 Click **OK** to save your definitions locally on the client and close the dialog box. The bridge group is displayed in the table on the Bridging page.

Note To edit a bridge group, select it from the Groups table, then click **Edit**. To remove a bridge group, select it, then click **Delete**.

Bridging Policy Page

Use the Bridging page to define bridge groups that can perform integrated routing and bridging on the router. For more information, see Defining Bridge Groups , on page 2408.

Navigation Path

- (Device view) Select **Platform > Device Admin > Bridging** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Bridging** from the Policy Type selector. Right-click **Bridging** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Table Columns and Column Heading Features , on page 51
- Filtering Tables , on page 50

Field Reference

Table 864: Bridging Page

Element	Description
Group Number	The number that identifies the bridge group.
Group Interfaces	The interfaces and interface roles that are included in the bridge group.
Add button	Opens the Bridge Group Dialog Box , on page 2410. From here you can define a bridge group.
Edit button	Opens the Bridge Group Dialog Box , on page 2410. From here you can edit the bridge group.
Delete button	Deletes the selected bridge groups from the table.

Bridge Group Dialog Box

Use the Bridge Group dialog box to define bridge groups on the router. Each bridge group can contain multiple Layer 3 interfaces of various types, including serial interfaces.

Note All bridge groups use the standard Spanning Tree Protocol (IEEE 802.1D). Use CLI commands or FlexConfigs to bridge other protocols, such as AppleTalk or IPX, and to use other spanning tree protocols, such as VLAN-Bridge.

Navigation Path

Go to the Bridging Policy Page , on page 2409, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Defining Bridge Groups , on page 2408
- Bridging on Cisco IOS Routers , on page 2407
- Understanding Interface Role Objects , on page 303

Field Reference

Table 865: Bridge Group Dialog Box

Element	Description
Group Number	The number assigned to the bridge group. Valid values range from 1 to 255.
Group Interfaces	The interfaces that are included in the bridge group. Enter the name of one or more interfaces and interface roles, or click **Select** to select them. If the object that you want is not listed, click the **Create** button to create it. You can select most Layer 3 interfaces, including serial interfaces, provided the serial interface is configured with high-level data link control (HDLC) or Frame Relay encapsulation. Each interface can belong to only one bridge group. You can select a LAN subinterface only if the parent interface is configured with Inter-Switch Link (ISL) or 802.1Q encapsulation. **Note** Certain types of interfaces, such as loopback, tunnel, null, and BVI, cannot be bridged. **Note** Make sure that your bridge group does not prevent Security Manager from communicating with the device.

Time Zone Settings on Cisco IOS Routers

The local time on a Cisco IOS router is typically set using the clock set command in the CLI command or by dynamically deriving the time from an NTP server. You can adjust these time settings by defining the time zone in which the router resides and the start and end dates of Daylight Saving Time (DST) in that time zone.

Related Topics

- Defining Time Zone and DST Settings , on page 2411
- NTP on Cisco IOS Routers , on page 2487

Defining Time Zone and DST Settings

Security Manager enables you to define the time zone in which a Cisco IOS router is located. You can also define the start and end dates for Daylight Saving Time (DST).

Related Topics

- Defining NTP Servers , on page 2487
- Time Zone Settings on Cisco IOS Routers , on page 2411

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Device Admin** > **Clock** from the Policy selector.

- (Policy view) Select **Router Platform > Device Admin > Clock** from the Policy Type selector. Select an existing policy or create a new one.

The Clock page is displayed. See Table 866: Clock Page , on page 2413 for a description of the fields on this page.

Step 2 Select the time zone in which the router is located. Time zones are listed according the number of hours behind or ahead of Greenwich Mean Time (GMT).

Step 3 (Optional) Select the method for determining the start and end dates for DST:

- Set by Date—Select this option when DST starts and ends on fixed dates. Continue with Step 4, on page 2412.
- Set by Day—Select this option when DST starts and ends on days whose specific dates vary from year to year. Continue with Step 5, on page 2412.
- None—Select this option when DST is not used.

Step 4 (When Set by Date is selected) Define the fixed dates when DST starts and ends:

a) Under Start, click the calendar icon, then click the appropriate date.
b) Select the hour and minute from the displayed lists.
c) Repeat steps a and b to configure the end date and time.

Step 5 (When Set by Day is selected) Select the **Specify Recurring Time** check box if you want to define a DST period *other* than the default, which is the period used throughout most of the United States.

Step 6 (When Specify Recurring Time is selected) Define the start and end of DST:

a) Under Start, select the month when DST begins.
b) Select the week of the month (1, 2, 3, 4, first, or last).
c) Select the day of the week.
d) Select the hour and minute from the displayed lists. For example, if DST begins at 1:00 a.m. on the last Sunday of each March, select March, last, Sunday, 1, and 00.
e) Repeat Steps a through d to configure the end date and time.

Clock Policy Page

Use the Clock page to configure the time zone in which the router is located and the settings for Daylight Saving Time (DST). For more information, see Time Zone Settings on Cisco IOS Routers , on page 2411.

Tip You can configure the local time on the router by defining an NTP policy or by configuring the **clock set** command using the CLI.

Navigation Path

- (Device view) Select **Platform > Device Admin > Clock** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Clock** from the Policy Type selector. Right-click **Clock** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- NTP Policy Page , on page 2489

Field Reference

Table 866: Clock Page

Element	Description
Device Time Zone	The time zone in which the router is located, expressed in relation to GMT (Greenwich Mean Time), also known as UTC (Coordinated Universal Time). **Caution** If you want to use the Command Line Interface (CLI) to configure the time zone on the router, you must use the required Time Zone acronym provided in the Cisco IOS Configuration Fundamentals Command Reference document. If you use any other format for the time zone and then use Security Manager to discover the router, Security Manager will not discover the time zone CLI.
Daylight Savings Time (Summer Time)	The type of DST to apply to the local time on the router: • Set by Date—Enables you to define the exact date and time when DST begins and ends. • Set by Day—Enables you to define the relative recurring date and time when DST begins and ends. For example, you can use this option when DST begins the last Sunday of March and ends the last Sunday of October. • None—Daylight savings time is not used.
Additional Set by Date fields	
Start	The date and time when DST begins: • Date—Click the calendar icon to select the start date. • Hour—Select the start hour. • Minute—Select the start minute.
End	The date and time when DST ends: • Date—Click the calendar icon to select the end date. • Hour—Select the end hour. • Minute—Select the end minute. **Note** Cisco IOS Software supports dates up to and including December 31st, 2035.
Additional Set by Day fields	

Element	Description
Specify Recurring Time	When selected, the router implements DST according to the dates and times specified in this policy. When deselected, the router implements DST according to the schedule used throughout most of the United States.
Start	The relative date and time when daylight savings time begins: • Month—Select the month. • Week—Select the week of the month (1, 2, 3, 4, first, or last). • Weekday—Select the day of the week. • Hour—Select the hour. • Minute—Select the minute. For example, if DST begins at 1:00 a.m. on the last Sunday of each March, select March, last, Sunday, 1, and 00.
End	The relative date and time when daylight savings time ends: • Month—Select the month. • Week—Select the week of the month (1, 2, 3, 4, first, or last). • Weekday—Select the day of the week. • Hour—Select the hour. • Minute—Select the minute.

CPU Utilization Settings on Cisco IOS Routers

The CPU policy configures settings relating to CPU utilization. This policy provides you with methods for monitoring CPU resources and tracking processes that exceed a predetermined level of utilization.

Note The CPU policy is supported on routers running Cisco IOS Software Release 12.3(14)T or later.

Related Topics

• Defining CPU Utilization Settings , on page 2414

Defining CPU Utilization Settings

You can use Security Manager to modify the following default CPU utilization settings:

• The size of the CPU history table.

- The size of the extended CPU load history table.
- Whether to enable the automatic CPU Hog profiling.

In addition, you can optionally define:

- The CPU utilization level that causes a process to be included in the history table.
- The types of CPU utilization thresholds to enable. For each type of threshold, you can determine the threshold values that trigger notifications.

Related Topics

- Defining CPU Utilization Settings , on page 2414
- Logging on Cisco IOS Routers , on page 2515

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > CPU** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > CPU** from the Policy Type selector. Select an existing policy or create a new one.

The CPU page is displayed.

Step 2 (Optional) Define the CPU utilization settings of the router, as required. See Table 867: CPU Page , on page 2416 for a description of the available fields.

CPU Policy Page

Use the CPU page to configure settings related to router CPU utilization, including the thresholds for sending log messages, the size of the CPU history table, and whether to enable automatic CPU Hog profiling.

For more information, see Defining CPU Utilization Settings , on page 2414.

Navigation Path

- (Device view) Select **Platform > Device Access > CPU** from the Policy selector.
- (Policy view) Select **Router Platform > Device Access > CPU** from the Policy Type selector. Right-click **CPU** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Memory Policy Page , on page 2469
- Syslog Logging Setup Policy Page , on page 2522
- Syslog Servers Policy Page , on page 2525

Field Reference

Table 867: CPU Page

Element	Description
CPU Utilization Statistics	Settings related to the history table for CPU utilization statistics: • History Table Entry Limit—The percentage of CPU utilization that a process must use to be included in the history table. • History Table Size—The length of time for which CPU statistics are stored in the history table. Valid values range from 5 to 86400 seconds (24 hours). The default is 600 seconds (10 minutes).
CPU Total Utilization	The thresholds for total CPU utilization that trigger notifications: • Enable CPU Total Utilization—When selected, CPU total utilization thresholds are enabled. When deselected, these thresholds are disabled and do not trigger notifications. This is the default. • Maximum Total Utilization Resources—The percentage of CPU resources that, when usage *exceeds* this level for the defined interval, triggers a notification. • Maximum Total Utilization Violation Duration—The violation interval that triggers a maximum CPU threshold notification. Valid values range from 5 to 86400 seconds (24 hours). • Minimum Total Utilization Resources—The percentage of CPU resources that, when usage *falls below* this level for the defined interval, triggers a notification. • Minimum Total Utilization Violation Duration—The violation interval that triggers a minimum CPU threshold notification. Valid values range from 5 to 86400 seconds (24 hours).
CPU Interrupt Utilization	The thresholds for CPU interrupt utilization that trigger notifications: • Enable CPU Interrupt Utilization—When selected, CPU interrupt utilization thresholds are enabled. When deselected, these thresholds are disabled and do not trigger notifications. This is the default. • Maximum Interrupt Utilization Resources—The percentage of CPU resources that, when usage *exceeds* this level for the defined interval, triggers a notification. • Maximum Interrupt Utilization Violation Duration—The violation interval that triggers a maximum CPU threshold notification. Valid values range from 5 to 86400 seconds (24 hours). • Minimum Interrupt Utilization Resources—The percentage of CPU resources that, when usage *falls below* this level for the defined interval, triggers a notification. • Minimum Interrupt Utilization Violation Duration—The violation interval that triggers a minimum CPU threshold notification. Valid values range from 5 to 86400 seconds (24 hours).

Element	Description
CPU Process Utilization	The thresholds for CPU process utilization that trigger notifications: • Enable CPU Process Utilization—When selected, CPU process utilization thresholds are enabled. When deselected, these thresholds are disabled and do not trigger notifications. This is the default. • Maximum Process Utilization Resources—The percentage of CPU resources that, when usage *exceeds* this level for the defined interval, triggers a notification. • Maximum Process Utilization Violation Duration—The violation interval that triggers a maximum CPU threshold notification. Valid values range from 5 to 86400 seconds (24 hours). • Minimum Process Utilization Resources—The percentage of CPU resources that, when usage *falls below* this level for the defined interval, triggers a notification. • Minimum Process Utilization Violation Duration—The violation interval that triggers a minimum CPU threshold notification. Valid values range from 5 to 86400 seconds (24 hours).
Extended CPU History Size	The size of the history to collect for the extended CPU load, in increments of 5 seconds. Valid values range from 2 to 720. The default is 12, which is equivalent to a 1-minute history.
Enable Automatic CPU Hog Profiling	When selected, automatic CPU Hog profiling is enabled. This is the default. When deselected, automatic CPU Hog profiling is disabled. This feature predicts when a process could hog the CPU and begins profiling that process. **Note** To view the CPU Hog profile data, use the **show processes cpu autoprofile hog** command in the CLI.

HTTP and HTTPS on Cisco IOS Routers

Security Manager enables you to configure HTTP and HTTP over Secure Socket Layer (known as HTTP over SSL or HTTPS) server functionality on Cisco IOS routers. This feature provides SSL version 3.0 support for the HTTP 1.1 server.

A secure HTTP connection means that data sent to and received from an HTTP server are encrypted before being sent out over the internet. HTTP with SSL encryption provides a secure connection to allow such functions as configuring a router from a web browser.

In addition to providing access to the device via the Cisco web browser user interface, HTTP and HTTPS are used by device management applications, such as the Cisco Router and Security Device Manager (SDM), to communicate with the device.

Related Topics

• Defining HTTP Policies , on page 2418

Defining HTTP Policies

When you define an HTTP policy, you can:

- Enable and disable HTTP and SSL functionality on the router.
- Specify the ports used by each protocol.
- Optionally define a standard, numbered ACL that restricts access to the device using these protocols.

In addition, you can define the methods of AAA authentication and authorization methods to perform on users.

You must use caution when defining an HTTP policy, as your settings may affect communication between Security Manager (as well as other management applications that use these protocols) and the device.

Note As a general rule, Cisco IOS routers that have been discovered by Security Manager already have HTTPS enabled because Security Manager uses SSL as the default protocol for communicating with them. See Setting Up SSL on Cisco IOS Routers , on page 60.

Before You Begin

- Enable AAA services on the router. See Defining AAA Services , on page 2392.

Related Topics

- HTTP and HTTPS on Cisco IOS Routers , on page 2417

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > HTTP** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Device Admin > Device Access > HTTP** from the Policy Type selector. Select an existing policy or create a new one.

The HTTP Setup tab is displayed. See Table 868: HTTP Page—Setup Tab , on page 2420 for a description of the fields on this tab.

Step 2 Select the check boxes to enable HTTP and SSL (HTTPS) server functionality on the router.

Note If SSL is disabled (or if the HTTP policy as a whole is unassigned), Security Manager cannot communicate with the device after deployment unless you change the transport protocol for this device to SSH. This setting can be found in Device Properties. See Managing Device Communication Settings and Certificates , on page 460.

Tip We recommend that you disable HTTP when SSL is enabled. This is required to ensure only secure connections to the server.

Step 3 (Optional) Modify the default ports used by HTTP (80) and HTTPS (443).

Step 4 (Optional) In the Allow Connection From field, enter the name of the standard, numbered ACL object that specifies which addresses can use HTTP and HTTPS on this device, or click **Select** to select the ACL object from a list or to create

a new one. Use this option to restrict access to these protocols. For more information about creating standard ACL objects, see Creating Standard Access Control List Objects , on page 286

Note Make sure that the ACL you select permits the Security Manager server; otherwise, communication with the device is lost.

Step 5 (Optional) On the AAA tab, modify the default type of authentication to perform on users who attempt to access the device using HTTP or HTTPS. Options include AAA, Enable Password (default), Local Database, and TACACS.

If you select AAA, continue with Step 6, on page 2419; otherwise, continue with Step 8, on page 2419.

Note The TACACS option applies only to devices using an IOS software version prior to 12.3(8).

See Table 869: HTTP Page—AAA Tab , on page 2422 for a description of the fields on the AAA tab.

Step 6 Select the authentication method to perform on users:

- If you want to use the default AAA login authentication methods defined in the device's AAA policy (see Defining AAA Services , on page 2392), do *not* select the Enable Device Login Authentication check box. Continue with Step 7, on page 2419.
- If you want to define a method list especially for this policy, do the following:

a) Select the **Enable Device Login Authentication** check box.
b) Under Prioritized Method List, enter the names of the AAA server groups to use for authentication, or click **Select** to select the AAA server groups from a list or to create new ones. Use the up and down arrows in the selector to define the order in which you want to apply these authentication methods.

Note Make sure that Security Manager users are defined on the AAA servers; otherwise communication with the device is lost.

Step 7 Select the authorization method to perform on users who use HTTP or HTTPS to begin an EXEC session:

- If you want to use the default AAA authorization methods defined in the device's AAA policy, do *not* select the Enable CLI/EXEC Operations Authorization check box. Continue with Step 8, on page 2419.
- If you want to define a method list especially for this policy, select the **Enable CLI/EXEC Operations Authorization** check box, then define the method list.

Note If you leave this option deselected, make sure that EXEC authorization is enabled in the router's AAA policy. Otherwise, you will be unable to connect to the device via HTTP or HTTPS (SSL). This applies to Security Manager as well as other applications, such as SDM. See Defining AAA Services , on page 2392.

Step 8 (Optional) Create command authorization definitions for specific privilege levels:

a) Click the **Add** button under the Command Authorization Override table. The Command Authorization Override dialog box is displayed. See Table 870: Command Authorization Dialog Box , on page 2424 for a description of the fields in this dialog box.
b) Configure the command authorization definition as required.
c) Click **OK**. The dialog box closes and the authorization method is displayed in the Command Authorization Override table.
d) Repeat 8.a, on page 2419 through 8.c, on page 2419 to create additional command authorization definitions.

HTTP Policy Page

Use the HTTP page to configure HTTP and HTTPS access on the router. You can configure HTTP policies on a Cisco IOS router from the following tabs on the HTTP policy page:

- HTTP Page—Setup Tab , on page 2420
- HTTP Page—AAA Tab , on page 2421

For more information, see HTTP and HTTPS on Cisco IOS Routers , on page 2417.

Navigation Path

- (Device view) Select **Platform** > **Device Admin** > **Device Access** > **HTTP** from the Policy selector.
- (Policy view) Select **Router Platform** > **Device Admin** > **Device Access** > **HTTP** from the Policy Type selector. Right-click **HTTP** to create a policy, or select an existing policy from the Shared Policy selector.

HTTP Page—Setup Tab

Use the Setup tab of the HTTP page to enable HTTP and HTTP over Secure Socket Layer (HTTP over SSL or HTTPS) on the router. You can optionally limit access to these protocols to the addresses defined in an access control list.

Note As a general rule, Cisco IOS routers that have been discovered by Security Manager already have HTTPS enabled because Security Manager uses SSL as the default protocol for communicating with them. See Setting Up SSL on Cisco IOS Routers , on page 60.

Navigation Path

Go to the HTTP Policy Page , on page 2420, then click the **Setup** tab.

Related Topics

- HTTP Page—AAA Tab , on page 2421
- HTTP and HTTPS on Cisco IOS Routers , on page 2417

Field Reference

Table 868: HTTP Page—Setup Tab

Element	Description
Enable HTTP	When selected, an HTTP server is enabled on the router. When deselected, HTTP is disabled on the router. This is the default for devices that were not discovered.

Element	Description
HTTP Port	The port number to use for HTTP. Valid values are 80 or any value from 1024 to 65535. The default is 80.
Enable SSL	When selected, a secure HTTP server (HTTP over SSL or HTTPS) is enabled on the router. When deselected, HTTPS is disabled. This is the default for devices that were not discovered. **Note** If SSL is disabled (or if the HTTP policy as a whole is unassigned), Security Manager cannot communicate with the device after deployment unless you change the transport protocol for this device to SSH. This setting can be found in Device Properties. **Note** We recommend that you disable HTTP when SSL is enabled. This is required to ensure only secure connections to the server.
SSL Port	The port number to use for HTTPS. Valid values are 443 or any value from 1025 to 65535. The default is 443.
Allow Connection From	The name of the standard numbered ACL that restricts use of HTTP and HTTPS on this device. Enter the name of an ACL object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it. **Note** If you define an ACL, make sure that it includes the Security Manager server. Otherwise, Security Manager cannot communicate with this device using SSL.

HTTP Page—AAA Tab

Use the AAA tab of the HTTP page to define the authentication and authorization methods to perform on users who attempt to access the router using HTTP or HTTPS.

Navigation Path

Go to the HTTP Policy Page , on page 2420, then click the **AAA** tab.

Related Topics

- HTTP Page—Setup Tab , on page 2420
- HTTP and HTTPS on Cisco IOS Routers , on page 2417
- Filtering Tables , on page 50

Field Reference

Table 869: HTTP Page—AAA Tab

Element	Description
Authenticate Using	The type of authentication to use: • AAA—Performs AAA login authentication. • Enable Password—Uses the enable password configured on the router. This is the default. • Local Database—Uses the local username database configured on the router. • TACACS—Uses the TACACS or XTACACS server configured on the router. Applies only to devices using an IOS software version prior to 12.3(8) or 12.3(8)T.
Login Authentication settings	
Enable Device Login Authentication	Applies only when AAA is selected as the authentication method. When selected, authentication is based on the methods defined in the Prioritized Method List field. When deselected, the default authentication list defined in the router's AAA policy is used. See AAA Page—Authentication Tab , on page 2395.
Prioritized Method List	Applies only when the Enable Device Login Authentication check box is selected. Defines a sequential list of methods to be queried when authenticating a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.
EXEC Authorization settings	

Element	Description
Enable CLI/EXEC Operations Authorization	Applies only when AAA is selected as the authentication method. When selected, EXEC authorization is based on the methods defined in the Prioritized Method List field. This type of authorization determines whether the user is permitted to open an EXEC (CLI) session. When deselected, the default EXEC authorization list defined in the router's AAA policy is used. See AAA Page—Authorization Tab , on page 2396. **Note** If you leave this option deselected, make sure that EXEC authorization is enabled in the router's AAA policy. Otherwise, you will be unable to connect to the device via HTTP or HTTPS (SSL). This applies to Security Manager as well as other applications, such as SDM and the device's web interface.
Prioritized Method List	Applies only when the Enable CLI/EXEC Operations Authorization check box is selected. Defines a sequential list of methods to be queried when authorizing a user to open an EXEC (CLI) session. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.
Command Authorization settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Authorization Override Dialog Box , on page 2423. From here you can configure a command authorization definition.
Edit button	Opens the Command Authorization Override Dialog Box , on page 2423. From here you can edit the command authorization definition.
Delete button	Deletes the selected command authorization definitions from the table.

Command Authorization Override Dialog Box

Use the Command Authorization Override dialog box to define which methods to use when authorizing the EXEC commands that are associated with a given privilege. This enables you to authorize all commands associated with a specific privilege level, from 0 to 15.

Navigation Path

From the HTTP Page—AAA Tab , on page 2421, click the **Add** button beneath the Command Authorization Override table.

Related Topics

- HTTP Policy Page , on page 2420
- AAA Policy Page , on page 2394

Field Reference

Table 870: Command Authorization Dialog Box

Element	Description
Privilege Level	The privilege level for which you want to define a command accounting list. Valid values range from 0 to 15.
Prioritized Method List	Defines a sequential list of methods to be used when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. Supported methods include TACACS+, Local, and None. **Note** If you select None as a method, it must appear as the last method in the list.

Line Access on Cisco IOS Routers

Security Manager enables you to configure command line access (also called EXEC access) to a router using the following methods:

- Console port—Physical connection via a standard RS232 cable for local access. For more information, see:
  - Defining Console Port Setup Parameters , on page 2425
  - Defining Console Port AAA Settings , on page 2426
- VTY lines—Virtual terminal lines for remote access, typically using protocols such as Telnet, SSH, or rlogin. For more information, see:
  - Defining VTY Line Setup Parameters , on page 2427
  - Defining VTY Line AAA Settings , on page 2429

After you configure and deploy these policies, you can use these lines to communicate with individual devices directly when you want to configure or diagnose them using the CLI.

Defining Console Port Setup Parameters

The console port on a router is generally used for local system access by an administrator with physical access to the device. By default, the console port is set up as follows:

- All permitted users have privileged access to the router, including all configuration commands (privilege level 15).
- The line is disconnected after 10 minutes without user input.
- Incoming connections are not permitted.
- Outgoing connections support Telnet only.

In addition to modifying any of the default settings, you can optionally define the following settings:

- The password for accessing the console.
- Whether to disable all EXEC sessions on the console.
- Incoming and outgoing ACLs that restrict the connections that are permitted on the console.
- Whether VRF connections are permitted on the console.

Related Topics

- Line Access on Cisco IOS Routers , on page 2424

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > Console** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > Console** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The Console Setup tab is displayed. See Table 871: Console Page—Setup Tab , on page 2432 for a description of the fields on this tab.

Step 2 (Optional) Enter the password for accessing the console port, then enter it again in the Confirm field.

Step 3 (Optional) Modify the default (15) granted to users of the console port. See Console Page—Authorization Tab , on page 2434.

Step 4 (Optional) Select the **Disable all the EXEC sessions to the router via this line** check box to prevent any incoming connections via the console.

Note Selecting this option blocks all access to the device via the console port.

Step 5 (Optional) Modify the default timeout after which the line is disconnected if no user input is detected.

Note Setting this value to 0 disables the timeout. Disabling the timeout could compromise the security of your network.

Step 6 (Optional) Specify which protocols can be used for outbound connections on the console port:

- All—All supported protocols are permitted.
- None—No protocols are permitted.
- Protocol—Enables one or more of the following protocols: SSH, Telnet, and rlogin.

Note You must configure AAA authentication on devices where the console port permits the SSH and rlogin protocols. See Defining Console Port AAA Settings , on page 2426.

Step 7 (Optional) Enter the names of ACLs that restrict incoming and outgoing connections between the device and the addresses in these lists, or click **Select** to select the ACL object or to create a new one. At the top of the selector, in the Type field, select the ACL type as either Standard or Extended.

Step 8 (Optional) Click the **AAA** tab to define authentication, authorization, and accounting settings for the console port. See Defining Console Port AAA Settings , on page 2426.

Defining Console Port AAA Settings

By default, authentication, authorization, and accounting are not performed on the console port. When you configure one or more of these access control options, you can either make use of the default method lists defined in the device's AAA policy or define a custom method list containing one or more AAA methods.

Related Topics

- Defining Console Port Setup Parameters , on page 2425
- Line Access on Cisco IOS Routers , on page 2424

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > Console** from the Policy selector, then click the **Authentication** tab in the work area.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > Console** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Authentication** tab.

The Console Authentication tab is displayed.

Step 2 (Optional) Select the authentication method to perform on users who attempt to access the console line.

See Table 872: Console Page—Authentication Tab , on page 2434 for a description of the fields on the Authentication tab.

Note If you select local authentication, preview the full configuration before deployment to make sure that the **aaa new-model** command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.

Step 3 (Optional) On the Authorization tab, select the authorization method to perform on users who access the console line and begin an EXEC session.

See Table 873: Console Page—Authorization Tab , on page 2435 for a description of the fields on the Authorization tab.

Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

Step 4 (Optional) Create command authorization definitions for specific privilege levels:

a) Click the **Add** button under the Commands Authorization table. The Command Authorization dialog box is displayed. See Table 881: Command Authorization Dialog Box—Line Access , on page 2450 for details.
b) Configure the command authorization definition as required.
c) Click **OK**. The dialog box closes and the authorization method is displayed in the Commands Authorization table.
d) Repeat 6.a, on page 2427 through 6.c, on page 2427 to create additional command authorization definitions.

Step 5 (Optional) On the Accounting tab, select the EXEC and connection accounting methods to perform on users who access the console line.

See Table 874: Console Page—Accounting Tab , on page 2436 for a description of the fields on this tab.

Step 6 (Optional) Create command accounting definitions for specific privilege levels:

a) Click the **Add** button under the Commands Accounting table. The Command Accounting Dialog Box—Line Access , on page 2451 is displayed.
b) Configure the command accounting definition as required.
c) Click **OK**. The dialog box closes and the accounting method is displayed in the Commands Accounting table.
d) Repeat 6.a, on page 2427 through 6.c, on page 2427 to create additional command accounting definitions.

Defining VTY Line Setup Parameters

All Cisco IOS routers are configured by default with five VTY lines (labeled 0-4) that have the following settings:

- All permitted users have privileged access to the router, including all configuration commands (privilege level 15).
- VTY lines are disconnected after 10 minutes without user input.
- Incoming connections are not permitted.
- Outgoing connections support Telnet only.

You can use Security Manager to modify the default settings on these five VTY lines or to configure additional lines (up to a maximum of 16). In addition, you can optionally configure the following settings on each line:

- The password for accessing the line.
- Whether to disable all EXEC sessions on the line.
- Incoming and outgoing ACLs that restrict the connections that are permitted on the line.
- Whether VRF connections are permitted on the line.

Defining Groups of VTY Lines

You can configure multiple VTY lines as a contiguous group, which enables you to define identical settings for all the lines in the group with one procedure. All the lines within the group must fall within one of two ranges, 0-4 or 6-15. The group cannot overlap these two ranges.

The rules for configuring VTY line 5 are as follows. Line 5 can be part of the same definition as lines 0-4 only when there are no lines configured above line 5. If there are lines configured above line 5, you cannot

include line 5 in the definition for lines 0-4, even if their configurations are the same. Line 5 *can* be included in the definition of the lines above line 5 if their configurations are the same.

For example, if lines 0-5 all share one configuration and lines 6-9 have a different configuration, you need to create three definitions—one definition for lines 0-4, a second definition for line 5, and a third definition for lines 6-9.

Note When you configure VTY lines, bear in mind that users are assigned a line at random when they connect to the device.

Note You can create only one definition per VTY line. An error is displayed if you create a VTY line definition that overlaps an existing definition.

Note If you use Security Manager to configure the default VTY lines (0-4), your definition overrides the default settings on the device. If you later delete this definition from Security Manager, the input protocol settings are retained and the other default settings are restored. This ensures that you always have VTY lines available for remote access to the device.

Note You can use the CLI or FlexConfigs to configure additional VTY lines on devices that support more than 16 lines.

Related Topics

- Line Access on Cisco IOS Routers , on page 2424

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > VTY** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > VTY** from the Policy Type selector. Select an existing policy or create a new one.

The VTY page is displayed. See Table 875: VTY Lines Page , on page 2439 for a description of the fields on this page.

Step 2 Click the **Add** button beneath the Lines table, or select a line definition and then click the **Edit** button. The Setup tab of the VTY Lines dialog box is displayed. See Table 876: VTY Line Dialog Box , on page 2441 for a description of the fields on this tab.

Step 3 Enter the relative line number of the VTY line. If you are configuring a group of VTY lines, enter the first and last numbers of the group in the fields provided.

Step 4 (Optional) Enter the password for accessing the console line, then enter it again in the Confirm field.

Step 5 (Optional) Modify the default Privilege (15) granted to users of this VTY line (or group of lines).

Step 6 (Optional) Select the **Disable all the EXEC sessions to the router via this line** check box to prevent any incoming connections over this VTY line (or group of lines).

Step 7 (Optional) Modify the default timeout after which the line is disconnected if no user input is detected.

Note Setting this value to 0 to disables the timeout. Disabling the timeout could cause abandoned sessions to block available VTY lines. It can also compromise the security of your network.

Step 8 (Optional) Specify which protocols can be used for inbound and outbound connections on this VTY line (or group of lines):

- All—All supported protocols are permitted.
- None—No protocols are permitted.
- Protocol—Enables one or more of the following protocols: SSH, Telnet, and rlogin.

Caution Setting the inbound connections setting to None might prevent Security Manager from connecting to the device after deployment.

Note You must configure AAA authentication when the VTY line permits the SSH and rlogin protocols. See Defining VTY Line AAA Settings , on page 2429.

Step 9 (Optional) Enter the names of ACLs that restrict incoming and outgoing connections between the device and the addresses in these lists, or click **Select** to select an ACL object from a list or to create a new one. You can choose from standard or extended ACLs.

Tip Defining an inbound ACL is a good way to reserve a VTY line for administrative access only.

Step 10 (Optional) Click the **AAA** tab to define authentication, authorization, and accounting settings for this VTY line (or group of lines). See Defining VTY Line AAA Settings , on page 2429.

Step 11 Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Lines table.

Note To remove a VTY line definition, select it, then click **Delete**. If you delete a VTY line from an IOS device, any subsequent lines are also deleted. For example, if the device contains lines 0-9 and you delete line 5, lines 6-9 are deleted as well. If you delete the definition for lines 0-4 from Security Manager, the router retains the inbound protocol definition and restores the other default settings for these lines on the device. This ensures that five VTY lines are always available.

Defining VTY Line AAA Settings

By default, authentication, authorization, and accounting are not performed on VTY lines. When you configure one or more of these access control options, you can either make use of the default method lists defined in the device's AAA policy or define a custom method list containing one or more AAA methods.

Before You Begin

- Define the basic parameters of the VTY line or group of VTY lines. See Defining VTY Line Setup Parameters , on page 2427.

Related Topics

- Defining VTY Line Setup Parameters , on page 2427

- Line Access on Cisco IOS Routers , on page 2424

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > VTY** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > VTY** from the Policy Type selector. Select an existing policy or create a new one.

The VTY page is displayed. See Table 875: VTY Lines Page , on page 2439 for a description of the fields on this page.

Step 2 Select a VTY line definition in the Lines tables, click the **Edit** button to display the VTY Line dialog box, then click the **Authentication** tab.

Step 3 (Optional) Select the authentication method to perform on users who attempt to access the VTY line.

See Table 878: VTY Line Dialog Box—Authentication Tab , on page 2445 for a description of the fields on this tab.

Note If you select local authentication, preview the full configuration before deployment to make sure that the **aaa new-model** command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.

Step 4 (Optional) On the Authorization tab, select the authorization method to perform on users who access the VTY line and begin an EXEC session.

See Table 879: VTY Line Dialog Box—Authorization Tab , on page 2446 for a description of the fields on the Authorization tab.

Note RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.

Step 5 (Optional) Create command authorization definitions for specific privilege levels:

a) Click the **Add** button under the Commands Authorization table. The Command Authorization Override Dialog Box , on page 2423 is displayed.
b) Configure the command authorization definition as required.
c) Click **OK**. The dialog box closes and the authorization method is displayed in the Commands Authorization table.
d) Repeat 5.a, on page 2430 through 5.c, on page 2430 to create additional command authorization definitions.

Step 6 (Optional) On the Accounting tab, select the EXEC and connection accounting methods to perform on users who attempt to access the VTY line.

See Table 880: VTY Line Dialog Box—Accounting Tab , on page 2447 for a description of the fields on the Accounting tab.

Step 7 (Optional) Create command accounting definitions for specific privilege levels:

a) Click the **Add** button under the Commands Accounting table. The Command Accounting Dialog Box—Line Access , on page 2451 is displayed.
b) Configure the command accounting definition as required.
c) Click **OK**. The dialog box closes and the accounting method is displayed in the Commands Accounting table.
d) Repeat 7.a, on page 2430 through 7.c, on page 2430 to create additional command accounting definitions.

Console Policy Page

Use the Console page to configure access to the router over the console port. You can configure console policies on a Cisco IOS router from the following tabs on the Console policy page:

- Console Page—Setup Tab , on page 2431
- Console Page—Authentication Tab , on page 2433
- Console Page—Authorization Tab , on page 2434
- Console Page—Accounting Tab , on page 2436

For more information, see Line Access on Cisco IOS Routers , on page 2424.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > Console** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > Console** from the Policy Type selector. Right-click **Console** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- VTY Policy Page , on page 2439

Console Page—Setup Tab

Use the Setup tab of the Console page to define the basic parameters of the console port. This includes the password for accessing the port, the privilege level assigned to users, the protocols that are permitted, and the ACLs that limit access.

Navigation Path

Go to the Console Policy Page , on page 2431, then click the **Setup** tab.

Related Topics

- Console Page—Authentication Tab , on page 2433
- Console Page—Authorization Tab , on page 2434
- Console Page—Accounting Tab , on page 2436
- VTY Line Dialog Box—Setup Tab , on page 2441

Field Reference

Table 871: Console Page—Setup Tab

Element	Description
Password	The password for accessing the console port. The password is case sensitive and can contain up to 80 alphanumeric characters. The first character cannot be a number. Spaces are not allowed. Enter the password again in the Confirm field.
Privilege Level	The privilege level assigned to users connected to the console port. Valid values range from 0 to 15: • 0—Grants access to these commands only: **disable**, **enable**, **exit**, **help**, and **logout**. • 1—Enables nonprivileged access to the router (normal EXEC-mode use privileges). • 15—Enables privileged access to the router (traditional enable privileges). **Note** Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig. **Note** If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.
Disable all the EXEC sessions to the router via this line	When selected, disables EXEC sessions over this line. Select this option when you want to allow only an outgoing connection on the console. This option is useful for keeping the console port free from unsolicited incoming data that can tie up the line. When deselected, EXEC sessions are enabled on the console port. This is the default. **Note** Selecting this option blocks all access to the device via the console port.
Exec Timeout	The amount of time (in seconds) that the EXEC command interpreter waits to detect user input on the console port. If no input is detected, the line is disconnected. Valid values range from 0 to 2147483. The default is 600 (10 minutes). Setting the value to 0 disables the timeout. **Note** Although the timeout is defined in seconds, it appears in the CLI in the format [mm ss].

Element	Description

Output Protocols	The protocols that you can use for outgoing connections on the console port:
	• All—All supported protocols are permitted. Supported protocols include LAT, MOP, NASI, PAD, rlogin, SSH, Telnet, and V.120.
	• None—No protocols are permitted. This makes the port unusable by outgoing connections.
	• Protocol—Enables one or more of the following protocols:
	  • SSH—Secure Shell protocol.
	  • Telnet—Standard TCP/IP terminal emulation protocol.
	  • rlogin—UNIX rlogin protocol.
	Note SSH and rlogin require that you configure AAA authentication. See Console Page—Authentication Tab , on page 2433.
	Note Not all IOS Software Versions support rlogin as an output protocol.

Inbound Access List	The name of the ACL object that restricts incoming connections on the console port. Enter the name of the ACL object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.
Permit VRF Interface Connections	Applies only when an inbound ACL is defined on the console port. When selected, accepts incoming connections from interfaces that belong to a VRF. When deselected, rejects incoming connections from interfaces that belong to a VRF.
Outbound Access List	The name of the ACL object that restricts outgoing connections on the console port. Enter the name of an ACL object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.

Console Page—Authentication Tab

Use the Authentication tab of the Console page to define the AAA authentication methods to perform on users who attempt to access the console port.

Navigation Path

Go to the Console Policy Page , on page 2431, then click the **Authentication** tab.

Related Topics

- Console Page—Setup Tab , on page 2431
- Console Page—Authorization Tab , on page 2434
- Console Page—Accounting Tab , on page 2436
- VTY Line Dialog Box—Authentication Tab , on page 2444

Field Reference

Table 872: Console Page—Authentication Tab

Element	Description
Authenticate Using	Authentication settings for the console port: • None—Authentication is not performed. This is the default. • Local Database—Uses the local username database for authentication. • AAA Policy Default List—Uses the default authentication method list that is defined in the device's AAA policy. See AAA Page—Authentication Tab , on page 2395. • Custom Method List—Uses the authentication methods specified in the Authentication Method List field. **Note** If you select local authentication, preview the full configuration before deployment to make sure that the **aaa new-model** command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.
Prioritized Method List	Applies only when Custom Method List is selected as the authentication method. Defines a sequential list of methods to be queried when authenticating a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.

Console Page—Authorization Tab

Use the Authorization tab of the Console page to define the EXEC and command authorization methods to perform on users who access the console port.

Note You must enable AAA services on the router to use this feature; otherwise, deployment will fail. See Defining AAA Services , on page 2392.

Navigation Path

Go to the Console Policy Page , on page 2431, then click the **Authorization** tab.

Field Reference

Table 873: Console Page—Authorization Tab

Element	Description
EXEC Authorization settings	
Authorize EXEC Operations Using	The authorization method that determines whether a user is allowed to run an EXEC session: • None—Authorization is not performed. This is the default. • AAA Policy Default List—Uses the default authorization method list that is defined in the device's AAA policy. See AAA Page—Authorization Tab , on page 2396. • Custom Method List—Uses the authorization methods specified in the EXEC Method List field.
Prioritized Method List	Applies only when Custom Method List is selected as the EXEC method. Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list. **Note** RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.
Command Authorization settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Authorization Dialog Box—Line Access , on page 2450. From here you can configure a command authorization definition.

Element	Description
Edit button	Opens the Command Authorization Dialog Box—Line Access , on page 2450. From here you can edit the command authorization definition.
Delete button	Deletes the selected command authorization definitions from the table.

Console Page—Accounting Tab

Use the Accounting tab of the Console page to define the EXEC, connection, and command accounting methods to perform on users who access the console port.

Note You must enable AAA services on the router to use this feature; otherwise, deployment will fail. See Defining AAA Services , on page 2392.

Navigation Path

Go to the Console Policy Page , on page 2431, then click the **Accounting** tab.

- Filtering Tables , on page 50

Field Reference

Table 874: Console Page—Accounting Tab

Element	Description
EXEC Accounting settings	

Element	Description
Perform EXEC Accounting Using	The accounting method to use for recording basic information about user EXEC sessions: • None—Accounting is not performed. This is the default. • AAA Policy Default List—Uses the default EXEC accounting method list that is defined in the device's AAA policy. See AAA Page—Accounting Tab , on page 2398. • Custom Method List—Uses the accounting methods specified in the EXEC Method List field. EXEC accounting records basic details about EXEC sessions, such as the username, date, start and stop times, and the access server IP address.
Generate Accounting Records for	Applies only when Custom Method List is selected as the EXEC method. Defines when the device sends an accounting notice to the accounting server: • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the "start" accounting record. This is the default. • Stop Only—Generates an accounting record at the end of the user process only. • None—No accounting records are generated.
Prioritized Method List	Applies only when Custom Method List is selected as the EXEC method. Defines a sequential list of methods to be queried when creating accounting methods for a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.
Enable Broadcast to Multiple Servers	Applies only when Method List is selected as the EXEC method. When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group. When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.
Connection Accounting settings	

Element	Description
Perform Connection Accounting Using	The accounting method to use for recording information about outbound connections made over the console line: • None—Accounting is not performed. This is the default. • AAA Policy Default List—Uses the default connection accounting method list that is defined in the device's AAA policy. See AAA Page—Accounting Tab , on page 2398. • Custom Method List—Uses the accounting methods specified in the Connection Method List field. Connection accounting records details about outgoing connections over the line, such as Telnet and rlogin connections.
Generate Accounting Records for	Applies only when Custom Method List is selected as the connection method. Defines when the device sends an accounting notice to the accounting server: • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the "start" accounting record. This is the default. • Stop Only—Generates an accounting record at the end of the user process only. • None—No accounting records are generated.
Prioritized Method List	Applies only when Custom Method List is selected as the connection method. Defines a sequential list of methods to be queried when creating accounting methods for a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.
Enable Broadcast to Multiple Servers	Applies only when Custom Method List is selected as the connection method. When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group. When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.
Command Accounting settings	

Element	Description
Privilege Level	The privilege level to which the command authorization definition applies.
Generate Accounting Records for	The points in the process where the device sends an accounting notice to the accounting server.
Enable Broadcast	Whether accounting records are broadcast to multiple servers simultaneously.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Accounting Dialog Box—Line Access , on page 2451. From here you can configure a command accounting definition.
Edit button	Opens the Command Accounting Dialog Box—Line Access , on page 2451. From here you can edit the command accounting definition.
Delete button	Deletes the selected command accounting definitions from the table.

VTY Policy Page

Use the VTY page to configure up to 16 VTY lines for remote access to the router. In addition to configuring individual lines, you can configure a group of lines that share the same definition.

For more information, see Line Access on Cisco IOS Routers , on page 2424.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Line Access > VTY** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Line Access > VTY** from the Policy Type selector. Right-click **VTY** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Console Policy Page , on page 2431

- Filtering Tables , on page 50

Field Reference

Table 875: VTY Lines Page

Element	Description
Line	The relative line number of the VTY line. This field may also contain multiple VTY lines configured as a contiguous group.

Element	Description
Line/Line Group Parameters	
Input Protocols	The protocols that you can use for incoming connections on the VTY line.
Output Protocols	The protocols that you can use for outgoing connections on the VTY line.
Privilege Level	The privilege level assigned to users.
Exec Timeout	The amount of time the EXEC command interpreter waits until user input is detected.
Inbound ACL	The ACL used to limit inbound traffic.
Outbound ACL	The ACL used to limit outbound traffic.
Authentication	The type of AAA authentication used.
Authorization	The types of AAA authorization used.
Accounting	The types of AAA accounting used.
VTY Line Page Buttons	
Add button	Opens the VTY Line Dialog Box , on page 2440. From here you can define a VTY line or line group.
Edit button	Opens the VTY Line Dialog Box , on page 2440. From here you can edit the VTY line or line group.
Delete button	Deletes the selected VTY lines from the table. If you delete a VTY line from an IOS device, any subsequent lines are also deleted. For example, if the device contains lines 0-9 and you delete line 5, lines 6-9 are deleted as well. **Note** If you delete any of the default VTY lines (0-4) on the device, the input protocol settings are retained and the other default settings are restored. This helps prevent you from cutting off remote access to the device.

VTY Line Dialog Box

Use the VTY Line dialog box to configure one or more VTY lines (up to 16) that enable remote users to access the router. When you configure a VTY line, you can define the type of authentication and authorization to perform on users who access the lines.

Navigation Path

Go to the VTY Policy Page , on page 2439, then click the **Add** or **Edit** button beneath the table.

Field Reference

Table 877: VTY Line Dialog Box—Setup Tab

Element	Description
Starting VTY Line Number	The relative line number of the VTY line. If you are configuring a group of VTY lines, enter the number of the first line in the group. Valid values range from 0 to 15. **Note** Although different routers support a different number of VTY lines (from four to several thousand), Security Manager supports a maximum of 16 lines per device. You cannot configure the same line number more than once.
Ending VTY Line Number	Applies only when configuring a group of lines. The relative line number of the last VTY line in the group. **Note** When you configure a group of lines, all the lines in the group must fall within one of two ranges, 0-4 or 6-15.
Password	The password for accessing this VTY line. The password is case sensitive and can contain up to 80 alphanumeric characters. The first character cannot be a number. Spaces are not allowed. Enter the password again in the Confirm field.
Privilege Level	The privilege level assigned to users on this VTY line. Valid values range from 0 to 15: • 0—Grants access to these commands only: **disable**, **enable**, **exit**, **help**, and **logout**. • 1—Enables nonprivileged access to the router (normal EXEC-mode use privileges). • 15—Enables privileged access to the router (traditional enable privileges). **Note** Levels 2-14 are not normally used in a default configuration, but custom configurations can be created by moving commands that are normally at level 15 to a lower level and commands that are normally at level 1 to a higher level. You can configure the privilege levels of commands using the CLI or by defining a FlexConfig. **Note** If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.
Disable all the EXEC sessions to the router via this line	When selected, EXEC sessions are disabled over this line. Select this option when you want to allow only an outgoing connection on this line. This option is useful for keeping a particular line free from unsolicited incoming data that can tie up the line. When deselected, EXEC sessions are enabled over this line. This is the default.

Element	Description
Exec Timeout	The amount of time (in seconds) that the EXEC command interpreter waits to detect user input on the line. If no input is detected, the line is disconnected. Valid values range from 0 to 2147483. The default is 600 (10 minutes). Setting the value to 0 disables the timeout. **Note** Although the timeout is defined in seconds, it appears in the CLI in the format [mm ss].
Input Protocols	The protocols that you can use for incoming connections on this line: • All—All supported protocols are permitted. Supported protocols include LAT, MOP, NASI, PAD, rlogin, SSH, Telnet, and V.120. • None—No protocols are permitted. This makes the port unusable by incoming SSH, Telnet, and rlogin connections. **Note** Setting the input protocols setting to None might prevent Security Manager from connecting to the device after deployment. The device can still be managed using SSL, if SSL is enabled in the HTTP policy. See HTTP Page—Setup Tab , on page 2420. • Protocol—Enables one or more of the following protocols: • SSH—Secure Shell protocol. • Telnet—Standard TCP/IP terminal emulation protocol. • rlogin—UNIX rlogin protocol. **Note** SSH and rlogin require that you configure AAA authentication. See VTY Line Dialog Box—Authentication Tab , on page 2444. **Note** Not all IOS Software Versions support rlogin as an input protocol.
Output Protocols	The protocols that you can use for outgoing connections on this line: • All—All supported protocols are permitted. Supported protocols include LAT, MOP, NASI, PAD, rlogin, SSH, Telnet, and V.120. • None—No protocols are permitted. This makes the port unusable by outgoing connections. • Protocol—Enables one or more of the following protocols: • SSH—Secure Shell protocol. • Telnet—Standard TCP/IP terminal emulation protocol. • rlogin—UNIX rlogin protocol. **Note** SSH and rlogin require that you configure AAA authentication. See VTY Line Dialog Box—Authentication Tab , on page 2444. **Note** Not all IOS Software Versions support rlogin as an output protocol.

Element	Description
Inbound Access List	The name of the ACL object that restricts incoming connections on this line. Enter the name of the ACL object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.
Permit VRF Interface Connections	Applies only when an inbound ACL is defined on this line. When selected, accepts incoming connections from interfaces that belong to a VRF. When deselected, rejects incoming connections from interfaces that belong to a VRF.
Outbound Access List	The name of the ACL object that restricts outgoing connections on this line. Enter the name of the ACL object, or click **Select** to select it. If the object that you want is not listed, click the **Create** button to create it.

VTY Line Dialog Box—Authentication Tab

Use the Authentication tab of the VTY Line dialog box to define the authentication methods to perform on users who attempt to access the selected VTY line or group of lines.

Navigation Path

Go to the VTY Line Dialog Box , on page 2440, then click the **Authentication** tab.

Field Reference

Table 878: VTY Line Dialog Box—Authentication Tab

Element	Description
Authenticate Using	Authentication settings for the VTY line: • None—Authentication is not performed. This is the default. • Local Database—Uses the local username database for authentication. • AAA Policy Default List—Uses the default authentication method list that is defined in the device's AAA policy. See AAA Page—Authentication Tab , on page 2395. • Custom Method List—Uses the authentication methods specified in the Prioritized Method List field. **Note** If you select local authentication, preview the full configuration before deployment to make sure that the **aaa new-model** command is not configured by another policy (for example, by configuring a method list in the AAA policy) or is already configured on the device itself.
Prioritized Method List	Applies only when Custom Method List is selected as the authentication method. Defines a sequential list of methods to be queried when authenticating a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authenticate users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.

VTY Line Dialog Box—Authorization Tab

Use the Authorization tab of the VTY Line dialog box to define the EXEC and command authorization methods to perform on users who access the selected VTY line or group of lines.

Note You must enable AAA services on the router to use this feature; otherwise, deployment will fail. See Defining AAA Services , on page 2392.

Navigation Path

Go to the VTY Line Dialog Box , on page 2440, then click the **Authorization** tab.

Field Reference

Table 879: VTY Line Dialog Box—Authorization Tab

Element	Description
EXEC Authorization settings	
Authorize EXEC Operations Using	The authorization method that determines whether a user is allowed to run an EXEC session: • None—Authorization is not performed. This is the default. • AAA Policy Default List—Uses the default authorization method list that is defined in the device's AAA policy. See AAA Page—Authorization Tab , on page 2396. • Custom Method List—Uses the authorization methods specified in the Prioritized Method List field.
Prioritized Method List	Applies only when Custom Method List is selected as the EXEC method. Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list. **Note** RADIUS uses the same server for authentication and authorization. Therefore, if you use define a RADIUS method list for authentication, you must define the same method list for authorization.
Command Authorization settings	
Privilege Level	The privilege level to which the command authorization definition applies.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Authorization Dialog Box—Line Access , on page 2450. From here you can configure a command authorization definition.

Element	Description
Edit button	Opens the Command Authorization Dialog Box—Line Access , on page 2450. From here you can edit the command authorization definition.
Delete button	Deletes the selected command authorization definitions from the table.

VTY Line Dialog Box—Accounting Tab

Use the Accounting tab of the VTY Line dialog box to define the EXEC, connection, and command accounting methods to perform on users who access the selected VTY line or group of lines.

Note You must enable AAA services on the router to use this feature; otherwise, deployment will fail. See Defining AAA Services , on page 2392.

Navigation Path

Go to the VTY Line Dialog Box , on page 2440, then click the **Accounting** tab.

Field Reference

Table 880: VTY Line Dialog Box—Accounting Tab

Element	Description
EXEC Accounting settings	

Element	Description
Perform EXEC Accounting Using	The accounting method to use for recording basic information about user EXEC sessions: • None—Accounting is not performed. This is the default. • AAA Policy Default List—Uses the default EXEC accounting method list that is defined in the device's AAA policy. See AAA Page—Accounting Tab , on page 2398. • Custom Method List—Uses the accounting methods specified in the Prioritized Method List field. EXEC accounting records basic details about EXEC sessions, such as the username, date, start and stop times, and the access server IP address.
Generate Accounting Records for	Applies only when Custom Method List is selected as the EXEC method. Defines when the device sends an accounting notice to the accounting server: • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the "start" accounting record. This is the default. • Stop Only—Generates an accounting record at the end of the user process only. • None—No accounting records are generated.
Prioritized Method List	Applies only when Custom Method List is selected as the EXEC method. Defines a sequential list of methods to be queried when creating accounting methods for a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.
Enable Broadcast to Multiple Servers	Applies only when Method List is selected as the EXEC method. When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group. When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.
Connection Accounting settings	

Element	Description
Perform Connection Accounting Using	The accounting method to use for recording information about outbound connections made over the VTY line: • None—Accounting is not performed. This is the default. • AAA Policy Default List—Uses the default connection accounting method list that is defined in the device's AAA policy. See AAA Page—Accounting Tab , on page 2398. • Custom Method List—Uses the accounting methods specified in the Prioritized Method List field. Connection accounting records details about outgoing connections over the line, such as Telnet and rlogin connections.
Generate Accounting Records for	Applies only when Custom Method List is selected as the connection method. Defines when the device sends an accounting notice to the accounting server: • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the "start" accounting record. This is the default. • Stop Only—Generates an accounting record at the end of the user process only. • None—No accounting records are generated.
Prioritized Method List	Applies only when Custom Method List is selected as the connection method. Defines a sequential list of methods to be queried when creating accounting methods for a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.
Enable Broadcast to Multiple Servers	Applies only when Custom Method List is selected as the connection method. When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group. When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.
Command Accounting settings	

Element	Description
Privilege Level	The privilege level to which the command authorization definition applies.
Generate Accounting Records for	The points in the process where the device sends an accounting notice to the accounting server.
Enable Broadcast	Whether accounting records are broadcast to multiple servers simultaneously.
Prioritized Method List	The method list to use when authorizing users with this privilege level.
Add button	Opens the Command Accounting Dialog Box—Line Access , on page 2451. From here you can configure a command accounting definition.
Edit button	Opens the Command Accounting Dialog Box—Line Access , on page 2451. From here you can edit the command accounting definition.
Delete button	Deletes the selected command accounting definitions from the table.

Command Authorization Dialog Box—Line Access

Use the Command Authorization dialog box to define which methods to use when authorizing the EXEC commands that are associated with a given privilege. This enables you to authorize all commands associated with a specific privilege level, from 0 to 15.

Navigation Path

From the Console Page—Authorization Tab , on page 2434 or the VTY Line Dialog Box—Authorization Tab , on page 2445, click the **Add** button beneath the Command Authorization table.

Related Topics

- Console Policy Page , on page 2431
- VTY Policy Page , on page 2439

Field Reference

Table 881: Command Authorization Dialog Box—Line Access

Element	Description
Privilege Level	The privilege level for which you want to define a command authorization list. Valid values range from 0 to 15. **Note** If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.
AAA Policy Default List	Select this option to apply the default authorization list defined in the device's AAA policy to the EXEC commands associated with this privilege level. See Command Accounting Dialog Box , on page 2401.
Custom Method List	Select this option to define an authorization method list for this privilege level.

Element	Description
Prioritized Method List	Applies only when the Custom Method List option is selected. Defines a sequential list of methods to be queried when authorizing a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to authorize users using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.

Command Accounting Dialog Box—Line Access

Use the Command Accounting dialog box to define which methods to use when recording information about the EXEC commands that are executed for a given privilege. Each accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the name of the user who executed it.

Navigation Path

From the Console Page—Accounting Tab , on page 2436 or the VTY Line Dialog Box—Accounting Tab , on page 2447, click the **Add** button beneath the Command Accounting table.

Related Topics

Field Reference

Table 882: Command Accounting Dialog Box—Line Access

Element	Description
Privilege Level	The privilege level for which you want to define a command accounting list. Valid values range from 0 to 15. **Note** If you do not define a value, level 1 is assigned by default. This value does not appear in the device configuration.
AAA Policy Default List	Select this option to apply the default accounting list defined in the device's AAA policy to the EXEC commands executed for this privilege level.
Custom Method List	Select this option to define an accounting method list for this privilege level.

Element	Description
Generate Accounting Records for	Applies only when Custom Method List is selected. Defines when the device sends an accounting notice to the accounting server: • Start and Stop—Generates accounting records at the beginning and the end of the user process. The user process begins regardless of whether the accounting server receives the "start" accounting record. This is the default. • Stop Only—Generates an accounting record at the end of the user process only. • None—No accounting records are generated.
Prioritized Method List	Applies only when the Custom Method List option is selected. Defines a sequential list of accounting methods to be used when creating accounting records for a user. Enter the names of one or more AAA server group objects (up to four), or click **Select** to select them. Use the up and down arrows in the object selector to define the order in which the selected server groups should be used. If the object that you want is not listed, click the **Create** button to create it. The device tries initially to perform accounting using the first method in the list. If that method fails to respond, the device tries the next method, and so on, until a response is received. **Note** If you select None as a method, it must appear as the last method in the list.
Enable Broadcast to Multiple Servers	Applies only when Custom Method List is selected. When selected, enables the sending of accounting records to multiple AAA servers. Accounting records are sent simultaneously to the first server in each AAA server group defined in the method list. If the first server is unavailable, failover occurs using the backup servers defined within that group. When deselected, accounting records are sent only to the first server in the first AAA server group defined in the method list.

Optional SSH Settings on Cisco IOS Routers

Secure Shell (SSH) is an application and a protocol that uses encryption to provide secure communication between a client and server. You can use SSH to connect remotely to a Cisco IOS router over a VTY line and establish an EXEC session. SSH is the recommended replacement for other protocols, such as Telnet and rlogin, in environments where security is a concern.

All Cisco IOS routers are required to have SSH configured before they can be added to Security Manager. This is because Security Manager uses SSH (in addition to SSL) to communicate with them. The SSH policy provides a way to modify selected default settings and configure selected optional settings.

Related Topics

• Defining Optional SSH Settings , on page 2453
• Understanding Device Communication Requirements , on page 57

- Setting Up SSH , on page 62

Defining Optional SSH Settings

SSH is configured by default with the following settings:

- Both SSH version 1 and SSH version 2 are supported.
- The negotiation phase is terminated if not completed successfully after 120 seconds.
- The router tries 3 times to authenticate SSH clients before disconnecting.

You can use Security Manager to modify these default settings and optionally configure the following settings:

- The source interface for SSH packets.
- The name of the RSA key pair to use.
- Whether to regenerate the key during the next deployment.

Before You Begin

- Make sure that SSH is enabled on the router. See Understanding Device Communication Requirements , on page 57.
- Make sure that the VTY lines on the router allow inbound SSH traffic. See Defining VTY Line Setup Parameters , on page 2427.
- Make sure that a hostname and domain name are configured on the router (unless you plan to use a different RSA key pair). You can use the CLI or the Hostname policy in Security Manager for this purpose. See Hostnames and Domain Names on Cisco IOS Routers , on page 2467.

Related Topics

- Optional SSH Settings on Cisco IOS Routers , on page 2452
- Setting Up SSH , on page 62

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > Secure Shell** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Secure Shell** from the Policy Type selector. Select an existing policy or create a new one.

The Secure Shell page is displayed. See Secure Shell Policy Page , on page 2454 for a description of the fields on this page.

Step 2 (Optional) Modify the following default settings:

a) The version of SSH to support.
b) The timeout for completing the negotiation phase of the SSH connection.
c) The number of times to attempt authentication of the SSH client.

Step 3 (Optional) In the Source Interface field, enter the name of the interface or interface role whose address should be used as the source interface for all SSH packets sent to SSH clients, or click **Select** to select an interface role object from a list or to create a new one. The source interface must have an IP address.

If you do not enter a value in this field, the address of the closest interface to the destination is used.

Step 4 (Optional) Enter the name of the RSA key pair to use for SSH connections. If you do not enter a value in this field, the router uses the key pair that is based on the hostname and domain name.

Tip Use the CLI command show crypto key mypubkey rsa to display the names and values of each key pair configured on the device.

Step 5 (Optional) Select the **Regenerate Key During Deployment** check box if you want the router to regenerate the RSA key pair used for SSH. This option is useful if you believe that the secrecy of the keys might be compromised. Enter the size of the modulus to use to regenerate the keys.

Note You must remember to return to this policy after deployment to deselect the check box. If you do not do this, a new key is generated during each deployment.

Note This option requires interaction with the device during deployment. Therefore, you should use it only when deploying to live devices, not when deploying to a file.

Note A key pair must already exist on the device *before* you select this option; otherwise, deployment will fail. (This will typically be the case, since IOS routers must have SSH enabled to be added to Security Manager.)

Secure Shell Policy Page

Use the Secure Shell page to change the default SSH settings on the router and to define additional optional settings, if required.

For more information, see Optional SSH Settings on Cisco IOS Routers , on page 2452.

Note You must configure SSH on the device using CLI commands before adding the device to Security Manager. This is because Security Manager uses SSH (as well as SSL) to communicate with Cisco IOS routers. For more information, see Setting Up SSH , on page 62.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > Secure Shell** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > Secure Shell** from the Policy Type selector. Right-click **Secure Shell** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Understanding Device Communication Requirements , on page 57

- Console Policy Page , on page 2431

Field Reference

Table 883: Secure Shell Page

Element	Description
SSH Version	The version of SSH to use when connecting to the router: • 1 and 2—SSH version 1 and SSH version 2. This is the default. • 1—SSH version 1 only. • 2—SSH version 2 only.
Timeout	The amount of time the router should wait for the SSH client to respond during the negotiation phase before disconnecting. The default value (and the maximum) is 120 seconds. **Note** After negotiation finishes and the EXEC session begins, the timeout configured for the VTY line applies. See VTY Line Dialog Box—Setup Tab , on page 2441.
Authentication Retries	The number of times the router attempts to authenticate SSH clients. Valid values range from 0 to 5. The default is 3.
Source Interface	The source address for all SSH packets sent to the SSH client. If you do not define a value in this field, the address of the closest interface to the destination (that is, the output interface through which SSH packets are sent) is used. Enter the name of an interface or interface role, or click **Select** to select the object from a list or to create a new one.
RSA Key Pair	The name of the RSA key pair to use for SSH connections. If you do not enter a value, the router uses the RSA key pair generated from its hostname and domain name. This is the default. **Tip** Use the CLI command **show crypto key mypubkey rsa** to display the names and values of each key pair configured on the device. These are the valid names that can be entered in this field.

Element	Description
Regenerate Key During Deployment	When selected, regenerates the RSA key pair on the router during the next deployment. This option is useful if you are concerned that the secrecy of the keys might be compromised. When deselected, a new key pair is not generated. **Note** This check box is *not* deselected automatically after deployment. If you do not return to this policy to deselect the check box, the key is regenerated each time you deploy. **Note** This option requires interaction with the device during deployment. Therefore, you should use it only when deploying to live devices, not when deploying to a file. **Note** A key pair must already exist on the device *before* you select this option; otherwise, deployment will fail. (This will typically be the case, since IOS routers must have SSH enabled in order to be added to Security Manager.)
Modulus Size	Applies only when the Regenerate Key check box is selected. The size of the modulus used to generate a new key pair. A larger modulus is more secure but takes longer to generate. Valid values range from 360 to 2048 bits. The default is 1024 bits.

SNMP on Cisco IOS Routers

Simple Network Management Protocol (SNMP) defines a standard way for network management stations or workstations to monitor the health and status of many types of devices, including switches, routers, and firewall devices. It comprises a protocol, a database-structure specification, and a set of management data objects. Each SNMP device or member is part of a *community* , which determines the access that each device has (read-only or read-write).

SNMP obtains information from the managed device through a Management Information Base (MIB). The MIB is a database of code blocks called MIB objects, each of which controls one specific function. The MIB object comprises MIB variables, which define the MIB object name, description, default value, and so forth. MIB objects are structured hierarchically in a MIB tree.

SNMP policies enable you to configure the behavior of the SNMP agent running on the router. The agent sends unsolicited information back to the SNMP host as events occur. These unsolicited messages, which are generated in response to significant, predetermined events on the router, are called traps.

The following topics describe the tasks you perform to create SNMP policies on Cisco IOS routers:

- Defining SNMP Agent Properties , on page 2456
- Enabling SNMP Traps , on page 2458

Defining SNMP Agent Properties

When you define the properties of the SNMP agent, you must define the community string and community string type, as well as the address and properties of the SNMP host that receives the traps.

SNMP community strings are embedded passwords to MIBs, which store data about the router's operation and are meant to be available to authenticated remote users. Two types of community strings exist: "public" community strings, which provide read-only access to all objects in the MIB (except community strings themselves), and "private" community strings, which provide read-write access to all objects in the MIB (except community strings).

SNMP hosts receive the traps generated by the router. You must define the address, password, and port number for accessing the SNMP host, as well as the SNMP version being used. Security Manager supports SNMP version 1, version 2c (also called "community-based SNMP") and version 3, which offers authentication and encryption.

Related Topics

- SNMP on Cisco IOS Routers , on page 2456

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Device Access > SNMP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > SNMP** from the Policy Type selector. Select an existing policy or create a new one.

The SNMP page is displayed. See Table 884: SNMP Page , on page 2459 for a description of the fields on this page.

Step 2 Define the community string needed to access the MIB:

a) Under Permissions, click **Add** to display the Permission dialog box.
b) Define the string. See Table 885: Permission Dialog Box , on page 2460 for a description of the available fields.
c) Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Permissions table.

Note A warning is displayed if you attempt to edit or delete a community string that is in use by an SNMP host. If you continue with the operation, the device creates a private, read-only string that matches the definition for the host in the Trap Receiver table.

Step 3 Define the SNMP host that receives the traps generated by the SNMP agent:

a) Under Trap Receiver, click **Add** to display the Trap Receiver dialog box.
b) Define the host. See Trap Receiver Dialog Box , on page 2461 for a description of the available fields.
c) Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Trap Receiver table.

Step 4 Under SNMP Server Properties, enter the location and contact information for the administrator responsible for routers configured with this SNMP policy.

This definition, which is text-only and does not affect the operation of the router, provides useful information to the manager of the SNMP host when the manager investigates a particular trap.

Step 5 Click **Configure Traps** to display the SNMP Traps dialog box, which is used to select which traps to enable on the router. For more information, see Enabling SNMP Traps , on page 2458.

Enabling SNMP Traps

The router immediately sends notifications, also called SNMP traps, to the designated SNMP host (management station) when a defined condition occurs, such as a link up, link down, or a syslog event.

To enable SNMP traps, select the check box next to each relevant trap. Certain check boxes activate multiple, related traps.

Note Each trap that you enable consumes system resources. To lessen the impact on system performance, select only those traps that you need for network monitoring.

Related Topics

- SNMP on Cisco IOS Routers , on page 2456

Step 1 Open the SNMP page for defining SNMP server policies on Cisco IOS routers, as described in Defining SNMP Agent Properties , on page 2456.

Step 2 On the SNMP page, click **Configure Traps**. The SNMP Traps dialog box is displayed.

Step 3 Select the check box next to each type of trap to enable. The traps are divided into the following four categories:

- Standard SNMP traps (for example, Authentication, Cold Start, and Warm Start).
- ISAKMP traps (related to Phase 1 of the IPsec process).
- IPsec traps (related to Phase 2 of the IPsec process).
- Other traps (includes syslog messages, protocol-related notifications, and CPU usage warnings).

See Table 887: SNMP Traps Dialog Box , on page 2463 for a description of the available traps.

Note You must add command-line interface (CLI) commands to fully implement the IP multicast and CPU traps. One method available for entering these commands is by using FlexConfigs. See Understanding FlexConfig Policies and Policy Objects , on page 342.

Tip Click **Select All** to enable all traps displayed in the dialog box or **Deselect All** to disable all the traps.

Step 4 Click **OK** to save your definitions locally on the client and close the dialog box.

Tip To configure SNMP traps not included in this dialog box, define a FlexConfig.

SNMP Policy Page

Use the SNMP page to configure the parameters necessary to send traps from the router to a designated SNMP host. These traps are unsolicited messages that notify the SNMP host of important events occurring on the router.

For more information, see Defining SNMP Agent Properties , on page 2456.

Navigation Path

- (Device view) Select **Platform > Device Admin > Device Access > SNMP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Device Access > SNMP** from the Policy Type selector. Right-click **SNMP** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 884: SNMP Page

Element	Description
Permissions table	
Community String	The community string used for accessing the router's MIB.
Type	The community string type—read-only or read-write.
ACL	The standard ACL that defines the IP addresses permitted to access the router's MIB.
Add button	Opens the Permission Dialog Box , on page 2460. From here you can enter the community string and type required to generate traps.
Edit button	Opens the Permission Dialog Box , on page 2460. From here you can edit the selected permissions profile.
Delete button	Deletes the selected permissions profiles from the table.
Trap Receiver table	
Host IP Address	The IP address of the SNMP host receiving the traps generated by the router.
SNMP Version	The SNMP version being used by the router.
UDP Port	The UDP port that is being used by the SNMP host.
Add button	Opens the Trap Receiver Dialog Box , on page 2461. From here you can define the SNMP host that receives the traps generated by the router.
Edit button	Open the Trap Receiver Dialog Box , on page 2461. From here you can edit the selected SNMP host.
Delete button	Deletes the selected SNMP hosts from the table.
Additional fields and buttons	

Element	Description
SNMP Server Properties	The name and contact information of the system administrator responsible for the SNMP server/agent (that is, the router). The person managing the SNMP host can use this information when tracking down the source of unusual events. The maximum length of each of these properties is 255 characters, including spaces. **Note** The values entered in these fields are text-only and do not affect the operation of the router.
Configure Traps button	Opens a dialog box for selecting which SNMP traps the router should generate. See SNMP Traps Dialog Box , on page 2462.

Permission Dialog Box

Use the Permission dialog box to define the community string and string type required by the SNMP policy. The community string is an embedded password for accessing the Management Information Base (MIB) that stores operational data about the router.

Navigation Path

Go to SNMP Policy Page , on page 2458, then click the **Add** or **Edit** button beneath the Permissions table.

Related Topics

Field Reference

Table 885: Permission Dialog Box

Element	Description
Community String	The community string for accessing the router's MIB. String length ranges from 1 to 128 characters.
Access Control Lists	Applies only to routers running Cisco IOS Software Release 12.3(2)T and up (T-train) or any 12.4 version. The standard ACL containing the IP addresses that can access the router's MIB. Defining an ACL provides an additional layer of security by limiting the source addresses that can make use of the community string. Enter the name of a standard ACL object, or click **Select** to select the object from a list or to create a new one.

Element	Description
Read-Write	This community string type provides read-write access to all objects in the MIB (except community strings).
Read-Only	This community string type provides read-only access to all objects in the MIB (except community strings). This is the default.

Trap Receiver Dialog Box

Use the Trap Receiver dialog box to define the SNMP hosts that receive traps generated by the router. This includes defining the version of SNMP to use.

Navigation Path

Go to the SNMP Policy Page , on page 2458, then click the **Add** or **Edit** button beneath the Trap Receiver table.

Related Topics

- SNMP Policy Page , on page 2458

- SNMP Traps Dialog Box , on page 2462
- Defining SNMP Agent Properties , on page 2456
- SNMP on Cisco IOS Routers , on page 2456

Field Reference

Table 886: Trap Receiver Dialog Box

Element	Description
Host IP Address	The IP address of the SNMP host receiving the traps generated by the router. Enter an IP address or the name of a network/host object, or click **Select** to select the object from a list or to create a new one.
SNMP Version	The version of SNMP to use—version 1, version 2c, or version 3.
Community String	Applies only when version 1 or version 2c is selected. The password required to access the SNMP host. Enter the string again in the Confirm field. **Note** We recommend that you use one of the strings defined in the Permissions table as the password to the SNMP host. You may, however, enter a different password. String length ranges from 1 to 128 characters. Your entry does not appear in the Permissions table and is read-only.

Element	Description
User Name	Applies only when version 3 is selected. The password required to access the SNMP host. Enter the string again in the Confirm field. **Note** We recommend that you use one of the strings defined in the Permissions table as the password to the SNMP host. You may, however, enter a different password. String length ranges from 1 to 128 characters. Your entry does not appear in the Permissions table and is read-only.
SNMPv3 Security	Applies only when version 3 is selected. The level of security to apply to SNMP traffic: • No MD5, No DES—No packet authentication. • MD5 (auth)—MD5 authentication, but no encryption. • DES (priv)—MD5 authentication and DES encryption.
UDP Port	The port number for the SNMP host. The default is 162. Valid values range from 0 to 65535.

SNMP Traps Dialog Box

Use the SNMP Traps dialog box to select the events in the router that should generate SNMP traps. To lessen possible degradation of system performance, select only those traps that are needed for network monitoring purposes.

Tip You can configure SNMP traps not included in this dialog box by defining FlexConfigs. For more information, see Understanding FlexConfig Policies and Policy Objects , on page 342.

Navigation Path

Go to the SNMP Policy Page , on page 2458, then click **Configure Traps**.

Field Reference

Table 887: SNMP Traps Dialog Box

Element	Description
Standard SNMP Traps	Enables or disables standard SNMP traps. Options are: • Cold start—Sends a trap when the router reinitializes in a way that could change the configuration of the SNMP agent (or any other trap-receiving entity). • Warm start—Sends a trap when the router reinitializes in a way that does not change the configuration of the SNMP agent (or any other trap-receiving entity). • Authentication—Sends a trap if an SNMP request from the SNMP host fails because of an invalid community string.
IPsec Traps	Enables or disables individual IPsec-related traps. Options are: • Cryptomap—Sends a trap when a crypto map entry is added to, or removed from, the device's crypto map set. Additionally, this option sends a trap when a crypto map set is attached to, or detached from, an active interface. • Too Many SAs—Sends a trap if an attempt is made to create a security association (SA) when there is insufficient memory on the device. • Tunnel—Sends a trap when an IPsec Phase 2 tunnel becomes active or inactive. For more information, see Understanding IPsec Proposals for Site-to-Site VPNs , on page 1168.
ISAKMP Traps	Enables or disables individual Internet Security Association and Key Exchange Protocol (ISAKMP) traps. Options are: • Policy—Sends a trap when an ISAKMP policy is created or deleted. • Tunnel—Sends a trap when a Phase 1 IKE tunnel becomes active or inactive. For more information, see Understanding IKE , on page 1153.

Element	Description
Other Traps	Enables or disables additional SNMP traps. Options are: • Syslog—Sends syslog messages to the SNMP host. • TTY—Sends Cisco-specific notifications when a Transmission Control Protocol (TCP) connection closes. • BGP—Sends notifications when Border Gateway Protocol (BGP) state changes occur. See BGP Routing on Cisco IOS Routers , on page 2565. • IP Multicast—(Applicable to multicast routers only) Sends a trap if the router fails to receive a defined number of heartbeat packets from heartbeat sources within a defined time interval. If you select IP Multicast, you must also manually configure the **ip multicast heartbeat** command on the device to configure the multicast address and heartbeat limits. You can use FlexConfigs to do this. • CPU—Sends a trap when CPU usage rises and remains above an upper threshold or falls and remains below a lower threshold. If you select CPU, you must also manually configure the **process cpu threshold type** command on the device to configure the thresholds. You can use FlexConfigs to do this. • HSRP—Sends Hot Standby Routing Protocol (HSRP) notifications.
Select All button	Enables all the SNMP traps displayed in the dialog box.
Deselect All button	Disables all the SNMP traps displayed in the dialog box.

DNS on Cisco IOS Routers

The Domain Name System (DNS) is a distributed database in which you can map hostnames to IP addresses through the DNS protocol from a DNS server. Each unique IP address can have an associated hostname. DNS is what makes it possible to connect to hosts without having to know the 32-bit IP address of that host. The DNS server takes the provided hostname and translates it into the appropriate IP address.

In addition to the translation provided by remote DNS servers, you can configure Cisco IOS routers with a local host table containing static mappings of hosts to IP addresses. When commands such as connect, telnet, and ping are used, the router checks this host table before querying the DNS servers, which speeds the translation process.

By default, the DNS feature is enabled on all Cisco IOS routers.

Related Topics

- Defining DNS Policies , on page 2465

Defining DNS Policies

When you define a DNS policy in Security Manager, you can specify the remote DNS servers used by the router for hostname-to-address translations. In addition, you can define a static host table that contains local translations used exclusively by this device. Having selected addresses in this type of cache can speed the translation process by eliminating the need to query the DNS servers.

Related Topics

- DNS on Cisco IOS Routers , on page 2464

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > DNS** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > DNS** from the Policy Type selector. Select an existing policy or create a new one.

The DNS page is displayed. See Table 888: DNS Page , on page 2466 for a description of the fields on this page.

Step 2 In the Servers field, enter the addresses of the DNS servers (up to 6) that can perform hostname-to-address translations for the router. You can use a combination of addresses and network/host objects, or click **Select** to display a selector. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Tip If the network you want is not listed in the selector, click the **Create** button or the **Edit** button in the selector to display the Add or Edit Network/Host Dialog Box , on page 314. From here you can create a network/host object to use in the policy.

Step 3 (Optional) In the Hosts field, enter the static host mappings that you want to define in the router's host table:

a) Click **Add** to display the IP Host Dialog Box , on page 2466.
b) Enter the hostname to translate.
c) Enter up to three addresses or network/host objects, or click **Select** to display a selector. These are the addresses to which the router translates the hostname.
d) Click **OK**. The mapping is displayed in the Hosts field on the DNS page.
e) Repeat 3.a, on page 2465 through 3.d, on page 2465 to add more hosts to the host table.

Note To edit a host mapping, select the definition from the Hosts field, then click **Edit**. To remove a host mapping, select it, then click **Delete**.

Step 4 (Optional) Deselect the **Domain Lookup** check box to disable DNS functionality on the router.

DNS Policy Page

Use the DNS policy page to define the local IP host table and the Domain Name System (DNS) servers that the router should use for translating hostnames to IP addresses. You can also prevent the router from performing DNS lookups by disabling the DNS feature.

Navigation Path

- (Device view) Select **Platform > Device Admin > DNS** from the Policy selector.

- (Policy view) Select **Router Platform > Device Admin > DNS** from the Policy Type selector. Right-click **DNS** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- DNS on Cisco IOS Routers , on page 2464

Field Reference

Table 888: DNS Page

Element	Description
Servers	The DNS servers used by the router to perform DNS lookups. Enter one or more addresses or network/host objects, or click **Select** to select an object from a list or to create a new one. You can define a maximum of six DNS servers.
Hosts	The local host table configured on the router. When a user types in a hostname, the router checks this table first before querying the DNS servers defined in the Servers field. Click **Add** to display the IP Host Dialog Box , on page 2466. From here you can define a hostname and the IP addresses to associate with that hostname. **Note** To edit an entry in the host table, select it, then click **Edit**. To remove an entry, select it, then click **Delete**.
Domain Lookup	When selected, the router performs lookups on the defined DNS servers. This is the default. When deselected, lookups on remote DNS servers are disabled.

IP Host Dialog Box

Use the IP Host dialog box to configure the host table on the router. This is the table of static, local mappings that the router uses to translate hostnames to IP addresses. If the router does not find the required entry in the host table, it queries the DNS servers that are defined on the DNS page.

Navigation Path

Go to the DNS Policy Page , on page 2465, then click **Add** under Hosts.

Related Topics

- DNS on Cisco IOS Routers , on page 2464

Field Reference

Table 889: IP Host Dialog Box

Element	Description
Host Name	The hostname to include in the router's local host table.

Element	Description
Addresses	The addresses to associate with the hostname. Enter one or more addresses or network/host objects, or click **Select** to select an object from a list or to create a new object. You can define a maximum of three addresses per hostname.

Hostnames and Domain Names on Cisco IOS Routers

The Hostname policy configures the hostname and domain name of the selected router. After you deploy this policy, any changes that you made to the hostname and domain name are reflected in the Device Properties page (see Viewing or Changing Device Properties , on page 109).

Related Topics

- Defining Hostname Policies , on page 2467

Defining Hostname Policies

When you define a hostname policy, Security Manager updates the hostname and domain name fields in the Device Properties dialog box after deployment. See Viewing or Changing Device Properties , on page 109.

Related Topics

- Hostnames and Domain Names on Cisco IOS Routers , on page 2467

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Device Admin** > **Hostname** from the Policy selector.
- (Policy view) Select **Router Platform** > **Device Admin** > **Hostname** from the Policy Type selector. Select an existing policy or create a new one.

The Hostname page is displayed. See Table 890: Hostname Page , on page 2468 for a description of the fields on this page.

Step 2 Enter the hostname for the router. Names must start with a letter, end with a letter or digit, and include only letters, digits, and hyphens. The maximum length is 63 characters.

Step 3 Enter the domain name for the router. The router uses this domain name for RSA key generation and in policies when you do not enter the fully-qualified domain name.

Hostname Policy Page

Use the Hostname page to define the hostname and domain name assigned to the router. For more information, see Defining Hostname Policies , on page 2467.

Navigation Path

- (Device view) Select **Platform** > **Device Admin** > **Hostname** from the Policy selector.

- (Policy view) Select **Router Platform > Device Admin > Hostname** from the Policy Type selector. Right-click **Hostname** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Hostnames and Domain Names on Cisco IOS Routers , on page 2467

Field Reference

Table 890: Hostname Page

Element	Description
Host Name	The hostname of the router. Names must start with a letter, end with a letter or digit, and include only letters, digits, and hyphens. The maximum length is 63 characters.
Domain Name	The default domain name of the router. The maximum length is 63 characters. The router uses this domain name for RSA key generation and in policies when you do not enter the fully-qualified domain name (FQDN).

Memory Settings on Cisco IOS Routers

The Memory policy configures settings relating to router memory. This policy provides you with methods for monitoring memory consumption, including the ability to generate notification messages when available memory drops below predefined thresholds.

Note The Memory policy is supported on routers running Cisco IOS Software Release 12.3(14)T or later.

Related Topics

- Defining Router Memory Settings , on page 2468

Defining Router Memory Settings

You can use Security Manager to modify the following default memory settings:

- The number of hours that the router maintains the log of memory consumption.
- Whether to enable the Memory Allocation Lite feature.
- The amount of memory to reserve for critical system log messages.

In addition, you can define:

- The lower thresholds for processor and I/O memory. Log messages are sent when available memory drops below these thresholds.

- The types of sanity checks to perform.

Related Topics

- Memory Settings on Cisco IOS Routers , on page 2468
- Logging on Cisco IOS Routers , on page 2515

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Memory** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Memory** from the Policy Type selector. Select an existing policy or create a new one.

The Memory page is displayed.

Step 2 (Optional) Define the memory settings of the router, as required. See Table 891: Memory Page , on page 2470 for a description of the available fields.

Memory Policy Page

Use the Memory page to define settings related to router memory, including:

- The amount of time to retain the memory log.
- The thresholds for available processor and I/O memory.
- The amount of memory reserved for critical log messages.
- Whether to perform sanity checks on buffers and queues.
- Whether to enable the "memory-allocation lite" feature.

For more information, see Defining Router Memory Settings , on page 2468.

Navigation Path

- (Device view) Select **Platform > Device Admin > Memory** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Memory** from the Policy Type selector. Right-click **Memory** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Memory Settings on Cisco IOS Routers , on page 2468
- CPU Policy Page , on page 2415
- Syslog Logging Setup Policy Page , on page 2522
- Syslog Servers Policy Page , on page 2525

Field Reference

Table 891: Memory Page

Element	Description
Maintain Memory Log	The number of hours that the router should maintain the log containing the history of memory consumption on the device. Valid values range from 12 to 72 hours. The default is 24 (1 day). **Note** The memory log is enabled by default and cannot be disabled.
Processor Threshold	The processor memory threshold in kilobytes. When available processor memory falls below this threshold, a notification message is triggered. Valid values range from 1 to 4294967295 kilobytes (4096 gigabytes). **Note** Another notification message is generated when available free memory rises to 5% above the threshold.
I/O Threshold	The I/O memory threshold in kilobytes. When available processor memory falls below this threshold, a notification message is triggered. Valid values range from 1 to 4294967295 kilobytes (4096 gigabytes). **Note** Another notification message is generated when available free memory rises to 5% above the threshold.
Memory Allocation Lite	When selected, the "memory-allocation lite" (malloc_lite) feature on the router is enabled. This feature avoids excessive memory allocation overhead for situations where less than 128 bytes are required. This is the default. When deselected, the "memory-allocation lite" feature is disabled. **Note** This feature is supported for processor memory pools only.
Memory Region For Critical Notifications	The amount of memory (in kilobytes) reserved for critical system log messages. Valid values range from 1 to 4294967295 kilobytes (4096 gigabytes), but the value you specify cannot exceed 25% of total memory. This option reserves a region of memory on the router so that the router can issue critical system log messages even when system resources are overloaded.
Perform Sanity Checks	The types of sanity checks to perform: • Buffer—When selected, performs sanity checks on all buffers. Sanity checks are performed when a packet buffer is allocated and when the packet buffer is returned to the buffer pool. • Queue—When selected, performs sanity checks on all queues. • All—When selected, performs sanity checks on all buffers and queues. **Note** Enabling any of these options may result in a slight degradation of router performance.

Secure Device Provisioning on Cisco IOS Routers

Secure Device Provisioning (SDP) offers an integrated solution for streamlining VPN and network security deployment. SDP (previously called Easy Secure Device Deployment, or EzSDD) enables remote-site users to securely bootstrap their VPN device through an easy-to-use web interface, thereby easing the deployment burden, lowering costs, and shortening the network development cycle. For example, a telecommuter or small branch office user can remove a new device from its shipping package, plug it in, open a simple web management interface, and establish VPN connectivity, all within a period of just a few minutes.

For more information about SDP, see *Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI* , which can be found in *Cisco IOS Security Configuration Guide, Release 12.4T* .

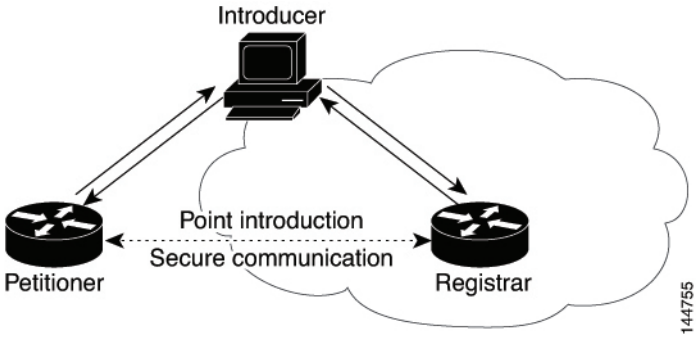
Note SDP requires Cisco IOS Software Release 12.3(8)T or later. Attempting to deploy this policy to a router running an earlier version could result in deployment failure. You also cannot configure the policy on NO-VPN router models (those that do not allow VPN configurations, such as the 3845 NOVPN).

Trusted Transitive Introduction (TTI) is the protocol that acts as the primary mechanism for implementing SDP. As shown in Figure 51: Secure Device Provisioning, on page 2471, TTI comprises the following three entities:

- Introducer—A mutually trusted device that introduces the petitioner to the registrar. Introducers can be end users who use SDP to deploy VPN devices associated with themselves to the PKI network, or an administrator/management system that uses SDP to deploy many VPN devices to the PKI network. This latter type is known as an administrative introducer. For more information, see Configuring a AAA Server Group for Administrative Introducers , on page 2474.
- Petitioner—A remote-site device that is joined to the secure domain. The petitioner serves web pages to the introducer and receives the bootstrap configuration from the introducer's web browser. The petitioner component is enabled by default on all Cisco IOS devices.
- Registrar—A server that authorizes the petitioner by communicating directly with an authentication, authorization, and accounting (AAA) server to verify user credentials, permit or deny enrollment, and retrieve user-specific configuration information.

Use the SDP policy in Security Manager to configure the router as a registrar.

Figure 51: Secure Device Provisioning



For more information about Secure Device Provisioning, see:

Contents of Bootstrap Configuration

The bootstrap configuration provided by SDP typically does the following:

- Sets the petitioner's hostname.
- Synchronizes the petitioner's system clock with the registrar.
- Sets the petitioner's trustpoint.
- Sets the petitioner's authentication and authorization mechanism.
- Pushes the CA certificate.
- Enrolls the petitioner with the PKI server.
- Sets other VPN configurations, such as the configuration required to establish a management tunnel.
- Sets Cisco Networking Services (CNS) configuration.
- Sets the petitioner's DHCP pool.

Related Topics

• Secure Device Provisioning Workflow , on page 2472
• Secure Device Provisioning on Cisco IOS Routers , on page 2471

Secure Device Provisioning Workflow

The following illustrates the steps required to use SDP to register a remote-site device in a secure network:

1. Unpack the router and connect the power, LAN, and WAN cables.
2. Turn on a computer (introducer) that is assigned an IP address from the DHCP server on the router, open a web browser, and go to the petitioner URL (http://device/ezsdd/welcome) on the router. The router responds with a registration page (also called the local login dialog box).
3. Enter the username and password, then click **OK**. On the welcome page, enter the URL for the registrar. The following actions occur:
   a. The browser opens an HTTPS-secured session to the central-site registrar, which verifies the username with the AAA server and returns the appropriate bootstrap configuration to the browser.
   b. The browser feeds the bootstrap configuration to the remote-site router, configuring PKI trustpoint enrollment and IPsec VPN connectivity, and provisioning system attributes and other information.
   c. You are notified that bootstrap configuration is complete.

Related Topics

- Contents of Bootstrap Configuration , on page 2472
- Secure Device Provisioning on Cisco IOS Routers , on page 2471

Defining Secure Device Provisioning Policies

The petitioner component is automatically enabled on all Cisco IOS routers. The SDP policy in Security Manager enables the registrar. To define an SDP policy you must define:

- The AAA server group containing the AAA server that the registrar uses to authenticate and authorize the introducer.
- The CA server to which the petitioner enrolls during the bootstrap process.
- The location of the introduction page that is displayed after authorization was performed.
- The location of the bootstrap configuration to be provided to the petitioner.

Related Topics

- Secure Device Provisioning Workflow , on page 2472
- Configuring a AAA Server Group for Administrative Introducers , on page 2474
- Secure Device Provisioning on Cisco IOS Routers , on page 2471

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Secure Device Provisioning** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Secure Device Provisioning** from the Policy Type selector. Select an existing policy or create a new one.

The Secure Device Provisioning page is displayed. See Table 892: Secure Device Provisioning Page , on page 2476 for a description of the fields on this page.

Step 2 Under Introducer Authentication, enter the name of the AAA server group containing the relevant AAA server, or click **Select** to select it from a list or to create a new object.

The selected AAA server determines whether the username and password supplied by the introducer represent an authorized user. The AAA server must use TACACS+, RADIUS, or be local.

Note Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails. If you want to configure a different AAA server group for authenticating and authorizing administrative introducers, see Configuring a AAA Server Group for Administrative Introducers , on page 2474.

Step 3 Under Petitioner Authentication, define the CA server that authenticates the identity of the petitioner by doing one of the following:

- Select **Local CA Server**, then enter the local CA name in the field provided. If you have already configured the CA server locally on the registrar, a trustpoint is generated automatically.

Note If you have not configured the router as the CA server, enter the command **Crypto pki server [name]** using the CLI or FlexConfigs. This command is mandatory when you deploy an SDP policy configured with a local CA server.

- Select Remote CA Server, then enter the name of a PKI enrollment object, or click **Select** to select it from a list or to create a new object.

The PKI enrollment object defines the external CA server used in the SDP policy.

Step 4 Select the source of the introduction page that is displayed after you log in to the registrar. The introduction page indicates whether authorization was successfully completed and contains a button for completing the process of obtaining the bootstrap configuration.

If you do not select the default welcome page, you must enter the URL required to access a different welcome page that you prepared elsewhere.

Step 5 Select the source of the bootstrap configuration provided to the petitioner to implement its first-time configuration:

- If the source of the bootstrap configuration is a non-Security Manager URL, enter the URL and also the username and password for accessing the URL, if required.
- If the source of the configuration file is a Security Manager URL:
  - Enter the name of a FlexConfig, or click **Select** to select it from a list or to create a new object. The FlexConfig contains the device commands required to retrieve the appropriate bootstrap configuration. For more information, see Add or Edit FlexConfig Dialog Box , on page 369.
  - Enter the device name formula required by the FlexConfig to derive the device name of the petitioner from the username submitted by the introducer. (The two names typically have a fixed relationship.) The default formula is $n, which uses the introducer name to determine the device name.

The device name determines which bootstrap configuration the petitioner should receive. The resulting URL contains the name of the FlexConfig you selected, as well as the parameters and formula you defined.

- Enter a username and password for accessing the Security Manager server containing the FlexConfig. The password can contain alphanumeric characters, but cannot consist of a single digit.

Configuring a AAA Server Group for Administrative Introducers

Administrative introducers are administrators or management systems that introduce many devices to the PKI network. You can configure a AAA server group for authenticating and authorizing administrative introducers by appending the following FlexConfig to the configuration of the router:

```
aaa new-model
radius-server host 1.2.3.4 auth-port 1645 acct-port 1646 key key
aaa group server radius default-radius-group2
server 1.2.3.4 auth-port 1645 acct-port 1646
exit
aaa authentication login CSM_SDP2 group default-radius-group2
crypto provisioning registrar
administrator authentication list CSM_SDP2
administrator authorization list CSM_SDP2
exit
```

This FlexConfig serves two functions—it configures the AAA server group to use and it associates this server group with the SDP crypto.

For more information about administrative introducers, see *Administrative Secure Device Provisioning Introducer* on Cisco.com at this URL:
http://www.cisco.com/en/US/docs/ios/12_3t/12_3t14/feature/guide/gtadintr.html

Related Topics

Secure Device Provisioning Policy Page

Secure Device Provisioning (SDP) policies (formerly known as Easy Secure Device Deployment or EzSDD) enable you to configure a Cisco IOS router as a *registrar* . This is the SDP component that retrieves bootstrap configurations for *petitioners* , which are remote-site devices that are enrolling in the network security infrastructure. These devices uses the bootstrap configuration for first-time configuration purposes. The registrar also verifies the identity of the *introducer* , which is the user who introduces the petitioner to the registrar.

For more information, see Defining Secure Device Provisioning Policies , on page 2473.

Navigation Path

- (Device view) Select **Platform > Device Admin > Secure Device Provisioning** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Secure Device Provisioning** from the Policy Type selector. Create a new policy or select an existing one.

Related Topics

- Secure Device Provisioning on Cisco IOS Routers , on page 2471

- Understanding AAA Server and Server Group Objects , on page 256
- Understanding FlexConfig Policies and Policy Objects , on page 342

Field Reference

Table 892: Secure Device Provisioning Page

Element	Description
Introducer Authentication (AAA)	The AAA server group that authenticates the username and password supplied by the introducer. Enter the name of a AAA server group object, or click **Select** to select it from a list or to create a new object. **Note** To configure a separate AAA server group for authenticating administrative introducers, see Configuring a AAA Server Group for Administrative Introducers , on page 2474.
Petitioner Authentication	The CA server that authenticates the identity of the petitioner: • Local CA Server—Select this option when the router itself is already configured to act as the CA server. Enter the name of the local CA in the field provided. **Note** If you have not configured the router as the CA server, enter the command **Crypto pki server [name]** using the CLI or FlexConfigs. This command is mandatory when you deploy an SDP policy configured with a local CA server. • Remote CA Server—Select this option when using an external CA server. Enter the name of a a PKI enrollment object, or click **Select** to select it from a list or to create a new object. For more information about PKI enrollment objects, see PKI Enrollment Dialog Box , on page 1208.
Introduction Page	The source of the introduction page to display to the introducer after authorization is performed: • Use default introduction page—Uses a default page provided with Security Manager. • Specify introduction page URL—Uses the introduction page specified in the URL field. Supported protocols include: FTP, HTTP, HTTPS, null, NVRAM, RCP, SCP, system, TFTP, Webflash, and XMODEM.

Element	Description
Bootstrap Configuration	The source of the bootstrap configuration to provide to the petitioner for first-time configuration: • Non-Security Manager URL—Used when the bootstrap configuration is located externally to Security Manager. Enter its location in the URL field. If required, enter a username and password to access the server containing the bootstrap configuration. • Security Manager URL—Used when Security Manager is providing the bootstrap configuration. Enter information in the following fields: • FlexConfig—The FlexConfig that contains the basic CLI structure required to create the bootstrap configuration. Enter the name of a FlexConfig object, or click **Select** to display a selector. After selecting the FlexConfig, you must enter a username and password to access the Security Manager server that contains the FlexConfig. • Device name formula—The formula required by Security Manager to determine the device name of the petitioner from the username that the introducer supplied. Typically a fixed relationship exists between the username and the device name, which enables a formula like this to be established. The default formula is $n, which uses the introducer name to determine the device name. The device name is required to determine the configuration file that the petitioner should receive. If required, enter a username and password to access the server containing the bootstrap configuration. The password can contain alphanumeric characters, but cannot consist of a single digit.

DHCP on Cisco IOS Routers

In Security Manager, certain security features, such as Easy VPN and 802.1x, require Dynamic Host Configuration Protocol (DHCP) client/server configuration. DHCP is widely used in LAN environments to dynamically assign host IP addresses from a centralized server, which significantly reduces the overhead of administering IP addresses.

DHCP servers assign and manage IP addresses from specified address pools within a router to DHCP clients. If the DHCP server cannot satisfy a DHCP request from its own database, it can forward the request to one or more secondary DHCP servers defined by the network administrator.

Security Manager enables you to configure a Cisco IOS device as a DHCP server for clients (hosts) that are connected to the device's inside interface. When you configure a DHCP server, you use IP pools (a range of IP addresses reserved for a DHCP server). The IP pools you select determine the range of IP addresses the server can use. These addresses are provided to client devices for a defined period of time called a lease. When this lease expires, the address is returned to the address pool, enabling the DHCP server to assign it to a different device.

For more information about DHCP, see:

• Understanding DHCP Database Agents , on page 2478

- Understanding DHCP Relay Agents , on page 2478
- Understanding DHCP Option 82 , on page 2479
- Understanding Secured ARP , on page 2479

To configure a DHCP policy, see:

- Defining DHCP Policies , on page 2480
- Defining DHCP Address Pools , on page 2481

Understanding DHCP Database Agents

A DHCP database agent is any external host—for example, an FTP, TFTP, or RCP server—that stores the DHCP bindings database. You can include one or more DHCP database agents in each DHCP policy, as well as configure the interval between database updates to the agent.

Note If you configure an external DHCP database agent, it is not necessary to define IP address pools, but you may do so. For more information about IP address pools, see Defining DHCP Address Pools , on page 2481.

Related Topics

- Understanding DHCP Relay Agents , on page 2478
- Understanding DHCP Option 82 , on page 2479
- Understanding Secured ARP , on page 2479
- Defining DHCP Policies , on page 2480
- DHCP on Cisco IOS Routers , on page 2477

Understanding DHCP Relay Agents

A DHCP relay agent is any host that forwards DHCP packets between clients and servers when they do not reside on the same physical subnet. Relay agents receive DHCP messages and then generate a new DHCP message to send on another interface. You can configure a reforwarding policy that determines what the DHCP relay agent should do if a forwarded message already contains relay information.

DHCP relay options in Security Manager include:

- Drop—The relay agent discards messages with existing relay information if Option 82 information is also present.
- Keep—The relay agent retains existing relay information.
- Replace—The relay agent overwrites existing information with its own relay information.

For example, you can have the DHCP relay agent replace the forwarded message with a new relay message. Additionally, you can choose whether to have the relay agent check the validity of relay information contained within forwarded BOOTREPLY messages.

Related Topics

- Understanding DHCP Database Agents , on page 2478
- Understanding DHCP Option 82 , on page 2479
- Understanding Secured ARP , on page 2479
- Defining DHCP Policies , on page 2480
- DHCP on Cisco IOS Routers , on page 2477

Understanding DHCP Option 82

DHCP option 82 enables the DHCP relay agent to include information about itself and its attached client when it forwards requests from a DHCP client to a DHCP server. The DHCP server can use this information to assign IP addresses, perform access control, and set quality of service (QoS) and security policies for each of its subscribers. When the DHCP option 82 feature is enabled, a subscriber is identified by the switch port through which it connects to the networks, instead of by its MAC address. Multiple hosts on the subscriber LAN can be connected to the same port on the access switch and are uniquely identified. Option 82 also enhances security on access switches by providing the ability to use a user's IP address to locate the port on which a user is attached.

- Understanding DHCP Relay Agents , on page 2478
- Understanding Secured ARP , on page 2479
- Defining DHCP Policies , on page 2480
- DHCP on Cisco IOS Routers , on page 2477

Understanding Secured ARP

The DHCP Secure IP Address Assignment feature (also called DHCP Authorized ARP) enables you to secure Address Resolution Protocol (ARP) table entries to DHCP leases in the DHCP database. This feature secures and synchronizes the client's MAC address to the DHCP binding, preventing unauthorized clients or hackers from spoofing the DHCP server and taking over a DHCP lease of an authorized client.

When you enable this feature and the DHCP server assigns an IP address to the DHCP client, the DHCP server adds a secure ARP entry to the ARP table with the assigned IP address and the MAC address of the client. These ARP entries cannot be updated by any other dynamic ARP packets, and they exist in the ARP table for as long as the lease is active.

Secure ARP entries can be deleted only by an explicit termination message from the DHCP client or by the DHCP server when the binding expires. To detect when a client has logged out, Secured ARP sends periodic

ARP messages to which only authorized users can respond. Unauthorized responses are blocked at the DHCP server, providing an additional level of security.

Note Secured ARP disables dynamic ARP learning on an interface.

Related Topics

- Understanding DHCP Database Agents , on page 2478
- Understanding DHCP Relay Agents , on page 2478
- Understanding DHCP Option 82 , on page 2479
- Defining DHCP Policies , on page 2480
- DHCP on Cisco IOS Routers , on page 2477

Defining DHCP Policies

When you configure a DHCP policy, you must define the IP address pools for the server to use to provide addresses to DHCP clients. In addition, you can optionally define the following:

- External DHCP database agent.
- IP ranges to exclude from DHCP.
- DHCP relay parameters.

Note When configuring DHCP on a Cisco IOS router, make sure that the router does not contain an access rule denying Bootstrap Protocol (BootP) traffic. Having such a rule blocks DHCP traffic from being transmitted.

Related Topics

- DHCP on Cisco IOS Routers , on page 2477

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Server Access > DHCP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Server Access > DHCP** from the Policy Type selector. Select an existing policy or create a new one.

The DHCP Policy page is displayed. See Table 893: DHCP Policy Page , on page 2482 for a description of the fields on this page.

Step 2 (Optional) Under Databases, click the **Add** button to display the DHCP Database Dialog Box , on page 2484. From here you can define external DHCP database agents. For more information, see Understanding DHCP Database Agents , on page 2478.

Step 3 (Optional) Under Excluded IPs, enter the IP addresses or address ranges within a DHCP address pool that should not be made available to DHCP clients. You can use a combination of addresses and network/host objects, or click **Select** to display a selector. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Tip If the network you want is not listed in the selector, click the **Create** button to display the Add or Edit Network/Host Dialog Box , on page 314. From here you can create a network/host object.

Step 4 Under IP Pools, click the **Add** button to display the IP Pool Dialog Box , on page 2485. From here you can define the address pools to be used by the DHCP server. For more information, see Defining DHCP Address Pools , on page 2481.

Step 5 (Optional) When you use a relay agent to manage requests from DHCP clients located on a different subnet from the DHCP server, define the following DHCP relay options:

a) Select the relay agent information reforwarding policy (Drop, Keep, or Replace). DHCP relay agents implement this policy when they receive messages already containing relay information.

b) Select the **Option** check box to enable the insertion of Option 82 data in requests that the relay agent forwards to the DHCP server.

c) Select the **Check** check box to validate DHCP Option 82 reply packets sent by the DHCP server.

When you enable this option, invalid messages are dropped. Valid messages are stripped of the option-82 field before they are forwarded to the DHCP client. When you disable this option, the option-82 field is removed from the packet without being checked first for validity.

See Understanding DHCP Relay Agents , on page 2478 for more information.

Defining DHCP Address Pools

When you configure a DHCP policy that does not include an external database agent, you must define at least one IP address pool. This pool contains the addresses that the DHCP server can dynamically assign to DHCP clients. Additionally, you can define the following IP pool-specific options:

- The default routers, DNS servers, WINS servers, and domain used by DHCP clients.
- Whether to use the Secured ARP feature.
- Whether to import information regarding IP pool options from a centralized DHCP server.
- The length of the lease.
- The location of the TFTP server that IP telephony devices require to use addresses from this pool.

Related Topics

- Defining DHCP Policies , on page 2480
- DHCP on Cisco IOS Routers , on page 2477

Step 1 On the DHCP page, click the **Create** button under IP Pools. The IP Pool dialog box is displayed.

Step 2 Define the address pool. See Table 895: IP Pool Dialog Box , on page 2485 for a description of the available fields.

Step 3 Click **OK** to save your definitions locally on the client and close the dialog box. The IP pool appears in the table displayed under IP Pools on the DHCP page.

Step 4 Repeat Step 1, on page 2481 through Step 3, on page 2481 to define additional address pools, if required.

Note To edit an IP pool, select it from the table, then click the **Edit** button. To delete an IP pool, select it from the table, then click the **Delete** button. You cannot delete a pool whose addresses have been assigned to DHCP clients.

DHCP Policy Page

Use the DHCP policy page to define a DHCP server policy on the selected router. This includes specifying the address pools used by the DHCP server when assigning addresses to requesting clients.

For more information, see Defining DHCP Policies , on page 2480.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > DHCP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Server Access > DHCP** from the Policy Type selector. Right-click **DHCP** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Filtering Tables , on page 50

Field Reference

Table 893: DHCP Policy Page

Element	Description
Databases Table	
Database URL	The URL of the external DHCP database agent.
Timeout	The amount of time to wait (in seconds) for a response from the external DHCP database agent before aborting a database transfer.
Write Delay	The interval (in seconds) between DHCP assignment updates sent to the external DHCP database agent.
Add button	Opens the DHCP Database Dialog Box , on page 2484. From here you can define a DHCP database agent.
Edit button	Opens the DHCP Database Dialog Box , on page 2484. From here you can edit the selected DHCP database agent.
Delete button	Deletes the selected DHCP database agents.
Excluded IPs	

Element	Description
Excluded IPs or IP Ranges	The IP addresses or address ranges to exclude from DHCP. These addresses are not assigned by the DHCP server to DHCP clients requesting addresses. Enter one or more network addresses or network/host objects, or click **Select** to select an object from a list or to create a new object. For more information, see Specifying IP Addresses During Policy Definition , on page 318.
IP Pools Table	
Name	The name of the IP pool.
Network	The IP address and subnet mask of the IP pool.
Default Router	The IP addresses of the default routers used by DHCP clients.
DNS Server	The IP addresses of the DNS servers used by DHCP clients.
NetBIOS (WINS) Server	The IP addresses of the Windows Internet Naming Service (WINS) servers used by Microsoft DHCP clients.
Domain Name	The domain name for DHCP clients.
Import All	Indicates whether the remote DHCP server imports certain DHCP options from a centralized DHCP server.
Secured ARP	Indicates whether secured ARP is enabled on this IP pool to help prevent IP spoofing by unauthorized users.
Lease	The duration of the lease for each IP address assigned by the DHCP server from this IP pool.
Option 150	The IP address of the TFTP server required by IP phones for configuration, as defined using DHCP option 150.
Option 66	The IP address of the TFTP server required by IP phones for configuration, as defined using DHCP option 66.
Add button	Opens the IP Pool Dialog Box , on page 2485. From here you can define a DHCP IP address pool.
Edit button	Opens the IP Pool Dialog Box , on page 2485. From here you can edit the selected IP pool.
Delete button	Deletes the selected IP pools.
Relay parameters	

Element	Description
Policy	The policy that DHCP relay agents implement when they receive messages already containing relay information: • Drop—The relay agent discards messages with existing relay information if option-82 information is also present. • Keep—The relay agent retains existing relay information. • Replace—The relay agent overwrites existing information with its own relay information.
Option	When selected, enables DHCP Option 82 data insertion in message requests forwarded from the DHCP client to the server. DHCP Option 82 provides the DHCP server with both the switch and port ID of the requesting client. This option makes it possible to locate where a user is physically connected to the network and prevent spoofing. See Understanding DHCP Relay Agents , on page 2478. When deselected, DHCP Option 82 is disabled.
Check	When selected, DHCP Option 82 reply packets received from the DHCP server are validated. Invalid messages are dropped; valid messages are stripped of the option-82 field before being forwarded to the DHCP client. When deselected, the option-82 field is removed from the packet without being checked first for validity.

DHCP Database Dialog Box

Use the DHCP Database dialog box to define external DHCP database agents that contain the automatic bindings. Each database URL that you define must be unique.

For more information, see Understanding DHCP Database Agents , on page 2478.

Navigation Path

Go to the DHCP Policy Page , on page 2482, then click the **Add** or **Edit** button beneath the Databases table.

Related Topics

- Defining DHCP Policies , on page 2480
- DHCP on Cisco IOS Routers , on page 2477
- IP Pool Dialog Box , on page 2485

Field Reference

Table 894: DHCP Database Dialog Box

Element	Description
Database URL	The URL of the external DHCP database agent containing the automatic bindings. The URL can be in HTTP, FTP, TFTP, or RCP format. **Note** If you define a URL, it is not necessary to define an IP address pool. However, you may do so.
Timeout	The amount of time (in seconds) the DHCP server should wait for a response from the external DHCP database agent before aborting a database transfer. The default is 300 seconds (5 minutes). **Note** A value of 0 disables the timeout.
Write Delay	The interval (in seconds) between updates sent from the DHCP server to the external DHCP database agent. The minimum delay is 60 seconds. The default is 300 seconds (5 minutes).

IP Pool Dialog Box

Use the IP Pool dialog box to define one or more address pools, which the DHCP server uses to assign dynamic addresses to DHCP clients. You must define at least one address pool, unless you have defined an external DHCP database agent.

Navigation Path

Go to the DHCP Policy Page , on page 2482, then click the **Add** or **Edit** button beneath the IP Pools table.

Related Topics

Field Reference

Table 895: IP Pool Dialog Box

Element	Description
Pool Name	The name of the IP pool.

Element	Description
Network	The IP address and subnet mask of the IP pool. This subnet contains the range of available IP addresses that the DHCP server may assign to clients. Enter an address and mask or the name of a network/host object, or click **Select** to select an object from a list or to create a new one. **Tip** You can exclude specific addresses within the range by defining them in the Excluded IPs field. See DHCP Policy Page , on page 2482.
Default Router Addresses	The IP addresses of the default routers for DHCP clients using this IP pool. After a DHCP client is booted, it begins sending packets to this router, which should be located on the same subnet as the client. Enter up to eight (8) network addresses or network/host objects, or click **Select** to select an object from a list or to create a new one.
DNS Server Addresses	The IP addresses of the DNS servers that DHCP clients using this IP pool should query when they need to correlate hostnames to IP addresses. Enter up to eight (8) network addresses or network/host objects, or click **Select** to select an object from a list or to create a new one.
NetBIOS (WINS) Server Addresses	The IP addresses of the Windows Internet Naming Service (WINS) servers used by Microsoft DHCP clients to correlate hostnames to IP addresses within a general grouping of networks. Enter up to eight (8) network addresses or network/host objects, or click **Select** to select an object from a list or to create a new one.
Domain Name	The domain name for DHCP clients using this IP pool. This name places these clients in the general grouping of networks that make up the domain.
Import All	When selected, enables remote DHCP servers to import specific DHCP options (such as the DNS server) from a centralized server. Use this option to enable configuration information to be updated automatically. When deselected, all DHCP options are local to this specific server.
Secured ARP	When selected, enables the DHCP Authorized ARP feature, which limits the leasing of IP addresses to authorized mobile users. This feature helps prevent IP spoofing by unauthorized users. See Understanding Secured ARP , on page 2479. When deselected, the DHCP Authorized ARP feature is disabled. **Note** This feature also disables dynamic ARP learning on an interface.
Lease Never Expires	When selected, the DHCP server permanently assigns IP addresses to its clients. When deselected, addresses are leased for a predefined amount of time, as defined in the Time Length field.
Time Length (DD:HH:MM)	Applies only when the Lease Never Expires check box is deselected. The duration of the lease provided to each IP address assigned from this IP pool (using the format DD:HH:MM). After the lease expires, the assigned IP address is no longer valid and is returned to the pool.

Element	Description
Option 66 (IP Addresses)	The IP address of the TFTP server used to provide configuration files to IP phones. These configuration files define parameters required by IP phones to connect to Cisco CallManager. Enter up to eight (8) network addresses or network/host objects, or click **Select** to select an object from a list or to create a new one. **Note** This option is functionally similar to option 150. Either or both options may be used.
Option 150 (IP Addresses)	The IP address of the TFTP server used to provide configuration files to IP phones. These configuration files define parameters required by IP phones to connect to Cisco CallManager. Enter up to eight (8) network addresses or network/host objects, or click **Select** to select an object from a list or to create a new one. **Note** This option is functionally similar to option 66. Either or both options may be used.

NTP on Cisco IOS Routers

The Network Time Protocol (NTP) is the standard for time synchronization between network devices. Synchronized time enables you to correlate syslog and other debug output to specific events, which is essential for troubleshooting, fault analysis, and security incident tracking. Time comparisons are not possible without precise time synchronization between the logging, management, and AAA functions occurring in your network.

NTP uses the concept of a stratum to describe how far removed a machine is from an authoritative time source. For example, a stratum 1 time server is directly attached to a radio or atomic clock. NTP then distributes the time from this authoritative time source across the network. A stratum 2 time server synchronizes with a stratum 1 time server; a stratum 3 time server synchronizes with a stratum 2 time server and so on. One NTP transaction per minute is sufficient to synchronize two machines to within a millisecond.

NTP runs over the User Datagram Protocol (UDP) using port 123. Security Manager supports NTP version 3, as defined in RFC 1305.

Related Topics

- Defining NTP Servers , on page 2487

Defining NTP Servers

This procedure describes how to define the NTP servers that the routers users to synchronize time. After the NTP policy is deployed, the router uses an algorithm (based on factors such as delay, dispersion, and jitter) to determine which NTP server is the most accurate and synchronizes to that one.

At the global level, you can enable MD5 authentication and specify a source address to use on all NTP packets sent from the router.

To add an NTP server to the policy, all you need to do is enter its IP address. In addition, you can optionally define authentication parameters and determine whether a particular server should be preferred over other NTP servers of similar accuracy.

Related Topics

- Defining NTP Servers , on page 2487

Step 1 Do one of the following:

- (Device view) Select **Platform > Device Admin > Server Access > NTP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Server Access > NTP** from the Policy Type selector. Select an existing policy or create a new one.

The NTP page is displayed. See Table 896: NTP Page , on page 2489 for a description of the fields on this page.

Step 2 (Optional) In the Source Interface field, enter the name of the interface or interface role whose address should be used as the source interface for all NTP packets sent from the router, or click **Select** to select an interface role from a list or to create a new one. The source interface must have an IP address.

This option is useful when the NTP server cannot reach the address from which the connection originated (for example, due to a firewall). If you do not enter a value in this field, the address of the outgoing interface is used.

Note You can override this global setting for individual NTP servers, as described in Step 5, on page 2488.

Step 3 (Optional) Select the **Enable NTP Authentication** check box to authenticate all associations between this router and the NTP servers defined in this policy.

Step 4 Click the **Add** button under the Servers table to display the NTP Server dialog box. From here you can define an NTP server.

Step 5 Define an NTP server. See Table 897: NTP Server Dialog Box , on page 2490 for a description of the available fields.

Step 6 (Optional) Define authentication parameters for this NTP server.

Note If you modify the value of a previously defined authentication key, the change affects all NTP servers that share this key.

Note When you define an authentication key in Security Manager, the value 0 is automatically appended to the end of the CLI command. This value, which represents the default authentication key encryption type, can be modified using the CLI.

Step 7 Repeat Step 5, on page 2488 and Step 6, on page 2488 to define additional NTP servers.

Step 8 Click **OK** to save your definitions locally on the client and close the dialog box. Your definitions are displayed in the Servers table.

Note To edit an NTP server, select it from the Servers table, then click **Edit**. To remove an NTP server, select it, then click **Delete**. If the key defined on the server you delete is not defined on a different NTP server, the key is also deleted.

NTP Policy Page

Use the NTP page to define one or more NTP servers that the router can use for time synchronization. This includes enabling authentication, if required, and defining a global source interface for all traffic sent to these servers.

For more information, see Defining NTP Servers , on page 2487.

Navigation Path

- (Device view) Select **Platform > Device Admin > Server Access > NTP** from the Policy selector.
- (Policy view) Select **Router Platform > Device Admin > Server Access > NTP** from the Policy Type selector. Right-click **NTP** to create a policy, or select an existing policy from the Shared Policy selector.

Field Reference

Table 896: NTP Page

Element	Description
Source Interface	The source address for all packets sent to an NTP server. This setting might be necessary when the NTP server cannot respond to the address from which the packet originated (for example, due to a firewall). The source interface must have an IP address. If you do not define a value in this field, the address of the outgoing interface is used. Enter the name of an interface or interface role, or click **Select** to select the object from a list or to create a new one. **Note** The source interface defined in this field is a global setting that you can override for individual NTP servers. For more information, see NTP Server Dialog Box , on page 2490.
Enable NTP Authentication	When selected, enables authentication using MD5 when connecting to an NTP server. When deselected, authentication is disabled.
Servers Table	
IP Address	The IP address of the NTP server.

Element	Description
Source Interface	The source address for all packets sent to this NTP server. This setting overrides the global setting defined at the top of the page.
Preferred	Indicates whether this NTP server is preferred over other NTP servers of similar accuracy. **Note** By default, preferred servers are listed first in the table.
Key Number	The ID number of the key used for authentication with this NTP server.
Trusted	Indicates whether the authentication key defined for this NTP server is a trusted key.
Add button	Opens the NTP Server Dialog Box , on page 2490. From here you can define an NTP server.
Edit button	Opens the NTP Server Dialog Box , on page 2490. From here you can edit the selected NTP server.
Delete button	Deletes the selected NTP server from the table. If the key defined on the server you delete is not defined on a different NTP server, the key is also deleted.

NTP Server Dialog Box

Use the NTP Server dialog box to define the address of an NTP server that the router can use to perform time synchronization. In addition, you can use this dialog box to define a default source interface for NTP packets sent to this server and authentication parameters.

Navigation Path

Go to the NTP Policy Page , on page 2489, then click the **Add** or **Edit** button beneath the table.

Related Topics

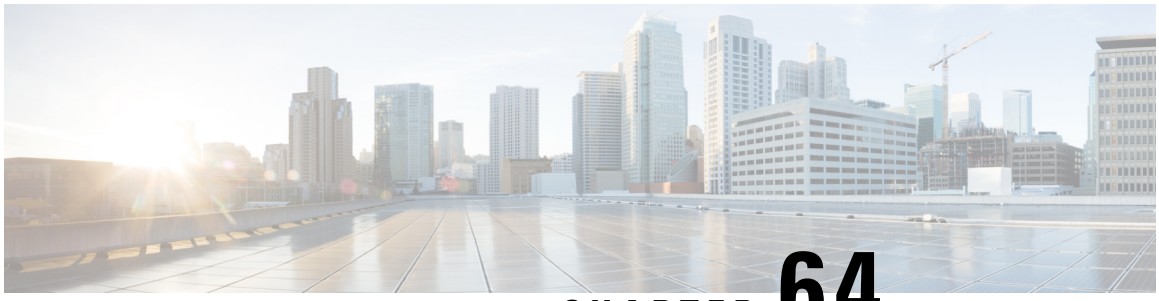
- Defining NTP Servers , on page 2487
- NTP on Cisco IOS Routers , on page 2487
- Understanding Interface Role Objects , on page 303

Field Reference

Table 897: NTP Server Dialog Box

Element	Description
IP Address	The IP address of the NTP server. Enter an address or the name of a network/host object, or click **Select** to select the object from a list or to create a new one.

Element	Description
Source Interface	The source address for all packets sent to this NTP server. This setting might be necessary when the NTP server cannot respond to the address from which the packet originated (for example, due to a firewall). The source interface must have an IP address. If you do not define a value in this field and there is no global setting, the address of the outgoing interface is used. **Note** This setting overrides the global setting you defined on the NTP Policy Page , on page 2489. Enter the name of an interface or interface role, or click **Select** to select the object from a list or to create a new one.
Preferred	When selected, this NTP server is preferred over other NTP servers of similar accuracy. If this server is used for synchronization, the time offset used to correct the local clock is calculated from this server only. **Note** If a different NTP server is significantly more accurate than the preferred server (for example, stratum 2 versus stratum 3), the router synchronizes to the more accurate server. When deselected, this NTP server is not given preference over other NTP servers of similar accuracy. The time offset used to correct the local clock is calculated by taking the combined offset of all NTP servers. We recommend that you configure an NTP server as preferred only when multiple servers have the same stratum and you can rely on the accuracy of the preferred server.
Authentication Key	The MD5 key that is used to authenticate associations with the NTP server. • Key Number—The ID number of the authentication key. Enter the key number or select a previously defined number from the list. • Key Value—An arbitrary string of up to 32 characters that defines the authentication key. Enter the string again in the Confirm field. • Trusted—When selected, this key authenticates the identity of systems attempting to synchronize with this server. When deselected, this key is not used for authentication. If you select a key number from the list and then change the key value, you are warned that saving this change affects any other NTP servers using the same authentication key. **Note** To use authentication, you must enable it from the NTP Policy Page , on page 2489.



CHAPTER 64

Configuring Identity Policies

The IEEE 802.1x standard defines 802.1x port-based authentication as a client-server based access control and authentication protocol that restricts unauthorized clients from connecting to a LAN through public ports. The authentication server validates each client connected to an interface before making available any services offered by the router or the LAN.

Until the client is authenticated, 802.1x access control allows only Extensible Authentication Protocol over LAN (EAPOL) traffic through the interface to which the client is connected. If authentication is successful, normal traffic can pass through the interface.

802.1x authentication provides VPN access control, enabling unauthenticated traffic to access the Internet while preventing it from accessing the VPN tunnel. This solution is especially useful for enterprises whose workers access the corporate VPN through a home access router that other family members use to access the Internet. When you use 802.1x, you create a virtual interface to carry unauthenticated traffic while authenticated traffic continues to pass through the physical interface.

802.1x requires that you use DHCP to provide IP addresses to the clients that request authentication. We recommend that you use two IP address pools, one for authenticated traffic and the other for unauthenticated traffic. If you use two pools, the DNS server in the corporate DHCP pool should point to the corporate DNS server. The DNS server for the noncorporate DHCP pool should use the DNS server provided by the ISP on the public interface. You configure DHCP by selecting a DHCP policy.

802.1x on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

The IEEE 802.1x standard defines 802.1x port-based authentication as a client-server based access control and authentication protocol that restricts unauthorized clients from connecting to a LAN through public ports. The authentication server validates each client connected to an interface before making available any services offered by the router or the LAN.

Until the client is authenticated, 802.1x access control allows only Extensible Authentication Protocol over LAN (EAPOL) traffic through the interface to which the client is connected. If authentication is successful, normal traffic can pass through the interface.

802.1x authentication provides VPN access control, enabling unauthenticated traffic to access the Internet while preventing it from accessing the VPN tunnel. This solution is especially useful for enterprises whose workers access the corporate VPN through a home access router that other family members use to access the Internet. When you use 802.1x, you create a virtual interface to carry unauthenticated traffic while authenticated traffic continues to pass through the physical interface.

802.1x requires that you use DHCP to provide IP addresses to the clients that request authentication. We recommend that you use two IP address pools, one for authenticated traffic and the other for unauthenticated traffic. If you use two pools, the DNS server in the corporate DHCP pool should point to the corporate DNS server. The DNS server for the noncorporate DHCP pool should use the DNS server provided by the ISP on the public interface. You configure DHCP by selecting a DHCP policy. See DHCP on Cisco IOS Routers , on page 2477 for more information.

Note 802.1x is supported on the following platforms—Cisco 800, 1700, 1800, 1900, 2600, 2800, 2900, 3600, 3700, 3800, 3900 Series Routers.

For more information about 802.1x, see:

- Understanding 802.1x Device Roles , on page 2494
- 802.1x Interface Authorization States , on page 2495
- Topologies Supported by 802.1x , on page 2496
- Defining 802.1x Policies , on page 2496

Understanding 802.1x Device Roles

802.1x port-based authentication uses the following device roles:

- Client—The workstation requesting access to the VPN. It must be running 802.1x-compliant client software, such as that offered with the Microsoft Windows XP operating system.
- Authentication server—Authenticates clients. The authentication server validates the client's identity and notifies the router whether the client is authorized to access the network. The Remote Authentication Dial-In User Service (RADIUS) security system with EAP extensions is the only supported authentication server. In Security Manager, a AAA (authentication, authorization, and accounting) server, as defined in a AAA server object, is the authentication server for 802.1x policies.
- Router (edge router or wireless access point)—Controls physical access to the network based on the authentication status of the client. The router is an intermediary (proxy) between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client. In Security Manager, the router on which you configure an 802.1x policy acts as the switch.

- 802.1x on Cisco IOS Routers , on page 2493

802.1x Interface Authorization States

When you use 802.1x, the interface state determines whether to grant the client network access. By default, the interface starts in the unauthorized state. While in this state, the interface disallows all traffic in both directions, except for EAPOL packets. After a client is authenticated, the interface transitions to the authorized state, enabling all client traffic to flow normally.

If a client that does not support 802.1x is connected to an unauthorized 802.1x interface, the router requests the client's identity. In this situation, the client does not respond to the request, the interface remains in the unauthorized state, and the client is not granted access to the network. In contrast, when an 802.1x-enabled client connects to an interface that is not running the 802.1x protocol, the client initiates the authentication process by sending the EAPOL-Start frame. If no response is received, the client sends the request a fixed number of times. Because no response is received, the client begins sending frames as if the interface were in the authorized state.

You can control the interface authorization state by selecting one of the following options:

- Auto—Enables 802.1x authentication, which causes the interface to start in the unauthorized state. Only EAPOL frames are sent and received through the interface. Authentication begins when the link state of the interface transitions from down to up or when an EAPOL-Start frame is received. The router requests the client's identity and begins relaying authentication messages between the client and the authentication server. The router uses the MAC address of each client trying to access the network as unique client identifiers.
- Force authorized—Disables 802.1x authentication, which causes the interface to move to the authorized state without authenticating the client.

After a client is successfully authenticated, the interface state changes to authorized, which enables all frames from the client to enter the network. If authentication fails, the interface remains in the unauthorized state, but authentication can be retried. If the authentication server cannot be reached, the router can retransmit the request. If the authentication server does not respond after the defined number of attempts, authentication fails and network access is denied to the client.

When a client logs off, it sends an EAPOL-Logoff message, which causes the interface to return to the unauthorized state.

Related Topics

- Understanding 802.1x Device Roles , on page 2494
- Topologies Supported by 802.1x , on page 2496
- Defining 802.1x Policies , on page 2496
- 802.1x on Cisco IOS Routers , on page 2493

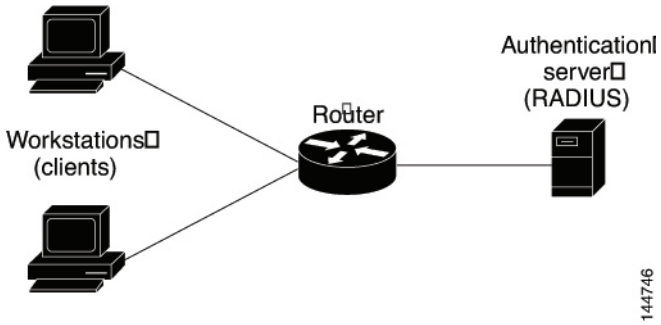
Topologies Supported by 802.1x

802.1x port-based authentication supports two topologies:

- Point-to-point
- Wireless LAN

In a point-to-point configuration, only one client can be connected to the 802.1x-enabled interface. The router detects the client when the interface state changes from down to up. If a client leaves the network or is replaced by another client, the interface state changes from up to down, which returns the interface to the unauthorized state.

Figure 52: 802.1x Topology



In a wireless LAN configuration, the 802.1x interface is configured in multihost mode, which is authorized as soon as one client is authenticated. After the interface is authorized, all other clients indirectly attached to the interface are granted access to the network. If the port becomes unauthorized (either because reauthentication fails or an EAPOL-Logoff message is received), the router denies access to the network to all attached clients. In this topology, the wireless access point is a client to the router and is responsible for authenticating the clients attached to it.

Related Topics

- Understanding 802.1x Device Roles , on page 2494
- 802.1x Interface Authorization States , on page 2495
- Defining 802.1x Policies , on page 2496
- 802.1x on Cisco IOS Routers , on page 2493

Defining 802.1x Policies

You configure an 802.1x policy by defining:

- The AAA server group containing the AAA server that authenticates hosts that are trying to connect to the network.
- The virtual interface that carries unauthenticated traffic and the physical interface that carries authenticated traffic.
- (Optional) Properties of the physical interface, including the control type, automatic reauthentication, and several timeout values.

If the router on which you are defining the 802.1x policy is not part of a VPN (for example, if it is directly connected to the corporate network to which you want to restrict access), you must manually define an access list. You can do this by defining an access rules policy (see Understanding Access Rules , on page 717).

Before You Begin

- Configure the selected router with a DHCP policy that contains two IP address pools, one for authenticated clients and one for unauthenticated clients. See Defining DHCP Policies , on page 2480.
- Make sure the router can route packets to the configured AAA (RADIUS) server. You can verify this by pinging the server from the router.

Related Topics

- Understanding 802.1x Device Roles , on page 2494
- 802.1x Interface Authorization States , on page 2495
- Topologies Supported by 802.1x , on page 2496
- 802.1x on Cisco IOS Routers , on page 2493

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Identity** > **802.1x** from the Policy selector.
- (Policy view) Select **Router Platform** > **Identity** > **802.1x** from the Policy Type selector. Select an existing policy or create a new one.

The 802.1x page is displayed. See Table 898: 802.1x Page , on page 2498 for a description of the fields on this page.

Step 2 Enter the name of the AAA server group containing the AAA server to use for authenticating clients using 802.1x, or click **Select** to select a server group from a list or to create a new one. The selected AAA server must use RADIUS with EAP extensions.

Note Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails.

Step 3 In the Virtual Template field, enter the name of the interface or interface role that serves as the untrusted, virtual interface for carrying unauthenticated traffic, or click **Select** to select an interface role from a list or to create a new role. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Note Integrated Services Routers (ISRs), such as the Cisco 800, 1800, 1900, 2800, 2900, 3800, and 3900 Series, automatically use VLANs to carry unauthenticated traffic. If you define a virtual template, however, it is used in place of the VLAN.

Note Deployment might fail if PPP is defined on the virtual template defined here. See Defining PPP Connections , on page 2378.

Step 4 Enter the name of the interface or interface role that serves as the trusted, physical interface for carrying authenticated traffic, or click **Select** to select a role from a list.

The interface role you select should represent the internal protected interface that was configured as part of the VPN topology and no other physical interface on the selected router. For more information, see Defining the Endpoints and Protected Networks , on page 1109.

Step 5 (Optional) Modify the defaults of the physical interface used for 802.1x authentication. See Table 898: 802.1x Page , on page 2498 for details.

802.1x Policy Page

Use the 802.1x policy page to create policies that limit VPN access to authorized users. Authenticated traffic is allowed to pass through a designated physical interface on the router. Unauthenticated traffic is allowed to pass through a virtual interface to the Internet but is not allowed to access the VPN.

For more information, see Defining 802.1x Policies , on page 2496.

Note 802.1x policies require DHCP address pools in order to assign IP addresses to clients. You define these pools by defining a DHCP policy on the same router. See DHCP Policy Page , on page 2482.

Navigation Path

- (Device view) Select **Platform** > **Identity** > **802.1x** from the Policy selector.
- (Policy view) Select **Router Platform** > **Identity** > **802.1x** from the Policy Type selector. Right-click **802.1x** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

Field Reference

Table 898: 802.1x Page

Element	Description
AAA Server Group	The RADIUS AAA server group that authenticates the credentials of users trying to access a VPN tunnel. Enter the name of a AAA server group object, or click **Add** to select one from a list or to create a new AAA server group object. **Note** Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails.

Element	Description
Virtual Template	Mandatory for all routers except Integrated Services Routers (ISRs). The untrusted, virtual interface that provides Internet access to unauthenticated traffic. Enter the name of an interface or interface role, or click **Select** to select one from a list or to create a new group object. **Note** You do not need to configure a virtual template for ISRs, because they automatically use VLANs to provide access. If you do define a virtual template, however, it is used instead of the VLAN. **Note** Deployment might fail if PPP is defined on the virtual template defined here. See PPP Dialog Box—PPP Tab , on page 2383.
Interface	The trusted, physical interface that provides VPN access to authenticated traffic. Enter the name of an interface or interface role, or click **Select** to select one from a list or to create a new group object. If you use an interface role, the pattern defined in the interface role must represent only one physical interface on the selected device. This interface should be the internal protected interface that you configured as part of the VPN topology. For more information, see Defining the Endpoints and Protected Networks , on page 1109.
Number of retries	The number of times the physical interface resends an Extensible Authentication Protocol (EAP) request/identity frame to a client if a response is not received before restarting authentication. Valid values range from 1 to 10. The default is 2. **Note** You should change the default only to adjust for unusual circumstances, such as unreliable links or specific problems with certain clients and authentication servers.
Control type	The control state of the interface, which determines whether the host is granted access to the network. Options are: • Force Authorize—Disables 802.1x authentication and causes the interface to move to the authorized state without requiring any authentication exchange. This means the interface transmits and receives normal traffic without 802.1x-based authentication of the host. This is the default. • Auto—Enables 802.1x authentication and causes the interface to begin in the unauthorized state, allowing only EAPOL frames to be sent and received through the interface. If a host is successfully authenticated, the interface state changes to authorized, which enables all frames from the host through the interface.
Enable client reauthentication	When selected, enables periodic reauthentication of client PCs on the 802.1x interface. Reauthentication is performed after the interval defined in the Client reauthentication period timeout field. The default period is 3600 seconds (1 hour). When deselected, periodic reauthentication is not performed.
Client reauthentication period timeout	Applies only when the Enable client reauthentication check box is selected. The number of seconds between client reauthentication attempts. Valid values range from 1 to 65535 seconds. The default is 3600 seconds (1 hour).

Element	Description
Quiet period	The amount of time the router remains in a quiet state after a failed authentication exchange with the client. Authentication exchanges might fail, for example, because the client provided an invalid password. Valid values range from 1 to 65535 seconds. The default is 120 seconds. **Note** Entering a value smaller than the default provides a faster response time to the user.
Rate Limit period	The interval after which the interface throttles the EAP-Start packets it receives from malfunctioning client PCs. Use this setting, called rate limiting, to prevent these clients from wasting router processing power. Valid values range from 1 to 65535 seconds. By default, rate limiting is disabled. **Note** To disable an existing rate limit, delete the value defined in this field and leave the field blank.
AAA Server timeout	The number of seconds the router waits before retransmitting packets to the AAA server. If the router sends an 802.1x packet to the AAA server and the server does not respond, the router sends another packet after this interval elapses. Valid values range from 1 to 65535 seconds. The default is 30 seconds.
Supplicant period	The number of seconds the router waits before retransmitting EAP-Request/Identity packets to the supplicant (client PC). If the router sends an EAP-Request/Identity packet to the client PC (supplicant) and the supplicant does not respond, the router sends the packet again after this interval elapses. Valid values range from 1 to 65535 seconds. The default is 30 seconds.

Network Admission Control on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Network Admission Control (NAC), an industry initiative sponsored by Cisco Systems, uses the network infrastructure to enforce security-policy compliance on all devices seeking to access network computing resources, thereby limiting damage from viruses and worms. By using NAC, organizations can provide network access to endpoint devices such as PCs, PDAs, and servers that are verified to be fully compliant with established security policy. NAC can also identify noncompliant devices and deny them access, place them in a quarantined area, or give them restricted access to computing resources.

Network access decisions are made through a process of posture validation, which evaluates the posture credentials presented by the endpoint device. These credentials can include such information as the endpoint's antivirus state, operating system version, operating system patch level, or Cisco Security Agent version and settings.

You can use NAC to enforce security policy compliance in many types of deployments, including branch offices, remote access, and dial-in access.

NAC policies in Security Manager enable a Cisco IOS router to act as a Network Access Device (NAD) for enforcing policy compliance on devices seeking to access the network. The following topics describe additional details about NAC:

- Understanding NAC Components , on page 2501
- Understanding NAC System Flow , on page 2502

The following topics describe the tasks you perform to create NAC policies on Cisco IOS routers:

- Defining NAC Setup Parameters , on page 2503
- Defining NAC Interface Parameters , on page 2504
- Defining NAC Identity Parameters , on page 2505

Router Platforms Supporting NAC

To configure NAC policies on a router, the router must be running Cisco IOS Software Release 12.3(8)T images and later (with the Advanced Security feature set). However, the following routers do not support NAC:

- Cisco 7600 Series (7603, 7604, 7606, 7609, 7613)
- Cisco 7300 Series (7301, 7304)
- Cisco 7100 Series VPN Routers (7120, 7140, 7160)
- Cisco 3600 Series Multiservice Platforms (3620, 3631, 3661, 3662)
- Cisco 1700 Series Modular Access Routers (1710, 1720, 1750)
- Cisco 1600 Series (1601, 1602, 1603, 1604, 1605)
- Cisco ASR 1000 Series Aggregation Services Routers (all models)
- Cisco 800 Series (801, 803, 805, 811, 813, 828, 851, 857, 871, 876, 877, 878)
- Cisco SOHO 90 Series Secure Broadband Routers (91, 96, 97)
- Cisco SOHO 77 Series (71, 76, 77 ADSL, 77 H ADSL, 78)

Understanding NAC Components

NAC contains the following components:

- Cisco Trust Agent (CTA)—The CTA acts as the NAC client. It provides posture credentials for the endpoint device on which it is installed, including the type of operating system and the version of antivirus software installed.
- Network access device (NAD)—The NAD initiates posture validation with the CTA when its Intercept ACL is triggered. It relays posture credentials received from the CTA to a AAA server. In return, the NAD receives configuration information from the AAA server, which it enforces on the selected interface. The NAD also:
  - Periodically polls the CTA to confirm that it is communicating with the same client at this IP address.

- Revalidates all current sessions.
- Sends username and password information from devices lacking a CTA (clientless hosts) to the AAA server for authentication.
- Supports an exception list of predefined actions applied to specific devices, based on the device IP address or MAC address.

When you configure NAC policies in Security Manager, you are configuring the behavior of the Cisco IOS router acting as the NAD.

- AAA server—The AAA server obtains and validates posture credentials received from the CTA and returns the access policy to be enforced on the NAD. The AAA server must be a Cisco Secure Access Control Server (ACS), running the RADIUS protocol. Existing ACS authorization support can be used to provide access to clientless hosts. Posture validation rules and the access policies resulting from those rules are configured on the ACS.

Related Topics

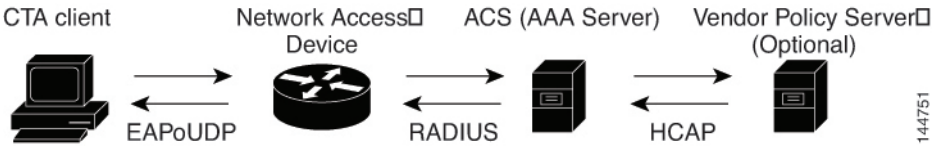
- Understanding NAC System Flow , on page 2502
- Network Admission Control on Cisco IOS Routers , on page 2500

Understanding NAC System Flow

As shown in Figure 53: NAC System Flow, on page 2502, the system flow for NAC is:

1. An IP packet from a connecting device triggers the Intercept ACL configured on the NAD.
2. The NAD triggers posture validation with the CTA configured on the device using the Extensible Authentication Protocol over User Datagram Protocol, otherwise known as EAP over UDP, or simply EoU.
3. The CTA sends its posture credentials to the NAD using EAP over UDP.
4. The NAD sends these posture credentials to the ACS using RADIUS.
5. The ACS performs posture validation, which determines whether to allow the device to access the network. (If necessary, the ACS requests additional posture validation from a third-party server. For example, if the CTA forwards credentials that are specific to a particular antivirus application, the ACS forwards this information via the HCAP protocol to a vendor server for validation.) If the device is a clientless host, the ACS checks the username and password it receives against its locally stored list.
6. The ACS directs the NAD to enforce the appropriate access policy on the requesting device. Access may be granted, denied, redirected, or restricted.

Figure 53: NAC System Flow



Related Topics

- Understanding NAC Components , on page 2501
- Network Admission Control on Cisco IOS Routers , on page 2500

Defining NAC Setup Parameters

You configure NAC setup parameters by selecting the AAA server groups that obtain and validate the posture credentials received from devices trying to connect to the network. You can configure an option that allows devices lacking the Cisco Trust Agent (CTA) to be authenticated by a predefined username and password stored on a Cisco Secure Access Control Server (ACS). Additionally, you can modify default settings for EAP over UDP. This is the protocol used for posture validation communications between the Cisco IOS router serving as the network access device (NAD) and the device trying to access your network.

Related Topics

- Defining NAC Interface Parameters , on page 2504
- Defining NAC Identity Parameters , on page 2505
- Network Admission Control on Cisco IOS Routers , on page 2500

Step 1 Do one of the following:

- (Device view) Select **Platform > Identity > Network Admission Control** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Identity > Network Admission Control** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The NAC Setup tab is displayed. See Table 902: Network Admission Control Identities Tab , on page 2511 for a description of the fields on this tab.

Step 2 Enter the name of the AAA server group containing the AAA server that performs posture validation, or click **Select** to select the server group from a list or to create a new one. The selected AAA server group must contain ACS devices running RADIUS.

Note Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails.

Step 3 (Optional) Select up to two AAA server groups as backups to the main server group. If all the servers in the main server group go down, the servers in the backup server group perform NAC.

Both backup server groups must consist of ACS devices running RADIUS.

Step 4 (Optional) Under EAP over UDP, select one or both of the following Allow parameters:

a) Select the **Allow IP Station ID** check box to include IP addresses in the RADIUS requests sent to the ACS.

b) Select the **Allow Clientless** check box to provide access to devices that do not have the CTA installed. In such cases, the ACS authenticates these devices by checking the username and password against a predefined list.

If you do not select this check box, devices without CTA are prevented from accessing the network if their traffic matches the Intercept ACL. This is because without CTA, posture validation cannot be performed.

Note This feature is not supported on routers running Cisco IOS Software Release 12.4(6)T or later.

Step 5 (Optional) Under EAP over UDP, modify the default settings related to the EAP over UDP (EoU) protocol, if required. See Table 899: Network Admission Control Setup Tab , on page 2507 for details.

Defining NAC Interface Parameters

You configure NAC interface parameters by selecting the interfaces on which NAC is performed. You must also define the Intercept ACL, which determines which traffic on these interfaces is subject to posture validation. Additionally, you can optionally override the device-level setting for initiating EAP over UDP sessions and subject all sessions to periodic revalidation (see Defining NAC Setup Parameters , on page 2503).

A NAC policy must include at least one interface definition to function.

Before You Begin

- Select the AAA server group containing the ACS device performing posture validation. See Defining NAC Setup Parameters , on page 2503.
- Define an ACL object that defines the traffic to subject to posture validation in NAC policies. See Creating Access Control List Objects , on page 283.
- Define an ACL object that defines the default access on the selected interface (default ACL). See Creating Access Control List Objects , on page 283.

Related Topics

- Defining NAC Setup Parameters , on page 2503
- Defining NAC Identity Parameters , on page 2505
- Network Admission Control on Cisco IOS Routers , on page 2500

Step 1 Do one of the following:

- (Device view) Select **Platform > Identity > Network Admission Control** from the Policy selector, then click the **Interfaces** tab in the work area.
- (Policy view) Select **Router Platform > Identity > Network Admission Control** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Interfaces** tab.

The NAC Interfaces tab is displayed. See for a description of the fields on this tab.

Step 2 On the NAC Interfaces tab, select an interface definition from the table, then click **Edit**, or click **Add** to create a definition. The NAC Interface Configuration dialog box appears. See NAC Identity Action Dialog Box , on page 2512 for a description of the fields in this dialog box.

Step 3 Enter the name of the interface or interface role on which NAC is performed, or click **Select** to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Step 4 (Optional) Enter the name of the ACL object that acts as the intercept ACL, or click **Select** to select it from a list or to create a new object.

The intercept ACL determines which traffic on the selected interfaces is subject to posture validation before being granted access to the network. If you do not select an ACL, all traffic on the selected interfaces is subject to posture validation.

Note If you defined an authentication proxy on the same interface as a NAC interface, you must use the same intercept ACL in both policies. Otherwise, deployment might fail. For more information about authentication proxies, see Configuring AAA Rules for IOS Devices , on page 691.

Step 5 (Optional) To override the device-level value defined for maximum attempts to initiate an EAP over UDP session, enter a new value in the EAP over UDP Max Retries field.

Step 6 (Optional) Deselect the **Enable EOU Session Revalidation** check box if you do not want the NAD to periodically revalidate all EAP over UDP sessions.

Note Subinterfaces support default values only for the options described in Step 5, on page 2505 and Step 6, on page 2505.

Step 7 Click **OK** to save your definitions locally on the client and close the dialog box. Your interface definitions appear in the table on the NAC Interfaces tab.

Defining NAC Identity Parameters

By default, any traffic over the selected interfaces that match the intercept ACL is subjected to posture validation before it is permitted to enter the network. However, you can create an exception list of predefined actions to apply to specific devices. You use identity profiles to create this exception list. Each profile contains two elements:

- A profile definition, identifies the device to which the profile applies. Devices can be identified by their IP addresses, MAC addresses, or types (for Cisco IP phones).
- An action, which defines the result when this device tries to access the network. Each action can include an ACL, a redirect URL, or both. If you do not specify an action, the default ACL is applied.

When you configure NAC identity parameters, you first define one or more identity actions and then create the identity profiles to which these actions apply. You can apply each action to multiple profiles.

Related Topics

- Defining NAC Setup Parameters , on page 2503
- Defining NAC Identity Parameters , on page 2505
- Network Admission Control on Cisco IOS Routers , on page 2500

Step 1 Do one of the following:

- (Device view) Select **Platform > Identity > Network Admission Control** from the Policy selector, then click the **Identities** tab in the work area.
- (Policy view) Select **Router Platform > Identity > Network Admission Control** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Identities** tab.

The NAC Identities tab is displayed. See Table 902: Network Admission Control Identities Tab , on page 2511 for a description of the fields on this tab.

Step 2 Define one or more identity actions:

a) On the NAC Identities tab, select an identity action from the lower table, then click **Add**. The NAC Identity Action dialog box appears.
b) Define an identity action. See Table 904: NAC Identity Action Dialog Box , on page 2512 for a description of the available fields.
c) Click **OK** to save your definitions and close the dialog box. The action appears in the Identity Actions table in the NAC Identities tab.
d) (Optional) Repeat 2.a, on page 2506 through 2.c, on page 2506 to define additional identity actions, as required.

Step 3 Define identity profiles:

a) Select an identity profile from the upper table on the NAC Identities tab, then click **Add**. The NAC Identity Profile dialog box appears. See Table 903: NAC Identity Profile Dialog Box , on page 2512 for a description of the fields in this dialog box.
b) Enter the name of an identity action (as defined in Step 2, on page 2505) or click **Select** to display a selector.
c) Select and define a profile definition, which identifies the device to which the profile should apply.
d) Click **OK** to save your definitions and close the dialog box. The profile appears in the Identity Profiles table in the NAC Identities tab.
e) (Optional) Repeat 3.a, on page 2506 through 3.d, on page 2506 to define additional identity profiles, as required.

Network Admission Control Policy Page

Network Admission Control (NAC) policies enable Cisco IOS routers acting as network access devices (NADs) to enforce access privileges when an endpoint tries to connect to a network. Access decisions are made on the basis of information provided by the endpoint device, such as its current antivirus state, thus keeping insecure nodes from infecting the network.

You can configure NAC policies on a Cisco IOS router from the following tabs on the Network Admission Control policy page:

- Network Admission Control Page—Setup Tab , on page 2506
- Network Admission Control Page—Interfaces Tab , on page 2508
- Network Admission Control Page—Identities Tab , on page 2510

For more information, see Network Admission Control on Cisco IOS Routers , on page 2500.

Navigation Path

- (Device view) Select **Platform > Identity > Network Admission Control** from the Policy selector.
- (Policy view) Select **Router Platform > Identity > Network Admission Control** from the Policy Type selector. Right-click **Network Admission Control** to create a policy, or select an existing policy from the Shared Policy selector.

Network Admission Control Page—Setup Tab

Use the Network Admission Control Setup tab to select the Cisco Secure Access Control Servers used for authentication during the NAC process, as well as to define the EAP over UDP settings for communications between the NAD and the client seeking access to the network.

Navigation Path

Go to the Network Admission Control Policy Page , on page 2506, then click the **Setup** tab.

Related Topics

- Defining NAC Setup Parameters , on page 2503

- Understanding AAA Server and Server Group Objects , on page 256

Field Reference

Table 899: Network Admission Control Setup Tab

Element	Description
AAA Server Group	The AAA server group used for NAC authentication. You must select a server group consisting of Cisco Secure Access Control Server (ACS) devices running the RADIUS protocol. Enter the name of a AAA server group object, or click **Select** to select the object from a list or to create a new one. **Note** Each AAA server in the selected group must be configured to communicate with an interface that exists on the router; otherwise, validation fails.
Backup AAA Server Group 1	The backup AAA server group in case the AAA servers in the main group are down.
Backup AAA Server Group 2	The secondary backup AAA server group in case the AAA servers in the main group and the first backup group are down.
EAP over UDP (EoU) settings	
Allow IP Station ID	When selected, enables an IP address to be included in the calling-station-id field of RADIUS requests sent to the ACS. When deselected, IP addresses are not included in the calling-station-id field of RADIUS requests sent to the ACS.

Element	Description
Allow Clientless	When selected, enables devices that do not have the Cisco Trust Agent (CTA) installed to be authenticated through the use of a username and password configured on the ACS. If you select this check box, enter the username and password (including confirmation) in the fields provided. When deselected, NAC prevents devices lacking the CTA from accessing the network, if their traffic matches the intercept ACL (see NAC Interface Configuration Dialog Box , on page 2509). **Note** This feature is not supported on routers running Cisco IOS Software Release 12.4(6)T or later.
Max Retry	The maximum number of retries that all NAC interfaces on this router should make when initiating an EAP over UDP session with a connecting device. Valid values range from 1 to 3. The default is 3. **Note** You can override this global value on a specific interface, if required. See Network Admission Control Page—Interfaces Tab , on page 2508 .
Rate Limit	The number of EAP over UDP posture validations that the router can handle simultaneously. Additional devices cannot be validated until one or more devices drop off. Valid values range from 1 to 200. The default is 20. If you set this value to 0, rate limiting is turned off.
Port	The UDP port to use for EAP over UDP sessions. Valid values range from 1 to 65535. The default is 21862. **Note** For NAC to work, the default ACL on this router must permit UDP traffic over the port designated here for EAP over UDP traffic. For more information, see Understanding Access Rules , on page 717.
Enable Logging	When selected, EAP over UDP events on this router are logged to the device. When deselected, EAP over UDP logging is disabled. This is the default.

Network Admission Control Page—Interfaces Tab

Use the Network Admission Control Interfaces tab to select and configure the router interfaces on which to perform NAC. This includes configuring the Intercept ACL and selected EoU interface parameters. A NAC policy must include at least one interface definition in order to function.

Navigation Path

Go to the Network Admission Control Policy Page , on page 2506, then click the **Interfaces** tab.

Field Reference

Table 901: NAC Interface Configuration Dialog Box

Element	Description
Interface	The interface that will perform NAC on connecting devices. Enter the name of an interface or interface role, or click **Select** to select an object from a list or to create a new one.
Intercept ACL	The ACL that defines the traffic requiring posture validation. Enter the name of an ACL object, or click **Add** to select an object from a list or to create a new one. **Note** If an authentication proxy is configured on the same interface as NAC, the same Intercept ACL must be used in both policies. Otherwise, deployment may fail. For more information about authentication proxies, see Configuring AAA Rules for IOS Devices , on page 691.
EAP over UDP Max Retries	The maximum number of times that the router should try to initiate an EoU session with a connecting device. Valid values range from 1 to 3. The default is 3. **Note** Subinterfaces support the default value only.
Enable EoU Session Revalidation	When selected, the router revalidates its EoU sessions as required. This is the default. When deselected, EoU session revalidation is not performed. **Note** Subinterfaces support the default value only.

Network Admission Control Page—Identities Tab

Use the Network Admission Control Identities tab to view, create, edit, and delete NAC identity profiles and identity actions. Identity profiles define a specific action to perform on traffic received from selected devices, as identified by their IP address, MAC address, or device type. In this way, devices with identity profiles are handled by NAC without having to undergo posture validation against an ACS.

Navigation Path

Go to the Network Admission Control Policy Page , on page 2506, then click the **Interfaces** tab.

Field Reference

Table 903: NAC Identity Profile Dialog Box

Element	Description
Action Name	The name of the action to assign to the profile. Enter the name of an action, or click **Select** to display a selector. For more information about creating actions, see NAC Identity Action Dialog Box , on page 2512.
Profile Definition	The device to which this profile is assigned: • IP Address—The IP address of the device to which this profile should be assigned. The same IP address cannot be used in more than one profile. • MAC Address—The MAC address of the device to which this profile should be assigned. • Cisco IP Phone—Used when defining a NAC identity profile for Cisco IP phones.

NAC Identity Action Dialog Box

Use the NAC Identity Action dialog box to add or edit the actions assigned to NAC identity profiles.

Navigation Path

Go to the Network Admission Control Page—Interfaces Tab , on page 2508, then click the **Add** or **Edit** button beneath the Identity Actions table.

Related Topics

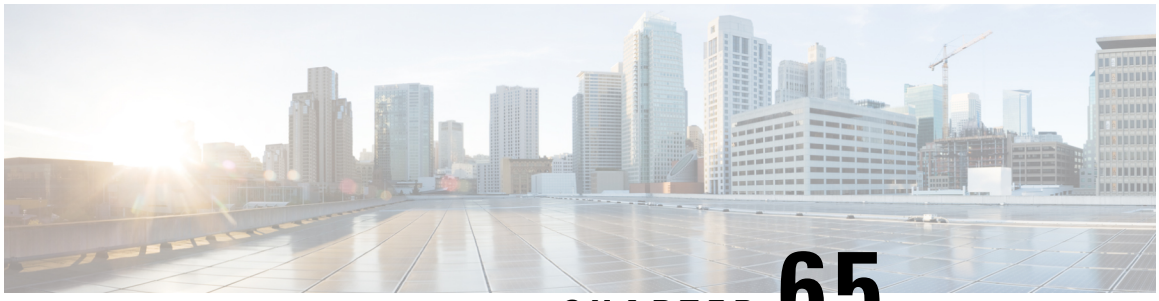
Field Reference

Table 904: NAC Identity Action Dialog Box

Element	Description
Name	A descriptive name for the identity action. Use this name when you select an action to assign to a NAC identity profile. See NAC Identity Action Dialog Box , on page 2512.
Access Control Lists	The ACL that defines how to handle traffic received from a device which is assigned a profile that includes this action. Enter the name of an ACL object, or click **Add** to select an object from a list or to create a new one. **Note** You cannot select the same ACL object that is being used for the intercept ACL. See NAC Interface Configuration Dialog Box , on page 2509.

Element	Description
Redirect URL	The address of the remediation server to which traffic from the device should be redirected. Redirect URLs are usually of the form **http://URL** or **https://URL**.



CHAPTER 65

Configuring Logging Policies

Security Manager provides the following policies for configuring logging on a Cisco IOS router:

Syslog Logging Setup—Enable the syslog-logging feature, and define basic logging parameters. For more information, see Defining Syslog Logging Setup Parameters .

Syslog Servers—Define the remote servers to which syslog messages are sent. For more information, see Defining Syslog Servers .

NetFlow—Enable NetFlow logging by providing parameters and interfaces. See Defining NetFlow Parameters .

Logging on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Security Manager provides the following policies for configuring logging on a Cisco IOS router:

- Syslog Logging Setup—Enable the syslog-logging feature, and define basic logging parameters. For more information, see Defining Syslog Logging Setup Parameters , on page 2516.
- Syslog Servers—Define the remote servers to which syslog messages are sent. For more information, see Defining Syslog Servers , on page 2517.
- NetFlow—Enable NetFlow logging by providing parameters and interfaces. See Defining NetFlow Parameters , on page 2520 for more information.

Note We strongly recommend configuring a Network Time Protocol (NTP) policy on all routers on which logging is enabled. NTP synchronization provides accurate timestamps for syslog messages, which is essential for comparing logs on multiple devices.

Defining Syslog Logging Setup Parameters

This procedure describes enabling syslog logging on the router, and defining which messages are sent to a syslog server. In addition, you can optionally define:

- The source interface for all syslog messages sent from this device.
- The messages that are saved to a local buffer.
- An origin identifier added to each message.
- A rate limit on the number of messages that can be sent.

Note To send syslog messages from the router to a syslog server, you must also define the IP address of the syslog server. For more information, see Defining Syslog Servers , on page 2517.

Related Topics

- Defining Syslog Servers , on page 2517
- Understanding Log Message Severity Levels , on page 2518
- Logging on Cisco IOS Routers , on page 2515

Step 1 Do one of the following to access the router's Syslog Logging Setup page:

- (Device view) Select **Platform > Logging > Syslog Logging Setup** from the Policy selector.
- (Policy view) Select **Router Platform > Logging > Syslog Logging Setup** from the Policy Type selector. Select an existing policy or create a new one.

The Syslog Logging Setup page is displayed. See Table 906: Syslog Logging Setup Page , on page 2523 for a description of the fields on this page.

Step 2 Select **Enable Logging** to turn on the syslog logging feature. If this option is not selected, no log messages are created.

Tip To use the device's default logging settings, or to restore the default settings, simply select Enable Logging, ensure all other fields are blank, then click **Save**. The default settings vary by device. See your router documentation for more details.

Step 3 (Optional) In the Source Interface field, enter the name of the interface or interface role whose address should be used as the source interface for all log messages sent to a syslog server; or click **Select** to select an interface role from a list or to create a new one. The source interface must have an IP address.

This option is useful when the syslog server cannot reach the address from which the connection originated (for example, due to a firewall). If you do not enter a value in this field, the address of the outgoing interface is used.

Step 4 (Optional) To send log messages to a syslog server:

a) Select **Enable Trap**. This option is selected by default.
b) Select a value from the Trap Level list. All messages of this severity or greater (that is, having the same or a lower severity-level number) are sent to the syslog server; messages of a lesser severity are ignored. For more information about severity levels, see Table 863: User Account Dialog Box , on page 2406.

Step 5 (Optional) To save log messages locally to a buffer on the router:

a) Select **Enable Buffer**. This option is selected by default.
b) Enter the Buffer Size in bytes.
c) Select the lowest severity level for messages to be saved to the buffer. All messages of that severity level or greater are saved to the buffer.
d) Select **Use XML Format** to save messages in XML format. (You can configure both the regular buffer and the XML buffer in the same policy.) If you select this option, enter the size of the XML buffer in bytes.

Note Make sure not to make buffers so large that the router runs out of memory for other tasks. If this happens, deployment may fail.

Step 6 (Optional) Define a rate limit to prevent a flood of output messages:

a) Select **Enable Rate Limit**. This option is selected by default.
b) Enter the maximum number of messages that can be sent per second.
c) Select the severity levels to *exclude* from the rate limit. For example, if you select 2 (critical), all syslog messages of severity levels 0-2 are sent to the syslog server regardless of the defined rate limit.
d) Select **All Messages** to apply the rate limit to all syslog messages *except* console messages (and excepting those severity levels specifically excluded above).
e) Select **Console Messages** to apply the rate limit to console messages only.

Note If you enable rate limiting without specifying any options, the default settings (10 messages per second, applied to console messages only) are applied.

Step 7 (Optional) To add an origin identifier to the beginning of each syslog message:

a) Select the type of origin ID to send—the IP address of the router, its host name, or a text string that you provide.
b) If you select String, enter the desired text in the field provided. Spaces are permitted.

The origin identifier is useful for identifying the source of syslog messages in cases where you send output from multiple devices to a single syslog server.

Note The origin identifier is not added to messages sent to local destinations, such as the buffer, the console, and the monitor.

Defining Syslog Servers

This procedure describes how to define the servers to which the router should send syslog messages. When you define a syslog server, you can choose whether the logging messages it receives should be forwarded as plain text or in XML format.

If you define multiple syslog servers, logging messages are sent to all of them.

Before You Begin

- Enable syslog logging and define basic logging parameters on the Syslog Logging Setup page. For more information, see Defining Syslog Logging Setup Parameters , on page 2516.

Related Topics

- Defining Syslog Logging Setup Parameters , on page 2516
- Understanding Log Message Severity Levels , on page 2518
- Logging on Cisco IOS Routers , on page 2515

Step 1 Do one of the following to access the router's Syslog Servers page:

- (Device view) Select **Platform > Logging > Syslog Servers** from the Policy selector.
- (Policy view) Select **Router Platform > Logging > Syslog Servers** from the Policy Type selector. Select an existing policy or create a new one.

The Syslog Servers page is displayed. See Table 907: Syslog Servers Page , on page 2526 for a description of the fields on this page.

Step 2 To define a server to receive syslog messages from this router, click the **Add** button below the table to open the Syslog Server dialog box. See Table 908: Syslog Server Dialog Box , on page 2526 for more about this dialog box.

Step 3 In the IP Address field, enter the address of the desired syslog server, or click **Select** to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 4 (Optional) Select **Forward Messages in XML Format** to forward received syslog messages in XML format instead of plain text.

Step 5 Click **OK** to save your definition and close the dialog box. The syslog server you defined is displayed in the table.

Note To edit a syslog server, select it from the table, then click **Edit**. To remove a syslog server, select it, then click **Delete**.

Understanding Log Message Severity Levels

Syslog messages on Cisco IOS routers are classified into eight severity levels. Each severity level is identified by a number and a corresponding name. The lower the number, the greater the severity, as shown in the following table.

Table 905: Syslog Message Severity Levels

Level Number	Level Name	Description
0	emergency	System unusable
1	alert	Immediate action needed
2	critical	Critical conditions

Level Number	Level Name	Description
3	errors	Error conditions
4	warnings	Warning conditions
5	notifications	Normal but significant condition
6	informational	Informational messages only
7	debugging	Debug messages

Related Topics

NetFlow on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

The ability to characterize IP traffic and understand how and where it flows is critical for network availability, performance and troubleshooting. Monitoring IP traffic flows facilitates accurate capacity planning, and ensures that network resources are used appropriately in support of organizational goals.

NetFlow is a logging feature available on IOS devices for recording, caching and transmitting IP traffic-flow information on a per-interface basis. The basic output of NetFlow is a flow record, where a “flow” is defined as a unidirectional stream of packets between a given source and destination—both defined by a network-layer IP address and transport-layer source and destination port numbers.

On the IOS device, NetFlow consists of two key components—a NetFlow cache which stores IP flow data, and the NetFlow export mechanism that transmits the NetFlow records to a collection server for data reporting. Thus, when enabled, NetFlow records and caches statistics for incoming and outgoing traffic flows, periodically transmitting these records from the device to a NetFlow collector, in the form of User Datagram Protocol (UDP) datagrams.

Several different formats for the export packet, or flow record, have evolved as NetFlow has matured, and these formats are commonly referred to as the NetFlow version. These versions are well documented, and include versions 1, 5, 7, and 9. The most commonly used format is NetFlow version 5, but version 9 is the latest format and has some advantages for extensibility, security, traffic analysis and multicasting.

Security Manager currently supports Traditional NetFlow on IOS devices. Traditional NetFlow provides a fixed flow record, even for version 9, meaning the device will use certain flags and predefined record combinations in generating the flow. The device configuration settings define export destinations, export interface, and certain version-specific transmission options.

More About Traffic Flows and NetFlow

Each packet that passes into or out of a router or switch is examined for a set of IP packet attributes. These attributes are the IP packet identity or "fingerprint," and they define whether the packet is unique, or related to other packets.

All packets with the same source/destination IP address, source/destination ports, protocol interface, and class of service are grouped into a flow and the packets and bytes are tallied. This method of flow determination (or "fingerprinting") is scalable because a large amount of network information can be condensed into a database of NetFlow information called the NetFlow cache.

In general, the NetFlow cache is constantly filling with flows, and software in the router or switch is searching the cache for flows that have terminated or expired, and these flows are exported to the NetFlow collector. (Unlike SNMP polling, NetFlow export periodically transmits information to the NetFlow collector.) The NetFlow collector has the job of assembling and organizing the exported flows to produce the real-time or historical reports used for traffic and security analysis.

NetFlow Summary

To summarize, the following steps outline NetFlow:

- NetFlow is configured on the router or switch to capture IP traffic flows
- Flow records are stored in the local NetFlow cache
- Periodically, approximately 30 to 50 flow records are bundled together and exported to a NetFlow collector server
- The collector software creates reports from the NetFlow data

Defining NetFlow Parameters

This procedure describes enabling NetFlow logging on the router.

Related Topics

- NetFlow on Cisco IOS Routers , on page 2519
- NetFlow Policy Page , on page 2527
- Logging on Cisco IOS Routers , on page 2515

Step 1 To access the router's NetFlow page, do one of the following:

- (Device view) Select **Platform** > **Logging** > **NetFlow** from the Policy selector.
- (Policy view) Select **Router Platform** > **Logging** > **NetFlow** from the Policy Type selector. Select an existing policy or create a new one.

The router's NetFlow page is displayed. See NetFlow Policy Page , on page 2527 for complete descriptions of the fields on this page.

Step 2 On the **Setup** tab of the NetFlow page, specify global NetFlow parameters for the router:

- **Primary Destination** – Choose IP Address or Hostname from this list to enable NetFlow collection and to specify how the primary NetFlow collector will be defined. You can choose the blank entry to disable this option.
  - **IP Address** – Enter the IP address of the device hosting the primary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)
  - **Hostname** – Enter the fully qualified domain name of the device hosting the primary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)
- **Redundant Destination** – Choose IP Address or Hostname from this list to specify how the back-up NetFlow collector will be defined. You can choose the blank entry to disable this option.
  - **IP Address** – Enter the IP address of the device hosting the secondary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)
  - **Hostname** – Enter the fully qualified domain name of the device hosting the secondary NetFlow Collection Engine, and then enter the number of the **UDP Port** monitored by that flow collector (port numbers can range from 1 to 65535)

Note If you define a Primary and a Redundant Destination, flow data is transmitted to both.

- **Source Interface** – Specify the router interface through which flow data will be transmitted to the collector destination(s).
- **Version** – Define the record format to be used for flow data by choosing the appropriate NetFlow version number from this drop-down list. You can choose the blank entry to disable this option.
  - **1** – The original record format. No additional parameters are required.
  - **5** – The most widely adopted format; includes Border Gateway Protocol (BGP) autonomous system (AS) information and flow sequence numbers.

If BGP is configured on your network, you can include either origin or peer AS information in the NetFlow records. Choose **origin-as** or **peer-as** from the AS Type drop-down list. You can choose the blank entry to disable this option.

Check **Enable BGP Nexthop** to include BGP next hop information in the flow caches. (Note that with version 5, this information is visible in the caches, but it is not exported.)

- • **9** – The most-recent, template-based version; not yet fully supported.

If BGP is configured on your network, you can include either origin or peer AS information in the NetFlow records. Choose **origin-as** or **peer-as** from the AS Type drop-down list. You can choose the blank entry to disable this option.

Check **Enable BGP Nexthop** to include BGP next hop information in the flow records.

Note AS information collection is resource intensive, especially for origin-as. If you are not interested in monitoring peering arrangements, disabling AS collection may improve performance.

Step 3 On the **Interfaces** tab, define the interfaces for which traffic flows are to be reported.

- To add an interface, click the Add Row button to open the Add NetFlow Interface Settings dialog box. This dialog box is described in Adding and Editing NetFlow Interface Settings , on page 2529.
- To edit an existing interface, select the appropriate entry in the Interfaces table and then click the Edit Row button to open the Edit NetFlow Interface Settings dialog box (described in Adding and Editing NetFlow Interface Settings , on page 2529).
- To delete an existing interface, select that entry in the Interfaces table and then click the Delete Row button, and then confirm the deletion.

Note You can disable NetFlow data collection on an interface without deleting it. Refer to Adding and Editing NetFlow Interface Settings , on page 2529 for more information.

Syslog Logging Setup Policy Page

Use the Syslog Logging Setup page to enable syslog logging and define basic logging parameters on the selected Cisco IOS router.

For more information, see Defining Syslog Logging Setup Parameters , on page 2516.

Note We strongly recommend that you define an NTP policy on all routers on which logging is enabled in order to create accurate timestamps for each log message. For more information, see NTP Policy Page , on page 2489.

Note If you unassign a logging setup policy, the default logging configuration is restored on the device upon deployment.

Navigation Path

- (Device view) Select **Platform > Logging > Syslog Logging Setup** from the Policy selector.
- (Policy view) Select **Router Platform > Logging > Syslog Logging Setup** from the Policy Type selector. Right-click **Syslog Logging Setup** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

- Logging on Cisco IOS Routers , on page 2515

Field Reference

Table 906: Syslog Logging Setup Page

Element	Description
Enable Logging	When selected, syslog logging is enabled on the device. When deselected, logging is disabled on the device. This is the default. **Tip** To use the device's default syslog logging settings, select the Enable Logging check box, then click **Save**, without entering additional values.
Source Interface	The source address for all outgoing log messages sent to a syslog server. This setting may be necessary when the syslog server cannot respond to the address from which the log message originated (for example, due to a firewall). If you do not define a value in this field, the address of the outgoing interface is used. Enter the name of an interface or interface role, or click **Select** to select an object from a list or to create a new one.
Trap	Defines which log messages are forwarded to a syslog server: • Enable Trap—When selected, log messages are sent to the syslog server. This is the default. When deselected, log messages are not sent. • Trap Level—The lowest severity level of messages that are logged and sent to the syslog server. All messages of this severity and greater are logged. Severity levels are identified by a name and a number. For more information, see Table 905: Syslog Message Severity Levels , on page 2518. **Tip** To restore the router's default trap settings, select **Enable Trap**, then select the blank setting from the Trap Level list.

Element	Description
Logging Buffer	Defines whether log messages are saved locally to a buffer on the device. • Enable Buffer—When selected, log messages are saved to a buffer on the device. This is the default. When deselected, a log buffer is not maintained on the device. • Buffer Size—The size of the buffer in bytes. Valid values range from 4096 to 4294967295 bytes (4 kilobytes to 4 gigabytes). The default size varies by platform. Make sure not to make the buffer so large that the router runs out of memory for other tasks; otherwise, deployment might fail. **Note** The maximum buffer size might be smaller on some devices. • Severity Level—The lowest severity level of messages that are saved in the buffer. All messages of this severity and greater are saved. On most Cisco IOS routers, the default severity level is 7 (debugging). Severity levels are identified by a name and a number. For more information, see Table 905: Syslog Message Severity Levels , on page 2518. • Use XML Format—When selected, log messages are saved to a buffer in XML format. (You can configure both the regular buffer and the XML buffer in the same policy.) When deselected, an XML buffer is not maintained on the device. • Buffer Size—The size of the XML buffer in bytes. Valid values range from 4096 to 4294967295 bytes (4 kilobytes to 4 gigabytes). **Note** The maximum buffer size might be smaller on some devices. **Tip** To restore the router's default buffer settings, select **Enable Trap**, erase the buffer size setting, then select the blank setting from the Severity Level list.
Rate Limit	Limits the rate of log messages sent to the syslog server. • Enable Rate Limit—When selected, the rate limit is enabled. When deselected, the rate limit is disabled. • Messages per Sec.—The maximum number of logging messages that can be sent per second. Valid values range from 1 to 10000. The default is 10 messages per second. • Exclude—The types of messages to *exclude* from the rate limit. This setting excludes the severity level you select as well as all messages with a lower severity level number (that is, more severe). The default is 3 (errors), which excludes all log messages with a severity level of 3, 2 (critical), 1 (alerts), or 0 (emergencies) from the rate limit. For more information about severity levels, see Table 905: Syslog Message Severity Levels , on page 2518. • All Messages—When selected, the rate limit applies to all messages except console messages. • Console Messages—When selected, the rate limit applies to console messages only. **Tip** To restore the router's default rate limit settings, select the **Enable Rate Limit** check box, then erase the rate limit value setting.

Element	Description

Origin ID	The origin identifier that is added to the beginning of all syslog messages sent from this device to the remote syslog server. The origin identifier is useful in cases where you send output from multiple devices to a single syslog server.
	• ID Type—The type of origin identifier added to the beginning of each syslog message. Options are:
	  • IP Address—The IP address of the source device.
	  • Hostname—The hostname of the source device.
	  • String—User-defined text.
	• Value—Applies only when you select String as the ID type. Enter the text of the user-defined string. Spaces are permitted, except for the first character.
	Note The origin identifier is not added to messages sent to local destinations, such as the buffer, the console, and the monitor.

Syslog Servers Policy Page

Use the Syslog Servers page to create, edit, and delete servers that collect log messages from the router.

For more information, see Defining Syslog Logging Setup Parameters , on page 2516.

Note To enable logging to the syslog servers defined on this page, you must enable logging and define basic parameters on the Syslog Logging Setup Policy Page , on page 2522.

Navigation Path

- (Device view) Select **Platform** > **Logging** > **Syslog Servers** from the Policy selector.
- (Policy view) Select **Router Platform** > **Logging** > **Syslog Servers** from the Policy Type selector. Right-click **Syslog Servers** to create a policy, or select an existing policy from the Shared Policy selector.

Table 908: Syslog Server Dialog Box

Element	Description
IP Address	The IP address of the syslog server. Enter an IP address or the name of a network/host object, or click **Select** to select the object from a list or to create a new one.
Forward Messages in XML Format	When selected, log messages are sent to the syslog server in XML format. When deselected, log messages are sent to the syslog server as plain text.

NetFlow Policy Page

Use the NetFlow page to enable NetFlow recording and define its parameters on the selected Cisco IOS router.

The NetFlow page consists of two tabbed panels: Setup and Interfaces. The Setup tab provides global configuration parameters for NetFlow collection on the router. The Interfaces tab lists router interfaces for which NetFlow data collection is configured, and allows enabling and disabling ingress and egress accounting on a per-interface basis.

Note We strongly recommend that you define an NTP policy on all routers on which logging is enabled in order to create accurate timestamps for each log message. For more information, see NTP Policy Page , on page 2489.

Navigation Path

- (Device view) Select **Platform** > **Logging** > **NetFlow** from the Policy selector.
- (Policy view) Select **Router Platform** > **Logging** > **NetFlow** from the Policy Type selector. Select an existing policy from the Shared Policy selector, or right-click **NetFlow** to create a new policy.

Table 909: NetFlow Page

Element	Description
Setup tab	

Element	Description
Primary Destination Redundant Destination	The primary and secondary NetFlow collector. You must select a primary collector to enable NetFlow data collection on this device. To disable transmission of NetFlow data to either of these collectors, choose the blank entry from the drop-down list. Select whether to identify the NetFlow collector using its IP address or host name, then configure the required fields for each option: • **IP Address**—Enter the IP address of the device hosting the primary NetFlow Collection Engine. You can also specify a network/host object that specifies the IP address, or click **Select** to select the object from a list or to create a new one. In the **UDP Port** field, enter the port number monitored by the flow collector (port numbers can range from 1 to 65535). You can enter a number or the name of a port list object, or click **Select** to select an object from a list or to create a new one. • **Hostname**—Enter the fully qualified domain name of the device hosting the primary NetFlow Collection Engine. You also must specify the UDP port as you do when specifying the IP address.
Source Interface	The router interface through which flow data will be transmitted to the collector destinations. Enter an interface or interface role name, or click **Select** to select an object from a list or to create a new one.
Version	The NetFlow version number, which defines the record format to be used for flow. You can choose the blank entry to disable this option. • **1**—The original record format. No additional parameters are required. • **5**—The most widely adopted format; includes Border Gateway Protocol (BGP) autonomous system (AS) information and flow sequence numbers. If BGP is configured on your network, you can include either origin or peer AS information in the NetFlow records. Choose **origin-as** or **peer-as** from the AS Type drop-down list. You can choose the blank entry to disable this option. Check **Enable BGP Nexthop** to include BGP next hop information in the flow caches. (Note that with version 5, this information is visible in the caches, but it is not exported.) • **9**—The most-recent, template-based version; not yet fully supported. If BGP is configured on your network, you can include either origin or peer AS information in the NetFlow records. Choose **origin-as** or **peer-as** from the AS Type drop-down list. You can choose the blank entry to disable this option. Check **Enable BGP Nexthop** to include BGP next hop information in the flow records. **Note** AS information collection is resource intensive, especially for origin-as. If you are not interested in monitoring peering arrangements, disabling AS collection might improve performance.
Interfaces tab	
Interface	The names of the interfaces on which NetFlow collection is configured.

Element	Description
Enable Ingress	"Enabled" indicates flow recording is enabled on this interface for incoming traffic; "Disabled" indicates incoming traffic is not recorded for this interface.
Enable Egress	"Enabled" indicates flow recording is enabled on this interface for outgoing traffic; "Disabled" indicates outgoing traffic is not recorded for this interface.
Add Row	Click this button to open the Add NetFlow Interface Settings dialog box. Adding a NetFlow interface is described in Adding and Editing NetFlow Interface Settings , on page 2529.
Edit Row	Click this button to open the Edit NetFlow Interface Settings dialog box for the selected interface. Editing NetFlow interfaces is described in Adding and Editing NetFlow Interface Settings , on page 2529.
Delete Row	Click this button to delete the selected interface. You will be asked to confirm the deletion.

Adding and Editing NetFlow Interface Settings

Use the Add NetFlow Interface Settings and Edit NetFlow Interface Settings dialog boxes to enable and disable NetFlow ingress and egress reporting for specific router interfaces.

Note Except for their titles, these two dialog boxes are identical. The following information applies to both.

Navigation Path

Go to the NetFlow Policy Page , on page 2527, then click the **Add Row** or **Edit Row** button beneath the table.

Interface	The name of the interface or interface role. Enter a name or click **Select** to select an interface role from a list or to create a new one.
Enable Ingress Accounting	When this option is selected, NetFlow records are collected for traffic arriving on this interface. Deselect this option to halt data collection on this interface for incoming traffic.

Element	Description
Enable Egress Accounting	When this option is selected, NetFlow records are collected for traffic departing from this interface. Deselect this option to halt data collection on this interface for outgoing traffic.

CHAPTER 66

Configuring Quality of Service

Cisco Security Manager supports the management and configuration of security services and other platform-specific services on Cisco Catalyst switches and Cisco 7600 Series routers.

You can manage Catalyst switches and 7600 devices configured in VTP transparent or VTP client/server mode. Security Manager manages switches configured in client/server mode by bypassing VLAN database management on the device (including VLAN creation, deletion, and monitoring VLANs in the VLAN database on switches).

This chapter contains the following topics

Quality of Service on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Quality of service (QoS) refers to the ability of a network to provide priority service to selected network traffic over various underlying technologies, including Frame Relay, ATM, Ethernet and 802.1 networks, SONET, and IP-routed networks. QoS features enhance the predictability of network service by:

- Supporting dedicated bandwidth.
- Improving loss characteristics.
- Avoiding and managing network congestion.
- Shaping network traffic.
- Setting traffic priorities across the network.

QoS is generally used at entry points to service providers, as well as at consolidation points where multiple lines converge. QoS is also useful where speed mismatches occur (for example, at the boundary between a WAN and a LAN), as these places are often traffic congestion points.

QoS policies in Security Manager are based on the Cisco Systems Modular QoS CLI (MQC). MQC standardizes the CLI and semantics for QoS features across all platforms supported by Cisco IOS software, which provides

a modular and highly extensible framework for deploying QoS. Security Manager provides an easy-to-use interface for MQC that concentrates key QoS features inside a single dialog box, streamlining the creation of QoS policies for selected traffic entering and leaving the router.

For a description of the procedure for defining a QoS policy in Security Manager, see Defining QoS Policies , on page 2541.

Quality of Service and CEF

Cisco Express Forwarding (CEF) is an advanced Layer 3 IP switching technology that optimizes network performance and scalability for all kinds of networks. It defines the fastest method by which a Cisco IOS router forwards packets from ingress to egress interfaces.

Certain QoS features configurable in Security Manager, such as Class-Based Policing and Class-Based Weighted Random Early Detection, are supported only on routers that run CEF. All routers from the Cisco 800 Series to the Cisco 7200 Series require CEF for these QoS features; the Cisco 7500 Series requires distributed CEF (dCEF).

Note For a complete list, see *When is CEF Required for Quality of Service* on Cisco.com at this URL: http://www.cisco.com/en/US/tech/tk39/tk824/technologies_tech_note09186a0080094978.shtml

By default, CEF is enabled as part of the router's initial configuration. To verify whether CEF is enabled on your router, use the **show ip cef** command. You can configure CEF using the CEF interface settings policy (see CEF Interface Settings on Cisco IOS Routers , on page 2330). Be aware, however, that if your router does not have CEF enabled, activating CEF could have a significant impact on your router's packet streaming. Consult your router documentation before enabling CEF.

Understanding Matching Parameters

You define matching parameters by identifying the traffic on which QoS is performed, that is, classifying the interesting packets. Various classification tools are available, including protocol type, IP precedence (IPP) value, Differentiated Service Code Point (DSCP) value, and ACLs.

Traffic classes consist of a series of match criteria and a means of evaluating these criteria. For example, you might define a class with matching criteria based on several specified protocols and a DSCP value. You can

then specify that a packet must match only one of these defined criteria to be considered part of this class. Your other option is to specify that packets must match all defined criteria considered part of the traffic class.

Packets that are members of a defined traffic class are forwarded according to the QoS specifications that you defined in the policy map. Packets that fail to meet any of the matching criteria are classified as members of the default traffic class.

For information about defining matching parameters in a QoS policy, see Defining QoS Class Matching Parameters , on page 2544.

Related Topics

Understanding Marking Parameters

Marking parameters enable you to classify packets, which entails using a traffic descriptor to categorize a packet within a specific group. This defines the packet and makes it accessible for QoS handling on the network. Both traffic policers and traffic shapers use the packet classification to ensure adherence to the contracted level of service agreed upon between the source and your network. Additionally, marking parameters enable you to take packets that might have arrived at the device with one QoS classification and reclassify them. Downstream devices use this new classification to identify the packets and apply the appropriate QoS functions to them.

Security Manager uses two types of marking for IPv4 packets—one based on IPP classes and one based on DSCP values. IPP is based on the three most significant bits in the Type of Service (ToS) byte of each packet, which means you can partition traffic into eight classes. For historical reasons, each precedence value corresponds with a name, as defined in RFC 791. Table 911: IP Precedence Classes , on page 2533 lists the numbers and their corresponding names, from least to most important.

Table 911: IP Precedence Classes

Class	Name
0	routine
1	priority
2	immediate
3	flash
4	flash-override
5	critical
6	internet
7	network

Note Classes 6 and 7 are generally reserved for network control information, such as routing updates.

DSCP is based on the six most significant bits in the ToS byte (the remaining two bits are used for flow control), with values ranging from 0 to 63. The DSCP bits contains the IPP bits, which makes DSCP backward-compatible with IPP.

Marking is generally used on devices that are close to the network edge or administrative domain so that subsequent devices can provide service based on the classification mark.

For information about defining marking parameters in a QoS policy, see Defining QoS Class Marking Parameters , on page 2546.

Related Topics

- Understanding Policing and Shaping Parameters , on page 2537
- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Understanding Queuing Parameters

Queuing manages congestion on traffic leaving a Cisco IOS router by determining the order in which to send packets out over an interface, based on priorities you assign to those packets. Queuing makes it possible to prioritize traffic to satisfy time-critical applications, such as desktop video conferencing, while still addressing the needs of less time-dependent applications, such as file transfer.

During periods of light traffic, that is, when no congestion exists, packets are sent out as soon as they arrive at an interface. However, during periods of transmission congestion at the outgoing interface, packets arrive faster than the interface can send them. By using congestion management features such as queuing, packets accumulating at the interface are queued until the interface is free to send them. They are then scheduled for transmission according to their assigned priority and the queuing mechanism configured for the interface. The router determines the order of packet transmission by controlling which packets are placed in which queue and how queues are serviced with respect to one another.

Security Manager uses a form of queuing called Class-Based Weighted Fair Queuing (CBWFQ). With CBWFQ, you define traffic classes based on match criteria. Packets matching the criteria constitute the traffic for this class. A queue is reserved for each class, containing the traffic belonging to that class. You assign characteristics to queues, such as the bandwidth (fixed or minimum) assigned to it and the queue limit, which is the maximum number of packets allowed to accumulate in the queue.

When you use CBWFQ, the sum of all bandwidth allocation on an interface cannot exceed 75 percent of the total available interface bandwidth. The remaining 25 percent is used for other overhead, including Layer 2 overhead, routing traffic, and best-effort traffic. Bandwidth for the CBWFQ default class, for instance, is taken from the remaining 25 percent.

For more information about queuing, see:

- Tail Drop vs. WRED , on page 2535
- Low-Latency Queuing , on page 2536

- Default Class Queuing , on page 2536

For information about defining queuing parameters in a QoS policy, see Defining QoS Class Queuing Parameters , on page 2546.

Related Topics

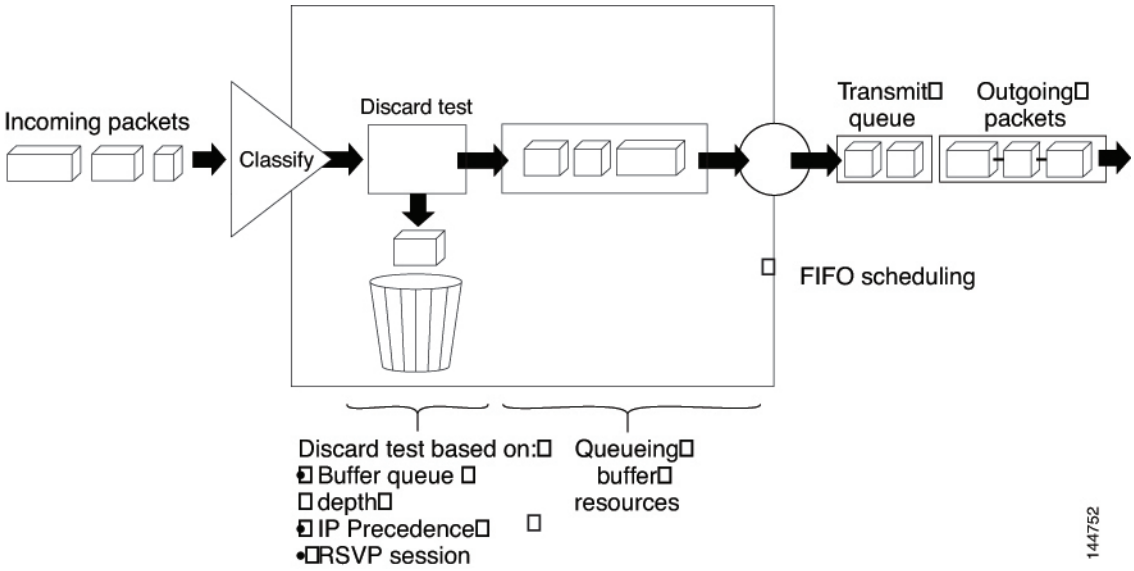
- Understanding Marking Parameters , on page 2533
- Understanding Policing and Shaping Parameters , on page 2537
- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Tail Drop vs. WRED

After a queue reaches its configured queue limit, the arrival of additional packets causes tail drop or packet drop to take effect, depending on how you configured the QoS policy. Tail drop, which is the default response, treats all traffic equally and does not differentiate between different classes of service. When tail drop is in effect, packets are dropped from full queues until the congestion is eliminated and the queue is no longer full. This often leads to global synchronization, in which a period of congestion is followed by a period of underutilization, as multiple TCP hosts reduce their transmission rates simultaneously.

A more sophisticated approach to managing queue congestion is offered by Cisco's implementation of Random Early Detection, called Weighted Random Early Detection, or WRED. As shown in Figure 54: Weighted Random Early Detection, on page 2535, WRED reduces the chances of tail drop by selectively dropping packets when the output interface begins to show signs of congestion. By dropping some packets early instead of waiting until the queue is full, WRED avoids dropping large numbers of packets at once and allows the transmission line to be used fully at all times.

Figure 54: Weighted Random Early Detection



WRED is useful only when the bulk of the traffic is TCP/IP traffic, because TCP hosts reduce their transmission rate in response to congestion. With other protocols, packet sources might not respond, or might resend dropped packets at the same rate. As a result, dropping packets does not decrease congestion.

Note WRED treats non-IP traffic as precedence 0, the lowest precedence value. Therefore, non-IP traffic is more likely to be dropped than IP traffic.

Related Topics

- Low-Latency Queuing , on page 2536
- Default Class Queuing , on page 2536
- Understanding Queuing Parameters , on page 2534

Low-Latency Queuing

The low-latency queuing (LLQ) feature brings strict priority queuing to CBWFQ. Strict priority queuing gives delay-sensitive data, such as voice traffic, preference over other traffic.

Note Although it is possible to assign various types of real-time traffic to the strict priority queue, we strongly recommend that you direct only voice traffic to it.

LLQ defines the maximum bandwidth that you can allocate to priority traffic during times of congestion. Setting a maximum ensures that nonpriority traffic does not starve (meaning that this traffic is also provided with bandwidth). When the device is not congested, the priority class traffic is allowed to exceed its allocated bandwidth. Policing drops packets from the priority queue; therefore, neither WRED nor tail drop (as configured in the Queue Limit field) is used.

When LLQ is not used, CBWFQ provides weighted fair queuing based on defined classes, with no strict priority queue available for real-time traffic.

Related Topics

- Default Class Queuing , on page 2536
- Understanding Queuing Parameters , on page 2534

Default Class Queuing

You use the Fair Queue field to define the number of dynamic queues that should be reserved for the default class to use. This is the class to which traffic that does not satisfy the match criteria of other classes is directed. By default, the number of queues that are created is based on the interface bandwidth.

Table 912: Default Number of Queues for Default Class , on page 2537 lists the default number of dynamic queues that CBWFQ uses when it is enabled on an interface:

Table 912: Default Number of Queues for Default Class

Bandwidth Range	Number of Dynamic Queues
Less than or equal to 64 kbps	16
More than 64 kbps and less than or equal to 128 kbps	32
More than 128 kbps and less than or equal to 256 kbps	64
More than 256 kbps and less than or equal to 512 kbps	128
More than 512 kbps	256

Understanding Policing and Shaping Parameters

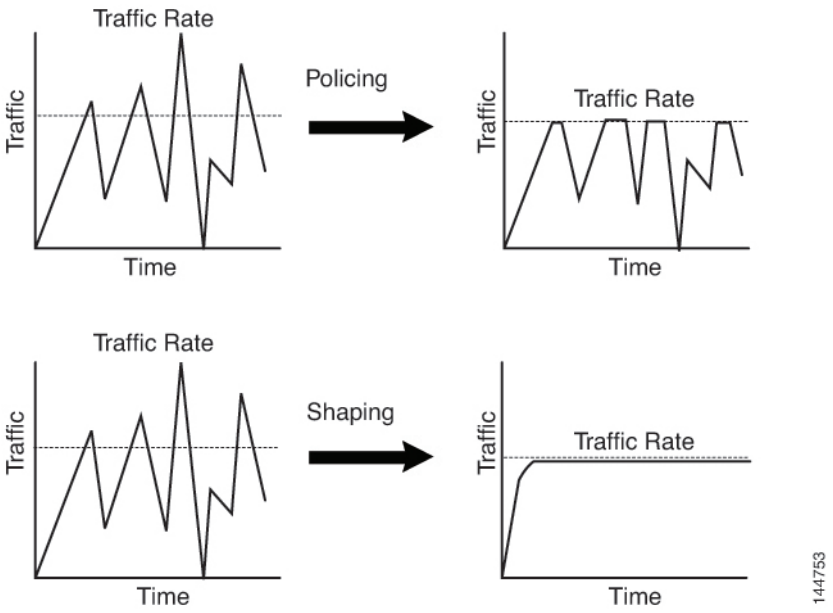
Security Manager offers two kinds of traffic regulation mechanisms:

- The rate-limiting feature of Class-Based Policing for policing traffic. Policing limits traffic flow to a configured rate. Policing can be performed on a selected interface or on the control plane. See Understanding Control Plane Policing , on page 2540.
- Distributed Traffic Shaping (DTS) for shaping traffic. Traffic shaping enables you to control the traffic leaving an interface (output traffic) in order to match its flow to the speed of the remote target interface and to ensure that the traffic conforms to the policies defined for it. By shaping traffic to meet downstream requirements, you can eliminate bottlenecks in topologies with data-rate mismatches. Shaping can either be performed on selected QoS classes or at the interface level (hierarchical shaping).

Both policing and shaping mechanisms use the traffic descriptor for a packet—indicated by the classification of the packet (see Understanding Marking Parameters , on page 2533)—to ensure adherence to the agreed upon level of service. Although policers and shapers usually identify traffic descriptor violations in the same way, they differ in the way they respond to violations, as shown in Figure 55: Traffic Policing vs. Traffic Shaping, on page 2538:

- A policer typically drops excess traffic. In other cases, it transmits the traffic with a different (usually lower) priority.
- A shaper typically delays excess traffic using a buffer, or queuing mechanism, to hold packets and shape the flow when the data rate of the source is later than expected.

Figure 55: Traffic Policing vs. Traffic Shaping



For information about defining policing and shaping parameters in a QoS policy, see Defining QoS Class Policing Parameters , on page 2548 and Defining QoS Class Shaping Parameters , on page 2549.

Understanding the Token-Bucket Mechanism

Both policing and shaping use a token-bucket mechanism to regulate data flow. A token bucket is a formal definition of a rate of transfer. It has three components: a burst size, a mean rate, and a time interval (Tc). Any two values may be derived from the third using this formula:

mean rate = burst size / time interval

These terms are defined as follows:

- Mean rate—Also called the committed information rate (CIR), it specifies how much data can be sent or forwarded per unit time on average. The CIR is defined either as an absolute value or as a percentage of the available bandwidth on the interface. When defined as a percentage, the equivalent value in bits per second (bps) is calculated after deployment based on the interface bandwidth and the percent value defined in the policy.

Note If the interface bandwidth changes (for example, more bandwidth is added), the bps value of the CIR is recalculated based on the revised amount of bandwidth.

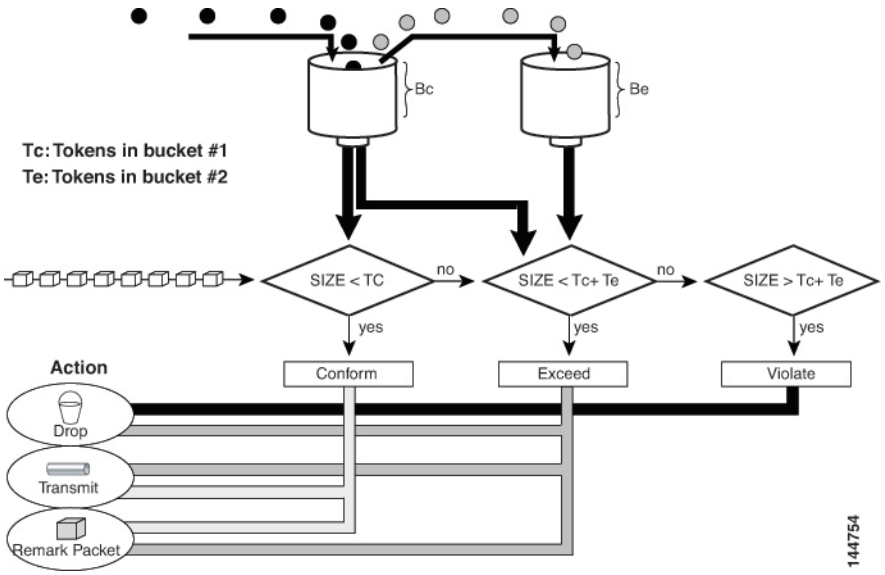
- Burst size—Also called the committed burst (Bc) size, it specifies for each burst how much data can be sent within a given time without creating scheduling concerns. When you use percentages to calculate the CIR, burst size is measured in milliseconds.
- Time interval—Also called the measurement interval, it specifies the amount of time in seconds per burst. Over any integral multiple of this interval, the bit rate of the interface does not exceed the mean rate. The bit rate, however, might be arbitrarily fast within the interval.

In the token-bucket metaphor, tokens are put into the bucket at a certain rate. These tokens represent permission for the source to send a certain number of bits into the network. To send a packet, the regulator (policer or shaper) must remove a number of tokens from the bucket that equals the packet size.

Security Manager uses a two-bucket algorithm, as shown in Figure 56: Two-Token Bucket Algorithm, on page 2539. The first bucket is the conform bucket and the second bucket is the exceed bucket. The full size of the conform bucket is the number of bytes specified as the normal burst size. The full size of the exceed bucket is the number of bytes specified in the maximum burst size. Both buckets are initially full, and they are updated based on the token arrival rate, which is determined by the CIR. If the number of bytes in the arriving packet is less than the number of bytes in the conform bucket, the packet conforms. The required number of tokens are removed from the conform bucket and the defined conform action is taken (for example, the packet is transmitted). The exceed bucket is unaffected.

If the conform bucket does not contain sufficient tokens, the excess token bucket is checked against the number of bytes in the packet. If enough tokens are present in the two buckets combined, the exceed action is taken on the packet and the required number of bytes are removed from each bucket. If the exceed bucket contains an insufficient number of bytes, the packet is in violation of the burst limits and the violate action is taken on the packet.

Figure 56: Two-Token Bucket Algorithm



When you use traffic policing, the token-bucket algorithm provides three actions for each packet: a conform action, an exceed action, and an optional violate action. For instance, packets that conform can be configured to be transmitted, packets that exceed can be configured to be sent with a decreased priority, and packets that violate can be configured to be dropped.

Traffic policing is often configured on interfaces at the edge of a network to limit the rate of traffic entering or leaving the network. In the most common traffic policing configurations, traffic that conforms is transmitted and traffic that exceeds is sent with a decreased priority or is dropped. You can change these configuration options to suit your network needs.

When you use traffic shaping, the token-bucket mechanism includes a data buffer for holding packets that cannot be sent immediately. (Policers do not have such a buffer.) The token buckets permit packets to be sent in bursts, but places bounds on this capability so that the flow is never faster than the capacity of the buckets plus the time interval multiplied by the refill rate. The buffer also guarantees that the long-term transmission rate does not exceed the CIR.

Understanding Control Plane Policing

The Control Plane Policing feature enables you to manage input traffic entering the control plane (CP) of the router. The CP is a collection of processes that run at the process level on the route processor. These processes collectively provide high-level control for most Cisco IOS functions. Control plane policing protects the CP of Cisco IOS routers and switches against reconnaissance and denial-of-service (DoS) attacks, enabling the CP to maintain packet forwarding and protocol states despite an attack or heavy traffic load on the router or switch.

The Control Plane Policing feature treats the CP as a separate entity with its own ingress (input) and egress (output) ports, enabling you to use Security Manager to configure QoS policies on input. These policies are applied when a packet enters the CP. You can configure a QoS policy to prevent unwanted packets from progressing after a specified rate limit is reached. For example, a system administrator can limit all TCP/SYN packets that are destined for the CP to a maximum rate of 1 megabit per second. Additional packets beyond this limit are silently discarded.

The following types of Layer 3 packets are forwarded to the CP and processed by aggregate control plane policing:

- Routing protocol control packets
- Packets destined for the local IP address of the router
- Packets from management protocols, such as SNMP, Telnet, and secure shell (SSH).

Note Support for output policing is available only in Cisco IOS Release 12.3(4)T and later T-train releases.

For information about how to define Control Plane Policing, see Defining QoS on the Control Plane , on page 2543. For more information about this feature, refer to the document, *Control Plane Policing* on Cisco.com at this URL:

http://www.cisco.com/en/US/docs/ios/qos/configuration/guide/ctrl_plane_policng.html

Defining QoS Policies

When you define QoS policies, you must first decide whether to configure the policy on specific interfaces or on the control plane. This initial choice determines how you configure the rest of the policy, as described in the following topics:

- Defining QoS on Interfaces , on page 2541
- Defining QoS on the Control Plane , on page 2543

Note If you define a QoS policy on both the interfaces and the control plane of the same device, only the control plane configuration is deployed.

Related Topics

- Quality of Service on Cisco IOS Routers , on page 2531

Defining QoS on Interfaces

You can create multiple QoS interface definitions, each of which applies to either input traffic (entering the router) or output traffic (exiting the router).

When you create a QoS interface definition on output traffic, you have the option of configuring hierarchical shaping on the interface as a whole instead of configuring shaping on individual QoS classes.

After you create your interface definitions, you must define one or more QoS classes on each interface. QoS classes contain the matching criteria that determine which packets are included in the class and the QoS functions (marking, queuing, policing, and shaping) to apply to that traffic. You can configure each interface (or interface role) with up to 16 QoS classes, each containing its own set of matching criteria and a defined set of QoS functions to apply to the traffic in that class.

For each interface, we recommend that for each interface you define at least one QoS class and a default class. If you do not configure a default class, packets that do not match the criteria of the other defined classes are treated as members of a default class that has no configured QoS functionality. Packets assigned to this class are placed in a simple first-in first-out (FIFO) queue, and are forwarded at a rate determined by the available underlying link bandwidth. This FIFO queue is managed by tail drop, which avoids congestion by dropping packets from the queue until it is no longer full.

Note QoS is applied to packets on a first-match basis. The router examines the table of QoS classes starting from the top and applies the properties of the first class whose matching criteria matches the packet. Therefore, it is important that you define and order your classes carefully. The default class should be placed last to prevent traffic that matches a specific class from being treated as unmatched traffic.

Before You Begin

Ensure that Cisco Express Forwarding (CEF) is enabled on the router. For more information, see CEF Interface Settings on Cisco IOS Routers , on page 2330.

Related Topics

- Defining QoS Policies , on page 2541
- Defining QoS on the Control Plane , on page 2543
- Quality of Service on Cisco IOS Routers , on page 2531

Step 1 Do one of the following:

- (Device view) Select **Platform > Quality of Service** from the Policy selector.
- (Policy view) Select **Router Platform > Quality of Service** from the Policy Type selector. Select an existing policy or create a new one.

The Quality of Service page is displayed. See <Table 913: Quality of Service Page , on page 2551 for a description of the fields on this page.

Step 2 In the Applied to field, select **Interfaces** to define QoS parameters for specific interfaces on the selected router.

Step 3 Click the **Add** button under the upper table to display the QoS Policy dialog box. See Table 914: QoS Policy Dialog Box , on page 2552 for a description of the fields in this dialog box.

Step 4 In the Interface field, enter the name of an interface or interface role, or click **Select** to display a selector.

Tip If the interface role you want is not listed in the selector, click the **Create** button or the **Edit** button to open the Interface Role Dialog Box , on page 305. From here you can define an interface role to use in the policy.

Step 5 Select the traffic direction on which you want to apply the QoS definition, Output (traffic exiting the interface) or Input (traffic entering the interface). Queuing and shaping can be applied only to output traffic.

Step 6 (Optional) Define interface-level (hierarchical) shaping parameters. See Table 914: QoS Policy Dialog Box , on page 2552 for details.

Note When you enable hierarchical shaping on an interface, you cannot define shaping parameters for specific QoS classes. Shaping can be used only on output traffic. See Understanding Policing and Shaping Parameters , on page 2537 for more information about shaping.

Step 7 Click **OK**. The QoS interface definition is displayed in the upper table of the Quality of Service page.

Note To edit a QoS interface definition, select an interface from the upper table, then click the **Edit** button. To remove an interface definition, select it from the table, then click the **Delete** button. You cannot delete an interface that has defined classes.

Step 8 With the interface selected in the upper table, click the **Add** button beneath the QoS Classes table. The QoS Class dialog box is displayed. See Table 915: QoS Class Dialog Box , on page 2555 for a description of the fields in this dialog box.

The QoS Class dialog box enables you to determine which traffic over the selected interface is included in the QoS class and how to handle that traffic.

Step 9 (Optional) Select the **Default class** check box if you are defining the properties of the default QoS class for this interface. The default class is assigned to all traffic that does not match the criteria of the other defined classes.

Step 10 Define the QoS class using one or more tabs in the QoS Class dialog box, as described in:

- Defining QoS Class Matching Parameters , on page 2544
- Defining QoS Class Marking Parameters , on page 2546
- Defining QoS Class Queuing Parameters , on page 2546
- Defining QoS Class Policing Parameters , on page 2548
- Defining QoS Class Shaping Parameters , on page 2549

Step 11 Repeat Step 8, on page 2543 through Step 10, on page 2543 to add QoS classes to the interface defined in Step 3, on page 2542. If required, use the **Up Row** and **Down Row** buttons to reorder the classes.

Note To edit a QoS class, select the relevant interface from the upper table to display its defined classes in the QoS Class table. Select the class to edit, then click the **Edit** button. To remove a class, select it from the table, then click the **Delete** button.

Step 12 Repeat Step 3, on page 2542 through Step 11, on page 2543 to define QoS classes for a different interface on the selected router.

Defining QoS on the Control Plane

When you configure QoS on input traffic entering the control plane, you can define multiple QoS classes, including a default class for traffic that does not match the criteria you define for the other classes. After defining the matching criteria for a particular class, you can configure a policing definition for that class. (Marking, queuing, and shaping are not available.) For more information, see Understanding Control Plane Policing , on page 2540.

QoS policies defined on the control plane override any QoS parameters defined on an interface of the same device.

Note QoS is applied to packets on a first-match basis. The router examines the table of QoS classes starting from the top and applies the properties of the first class whose matching criteria matches the packet. Therefore, it is important that you define and order your classes carefully. The default class should be placed last to prevent traffic that matches a specific class from being treated as unmatched traffic.

Before You Begin

Ensure that Cisco Express Forwarding (CEF) is enabled on the router. For more information, see CEF Interface Settings on Cisco IOS Routers , on page 2330.

Related Topics

- Defining QoS Policies , on page 2541
- Defining QoS on Interfaces , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Quality of Service** from the Policy selector.
- (Policy view) Select **Router Platform** > **Quality of Service** from the Policy Type selector. Select an existing policy or create a new one.

The Quality of Service page is displayed. See Table 913: Quality of Service Page , on page 2551 for a description of the fields on this page.

Step 2 In the Applied to field, select **Control Plane** to define QoS policing on input traffic entering the control plane.

Step 3 Click the **Add** button beneath the Control Plane QoS Classes table. The QoS Class dialog box is displayed. See Table 915: QoS Class Dialog Box , on page 2555 for a description of the fields in this dialog box.

The QoS Class dialog box enables you to determine which traffic over the selected interface is included in the QoS class and how to handle that traffic.

Step 4 (Optional) Select the **Default class** check box if you are defining the properties of the default QoS class for the control plane. The default class is assigned to all traffic that does not match the criteria of the other defined classes.

Step 5 Define the QoS class using the tabs in the QoS Class dialog box, as described in the following sections:

- Defining QoS Class Matching Parameters , on page 2544
- Defining QoS Class Policing Parameters , on page 2548

Step 6 Repeat Step 3, on page 2544 through Step 5, on page 2544 to add QoS classes to the control plane. If required, use the **Up Row** and **Down Row** buttons to reorder the classes.

Defining QoS Class Matching Parameters

When you define matching parameters, you must define matching criteria and specify whether packets must meet one or all of the criteria to be considered part of the class. See Understanding Matching Parameters , on page 2532 for more information.

Note You do not define matching parameters when configuring the default class.

Related Topics

- Defining QoS Class Marking Parameters , on page 2546

- Defining QoS Class Policing Parameters , on page 2548
- Defining QoS Class Shaping Parameters , on page 2549

- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Step 1 On the Quality of Service page, click the **Add** button beneath the QoS Classes table, or select a class and then click the **Edit** button. The QoS Class dialog box is displayed.

Step 2 Click the **Matching** tab. SeeTable 915: QoS Class Dialog Box , on page 2555 for a description of the fields on this tab.

Step 3 Select a matching method:

- Any—Traffic matching any of the defined parameters is included in this class.
- All—Only traffic matching all of the defined parameters is included in this class.

Step 4 (Optional) Under Protocol, click **Add** to display a selector for choosing the protocols to include in this class. Select one or more items from the Available Protocols list, then click >> to add them to the Selected Protocols list.

Note When configuring QoS on the control plane, only the ARP protocol can be selected.

When you finish, click **OK** to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the Protocol field.

Step 5 (Optional) Under Precedence, click **Add** to display a selector for choosing which IP precedence values (from 0 to 7) to include in this class. Select one or more items from the Available Precedences list, then click >> to add them to the Selected Precedences list. Traffic that arrives marked with one of these values matches this criterion.

Note For more information about IP precedence values, see Table 911: IP Precedence Classes , on page 2533.

When you finish, click **OK** to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the Precedences field.

Step 6 (Optional) Under DSCP, click **Add** to display a selector for choosing which DSCP values (from 0 to 63) to include in this class. Select one or more items (up to eight) from the Available DSCPs list, then click >> to add them to the Selected DSCPs list. Traffic that arrives marked with one of these values matches this criterion.

When you finish, click **OK** to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the DSCP field.

Step 7 (Optional) Under ACL, define ACLs as part of the matching criteria for this class:

a) Click **Edit** to display the Edit ACLs dialog box. Use this dialog box to define which ACLs to include in this class.
b) Enter one or more ACLs, or click **Select** to select an ACL object from a list or to create a new one. Traffic that matches these ACL definitions matches this criterion.
c) When you finish, click **OK** twice to save your definitions and return to the QoS Class dialog box. Your selections are displayed in the ACL field.

Tip Use the up and down arrows to order the ACLs. We recommend placing more frequently used ACLs at the top of the list to optimize the matching process.

Step 8 Go to another tab or click **OK** to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 9 Do one of the following:

- When defining QoS on interfaces, continue as described in Defining QoS on Interfaces , on page 2541.

- When defining control plane policing, continue as described in Defining QoS on the Control Plane , on page 2543.

Defining QoS Class Marking Parameters

When you define marking parameters, you can mark the packets in this QoS class with either a precedence value or a DSCP value. See Understanding Marking Parameters , on page 2533 for more information.

Note Marking is not available when you configure QoS on the control plane.

Related Topics

- Defining QoS Class Matching Parameters , on page 2544

- Defining QoS Class Policing Parameters , on page 2548
- Defining QoS Class Shaping Parameters , on page 2549
- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Step 1 On the Quality of Service page, click the **Add** button beneath the QoS Classes table, or select a class and then click the **Edit** button. The QoS Class dialog box is displayed.

Step 2 Click the **Marking** tab. See Table 917: QoS Class Dialog Box—Marking Tab , on page 2558 for a description of the fields on this tab.

Step 3 Select the **Enable Marking** check box.

Step 4 Select one of the following marking options:

- Precedence—Select an IP precedence value (0 to 7) from the displayed list. For more information about these values, see Table 911: IP Precedence Classes , on page 2533.
- DSCP—Select a DSCP value (0 to 63) from the displayed list.

Step 5 Go to another tab or click **OK** to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 6 Continue as described in Defining QoS Policies , on page 2541.

Defining QoS Class Queuing Parameters

When you define queuing parameters, you can specify the amount of available bandwidth to provide to the traffic in this QoS class. You can also define a fixed amount of bandwidth that must be provided to high-priority traffic; you can define the priority parameter on only one class per interface. In addition, you must specify the type of queue management to perform on this class. See Understanding Queuing Parameters , on page 2534 for more information.

Note Queuing is not available when you configure QoS on the control plane.

Related Topics

- Defining QoS Class Matching Parameters , on page 2544
- Defining QoS Class Marking Parameters , on page 2546
- Defining QoS Class Policing Parameters , on page 2548
- Defining QoS Class Shaping Parameters , on page 2549
- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Step 1 On the Quality of Service page, click the **Add** button beneath the QoS Classes table, or select a class and then click the **Edit** button. The QoS Class dialog box is displayed.

Step 2 Click the **Queuing and Congestion Avoidance** tab. See Table 918: QoS Class Dialog Box—Queuing and Congestion Avoidance Tab , on page 2559 for a description of the fields on this tab.

Step 3 Click the **Enable Queuing and Congestion Avoidance** check box.

Queuing options depend on whether you are defining the default class or a different class:

- When you define any class other than the default class, select one of the following queuing options:
  - Priority—Define the amount of bandwidth to make available to high-priority traffic. Low-Latency Queuing , on page 2536 (LLQ) ensures that this traffic receives this fixed amount of bandwidth at all times. This is particularly useful for voice traffic, which requires low latency. You can define this amount by percentage or by an absolute value of kilobits per second.

Note You can define this option for only one class per interface.

- • Bandwidth—Enter the amount of bandwidth to allocate to this class. You can define this amount by percentage or by an absolute value of kilobits per second.

Note The sum of all class bandwidth allocations on an interface cannot exceed 100 percent of the total available bandwidth.

- When you define the default class, select one of the following queuing options:
  - Fair queue—Enter the number of queues to reserve for the default class. Values range in powers of 2 from 16 to 4096. By default, the number of queues is based on the available bandwidth of the selected interface. For more information, see Table 912: Default Number of Queues for Default Class , on page 2537.
  - Bandwidth—Enter the amount of bandwidth to allocate to this class. You can define this amount by percentage or by an absolute value of kilobits per second.

Step 4 (Optional) Define *one* of the following queue length management options:

- Queue Limit—(Default) Specify the maximum number of packets allowed. If you select this option, tail drop drops excess packets when the queue reaches its capacity.
- WRED Weight for Mean Queue Depth—WRED proactively drops packets until the transmitting protocol (usually TCP) responds by dropping its transmission rate, thereby alleviating congestion. Configure WRED by entering an exponential weight factor that is used to calculate the average queue size.

For more information, see Tail Drop vs. WRED , on page 2535.

Note You should change the default only if you are certain that your applications will benefit from a different value.

Note Do not use WRED with protocols that are not sufficiently robust to reduce their transmission rates in response to packet loss, such as IPX or AppleTalk. WRED cannot be configured when you select the Priority percent option.

Step 5 Go to another tab or click **OK** to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 6 Continue as described in Defining QoS Policies , on page 2541.

Defining QoS Class Policing Parameters

When you define policing parameters, you must specify the average data rate, which determines the amount of traffic that can be transmitted. In addition, you must specify the action to take on traffic bursts that exceed this data rate.

You can configure policing for all QoS classes, including the default class. For more information about policing, see Understanding Policing and Shaping Parameters , on page 2537.

You can also configure policing on the control plane. For more information, see Understanding Control Plane Policing , on page 2540.

Related Topics

- Defining QoS Class Matching Parameters , on page 2544
- Defining QoS Class Marking Parameters , on page 2546
- Defining QoS Class Queuing Parameters , on page 2546
- Defining QoS Class Shaping Parameters , on page 2549
- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Step 1 On the Quality of Service page, click the **Add** button beneath the QoS Classes table, or select a class and then click the **Edit** button. The QoS Class dialog box is displayed.

Step 2 Click the **Policing** tab. See Table 915: QoS Class Dialog Box , on page 2555 for a description of the fields on this tab.

Step 3 Select the **Enable Policing** check box.

Step 4 Define CIR, confirm burst, and excess burst values. You can define the CIR by percentage or by an absolute value of bits per second. The option you choose determines how you define the burst values.

Step 5 Select the action to perform on packets that conform to the rate limit:

- transmit—Transmit the packet.
- set-prec-transmit—Set the IP precedence to a defined value, then send the packet. This option is not available when configuring QoS on the control plane.
- set-dscp-transmit—Set the DSCP to a defined value, then send the packet. This option is not available when configuring QoS on the control plane.
- drop—Drop the packet.

Step 6 Select the action to perform on exceed packets. The list of available actions depends on the selected conform action.

For example, if transmit is performed on conforming packets, you can select any of the actions listed in Step 5, on page 2548 for exceeding packets. However, if you selected one of the set actions for conforming packets, you can select only a set action or the drop action for exceeding packets. If you selected drop as the conform action, you must select drop as the exceed action.

Step 7 Select the action to perform on violate packets. The list of available actions depends on the selected exceed action.

For example, if transmit is performed on exceeding packets, you can select any of the actions listed in Step 5, on page 2548 for violating packets. However, if you selected one of the set actions for exceeding packets, you can select only a set action or the drop action for violating packets. If you selected drop as the exceed action, you must select drop as the violate action.

Step 8 Go to another tab, or click **OK** to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 9 Do one of the following:

- When defining QoS on interfaces, continue as described in Defining QoS Policies , on page 2541.
- When defining control plane policing, continue as described in Defining QoS on the Control Plane , on page 2543.

Defining QoS Class Shaping Parameters

When you define shaping parameters, you must specify whether to base traffic shaping on the average data rate or on the average data rate plus the excess burst rate that occurs during traffic peaks. In both cases, traffic that exceeds these definitions is buffered until the rate lowers, allowing the packets to be sent.

The following conditions pertain:

- Shaping can be used only on output traffic.
- Shaping can be configured for all QoS classes, including the default class.
- Shaping is not available when you configure the QoS class for priority traffic.
- Shaping is not available when you configure QoS on the control plane.

For more information about shaping, see Understanding Policing and Shaping Parameters , on page 2537.

Tip To configure shaping on all the QoS classes defined for the interface (hierarchical shaping), see Defining QoS on Interfaces , on page 2541.

Related Topics

- Defining QoS Class Matching Parameters , on page 2544

- Defining QoS Class Policing Parameters , on page 2548
- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531

Step 1 On the Quality of Service page, click the **Add** button beneath the QoS Classes table, or select a class and then click the **Edit** button. The QoS Class dialog box is displayed.

Step 2 Click the **Shaping** tab. See Table 920: QoS Class Dialog Box—ShapingTab, on page 2563 for a description of the fields on this tab.

Step 3 Select the **Enable Shaping** check box.

Step 4 Select the shaping type (Average or Peak).

Step 5 Define CIR, sustained burst, and excess burst values. You can define the CIR by percentage or by an absolute value of bits per second. The option you choose determines how you define the burst values.

Step 6 Proceed to another tab or click **OK** to save your definitions locally on the client and close the dialog box. The defined class is displayed in the QoS Classes table on the Quality of Service page.

Step 7 Continue as described in Defining QoS Policies , on page 2541.

Quality of Service Policy Page

Use the Quality of Service page to view, create, and edit QoS classes on specific interfaces of the selected device or on the control plane. QoS policies enable you to define techniques for managing the delay, delay variation (jitter), bandwidth, and packet loss parameters on a network. In addition, you can use the Quality of Service page to configure hierarchical shaping on an interface as an alternative to configuring shaping parameters for individual QoS classes.

For more information, see Quality of Service on Cisco IOS Routers , on page 2531.

Navigation Path

- (Device view) Select **Platform > Quality of Service** from the Policy selector.
- (Policy view) Select **Router Platform > Quality of Service** from the Policy Type selector. Create a new policy or select an existing policy from the Shared Policy selector.

Related Topics

- Defining QoS Policies , on page 2541
- Table Columns and Column Heading Features , on page 51
- Filtering Tables , on page 50

Field Reference

Table 913: Quality of Service Page

Element	Description
Apply To	The router component on which to define the QoS policy: • Interfaces—Configures QoS classes on specific interfaces. • Control Plane—Configures QoS on the router control plane. See Understanding Control Plane Policing , on page 2540. **Note** If you configure QoS on both the interfaces and the control plane of the same device, only the control plane configuration is deployed.
Interface Table	If you are defining classes on interfaces, the upper table lists the interfaces on which you are defining QoS classes. The direction column indicates the direction of traffic through the interface to which the classes apply (Output or Input). The classes you can define vary based on the direction. The other fields indicate whether you defined shaping on the interface, and if shaping is defined, the type of hierarchical shaping (average or peak), the committed information rate (CIR), and the sustained and excess burst size. For detailed information about the attributes, see QoS Policy Dialog Box , on page 2552 . • To add an interface to the table, click the Add button. • To edit the settings for an interface, select it and click the Edit button. • To delete an interface, select it and click the Delete button.
QoS Classes Table	The classes defined for the interface selected in the upper table, or for the control plane. Each row represents a separate class. The No. column indicates the order of the classes, and is very important: QoS is applied to packets on a first-match basis, based on class order. The Default Class column indicates whether this class is the default for all packets on the interface that do not match the criteria of the other defined classes. Make this the last class in the list. The remaining columns indicate the match criteria for the class, and the packet marking, queuing and congestion avoidance, policing, and shaping defined for the class, if any. For detailed information about the attributes, see QoS Policy Dialog Box , on page 2552. • To add class to the table, click the Add button. • To edit the settings for a class, select it and click the Edit button. • To delete a class, select it and click the Delete button. • To change the order of a class, select it and click the Up and Down arrow buttons to reposition it.

QoS Policy Dialog Box

Use the QoS Policy dialog box to select an interface on which you want to define QoS parameters. In addition, you can use this dialog box to configure a single set of shaping parameters for all the traffic on the selected interface (known as hierarchical shaping). Using hierarchical shaping eliminates the need to configure shaping parameters for each QoS class defined on the interface.

Note This dialog box is not applicable when defining a QoS policy on the control plane. For more information, see Defining QoS on the Control Plane , on page 2543.

After you create your QoS interface definitions, you can define one or more QoS classes for each interface. For more information, see QoS Class Dialog Box , on page 2554.

Navigation Path

Go to the Quality of Service Policy Page , on page 2550, then click the **Add** or **Edit** button beneath the upper table to define a QoS interface definition.

Related Topics

- Defining QoS Policies , on page 2541
- Quality of Service on Cisco IOS Routers , on page 2531
- Basic Interface Settings on Cisco IOS Routers , on page 2307
- Understanding Interface Role Objects , on page 303

Field Reference

Table 914: QoS Policy Dialog Box

Element	Description
Interface	The interface on which QoS is defined. Enter the name of an interface or interface role, or click **Select** to select an object from a list or to create a new object.
Direction	The direction of the traffic on which to configure QoS: • Output—Traffic that exits the interface. • Input—Traffic that enters the interface.
Hierarchical Shaping settings	
Enable Shaping	When selected, configures hierarchical traffic shaping on the selected interface. When deselected, hierarchical shaping is not used. **Note** Shaping can be performed only on output traffic.

Element	Description
Type	The type of shaping to perform: • Average—Limits the data rate for each interval to the sustained burst rate (also known as the Committed Burst rate or Bc), achieving an average rate no higher than the committed information rate (CIR). Additional packets are buffered until they can be sent. • Peak—Limits the data rate for each interval to the sustained burst rate plus the excess burst rate (Be). Additional packets are buffered until they can be sent.
CIR	The average data rate (also known as the committed information rate or CIR). You can define this amount by: • Percentage—Valid values range from 0 to 100% of the overall available bandwidth. • Bit/sec—Valid values range from 8000 to 1000000000 bits per second, and must be in multiples of 8000. Although data bursts during an interval may exceed this rate, the average data rate over any multiple integral of the interval will not exceed this rate.
Sustained Burst	The normal burst size. If you select average as the shaping type, data bursts during an interval are limited to this value. The range of valid values is determined by the CIR: • When the CIR is defined by percentage—Valid values range from 10 to 2000 milliseconds. • When the CIR is defined by an absolute value—Valid values range from 1000 to 154400000 bytes, in multiples of 128 bytes. **Note** We recommend that you leave this field blank when the CIR is defined by an absolute value. This allows the algorithms used by the device to determine the optimal sustained burst value.
Excess Burst	The excess burst size. If you select peak as the shaping type, data bursts during an interval can equal the sum of the sustained burst value plus this value. The average data rate over multiple intervals, however, will continue to conform to the CIR. The range of valid values is determined by the CIR: • When the CIR is defined by percentage—Valid values range from 10 to 2000 milliseconds. • When the CIR is defined by an absolute value—Valid values range from 1000 to 154400000 bytes, in multiples of 128 bytes. **Note** If you do not configure this field when the CIR is defined by an absolute value, the sustained burst value is used.

QoS Class Dialog Box

Use the QoS Class dialog box to create or edit a QoS class on a selected interface or control plane of a Cisco IOS router. You can define up to 16 classes on a single interface and 256 classes for the device as a whole.

Note QoS is applied to packets on a first-match basis. The router examines the table of QoS classes starting from the top and applies the properties of the first class whose matching criteria matches the packet. Therefore, it is important that you define and order your classes carefully. The default class should be placed last to prevent traffic that matches a specific class from being treated as unmatched traffic.

Navigation Path

Go to the Quality of Service Policy Page , on page 2550. Complete the options at the top of the page, then do one of the following:

- To create a QoS class, select an interface from the upper table, then click the **Add** button beneath the QoS Class table. When creating a QoS class for the control plane, just click the **Add** button beneath the table.
- To edit a QoS class:
  - Select the interface whose class you want to edit from the upper table (Not required when selecting the control plane.).
  - Select the relevant class defined for that interface in the QoS Classes table. (Not required when selecting the control plane.)
  - Click the **Edit** button under the QoS Class table.

Related Topics

- QoS Policy Dialog Box , on page 2552

Field Reference

Table 915: QoS Class Dialog Box

Element	Description
Set as Default Class	When selected, enables you to define the default class for all traffic that does not match the other QoS classes on this interface. When deselected, enables you to define a specific QoS class on this interface. **Note** When you define the default class, you do not configure any matching parameters; by definition the class consists of all traffic that does not match any of the other classes. Therefore, the Matching tab is disabled.
Matching tab	Defines the traffic that is included in this QoS class. See QoS Class Dialog Box—Matching Tab , on page 2555.
Marking tab	Marks the traffic in this class so that downstream devices can properly identify it. See QoS Class Dialog Box—Marking Tab , on page 2557.
Queuing and Congestion Avoidance tab	Defines how to queue the output traffic in this class. See QoS Class Dialog Box—Queuing and Congestion Avoidance Tab , on page 2558.
Policing tab	Limits the traffic flow for this class to a configured rate. See QoS Class Dialog Box—Policing Tab , on page 2560.
Shaping tab	Controls the flow of output traffic for this class so that it conforms with the requirements of downstream devices. See QoS Class Dialog Box—Shaping Tab , on page 2562.

Note When you configure a QoS policy on the control plane, only the Matching tab and Policing tab are available.

QoS Class Dialog Box—Matching Tab

Use the Matching tab of the QoS Class dialog box to define which traffic over the selected interface is considered to be part of this class.

Note When you define the default class, the Matching tab is disabled.

Navigation Path

Go to the QoS Class Dialog Box , on page 2554, then click the **Matching** tab.

Related Topics

- Creating Access Control List Objects , on page 283

Field Reference

Table 916: QoS Class Dialog Box—Matching Tab

Element	Description
Match Method	The traffic matching option used for this class: • Any—Assigns traffic matching any of the defined class map criteria to this QoS class. • All—Assigns only traffic matching all of the defined class map criteria to this QoS class.
Protocol	One or more protocols included in this class map. Click **Add** to display a selector. Select one or more items from the Available Protocols list, then click >> to add them to the Selected Protocols list. The only protocol available for the control plane is ARP; ARP and CDP are not available for input classes configured on an interface. When you finish, click **OK** to return to the QoS Class dialog box. Your selections are displayed in the Protocol field. **Note** To remove a protocol from the QoS class, select it from the Protocol field, then click **Delete**.
Precedence	One or more IP Precedence (IPP) values included in this class map. Click **Add** to display a selector. Select one or more items from the Available Precedences list, then click >> to add them to the Selected Precedences list. For more information about IP precedence values, see Table 911: IP Precedence Classes , on page 2533. When you finish, click **OK** to return to the QoS Class dialog box. Your selections are displayed in the Precedence field. **Note** To remove an IPP value from the QoS class, select it from the Precedence field, then click **Delete**.
DSCP	One or more Differentiated Services Code Point (DSCP) values included in this class map. Click **Add** to display a selector. Select one or more items (up to eight) from the Available DSCPs list, then click >> to add them to the Selected DSCPs list. When you finish, click **OK** to return to the QoS Class dialog box. Your selections are displayed in the DSCP field. **Note** To remove a DSCP value from the QoS class, select it from the DSCP field, then click **Delete**.

Element	Description
ACL	The ACLs that are used for defining which traffic requires QoS. Click **Edit** to add or remove ACL objects. Use the up and down arrows to order the ACLs in the list. We recommend that you place frequently used ACLs at the top of the list to optimize the matching process.

Edit ACLs Dialog Box—QoS Classes

When configuring a QoS policy on a Cisco IOS router, use the Edit ACLs dialog box to specify which ACLs should be included in the matching criteria for the selected QoS class. Traffic matching this criteria is included as part of the class.

Enter the names of the extended ACLs or click **Select** to select an ACL object from a list or to create a new one. Separate multiple ACL objects with commas and place them in priority order.

For more information, see Creating Extended Access Control List Objects , on page 284.

Navigation Path

Go to the QoS Class Dialog Box—Matching Tab , on page 2555, then click **Edit** in the ACL field.

Related Topics

- Selecting Objects for Policies , on page 230

QoS Class Dialog Box—Marking Tab

Use the Marking tab of the QoS Class dialog box to classify packets. Traffic policers and shapers use these classifications to ensure adherence to the contracted level of service. Downstream devices use this classification to identify the packets and apply the appropriate QoS functions to them.

Note The Marking tab is unavailable when you define a QoS policy on the control plane.

Navigation Path

Go to the QoS Class Dialog Box , on page 2554, then click the **Marking** tab.

Related Topics

- Defining QoS Class Marking Parameters , on page 2546
- Defining QoS on Interfaces , on page 2541

- Defining QoS on the Control Plane , on page 2543
- Quality of Service Policy Page , on page 2550

Field Reference

Table 917: QoS Class Dialog Box—Marking Tab

Element	Description
Enable Marking	When selected, enables you to mark the traffic in this QoS class with a specific precedence or DSCP value (regardless of any value the traffic might have had when it first entered the device). This mark enables downstream devices to identify the traffic and apply the appropriate QoS features to it. When deselected, disables all marking options for the selected QoS class. The traffic in this QoS class maintains its original precedence or DSCP value, if any.
Precedence	The precedence value with which to mark the traffic in this class: • network (7) • internet match (6) • critical (5) • flash-override (4) • flash (3) • immediate (2) • priority (1) • routine (0)
DSCP	The DSCP value (0 to 63) with which to mark the traffic in this class.

QoS Class Dialog Box—Queuing and Congestion Avoidance Tab

Use the Queuing and Congestion Avoidance tab of the QoS Class dialog box to perform Class-Based Weighted Fair Queuing (CBWFQ) on the output traffic in the selected QoS class. Queuing prioritizes traffic and manages congestion on your network by determining the order in which packets are sent out over an interface. Queuing and congestion avoidance applies only to interface classes for output traffic.

The fields displayed in the Queuing tab depend on whether you are defining a specific QoS class or the default class (by selecting **Set as Default Class**), and also by the type of router and the Cisco IOS software version.

Navigation Path

Go to the QoS Class Dialog Box , on page 2554, then click the **Queuing and Congestion Avoidance** tab.

Related Topics

- Defining QoS Class Queuing Parameters , on page 2546

- Defining QoS on Interfaces , on page 2541
- Defining QoS on the Control Plane , on page 2543
- Quality of Service Policy Page , on page 2550

Field Reference

Table 918: QoS Class Dialog Box—Queuing and Congestion Avoidance Tab

Element	Description
Enable Queuing and Congestion Avoidance	Whether to configure queuing and congestion avoidance properties in the QoS class.
Priority (Non-default classes only.)	Configure low-latency queuing (LLQ) in this class to ensure that priority traffic, such as voice traffic, receives the defined bandwidth (see Low-Latency Queuing , on page 2536). Specify the amount of bandwidth allocated to high-priority traffic on this interface by: • Percentage—Valid values range from 1 to 100%. • Kbit/sec—Valid values range from 8-2000000 kilobits per second. **Note** You can define this option for one class only per interface. If you select this option, the Shaping tab is disabled.
Fair Queue Number of Dynamic Queues (Default class only.)	Configure class-based weighted fair queuing in this class. If the device is running an IOS software version lower than 12.4(20)T, you must specify the number of dynamic queues to reserve for this class. You should base your number on the available bandwidth of the interface. You can specify a number between 16 and 4096 that is a power to 2. For information on the default number of queues the device uses, see Default Class Queuing , on page 2536. Available bandwidth is evenly distributed among the queues unless you configure a queue limit. **Tip** Failure to provide a sufficient number of queues for the default class (a condition known as starvation) could result in the traffic not being sent.
Bandwidth	Configure the minimum bandwidth to guarantee to this class. You can define this amount by: • Percentage—Valid values range from 1 to 100% of the total available bandwidth. • Kbit/sec—Valid values range from 8-2000000 kilobits per second.
Enable Fair Queue (Non-default class only.)	When you configure bandwidth for a non-default class, whether to also enable class-based weighted fair queuing (CBWFQ). The device calculates the number of queues to configure based on the available bandwidth, and distributes the bandwidth evenly among the queues unless you configure a queue limit. This option is available only for Aggregation Services Routers (ASR) and for routers running 12.4(20)T and later.

Element	Description
Queue Limit	The maximum number of packets that can be queued for the class. Any additional packets are dropped using tail drop until the congestion is gone. This is the default option for limiting queue size unless Weighted Random Early Detection (WRED) is configured.
WRED Weight for Mean Queue Depth	The exponential weight factor to use to calculate the average queue size. Use this option when defining WRED instead of tail drop (queue limit) for this class. When the queue size exceeds the value determined by this weight factor, WRED randomly discards packets until the transmitting protocol decreases its transmission rate to ease congestion. Exponent values range from 1 to 16. The default is 9. This option is best suited for protocols like TCP, which respond to dropped packets by decreasing the transmission rate. We recommend that you do not change the default unless you determine that your applications would benefit from the change.

QoS Class Dialog Box—Policing Tab

Use the Policing tab of the QoS Class dialog box to configure rate limits on the traffic in a selected QoS class. Excess traffic is either dropped or transmitted with a different (typically lower) priority.

Navigation Path

Go to the QoS Class Dialog Box , on page 2554, then click the **Policing** tab.

Related Topics

- Defining QoS Class Policing Parameters , on page 2548
- Defining QoS on Interfaces , on page 2541
- Defining QoS on the Control Plane , on page 2543
- Quality of Service Policy Page , on page 2550

Field Reference

Table 919: QoS Class Dialog Box—Policing Tab

Element	Description
Enable Policing	When selected, enables you to configure Class-Based Policing to control the maximum rate of traffic for this class. Security Manager uses a two-token bucket algorithm, which includes a defined violate action that is performed when neither bucket can accommodate the incoming packet. When deselected, disables all policing options for the selected QoS class.

Element	Description
CIR	The average data rate (also known as the committed information rate or CIR). You can define this amount by: • Percentage—Valid values range from 0 to 100% of the overall available bandwidth. • Bit/sec—Valid values range from 8000 to 2000000000 bits per second. In the token bucket algorithm, this rate represents the token arrival rate for filling both token buckets. Traffic that falls under this rate always conforms. **Note** When you configure Understanding Control Plane Policing , on page 2540, you must define the CIR in bits per second.
Conform Burst	The normal burst size, which determines how large traffic bursts can be before some traffic exceeds the rate limit. In the token bucket algorithm, it represents the full size of the first (conform) token bucket. The range of valid values is determined by the CIR: • When the CIR is defined by percentage—Valid values range from 1 to 2000 milliseconds. • When the CIR is defined by an absolute value—Valid values range from 1000-512000000 bytes.
Excess Burst	The excess burst size, which determines how large traffic bursts can be before all traffic exceeds the rate limit. In the token bucket algorithm, it represents the full size of the second (exceed) token bucket. The range of valid values is determined by the CIR: • When the CIR is defined by percentage—Valid values range from 1 to 2000 milliseconds. • When the CIR is defined by an absolute value—Valid values range from 1000-512000000 bytes.
Conform action	The action to take on packets that conform to the rate limit: • transmit—Transmits the packet. • set-prec-transmit—Sets the IP precedence to a value you specify (0 to 7) and then sends the packet. Not available on the control plane. • set-dscp-transmit—Sets the DSCP to a value you specify (0 to 63) and then sends the packet. Not available on the control plane. • drop—Drops the packet.

Element	Description
Exceed action	The action to take on packets that exceed the rate limit, but can be handled using the second (exceed) token bucket. The actions available for selection depend on the defined conform action. For example, if you select one of the set options as the conform action, you cannot select transmit as the exceed action. If you select drop as the conform action, then you must also select drop as the exceed action.
Violate action	The action to take on packets that cannot be serviced by either the conform bucket or the exceed bucket. The actions available for selection depend on the defined exceed action. For example, if you select one of the set options as the exceed action, you cannot select transmit as the violate action. If you select drop as the exceed action, then you must also select drop as the violate action.

QoS Class Dialog Box—Shaping Tab

Use the Shaping tab of the QoS Class dialog box to control the rate of output traffic for the selected QoS class. Shaping typically delays excess traffic by using a buffer, or queuing mechanism, to hold packets and shape the flow when the data rate of the source is higher than expected.

Note The Shaping tab is unavailable when you define a QoS policy on the control plane, use hierarchical shaping on the interface, define a QoS class for input traffic, or perform queuing on priority traffic.

Navigation Path

Go to the QoS Class Dialog Box , on page 2554, then click the **Shaping** tab.

Related Topics

- Defining QoS Class Shaping Parameters , on page 2549
- Defining QoS on Interfaces , on page 2541
- Defining QoS on the Control Plane , on page 2543
- Quality of Service Policy Page , on page 2550

Field Reference

Table 920: QoS Class Dialog Box—ShapingTab

Element	Description
Enable Shaping	When selected, enables you to configure Distributed Traffic Shaping (DTS) to control the rate of traffic for this class. DTS uses queues to buffer traffic surges that can congest the network. When deselected, disables all shaping options for the selected QoS class. **Note** Shaping can be performed only on output traffic.
Type	The type of shaping to perform: • Average—Limits the data rate for each interval to the sustained burst rate (also known as the committed burst rate or Bc), achieving an average rate no higher than the committed information rate (CIR). Additional packets are buffered until they can be sent. • Peak—Limits the data rate for each interval to the sustained burst rate plus the excess burst rate (Be). Additional packets are buffered until they can be sent.
CIR	The average data rate (also known as the committed information rate or CIR). You can define this amount by: • Percentage—Valid values range from 0 to 100% of the overall available bandwidth. • Bit/sec—Valid values range from 8000 to 1000000000 bits per second, and must be in multiples of 8000. Although data bursts during an interval may exceed this rate, the average data rate over any multiple integral of the interval will not exceed this rate.
Sustained Burst	The normal burst size. If you select average as the shaping type, data bursts during an interval are limited to this value. The range of valid values is determined by the CIR: • When the CIR is defined by percentage—Valid values range from 10 to 2000 milliseconds. • When the CIR is defined by an absolute value—Valid values range from 1000 to 154400000 bytes, in multiples of 128 bytes. **Note** We recommend that you leave this field blank when the CIR is defined by an absolute value. This allows the algorithms used by the device to determine the optimal sustained burst value.

Element	Description
Excess Burst	The excess burst size. If you select peak as the shaping type, data bursts during an interval can equal the sum of the sustained burst value plus this value. The average data rate over multiple intervals, however, will continue to conform to the CIR. The range of valid values is determined by the CIR: • When the CIR is defined by percentage—Valid values range from 10 to 2000 milliseconds. • When the CIR is defined by an absolute value—Valid values range from 1000 to 154400000 bytes, in multiples of 128 bytes. **Note** If you do not configure this field when the CIR is defined by an absolute value, the sustained burst value is used.

CHAPTER 67

Configuring Routing Policies

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

This chapter contains the following topics:

BGP Routing on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

BGP is an Exterior Gateway Protocol (EGP) that guarantees the loop-free exchange of routing information between autonomous systems (ASs). The *primary* function of a BGP system is to exchange information with other BGP systems about the networks it can reach, including AS path information. This information can be used to construct a graph of AS connectivity from which routing loops can be pruned and with which AS-level policy decisions can be enforced.

BGP is the routing protocol used on the Internet and is commonly used between Internet service providers. To achieve scalability at this level, BGP uses several route parameters (attributes) to define routing policies

and maintain a stable routing environment. Additionally, BGP uses classless interdomain routing (CIDR) to greatly reduce the size of Internet routing tables.

A BGP route consists of a network number, a list of ASs through which information has passed (called the *autonomous system path*), and the defined path attributes.

A BGP router exchanges routing information only with those routers that you define as its neighbors. BGP neighbors exchange complete routing information when the TCP connection between them is established. Updates are sent to neighbors only when changes to the routing table are detected. BGP routers do not send regular, periodic updates.

The following topics describe the tasks you perform to create a BGP routing policy:

- Defining BGP Routes , on page 2566
- Redistributing Routes into BGP , on page 2567

Note Security Manager supports versions 2, 3 and 4 of BGP, as defined in RFCs 1163, 1267 and 1771.

Related Topics

- Static Routing on Cisco IOS Routers , on page 2617
- RIP Routing on Cisco IOS Routers , on page 2608
- OSPF Routing on Cisco IOS Routers , on page 2585
- EIGRP Routing on Cisco IOS Routers , on page 2573

Defining BGP Routes

As with all EGPs, when you configure a BGP routing policy, you must define the relationship the router has with its neighbors. BGP supports two kinds of neighbors: internal (located in the same AS) and external (located in a different AS). Typically, external neighbors are adjacent to each other and share a subnet; internal neighbors can be anywhere in the same AS.

In addition, you can select whether to enable the following optional features:

- Auto-summarization
- Synchronization
- Neighbor logging

If enabled, *auto-summarization* injects only the network route when a subnet is redistributed from an Interior Gateway Protocol (IGP) such as OSPF or EIGRP into BGP. *Synchronization* is useful if your AS acts as an intermediary, passing traffic from one AS to another AS, because it ensures that your AS is consistent about the routes it advertises. For example, if BGP were to advertise a route before all routers in your network had learned about the route through your IGP, your AS might receive traffic that some routers cannot yet route. *Neighbor logging* enables the router to keep track of messages issued by BGP neighbors when they reset, become unreachable, or restore their connection to the network.

This procedure describes how to define a BGP route. You can define only one BGP route on each router.

Related Topics

- Redistributing Routes into BGP , on page 2567
- BGP Routing on Cisco IOS Routers , on page 2565

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > BGP** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform > Routing > BGP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The BGP Setup is displayed. See Table 921: BGP Setup Tab , on page 2569 for a description of the fields on this tab.

Step 2 On the BGP Setup tab, enter the AS number to which the router belongs.

Step 3 (Optional) Enter the addresses of the networks that are local to this AS. You can use a combination of addresses and network/host objects, or click **Select** to select an object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 4 Define external and internal BGP neighbors for the routers:

a) Click **Add** under Neighbors to display the BGP Neighbors dialog box. See Table 922: Neighbors Dialog Box , on page 2570 for a description of the fields in this dialog box.
b) Enter an AS number and then click **Select** to select the hosts that are neighbors within the defined AS. Internal neighbors are located in the same AS as the router; external neighbors are located in a different AS.
c) Click **OK** to save your definitions and return to the BGP Neighbors dialog box.
d) (Optional) Repeat 4.b, on page 2567 and 4.c, on page 2567 to define neighbors in additional ASs.

Note When you define BGP neighbors, the IP addresses cannot belong to an interface on the selected router. In addition, you cannot define the same IP address in more than one AS.

When you finish, click **OK** in the BGP Neighbors dialog box to return to the BGP Setup tab. Your selections are displayed in the Neighbors field.

Step 5 (Optional) Select the Auto-Summary check box to enable automatic summarization. If automatic summarization is enabled, only the network route is injected into the BGP table when a subnet is redistributed from an IGP (such as OSPF or EIGRP) into BGP.

Step 6 (Optional) Select the **Synchronization** check box to synchronize BGP with the IGP. Enabling this feature causes BGP to wait until the IGP propagates routing information across the AS.

You do not need synchronization if your AS does not pass traffic it receives from one AS to another AS, or if all the routers in your AS run BGP. Disabling synchronization enables BGP to converge more quickly.

Step 7 (Optional) Select the **Log-Neighbor** check box to enable the logging of messages generated when a BGP neighbors resets, comes up, or goes down.

Redistributing Routes into BGP

Redistribution refers to using a routing protocol, such as BGP, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you

can redistribute routes from the OSPF routing protocol into your BGP autonomous system (AS). Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

Before You Begin

- Define a BGP AS. See Defining BGP Routes , on page 2566.

Related Topics

- Defining BGP Routes , on page 2566
- BGP Routing on Cisco IOS Routers , on page 2565

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > BGP** from the Policy selector, then click the **Redistribution** tab in the work area.
- (Policy view) Select **Router Platform > Routing > BGP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The BGP Redistribution tab is displayed. See Table 923: BGP Redistribution Tab , on page 2571 for a description of the fields on this tab.

Step 2 On the BGP Redistribution tab, select a row from the BGP Redistribution Mappings table, then click **Edit**, or click **Add** to create a mapping. The BGP Redistribution Mapping dialog box appears. See Table 924: BGP Redistribution Mapping Dialog Box , on page 2573 for a description of the fields in this dialog box.

Step 3 Select the protocol whose routes you want to redistribute into BGP.

Note You can create a single mapping for each static route, RIP route, EIGRP AS, and OSPF process.

Step 4 (Optional) Modify the default metric (cost) of the redistributed routes. The metric determines the priority of the routes.

Step 5 Click **OK** to save your definitions locally on the client and close the dialog box. The redistribution mapping appears in the Redistribution Mapping table in the BGP Redistribution tab.

BGP Routing Policy Page

Border Gateway Protocol (BGP) is an exterior gateway protocol (EGP) that performs routing between multiple autonomous systems or domains and exchanges routing and reachability information with other BGP systems. BGP is used to exchange routing information on the Internet and is the protocol used between Internet service providers.

You can configure BGP routing policies from the following tabs on the BGP Routing page:

- BGP Page—Setup Tab , on page 2569
- BGP Page—Redistribution Tab , on page 2571

For more information, see BGP Routing on Cisco IOS Routers , on page 2565.

Navigation Path

- (Device view) Select **Platform** > **Routing** > **BGP** from the Policy selector.
- (Policy view) Select **Router Platform** > **Routing** > **BGP** from the Policy Type selector. Right-click **BGP** to create a policy, or select an existing policy from the Shared Policy selector.

BGP Page—Setup Tab

Use the BGP Setup tab to define the number of the autonomous system (AS) in which the selected router is located. You must then define which networks are included in the AS and which networks are the internal and external neighbors of the router. Additionally, you can enable or disable options that govern the interaction between BGP and Interior Gateway Protocols (IGPs), such as OSPF and EIGRP. Use a third option to enable the logging of messages from BGP neighbors.

Navigation Path

Go to the BGP Routing Policy Page , on page 2568, then click the **Setup** tab.

Related Topics

- Understanding Networks/Hosts Objects , on page 310

Field Reference

Table 921: BGP Setup Tab

Element	Description
AS Number	The number of the autonomous system in which the router is located. Valid values range from 1 to 65535. This number enables a BGP routing process. If BGP is already configured on the device, you cannot successfully change and deploy this number. If you need to change the AS number, first unassign the BGP policy, deploy your change (thus removing the BGP configuration from the device), then configure the BGP policy with the new number and redeploy the configuration.
Networks	The networks associated with the BGP route. Enter one or more network addresses or network/host objects, or click **Select** to select the object from a list or to create a new one. **Note** To remove a network from the route, select it from the Network field, then click **Delete**.
Neighbors	The *internal* neighbors (those located in the same AS as the router) and *external* neighbors (located in different ASs) of the router. See Neighbors Dialog Box , on page 2570.

Element	Description
Auto-Summary	When selected, automatic summarization is enabled. When a subnet is redistributed from an IGP (such as RIP, OSPF or EIGRP) into BGP, this BGP version 3 feature injects only the network route into the BGP table. Automatic summarization reduces the size and complexity of the routing table that the router must maintain. When deselected, automatic summarization is disabled. This is the default.
Synchronization	When selected, synchronization is enabled. Use this feature to ensure that all routers in your network are consistent about the routes they advertise. Synchronization forces BGP to wait until the IGP propagates routing information across the AS. When deselected, synchronization is disabled. You can disable synchronization if this router does not pass traffic from a different AS to a third AS, or if all the routers in the AS are running BGP. Disabling this feature has the benefit of reducing the number of routes the IGP must carry, which improves convergence times. This is the default.
Log-Neighbor	When selected, enables the logging of messages that are generated when a BGP neighbors resets, connects to the network, or is disconnected. This is the default. When deselected, message logging is disabled.

Neighbors Dialog Box

Use the Neighbors dialog box to define the internal and external neighbors of the selected router.

Navigation Path

Go to the BGP Page—Setup Tab , on page 2569, then click the **Add** or **Edit** button in the Neighbors field.

Related Topics

- Understanding Networks/Hosts Objects , on page 310

Field Reference

Table 922: Neighbors Dialog Box

Element	Description
AS Number	The number of the AS containing BGP neighbors. Internal neighbors have the same AS number as the network of the selected router. External neighbors have a different AS number.

Element	Description
IP Address	The IP addresses of the hosts that are neighbors of the router. BGP neighbors exchange routing information with each other whenever changes to the routing table are detected. When you define BGP neighbors, the IP addresses cannot belong to an interface on the selected router. In addition, you cannot define the same IP address in more than one AS. Enter one or more addresses or network/host objects, or click **Select** to select an object from a list or to create a new one. **Note** To remove a host from the list of BGP neighbors, select it from the Hosts field, then click **Delete**.

BGP Page—Redistribution Tab

Use the BGP Redistribution tab to view, create, edit, and delete redistribution settings when performing redistribution into a BGP autonomous system (AS).

Note You must define BGP setup parameters before you can access the BGP Redistribution tab. See BGP Page—Setup Tab , on page 2569.

Navigation Path

Go to the BGP Routing Policy Page , on page 2568, then click the **Redistribution** tab.

Field Reference

Table 923: BGP Redistribution Tab

Element	Description
Protocol	The protocol that is being redistributed.
AS/Process ID	The AS number or process ID of the route being redistributed.
Metric	The value that determines the priority of the redistributed route.
Match	When redistributing an OSPF process, indicates the types of OSPF routes that are being redistributed.

Element	Description
Static Type	When redistributing static routes, indicates the type of static route, IP or OSI.
Add button	Opens the BGP Redistribution Mapping Dialog Box , on page 2572. From here you can define BGP redistribution mappings.
Edit button	Opens the BGP Redistribution Mapping Dialog Box , on page 2572. From here you can edit the selected BGP redistribution mapping.
Delete button	Deletes the selected BGP redistribution mappings from the table.

BGP Redistribution Mapping Dialog Box

Use the BGP Redistribution Mapping dialog box to add or edit the properties of a BGP redistribution mapping.

Navigation Path

Go to the BGP Page—Redistribution Tab , on page 2571, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Redistributing Routes into BGP , on page 2567

Field Reference

Table 924: BGP Redistribution Mapping Dialog Box

Element	Description

Protocol to Redistribute	The routing protocol that is being redistributed:
	• Static—Redistributes IP or OSI static routes. You can define a single mapping for each route.
	• EIGRP—Redistributes an EIGRP autonomous system. Enter the AS number in the displayed field. You can define a single mapping for each AS.
	• RIP—Redistributes RIP routes. You can define a single mapping for each route.
	• OSPF—Redistributes a different OSPF process. You can define a single mapping for each process. Select a process from the displayed list, then select one or more match criteria:
	  • Internal—Routes that are internal to a specific AS.
	  • External1—Routes that are external to the AS and imported into OSPF as a Type 1 external route.
	  • External2—Routes that are external to the AS and imported into the selected process as a Type 2 external route.
	  • NSAAExternal1—Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes.
	  • NSAAExternal2—(NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes.
	• Connected—Redistributes routes that are established automatically by virtue of having enabled IP on an interface. These routes are redistributed as external to the AS.

Metric	A value representing the cost of the redistributed route. Valid values range from 0 to 4294967295.

EIGRP Routing on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Enhanced Interior Gateway Routing Protocol (EIGRP) is an enhanced distance vector protocol developed by Cisco Systems that integrates the capabilities of link-state protocols. EIGRP is suited for many different topologies and media. Key capabilities that distinguish EIGRP from other routing protocols are fast convergence, support for variable-length subnet masks, partial updates, and multiple network-layer protocols.

The metric that the router uses to reach the destination, and to advertise to other routers, is the sum of the best-advertised metrics from all neighbors and the link cost to the best neighbor.

EIGRP uses neighbor tables to store address and interface information about each of the router's neighbors. Hello packets advertise hold times, which is the length of time a neighbor can be considered reachable and operational. Topology tables contain all destinations advertised by neighboring routers. For each neighbor, the entry records the advertised metric, which the neighbor stores in its routing table.

A router running EIGRP stores all its neighbors' routing tables so that it can quickly adapt to alternate routes. If no appropriate route exists, EIGRP queries its neighbors to discover an alternate route. These queries propagate until an alternate route is found. EIGRP sends incremental updates when the state of a destination changes, instead of sending the entire contents of the routing table. EIGRP ensures that only those routers needing the information are updated. This feature minimizes the bandwidth required for EIGRP packets.

EIGRP supports both internal and external routes. Internal routes originate within an EIGRP Autonomous System (AS). Therefore, a directly attached network that is configured to run EIGRP is considered an internal route and is propagated with this information throughout the AS. External routes are learned by another routing protocol or reside in the routing table as static routes. These routes are tagged individually with the identity of their origin.

The following topics describe the tasks you perform to create an EIGRP routing policy:

- Defining EIGRP Routes , on page 2574
- Defining EIGRP Interface Properties , on page 2575
- Redistributing Routes into EIGRP , on page 2577

Related Topics

- Static Routing on Cisco IOS Routers , on page 2617
- RIP Routing on Cisco IOS Routers , on page 2608
- OSPF Routing on Cisco IOS Routers , on page 2585
- BGP Routing on Cisco IOS Routers , on page 2565

Defining EIGRP Routes

To configure an EIGRP routing policy, you must assign each autonomous system a number, which identifies the autonomous system to other routers. You then must select the networks to which routes will be created. In addition, you can select which interfaces should be passive. Unlike other routing protocols, passive interfaces in EIGRP neither send nor receive routing updates from their neighbors, resulting in the loss of their neighbor relationship.

When you configure EIGRP routing policies, you can also decide whether to enable auto-summarization, which greatly simplifies routing tables and the exchange of routing information by having many subnets represented by a single network entry.

Related Topics

- Defining EIGRP Interface Properties , on page 2575
- Redistributing Routes into EIGRP , on page 2577
- EIGRP Routing on Cisco IOS Routers , on page 2573

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Routing** > **EIGRP** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform** > **Routing** > **EIGRP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The EIGRP Setup tab is displayed (see EIGRP Page—Setup Tab , on page 2578).

Step 2 On the EIGRP Setup tab, select an EIGRP route from the table, then click **Edit**, or click **Add** to create a route. The EIGRP Setup dialog box appears. See Table 926: EIGRP Setup Dialog Box , on page 2580 for a description of the fields in this dialog box.

Step 3 Enter the autonomous system number for the route. This number identifies the autonomous system to other routers.

Step 4 Enter the addresses of the networks to include in the EIGRP route. You can use a combination of addresses and network/host objects; separate addresses with commas. Click **Select** to select network/host objects from a list of existing objects, or to create new network/host objects. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 5 Enter the addresses of the passive interfaces, which are interfaces that should not send routing updates to their neighbors, if any. Enter the names of one or more interfaces or interface roles; separate addresses with commas. Click **Select** to select interface names or roles from a list of existing objects, or to create new interface role objects. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 6 (Optional) Select **Auto-Summary** to enable the auto summarization of subnet routes into network-level routes. Summarization reduces the size of routing tables, thereby reducing the complexity of the network.

Step 7 Click **OK** to save your definitions. The EIGRP route appears in the table displayed in the EIGRP Setup tab.

Defining EIGRP Interface Properties

You can optionally modify the default values of the following two interface properties in a selected EIGRP autonomous system:

- Hello interval.
- Split horizon.

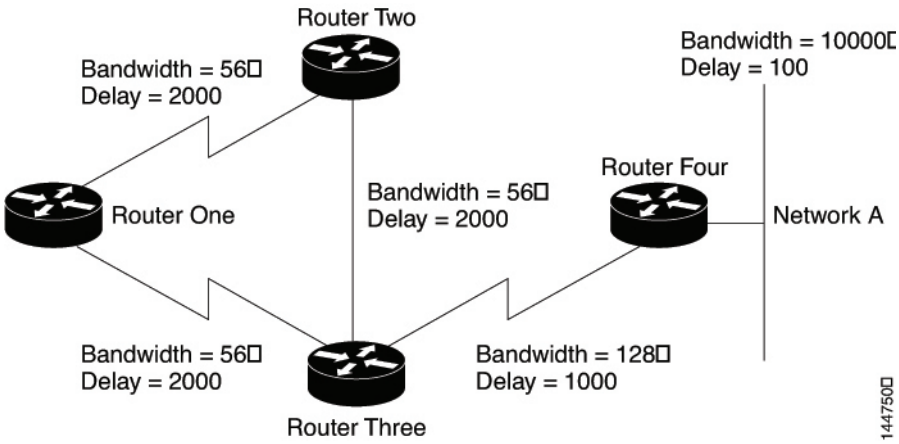
The hello interval defines the interval between hello packets. Routing devices periodically send these packets to each other to dynamically learn of other routers on their directly attached networks. This information is used to discover neighbors and to learn when neighbors become unreachable or inoperative. By default, hello packets are sent every 5 seconds. The default interval for low speed (T1 or slower), nonbroadcast multiaccess (NBMA) media is every 60 seconds.

Split horizon is a feature that prevents route information from being sent back in the direction from which that information originated. If you enable split horizon on an interface (this is the default), update and query packets are not sent to destinations for which this interface is the next hop. This helps to prevent routing loops.

For example, as shown in Figure 57: EIGRP Split Horizon Example, on page 2576, if Router One is connected to Routers Two and Three through a single multipoint interface, and Router One learned about Network A from Router Two, Router One does not advertise the route to Network A over that same multipoint interface

to Router Three. Router One assumes that Router Three would learn about Network A directly from Router Two.

Figure 57: EIGRP Split Horizon Example



Split horizon is enabled by default on all EIGRP interfaces, because it typically optimizes communications among multiple routing devices. However, in certain cases with nonbroadcast networks (such as Frame Relay and SMDS), you might want to disable split horizon.

If you decide to disable split horizon on an EIGRP interface, keep the following in mind:

- In a hub-and-spoke network, you should disable split horizon only at the hub. This is because disabling split horizon on the spokes greatly increases EIGRP memory consumption on the hub router, as well as the amount of traffic generated on the spoke routers.
- Changing the split horizon setting on an interface resets all adjacencies with the EIGRP neighbors that are reachable over that interface.

Before You Begin

- Define at least one EIGRP autonomous system. See Defining EIGRP Routes , on page 2574.

Related Topics

- Defining EIGRP Routes , on page 2574
- Redistributing Routes into EIGRP , on page 2577
- EIGRP Routing on Cisco IOS Routers , on page 2573

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > EIGRP** from the Policy selector, then click the **Interfaces** tab in the work area.
- (Policy view) Select **Router Platform > Routing > EIGRP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Interfaces** tab.

The EIGRP Interfaces tab is displayed. See Table 927: EIGRP Interfaces Tab , on page 2581 for a description of the fields on this tab.

Step 2 On the EIGRP Interfaces tab, select an interface from the table, then click **Edit**, or click **Add** to create an interface definition. The EIGRP Interface dialog box appears. See Table 928: EIGRP Interface Dialog Box , on page 2581 for a description of the fields in this dialog box.

Step 3 Select the AS number of the autonomous system whose interface properties you want to modify. See Defining EIGRP Routes , on page 2574 for more information about defining an autonomous system.

Step 4 Enter the name of the interface or interface role to define, or click **Select** to select an interface role from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 5 (Optional) In the Hello Interval field, modify the default interval between hello packets sent over the selected interfaces.

The default is 5 seconds for all interfaces, except for low-speed (T1 or less) NBMA media, for which the default interval is 60 seconds.

Step 6 (Optional) Deselect the **Split Horizon** check box to disable the split horizon feature. If you disable this feature, the selected interfaces can advertise a route out of the interface from which they learned the route.

Note In general, we recommend that you not disable split horizon unless you are certain that your application requires the change to properly advertise routes. If you disable split horizon on a serial interface, and that interface is attached to a packet-switched network, you must disable split horizon for all routers and access servers in all relevant multicast groups on that network.

Step 7 Click **OK** to save your definitions locally on the client and close the dialog box. The interface definition appears in the table on the EIGRP Interfaces tab.

Redistributing Routes into EIGRP

Redistribution refers to using a routing protocol, such as EIGRP, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you can redistribute routes from the RIP routing protocol into your EIGRP autonomous system (AS). Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

Before You Begin

- Define at least one EIGRP autonomous system. See Defining EIGRP Routes , on page 2574.

Related Topics

- Defining EIGRP Routes , on page 2574
- Defining EIGRP Interface Properties , on page 2575
- EIGRP Routing on Cisco IOS Routers , on page 2573

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Routing** > **EIGRP** from the Policy selector, then click the **Redistribution** tab in the work area.
- (Policy view) Select **Router Platform** > **Routing** > **EIGRP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The EIGRP Redistribution tab is displayed. See Table 929: EIGRP Redistribution Tab , on page 2582 for a description of the fields on this tab.

Step 2 On the EIGRP Redistribution tab, select a row from the EIGRP Redistribution Mappings table, then click **Edit**, or click **Add** to create a mapping. The EIGRP Redistribution Mapping dialog box appears. See Table 930: EIGRP Redistribution Mapping Dialog Box , on page 2583 for a description of the fields in this dialog box.

Step 3 Select an existing EIGRP AS from the displayed list.

Step 4 Select the protocol whose routes you want to redistribute into the selected EIGRP AS.

Note You can create a single mapping for each static route, RIP route, BGP AS, EIGRP AS, and OSPF process.

Step 5 (Optional) Under Metrics, modify the default metric (cost) of the redistributed routes by entering values in the fields used to calculate the metric. The metric determines the priority of the routes.

Note Entering a metric is optional, but if you do specify a value, you must enter values for all five parameters. You need not define metric values when redistributing one EIGRP process into another.

Step 6 Click **OK** to save your definitions locally on the client and close the dialog box. The redistribution mapping appears in the Redistribution Mapping table in the EIGRP Redistribution tab.

EIGRP Routing Policy Page

Enhanced Interior Gateway Routing Protocol (EIGRP) is a scalable interior gateway protocol that provides extremely quick convergence times with minimal network traffic.

You can configure EIGRP routing policies from the following tabs on the EIGRP Routing page:

- EIGRP Page—Setup Tab , on page 2578
- EIGRP Page—Interfaces Tab , on page 2580
- EIGRP Page—Redistribution Tab , on page 2582

For more information, see EIGRP Routing on Cisco IOS Routers , on page 2573.

Navigation Path

- (Device view) Select **Platform > Routing > EIGRP** from the Policy selector.
- (Policy view) Select **Router Platform > Routing > EIGRP** from the Policy Type selector. Right-click **EIGRP** to create a policy, or select an existing policy from the Shared Policy selector.

EIGRP Page—Setup Tab

Use the EIGRP Setup tab to view, create, edit, and delete EIGRP routes.

Navigation Path

Go to the EIGRP Routing Policy Page , on page 2578, then click the **Setup** tab.

Related Topics

- Defining EIGRP Routes , on page 2574
- EIGRP Page—Interfaces Tab , on page 2580

- Table Columns and Column Heading Features , on page 51
- Filtering Tables , on page 50

Field Reference

Table 925: EIGRP Setup Tab

Element	Description
AS Number	The autonomous system number that identifies the autonomous system to other routers.
Networks	The names of the networks included in the route.
Passive Interfaces	The interfaces that neither send nor receive routing updates from their neighbors.
Auto-Summary	Indicates whether auto summarization is activated on the selected route.
Add button	Opens the EIGRP Setup Dialog Box , on page 2579. From here you can create an EIGRP route.
Edit button	Opens the EIGRP Setup Dialog Box , on page 2579. From here you can edit the selected EIGRP route.
Delete button	Deletes the selected EIGRP routes from the table.

EIGRP Setup Dialog Box

Use the EIGRP Setup dialog box to add or edit EIGRP routes.

Navigation Path

Go to the EIGRP Page—Setup Tab , on page 2578, then click the **Add** or **Edit** button beneath the table.

Related Topics

Field Reference

Table 926: EIGRP Setup Dialog Box

Element	Description
AS Number	The autonomous system number for the EIGRP route. This number is used to identify the autonomous system to other routers. Valid values are from 1 to 65535.
Networks	The networks associated with the EIGRP route. Enter one or more network addresses or network/host objects, separated by commas. Click **Select** to select network/host objects from a list of existing objects, or to create new objects.
Passive Interfaces	The interfaces that do not send updates to their routing neighbors. Enter one or more interface names or roles, separated by commas. Click **Select** to select interface names or roles from a list of existing objects, or to create new interface role objects. **Note** When you make an interface passive, EIGRP suppresses the exchange of hello packets between routers, resulting in the loss of their neighbor relationship. This not only stops routing updates from being advertised but also suppresses incoming routing updates.
Auto-Summary	When selected, enables the automatic summarization of subnet routes into network-level routes. Summarization reduces the size of routing tables, thereby reducing the complexity of the network. When deselected, automatic summarization is disabled.

EIGRP Page—Interfaces Tab

Use the EIGRP Interfaces tab to create, edit, and delete interface properties for selected EIGRP autonomous systems. This includes modifying the default hello interval and disabling split horizon.

Note You can access the EIGRP Interfaces tab only after defining at least one EIGRP autonomous system in the Setup tab. See EIGRP Page—Setup Tab , on page 2578.

Navigation Path

Go to the EIGRP Routing Policy Page , on page 2578, then click the **Interfaces** tab.

Field Reference

Table 927: EIGRP Interfaces Tab

Element	Description
AS Number	The EIGRP autonomous system number for which interface properties are defined.
Interfaces	The interfaces related to the selected EIGRP autonomous system that have specially defined values.
Split Horizon	Indicates whether the split horizon feature is enabled or disabled for the selected interface.
Hello Interval	The defined interval between hello packets sent to neighboring routers.
Add button	Opens the EIGRP Interface Dialog Box , on page 2581. From here you can create an EIGRP interface definition.
Edit button	Opens the EIGRP Interface Dialog Box , on page 2581. From here you can edit the selected EIGRP interface definition.
Delete button	Deletes the selected EIGRP interface definitions from the table.

EIGRP Interface Dialog Box

Use the EIGRP Interface dialog box to add or edit interface definitions for a selected EIGRP autonomous system.

Navigation Path

Go to the EIGRP Page—Interfaces Tab , on page 2580, then click the **Add** or **Edit** button beneath the table.

Related Topics

Field Reference

Table 928: EIGRP Interface Dialog Box

Element	Description
AS Number	Selects the EIGRP autonomous system number whose interface properties you want to modify. For more information about EIGRP autonomous systems, see EIGRP Setup Dialog Box , on page 2579.
Interface	Specifies the EIGRP interface you wish to configure. Enter the name of an interface or interface role, or click **Select** to select an interface role object from a list or to create a new one.

Element	Description
Hello Interval	The default interval between hello packets sent by the router to its neighbors. Routers send hello packets to each other to dynamically learn of other routers on their directly attached networks. Valid values range from 1 to 65535 seconds. The default is 5 seconds.
Split Horizon	When selected, the split horizon feature is used to prevent routing loops. When deselected, split horizon is disabled. When split horizon is disabled, the router can advertise a route out of the same interface through which it learned the route. Disabling split horizon is often useful when dealing with nonbroadcast networks, such as Frame Relay and SMDS. **Note** Changing the split horizon setting on an interface resets all adjacencies with EIGRP neighbors that are reachable over that interface.

EIGRP Page—Redistribution Tab

Use the EIGRP Redistribution tab to create, edit, and delete EIGRP redistribution mappings.

Navigation Path

Go to the EIGRP Routing Policy Page , on page 2578, then click the **Redistribution** tab.

Related Topics

Field Reference

Table 929: EIGRP Redistribution Tab

Element	Description
EIGRP AS Number	The area ID of the EIGRP route into which other routes are being redistributed.
Protocol	The protocol that is being redistributed.
AS/Process ID	The AS number or process ID of the route being redistributed.
Bandwidth	The minimum bandwidth of the path for the EIGRP route, as defined for the route metric.
Delay	The mean latency of the path, as defined for the route metric.
Reliability	A value representing the estimated reliability of the path, as defined for the route metric.

Element	Description
Effective Bandwidth	A value representing the effective load on the link, as defined for the route metric.
MTU	The minimum MTU of the path, as defined for the route metric.
Match	When redistributing an OSPF process, indicates the types of OSPF routes that are being redistributed.
Add button	Opens the EIGRP Redistribution Mapping Dialog Box , on page 2583. From here you can define EIGRP redistribution mappings.
Edit button	Opens the EIGRP Redistribution Mapping Dialog Box , on page 2583. From here you can edit the selected EIGRP redistribution mapping.
Delete button	Deletes the selected EIGRP redistribution mappings from the table.

EIGRP Redistribution Mapping Dialog Box

Use the EIGRP Redistribution Mapping dialog box to add or edit the properties of an EIGRP redistribution mapping.

Navigation Path

Go to the EIGRP Page—Redistribution Tab , on page 2582, then click the **Add** or **Edit** button beneath the table.

Note You must create at least one EIGRP AS before you can access the EIGRP Redistribution dialog box. See EIGRP Page—Setup Tab , on page 2578.

Related Topics

- Redistributing Routes into EIGRP , on page 2577

Field Reference

Table 930: EIGRP Redistribution Mapping Dialog Box

Element	Description
EIGRP AS Numbers	The EIGRP AS into which other routes are being redistributed. You must select an ID number from the list of EIGRP autonomous systems defined in the EIGRP Page—Setup Tab , on page 2578.

Element	Description
Protocol to Redistribute	The routing protocol that is being redistributed: • Static—Redistributes static routes. You can define a single mapping for each route. • EIGRP—Redistributes an EIGRP autonomous system. Enter the AS number in the displayed field. You can define a single mapping for each AS. • BGP—Redistributes a BGP autonomous system. You can define a single BGP mapping on each device. If you configured a BGP AS in the BGP Setup tab, the AS number is displayed. Otherwise, a message is displayed indicating that no BGP AS was defined. See BGP Page—Redistribution Tab , on page 2571.

Protocol to Redistribute (continued)	• OSPF—Redistributes a different OSPF process. You can define a single mapping for each process. Select a process from the displayed list, then select one or more match criteria:
	  • Internal—Routes that are internal to a specific AS.
	  • External1—Routes that are external to the AS and imported into OSPF as a Type 1 external route.
	  • External2—Routes that are external to the AS and imported into the selected process as a Type 2 external route.
	  • NSAAExternal1—Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes.
	  • NSAAExternal2—(NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes.
	• RIP—Redistributes RIP routes.
	• Connected—Redistributes routes that are established automatically by virtue of having enabled IP on an interface. These routes are redistributed as external to the AS.

Metrics	The default metric (cost) of the redistributed route. Metric parameters include: • Bandwidth—The minimum bandwidth of the path in kilobits per second. Valid values range from 1 to 4294967295. • Delay—The mean latency of the path in units of 10 microseconds. Valid values range from 0 to 4294967295. • Reliability—A value expressing the estimated reliability of the link. Valid values range from 0 to 255, where 255 represents 100% reliability. • Effective Bandwidth—A value expressing the effective load on the link. Valid values range from 1 to 255, where 255 represents 100% utilization. • MTU of Path—The maximum transmission unit of the path. Valid values range from 1 to 65535 bytes.

OSPF Routing on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Open Shortest Path First (OSPF) is an interior gateway routing protocol that uses link states instead of distance vectors to distribute routing information within a single autonomous system (AS). OSPF propagates link-state advertisements (LSAs) instead of routing table updates, which allows OSPF networks to converge more quickly than RIP networks. You define areas to limit the number of LSAs that need to be propagated to changes that occur within the area.

A router that has interfaces in multiple OSPF areas is called an Area Border Router (ABR). An ABR uses LSAs to send information about available routes to other OSPF routers. A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR). Any router can act as an ABR or ASBR.

The following topics describe the tasks you perform to create an OSPF routing policy:

- Defining OSPF Process Settings , on page 2585
- Defining OSPF Area Settings , on page 2586
- Redistributing Routes into OSPF , on page 2587
- Defining OSPF Interface Settings , on page 2590

Related Topics

- Static Routing on Cisco IOS Routers , on page 2617
- RIP Routing on Cisco IOS Routers , on page 2608
- EIGRP Routing on Cisco IOS Routers , on page 2573
- BGP Routing on Cisco IOS Routers , on page 2565

Defining OSPF Process Settings

You configure OSPF process parameters by specifying a process ID number, which identifies the OSPF process to other routers, and by deciding whether any interfaces should be passive. Passive interfaces do not send routing updates to their neighbors.

Related Topics

- Defining OSPF Area Settings , on page 2586
- Defining OSPF Interface Settings , on page 2590
- Redistributing Routes into OSPF , on page 2587
- OSPF Routing on Cisco IOS Routers , on page 2585

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Routing** > **OSPF Process** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform** > **Routing** > **OSPF Process** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The OSPF Process Setup tab is displayed. See Table 933: OSPF Process Setup Tab , on page 2601 for a description of the fields on this tab.

Step 2 On the OSPF Process Setup tab, select an OSPF process from the table, then click **Edit**, or click **Add** to create a process. The OSPF Setup dialog box appears. See Table 934: OSPF Setup Dialog Box , on page 2602 for a description of the fields in this dialog box.

Step 3 Enter the process ID number in the field provided. The process ID defined here does not need to match the process ID on any other devices.

Step 4 Define which interfaces should not send routing updates to its neighbors:

a) Click **Edit** under Passive Interfaces to display the Edit Interfaces dialog box. Use this dialog box to define which interfaces should *not* send routing updates to its neighbors.

b) Enter the names of one or more interfaces or interface roles, or click **Select** to select an interface role from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

c) Click **OK** to save your changes and return to the OSPF Setup dialog box.

Step 5 Click **OK** to save your definitions locally on the client and close the dialog box.

Defining OSPF Area Settings

You configure OSPF area settings by associating an area ID with a particular OSPF process, selecting the networks included in the area, and selecting the type of authentication used by the routers in the area.

Each OSPF process that you define should contain at least one defined area. If you define more than one area, one area must be area 0. This is called the backbone. All other areas must be physically connected to the backbone. This enables other areas to inject routing information into the backbone, which the backbone distributes to the remaining areas.

You must configure at least one OSPF process before defining OSPF area/network settings for that process.

Related Topics

- Defining OSPF Process Settings , on page 2585
- Defining OSPF Interface Settings , on page 2590
- Redistributing Routes into OSPF , on page 2587
- OSPF Routing on Cisco IOS Routers , on page 2585

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > OSPF Process** from the Policy selector, then click the **Area** tab in the work area.
- (Policy view) Select **Router Platform > Routing > OSPF Process** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Area** tab.

The OSPF Process Area tab is displayed. See Table 935: OSPF Process Area Tab , on page 2603 for a description of the fields on this tab.

Step 2 On the OSPF Process Area tab, select an OSPF area from the table, then click **Edit**, or click **Add** to create an area. The OSPF Area dialog box appears. See Table 936: OSPF Area Dialog Box , on page 2604 for a description of the fields in this dialog box.

Step 3 Select a process ID from the displayed list.

Step 4 Enter an area ID to associate with the selected OSPF process.

Step 5 Enter the addresses of the networks to include in the OSPF area. You can enter a combination of addresses and network/host objects, or click **Select** to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 6 Select the authentication type to use in the OSPF area: MD5, clear text, or none. We recommend MD5 when security is of concern. Please note the following:

- The authentication type must be the same for all routers and access servers in the same area.
- Specifying clear-text authentication for an area sets the authentication to Type 1 (simple password). All routers on a network must use the same clear-text password to communicate with each other using OSPF.
- MD5 passwords need not be the same throughout an area, but they must be the same between neighbors.
- If you use interface authentication (see Defining OSPF Interface Settings , on page 2590), the authentication type used for the area must match the authentication type used for the interface.

Step 7 Click **OK** to save your definitions. The OSPF area appears in the table displayed on the OSPF Area tab.

Redistributing Routes into OSPF

Redistribution refers to using a routing protocol, such as OSPF, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you can redistribute routes from the RIP routing protocol into your OSPF domain. Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

Redistributing routes into OSPF from other routing protocols or from static routes causes these routes to become OSPF external routes (Type 1 or Type 2).

Redistributing routes into OSPF involves:

- Defining OSPF Redistribution Mappings , on page 2588
- Defining OSPF Maximum Prefix Values , on page 2589

Related Topics

- Defining OSPF Process Settings , on page 2585

- Defining OSPF Area Settings , on page 2586
- Defining OSPF Interface Settings , on page 2590
- OSPF Routing on Cisco IOS Routers , on page 2585

Defining OSPF Redistribution Mappings

When you define OSPF redistribution mappings, you must select the protocol to redistribute and the OSPF process into which routes from that protocol are redistributed. Additionally, you can manually define the metric, which determines the priority of the redistributed routes, and the type of external OSPF route to create, Type 1 or Type 2.

You can create multiple mappings to the same OSPF process. For example, you can redistribute both RIP and EIGRP routes into the same OSPF process. You can also redistribute routes from other OSPF processes.

Note Redistribution into an OSPF Not-So-Stubby Area (NSSA) creates a special type of link-state advertisement (LSA) called type 7, which can exist only in an NSSA area. An NSSA autonomous system router (ASBR) generates this LSA, and an NSSA area border router (ABR) translates it into a type 5 LSA, which is propagated into the OSPF domain.

Type 1 versus Type 2 External Routes

Two types of OSPF external routes exist, Type 1 and Type 2. The difference between the two is related to how the cost (metric) of the route is calculated. The cost of a Type 1 route is the sum of the external cost and the internal cost used to reach that route. The cost of a Type 2 route is based on the external cost only. By default, external routes are defined as Type 2. However, a Type 1 route is always preferred over a Type 2 route to the same destination.

Before You Begin

- Define at least one OSPF process. See Defining OSPF Process Settings , on page 2585.

Related Topics

- Defining OSPF Maximum Prefix Values , on page 2589
- Redistributing Routes into OSPF , on page 2587

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > OSPF Process** from the Policy selector, then click the **Redistribution** tab in the work area.
- (Policy view) Select **Router Platform > Routing > OSPF Process** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The OSPF Process Redistribution tab is displayed. See Table 937: OSPF Process Redistribution Tab , on page 2605 for a description of the fields on this tab.

Step 2 On the OSPF Process Redistribution tab, select a row from the OSPF Redistribution Mappings table, then click **Edit**, or click **Add** to create a mapping. The OSPF Redistribution Mapping dialog box is displayed. See Table 938: OSPF Redistribution Mapping Dialog Box , on page 2606 for a description of the fields in this dialog box.

Step 3 Select an existing OSPF process from the displayed list.

Step 4 Select the protocol whose routes you want to redistribute into the selected OSPF process.

Note You can create a single mapping for each static route, RIP route, BGP AS, EIGRP AS, and OSPF process.

Step 5 (Optional) Modify the default metric (cost) of the redistributed routes. The metric determines the priority of the routes.

Step 6 Select the Metric Type of external route to create, Type 1 or Type 2. The default is Type 2.

Step 7 (Optional) Select the **Limit to Subnets** check box to redistribute only subnetted routes. By default, this option is not selected.

Step 8 Click **OK** to save your definitions. The redistribution mapping appears in the Redistribution Mapping table on the OSPF Process Redistribution tab.

Defining OSPF Maximum Prefix Values

You can define a maximum number of prefixes (routes) that may be redistributed from other protocols or OSPF processes into a selected OSPF process. Setting a limit helps prevent the router from being flooded by too many redistributed routes. For example, without a defined maximum, flooding can occur when BGP is redistributed into OSPF.

When you define a maximum prefix value, you can decide whether to prevent additional routes from being redistributed once this maximum is reached, or whether to only issue a warning.

The redistribution limit applies to all IP redistributed prefixes, including summarized ones. The limit does not apply to default routes or prefixes that are generated as a result of type 7 to type 5 translations.

Before You Begin

- Define at least one OSPF process. Define at least one OSPF process. See Defining OSPF Process Settings , on page 2585.
- Define at least one OSPF redistribution mapping. See Defining OSPF Redistribution Mappings , on page 2588.

Related Topics

- Defining OSPF Redistribution Mappings , on page 2588
- Redistributing Routes into OSPF , on page 2587

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > OSPF Process** from the Policy selector, then click the **Redistribution** tab in the work area.
- (Policy view) Select **Router Platform > Routing > OSPF Process** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The OSPF Process Redistribution tab is displayed. See Table 937: OSPF Process Redistribution Tab , on page 2605 for a description of the fields on this tab.

Step 2 On the OSPF Process Redistribution tab, select a row from the Max Prefix Mapping table, then click **Edit**, or click **Add** to create a definition. The Max Prefix Mapping dialog box appears. See Table 939: OSPF Max Prefix Mapping Dialog Box , on page 2608 for a description of the fields in this dialog box.

Step 3 Select an existing OSPF process from the displayed list.

Step 4 In the Max Prefix field, enter the maximum number of routes that can be redistributed into the selected OSPF process.

Step 5 (Optional) Modify the default threshold percentage. When the number of redistributed routes reaches this threshold, a warning is issued. By default, the threshold value is 75% of the defined maximum prefix value.

Step 6 (Optional) Select what should happen when the maximum prefix value is reached:

- Enforce Maximum Route—Prevents additional routes from being redistributed to the selected process.
- Warning Only—Issues an additional warning, but allows route redistribution to continue even after the maximum prefix value is reached.

Note Flooding can result if you allow route redistribution to continue after exceeding the maximum prefix value.

Step 7 Click **OK** to save your definitions. The maximum prefix definition appears in the Maximum Prefix table on the OSPF Process Redistribution tab.

Defining OSPF Interface Settings

You can modify a variety of interface-specific OSPF parameters. This procedure describes how to define these parameters. For more information about a particular parameter, see the following topics:

- Understanding Interface Cost , on page 2591
- Understanding Interface Priority , on page 2592
- Disabling MTU Mismatch Detection , on page 2592
- Understanding OSPF Timer Settings , on page 2593
- Blocking LSA Flooding , on page 2593
- Understanding the OSPF Network Type , on page 2594
- Understanding OSPF Interface Authentication , on page 2595

Related Topics

- Defining OSPF Process Settings , on page 2585
- Defining OSPF Area Settings , on page 2586
- Redistributing Routes into OSPF , on page 2587
- OSPF Routing on Cisco IOS Routers , on page 2585

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > OSPF Interface** from the Policy selector.

- (Policy view) Select **Router Platform > Routing > OSPF Interface** from the Policy Type selector. Select an existing policy or create a new one.

The OSPF Interface page is displayed. See Table 931: OSPF Interface Page , on page 2596 for a description of the fields on this page.

Step 2 On the OSPF Interface page, select an interface definition from the table, then click **Edit**, or click **Add** to create a definition. The OSPF Interface dialog box appears. See Table 932: OSPF Interface Dialog Box , on page 2597 for a description of the fields in this dialog box.

Step 3 Enter the name of the interface or interface role to define, or click **Select** to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Step 4 Define interface authentication. The authentication type you select for the interface must match the authentication type you select for the area (see Defining OSPF Area Settings , on page 2586).

All neighboring routers on the same network must have the same password to be able to exchange OSPF information. For more information, see Understanding OSPF Interface Authentication , on page 2595.

The key ID number can be associated with multiple passwords. This is an easy and secure way to migrate passwords. For example, to migrate from one password to another, configure a password under a different key ID, then remove the first key.

Tip The key ID number can be associated with multiple passwords. This is an easy and secure way to migrate passwords. For example, to migrate from one password to another, configure a password under a different key ID, then remove the first key.

Note Do not use clear text authentication in OSPF packets for security purposes, because the unencrypted authentication key is sent in every packet. Use clear text authentication only when security is not an issue, for example, to ensure that misconfigured hosts do not participate in routing.

Step 5 (Optional) Under **Properties**, configure interface parameters as required. See Table 932: OSPF Interface Dialog Box , on page 2597 for information about each parameter.

Step 6 Click **OK** to save your definitions. The defined interfaces appear on the OSPF Interface page.

Step 7 Repeat the process to define interface-specific parameters on additional OSPF interfaces.

Understanding Interface Cost

The cost of an OSPF interface is a metric representing the cost of sending a packet over that interface. By default, this cost is calculated using this formula:

10^8 / bandwidth [bits per second]

For example, if the bandwidth of a Fast Ethernet interface is 10 Mbps (equal to 10^7), the cost of sending packets over that interface is calculated as $10^8 / 10^7$ or 10. This formula establishes an inverse relationship between the bandwidth of an interface and its cost; the greater the bandwidth, the lower the cost.

Although cost is a calculated value, you can manually enter the cost of a selected interface.

- Understanding OSPF Interface Authentication , on page 2595
- Defining OSPF Interface Settings , on page 2590

Understanding Interface Priority

Routers that share a common segment are elected through the Hello protocol to be neighbors on that segment. Election occurs as soon as the routers see themselves listed in their neighbor's hello packet. Adjacency is the next step. Adjacent routers are routers that proceed beyond the simple Hello exchange to a database exchange.

On each multiaccess (as opposed to point-to-point) segment, OSPF elects one router as the designated router (DR) for that segment. The DR acts as a central point of contact to minimize information exchange. Each router in the segment sends updates to the DR, which in turn relays the information to the other routers. A second router is elected as the backup designated router (BDR) in case the DR goes down.

DR and BDR election is performed via the Hello protocol. The router with the highest OSPF priority becomes the DR for that segment. The same process is then repeated for the BDR. In the case of a tie, the router with the higher router ID (RID) is elected. By default, each interface is given a priority of 1, but you can assign a higher priority to selected interfaces, as required.

Note The priority setting does not apply to point-to-point, nonbroadcast interfaces.

Disabling MTU Mismatch Detection

The MTU is the largest packet size that a particular interface can handle. If one router sends a DBD packet that is larger than the MTU setting on a neighboring router, the neighboring router ignores the packet. In many cases, an MTU mismatch causes the two routers to become stuck in exstart/exchange state, which prevents OSPF adjacency from being established. This is why it is important that all neighboring routers share the same MTU setting and that MTU mismatch detection be enabled.

You can, however, disable MTU mismatch detection. This is useful in cases where mismatch detection is preventing adjacency from taking place in an otherwise valid setup between two devices with different MTUs.

Blocking LSA Flooding

By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. Although some redundancy is desirable, too much redundancy can waste bandwidth. In certain topologies, such as full mesh, LSA flooding can destabilize the network because of excessive link and CPU usage. Therefore, you can block LSA flooding to selected interfaces on broadcast, nonbroadcast, and point-to-point networks.

- Defining OSPF Interface Settings , on page 2590

Understanding OSPF Timer Settings

OSPF uses a series of timers during operation:

- Hello Interval—Determines how often an interface sends hello packets, which are used to acquire neighbors and act as indicators that the router is still functioning. The smaller the interval, the faster topological changes on the network are detected. However, a smaller interval also results in more traffic being sent over the interface. The hello interval must be the same on all routers and access servers on a specific network.
- Transmit Delay—Determines the delay before an LSA is flooded over the link. The transmit delay setting should take into account the transmission and propagation delays for the interface. These factors are particularly important when configuring low-speed and on-demand links.
- Retransmit Interval—Determines how long to wait before retransmitting an unacknowledged database description (DBD) packet to its neighbors. The retransmit interval setting should be low enough to prevent excessive retransmissions.

Note You should increase the retransmit interval for serial lines and virtual links.

- Dead Interval—Determines how long an interface should wait before declaring its neighbor to be down. This declaration is caused by an absence of hello packets from the neighbor during this interval. The dead interval setting must be the same for all routers and access servers on a specific network. By default, this interval is four times the hello interval.

Understanding the OSPF Network Type

You can manually configure the OSPF network type on an interface as either broadcast or nonbroadcast multiaccess (NBMA), regardless of the default media type. For example, you can use this feature to configure broadcast networks (such as Ethernet, Token Ring, and FDDI) as NBMA when your network contains routers that do not support multicast addressing. You can also configure NBMA networks (such as X.25, Frame Relay, and SMDS) as broadcast networks, which eliminates the need to configure neighbors.

Configuring NBMA networks as either broadcast or nonbroadcast assumes the existence of virtual circuits (VCs) from every router to every router (fully meshed network). If VCs do not exist between each router, due to cost constraints or the existence of an only partially meshed network, you can configure the OSPF network type as point-to-multipoint. An OSPF point-to-multipoint interface is defined as a numbered point-to-point interface having one or more neighbors. It creates multiple host routes.

If you use the point-to-multipoint network type, routing between two routers that are not directly connected go through a third router that has VCs to both routers. You do not need to configure neighbors when using this feature. OSPF point-to-multipoint networks have the following benefits compared to NBMA and point-to-point networks:

- Point-to-multipoint is easier to configure because it consumes only one IP subnet and does not require neighbor configuration or designated router election.
- It costs less because it does not require a fully meshed topology.
- It is more reliable because it maintains connectivity in the event of VC failure.

Note For point-to-multipoint, broadcast networks, you can optionally define neighbors, in which case you should specify the cost to each neighbor. For point-to-multipoint, nonbroadcast networks, you must identify neighbors, but specifying a cost to each neighbor is optional. In both cases, you define neighbors using FlexConfig. See Understanding FlexConfig Policies and Policy Objects , on page 342 for more information.

- Defining OSPF Interface Settings , on page 2590

Understanding OSPF Interface Authentication

You define neighbor authentication settings for OSPF interfaces by selecting the interfaces and selecting an authentication type, either MD5 or clear text.

When you use MD5 authentication, neighboring routers must share the same password. When you use clear-text authentication, all routers on the network using OSPF must share the same password.

Whenever you configure an interface with a new key, the router sends multiple copies of the same packet, each authenticated by different keys. The router stops sending duplicate packets when it detects that all of its neighbors have adopted the new key.

Note You should use authentication with all routing protocols when possible, because attackers can use route redistribution between OSPF and other protocols (such as RIP) to subvert routing information.

Field Reference

Table 931: OSPF Interface Page

Element	Description
Interfaces	The name of an interface (as defined by an interface role) on which OSPF is enabled.
Authentication	The type of OSPF neighbor authentication enabled for the selected interface.
Key ID	The identification number of the authentication key used for MD5 authentication.
Cost	The cost of sending packets over the selected interface, if this value is different from the cost as normally calculated.
Priority	The priority of the selected interface.
MTU Ignore	Indicates whether Maximum Transmission Rate (MTU) detection is disabled on the selected interface.
Database Filter	Indicates whether link-state advertisement (LSA) flooding is disabled on the selected interface.
Hello Interval	The interval between hello packets (in seconds) sent over this interface.
Transmit Delay	The amount of time OSPF waits (in seconds) before flooding an LSA over the link.
Retransmit Interval	The interval between LSA retransmissions (in seconds) over the selected interface.
Dead Interval	The interval OSPF waits (in seconds) before declaring a neighboring router dead because of an absence of hello packets.

Element	Description
Network Type	The network type configured for the selected interface, if it differs from the default medium.
Add button	Opens the OSPF Interface Dialog Box , on page 2597. From here you can define the properties of an OSPF interface.
Edit button	Opens the OSPF Interface Dialog Box , on page 2597. From here you can edit the properties of the selected OSPF interface.
Delete button	Deletes the selected OSPF interface definitions from the table.

OSPF Interface Dialog Box

Use the OSPF Interface dialog box to add or edit the properties of OSPF interfaces.

Navigation Path

Go to the OSPF Interface Policy Page , on page 2596, then click the **Add** or **Edit** button beneath the table.

Related Topics

Field Reference

Table 932: OSPF Interface Dialog Box

Element	Description
Interface	The OSPF interface to configure. Enter the name of an interface or interface role, or click **Select** to select the object from a list or to create a new one.

Element	Description
Authentication	Type—The authentication type used by the selected interface: • MD5—Uses the MD5 hash algorithm for authentication. This is the default. • Clear Text—Uses a clear text password for authentication. • None—Uses no authentication. **Note** The authentication type used on an interface must match the authentication type defined for the area. **Note** Use plain text authentication only when security is not an issue, for example, to ensure that misconfigured hosts do not participate in routing. • Key ID—Available only when MD5 is selected as the authentication type. The identification number of the authentication key. This number must be shared with all other devices sending updates to, and receiving updates from, the selected device. Valid values range from 1 to 255. • Key—The shared key used for authentication (MD5 or clear text). This key must be shared with all other devices sending updates to, and receiving updates from, the selected device. Enter this key again in the Confirm field. When using clear text, the key can include any continuous string of characters that can be entered from the keyboard (up to 8 bytes). When using MD5, the key can include alphanumeric characters only (up to 16 bytes).
Cost	The cost of sending packets over this interface. A value entered here overrides the default calculated cost (10 8 /bandwidth in bits per second). Valid values range from 1 to 65535.
Priority	The default priority of the interface. The priority is used to determine which routers become the designated router (DR) and backup designated router (BDR) for that segment. The higher the number, the higher the priority. The default priority is 1. Valid values range from 0 to 255. **Note** To exclude the interface from election as DR or BDR, assign a priority of 0. Configure router priority only for interfaces to multiaccess networks, not point-to-point networks.
MTU Ignore	When selected, ignores MTU mismatches between neighboring routers. When deselected, MTU mismatch detection is enabled. **Note** Typically, this option is not used, because it can cause routers to become stuck in exstart/exchange state, which prevents OSPF adjacency from being established.
Database Filter	When selected, blocks link-state advertisement (LSA) flooding to the selected interface. When deselected, LSA flooding is permitted. **Note** We recommend that you enable this option on fully-meshed networks. This option is not available for point-to-multipoint networks.

Element	Description
Hello Interval	The default interval (in seconds) between hello packets sent over the selected interface. These packets are used by neighboring routers to confirm the router sending the packets is still operating. Valid values range 1 to 65535 seconds. **Note** The hello interval must be the same for all routers and access servers in the network.
Transmit Delay	The amount of time OSPF waits (in seconds) before flooding an LSA over the link. The default is 1 second. Valid values range from 1 to 65535 seconds. **Note** When you configure slow links or on-demand links that queue traffic before sending it in bursts, we recommend that you take these link delays into account when defining this value.
Retransmit Interval	The interval between LSA retransmissions (in seconds) over the selected interface. The default is 5 seconds. Valid values range from 1 to 65535 seconds. **Note** We recommend that you increase this value for serial lines and virtual links.
Dead Interval	The interval (in seconds) after which an interface declares its neighbor dead if no hello packets are received. Valid values range from 1 to 655335 seconds. **Note** The value of the dead interval is typically the hello interval value multiplied by 4. The dead interval must be the same for all routers and access servers in the network.

Element	Description
Configure Network Type	When selected, enables you to select a network type that differs from the default medium used by the interface. When deselected, the network type is equivalent to the default medium used by the interface. For nonbroadcast multiaccess (NBMA) networks (such as ATM and Frame Relay), options are: • Broadcast—Treats the NBMA network as a broadcast network, which eliminates the need to configure neighbors. Use this option when there are virtual circuits from every router to every router (fully meshed network). • Point-to-Multipoint—Treats the nonbroadcast network as a series of point-to-point links. This option is easier to configure, less costly, and more reliable than NBMA or point-to-point networks. • Point-to-Multipoint Non-Broadcast—Statically maintains the known neighbors of the network. Selecting this option helps avoid the problem of losing neighbors that were learned dynamically through the reception of hello packets. **Note** Another option for NBMA networks is to configure neighbors manually using FlexConfigs. See Understanding FlexConfig Policies and Policy Objects , on page 342. For broadcast networks (such as Ethernet, Token Ring, and FDDI), you can select: • Non-Broadcast—Treats the broadcast network as a nonbroadcast network. • Point-to-Point—Treats the broadcast network as a point-to-point network. You can use this option, for example, to configure a broadcast network (such as Ethernet) as a nonbroadcast multiaccess (NBMA) network if not all routers in the network support multicast addressing.

OSPF Process Policy Page

OSPF is an interior gateway routing protocol that uses link states instead of distance vectors for path selection. OSPF propagates link-state advertisements (LSAs) instead of routing table updates, which enables OSPF networks to converge quickly.

You can configure OSPF process policies from the following tabs on the OSPF Process page:

- OSPF Process Page—Setup Tab , on page 2601
- OSPF Process Page—Area Tab , on page 2602
- OSPF Process Page—Redistribution Tab , on page 2604

For more information, see OSPF Routing on Cisco IOS Routers , on page 2585.

Note For more information about OSPF interface policies, see OSPF Interface Policy Page , on page 2596.

Navigation Path

- (Device view) Select **Platform** > **Routing** > **OSPF Process** from the Policy selector.
- (Policy view) Select **Router Platform** > **Routing** > **OSPF Process** from the Policy Type selector. Right-click **OSPF Process** to create a policy, or select an existing policy from the Shared Policy selector.

OSPF Process Page—Setup Tab

Use the OSPF Process Setup tab to create, edit, and delete OSPF processes. This includes selecting those interfaces that will remain passive, which means that they will not send routing updates to their neighbors. You can create as many processes for each router as required.

Navigation Path

Go to the OSPF Process Policy Page , on page 2600, then click the **Setup** tab.

Field Reference

Table 933: OSPF Process Setup Tab

Element	Description
Process ID	The process ID that identifies the OSPF routing process to other routers.
Passive Interfaces	The interfaces that do not send out routing updates.
Add button	Opens the OSPF Setup Dialog Box , on page 2601. From here you can define an OSPF process.
Edit button	Opens the OSPF Setup Dialog Box , on page 2601. From here you can edit the selected OSPF process.
Delete button	Deletes the selected OSPF processes from the table.

OSPF Setup Dialog Box

Use the OSPF Setup dialog box to add or edit an OSPF process.

Navigation Path

Go to the OSPF Process Page—Setup Tab , on page 2601, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Defining OSPF Process Settings , on page 2585

Field Reference

Table 934: OSPF Setup Dialog Box

Element	Description
Process ID	The process ID number for the OSPF process. This number identifies the OSPF process to other routers. It does not need to match the process ID on other devices. Valid values are from 1 to 65535.
Passive Interfaces	The interfaces that do not send updates to their routing neighbors. Click **Edit** to display the Edit Interfaces Dialog Box—OSPF Passive Interfaces , on page 2602. From here you can define these interfaces. **Note** When you make an interface passive, OSPF suppresses the sending of hello packets to neighboring routers. The interface will continue to receive routing updates, however.

Edit Interfaces Dialog Box—OSPF Passive Interfaces

When you configure an OSPF routing policy on a Cisco IOS router, use the Edit Interfaces dialog box to specify which interfaces will not send updates to their routing neighbors. Separate multiple names or roles with commas. Click **Select** to select interface names or roles from a list of existing objects, or to create new interface role objects.

Navigation Path

Go to the OSPF Setup Dialog Box , on page 2601, then click the **Edit** button in the Passive Interfaces field.

Related Topics

Field Reference

Table 937: OSPF Process Redistribution Tab

Element	Description
OSPF Redistribution Mapping Table	
OSPF Process ID	The ID of the OSPF routing domain into which other routes are being redistributed.
Protocol	The protocol that is being redistributed.
AS/Process ID	The AS number or process ID of the route that is being redistributed.
Match	When redistributing an OSPF process, indicates the types of OSPF routes that are being redistributed.
Metric	The value that determines the priority of the redistributed route.
Metric Type	The external link type associated with the default route advertised into the OSPF routing domain.
Subnets	Indicates whether routes that are subnetted are also being redistributed.
Add button	Opens the OSPF Redistribution Mapping Dialog Box , on page 2606. From here you can define OSPF redistribution mappings.
Edit button	Opens the OSPF Redistribution Mapping Dialog Box , on page 2606. From here you can edit the selected OSPF redistribution mapping.
Delete button	Deletes the selected redistribution mappings from the table.
OSPF Max Prefix Mapping Table	
OSPF Process ID	The ID of the OSPF routing domain for which a maximum prefix values has been defined.
Max Prefix	The maximum number of prefixes (routes) that may be redistributed to the selected OSPF process.
Threshold	The percentage of the maximum prefix value that acts as a threshold for triggering a warning message.
Action	Indicates whether redistribution to this OSPF process will stop when the maximum is reached, or whether only a warning is displayed.
Add button	Opens the OSPF Max Prefix Mapping Dialog Box , on page 2607. From here you can define maximum prefix values for OSPF processes.
Edit button	Opens the OSPF Max Prefix Mapping Dialog Box , on page 2607. From here you can edit the maximum prefix value defined for the selected OSPF process.
Delete button	Deletes the selected max prefix mappings from the table.

OSPF Redistribution Mapping Dialog Box

Use the OSPF Redistribution Mapping dialog box to add or edit the properties of an OSPF redistribution mapping.

Navigation Path

Go to the OSPF Process Page—Redistribution Tab , on page 2604, then click the **Add** or **Edit** button beneath the Redistribution Mapping table.

Note You must create at least one OSPF process before you can access the OSPF Redistribution dialog box. See OSPF Process Page—Setup Tab , on page 2601.

Related Topics

- OSPF Max Prefix Mapping Dialog Box , on page 2607

Field Reference

Table 938: OSPF Redistribution Mapping Dialog Box

Element	Description
Process ID	The OSPF process into which other routes are being redistributed. You must select a process ID number from the list of OSPF processes defined in the OSPF Process Page—Setup Tab , on page 2601.
Protocol to Redistribute	The routing protocol that is being redistributed: • Static—Redistributes static routes. You can define a single mapping for each route. • EIGRP—Redistributes an EIGRP autonomous system. Enter the AS number in the displayed field. You can define a single mapping for each AS. • BGP—Redistributes a BGP autonomous system. You can define a single BGP mapping on each device. If you configured a BGP AS in the BGP Setup tab, the AS number is displayed. Otherwise, a message is displayed indicating that no BGP AS was defined. See BGP Page—Redistribution Tab , on page 2571.

Element	Description
Protocol to Redistribute (continued)	• OSPF—Redistributes a different OSPF process. You can define a single mapping for each process. Select a process from the displayed list, then select one or more match criteria: • Internal—Routes that are internal to a specific AS. • External1—Routes that are external to the AS and imported into OSPF as a Type 1 external route. • External2—Routes that are external to the AS and imported into the selected process as a Type 2 external route. • NSAAExternal1—Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes. • NSAAExternal2—(NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes. • RIP—Redistributes RIP routes. You can define a single mapping for each route. • Connected—Redistributes routes that are established automatically by virtue of having enabled IP on an interface. These routes are redistributed as external to the AS.
Default Metric	A value representing the cost of the redistributed route.
Metric Type	The external link type that is associated with the route being redistributed into the OSPF routing domain: • 1—Type 1 external route. The metric is the sum of the external redistributed cost and the internal OSPF cost. • 2—Type 2 external route. The metric is equal to the external redistributed cost, as defined in the Metric field. This is the default.
Limit to Subnets	When selected, only subnetted routes are redistributed. When deselected, subnetted routes are not redistributed.

OSPF Max Prefix Mapping Dialog Box

Use the OSPF Max Prefix Mapping dialog box to add or edit the maximum number of routes that can be redistributed into an OSPF process.

Navigation Path

Go to the OSPF Process Page—Redistribution Tab , on page 2604, then click the **Add** or **Edit** button beneath the Prefix Mapping table.

Related Topics

- OSPF Redistribution Mapping Dialog Box , on page 2606

Field Reference

Table 939: OSPF Max Prefix Mapping Dialog Box

Element	Description
Process ID	The OSPF process into which other routes are being redistributed. The list contains the OSPF processes defined in the OSPF Process Page—Setup Tab , on page 2601.
Max Prefix	The maximum number of prefixes (routes) that can be redistributed into the selected OSPF process. Limiting the number of redistributed routes helps prevent the router from being flooded by an excessive number of routes.
Threshold	The percentage of the maximum prefix value that acts as a threshold for triggering warning messages. The default is 75%. **Note** This warning is triggered whether or not the Warning-Only check box is selected.
When maximum routes reached	The action to take when the maximum number of redistributed routes is reached: • Enforce Maximum Route—Prevents additional routes from being redistributed when the defined maximum prefix value is reached. This is the default. • Warning Only—Issues a warning when the maximum number of routes is reached, but does not prevent additional routes from being redistributed.

RIP Routing on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

Routing Information Protocol (RIP) is an Interior Gateway Protocol (IGP) that was created for use in small, homogeneous networks. RIP is a distance-vector protocol that sends routing-update messages at regular intervals (in a process called *advertising*) and whenever the network topology changes. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. If a router does not receive an update from another router for 180 seconds or more, it marks the routes served by the non-updating router as being unusable. If there is still no update after 240 seconds, the router removes all routing table entries for the non-updating router. Routing information is exchanged using UDP packets.

RIP evaluates routes by measuring the number of hops (the number of routers traversed) from the source to the destination. A directly connected network has a metric of zero. The maximum hop count allowed by RIP is 15. Any route with a hop count greater than 15 is considered unreachable.

Security Manager supports RIP version 2 only, which is described in RFC 1723. RIP 2 improves on the original RIP by enabling RIP messages to carry more information, which permits the use of a simple authentication

mechanism (clear text or MD5) to secure table updates. RIP 2 also supports subnet masks, a critical feature that was not available in the original version of RIP.

The following topics describe the tasks you perform to create a RIP routing policy:

- Defining RIP Setup Parameters , on page 2609
- Defining RIP Interface Authentication Settings , on page 2610
- Redistributing Routes into OSPF , on page 2587

Related Topics

- Static Routing on Cisco IOS Routers , on page 2617
- OSPF Routing on Cisco IOS Routers , on page 2585
- EIGRP Routing on Cisco IOS Routers , on page 2573
- BGP Routing on Cisco IOS Routers , on page 2565

Defining RIP Setup Parameters

You configure RIP setup parameters by selecting the networks to include in the route and deciding whether any interfaces should be passive. These interfaces do not send routing updates to their neighbors. Additionally, you can enable auto-summarization, which reduces the size and complexity of the routing tables the router must maintain.

Related Topics

- Defining RIP Interface Authentication Settings , on page 2610
- Redistributing Routes into OSPF , on page 2587
- RIP Routing on Cisco IOS Routers , on page 2608

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Routing** > **RIP** from the Policy selector, then click the **Setup** tab in the work area.
- (Policy view) Select **Router Platform** > **Routing** > **RIP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Setup** tab.

The RIP Setup tab is displayed (see RIP Page—Setup Tab , on page 2612).

Step 2 Enter the addresses of the directly connected networks whose interfaces are to receive RIP updates. You can use a combination of addresses and network/host objects; separate addresses with commas. Click **Select** to select network/host objects from a list of existing objects, or to create new network/host objects. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 3 Enter the addresses of the passive interfaces, which are interfaces that should not send routing updates to their neighbors, if any. These interfaces continue to receive RIP routing broadcasts, which they use to populate their routing tables. Enter the names of one or more interfaces or interface roles; separate addresses with commas. Click **Select** to select interface names or roles from a list of existing objects, or to create new interface role objects. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Step 4 (Optional) Select the **Auto Summary** check box to enable the automatic summarization of subnet routes into network-level routes. Summarization reduces the size of routing tables, thereby reducing the complexity of the network.

Disable automatic summarization when you perform routing between disconnected subnets. When automatic summarization is turned off, subnets are advertised.

Defining RIP Interface Authentication Settings

You define neighbor authentication settings for RIP interfaces by selecting the interfaces and then selecting an authentication type, either MD5 or clear text.

Related Topics

- Defining RIP Setup Parameters , on page 2609
- Redistributing Routes into OSPF , on page 2587
- RIP Routing on Cisco IOS Routers , on page 2608

Step 1 Do one of the following:

- (Device view) Select **Platform > Routing > RIP** from the Policy selector, then click the **Authentication** tab in the work area.
- (Policy view) Select **Router Platform > Routing > RIP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Authentication** tab.

The RIP Authentication tab is displayed. See Table 941: RIP Authentication Tab , on page 2613 for a description of the fields on this tab.

Step 2 On the RIP Authentication tab, select an interface definition from the table, then click **Edit**, or click **Add** to create a definition. The RIP Authentication dialog box appears. See Table 942: RIP Authentication Dialog Box , on page 2614 for a description of the fields in this dialog box.

Step 3 Enter the name of the interface or interface role for which authentication is defined, or click **Select** to select an interface role from a list or to create a new one. For more information, see Specifying Interfaces During Policy Definition , on page 306.

Step 4 Define interface authentication (MD5 or clear text).

Note We do not recommend that you use clear text authentication in RIP packets, because the unencrypted authentication key is sent in every packet. Use plain text authentication only when security is not an issue, for example, to ensure that misconfigured hosts do not participate in routing.

Step 5 Click **OK** to save your definitions locally on the client and close the dialog box. The defined interface appears on the RIP Authentication tab.

Redistributing Routes into RIP

Redistribution refers to using a routing protocol, such as RIP, to advertise routes that are learned by some other means, such as a different routing protocol, static routes, or directly connected routes. For example, you

can redistribute routes from the OSPF routing protocol into your RIP route. Redistribution is necessary in networks that operate in multiple-protocol environments and can be applied to all IP-based routing protocols.

When you redistribute into RIP, you can maintain the original metric of the route by redistributing it transparently.

Before You Begin

- Define at least one RIP route. See Defining RIP Setup Parameters , on page 2609.

Related Topics

- Defining RIP Setup Parameters , on page 2609
- Defining RIP Interface Authentication Settings , on page 2610
- RIP Routing on Cisco IOS Routers , on page 2608

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Routing** > **RIP** from the Policy selector, then click the **Redistribution** tab in the work area.
- (Policy view) Select **Router Platform** > **Routing** > **RIP** from the Policy Type selector. Select an existing policy or create a new one, and then click the **Redistribution** tab.

The RIP Redistribution tab is displayed. See Table 943: RIP Redistribution Tab , on page 2615 for a description of the fields on this tab.

Step 2 On the RIP Redistribution tab, select a row from the RIP Redistribution Mappings table, then click **Edit**, or click **Add** to create a mapping. The RIP Redistribution Mapping dialog box appears. See Table 944: RIP Redistribution Mapping Dialog Box , on page 2616 for a description of the fields in this dialog box.

Step 3 Select the protocol whose routes you want to redistribute into RIP.

Note You can create a single mapping for each static route, BGP AS, EIGRP AS, and OSPF process.

Step 4 Define the metric (cost) of the redistributed routes by doing one of the following:

- Select the **Default Metric** check box, then enter the default metric of the redistributed routes. The metric determines the priority of the routes.
- Select the **Transparent** check box to maintain the original metric of the routes being redistributed into RIP.

Step 5 Click **OK** to save your definitions locally on the client and close the dialog box. The redistribution mapping appears in the Redistribution Mapping table on the RIP Redistribution tab.

RIP Routing Policy Page

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection. Security Manager supports RIP version 2 only, which includes support for neighbor authentication when routing updates are exchanged.

You can configure RIP routing policies from the following tabs on the RIP Routing page:

- RIP Page—Setup Tab , on page 2612
- RIP Page—Authentication Tab , on page 2613
- RIP Page—Redistribution Tab , on page 2614

For more information, see RIP Routing on Cisco IOS Routers , on page 2608.

Navigation Path

- (Device view) Select **Platform** > **Routing** > **RIP** from the Policy selector.
- (Policy view) Select **Router Platform** > **Routing** > **RIP** from the Policy Type selector. Right-click **RIP** to create a policy, or select an existing policy from the Shared Policy selector.

RIP Page—Setup Tab

Use the RIP Setup tab to create, edit, and delete RIP routes.

Navigation Path

Go to the RIP Routing Policy Page , on page 2611, then click the **Setup** tab.

Related Topics

- Specifying IP Addresses During Policy Definition , on page 318
- Understanding Networks/Hosts Objects , on page 310

Field Reference

Table 940: RIP Setup Tab

Element	Description
Networks	The directly connected networks associated with the RIP route. Enter one or more network addresses or network/host objects, separated by commas. Click **Select** to select network/host objects from a list of existing objects, or to create new objects.
Passive Interfaces	The interfaces that do not send updates to their routing neighbors. Enter one or more interface names or roles, separated by commas. Click **Select** to select interface names or roles from a list of existing objects, or to create new interface role objects.

Element	Description
Auto-Summary	When selected, enables the automatic summarization of subnet routes into network-level routes. Summarization reduces the size of routing tables, thereby reducing the complexity of the network. When deselected, automatic summarization is disabled. **Note** Disable automatic summarization when performing routing between disconnected subnets. When this feature is disabled, subnets are advertised.

RIP Page—Authentication Tab

Use the RIP Authentication tab to view, create, edit, and delete the neighbor authentication settings of RIP interfaces.

Navigation Path

Go to the RIP Routing Policy Page , on page 2611, then click the **Authentication** tab.

Related Topics

- Defining RIP Interface Authentication Settings , on page 2610

Field Reference

Table 941: RIP Authentication Tab

Element	Description
Interfaces	The name of an interface (as defined by an interface role) on which RIP is enabled.
Authentication	The type of RIP neighbor authentication that is enabled for the selected interface role—clear text or MD5.
Key ID	The identification number of the authentication key used for MD5 authentication.
Add button	Opens the RIP Authentication Dialog Box , on page 2614. From here you can define authentication for an additional RIP interface.
Edit button	Opens the RIP Authentication Dialog Box , on page 2614. From here you can edit the authentication properties of the selected RIP interface.
Delete button	Deletes the selected authentication definitions from the table.

RIP Authentication Dialog Box

Use the RIP Authentication dialog box to add or edit the neighbor authentication properties of RIP interfaces.

Navigation Path

Go to the RIP Page—Authentication Tab , on page 2613, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Defining RIP Interface Authentication Settings , on page 2610

Field Reference

Table 942: RIP Authentication Dialog Box

Element	Description
Interface	The interface for which you want to define authentication properties. Enter the name of an interface or interface role, or click **Select** to select the object from a list or to create a new one. **Note** You cannot specify two different authentication configurations for the same interface.
Authentication	The type of authentication to apply to the interface: • MD5—(Recommended) Uses the MD5 hash algorithm for authentication. • Clear Text—Uses clear text for authentication. **Note** Use plain text authentication only when security is not an issue, for example, to ensure that misconfigured hosts do not participate in routing.
Key ID	Available only when MD5 is selected as the authentication type. The identification number of the authentication key. This number must be shared with all other devices sending updates to, and receiving updates from, the selected device. Valid values range from 0 to 2147483647.
Key	The shared key used for authentication (MD5 or clear text). This key must be shared with all other devices sending updates to, and receiving updates from, the selected device. The key can contain up to 80 alphanumeric characters; the first character cannot be a number. Spaces are allowed. Enter the key again in the Confirm field.

RIP Page—Redistribution Tab

Use the RIP Redistribution tab to view, create, edit, and delete redistribution settings when performing redistribution into an RIP routing domain.

Note You must define RIP setup parameters before you can access the RIP Redistribution tab. See RIP Page—Setup Tab , on page 2612.

Navigation Path

Go to the RIP Routing Policy Page , on page 2611, then click the **Redistribution** tab.

Field Reference

Table 943: RIP Redistribution Tab

Element	Description
Protocol	The protocol that is being redistributed.
AS/Process ID	The autonomous system (AS) number or process ID of the route being redistributed.
Metric	The value that determines the priority of the redistributed route.
Match	When redistributing an OSPF process, indicates which types of OSPF routes are being redistributed.
Add button	Opens the RIP Redistribution Mapping Dialog Box , on page 2615. From here you can define a RIP redistribution mapping.
Edit button	Opens the RIP Redistribution Mapping Dialog Box , on page 2615. From here you can edit the selected RIP redistribution mapping.
Delete button	Deletes the selected redistribution mappings from the table.

RIP Redistribution Mapping Dialog Box

Use the RIP Redistribution Mapping dialog box to add or edit the properties of an RIP redistribution mapping.

Navigation Path

Go to the RIP Page—Redistribution Tab , on page 2614, then click the **Add** or **Edit** button beneath the table.

Related Topics

- Redistributing Routes into RIP , on page 2610

Field Reference

Table 944: RIP Redistribution Mapping Dialog Box

Element	Description
Protocol to Redistribute	The routing protocol that is being redistributed: • Static—Redistributes static routes. You can define a single mapping for each route. • EIGRP—Redistributes an EIGRP autonomous system. Enter the AS number in the displayed field. You can define a single mapping for each AS. • BGP—Redistributes a BGP autonomous system. You can define a single BGP mapping on each device. If you configured a BGP AS in the BGP Setup tab, the AS number is displayed. Otherwise, a message is displayed indicating that no BGP AS was defined. See BGP Page—Redistribution Tab , on page 2571.

Protocol to Redistribute (continued)	• OSPF—Redistributes a different OSPF process. You can define a single mapping for each process. Select a process from the displayed list, then select one or more match criteria:
	  • Internal—Routes that are internal to a specific AS.
	  • External1—Routes that are external to the AS and imported into OSPF as a Type 1 external route.
	  • External2—Routes that are external to the AS and imported into the selected process as a Type 2 external route.
	  • NSAAExternal1—Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes.
	  • NSAAExternal2—(NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes.
	• Connected—Redistributes routes that are established automatically by virtue of having enabled IP on an interface. These routes are redistributed as external to the AS.

Default Metric	Establishes a default value for the redistributed route. Valid values range from 0 to 16.
Transparent Metric	When selected, maintains the original metric of the route being redistributed. When deselected, the value specified in the Metric field is used.

Static Routing on Cisco IOS Routers

Note From version 4.17, though Cisco Security Manager continues to support IOS features/functionality, it does not support any bug fixes or enhancements.

You can configure static routing policies to ensure that the router correctly forwards packets to their destination when a route cannot be built dynamically. By default, static routes have a default administrative distance of 1 (implying a directly connected network), which causes them to override any dynamic routes discovered for the same host or network. You can, however, define a larger administrative distance to a static route so that it does not take precedence over a corresponding dynamic route.

For example, EIGRP routes have a default administrative distance of 5. To have a static route that can be overridden by an EIGRP route, you must specify an administrative distance greater than 5. This feature is useful when you define the static route as a "floating" route, which is inserted into the routing table only when the preferred route is unavailable.

Tip When you use the static route as a backup, "floating" route, specify the interface through which the next hop IP address can be reached instead of entering a specific IP address. Otherwise, the "floating" route is not inserted in the routing table if the primary link fails. For more information, see *Specifying a Next Hop IP Address for Static Routes* on Cisco.com at this URL: http://www.cisco.com/en/US/tech/tk365/technologies_tech_note09186a00800ef7b2.shtml

Related Topics

- Defining Static Routes , on page 2617

Defining Static Routes

To define a static route, you must define the IP address (and optionally, the metric) of the hop gateway to which the router forwards packets destined to the selected host or network. You can define as many static routes as required.

Related Topics

- Static Routing on Cisco IOS Routers , on page 2617
- RIP Routing on Cisco IOS Routers , on page 2608
- OSPF Routing on Cisco IOS Routers , on page 2585
- EIGRP Routing on Cisco IOS Routers , on page 2573
- BGP Routing on Cisco IOS Routers , on page 2565

Step 1 Do one of the following:

- (Device view) Select **Platform** > **Routing** > **Static Routing** from the Policy selector.
- (Policy view) Select **Router Platform** > **Routing** > **Static Routing** from the Policy Type selector. Select an existing policy or create a new one.

The Static Routing page is displayed. See Table 945: Static Routing Page , on page 2619 for a description of the fields on this page.

Step 2 On the Static Routing page, select a static route from the table, then click **Edit**, or click **Add** to create a route. The Static Routing dialog box appears. See Table 946: Static Routing Dialog Box , on page 2620 for a description of the fields in this dialog box.

Step 3 (Optional) Select the **Use as Default Route** check box to make this route the default route for all unknown outbound packets.

Step 4 In the Prefix field, enter the address for the destination network, or click **Select** to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 5 Select a forwarding option:

- To define the router interface that forwards packets to the remote network, select **Forwarding Interface** and enter the name of an interface or interface role. You can click Select to select an interface role from a list or to create a new one. See Understanding Interface Role Objects , on page 303 and Selecting Objects for Policies , on page 230.
- To specify the next hop router that receives and forwards packets to the remote network, select **Forwarding IP**, then enter the address in the field provided, or click **Select** to select a network/host object from a list or to create a new one. For more information, see Specifying IP Addresses During Policy Definition , on page 318.

Step 6 (Optional) In the Distance Metric field, enter the number of hops to the next hop address for this router. This metric identifies the priority of the static route. If two routing entries specify the same network, the route with the lower metric value (that is, the lower cost) is given a higher priority and is selected.

If no value is specified, the default is 1, which implies a directly connected network.

Step 7 (Optional) Select the **Permanent route** check box to prevent this static route entry from being deleted, even in cases in which the interface is shut down or the router cannot communicate with the next router.

Step 8 Click **OK** to save your definitions locally on the client and close the dialog box. The static route appears in the table on the Static Routing page.

Static Routing Policy Page

Use the Static Routing page to create, edit, and delete static routes. For more information, see Defining Static Routes , on page 2617.

Navigation Path

- (Device view) Select **Platform** > **Routing** > **Static Routing** from the Policy selector.
- (Policy view) Select **Router Platform** > **Routing** > **Static Routing** from the Policy Type selector. Right-click **Static Routing** to create a policy, or select an existing policy from the Shared Policy selector.

Related Topics

Field Reference

Table 945: Static Routing Page

Element	Description
Prefix	The destination IP address of the static route.
Prefix Mask	The net mask of the selected IP address.
Default Route	Indicates whether the static route is the default route for unknown packets being forwarded by this router.
Interface or IP Address	The IP address or the interface name associated with the gateway router that is the next hop address for this router.
Distance	The number of hops from the gateway IP to the destination. The metric determines the priority of this route. The fewer the hops, the higher the priority assigned to the route, based on lower costs. When two routing entries specify the same network, the entry with the lower metric (that is, the higher priority) is selected.
Permanent Route	Indicates whether the static route is defined as a permanent route, which means that it will not be removed even if the interface is shut down or if the router is unable to communicate with the next router.
Add button	Opens the Static Routing Dialog Box , on page 2619. From here you can create a static route.
Edit button	Opens the Static Routing Dialog Box , on page 2619. From here you can edit the selected static route.
Delete button	Deletes the selected static routes from the table.

Static Routing Dialog Box

Use the Static Routing dialog box to add or edit static routes.

Navigation Path

Go to the Static Routing Policy Page , on page 2618, then click the **Add** or **Edit** button beneath the table.

Related Topics

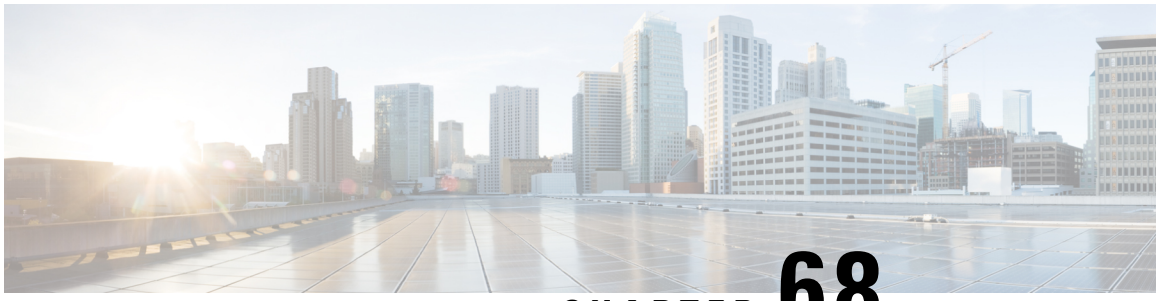
- Defining Static Routes , on page 2617

- Static Routing on Cisco IOS Routers , on page 2617

Field Reference

Table 946: Static Routing Dialog Box

Element	Description
Destination Network	Address information for the destination network defined by this static route. • Use as Default Route—When selected, makes this the default route on this router. A default route is used when the route from a source to a destination is unknown or when it is not feasible for the router to maintain many routes in its routing table. All unknown outbound packets are forwarded over the default route. When deselected, this static route is not the default route. • Prefix—The IP address of the destination network. Enter an IP address or the name of a network/host object, or click **Select** to select the object from a list or to create a new one. The prefix must be a class A, B, or C network or host IP. A host IP can begin with 0 unless it contains a discontiguous mask. All subnet addresses are valid.
Forwarding (Next Hop)	The method of forwarding data to the destination network: • Forwarding Interface—The router interface that forwards packets to the remote network. Enter the name of an interface or interface role, or click **Select** to select the object from a list or to create a new one. • Forwarding IP—The IP address of the next hop router that receives and forwards packets to the remote network. Enter an IP address or the name of a network/host object, or click **Select** to select the object from a list or to create a new one.
Distance Metric	The number of hops to the destination network (gateway IP). The default is 1 if no value is specified. The range is from 1 to 255. This metric (also known as *administrative distance*) is a measurement of route expense based on the number of hops to the network on which a specified host resides. This hop count includes all the networks a packet must traverse, including the destination network. Therefore, all directly connected networks have a metric of 1. Because the metric is based on expense, it is used to identify the priority of the static route. If two routing entries specify the same network, the route with the lower metric value (that is, the lower cost) is given a higher priority and is selected. **Note** Under certain circumstances, it is useful to assign a static route a lower priority (larger distance metric) than a dynamic route. This enables the static route to act as a backup, “floating,” route when the dynamic route is unavailable.
Permanent route	When selected, prevents this static route entry from being deleted, even in cases where the interface is shut down or the router cannot communicate with the next router. When deselected, this static route can be deleted.



CHAPTER 68

Managing Cisco Catalyst Switches and Cisco 7600 Series Routers

Note From version 4.17, though Cisco Security Manager continues to support Cisco Catalyst switches features/functionality, it does not support any bug fixes or enhancements.

Cisco Security Manager supports the management and configuration of security services and other platform-specific services on Cisco Catalyst switches and Cisco 7600 Series routers.

You can manage Catalyst switches and 7600 devices configured in VTP transparent or VTP client/server mode. Security Manager manages switches configured in client/server mode by bypassing VLAN database management on the device (including VLAN creation, deletion, and monitoring VLANs in the VLAN database on switches).

This chapter contains the following topics:

Discovering Policies on Cisco Catalyst Switches and Cisco 7600 Series Routers

Note From version 4.17, though Cisco Security Manager continues to support Cisco Catalyst switches features/functionality, it does not support any bug fixes or enhancements.

You can discover the configurations of your Cisco Catalyst switches and Cisco 7600 Series Routers (as well as the configurations of the services modules and security contexts associated with them) and import the configurations as policies into Security Manager. This makes it possible to add existing devices and manage them with Security Manager without having to configure each device manually, policy by policy. For more information, see Adding Devices to the Device Inventory , on page 77.

You can discover any command that Security Manager can configure. Discovery ignores unsupported commands, which means that they are left intact on the device even after subsequent deployments. Additionally, in cases where Security Manager can discover the command, but not all the subcommands and keywords related to that command, the unsupported elements are ignored and left intact on the device.

At any time, you can also *rediscover* the configurations of devices that you are already managing with Security Manager. Be aware, however, that we do not recommend rediscovery generally because performing rediscovery overwrites the policies that you have defined in Security Manager. For more information, see Discovering Policies on Devices Already in Security Manager , on page 181

Note We recommend that you perform deployment immediately after you discover policies, *before* you make any changes to policies or unassign policies from the device. (This recommendation also applies to any services module or security context hosted by the device.) Otherwise, the changes that you configure in Security Manager might not be deployed to the device. See Working with Deployment and the Configuration Archive , on page 405.

Viewing Catalyst Summary Information

Use the Catalyst Summary Info page to view high-level system information, including any service modules, ports, and VLANs that Security Manager has discovered.

To view Catalyst summary information, in Device view, right-click a Catalyst switch or Cisco 7600 Series router, then select **Catalyst Summary Info**, or select **Tools > Catalyst Summary Info**.

Note If Security Manager has not completed discovery for a particular Cisco Catalyst switch or Cisco 7600 Series router, the Catalyst Summary Info page for that device displays this message: “No information is available. This information is acquired during device discovery.”

Field Reference

Table 947: Catalyst Summary Info Page

Element	Description
Hostname	Displays the configured hostname of the device.
Device Type	Displays the device type.
Serial Number	Displays the serial number of the device.
OS Version	Displays the Cisco IOS image version the device is running.
Image	Displays the name of the image running on the device.
Last Update	Displays a time stamp for the most recent discovery.
Total Ports	Displays the total number of configured ports, combining access ports, routed ports, and trunk ports.
Access Ports	Displays the number of configured access ports on the chassis.
Trunk Ports	Displays the number of configured trunk ports on the chassis.
Routed Ports	Displays the number of configured routed ports on the chassis.
Total VLANs	Displays the total number of configured VLANs on the chassis and all its services modules.
Layer 2 VLANs	Displays the number of VLANs that run on Layer 2.
Layer 3 VLANs	Displays the number of VLANs that run on Layer 3.
Service Module Table	
Slot	Identifies the slot to which a service module is attached.
Device Type	Displays a brief description of the service module.
Serial Number	Displays the serial number of the service module.
Model	Displays the model type of the service module.
OS Version	Identifies the OS version that is installed and running on the service module.
Assigned VLANs	Displays the total number of VLANs to which an FWSM is assigned. **Tip** Click the Summary tab of the Interfaces/VLANs policy to learn which VLANs are assigned to an IDSM or a VPNSM.

Element	Description
Contexts	Displays the total number of configured security contexts for an FWSM that runs in multicontext mode. **Tip** Click the Summary tab of the Interfaces/VLANs policy to learn how many virtual sensors are configured for an IDSM.

Viewing a Summary of Catalyst Interfaces, VLANs, and VLAN Groups

Use the Summary tab of the Interfaces/VLAN policy to view attributes of all VLANs, VLAN groups, interfaces, and subinterfaces configured on supported Catalyst 6500 Series and 7600 Series chassis and their associated services modules.

To view summary interface information, in Device view, select **Interfaces/VLANs** from the Policy selector, then click the **Summary** tab.

Note The Summary tab is available only for Cisco Catalyst 6500 Series switches and Cisco 7600 Series routers.

Field Reference

Table 948: Interfaces/VLANs Page—Summary Tab

Element	Description
VLAN ID	The VLAN ID associated with an interface or subinterface. The VLAN ID specifies where 802.1Q tagged packets are sent and received on the specified an interface or subinterface; without a VLAN ID, the interface or subinterface cannot send or receive traffic. **Note** All VLAN IDs must be unique among all subinterfaces configured on the same physical interface.
VLAN Name	Name of the VLAN that corresponds to an interface or subinterface. For example, VLAN003 or Trunk1.

Element	Description
VLAN Group	Numeric identity of a VLAN group that is configured on the VLAN that a table row describes.
VLAN Type	Specifies whether a VLAN has access to Layer 2 or Layer 3.
IP Address/Mask	The IP address and corresponding subnet mask of the VLAN configured on an interface or subinterface.
Access Port	Displays the assigned name, if a name is assigned, of the access port that a VLAN uses.
Trunk Port	Specifies which VLANs are permitted to carry traffic over the trunk.
Slot (-Port)	Associates the chassis slot number (in which the relevant services module is installed) with the port number, as a hyphenated pair in the format *x* -*y* , for example 3-1.
Blade Type	Identifies the kind of services module on which a particular VLAN is configured, such as FWSM or VPNSM.
Security Context	Identifies the security context associated with an interface, but only if Multiple Mode is active on the installed module and an Admin context is configured for the module.
Security Context Interface	Displays the physical interface and subinterface IDs for which a security context inspects traffic. The displayed ID can represent a physical interface, a single sub-interface (defined as a range of one), or a range of sub-interfaces.
Security Level	Displays the security level of an interface, where values range from 0 (the lowest security) to 100 (the highest): • For an outside interface, the default is 0. • For an inside interface, the default is 100. • For an interface in the DMZ, the default is typically from 1 to 99.

Interfaces

You use the Interfaces tab on the Interfaces/VLANs page to view and manage the following types of ports:

- Access ports—A switching port that is used to connect host machines or servers. An access port belongs to and carries the traffic of only one VLAN. Traffic is received and sent in native formats with no VLAN tagging.
- Trunk ports—A switching port operating at Layer 2 to carry the traffic of multiple VLANs. Traffic is tagged with a VLAN number to differentiate traffic from each VLAN. A trunk port is used to connect switches to switches or to connect switches to routers.

- Routed ports—A physical port that acts like a port on a router. A routed port is not associated with a particular VLAN, and it behaves like a regular router interface. You can configure a routed port with a Layer 3 routing protocol.
- Dynamic ports—A port that can change dynamically to a trunk port if the neighboring port is configured as a trunk port.
- Unsupported ports—Ports on the Catalyst device that are not supported by Security Manager.

To display the Interfaces tab, select a Catalyst device in Device view, select **Interfaces/VLANs** from the Policy selector, then click the **Interfaces** tab in the work area.

The following topics describe the actions you can perform when defining interfaces on Catalyst devices:

- Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers , on page 2626
- Deleting Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers , on page 2628
- Interfaces/VLANs Page—Interfaces Tab , on page 2628

Related Topics

- VLANs , on page 2647

Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers

Note From version 4.17, though Cisco Security Manager continues to support Cisco Catalyst switches features/functionality, it does not support any bug fixes or enhancements.

You can create access ports, routed ports, or trunk ports on Cisco Catalyst Switches and Cisco 7600 Series Routers, with these restrictions:

- Each interface must have a name.
- You can associate an access port with only one VLAN.
- You can associate a trunk port with one or more VLANs.

Related Topics

- Creating or Editing VLANs , on page 2648
- Creating or Editing VLAN Groups , on page 2654
- Interfaces/VLANs Page—Interfaces Tab , on page 2628

- Interfaces , on page 2625

Step 1 (Device view) Select a Catalyst device, select **Interfaces/VLANs** from the Policy selector, then click the Interfaces tab in the work area.

The Interfaces tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—Interfaces Tab , on page 2628.

Step 2 Do one of the following:

- To define the attributes of a new interface, click **Add Row**.
- To edit the attributes of an interface, select it in the list, then click **Edit Row**.

Step 3 (Optional) Deselect the **Enable Interface** check box if you want this interface to be in shutdown mode.

Step 4 From the Type list, select **Interface** or **Subinterface**:

Step 5 (Interfaces only) Enter a name for the interface. You can click **Select** to open a dialog box that will help you generate a standard name based on interface type and details about the interface's location, such as card, slot, and subinterface. For more information on using the dialog box to generate an interface name, see Interface Auto Name Generator Dialog Box , on page 2318.

Step 6 (Interfaces only) Select an option from the **Mode** list to specify the port configuration type. The fields in the dialog box vary according to your selection.

Step 7 (Subinterfaces only) Select the parent interface of the subinterface, then enter the ID number.

Step 8 Define or configure the settings for the type that you selected:

- Access Port—See Create and Edit Interface Dialog Boxes—Access Port Mode , on page 2630 for a description of the fields.
- Routed Port—See Create and Edit Interface Dialog Boxes—Routed Port Mode , on page 2633 for a description of the fields.
- Trunk Port—See Create and Edit Interface Dialog Boxes—Trunk Port Mode , on page 2636 for a description of the fields.
- Dynamic Port—See Create and Edit Interface Dialog Boxes—Dynamic Mode , on page 2640 for a description of the fields.
- Subinterface—See Create and Edit Interface Dialog Boxes—Subinterfaces , on page 2644 for a description of the fields.
- Unsupported—See Create and Edit Interface Dialog Boxes—Unsupported Mode , on page 2645 for a description of the fields.

Step 9 From the **Speed** list, select an option to define the speed of the interface.

Step 10 If you defined a specific speed for the interface, and therefore the Duplex list is enabled, select a duplexing option.

Step 11 In the MTU field, enter the maximum transmission unit value.

Step 12 Configure whether to use flow control on inbound (Receive) and outbound (Send) traffic.

Step 13 (Optional) Enter a description for the interface in the **Description** field.

Step 14 Click **OK** to save your definitions locally on the client and close the dialog box.

Deleting Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers

Note From version 4.17, though Cisco Security Manager continues to support Cisco Catalyst switches features/functionality, it does not support any bug fixes or enhancements.

Although you can delete the definition of an interface at any time, use this option with great care. If the relevant device includes the interface definition in any policy definitions, deleting the interface causes these policy definitions to fail when they are deployed to the device.

Related Topics

- Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers , on page 2626
- Interfaces , on page 2625

Step 1 (Device view) Select a Cisco Catalyst switch or Cisco 7600 Series router from the Device selector.

Step 2 Select **Interfaces/VLANs** from the Policy selector.

Step 3 Click the Interfaces tab in the work area.

The Interfaces tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—Interfaces Tab , on page 2628.

Step 4 Select an interface from the table, then click **Delete Row**. The interface is deleted.

Interfaces/VLANs Page—Interfaces Tab

Use the Interfaces tab to view and configure interfaces and subinterfaces on supported Cisco Catalyst switches and Cisco 7600 Series routers and their associated services modules (blades).

Navigation Path

(Device view) Select **Interfaces/VLANs** from the Device selector, then click the **Interfaces** tab.

Field Reference

Table 949: Interfaces/VLANs Page—Interfaces Tab

Element	Description
Name	Interface type, chassis slot, and the number of the interface card. For example, *FastEthernet 2/7* means Fast Ethernet, slot 2, interface 7.
Mode	Configuration mode for physical ports: • Access • Routed • Trunk • Dynamic Auto • Dynamic Desirable • Unsupported
VLAN ID	The VLAN ID associated with the described subinterface, displayed only for Ethernet interfaces and VLAN interfaces.
IP Address	The IP address of the interface.
Enabled	Indicates whether the interface is enabled or disabled (shutdown state).
Interface Roles	The interface roles whose naming patterns match this interface. See Understanding Interface Role Objects , on page 303.
Description	An optional description of the interface.
Add Row button	Opens the Create Interface dialog box, where you can define a new interface. For more information, see the instructions for the relevant mode: • Access Port Mode— Create and Edit Interface Dialog Boxes—Access Port Mode , on page 2630. • Routed Port Mode— Create and Edit Interface Dialog Boxes—Routed Port Mode , on page 2633 • Trunk Port Mode— Create and Edit Interface Dialog Boxes—Trunk Port Mode , on page 2636 • Dynamic Mode— Create and Edit Interface Dialog Boxes—Dynamic Mode , on page 2640

Element	Description
Edit Row button	Opens the Edit Interface dialog box, where you can edit the selected interface. For more information, see the instructions for the relevant mode: • Access Port Mode— Create and Edit Interface Dialog Boxes—Access Port Mode , on page 2630. • Routed Port Mode— Create and Edit Interface Dialog Boxes—Routed Port Mode , on page 2633 • Trunk Port Mode— Create and Edit Interface Dialog Boxes—Trunk Port Mode , on page 2636 • Dynamic Mode— Create and Edit Interface Dialog Boxes—Dynamic Mode , on page 2640 • Unsupported— Create and Edit Interface Dialog Boxes—Unsupported Mode , on page 2645
Delete Row button	Deletes the selected interface.

Create and Edit Interface Dialog Boxes—Access Port Mode

Use the Create Interface dialog box (or the Edit Interface dialog box) to configure the attributes of physical and virtual interfaces that run in access port mode.

Navigation Path

Go to the Interfaces/VLANs Page—Interfaces Tab , on page 2628, click **Add** or **Edit** to open the Create/Edit Interface dialog box, then select **Access Port** from the Mode list.

- Understanding Interface Role Objects , on page 303

Field Reference

Table 950: Create and Edit Interface Dialog Boxes—Access Port Mode

Element	Description
Enable Interface	When selected, enables the interface. When deselected, disables the interface using the shutdown command.

Element	Description
Type	Specifies whether the definitions apply to an interface or a subinterface. For details about defining a subinterface, see Create and Edit Interface Dialog Boxes—Subinterfaces , on page 2644.
Name (Select button)	Displays the generated interface name, if the name has been set. Click **Select** to open the Interface Auto Name Generator Dialog Box , on page 2318. From here, you can enter or edit the details that Security Manager uses to generate an interface name.
Mode	The port configuration type for this interface. Select **Access Port** to display the configuration options that are relevant for access ports.
Access Port settings	
VLAN ID (Select button)	Displays the interface-specific identity of the VLAN to use in access port mode, if you have selected a VLAN. Otherwise, click **Select** to open the VLAN Selector Dialog Box , on page 2658. The VLAN ID specifies where 802.1Q tagged packets are sent and received on the subinterface; without a VLAN ID, the subinterface cannot send or receive traffic. Valid values range from 1 to 4094. Some VLAN IDs might be reserved on connected devices, so see the device documentation for more information. For multiple context mode, you can only set the VLAN in the system configuration. **Note** All VLAN IDs must be unique among all subinterfaces configured on the same physical interface. **Tip** To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the **vlan-id dot1q** command using CLI commands or FlexConfigs. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the device.
Enable Port Security	When selected, enables you to restrict input to an interface by limiting the MAC addresses that are allowed to access the port. When deselected, disables port security.
Max. MAC Addresses	Applies only when Enable Port Security is selected. The maximum number of secure MAC addresses for the interface. Valid values range from 1 to 4097. **Note** Secure MAC addresses are configured dynamically using the MAC addresses of connected devices.

Element	Description
Violation Policy	The action to take if a security violation occurs: • Port Security Protect—Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value. • Port Security Restrict—Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value. In addition, it causes the SecurityViolation counter to increment. • Port Security Shutdown—Immediately puts the interface into the error-disabled state and sends an SNMP trap notification. A security violation occurs if a workstation whose MAC address is not in the address table attempts to access the interface after the maximum number of secure MAC addresses is configured.
Enable VACL Capture	When selected, enables VACL capture. If the capture bit is set, ports with the capture function enabled can receive forwarded packets. When deselected, disables VACL capture.
Capture VLANs (Select button)	Enables you to identify the VLANs where VACLs should receive forwarded VLAN packets. This option is available if you selected the Enable VACL Capture check box. Enter a comma-separated list of VLAN IDs or click **Select** to open the VLAN Selector Dialog Box , on page 2658. VACLs can capture VLAN packets only when they are initially routed or bridged into the VLAN. Only forwarded packets can be captured.
Common interface settings	
Speed	The speed of the physical interface: • 10—Transmits at 10 Mbps. • 100—Transmits at 100 Mbps. • 1000—Transmits at 1,000 Mbps. • 10000—Transmits at 10,000 Mbps. • Auto—If Speed is set to Auto, both Speed and Duplex are autonegotiated. • Non-Negotiate—Disables link negotiation.

Element	Description
Duplex	The duplex setting of the interface: • Auto—Autonegotiates the duplex. • Half—Sends and receives data, but not at the same time • Full—Sends and receives data at the same time. If the speed is set to Auto, the duplex setting must also be set to Auto.
MTU	The maximum transmission unit, which refers to the largest packet size (in bytes) that can be handled by the interface. The range of valid values depends on the interface type.
Description	A text description of the interface. Enter up to 240 characters on a single line, without using carriage returns. **Note** For multiple context mode, the system description is independent of the context description.
Flow Control Receive	The flow control setting for incoming frames: • Off—The port does not use flow control, regardless of whether the neighboring port requests flow control. • On—The port uses flow control, as dictated by the neighboring port. • Desired—The port allows, but does not require, flow control frames. Flow control frames (also called pause frames) are special packets that signal a source to stop sending frames for a defined interval when buffers are full.
Flow Control Send	The flow control setting for outgoing frames: • Off—The port does not send flow control frames to the neighboring port. • On—The port sends flow control frames to the neighboring port. • Desired—The port allows, but does not require, flow control frames.
Roles	Lists the interface roles associated with the interface. Interface roles are objects that are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces. See Understanding Interface Role Objects , on page 303.

Create and Edit Interface Dialog Boxes—Routed Port Mode

Use the Create Interface dialog box (or the Edit Interface dialog box) to configure the attributes of physical interfaces that run in routed port mode on Layer 3.

Navigation Path

Go to the Interfaces/VLANs Page—Interfaces Tab , on page 2628, click **Add** or **Edit** to open the Create/Edit Interface dialog box, then select **Routed Port** from the Mode list.

Field Reference

Table 951: Create and Edit Interface Dialog Boxes—Routed Port Mode

Element	Description
Enable Interface	When selected, enables the interface. When deselected, disables the interface using the shutdown command.
Type	Specifies whether the definitions apply to an interface or a subinterface. For details about defining a subinterface, see Create and Edit Interface Dialog Boxes—Subinterfaces , on page 2644.
Name (Select button)	Displays the generated interface name, if the name has been set. Click **Select** to open the Interface Auto Name Generator Dialog Box , on page 2318. From here, you can enter or edit the details that Security Manager uses to generate an interface name.
Mode	The port configuration type for this interface. Select **Routed Port** to display the configuration options that are relevant for routed ports.
Routed Port settings	
IP Type	The type of IP address used by the port: • Static IP—Specifies that the interface uses a permanent IP address and activates related GUI elements.
IP Address (Select button)	Enables you to enter an IP address, or you can click **Select** to open the Networks/Hosts Selector, where you can select an IP address.
Helper IP Addresses (Select button)	Enables you to assign a helper IP address to the interface. A helper IP address converts broadcast DHCP requests to unicast requests that are directed exclusively to the DHCP server.

Element	Description
Mask	Enables you to specify the subnet mask. You can enter a netmask value or you can select a netmask from the list. If you enter a netmask, you can express its value in dotted decimal format (for example, 255.255.255.0) or you can enter the number of bits (for example, 24). **Note** Do not use 255.255.255.254 or 255.255.255.255 for any interface that is connected to your network; these netmasks cause all traffic on an interface to stop.
Common interface settings	
Speed	The speed of the physical interface: • 10—Transmits at 10 Mbps. • 100—Transmits at 100 Mbps. • 1000—Transmits at 1,000 Mbps. • 10000—Transmits at 10,000 Mbps. • Auto—If Speed is set to Auto, both Speed and Duplex are autonegotiated. • Non-Negotiate—Disables link negotiation.
Duplex	The duplex setting of the interface: • Auto—Autonegotiates the duplex. • Half—Sends and receives data, but not at the same time • Full—Sends and receives data at the same time. If the speed is set to Auto, the duplex setting must also be set to Auto.
MTU	The maximum transmission unit, which refers to the largest packet size (in bytes) that can be handled by the interface. The range of valid values depends on the interface type.
Description	A text description of the interface. Enter up to 240 characters on a single line, without using carriage returns. **Note** For multiple context mode, the system description is independent of the context description.
Flow Control Receive	The flow control setting for incoming frames: • Off—The port does not use flow control, regardless of whether the neighboring port requests flow control. • On—The port uses flow control, as dictated by the neighboring port. • Desired—The port allows, but does not require, flow control frames. Flow control frames (also called pause frames) are special packets that signal a source to stop sending frames for a defined interval when buffers are full.

Element	Description
Flow Control Send	The flow control setting for outgoing frames: • Off—The port does not send flow control frames to the neighboring port. • On—The port sends flow control frames to the neighboring port. • Desired—The port allows, but does not require, flow control frames.
Roles	Lists the interface roles associated with the interface. Interface roles are objects that are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces. See Understanding Interface Role Objects , on page 303.

Create and Edit Interface Dialog Boxes—Trunk Port Mode

Use the Create Interface dialog box (or the Edit Interface dialog box) to configure the attributes of physical and virtual interfaces that run in trunk port mode.

Navigation Path

Go to the Interfaces/VLANs Page—Interfaces Tab , on page 2628, click **Add** or **Edit** to open the Create/Edit Interface dialog box, then select **Trunk Port** from the Mode list.

Related Topics

Field Reference

Table 952: Create and Edit Interface Dialog Boxes—Trunk Port Mode

Element	Description
Enable Interface	When selected, enables the interface. When deselected, disables the interface using the shutdown command.
Type	Specifies whether the definitions apply to an interface or a subinterface. For details about defining a subinterface, see Create and Edit Interface Dialog Boxes—Subinterfaces , on page 2644.

Element	Description
Name (Select button)	Displays the generated interface name, if the name has been set. Click **Select** to open the Interface Auto Name Generator Dialog Box , on page 2318. From here, you can enter or edit the details that Security Manager uses to generate an interface name.
Mode	The port configuration type for this interface. Select **Trunk Port** to display the configuration options that are relevant for trunk ports.
Trunk Port settings	
Encapsulation	Select one of the following: • DOT1Q—Specifies VLAN encapsulation on the trunk link, as defined by the IEEE 802.1Q standard. Applies only to Ethernet subinterfaces. • ISL—Specifies ISL encapsulation on the trunk link. 10-Gigabit Ethernet ports do not support ISL encapsulation. **Tip** To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the **vlan-id dot1q** command using CLI commands or FlexConfigs. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the router.
Native VLAN (Select button)	Enables you to select the Native VLAN to associate with this interface, using the ID specified in the VLAN ID field. (If no VLAN ID is specified for the Native VLAN, the default is 1.) This option applies to you only if you are configuring a physical interface that is meant to serve as an 802.1Q trunk interface. You must first specify DOT1Q as the encapsulation type. The Native VLAN of a trunk interface is the VLAN to which all untagged VLAN packets are logically assigned. This includes the management traffic associated with the VLAN. When deselected, the Native VLAN is not associated with this interface. **Note** The Native VLAN cannot be configured on a subinterface of the trunk interface. Be sure to configure the same Native VLAN value at both ends of the link; otherwise, traffic may be lost or sent to the wrong VLAN. Click **Select** to open the VLAN Selector Dialog Box , on page 2658. From here, you can associate a native VLAN with the described interface.
Enable DTP negotiation	When selected, enables Dynamic Trunking Protocol (DTP) negotiation. DTP manages trunk auto-negotiation (ISL and 802.1Q) between devices. When deselected, disables DTP negotiation.

Element	Description
Allowed VLANs (Select button)	Enables you to specify which VLANs are allowed on the trunk. Enter the VLAN IDs. Use commas to separate multiple VLANs or use a hyphen to indicate a range of VLANs (for example, 12,17,22 or 2-200). Valid IDs range from 1 to 4094. Or, click **Select** to open the VLAN Selector Dialog Box , on page 2658. From here, you can select the VLANs to include on the trunk.
Prune VLANs (Select button)	Enables you to specify which VLANs are eligible for pruning. Enter the VLAN IDs. Use commas to separate multiple VLANs or use a hyphen to indicate a range of VLANs (for example, 12,17,22 or 2-200.) Or, click **Select** to open the VLAN Selector Dialog Box , on page 2658. From here, you can select the VLANs that are eligible for pruning.
Enable VACL Capture	When selected, enables VACL capture. If the capture bit is set, ports with the capture function enabled can receive forwarded packets. When deselected, disables VACL capture.
Capture VLANs (Select button)	Enables you to identify the VLANs where VACLs should receive forwarded VLAN packets. This option is available if you selected the Enable VACL Capture check box. Enter a comma-separated list of VLAN IDs, or click **Select** to open the VLAN Selector Dialog Box , on page 2658. VACLs can capture VLAN packets only when they are initially routed or bridged into the VLAN. Only forwarded packets can be captured.
Enable Port Security	Applies only to devices running IOS Software Version 12.2(18)SXE2 or later. When selected, enables you to restrict input to an interface by limiting the MAC addresses that are allowed to access the port. When deselected, disables port security. **Note** If you select this option, the Enable DTP Negotiation option is automatically deselected.
Max. MAC Addresses	Applies only when Enable Port Security is selected. The maximum number of secure MAC addresses for the interface. Valid values range from 1 to 4097. **Note** Secure MAC addresses are configured dynamically using the MAC addresses of connected devices.

Element	Description
Violation Policy	The action to take if a security violation occurs: • Port Security Protect—Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value. • Port Security Restrict—Drops packets with unknown source addresses until you remove a sufficient number of secure MAC addresses and the count drops below the maximum value. In addition, it causes the SecurityViolation counter to increment. • Port Security Shutdown—Immediately puts the interface into the error-disabled state and sends an SNMP trap notification. A security violation occurs if a workstation whose MAC address is not in the address table attempts to access the interface after the maximum number of secure MAC addresses is configured.
Common interface settings	
Speed	The speed of the physical interface: • 10—Transmits at 10 Mbps. • 100—Transmits at 100 Mbps. • 1000—Transmits at 1,000 Mbps. • 10000—Transmits at 10,000 Mbps. • Auto—If Speed is set to Auto, both Speed and Duplex are autonegotiated. • Non-Negotiate—Disables link negotiation.
Duplex	The duplex setting of the interface: • Auto—Autonegotiates the duplex. • Half—Sends and receives data, but not at the same time • Full—Sends and receives data at the same time. If the speed is set to Auto, the duplex setting must also be set to Auto.
MTU	The maximum transmission unit, which refers to the largest packet size (in bytes) that can be handled by the interface. The range of valid values depends on the interface type.
Description	A text description of the interface. Enter up to 240 characters on a single line, without using carriage returns. **Note** For multiple context mode, the system description is independent of the context description.

Element	Description
Flow Control Receive	The flow control setting for incoming frames: • Off—The port does not use flow control, regardless of whether the neighboring port requests flow control. • On—The port uses flow control, as dictated by the neighboring port. • Desired—The port allows, but does not require, flow control frames. Flow control frames (also called pause frames) are special packets that signal a source to stop sending frames for a defined interval when buffers are full.
Flow Control Send	The flow control setting for outgoing frames: • Off—The port does not send flow control frames to the neighboring port. • On—The port sends flow control frames to the neighboring port. • Desired—The port allows, but does not require, flow control frames.
Roles	Lists the interface roles associated with the interface. Interface roles are objects that are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces. See Understanding Interface Role Objects , on page 303.

Create and Edit Interface Dialog Boxes—Dynamic Mode

Use the Create Interface dialog box (or the Edit Interface dialog box) to configure the attributes of physical and virtual interfaces that run in dynamic mode. Dynamic ports can convert the link into a trunk link based on the settings of the neighboring port.

Navigation Path

Go to the Interfaces/VLANs Page—Interfaces Tab , on page 2628, click **Add** or **Edit** to open the Create/Edit Interface dialog box, then select **Dynamic** from the Mode list.

Field Reference

Table 953: Create and Edit Interface Dialog Boxes—Dynamic Mode

Element	Description
Enable Interface	When selected, enables the interface. When deselected, disables the interface using the shutdown command.
Type	Specifies whether the definitions apply to an interface or a subinterface. For details about defining a subinterface, see Create and Edit Interface Dialog Boxes—Subinterfaces , on page 2644.
Name (Select button)	Displays the generated interface name, if the name has been set. Click **Select** to open the Interface Auto Name Generator Dialog Box , on page 2318. From here, you can enter or edit the details that Security Manager uses to generate an interface name.
Mode	The port configuration type for this interface. Select **Dynamic** to display the configuration options that are relevant for dynamic ports.
Dynamic Port settings	
Dynamic Mode	The dynamic trunk mode: • Auto—Allows the port to convert the link to a trunk link. The port becomes a trunk port if the neighboring port is set to Trunk or Desirable mode. • Desirable—Makes the port actively attempt to convert the link to a trunk link.
Access VLAN ID	The access VLAN ID to use when the port does *not* function as a trunking link. This can occur when the neighboring interface is not set to trunk, auto, or desirable mode. Valid values range from 1 to 4094.
Encapsulation	Select one of the following: • DOT1Q—Specifies VLAN encapsulation on the trunk link, as defined by the IEEE 802.1Q standard. Applies only to Ethernet subinterfaces. • ISL—Specifies ISL encapsulation on the trunk link. 10-Gigabit Ethernet ports do not support ISL encapsulation. • Negotiate—Specifies that the interface negotiates with the neighboring interface to become either an ISL or 802.1Q trunk, based on the configuration and capabilities of the neighboring interface. **Tip** To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the **vlan-id dot1q** command using CLI commands or FlexConfigs. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the router.

Element	Description
Native VLAN (Select button)	Enables you to select the Native VLAN to associate with this interface, using the ID specified in the VLAN ID field. (If no VLAN ID is specified for the Native VLAN, the default is 1.) This option applies to you only if you are configuring a physical interface that is meant to serve as an 802.1Q trunk interface. You must first specify DOT1Q as the encapsulation type. The Native VLAN of a trunk interface is the VLAN to which all untagged VLAN packets are logically assigned. This includes the management traffic associated with the VLAN. When deselected, the Native VLAN is not associated with this interface. **Note** The Native VLAN cannot be configured on a subinterface of the trunk interface. Be sure to configure the same Native VLAN value at both ends of the link; otherwise, traffic may be lost or sent to the wrong VLAN. Click **Select** to open the VLAN Selector Dialog Box , on page 2658. From here, you can associate a native VLAN with the described interface.
Allowed VLANs (Select button)	Enables you to specify which VLANs are allowed on the trunk. Enter the VLAN IDs. Use commas to separate multiple VLANs or use a hyphen to indicate a range of VLANs (for example, 12,17,22 or 2-200). Valid IDs range from 1 to 4094. Alternatively, click **Select** to open the VLAN Selector Dialog Box , on page 2658. From here, you can select the VLANs to include on the trunk.
Prune VLANs (Select button)	Enables you to specify which VLANs are eligible for pruning. Enter the VLAN IDs. Use commas to separate multiple VLANs or use a hyphen to indicate a range of VLANs (for example, 12,17,22 or 2-200.) Alternatively, click **Select** to open the VLAN Selector Dialog Box , on page 2658. From here, you can select the VLANs that are eligible for pruning.
Enable VACL Capture	When selected, enables VACL capture. If the capture bit is set, ports with the capture function enabled can receive forwarded packets. When deselected, disables VACL capture.
Capture VLANs (Select button)	Enables you to identify the VLANs where VACLs should receive forwarded VLAN packets. This option is available if you selected the Enable VACL Capture check box. Enter a comma-separated list of VLAN IDs or click **Select** to open the VLAN Selector Dialog Box , on page 2658. VACLs can capture VLAN packets only when they are initially routed or bridged into the VLAN. Only forwarded packets can be captured.
Common interface settings	

Element	Description
Speed	The speed of the physical interface: • 10—Transmits at 10 Mbps. • 100—Transmits at 100 Mbps. • 1000—Transmits at 1,000 Mbps. • 10000—Transmits at 10,000 Mbps. • Auto—If Speed is set to Auto, both Speed and Duplex are autonegotiated. • Non-Negotiate—Disables link negotiation.
Duplex	The duplex setting of the interface: • Auto—Autonegotiates the duplex. • Half—Sends and receives data, but not at the same time • Full—Sends and receives data at the same time. If the speed is set to Auto, the duplex setting must also be set to Auto.
MTU	The maximum transmission unit, which refers to the largest packet size (in bytes) that can be handled by the interface. The range of valid values depends on the interface type.
Description	A text description of the interface. Enter up to 240 characters on a single line, without using carriage returns. **Note** For multiple context mode, the system description is independent of the context description.
Flow Control Receive	The flow control setting for incoming frames: • Off—The port does not use flow control, regardless of whether the neighboring port requests flow control. • On—The port uses flow control, as dictated by the neighboring port. • Desired—The port allows, but does not require, flow control frames. Flow control frames (also called pause frames) are special packets that signal a source to stop sending frames for a defined interval when buffers are full.
Flow Control Send	The flow control setting for outgoing frames: • Off—The port does not send flow control frames to the neighboring port. • On—The port sends flow control frames to the neighboring port. • Desired—The port allows, but does not require, flow control frames.

Element	Description
Roles	Lists the interface roles associated with the interface. Interface roles are objects that are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces. See Understanding Interface Role Objects , on page 303.

Create and Edit Interface Dialog Boxes—Subinterfaces

Use the Create Interface dialog box (or the Edit Interface dialog box) to configure the attributes of subinterfaces defined on Catalyst 6500/7600 devices.

Navigation Path

Go to the Interfaces/VLANs Page—Interfaces Tab , on page 2628, click **Add** or **Edit** to open the Create/Edit Interface dialog box, then select **Subinterface** from the Type list.

Related Topics

Field Reference

Table 954: Create and Edit Interface Dialog Boxes—Subinterfaces

Element	Description
Enable Interface	When selected, enables the subinterface. When deselected, disables the subinterface using the shutdown command.
Type	Specifies whether the definitions apply to an interface or a subinterface. Select **Subinterface**.
Parent	Identifies the parent interface of the subinterface.
Subint. ID	Specifies the ID for the subinterface. The numeric ID string cannot exceed 10 characters.
IP Type	The type of IP address used by the subinterface: • Static IP—Specifies that the subinterface uses a permanent IP address and activates related GUI elements.
IP Address	Enables you to enter an IP address.

Element	Description
Helper IP Addresses	Enables you to assign a helper IP address to the subinterface. A helper IP address converts broadcast DHCP requests to unicast requests that are directed exclusively to the DHCP server.
Mask	Enables you to specify the subnet mask. You can enter a netmask value or you can select a netmask from the list. If you enter a netmask, you can express its value in dotted decimal format (for example, 255.255.255.0) or you can enter the number of bits (for example, 24). **Note** Do not use 255.255.255.254 or 255.255.255.255 for any interface that is connected to your network; these netmasks cause all traffic on an interface to stop.
Encapsulation	The encapsulation type defined for the subinterface: • [blank]—No encapsulation is defined. • DOT1Q—Specifies VLAN encapsulation on the trunk link, as defined by the IEEE 802.1Q standard. Applies only to Ethernet subinterfaces. • ISL—Specifies ISL encapsulation on the trunk link. 10-Gigabit Ethernet ports do not support ISL encapsulation. **Tip** To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the **vlan-id dot1q** command using CLI commands or FlexConfigs. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the router.
VLAN ID	Applies only when encapsulation is defined for the subinterface. The VLAN ID associated with the subinterface.
Description	A text description of the interface. Enter up to 240 characters on a single line, without using carriage returns. **Note** For multiple context mode, the system description is independent of the context description.

Create and Edit Interface Dialog Boxes—Unsupported Mode

If you discover an interface configured with a mode that is not supported by Security Manager (such as dot1q-tunnel or private-vlan), the interface is displayed in Unsupported mode. You can view the attributes of this interface, but you cannot make any changes to the configuration unless you first change the mode. All definition fields, other than Mode, are read-only.

Navigation Path

Go to the Interfaces/VLANs Page—Interfaces Tab , on page 2628, select an interface whose mode is defined as Unsupported, then click **Add** or **Edit** to open the Create/Edit Interface dialog box.

Related Topics

- Create and Edit Interface Dialog Boxes—Access Port Mode , on page 2630
- Create and Edit Interface Dialog Boxes—Routed Port Mode , on page 2633
- Create and Edit Interface Dialog Boxes—Trunk Port Mode , on page 2636
- Create and Edit Interface Dialog Boxes—Dynamic Mode , on page 2640

Field Reference

Table 955: Create and Edit Interface Dialog Boxes—Unsupported Mode

Element	Description
Enable Interface	When selected, indicates that the interface is enabled. When deselected, indicates that the interface has been disabled using the shutdown command.
Type	Specifies whether the definitions apply to an interface or a subinterface.
Name (Select button)	Displays the name of the interface.
Mode	Displays Unsupported, which designates an interface whose mode is not supported by Security Manager. Select a different option to change the interface mode. **Note** If you change the interface mode, you can then modify the other settings in this dialog box.
Speed	Displays the speed of the physical interface: • 10—Transmits at 10 Mbps. • 100—Transmits at 100 Mbps. • 1000—Transmits at 1,000 Mbps. • 10000—Transmits at 10,000 Mbps. • Auto—If Speed is set to Auto, both Speed and Duplex are autonegotiated. • Non-Negotiate—Disables link negotiation.
Duplex	Displays the duplex setting of the interface: • Auto—Autonegotiates the duplex. • Half—Sends and receives data, but not at the same time • Full—Sends and receives data at the same time. If the speed is set to Auto, the duplex setting must also be set to Auto.

Element	Description
MTU	Displays the maximum transmission unit, which refers to the largest packet size (in bytes) that can be handled by the interface. The range of valid values depends on the interface type.
Description	Displays a text description of the interface. For multiple context mode, the system description is independent of the context description.
Flow Control Receive	Displays the flow control setting for incoming frames: • Off—The port does not use flow control, regardless of whether the neighboring port requests flow control. • On—The port uses flow control, as dictated by the neighboring port. • Desired—The port allows, but does not require, flow control frames. Flow control frames (also called pause frames) are special packets that signal a source to stop sending frames for a defined interval when buffers are full.
Flow Control Send	Displays the flow control setting for outgoing frames: • Off—The port does not send flow control frames to the neighboring port. • On—The port sends flow control frames to the neighboring port. • Desired—The port allows, but does not require, flow control frames.
Roles	Lists the interface roles associated with the interface. Interface roles are objects that are replaced with the actual interface IP addresses when the configuration is generated for each device. They allow you to define generic rules—ones that can apply to multiple interfaces. See Understanding Interface Role Objects , on page 303.

VLANs

A VLAN is a switched network that is segmented logically instead of on the basis of geography. For example, a VLAN might interconnect members of a geographically dispersed workgroup. VLANs offer a practical convenience for many organizations because they reduce the need to rearrange the physical placement of personnel, equipment, and network infrastructure. Properly configured VLANs are scalable, secure, and can simplify the tasks of network management.

A VLAN consists of hosts and network devices (such as bridges and routers), connected by a single bridging domain. Traffic between VLANs must be routed.

Security Manager helps you to create VLANs and define VLAN settings for the defined interfaces on Cisco Catalyst switches and Cisco 7600 Series routers, their supported services modules, and their security contexts.

The following topics describe the actions you can perform when defining VLANs on Catalyst devices:

• Creating or Editing VLANs , on page 2648
• Deleting VLANs , on page 2649
• Interfaces/VLANs Page—VLANs Tab , on page 2649

Related Topics

- VLAN Groups , on page 2654
- VLAN ACLs (VACLs) , on page 2659

Creating or Editing VLANs

You can create a VLAN or reconfigure the attributes of a VLAN.

Related Topics

- Deleting VLANs , on page 2649
- Creating or Editing VLAN Groups , on page 2654
- Creating or Editing VACLs , on page 2660
- Create and Edit VLAN Dialog Boxes , on page 2650
- VLANs , on page 2647

Step 1 (Device view) Select a Catalyst device, select Interfaces/VLANs from the Policy selector, then click the VLANs tab in the work area.

The VLANs tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLANs Tab , on page 2649.

Step 2 Do one of the following:

- To define the attributes of a new VLAN, click **Add Row**.
- To edit the attributes of a VLAN, select it in the list, then click **Edit Row**.

See Create and Edit VLAN Dialog Boxes , on page 2650, for a description of the fields in the dialog box.

Step 3 In the VLAN ID field, enter a unique ID number for the VLAN. The number that you enter must not be assigned to any other VLAN in the bridging group.

Step 4 (Optional) Enter a name for the VLAN.

Step 5 (Optional) If the VLAN is part of a VLAN group, select the group ID, or select **Add Group** to open the Create VLAN Group dialog box. For more information, see Creating or Editing VLAN Groups , on page 2654.

Step 6 From the Status list, specify the status of the VLAN (active or suspended).

Step 7 From the Type list, select either **Layer 2** or **Layer 3**.

Step 8 (Optional) For a Layer 3 VLAN, define a switched virtual interface (SVI):

a) To make the SVI active, select the **Enable Interface** check box. An SVI enables routing between VLANs and provides IP host connectivity to the switch. If you do not select this check box, the SVI is created in shutdown mode.
b) Enter the IP address for the SVI.
c) Enter the SVI subnet mask by typing it, or select a netmask value from the Subnet Mask list.
d) Enter an optional description, if required.

Step 9 Do one or both of the following:

- To associate access ports with the VLAN, enter their names in the Access Ports text box or click **Select** to open an interface selector.
- To associate trunk ports with the VLAN, enter their names in the Trunk Ports text box or click **Select** to open an interface selector.

See Interface Selector Dialog Box—VLAN ACL Content , on page 2665 for a description of the fields in the dialog box. For more information about defining ports, see Creating or Editing Ports on Cisco Catalyst Switches and Cisco 7600 Series Routers , on page 2626.

Step 10 Click **OK** to save your definitions locally on the client and close the dialog box.

Deleting VLANs

You can delete a VLAN. However, deleting a VLAN does not delete it from any policy that might reference it. Ensure that your other policies do not use the VLAN before you delete it. When you submit your changes to the database, Security Manager points out any undefined VLANs that are referenced by other policies.

Related Topics

- Creating or Editing VLANs , on page 2648
- VLANs , on page 2647

Step 1 (Device view) Select a Cisco Catalyst switch or Cisco 7600 Series router from the Device selector.

Step 2 Select **Interfaces/VLANs** from the Policies selector.

Step 3 Click the VLANs tab in the work area.

The VLANs tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLANs Tab , on page 2649.

Step 4 Select a VLAN from the table, then click **Delete Row**.

The VLAN is deleted.

Interfaces/VLANs Page—VLANs Tab

Use the VLANs tab to view and configure VLANs on supported Cisco Catalyst switches and Cisco 7600 Series routers.

Navigation Path

- (Device view) Select **Interfaces/VLANs** from the Device selector, then click the **VLANs** tab.

Field Reference

Table 956: Interfaces/VLANs Page—VLANs Tab

Element	Description
VLAN ID	Interface-specific identity of the VLAN that a table row describes. The VLAN ID specifies where 802.1Q tagged packets are sent and received on the subinterface; without a VLAN ID, the subinterface cannot send or receive traffic. Valid values range from 2 to 4094 (VLAN ID 1 is reserved). **Note** All VLAN IDs must be unique among all subinterfaces configured on the same physical interface. **Tip** To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the **vlan-id dot1q** command using CLI commands or FlexConfigs. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the device.
Name	Name of the corresponding VLAN for an interface or subinterface.
Interface	Identifies the logical name of the interface (interface role) or physical interface.
Type	Specifies whether a VLAN has access to Layer 2 or Layer 3.
Status	Indicates whether a VLAN is active or suspended.
Add Row button	Opens the Create VLAN dialog box to define a new VLAN.
Edit Row button	Opens the Edit VLAN dialog box to edit the selected VLAN.
Delete Row button	Deletes the selected VLAN.

Create and Edit VLAN Dialog Boxes

Use the Create VLAN dialog box (or the Edit VLAN dialog box) to configure or reconfigure VLAN settings and attributes.

Navigation Path

Go to the Interfaces/VLANs Page—VLANs Tab , on page 2649, then click the **Add** or **Edit** button beneath the table.

- Interface Selector Dialog Box—VLAN ACL Content , on page 2665

Field Reference

Table 957: Create and Edit VLAN Dialog Box

Element	Description
VLAN ID	Displays the VLAN ID if one is configured. Otherwise, enter the ID manually. The VLAN ID specifies where 802.1Q tagged packets are sent and received on an interface or subinterface; without a VLAN ID, the interface or subinterface cannot send or receive traffic. Each VLAN must have an ID. Valid values range from 1 to 4094. **Note** All VLAN IDs must be unique among all subinterfaces configured on the same physical interface. **Tip** To configure DOT1Q encapsulation on an Ethernet interface without associating the VLAN with a subinterface, enter the **vlan-id dot1q** command using CLI commands or FlexConfigs. Configuring VLANs on the main interface increases the number of VLANs that can be configured on the device.
Name	Enter a name for the VLAN, or view the VLAN name if you entered one previously. Each VLAN must have an ID, and can optionally have a name. The maximum length is 32 characters.
Group	The VLAN group to which the VLAN belongs. A VLAN can be associated with one group only. You can associate the VLAN with an existing group, or select **Add Group** to open the Create VLAN Group dialog box.
Status	The current status of the VLAN: • Active—The VLAN carries traffic. • Suspended—The VLAN does not pass packets.
Type	Indicates whether the specified VLAN is configured for Layer 2 or Layer 3, and enables you to choose the kind of VLAN that you prefer. A Layer 3 VLAN requires an IP address and creates a VLAN interface.

Element	Description
Switch Virtual Interface	Applies only when defining a Layer 3 VLAN. • Enable Interface—When selected, enables the switched virtual interface (SVI), which is a virtual interface that you can attach to any VLAN. The SVI enables routing between VLANs and provides IP host connectivity to the switch. When deselected, disables the SVI. • IP Address—The IP address for the SVI. An IP address is required for management access. • Subnet Mask—The subnet mask for the SVI. Select any option from the list of valid subnet mask entries. • Description—Enables you to enter a description of up to 240 characters on a single line, without carriage returns. For multiple context mode, the system description is independent of the context description.
Access Ports (Select button)	Lists which access ports are associated with the specified VLAN, if any are associated, and enables you to add or remove access port associations for the specified VLAN. You can associate any number of access ports with a VLAN. Click **Select** to open the Access Port Selector Dialog Box , on page 2652. From here, you can associate access ports with the specified VLAN, or remove access port associations from the VLAN.
Trunk Ports (Select button)	Lists which trunk ports are associated with the specified VLAN, if any are associated, and enables you to add or remove trunk port associations for the specified VLAN. A VLAN can belong to the allowed list of one or more trunk ports. You can include a VLAN in a trunk port group. Click **Select** to open the Trunk Port Selector Dialog Box , on page 2653. From here, you can associate trunk ports with the specified VLAN, or remove trunk port associations from the VLAN.

Access Port Selector Dialog Box

Use the Access Port Selector dialog box to define which access ports are associated with a selected VLAN.

Navigation Path

Open the Create and Edit VLAN Dialog Boxes , on page 2650, then click **Select** in the Access Ports field.

Related Topics

Element	Description
Available Trunk Ports	Displays all available trunk ports.
Add >> button	Adds interfaces that are selected in the Available Trunk Ports list to the Selected Trunk Ports list.
Remove << button	Removes selected interfaces from the Selected Trunk Ports list.
Selected Trunk Ports	Displays the interface objects that are selected.
Add Row button	Opens the Create Interface dialog box to define a new interface.
Edit Row button	Opens the Edit Interface dialog box to edit the selected interface.

VLAN Groups

A VLAN group defines a logical collection of VLANs. The VLAN Groups tab on the Interfaces/VLANs page displays:

- All VLAN groups that are defined on the selected device.
- The service module slots to which a VLAN group is bound.
- Which VLANs belong to each VLAN group.

VLAN groups can be used when assigning VLANs to an FWSM security context. A VLAN group can be assigned to multiple FWSMs, and each FWSM can have multiple VLAN groups assigned to it. To perform this assignment, see Add/Edit Security Context Dialog Box (FWSM) , on page 2291.

The following topics describe the actions you can perform when defining VLAN groups on Catalyst devices:

- Create and Edit VLAN Dialog Boxes , on page 2650
- Deleting VLAN Groups , on page 2655
- Interfaces/VLANs Page—VLAN Groups Tab , on page 2655

Related Topics

- Interfaces , on page 2625
- VLANs , on page 2647
- VLAN ACLs (VACLs) , on page 2659

Creating or Editing VLAN Groups

You can create VLAN groups. When you create a VLAN group, remember that:

- Each group must have an ID.
- You can associate a VLAN group with one or more FWSM modules.
- Each VLAN can be a member of only one VLAN group.

Related Topics

- Deleting VLAN Groups , on page 2655
- Creating or Editing VLANs , on page 2648
- Creating or Editing VACLs , on page 2660
- Interfaces/VLANs Page—VLAN Groups Tab , on page 2655
- VLAN Groups , on page 2654

Step 1 (Device view) Select a Catalyst device, select **Interfaces/VLANs** from the Policy selector, then click the VLAN Groups tab in the work area.

The VLAN Groups tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLAN Groups Tab , on page 2655.

Step 2 Do one of the following:

- To define the attributes of a new VLAN group, click **Add Row**.
- To edit the attributes of a VLAN group, select it in the list, then click **Edit Row**.

See Create and Edit VLAN Group Dialog Boxes , on page 2656, for a description of the fields in this dialog box.

Step 3 In the VLAN Group ID field, enter a unique ID number for the VLAN group. The number that you enter must not be assigned to any other VLAN group.

Step 4 To associate the VLAN group with specific servic Add/Edit Security Context Dialog Box (FWSM) , on page 2291e module slots, enter their slot numbers in the Service Module Slots text box, or click **Select** to open a selector.

Note Defining this association makes it possible to later assign this VLAN group to a security context on the FWSM. See Add/Edit Security Context Dialog Box (FWSM) , on page 2291.

Step 5 Enter the VLANs to add to the VLAN group, or click **Select** to open a selector.

Step 6 Click **OK** to save your definitions locally on the client and close the dialog box.

Deleting VLAN Groups

You can delete VLAN groups. Deleting a VLAN group has no affect on the VLANs in the group.

Related Topics

- Creating or Editing VLAN Groups , on page 2654
- VLAN Groups , on page 2654

Step 1 (Device view) Select a Catalyst 6500 Series switch or Cisco 7600 Series router from the Device selector.

Step 2 Select **Interfaces/VLANs** from the Policy selector.

Step 3 Click the VLAN Groups tab in the work area.

The VLANs tab is displayed. For a description of the fields on this tab, see Interfaces/VLANs Page—VLAN Groups Tab , on page 2655.

Step 4 Select a VLAN group from the table, then click **Delete Row**. The VLAN group is deleted.

Interfaces/VLANs Page—VLAN Groups Tab

Use the VLAN Groups tab to view and configure VLAN groups on supported 6500 Series switches and 7600 Series routers.

Note The VLAN Groups tab is available only for Cisco Catalyst 6500 Series switches and Cisco 7600 Series routers.

Navigation Path

- (Device view) Select **Interfaces/VLANs** from the Device selector, then click the **VLAN Groups** tab.

Related Topics

Field Reference

Table 960: Interfaces/VLANs Page—VLAN Groups Tab

Element	Description
VLAN Group	Numeric ID of a VLAN group that is configured on the selected device.
Service Module Slots	Associates the chassis slot number (in which the relevant services module is installed) with the interface through which a particular VLAN participates in the VLAN group.
VLAN IDs	The VLAN IDs associated with this group. Valid values range from 1 to 65535.
Add Row button	Opens the Create VLAN Group dialog box to define a new VLAN group.
Edit Row button	Opens the Edit VLAN Group dialog box to edit the selected VLAN group.
Delete Row button	Deletes the selected VLAN group.

Create and Edit VLAN Group Dialog Boxes

Use the Create and Edit VLAN Group dialog box to configure or reconfigure the attributes of VLAN groups, which are logical groups of VLANs that you want to associate with one another when you define VLAN port policies.

Navigation Path

Do one of the following:

- Go to the Interfaces/VLANs Page—VLAN Groups Tab , on page 2655, then click the **Add** or **Edit** button beneath the table.

- Go to the Interfaces/VLANs Page—VLANs Tab , on page 2649, click the **Add** or **Edit** button beneath the table, then select **Add Group** from the Group list.

Related Topics

Field Reference

Table 963: VLAN Selector Dialog Box

Element	Description
Available VLANs	Displays defined VLANs that are available to be associated with the object you are configuring. **Note** The VLANs that are available will depend on the type of object you are configuring and other settings defined on the device. For example, when selecting VLANs to assign to a VLAN group, the Available VLANs list will only contain VLANs that have not been assigned to another VLAN group. When selecting VLANs to assign to a security context, the Available VLANs list will only contain VLANs that are part of a VLAN group that has been assigned to the service module you are configuring.
Add >> button	Moves selected VLANs from the Available VLANs list to the Selected VLANs list.
Remove << button	Removes selected VLANs from the Selected VLANs list.
Selected VLANs	Displays the selected VLANs.

Element	Description
VLAN Ranges	The VLAN ranges entered manually before the selector was opened, if any.

VLAN ACLs (VACLs)

Cisco IOS standard or extended ACLs are configured on router interfaces only, and are applied on routed packets only. In contrast, Cisco Catalyst switches and Cisco 7600 Series routers can use VLAN ACLs (VACLs) to control the access of all packets that are bridged within a VLAN or that are routed to or from a VLAN for VACL capture through a WAN interface. VACLs:

- Are processed in hardware.
- Use Cisco IOS ACLs.
- Ignore any Cisco IOS ACL fields that are not supported in hardware.

Note Security Manager does not support the creation or configuration of MAC ACLs (MACLs), which are named ACLs that are sometimes used with VACLs to filter IPX, DECnet, AppleTalk, VINES, or XNS traffic based on MAC addresses.

When you configure a VACL and apply it to a VLAN, all packets entering the VLAN are checked against the VACL.

If you apply a VACL to a VLAN and you apply an ACL to a routed interface in that same VLAN, any packet coming into the VLAN is first checked against the VACL. Then, if permitted, the packet is checked against the input ACL before it reaches the routed interface.

When a packet is routed from one VLAN to another, it is first checked against the output ACL that is applied to the routed interface. Then, if permitted, the packet is checked against any VACLs that are configured for the destination VLAN.

If a VACL is configured for a packet type, and a packet of that type does not match the VACL, the default action is deny.

VLAN Access Maps

Security Manager uses *VLAN access maps* to configure VACLs. Conceptually similar to a route map, a VLAN access map is a container in which you place one or more *statements* (conditions that match an action) and number them by their order of importance. A VLAN access map must also identify the VLANs to which it is applied, contain the map name, and identify at least one VACL sequence.

A VACL sequence must have a sequence number and at least one action, and must match at least one ACL.

Devices evaluate map statements in sequence and you can associate more than one VLAN access map with any device chassis.

To manage a VACL, select a Catalyst device in Device View, then select **Platform > VLAN Access Lists**. You use VLAN access maps to configure VACLs for IP traffic.

The following topics describe the actions you can perform when defining VACLs on Catalyst devices:

- Creating or Editing VACLs , on page 2660

- Deleting VACLs , on page 2661
- VLAN Access Lists Page , on page 2662

Related Topics

- VLANs , on page 2647
- VLAN Groups , on page 2654

Creating or Editing VACLs

When you can create or edit a VACL, you must:

- Name the VACL.
- Define the VLANs to which the VACL applies.
- Define a sequence map containing at least one VACL sequence.

Related Topics

- Deleting VACLs , on page 2661
- Creating or Editing VLANs , on page 2648
- Creating or Editing VLAN Groups , on page 2654
- Create and Edit VLAN ACL Dialog Boxes , on page 2663
- VLAN Access Lists Page , on page 2662

Step 1 Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform > VLAN Access Lists** from the Policy selector.
- (Policy view) Select **Catalyst Platform > VLAN Access Lists**.

The VLAN Access Lists page is displayed. For a description of the fields on this page, see VLAN Access Lists Page , on page 2662.

Step 2 Do one of the following:

- To define the attributes of a new VACL, click **Add Row**.
- To edit the attributes of a VACL, select it in the list, then click **Edit Row**.

A dialog box opens. See Create and Edit VLAN ACL Dialog Boxes , on page 2663, for a description of the fields in the dialog box.

Step 3 Enter a name for the VACL in the **VLAN ACL Name** field.

Step 4 In the VLANs field, specify the VLANs to which the VACL should be applied, or click **Select** to open a VLAN selector.

Step 5 Define the sequence map:

a) Click **Add Row** or **Edit Row** beneath the Sequence Map table. A dialog box opens. See Create and Edit VLAN ACL Content Dialog Boxes , on page 2664.
b) Enter a number to identify the sequence.
c) Specify the standard and extended ACLs to assign to the sequence, or click **Select** to select the ACL object from a list or to create a new ACL object. For more information about ACL objects, see Creating Access Control List Objects , on page 283.
d) Specify the action to perform on traffic that matches the ACLs defined in this sequence. (When you select Redirect as the action, you must specify the physical destination interfaces, or click **Select** to display a selector. See Specifying Interfaces During Policy Definition , on page 306.)
e) Click **OK** to save your definitions locally on the client and close the dialog box. The sequence is displayed in the Sequence Map table.
f) Repeat the process to add sequences to the sequence map.
g) Use the up and down arrows to reorder the sequences, if required.

Note The order in which you place the sequences is significant. When a flow matches a permit ACL entry, the associated action is taken without checking the remaining sequences. When a flow matches a deny ACL entry, it is checked against the next ACL in the same sequence or the next sequence. If a flow does not match any ACL entry and at least one ACL is configured for that packet type, the packet is denied.

Deleting VACLs

You can delete a VACL if it is not being used by any device, policy, or object.

Before You Begin

You must delete all references to the VACL before you can remove it from the database. To locate all references to the VACL, run an object usage report for it. See Generating Object Usage Reports , on page 243.

Related Topics

- Creating or Editing VACLs , on page 2660

- VLAN ACLs (VACLs) , on page 2659

Step 1 Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform > VLAN Access Lists** from the Policy selector.
- (Policy view) Select **Catalyst Platform > VLAN Access Lists**.

The VLAN Access Lists page is displayed. For a description of the fields on this page, see .

Step 2 Click in a row to select a VACL, then click **Delete**.

Step 3 Click **OK** to save your changes. VLAN Access Lists Page , on page 2662

VLAN Access Lists Page

Use the VLAN Access Lists page to view and configure VLAN access lists for Cisco Catalyst switches and Cisco 7600 Series routers.

Navigation Path

You can access this page from:

- (Device view) Select **Platform > VLAN Access Lists** from the Device Policy selector.
- (Device view) Select **Catalyst Platform >VLAN Access Lists** from the Policy Types selector.

Related Topics

- Creating Access Control List Objects , on page 283

- Filtering Tables , on page 50

Field Reference

Table 964: VLAN Access Lists Page

Element	Description
VLAN Access Lists table	
VLAN ACL	Displays the VLAN ACL name.
Sequence	Specifies the map sequence number. VACL sequences are applied in order of sequence, from lowest number to highest.
Matching	Displays the Match ACLs, if any are defined. VACL matching occurs only when an ACL permit is encountered. ACL denies are ignored.
Action	Specify whether the action is to drop, drop and log, forward, forward and capture, or redirect packets. **Note** The redirect action helps you to specify as many as five interfaces, which can be physical interfaces or EtherChannels. You cannot redirect packets to an EtherChannel member or a VLAN interface.
VLAN IDs	Interface-specific identity of the VLAN that a table row describes. The VLAN ID specifies where 802.1Q tagged packets are sent and received on the subinterface; without a VLAN ID, the subinterface cannot send or receive traffic.
Add Row button	Opens the Create VLAN ACL dialog box, where you can define a new VACL.
Edit Row button	Opens the Edit VLAN ACL dialog box, where you can edit the selected VACL.
Delete Row button	Deletes the selected access list.

Element	Description
Additional fields	
Log Table Size	Displays the log table size. Valid sizes range from 0 to 2048 and the default is 500. Logged packets from new flows are dropped when the table is full.
Max. Packet Rate	Displays the maximum redirect VACL logging packet rate per second. Valid rates range from 10 to 5000 packets per second and the default rate is 2000. Packets that exceed the limit are dropped.
Logging Threshold	Displays the logging threshold if one is set. By default, no threshold is set. When you configure VACL logging, IP packets that are denied generate log messages on a per-flow basis if the threshold for a flow is reached in any interval of less than 5 minutes. Only dropped IP packets can be logged.
Capture Interfaces	Identifies the interface that captures forwarded packets in which the capture bit is set. You can configure any interface as the capture interface. The capture action sets the capture bit for the forwarded packets so that ports with the capture function enabled can receive the packets. Only forwarded packets can be captured. **Note** The information shown here is read-only. To define capture interfaces, use the Create/Edit Interface dialog box. See Interfaces/VLANs Page—Interfaces Tab , on page 2628.

Create and Edit VLAN ACL Dialog Boxes

Use the Create VLAN ACL dialog box (or the Edit VLAN ACL dialog box) to configure or reconfigure VACL attributes.

Navigation Path

Go to the VLAN Access Lists Page , on page 2662, then click the **Add** or **Edit** button beneath the table.

Related Topics

Field Reference

Table 965: Create and Edit VLAN ACL Dialog Boxes

Element	Description
VLAN ACL Name	The user-defined name for the VACL.

Element	Description
VLANs (Select button)	Enables you to designate the VLANs to which the VACL should be applied. Do one of the following: • Enter VLAN IDs. You can use commas to separate multiple VLANs or use a hyphen to indicate a range of VLANs. For example: 12,17,22 or 2-200. Valid IDs range from 1 to 4094. • Click **Select** to open the VLAN Selector Dialog Box , on page 2658.
Sequence Map table	The sequence maps included in the VLAN access map. A VLAN access map can consist of one or more map sequences, where each sequence pairs a *match clause* , which specifies an ACL object for traffic filtering, to an *action clause* , which specifies the action to take on packets that meet the criteria defined in the match ACLs. • To add a sequence map, click the Add Row (+) button and fill in the Create VLAN ACL Content dialog box (see Create and Edit VLAN ACL Content Dialog Boxes , on page 2664). • To edit a sequence map, select it and click the Edit Row button. • To delete a sequence map, select it and click the Delete Row button. • To change the order of a map, select it and click the Up or Down arrow buttons until it is in the desired position. The sequence number changes as you move it.

Create and Edit VLAN ACL Content Dialog Boxes

Use the Create VLAN ACL Content dialog box (or the Edit VLAN ACL Content dialog box) to configure or reconfigure VACL sequences.

Navigation Path

Go to the Create and Edit VLAN ACL Dialog Boxes , on page 2663, then click the **Add** or **Edit** button beneath the Sequence Map table.

Related Topics

Field Reference

Table 966: Create and Edit VLAN ACL Content Dialog Boxes

Element	Description
Sequence	Specify the map sequence number for the VLAN access map. Valid values range from 1 to 65535.

Element	Description
Match ACLs	Specify which ACLs the sequence should include in its match clause. Enter the names of the standard and extended ACL objects to include in the sequence, or click **Select** to select them from a list or to create new ones. You cannot use a MAC-layer ACL.
Action	The option to perform on packets that meet the criteria defined in the match ACLs: • Drop—Drops the packets. • Drop/Log—Logs the dropped packets. • Forward—Forwards the packets to their destination (using hardware switching). • Forward/Capture—Sets the capture bit for the forwarded packets so that ports with the capture function enabled also receive the packets. • Redirect—Redirects packets to the Ethernet interfaces defined in the Interfaces field.
Interfaces (Select button)	Applies only when the specified action is Redirect. The destination interfaces for redirect packets. Enter the names of up to five physical interfaces, or click **Select** to open the Interface Selector Dialog Box—VLAN ACL Content , on page 2665. The redirect interfaces must be in the VLAN for which the VACL access map is configured. **Note** You cannot redirect packets to an EtherChannel member or a VLAN interface. You also cannot redirect packets to a subinterface.

Interface Selector Dialog Box—VLAN ACL Content

Use the Interface Selector dialog box to define redirect interfaces when you create entries for a VACL sequence map.

Navigation Path

Element	Description
Available Interfaces	Displays the physical interfaces that are defined in the Interfaces/VLANs policy.
Add >> button	Adds interfaces that are selected in the Available Interfaces list to the Selected Interfaces list.

Element	Description
Remove << button	Removes selected interfaces from the Selected Interfaces list.
Selected Interfaces	Displays the interfaces that are selected.

IDSM Settings

When you select a Catalyst device in Device view, then select **Platform > IDSM Settings** from the Policy selector, a list is displayed that:

- Displays the settings for data ports on Intrusion Detection System Service Modules (IDSMs).
- Helps you to organize IDSM data ports in channel groups.

The IDSM card detects and stops security threats on network connections. The card inspects the traffic that enters its two data ports and drops packets if a security threat is detected. The data port settings define:

- Which traffic is received by the data ports, as defined by the VLAN IDs.
- The sensing mode used by the data ports:
  - Trunk (IPS)—The IDSM performs VLAN bridging between pairs of VLANs within the same data port, operating as an 802.1q trunk. The IDSM inspects the traffic it receives on each VLAN in a VLAN pair and can either forward the packets on the other VLAN in the pair or drop the packet if an intrusion attempt is detected.
  - Capture (IDS)—The IDSM passively monitors network traffic that was copied to the data ports by the Catalyst switch using either VACL capture or SPAN. The data ports operate as 802.1q trunks that can be configured to trunk different VLANs. When operating in this passive mode, the IDSM cannot drop packets in response to a network intrusion attempt, but it can send TCP resets over the data ports in an attempt to block the intrusion.

Note Security Manager supports a subset of IDSM settings on chassis running IOS 12.2(18)SXF4 or later. Trunk (IPS) and Capture (IDS) modes are supported; inline mode is not supported. Security Manager cannot manage IDSM data ports that are part of a spanning tree or access VLAN.

For high-traffic networks, EtherChannel is used to perform load balancing among multiple data ports. These data ports might be located on different IDSM cards within the same Catalyst device.

EtherChannel is also used to redirect traffic in the event of port failure to the remaining ports within the channel group. This resiliency help preserve intrusion detection and prevention without user intervention and with minimum packet loss.

The following topics describe the actions you can perform when defining IDSM settings:

- Creating or Editing EtherChannel VLAN Definitions , on page 2667
- Deleting EtherChannel VLAN Definitions , on page 2668
- Creating or Editing Data Port VLAN Definitions , on page 2668

- Deleting Data Port VLAN Definitions , on page 2670
- IDSM Settings Page , on page 2670

Related Topics

- VLANs , on page 2647

Creating or Editing EtherChannel VLAN Definitions

When defining an EtherChannel VLAN definition, you must:

- Define the slot-port combination containing the data ports to include in the channel group.
- Select the sensing mode used by the data ports.
- Define which VLANs are forwarded to the data ports.

The following restrictions apply:

- You can have a single definition only for each channel group.
- You can have a single definition only for each slot-data port combination. This means that you cannot create an EtherChannel VLAN definition if a data port definition already exists for this slot-data port.

Related Topics

- Deleting EtherChannel VLAN Definitions , on page 2668
- Creating or Editing Data Port VLAN Definitions , on page 2668
- IDSM Settings , on page 2666

Step 1 Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform** > **IDSM Settings** from the Policy selector.
- (Policy view) Select **Catalyst Platform** > **IDSM Settings**.

The IDSM Settings page is displayed. For a description of the fields on this page, see IDSM Settings Page , on page 2670.

Step 2 Do one of the following:

- To create an IDSM EtherChannel VLAN definition, click **Add Row** beneath the EtherChannel VLANs table.
- To edit an IDSM EtherChannel VLAN definition, select it in the list, then click **Edit Row** beneath the table.

The IDSM EtherChannel VLAN dialog box is displayed. For a description of the fields in this dialog box, see Create and Edit IDSM EtherChannel VLANs Dialog Boxes , on page 2672.

Step 3 To assign a channel group number to the Ethernet interface for the VLAN, or to change the channel group number, enter a number in the **Channel Group** text box.

Step 4 To associate the VLAN with the numbered chassis slot where you installed your IDSM services module and to associate one module data port with the VLAN, do one of the following:

- Enter the slot-port number in the **Slot-Ports** text box.
- Click **Select** to open the IDSM Slot-Port Selector dialog box.

Note Associating one module data port with the VLAN enables you to configure the port at the group level instead of configuring it manually.

Step 5 From the Mode list, select the running mode of the EtherChannel VLAN. If you select Capture, select the check box to configure the specified channel group as a capture destination.

Note If you do not select this check box, the capture port is created in shutdown mode.

Step 6 To include a VLAN in the specified channel group, do one of the following:

- Enter its numeric ID in the VLAN IDs text box.
- Click **Select** to open the VLAN Selector dialog box.

You can enter or select more than one VLAN ID.

Step 7 Click **OK** to save your definitions locally on the client and close the dialog box.

Deleting EtherChannel VLAN Definitions

You can delete an EtherChannel VLAN definition on the IDSM.

Related Topics

Step 1 Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform > IDSM Settings** from the Policy selector.
- (Policy view) Select **Catalyst Platform > IDSM Settings**.

The IDSM Settings page is displayed. For a description of the fields on this page, see IDSM Settings Page , on page 2670.

Step 2 Click a row in the table to select the VLAN definition to delete.

Step 3 Click **Delete Row**.

Creating or Editing Data Port VLAN Definitions

When defining a data port VLAN definition, you must:

- Define the slot-port combination where the data port is located.
- Select the sensing mode used by the data port.
- Define which VLANs are forwarded to the data port.

The following restrictions apply:

- You may have a single definition only for each data port.
- You cannot create a data port definition if the port is already defined as part of a channel group.

Related Topics

- Deleting Data Port VLAN Definitions , on page 2670

Step 1 Do one of the following:

- (Device view) Select a Catalyst device, then select **Platform > IDSM Settings** from the Policy selector.
- (Device view) Select **Catalyst Platform > IDSM Settings**.

The IDSM Settings page is displayed. For a description of the fields on this page, see IDSM Settings Page , on page 2670.

Step 2 Do one of the following:

- To create an IDSM data port VLAN definition, click **Add Row** beneath the Data Port VLANs table.
- To edit an IDSM data port VLAN definition, select it in the list, then click **Edit Row** beneath the table.

The IDSM Data Port VLAN dialog box is displayed. For a description of the fields in this dialog box, see Create and Edit IDSM Data Port VLANs Dialog Boxes , on page 2673.

Step 3 To associate the VLAN with the numbered chassis slot where you installed your IDSM services module and to associate one module data port with the VLAN, do one of the following:

- Enter the slot-port number in the **Slot-Ports** text box.
- Click **Select** to open the IDSM Slot-Port Selector dialog box.

Note Associating one module data port with the VLAN enables you to configure the port at the group level instead of configuring it manually.

Step 4 From the Mode list, select the running mode of the data port VLAN. If you select Capture, select the check box to configure the specified data port as a capture destination.

Note If you do not select this check box, the capture port is created in shutdown mode.

Step 5 To assign a VLAN to the specified data port, do one of the following:

- Enter its numeric ID in the VLAN IDs text box.
- Click **Select** to open the VLAN Selector dialog box.

You can enter or select more than one VLAN ID.

Step 6 Click **OK** to save your definitions locally on the client and close the dialog box.

Deleting Data Port VLAN Definitions

You can delete a data port VLAN definition on the IDSM.

Field Reference

Table 968: IDSM Settings Page

Element	Description
EtherChannel VLANs table	
Channel Group	Identifies the EtherChannel group to which the Ethernet interface is assigned.
Module Slot-Data Port	Identifies the IDSM service module data port by number (1 or 2) to distinguish between the two ports. Each IDSM service module (blade) has two data ports. You can configure a data port individually or you can assign it to an EtherChannel group. All data ports in a channel group are configured at the group level
Mode	Indicates whether the running mode is trunk (IPS) or capture (IDS).
Capture Enabled	Indicates whether the specified channel group is configured as a capture destination.
Allowed VLANs	Lists which VLANs are allowed for the specified channel group.
Add Row button	Opens the Create IDSM EtherChannel VLANs dialog box. From here you can define which traffic is directed to the data ports in an EtherChannel group and which sensing mode is used.
Edit Row button	Opens the Edit IDSM EtherChannel VLANs dialog box. From here you can modify the attributes of an EtherChannel VLAN definition.
Delete Row button	Deletes the selected VLAN from the IDSM.
Data Port VLANs table	
Module Slot-Data Port	Identifies the IDSM service module data port by number (1 or 2), to distinguish between the two ports.
Mode	Indicates whether the running mode is trunk (IPS) or capture (IDS). To change the mode, select and edit the relevant table row.
Capture Enabled	Indicates whether the specified data port is configured as a capture destination.
Allowed VLANs	Lists which VLANs are allowed for the specified data port.
Add Row button	Opens the Create IDSM Data Port VLANs dialog box. From here you can define which traffic is directed to a specific data port and which sensing mode is used.
Edit Row button	Opens the Edit IDSM Data Port VLANs dialog box. From here you can modify the attributes of a data port VLAN definition.
Delete Row button	Deletes the selected VLAN from the IDSM.

Create and Edit IDSM EtherChannel VLANs Dialog Boxes

Use the Create IDSM EtherChannel VLANs dialog box (or the Edit IDSM EtherChannel VLANs dialog box) to configure or reconfigure the attributes of an IDSM EtherChannel VLAN.

Navigation Path

Go to the IDSM Settings Page , on page 2670, then click the **Add** or **Edit** button beneath the EtherChannel VLANs table.

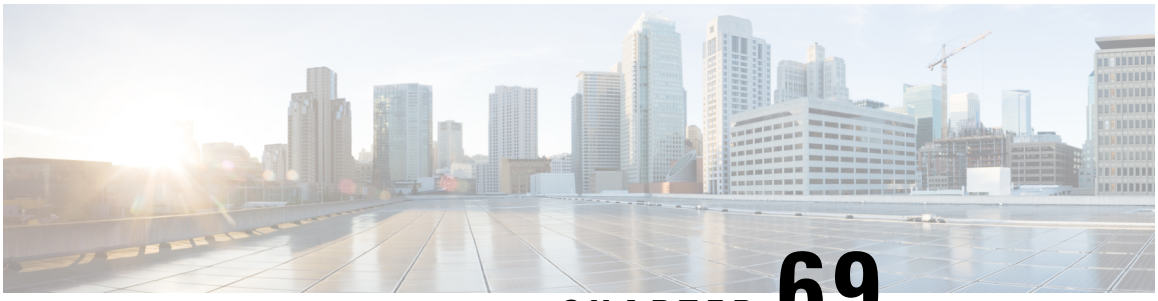
Selected IDSM Slot-Ports list	Displays the IDSM slot-port objects that are selected for an association with a data port or an EtherChannel group.

PART VII

Monitoring, Reporting, and Diagnostics



CHAPTER 69

Viewing Events

Event Viewer enables you to selectively monitor, view, and examine events from ASA (including ASA-SM), FWSM and IPS devices. Events are organized into views that you can filter or search to find events that interest you. You can create customized views and filters to fit your needs, or use the predefined views included in the application.

This chapter contains the following topics:

Introduction to Event Viewer Capabilities

Event Viewer monitors your network for syslog (system log) events from ASA and FWSM devices and security contexts and SDEE (Secure Device Event Exchange) events from IPS devices and virtual sensors. Event Viewer collects these events and provides an interface by which you can view them, group them, and examine their details.

Note Beginning with version 4.5, Security Manager enables you to forward syslogs to one local collector and two remote collectors. For more information, see Event Management Page , on page 538.

Tip Event Viewer and its related applications, Report Manager and Health and Performance Monitor, are useful for operational monitoring and troubleshooting of certain types of Cisco devices in your network. These applications do not provide extensive event correlation, compliance reporting, long-term forensics, or the integrated monitoring of both Cisco and non-Cisco devices.

When working with IPS events, the Report Manager component of Cisco Security Manager reports events individually; the Event Viewer component of Cisco Security Manager displays alerts. In the Event Viewer component, the IPS Summarizer groups events into a single alert, thus decreasing the number of alerts that the IPS sensor sends out.

Tip Cisco IPS Manager Express (IME) and Cisco Security Manager do not summarize events in precisely the same way.

This section briefly describes some key activities that Event Viewer facilitates:

Historical View

An historical view is one that displays events from a selected period of time (for example, the last 10 minutes) and does not automatically update as new events are collected. You must refresh the view to see newer events.

Consider the following activities among the many possibilities for employing Event Viewer with an historical view:

- **Troubleshoot Connectivity**—When a report comes in that a user cannot reach a particular server, you can set an historical view (for example, the last 10 minutes) that displays all events that affect that user's IP address as a source or destination. Then, you can go from a particular displayed event to the policy denying that user's access to the resource.
- **Tune Signatures**—After setting a view of all IPS messages, or all IPS messages of a given category, you might decide that an event is actually a false positive. You can then cross launch into the associated policy and either tune the signature to exclude the host or lessen the reported severity of the particular event.

Also consider creating an event action filter to modify how the alert is handled. Frequently, event action filters are a better way of dealing with false positives than editing the actual signature. For more information, see Tips for Managing Event Action Filter Rules , on page 1716.

- **Validate Policy Deployment**—After deploying a new or changed policy, you might want to confirm that it is operating effectively by selecting events corresponding to the given policy. For example, you could identify firewall-deny messages triggered by the new policy.

Real-Time View

A real-time view displays events as they are received and automatically updates the Event Table in waterfall fashion. Keep in mind that the term "real-time" is not precise. System latency and other factors prevent true real-time system response.

Consider the following activities among the many possibilities for employing Event Viewer with a real-time view:

- **Investigate Attacks in Near Real-time**—By isolating details of a particular source IP address, or a source/destination pair, Event Viewer can provide details about attacks on your monitored devices, or attacks that are going through those devices.
- **Validate Device Activity**—You can examine a device in your network and determine whether it is present and whether it is sending events.
- **View High Threat IPS Events**—You can filter a view to display all events that exceed a certain threat level. On a properly tuned IPS sensor, this should be a manageable flow of events to watch in a real-time view.

Views and Filters

When you view events in Event Viewer, you open a view. A *view* is a set of filters and other properties, including color rules, selected columns and their positions and widths, and the default time window, that let you define a subset of events. Views help to limit the scope of the events list so that you can more easily find what you are looking for.

Event Viewer includes a number of predefined views. Although you cannot change the filter rules for these views, you can create copies of the views and change the filter rules in your copy. Views you create are called custom views. For more information, see Creating Custom Views , on page 2717.

Using filters is key to getting the most from Event Viewer. You can distill from all the events being received a view of only the information that you need or want. You can use the various methods of filtering to reduce the events list, filtering lists that have already been filtered. The following list explains the general filtering features; for more information, see Filtering and Querying Events , on page 2720.

- **Time filters**—You can use time filters to limit the events that are loaded into your client as well as to limit the events displayed in the Event Table. With time filtering you can select predefined values, such as **the last hour**, or specify a particular time range by dates and times. For more information, see Selecting the Time Range for Events , on page 2720.
- **Column filters**—You can use column filters to filter events based on a particular value of an event. For example, you could filter on a particular source or destination, or both. For certain columns you can also filter on a range of values or on a policy object. Column filters are part of the view settings for a view. For more information, see Creating Column-Based Filters , on page 2722.
- **Quick filters**—You can use quick filters to execute a text-based filter on events listed in the event table. The search is not column-sensitive, showing all events in which the string appears in any column. You can use the Quick Filter drop-down list (shown as a magnifier) to modify the scope of the filter. For more information, see Filtering on a Text String , on page 2725.
- **Drilling down with filters**—Aggregating additional filters allows you to become more and more selective, to “drill down” until you can view a particular event or set of events that meet your requirements. The View Settings pane at the top of the Event Monitoring window updates with each additional filter choice you make to show the current aggregate filter definition of the view selected.

Policy Navigation

You can navigate from a particular event to the policy within Security Manager that governs that event. You can also navigate from certain policies to events associated with those policies. For more information, see Looking Up a Security Manager Policy from Event Viewer , on page 2731 and Looking Up Events for a Security Manager Policy , on page 2732.

Understanding Event Viewer Access Control

The user privileges assigned to your username control what you can do in Event Viewer. If you use local users, or other types of non-ACS access control, then all users have access to Event Viewer. However, the following access limits are imposed:

- You must have system administrator, network administrator, or approver privileges to select or deselect devices for monitoring. See Selecting Devices to Monitor , on page 2711.
- You must have system administrator privileges to change the Event Management administrative settings page, where you enable or disable the service and configure storage location and other settings, as described in Starting, Stopping, and Configuring the Event Manager Service , on page 2707 and Event Management Page , on page 538

If you use ACS to control access to Security Manager, you can also control the following:

- You can control access to the Event Viewer application using the View Event Viewer privilege. Using this privilege, you could prevent certain users from accessing Event Viewer, or create roles that allow access to Event Viewer without allowing access to Report Manager. All default ACS roles are permitted to use Event Viewer.
- You can control which users can enable or disable monitoring for devices using the Modify > Manage Event Monitoring privilege. A user must have this privilege to select devices for monitoring as described in Selecting Devices to Monitor , on page 2711. The default ACS roles that have this permission are system administrator, network administrator, approver, security administrator, and security approver.
- You can control the use of the policy lookup feature. Users must have View Device privileges to the device, and also View privileges to the firewall or IPS policy, to perform policy lookup. If users do not have all permissions, they will get an “Unable to Find Matching Rule” error if they try to look up a matching rule. For more information about policy lookup, see Looking Up a Security Manager Policy from Event Viewer , on page 2731.
- Users can view events on devices only if they have at least View privileges to the device.
- You can control access to the Event Management administrative settings page, where you enable or disable the service and configure storage location and other settings, as described in Starting, Stopping, and Configuring the Event Manager Service , on page 2707 and Event Management Page , on page 538. The user must have Admin privileges to access this page (or any other administrative settings page). All default ACS roles except help desk can view the page, but only system administrators can change settings.
- You can control the use of network/host and service policy objects for column filters (such as the Device, Source, Destination, Source Service, and Destination Service columns). Users must have the appropriate View Object permissions for network/host, network/host-IPv6, and service objects to use them in filters. For more information on creating column filters, see Creating Column-Based Filters , on page 2722.

For information on integrating Security Manager with Cisco Secure ACS, see the Installation Guide for Cisco Security Manager .

Scope and Limits of Event Viewer

The following table provides details on the functional scope and limits of Event Viewer:

Table 972: Event Viewer Scope and Limits

Item	Description
Device Support	You can view events collected from the following types of devices. Although Event Viewer has been tested with the indicated software releases, you might be able to use it with older software releases. • **ASA devices (including ASA-SM) and security contexts**—All 8.x releases. • **FWSM devices and security contexts**—Releases 3.1.17, 3.2.17, 4.0.10, and 4.1.1 and later. • **IPS devices and virtual sensors**—Releases 6.1 and later. IPS support does not include IOS IPS.
Event Data Store Size and Location	You can control the location and disk space allocated to holding events collected from monitored devices. After the Event Data Store is 90 percent filled, newest events replace oldest events. You can also configure an extended storage, or archive, location on attached storage devices. Security Manager automatically copies events into the extended storage; when you view historical events, they are automatically retrieved from extended storage if they no longer reside on the local disk. For more information on configuring these settings, see the Event Management Page , on page 538.
Event Limit	You can control the maximum number of events that can be viewed at one time in the events table using the Event Data Pagination Size option. For information on configuring the option, see Event Management Page , on page 538.
Policy Objects	You can use some types of policy objects, such as network/host and services objects, when creating column filters. You can also view host object names instead of IP addresses in the source and destination columns by selecting **View > Show Network Host Objects**. This option is selected by default. IP address to host name mapping is supported only for the source and destination of events. Also, the mapping applies to Host objects only; Event Viewer will not show an object name when the source or destination of an event matches a Network object, Group object, or Address Range object. **Tip** Hover over a host object name to view the IP address associated with that object.
Views	A single Event Viewer client can open at most four historical views and one real-time view at a time.

Item	Description
Clients	For a single Security Manager server, a maximum of 5 Security Manager clients can open Event Viewer at one time, and a Security Manager client can open one copy of Event Viewer.

Deeply Parsed Syslogs

The structure and contents of standard syslogs and the elements comprised by each are detailed in the System Logs documentation for the device and software version you are using.

You can find the documentation on Cisco.com at these locations:

- ASA Devices: http://www.cisco.com/en/US/products/ps6120/products_system_message_guides_list.html
- FWSM Devices: http://www.cisco.com/en/US/products/hw/modules/ps2706/products_system_message_guides_list.html

Syslogs other than those listed here are presented as raw syslogs. Only deeply parsed syslogs present the full content carried by the syslog.

The deeply parsed syslogs in Security Manager are detailed in the following table.

Table 973: Deeply Parsed Syslogs

Syslog Category	Syslog ID	Total Number of Syslogs
Flow, Session Syslogs	110002-110003, 209003-209005, 302003-302004, 302009-302010, 302012-302018, 302020-302021, 302035-302036, 302303-302306, 302033-302034, 303002-302005, 313001, 313004, 313005, 313008, 324000-324006, 337001-337009, 431001-431002, 407001-407002, 416001, 418001-418002, 419001-419003, 424001-424002, 450001, 448001, 609001-609002 **Note** The 302303-302306 state-bypass syslog has been deep parsed only for event manager. However, the event description in the event manager for TCP, UDP, and SCTP state-bypass syslogs, does not display the "State-bypass" keyword. **Note** Reporting, Event to Policy, and Policy to Event are not supported for state-bypass syslog.	66
Botnet	338001-338004, 338101-338104, 338201-338202, 338301	11
ACL	106100, 106023, 106002, 106006, 106018	5
Denied Firewall	106001, 106007, 106008, 106010-106017, 106020-106022, 106025-106027	17
Identity Firewall	746003, 746005, 746010, 746016	4

Syslog Category	Syslog ID	Total Number of Syslogs
AAA	109001-109010, 109012, 109016-109020, 109023-109029, 109031-109035, 113001-113025	53
Inspect	108002-108007, 303004-303005, 400000-400050, 406001-406002, 415001-415020, 500001-500005, 508001-508002, 608001-608005, 607001- 607003, 703001-703002, 726001	99
NAT	201002-201006, 201009-201013, 202005, 202011, 305005-305012	20
IPSec VPN	402114-402122, 602103-602104, 602303-602304, 702305, 702307	15
Failover (HA)	101001-101005, 102001, 103001-103007, 104001-104004, 311001-311004, 709001-709007, 210001-210022 (except 210008, 210010)	48
SSL VPN	725001-725009, 725012-725013, 716001-716020, 716023 -716039, 716041-716060, 722001-722023, 722026-722044, 722046-722051, 723001-723002, 723009-723012, 723014, 724001-724004	128
Etherchannel	426001-426003	3
Cluster	302022- 302027	6

Overview of Event Viewer

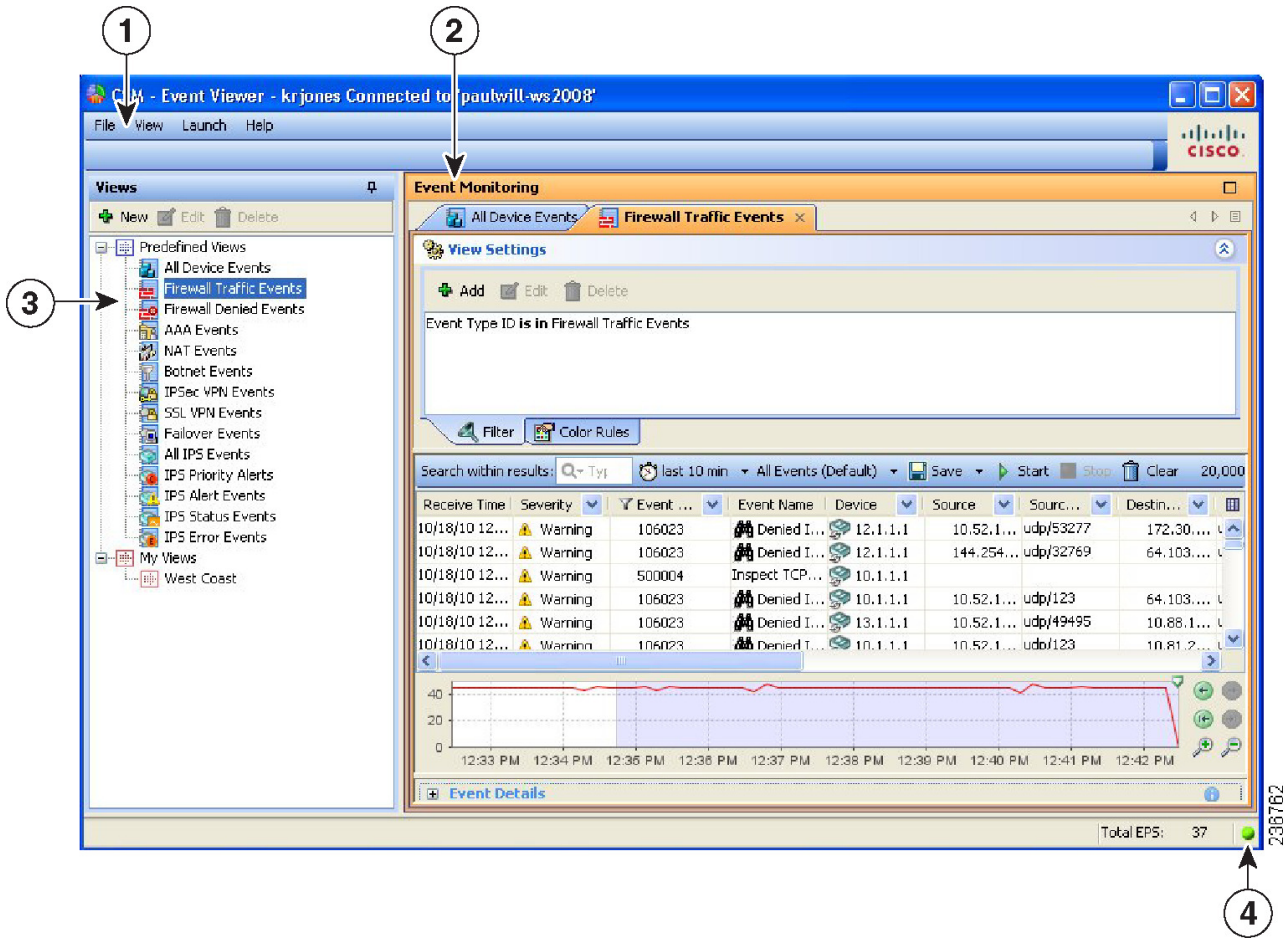
Use Event Viewer to view events and alerts collected from monitored firewall and IPS devices. For more information about selecting devices for monitoring, see Selecting Devices to Monitor , on page 2711.

To open Event Viewer, do any of the following:

- Select **Start > All Programs > Cisco Security Manager Client > Event Viewer** from the Windows Start menu (your exact command path might differ), or double-click the Event Viewer icon on the desktop. You are prompted to log in. For more information about starting a Security Manager client application, see Logging In to and Exiting the Security Manager Client , on page 13.
- Select **Launch > Event Viewer** from the Configuration Manager or Report Manager applications, or click the Event Viewer button on the Configuration Manager toolbar. Event Viewer is opened using the same user account that you used to log into the other application.

The following illustration and subsequent list explain the basics of Event Viewer.

Figure 58: Event Viewer Main Window



The following list explains the main Event Viewer window in more detail.

- **(1) Menu Bar**—General commands for performing actions in Event Viewer, including the following menus:
  - File, for operations on views. For information on the commands, see Event Viewer File Menu , on page 2685.
  - View, for operations within a view and general system management. For information on the commands, see Event Viewer File Menu , on page 2685.
  - Launch, for opening the Configuration Manager or Report Manager applications.
  - Help, for opening the online help or for viewing copyright and licensing information.
- **(2) Event Monitoring Window**—The right pane shows the open views. Each open view is represented on separate tabs (you can have up to four open historical views and one real-time view). Note that you can arrange views horizontally or vertically in this space, or even make a view float to a separate window. For more information about how you can arrange or float views, see Floating and Arranging Views , on page 2714.

For detailed information about the many parts of the event monitoring window, see Event Monitoring Window , on page 2690.

- **(3) View List**—The left pane is a list of views. The list is organized into folders that separate the predefined views from the custom views, which are listed in the My Views folder. The simplest way to open a view is to double-click it, which replaces the currently open view. To open a view without replacing the currently open view, right-click the view and select **Open in New Tab**. For more information on opening views, see Opening Views , on page 2714.

For information about other things you can do with the view list pane, see View List , on page 2688.

- **(4) Status Information**—The lower right portion of the status bar shows the current events per second (EPS) rate and an icon that indicates the current health of the monitoring system. Click the alert status icon to open a bubble that shows statistics for the past five minutes and any current system alerts. From this view, you can click the Details link to see more detailed information; click the alert status icon again to close the bubble. For more information, see Managing the Event Manager Service , on page 2707.

Note The Events per Second (EPS) information that is displayed on the Status Bar is calculated based on the number of events received every two seconds. Whereas, the EPS information that is displayed on the Time Slider graph is calculated by performing an aggregation of all the events that are available in a selected time range. Therefore, the numbers displayed on the Status Bar and the Time Slider graph might differ.

See an example below:

Example of EPS information display on the Status Bar

Assume at time T1, the Event Viewer application received 192 events. The Events per second (EPS) that will be displayed on the Status Bar is 192 / 2 = 96. This is because Security Manager collects events every 2 seconds and displays the Events per Second on the Status Bar. Let us say at T1 + 2 seconds, the Event Viewer application received 384 events. The EPS that will be displayed on the Status Bar is equal to (384 - 192)/2 = 96. This is the difference between current and previous value divided by 2.

Example of EPS information display on the Time Slider graph

Security Manager persists the events per second at an interval of 10 seconds. For example, if the Event Viewer application received 352 events in 10 seconds interval, the EPS is equal to 352 / 10 = 35. This value is persisted by Security Manager. For the next 10 seconds interval, if the Event Viewer receives 1056 events, the EPS will be equal to (1056 – 352)/ 10 = 70, which is persisted by Security Manager.

Displaying values on the Time Slider graph

The Time Slider graph displays the information for a period of time which has a Start Time and an End Time. All events per second that were collected in the given time interval are aggregated and plotted on the graph. In the given example, 35 and 70 are the values stored every 10 seconds. Therefore the Time Slider graph displays EPS as 35 and 70, which are different from the values displayed in the Status Bar.

Event Viewer File Menu

The following table describes the commands on the File menu in Event Viewer.

Table 974: File Menu in Event Viewer

Command	Description
New View	Creates a new custom view. You are prompted for a name and description. See Creating Custom Views , on page 2717. Alternatively, click the **New (+)** button in the view list.
Open View	Opens a view on a new tab. You are prompted to select the view to open. You can open at most four historical views and one real-time view. See Opening Views , on page 2714. **Tip** You can double-click in the view list to open the view and replace the view that is displayed.
Save	Saves changes made to the active view, including filters (for custom views only), table preferences such as selected columns, column width, and sort order, the time range, and color rules. See Saving Views , on page 2719. If you want to save filter changes for a predefined view, you must use Save As to create a new custom view.
Save As	Saves as a custom view the changes you have made to the displayed view. See Saving Views , on page 2719.
Close View	Closes the displayed view.
Close All Views	Closes all open views.
Exit	Closes Event Viewer. Exiting the application closes any floating Event Viewer window that is open.

Event Viewer View Menu

The following table describes the commands on the View menu in Event Viewer.

Table 975: View Menu in Event Viewer

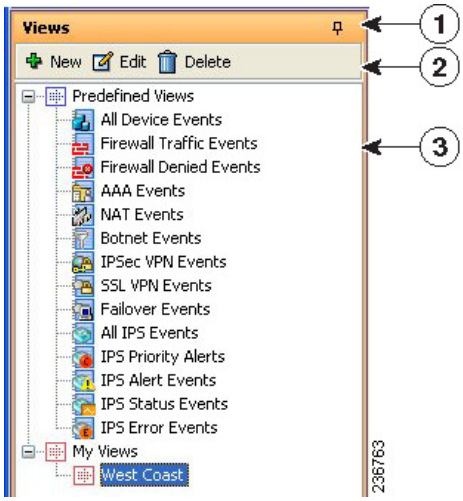
Command	Description
Mode	Specifies the time interval for selecting the events to display in the event table. From the submenu, select one of the following options: • **last 10 minutes** • **last 1 hour** • **last 12 hours** • **last 1 day** • **last 1 week** • **is today** • **is yesterday** • **is on . . .** (Opens a calendar on which you click to specify a single date.) • **is between** (Opens two calendars on which to specify a beginning and ending date and time.) • **Real Time** (Sets the mode to display events as they are received.) Alternatively, click the **Time Selector** control on the toolbar and select from the same options. See Event Table Toolbar , on page 2692.
Customize Column	Changes the columns shown in the event table. The Choose Columns to Display dialog box opens, where you can select the columns that you want to display. For details on the columns available, see Columns in Event Table , on page 2694.
Start	Initiates retrieving events to update the current view's event table. The event table then displays events received from the moment you clicked **Start** back to either the limit of the time mode or the event table pagination limit. Alternatively, click the **Start** button on the event table toolbar.
Stop	Stops event retrieval. The event table then displays the events received until the moment you clicked Stop. Alternatively, click the **Stop** button on the event table toolbar.
Show View Settings	Opens the View Settings pane, which displays the filters and color settings for the current view. You can alter these settings using the View Settings pane. Alternatively, click anywhere in the View Settings pane title bar, such as on the icon, on the text, or on the double arrow on the right side of the title bar. Clicking the heading opens and closes the pane.

Command	Description
Show Event Details	Opens the Event Details pane and displays the selected event's details. Alternatively: • Click the expand icon (+) on the left of the Event Details pane title bar. • Double-click an event in the event table to display the event details data in a pop-up window. **Tip** From the Event Details dialog box you can print the event details or you can copy one or more of the detail rows to your clipboard. You can also scroll through the events list using the Next and Previous buttons.
Manage Monitored Devices	Allows you to select which devices, or groups of devices, can have events displayed in Event Viewer. For more information, see Selecting Devices to Monitor , on page 2711. **Note** By default, any ASA, FWSM, or IPS device added to the Security Manager inventory is monitored.
Show Event Store Disk Usage	Opens a window that displays the amount of disk space used as well as the age of the oldest event stored. See Monitoring Event Data Store Disk Space Usage , on page 2712.
Show Network Host Objects	When selected, the host object name is displayed, if available, instead of the Source or Destination IP address. This option is selected by default. **Tip** Hover over a host object name to view the IP address associated with that object.
Reset Layout	Re-establishes the width of the view list pane to its original setting after it has been hidden or manually narrowed or widened

View List

The left pane of the Event Viewer main window displays a list of available views as shown in the following illustration. A *view* is a set of filters and other properties, including color rules, selected columns and their positions and widths, and the default time window, that let you define a subset of events.

Figure 59: Event Viewer View List



The view list includes the following controls:

- **(1) Push Pin button**—Click the Push Pin icon to control whether the view list pane is opened or closed. If the pin is vertical, the view list remains open unless you maximize the event monitoring window (the right pane). If the pin is horizontal, the view list collapses to the left margin, and you must click the Views heading in the left margin to open the list.
- **(2) Toolbar**—The toolbar contains these buttons:
  - **New button**—Click the New button to create a new custom view. You are prompted for a view name and description. For more information, see Creating Custom Views , on page 2717.
  - **Edit button**—Click the Edit button to change the name or description of the selected custom view. You can edit custom views only. For more information, see Editing a Custom View Name or Description , on page 2718.
  - **Delete button**—Click the Delete button to delete the selected custom view. You can delete custom views only. For more information, see Deleting Custom Views , on page 2719.
- **(3) List of views**—The list is organized into folders that separate the predefined views from the custom views, which are listed in the My Views folder. The simplest way to open a view is to double-click it, which replaces the currently open view. To open a view without replacing the currently open view, right-click the view and select **Open in New Tab**. For more information on opening views, see Opening Views , on page 2714.
- **Right-click shortcut menu**—If you right-click on a view, you get a list of additional commands that you can perform:
  - Open—Opens the view and uses it to replace the currently active view. If the currently active view contains unsaved changes, you are prompted to save them. If the view is already open, it is brought to the foreground. See Opening Views , on page 2714.
  - Open in New Tab—Opens the view in a new tab, so that no existing open views are closed. See Opening Views , on page 2714.
  - Save As—Saves the view as a new custom view. See Saving Views , on page 2719.

- Edit—Edits the custom view name and description. See Editing a Custom View Name or Description , on page 2718.
- Delete—Deletes the custom view. See Deleting Custom Views , on page 2719.
- View Description—Displays the description for the view.

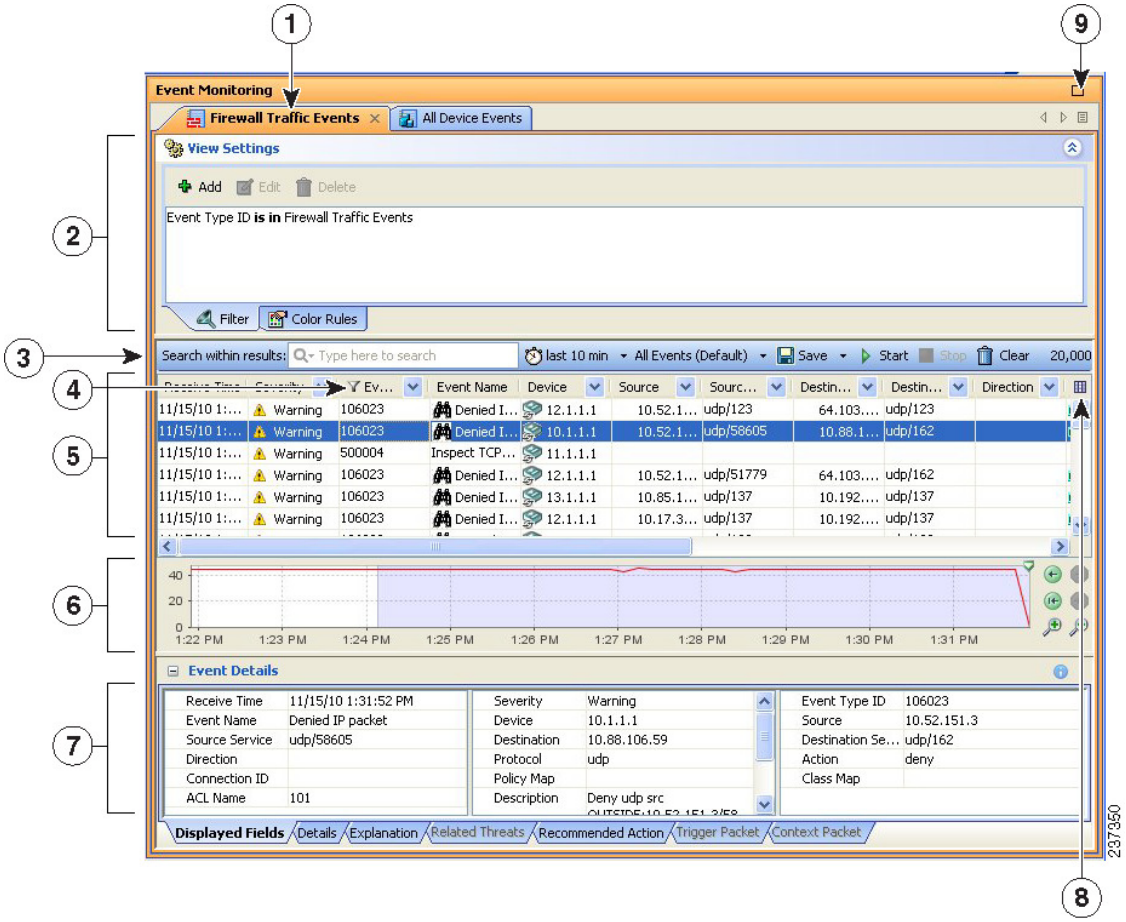
- Floating and Arranging Views , on page 2714

Event Monitoring Window

The Event Monitoring window shows the event views that you have opened. From this window, you can configure views and analyze and filter events.

Figure 60: Event Monitoring Window



1	**View tabs.**	**6**	**Time slider.**
2	View Settings pane.	7	Event Details pane.
3	Event table toolbar.	8	Column selector button.
4	Filtered column icon.	9	Open view scroll buttons and list.
5	Event table.		

The Event Monitoring window contains these main elements:

- **View tabs (1, 9)**—When you open a view, it is represented as a tab in the window. To change views, click the tab, click the left or right arrow buttons to scroll through the tabs, or click the Open View List button and select the desired view. You can arrange views to be side by side or to float to separate windows by right-clicking the tab name and selecting an appropriate command; for more details, see Floating and Arranging Views , on page 2714.

Note You can open at most four historical views and one real-time view.

- **View Settings pane (2)**—Use the View Settings pane to define the column filters and color rules to use in a view. You can open and close the pane by clicking anywhere in the heading or by toggling the **View** > **Show View Settings** command.

The View Settings pane contains two tabs: Filter and Color Rules. These tabs are shown along the bottom of the pane. On each tab, the body of the tab shows the current filter or rules; to change a rule, you select it and click the Edit or Delete buttons along the top of the pane, as appropriate. To create new rules, click the Add button.

You can also add filters using the column filtering controls in the events table, as described in Creating Column-Based Filters , on page 2722. For more information on color rules, see Configuring Color Rules for a View , on page 2717.

- **Event Table Toolbar (3)**—The toolbar above the event table includes shortcut buttons and other controls that relate specifically to the events listed in the table. For a description of the toolbar controls, see Event Table Toolbar , on page 2692.
- **Event Table (4, 5, 8)**—The event table shows the events that match your filter criteria, one event per row. These events might be retrieved from the primary or the extended data store; you do not have to explicitly request data from the extended data store. To see events from a device, you must have View Device privileges to the device.

The columns that make up the event table can be hidden, resized, reordered, and sorted upon as described in Customizing the Event Table Appearance , on page 2715. For a description of the columns, and how to use the column selector button to choose which columns are shown, see Columns in Event Table , on page 2694.

If a column has a filter applied to it, an icon appears in the column heading.

- **Time Slider (6)**—For historical views, the time slider shows the current slice of time displayed in the table and the events per second rate as a linear graph. For more information about using the time slider, see Time Slider , on page 2702.

- **Event Details Pane (7)**—The event details pane shows detailed information about the currently selected event. You can open and close the pane by clicking anywhere in the heading or by toggling the **View > Show Event Details** command. For more information, see Event Details Pane , on page 2703.

Event Table Toolbar

The following illustration and table explain the elements in the toolbar that resides immediately above the event table in Event Viewer.

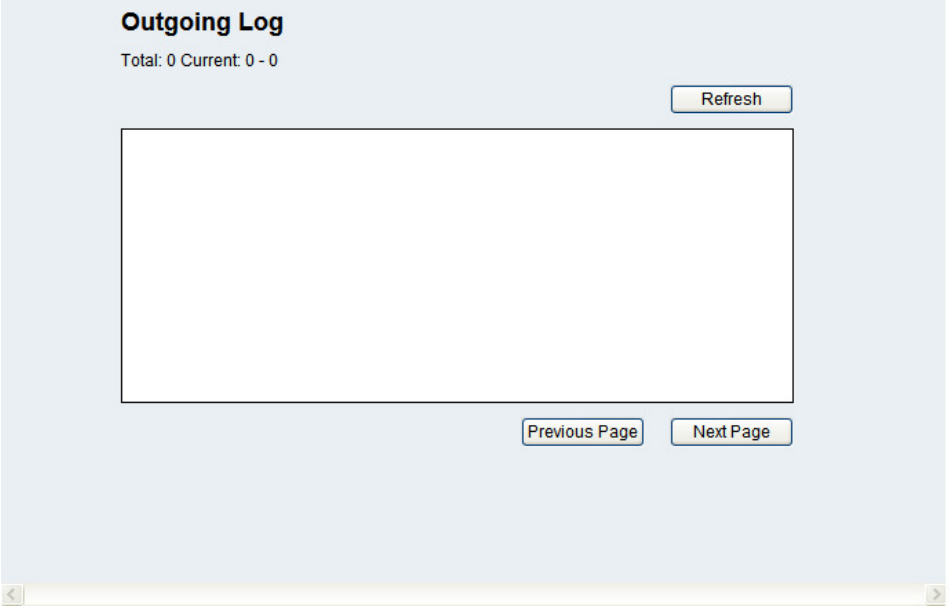


Table 976: Event Table Toolbar Elements

Callout	Name	Description
1	Search Within Results Field (Quick Filter)	This tool is also known as the *Quick Filter* . Use it to search for a word or phrase as well as to limit the scope of the search to certain columns. Further, you can select whether the search term used should be considered case sensitive, whether wildcards may be used, and whether a match may be partial, case sensitive, exact, or anywhere within a string. This search operates only on the selected view and within the data loaded. For more information, see Filtering on a Text String , on page 2725.

Callout	Name	Description
2	Time Selector (Mode) (Equivalent to **View** > **Mode**.)	You use the time selector to do the following: • Filter the events shown in the event table pane according to the time they were received. See Selecting the Time Range for Events , on page 2720. • Select between a real-time view or historical views. See Switching Between Real-Time and Historical Views , on page 2719. • Determine the time interval loaded in the client. If you are using one of the modes that shows events from the current time into the past, hovering the pointer over the field shows the start and end times for the displayed events. If you are using a specific time interval, the interval is shown in the toolbar.
3	Events by IP Address Type Selector	You use the events by IP address type selector to filter the list based on the type of IP address included in the events. Options are: • **All Events (Default)**—Show all events regardless of the address type. This is the default option. • **IPv4 Events Only**—Show events only if all addresses in the event are in IPv4 format. • **IPv6 Events Only**—Show events only if at least one address in the event is in IPv6 format. **Tip** You cannot save your selection. The next time you open the view, you need to reselect your option if you want something other than the default.
4	Save (Equivalent to **File** > **Save** or **File** > **Save As**.)	Click **Save** to save changes to the current view, including filters (for custom views only), table preferences such as selected columns, column width, and sort order, the time range, and color rules. Alternatively, click the down arrow and select **Save As** to save changes as a new custom view. If you want to save filter changes for a predefined view, you must use Save As to create a new custom view. For more information, see Creating Custom Views , on page 2717.
5	Start (Equivalent to **View** > **Start**.)	Click **Start** to reload or restart the listing of events in the Event Table. Clicking Start retrieves any events that have occurred since you originally loaded the table.
6	Stop (Equivalent to **View** > **Stop**.)	Click **Stop** to halt the listing of events in the Event Table. If you are in a real-time view, the Time Selector indicates the time stopped as well as the time interval that is loaded. Clicking on stop can also halt a query and display the set of events currently loaded in event viewer.
7	Clear	Click **Clear** to empty the event table.

Callout	Name	Description
8	Event Enumerator and messages	The number shown on the right of the toolbar indicates how many events are loaded onto the Event Viewer client. The number grows as events are loaded until either all events matching the filter criteria are displayed, or the pagination limit is reached, whichever is lowest. If you change the pagination limit (see Event Management Page , on page 538), you must exit Event Viewer and open it again for the new limit to be in effect. If your query requires that events be retrieved from the extended event storage area, a message such as "Data being fetched from extended store" appears. Fetching events from the extended storage area typically takes longer than fetching them from the primary storage area.

Columns in Event Table

The following table lists alphabetically, and describes, all the columns that you can display in a view in Event Viewer. The columns applicable to a particular device vary, as does the presence or absence of event data for a particular event type.

When you save a view, the columns you selected, and their order, are preserved and displayed the next time you open the view. To select which columns to display in the open (and active) view, do one of the following:

- (Preferred method.) Click the **Column Chooser** icon in the far right of the event table header row (see Event Monitoring Window , on page 2690). The Choose Columns to Display dialog box that opens lists the columns in alphabetical order. You can select or deselect the columns either individually or by using the **Select/Unselect All** check box. Also, you can click Revert to return to the default column selection for the view.
- Select **View > Customize Columns**.
- Right-click any column heading and select or deselect a column individually, or select More to open the same dialog box that is used by the View > Customize Columns command.

Note Most columns other than Description, Event Name, and Receive Time include a filtering function. For more information, see Creating Column-Based Filters , on page 2722.

Table 977: Event Viewer Column Descriptions

Column Label	Description
AAA Group	The AAA group policy.
AAA Server	The server that handles user requests for access; it performs authentication, authorization, and accounting.
AAA User	The AAA username.

Column Label	Description
ACE Hash1 ACE Hash2	The hashcode1 and hashcode2 of the access control list entry (ACE). Hash codes are required for successful policy lookups from syslog 106023 and 106100 events. These hash codes are available only if you deployed the configuration using Security Manager.
ACL Name	The name or ID of the access control list (ACL).
Action	The action performed on the flow. For example: Terminated or denied.
Alert Details	The details regarding the alerts.
App Name	The name of the application originating the event.
App Stop Reason	An explanation of how or why the application was shut down.
App Version	The version of the application originating the event.
Attack Relevance Rating	A numerical value used to indicate an attack's relevance to its destination target or targets.
Backplane Interface	The backplane interface, which is identified only when the backplane interface differs from the physical interface.
Botnet Category	The category showing the reason a domain name is added to the block list, for example, botnet, Trojan, spyware, and so on.
Botnet Domain	The domain name or IP address in the dynamic filter database to which the traffic was initiated. It can be added to the block list, allow list, or grey list.
Build Time	The date and time of the software build.
Build Type	The type of build. Typically this is a word such as "release" or "debug." In some cases, it is the ID of the builder of the application.
Byte Count	The number of bytes in the data transfer of the connection.
Call Id	The peer's Call ID for the session to which this packet belongs.
Class Map	The class map name.
Connection Duration	The lifetime of the connection.
Connection ID	A unique identifier for the connection.
Connection Limit	The maximum number of connections or sessions.
Connection Termination Value	A factor for which the connection is terminated, for example, incorrect version or invalid payload-type.
Current Connection Count	The number of current connections.
Description	For syslogs this shows the raw message, for IPS it shows a description of the event.

Column Label	Description
Destination	The IP Address or hostname of the traffic destination (for ASA and FWSM) or the attack target (for IPS). It can be multi-valued and contain IPv4 or IPv6 addresses. If View > Show Network Host Objects is selected and a host object is defined that matches the destination IP address, the host object name is displayed. **Tip** Hover over a host object name to view the IP address associated with that object.
Destination Context Data	Context buffer indicating the data that was sent just prior to, and immediately after, the alert was triggered. A Base64-encoded representation of the stream data that was sourced by the target.
Destination FQDN	The fully-qualified domain name of the destination IP address, if any.
Destination Interface	The destination interface. For Etherchannel alerts (426001-426003), this is the name of the Etherchannel interface for which this event occurred. The member interface is identified in the Source Interface column.
Destination Locality	Whether the target address is located inside or outside of a given network as specified by the intrusion.
Destination OS	The target's operating system information.
Destination OS Relevance	A numerical value indicating the relevance of the destination target OS value.
Destination OS Source	The source of the Target OS data. Possible values are: learned, imported, or configured.
Destination Service	The destination port. It can be multi-valued.
Destination User Identity	The user name for the traffic destination, if any.
Device	The source of the event; usually the device ID. A device identified as Not Available has been deleted from the Security Manager inventory.

Column Label	Description
Device Identifier	For a cluster of ASA devices, the ID of the event's source node, which is based on the "Enable Syslog Device ID" configuration on the Server Setup Page , on page 2053. You can use a "Device Identifier" to filter the syslogs generated by a failover device. In the event of a failover, the IP address of the failover device, that generated the syslog messages is displayed here. However, the Device Identifier column will be blank for syslog messages generated by failover device managed in Cisco Security Manager. **Note** Enable the Process Syslogs from Failover Standby Device check box in the Event Management Page in Tools > Cisco Security Manager Administration. A cluster is managed by Security Manager as a single device with multiple nodes. Thus, all the node's events are mapped to the cluster virtual IP and are displayed with the cluster virtual IP in Event Viewer. You can use "Device Identifier" to filter the syslogs generated by a specific cluster member of a node.
Direction	The direction of the traffic: inbound or outbound.
Event ID	A unique sequential number for each event, assigned internally.
Event Name	A user-friendly name given to the event.
Event Summary	Specifies that this is a summary alert, representing one or more alerts with common characteristics. The numeric value indicates the number of times the signature fired since the last summary alert with a matching initialAlert attribute value.
Event Type ID	For ASA or FWSM, the syslog ID. For IPS, this value could be: • A combination of Sig Id & Sub-Sig ID (for IPS Alert Events) • IPS Status (for IPS Status Events) • IPS Error (for IPS Error Events).
Execution State	The execution status of the application.
Final Alert	Applies to a summary alert, representing one or more alerts with common characteristics. It indicates whether this is the last event alert containing the same value in the initialAlert attribute.
Generation Time	Represents device local event generation time (available only for IPS events).
Global Correlation Audit Mode	Whether the alert was handled with audit mode processing: true or false.
Global Correlation Deny Attacker	Whether a deny-attacker action occurred (or would have occurred) because an internal override was exceeded due to the calculated risk rating: true or false.

Column Label	Description
Global Correlation Deny Packet	Whether a deny-packet action occurred (or would have occurred) because an internal override was exceeded due to the calculated risk rating: true or false.
Global Correlation Modified Risk Rating	Whether the risk rating was adjusted by adding the reputation risk delta due to the risk rating: true or false.
Global Correlation Other Overrides	Whether any other defensive actions were taken because an override threshold was exceeded due to the calculated risk rating: true or false.
Global Correlation Risk Delta	A value from 0 to 99 that indicates how much the risk rating was increased due to the reputation score. If audit-mode is enabled, then it indicates how much the risk rating would have been adjusted had audit-mode not been enabled.
Hit Count	The number of times the flow was permitted or denied by the ACL entry in the configured time interval. The value is 1 when the ASA or FWSM generates the first syslog message for a particular flow. **Note** When you navigate to the ACL policy page after moving across screens, the **HitCount** and **LastHitTime** values display **0** and **Never**, respectively for all the ACL rules. To get the actual **HitCount** and **LastHitTime** values, click the **Refresh Hit Count** button on the ACL policy page. The values are retrieved from the database and displayed on all the ACL rules.
Hit Count Info	ACL Hit Count information, for example, *First hit* .
Host ID	The globally unique identifier for the host that originated the event.
ICMP Code	The code of the ICMP type. For example, ICMP Type 3 and Code 0 is Net Unreachable or Code 1 is Host Unreachable.
ICMP Type	The type of ICMP message. For example, 3 for Destination unreachable, 8 for Echo.
Initial Alert	This field applies to a summary alert, representing one or more alerts with common characteristics. The value of InitialAlert provides the event ID of the last non-summary evIdsAlert with the same characteristic (sigid/subsigid).
Ip Log ID	The IP Log Identifier that uniquely identifies (with host-scope) an iplog document.
IpLog Address	The IPv4 or IPv6 address associated with the IP log.
IpLog Alert Reference	The global event ID of the evAlert event that triggered the log to be initiated.
IpLog Begin Time	The start of the time range that is currently available in the log document.
IpLog Bytes Captured	The total bytes captured. Note that some packets that were captured may have already been deleted from the log due to memory limitations.

Column Label	Description
IpLog Bytes Remaining	The number of bytes remaining until the log will be terminated.
IpLog End Time	The end of the time range that is currently available in the log document.
IpLog Minutes Remaining	The minutes remaining until the log will be terminated.
IpLog Packets Captured	The total number of packets captured and logged.
IpLog Packets Remaining	The packets remaining until the log will be terminated.
IpLog Status	A string that represents the log status.
IPS Category	The SEE event category.
IPS User	The username of the user initiating the operation.
License Limit	The maximum number of licenses.
List Name	The list that includes the domain name, administrator allow list, block list, or IronPort list.
Login Action	The login action that occurred: loggedIn, loggedOut, or loginFailed.
Malicious Host	The hostname of the malicious host.
Malicious IP	The IP address of malicious device.
Max Connection	The maximum number of NAT connections.
MaxEmbryonic Connection	The maximum number of embryonic connections.
NAT Destination	The translated (also called natted) destination IP address. The host name of the translated destination.
NAT Destination Service	The translated (or natted) destination port.
NAT Global IP	The global address. It can contain IPv4 or IPv6 addresses.
NAT Source	The translated (or natted) source IP address. It can contain IPv4 or IPv6 addresses. The host name of the translated source.
NAT Source Service	The translated (or natted) source port.
NAT Type	The type of network address translation, for example *Static* or *Dynamic* .
New Time	The time to which the device clock was changed.
New Version	The system software version after an upgrade installation.
No.	The number of the event (row) in the current display. This is a simple sequential number and is not related to the content of the event. See the Event ID and Event Name fields for information about the type of event.

Column Label	Description
Old Time	The device clock time prior to a change.
Old Version	The system software version before an upgrade was uninstalled.
Operation Successful	Indicates whether an operation was successfully performed.
Package File	The name of package file to be auto-downloaded and installed.
Physical Interface	The physical interface, which is identified only if physical interface is different from the respective value in the Interface column.
Policy Map	The policy map name.
Protocol	The Level-3 or Level-4 protocol.
Protocol Version	The protocol version.
Protocol (Non L3)	Some non-Level-3 or -4 protocol seen in the event, for example, TACACS, RADIUS, FTP, or H245.
Reason	A rationale associated with certain events. For example, a connection tear down may have an associated reason.
Receive Time	The time the event was received by Security Manager.
Reputation	The attacker's reputation score in the range -10.0 to +10.0. A lower (more negative) score indicates a greater likelihood that the host is malicious.
Result Status	The status of an operation, which indicates whether the operation successfully completed.
Risk Rating	A value that represents the calculated risk associated with the event.
Role in Group	The role of this member of an ASA load-balancing group: Group, Control, or Data.
Security Context	The security context with which the named interface, specified in the corresponding Interface column, is associated.
Sensor Event ID	The serial number for an event, which is guaranteed unique within the scope of the originating host.
Severity	The firewall or IPS severity values.
SIA Event Name	The event that occurred for the service identified in the SIA Service Name field.
SIA Service Name	The name of the Service Insertion Architecture (SIA) service for which this event occurred.
Sig Details	The details of the reported signature that was triggered and resulted in the generation of the alert.

Column Label	Description
Sig ID	The Sig ID value is used by the alert originator to identify the activity. It identifies the pre-defined signature defined for this activity.
Signature Version	The version of the signature definition used to generate an alert.
Source	The IP Address or hostname of the traffic source (for ASA and FWSM) or the attacker (for IPS). It can be multi-valued and contain IPv4 or IPv6 addresses. If View > Show Network Host Objects is selected and a host object is defined that matches the source IP address, the host object name is displayed. **Tip** Hover over a host object name to view the IP address associated with that object.
Source Context Data	The context buffer indicating the data that was sent just prior to and immediately after the alert was triggered. A Base64-encoded representation of the data stream that was sourced by the attacker.
Source FQDN	The fully-qualified domain name of the source IP address, if any.
Source Interface	The source interface. For Etherchannel alerts (426001-426003), this is the name of the interface that is part of the Etherchannel bundle for which this event occurred. The Etherchannel interface is identified in the Destination Interface column.
Source Locality	Identifies whether the attacker address is located inside or outside of a given network, as specified by the intrusion detection device's configuration.
Source Service	The source port.
Source User Identity	The username associated with the traffic source, if any.
SSO Server	The single sign-on (SSO) server name.
SSO Server Type	The single sign-on (SSO) server type, for example, SiteMinder.
Sub SigId	The sub-sig ID value, which is used by the alert originator in combination with the signature ID (sigId) to identify the activity.
Summary Type	Defines the common characteristics of all alerts in a summary alert.
Target Value Rating	The asset values associated with targets identified in alerts.
Threat Level	Shows one of the following values, if any threat level pertains: none, very-low, low, moderate, high, or very-high.
Threat Rating	The threat rating of the event, if any.
Time Zone	The local time zone at the originating host's location.
Translated Call ID	The peer's Translated Call ID for the session to which this packet belongs.

Column Label	Description
Trigger Packet	The single, complete packet (in base64 binary format) that triggered the alert.
Truncated	Whether the trigger packet contained in the event is truncated.
Tunnel Type	The VPN tunnel type.
Type	The AAA type, for example authentication, authorization, or accounting.
Upgrade Name	The name of the upgrade package that was uninstalled.
URI	The URI of the auto-upgrade server directory.
UTC Offset	The offset attribute of sensor local time indicates the number of minutes that must be added to the UTC time to convert to local time at the originating host.
Virtual Sensor	The name of the virtual sensor associated with the event.
VLAN Id	The VLAN number associated with packets involved in the activity that triggered the alert.
VPN Group	The VPN group policy.
VPN IPSec SPI	The IPSec Security Parameter Index.
VPN User	The VPN username.
Watchlist Delta	The amount that the risk rating value was increase due to the source of the activity associated with the alert being on a watchlist.

Time Slider

The time slider resides below the events table when you are using an historical view; it is not used with real-time views. The following illustration explains the time slider; the pagination controls on the right are explained in Figure 61: Time Slider Elements, on page 2702.

Figure 61: Time Slider Elements

You can use the time slider to do the following:

- View the EPS (events per second) trends for the server. You can use the controls on the right to zoom in or out to get a better view of the EPS trends over the time frame that concerns you.

You can also click and drag the background of the time slider to position the time ranges within the window. Moving the background does not affect the selected time range.

- Select a slice of time for displaying events in the table, either by moving the vertical slider or by using the pagination controls. The position of the vertical slider determines the most recent event displayed in the event table. Whenever you alter the time slice, the event table is reloaded with the events that match the time period.

The time range of the events displayed in the event table is determined by the selected time interval. For more information, see Selecting the Time Range for Events , on page 2720.

The following table explains the pagination controls to the right of the time slider.

Table 978: Time Slider Paging Controls

Element	Description
	Previous page (earlier) and next page (later). The size of page varies according to the selected time mode. **Note** Using the page controls alternately, for example forward and then back, causes the sort order in the event table to reverse. That is, the latest events go from the top of the table to the bottom, or from the bottom to the top.
	First page (earliest) and last page (most recent).
	Zoom in (smaller total time interval shown) and zoom out (greater time interval shown). Zooming does not change the content of the event table. A shaded blue area indicates the time interval currently displayed in the event table.

Event Details Pane

The Event Details pane (illustrated in Event Monitoring Window , on page 2690) presents information contained within a single event. The information, which is displayed in multiple tabs within the pane, varies according to the richness of the event and the capability of Event Viewer to parse the data. Components include:

- **Displayed Fields Tab**—Displays the fields shown in the Event Table.
- **Details Tab**—Displays all available fields for the selected event. The fields are presented in alphabetical order.
- **Explanation Tab**—Displays a generic explanation for this event type.
- **Related Threats Tab**—Displays threats correlated to the event. (IPS Events only.)
- **Recommended Action Tab**—Displays a generic recommendation for an event of this type. (Syslogs only.)
- **Trigger Packet Tab**—Displays trigger packet data. (IPS Events only.)
- **Context Packet Tab**—Displays context packet data from the Source (Attacker) and Destination (Target). (IPS events only.)

- **Notes**—Enables you to add a note so that you can revisit particular signatures later to see what you or other users have added for a signature or an event. For more detailed information, refer to Signatures Page , on page 1680.

Note The notes added here will be persistent when you cross-launch to Configuration Manager.

Note If you have more than one event for a particular signature, then annotating one event will annotate all the events related to that signature.

Preparing for Event Management

Before you can view events generated from a device, you must configure the device to work with Event Viewer.

Ensuring Time Synchronization

Standard network management practice includes consideration of time differences and network device synchronization. Typically, this includes the use of a Network Time Protocol (NTP) server. Event Viewer is most easily used with a common time standard. However, it is worth noting that you can view the time an event is received by Security Manager (Receive Time), and for IPS devices, the time the event was generated by a device (Generation Time).

Whenever possible, configure the Security Manager server and the devices it is monitoring with the same NTP server.

Differences between the clock on the Security Manager server and the clock on a Security Manager client at the time the client is opened are taken into account while translating/mapping event data from the server time to the client time. If the time difference changes dynamically due to the Security Manager server time moving ahead, for example, the data retrieved from the server will show an updated timestamp, but the client will continue to map the time difference based on the times on the server and the client when the client was opened. In such a situation, no data will be seen on Event Viewer for a brief interval that corresponds to the time change on the server. For this reason, we recommend that Security Manager server clock changes are done less frequently and at a time that would be the least impacting.

Configuring ASA and FWSM Devices for Event Management

Note From version 4.17, though Cisco Security Manager continues to support FWSM features/functionality, it does not support any bug fixes or enhancements.

Before you can use Event Viewer, or any other application that analyzes syslog events, to view events generated from an ASA (including ASA-SM) or FWSM device, you must configure the logging policies on the device to generate and transmit syslog messages.

Note A cluster device with a Virtual IP address (beginning with Security Manager version 4.4) can be added if configured in both Security Manager and on the virtual device.

Tip Although you can configure devices individually to specify the appropriate logging configuration, it is likely that more than one ASA or FWSM device in your network would use the same logging configuration. Although this topic describes how to configure an individual device, you can also create shared policies and assign them to multiple devices. For more information about configuring and assigning shared policies, see Creating a New Shared Policy , on page 221 and Modifying Policy Assignments in Policy View , on page 221.

Besides the logging configuration described here, you can also configure logging for individual access control entries when you configure them either in firewall policies or ACL policy objects. The default is to log denied access only, but you can configuring ACL logging options to provide increased logging.

Note To reliably report events from contexts in multiple-context mode, Cisco Event Viewer requires an IP address for the management interface of each context.

Step 1 (Device view) Select the ASA or FWSM device or security context, then select **Platform > Logging > Syslog > Logging Setup** from the Policies selector.

In the policy, select **Enable Logging**. You can configure other options as needed. For detailed information about the options, see Logging Setup Page , on page 2046.

Step 2 Select **Platform > Logging > Syslog > Syslog Servers**.

Add the Security Manager server's IP address to the syslog servers table. Configure the server to use the UDP protocol. The default port, 514, is correct unless you configure a different port on the Security Manager Administration Event Management Page , on page 538.

If you are using other event management applications, such as CS-MARS, also add those servers to this policy.

Note You can use EMBLEM message format if you desire; both traditional and EMBLEM formats are supported. Keep in mind that EMBLEM is not supported by CS-MARS, so do not send EMBLEM-formatted messages to a CS-MARS server.

For detailed information about the options in the Syslog Servers policy, see Syslog Servers Page , on page 2058.

Step 3 If you want to configure non-default syslog server settings, such as adding time stamps to syslog messages, changing the severity level of messages, or suppressing the generation of specific messages altogether, configure the **Platform > Logging > Syslog > Server Setup** policy. For detailed information, see Server Setup Page , on page 2053.

Step 4 (Optional)You can configure the **Platform > Logging > Syslog > Logging Filters** policy to fine-tune the kinds of messages sent to syslog servers. For detailed information about this policy, see Logging Filters Page , on page 2043 and Edit Logging Filters Dialog Box , on page 2044.

Following are some tips for configuring this policy:

- When adding the logging filter, select **Syslog Servers** for Logging Destination.

- You can create a simple filter based on message severity, or you can configure a much more complex filter based on event classes. If you elect to use event classes, you can do the configuration directly in the Logging Filters policy, or you can configure event lists separately in the **Event Lists** policy (see Event Lists Page , on page 2039).

Step 5 (Optional) You can configure the **Platform > Logging > Syslog > Rate Limit** policy to limit the quantity of messages generated per time interval, either by message severity or message number. This can help you avoid flooding the syslog server. See Rate Limit Page , on page 2049.

Step 6 (Optional, but recommended) You can configure the **Platform > Device Admin > Server Access > NTP** policy to specify a network time protocol server for ASA devices. Using NTP ensures consistent date and time information for easy event correlation. Specify the same NTP server you use for the Security Manager server. If you use different servers, ensure the servers are synchronized. See NTP Page , on page 2021.

Configuring IPS Devices for Event Management

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

Before you can use Event Viewer to view events generated from an IPS device, you must configure the Allowed Hosts policy on the device to allow the Security Manager server access to the device. Because Security Manager also needs to be configured in the Allowed Hosts policy to allow configuration access, your IPS devices might already be configured correctly. You should also configure the network time protocol (NTP).

Configure the following policies for IPS devices in Device view to enable effective event management on those devices:

- **Platform > Device Admin > Device Access > Allowed Hosts**—(Required) Add the Security Manager server to the table. You can either identify the Security Manager server by its host IP address (for example, 10.100.10.10), or you can specify the network that it is on (for example, 10.100.10.0/24).

If you are using other event management applications with the device, such as CS-MARS, ensure that you also add those servers to the policy.

For more information about configuring the Allowed Hosts policy, see Identifying Allowed Hosts , on page 1620.

- **Platform > Device Admin > Server Access > NTP**—(Recommended) Configure the same NTP server that you use for the Security Manager server to ensure consistent date and time information for easy event correlation. If you use different servers, ensure the servers are synchronized. For more information, see Identifying an NTP Server , on page 1636.

Tip Although you can configure devices individually to specify the appropriate allowed hosts and NTP configuration, it is likely that more than one IPS device in your network would use the same configuration. Although this topic describes how to configure an individual device, you can also create shared versions of these policies and assign them to multiple devices. For more information about configuring and assigning shared policies, see Creating a New Shared Policy , on page 221 and Modifying Policy Assignments in Policy View , on page 221.

Managing the Event Manager Service

The Event Manager service enables the use of the Event Viewer application. For Event Viewer to function, the service must be started. There are several tasks that you can perform to configure and manage the overall functioning of the service.

This section contains the following topics:

Starting, Stopping, and Configuring the Event Manager Service

The Event Manager service must be running for you to use Event Viewer or Report Manager.

When you install Security Manager, the Event Manager service is automatically enabled unless the server does not meet the minimum memory requirements that are documented in the Installation Guide for Cisco Security Manager . Although you can manually start the service on a system that does not meet the minimum memory requirements, you might find the performance to be dissatisfactory. The key factors are the number of devices managed and their rate of event generation.

Tip If you get a message that Event Viewer is unavailable when you select Launch > Event Viewer, but the **Enable Event Management** option is selected in the Tools > Security Manager Administration > Event Management page, try restarting the Event Manager Service. First, deselect the Enable option and click Save. Wait for the service to stop. Then, select the Enable option, click Save, and wait for the service to finish restarting. You can then try opening Event Viewer again.

The following procedure explains how to start, stop, and configure the Event Manager service.

Related Topics

- Monitoring Event Data Store Disk Space Usage , on page 2712

Step 1 In the main Security Manager window (not Event Viewer), select **Tools > Security Manager Administration** and select **Event Management** from the table of contents.

Step 2 Do one of the following:

- To enable, or start, the Event Manager service, select **Enable Event Management**.
- To disable, or stop, the Event Manager service, deselect **Enable Event Management**.

You can also change the other settings, such as the event data store location and maximum size, the syslog port to which devices should send events, and the pagination size (which determines the maximum number of events loaded into the event table). You can also configure an extended event storage location to augment your primary storage location. For detailed information about these settings, see Event Management Page , on page 538.

Note Beginning with version 4.5, Security Manager enables you to forward syslogs to one local collector and two remote collectors. For more information, see Event Management Page , on page 538.

Step 3 Click **Save** to save your changes.

If you changed the Enable Event Management option, you are prompted to confirm that you want to start or stop the Event Manager Service. If you click **Yes**, the service is started or stopped immediately, and you are shown a progress indicator and told when the change is completed. Wait until the status change is completed before continuing.

If you change other settings, with the exception of the pagination size, the Event Manager service must be briefly stopped and restarted. You are shown a progress indicator.

Monitoring the Event Manager Service

The Event Manager service processes incoming syslog messages and retrieves SDEE alerts from monitored IPS devices. The amount of data processed varies depending on network activity. There can be times when the events per second (EPS) generated in the network is higher than the service can handle, in which case the service goes into throttle mode, selectively dropping events.

You can monitor the status of the service to identify congestion and address problems that arise. The status of the service is shown in an icon in the lower right corner of the status bar in Event Viewer, as shown in Overview of Event Viewer , on page 2683. The Total EPS indicates the current events per second rate that the service is experiencing. The alert status icon color indicates the following:

- Green dot—There are no problems. All events are being processed normally.
- Yellow dot—There are some warnings, for example, low severity events are being dropped.
- Orange dot—There are more serious issues, for example, low and medium severity events are being dropped.
- Red dot—There is a critical situation, for example, high severity events are being dropped or there is a significant problem with the system, such as problems with the syslog port or with the event data store location.
- Disconnected network wire—The Event Manager service is disabled, either intentionally or due to some server problem; no events are being stored or retrieved. If this is not intentional, restart the Event Manager service as described in Starting, Stopping, and Configuring the Event Manager Service , on page 2707.

To view detailed information, click on the alert status icon. A bubble opens that shows summary statistics for the past five minutes, including the number of events received and dropped and event server alert messages, if any. Click the alert status icon again to close the bubble.

When the bubble is open, you can click the **Details** link in the bubble to view more detailed information. Clicking the Details link opens the Event Statistics Details dialog box, which shows the following information:

- **Last 5 Minutes Statistics:**
  - **Events Received**—The total number of syslog events Received and SDEE alerts retrieved in the past five minutes by the service.
  - **Events Dropped**—The total number of events or alerts that the service had to drop due to congestion. This number indicates drops from monitored devices only, so the number should be zero in normal circumstances. A non-zero number indicates that the service is in throttle mode; look for messages in the Event Server Alerts section.
  - **Events from Unmonitored Devices**—The number of syslog messages sent to the server that came from devices that are not selected for monitoring (as described in Selecting Devices to Monitor , on page 2711).

Events from unmonitored devices are always dropped, but they do place a load on the service. The IP address of the last unmonitored device detected is shown; use the IP address to determine the source of the messages. You can then determine if the device should be added to the monitored devices list, or if you need to alter the device's configuration to remove the Security Manager server from its list of syslog servers.

If the device that is sending messages is outside of your network, adjust the firewall configuration to prevent this syslog traffic from entering your network.

- **Status Information:**
  - **Total Events Per Second (EPS)**—The rate at which events are currently being processed. This measure does not include dropped events.
  - **Event Buffer Used**—The percentage of the shared event buffer that is currently being used to process events. The bar is color-coded to indicate the throttle level:

Green—Not in throttle mode.

Yellow—Low severity events are being dropped.

Orange—Low and medium severity events are being dropped.

Red—High severity events are being dropped.

- **Event Server Alerts**—These messages indicate specific status problems that you might need to address. Table 979: Event Manager Status Messages , on page 2710 explains the messages that you might see with possible solutions.
- **Copy button**—Click the Copy button to copy the information to the clipboard. The copied information includes HTML markup. You can paste the information into an HTML file.

Table 979: Event Manager Status Messages

Alert Message	Alert Level	Possible Action
UDP port <514> could not be acquired, therefore syslog events cannot be collected.	High	Some external application might already be using the indicated port (the default syslog port is 514). You might need to stop that external application. You can use the netstat command to identify the PID of the process, for example, **netstat -ao | findstr 514**.
The event data store location does not exist, therefore events cannot be stored.	High	The event data store location as configured in the Security Manager Administrative Settings does not exist or the Security Manager server does not have the required read/write permissions to the location. For more information about configuring the location, see Event Management Page , on page 538.
Low severity events are being dropped.	Low	Either events are being received at a very high rate or the system is under a heavy load. To identify if a device is sending events too frequently, you can open the All Device Events view and switch to real-time mode, as described in Switching Between Real-Time and Historical Views , on page 2719. To identify if the server is under a heavy load, log into Windows on the server and use Task Manager or another tool to see if there is an application other than Security Manager that is taxing the system. If possible, disable or stop the application. If the problem occurs frequently, consider uninstalling the other application from the server.
Low and medium severity events are being dropped.	Medium	
All events are being dropped.	High	
Events from unknown devices are being received.	Low	Syslog events are being sent to the Security Manager server from devices that are not selected for monitoring as described in Selecting Devices to Monitor , on page 2711. These devices might not be supported device types for monitoring and they might not even be in the Security Manager inventory. The message varies based on the EPS rate for these devices. A low severity message indicates the EPS rate is between 500 and 5,000; a medium indicates an EPS rate between 5,000 and 10,000; a high indicates an EPS rate greater than 10,000. The **Events from Unmonitored Devices** statistic in the Last 5 Minutes Statistics shows the number of these events and the IP address of the last unsupported device. Either select the device for monitoring or change the syslog policy for the device to remove the address of the Security Manager server. You will need to repeat the process if more than one unmonitored device is sending messages.
Events from unknown devices are being received at a high rate.	Medium	
Events from unknown devices are being received at a very high rate.	High	

Selecting Devices to Monitor

All ASA and FWSM devices and security contexts, and IPS devices and virtual sensors, that are added to the Security Manager database are automatically selected for monitoring in Event Viewer.

Note To reliably report events from contexts in multiple-context mode, Cisco Event Viewer requires an IP address for the management interface of each context.

Beginning with version 4.17, Cisco Security Manager receives events from non-management interfaces also, with following limitations:

- Only Static IP address Interface is supported.
- The events from cluster devices will not be displayed because cluster pool IP ranges for syslog would be used.
- Only after deployment of syslog server configuration, the device event manager is notified to get the non-managed interface IP. Hence, there can be initial event drop.
- This enhancement is not supported in syslog relay services.

If you do not want to use Event Viewer with a device, you can deselect the device for monitoring. Note that if an ASA or FWSM device or security context is not configured to use the Security Manager server as a syslog server, you will not get events from the device or security context anyway, so you might not need to deselect an ASA or FWSM that you do not want to monitor.

Tip You cannot monitor Cisco IOS IPS devices in Event Viewer.

Related Topics

- Adding Devices to the Device Inventory , on page 77
- Configuring ASA and FWSM Devices for Event Management , on page 2704
- Configuring IPS Devices for Event Management , on page 2706

Step 1 In Event Viewer, select **View > Manage Monitored Device** to open the Manage Monitored Devices dialog box.

The device list shows all devices in the Security Manager inventory to which you have view permissions. You cannot see any devices for which you have no permissions. Any selections you make are limited to the displayed devices. If you do not have permission to select or deselect any devices, the list is read-only and you cannot select devices for monitoring. For more information on access permissions, see Understanding Event Viewer Access Control , on page 2680.

Step 2 Ensure that only those devices whose events you want to monitor in Event Viewer are selected. Deselect any undesired devices.

You can change the selection status for all devices in a device group by selecting or deselecting the group.

Step 3 Click **OK**.

You might need to wait for the changes take effect in Event Viewer.

Monitoring Event Data Store Disk Space Usage

The Event Manager service uses a specified amount of disk space for the primary and extended event data stores. This ensures that the service does not overwhelm the server computer or the extended storage location. You configure the size of the primary and extended event data stores on the **Tools > Security Manager Administration > Event Management** page as described in Event Management Page , on page 538.

For both the primary and extended locations, when the allocated space is 90% full, the oldest event data is deleted from storage to make room for new data. Data is copied from the primary store to the extended store, if you configure one, so in most cases events deleted from the primary storage continue to be available for querying from the extended storage location, until they are rotated out of the extended storage. (The timing of the copy from the primary to extended data store depends on a number of factors, including the events per second (EPS) rate, the relative size of the primary store to the extended store, and the percentage of the primary data that has already been copied to the extended store.)

You can monitor how much of the allocated space is currently being used, and the age of the oldest event, by selecting **View > Show Event Store Disk Usage** in Event Viewer. The information is displayed as a pie chart that shows the used and unused space in gigabytes (GB) for each location. There is also an indication of the oldest event currently stored in each location.

You can use this information to help you decide whether to increase or decrease the space allocated to each location.

Tip If you decrease the size of either location, and your new size is less than the amount of space currently being used, the oldest events are immediately deleted until your new target size is reached.

Archiving or Backing Up and Restoring the Event Data Store

The event data store is not included with the regular Security Manager database backup. If you want to archive or back up the event data store, whether the primary or extended location, you must do so separately. You can restore the backups if necessary.

This procedure explains the steps required for backup and restore for the event data store.

Tip When you disable the Event Manager service, events are not written to the data store, so you will miss any events generated during the backup or restore process.

Step 1 To back up the event data store:

a) Using the Security Manager client, select **Tools > Security Manager Administration**, and select **Event Management** from the table of contents.

b) Determine the name of the event data store folder. The folder is shown in the Event Data Store Location field; the default is *NMSROOT***MDC\eventing\database**, where NMSROOT is the installation directory (usually C:\Program Files\CSCOpx).

If you are backing up the extended data store, the location is identified in the Extended Data Store Location field.

c) Deselect the Enable Event Management check box to stop the Event Manager service. Click **Save** to save your changes. You are prompted to verify that you want to stop the service; click **Yes** and wait until you are notified that the service has stopped.

d) Outside of Security Manager, make a copy of the *NMSROOT***MDC\eventing\config\collector.properties** file and the event data store folder. Place the copy on a separate server so that the backup is available in case of hardware failure.

If you are also backing up the extended data store, make a copy of that folder as well.

e) In the Security Manager client's **Tools > Security Manager Administration > Event Management** page, select the **Enable Event Management** check box and click **Save**. You are prompted to verify that you want to start the service; click **Yes** and wait until you are notified that the service has started.

Step 2 To restore the event data store, use the same process you used to back up the data with the following exceptions:

- Instead of making a copy of the existing event data store, copy the backup into the event data store location. You can optionally delete the existing data before copying in the backup data. However, as long as you do not exceed the data store size limit, you can mix the backup and existing data. (The data store limit is configured in the **Tools > Security Manager Administration > Event Management** page.)

Note Mixing old and new data works only if you are preserving the existing copy of collector.properties (that is, you are not restoring the file), and the new and old data are from the same server. You cannot merge the data store from two or more separate servers.

- Do not restore collector.properties unless you are recovering from a hardware failure or some other event that required you to reinstall Security Manager.

Using Event Viewer

Use Event Viewer to help troubleshoot network problems involving monitored devices. Using views and filtering, you can analyze problems to help identify the cause and possible remedies.

This section contains the following topics:

Using Event Views

When you view events in Event Viewer, you open a view. A *view* is a set of filters and other properties, including color rules, selected columns and their positions and widths, and the default time window, that let you define a subset of events. Views help to limit the scope of the events list so that you can more easily find what you are looking for.

This section contains the following topics:

Opening Views

You can open up to four historical views and one real-time view in Event Viewer. When you open a view, Event Viewer uses the view settings and time range to retrieve events from the event data store and display them in the event table.

- To open a view so that it replaces the currently active open view, do one of the following in Event Viewer:
  - Double-click the view in the views list.
  - Right-click the view in the view list and select **Open**.
- To open a view in a new tab, do one of the following:
  - Select **File > Open View** from the menu bar. The Open a View dialog box opens, which is essentially the same as the view list. Select the view and click **OK**.
  - Right-click the view in the views list and select **Open In New Tab**.

Floating and Arranging Views

You can open up to four historical views and one real-time view at one time. When you have multiple views open, they are opened as tabbed windows in the right pane of the main Event Viewer window, in the most recently used area (“tabbed group”) if there is more than one area. The commands to arrange the windows appear if you right-click the tab for the view window as shown in the following illustration.

You have many options for arranging view windows based on your requirements. For example, you might want to compare two views side-by-side, or remove a view from the main window without closing it.

You can use the following techniques to arrange the view windows to get the display that you desire:

- Floating a view—To remove a view from the main Event Viewer window without closing it, right-click the view tab and select **Floating**. The view is moved to its own window.

If you have already floated a view, you can select **Floating to** and choose one of the already-floated windows. The view becomes a new tab in that window.

- Docking a view—To move a floating view back to the main Event Viewer window, right-click the view tab and select **Docking**.
- Arranging views horizontally or vertically for side-to-side comparison—To create a vertical or horizontal arrangement of views to allow for easy comparison, without floating the views, right-click the view tab and select **New Horizontal Group** or **New Vertical Group**. These commands split the current tabbed group into the selected layout. You must have at least two views open to use these commands. If you have more than two open views, and you want all of them in separate windows, you need to use the command multiple times.
- Move views to different tabbed groups—If you have several open views, and you have arranged them into horizontal or vertical groups, you can move views among the groups by right-clicking the view tab and selecting **Move to Next Tab Group** or **Move to Previous Tab Group**. The commands appear only if views are arranged in a manner where such movement is possible:
- Change the orientation of groups—You can switch between horizontal and vertical layouts by right-clicking the view tab and selecting **Change Tab Groups Orientation**.

Customizing the Event Table Appearance

You can customize the appearance of predefined or custom views in the event table to meet your requirements. You can save these changes even in the predefined views.

You can do the following to customize the event table:

- Create column filters to limit the type of events listed. Use the down arrows in the column heading to define the filter as described in Creating Column-Based Filters , on page 2722.
- Create color rules to highlight events based on severity, as described in Configuring Color Rules for a View , on page 2717.

- Change which columns appear in the table by clicking the Column Selector icon to the right of the table heading row, as described in Columns in Event Table , on page 2694.
- Change the width of a column by clicking the right edge of the column heading and dragging it to the desired size.
- Change the order of the columns by clicking the column heading and dragging the column to the position you want.
- Sort the events list by a column by clicking the column heading. The column sorts based on a three-click cycle: ascending, descending, and default order (which is by event reception time).
- Reset the width of the View Selector and Event Monitoring window to their default values by selecting **View > Reset Layout**.
- Change whether the source and destination columns show IP addresses or host object names, as described in Switching Between Source/Destination IP Addresses and Host Object Names , on page 2716.

Related Topics:

- Creating Custom Views , on page 2717
- Saving Views , on page 2719

Switching Between Source/Destination IP Addresses and Host Object Names

You can view source and destination IP addresses or you can view the host object name of objects that match a source or destination IP address. By default, the Event Viewer shows host object names when available.

IP address to host name mapping is supported only for the source and destination of events. Also, the mapping applies to Host objects only; Event Viewer will not show an object name when the source or destination of an event matches a Network object, Group object, or Address Range object.

Please clarify the type and content of the object. E.g. is this feature for host type network/host objects only, that is, the single-value host version of the object? does it work for single-value group objects, or for network or range objects?

To switch between source/destination IP addresses and host object names, do the following:

- To see host objects names for any objects that match a source or destination IP address, select **View > Show Network Host Objects**. This option is selected by default.

Tip Hover over a host object name to view the IP address associated with that object.

Note An IP address to host object name cache is created when Event Viewer is launched. If you define new host objects, you must submit those changes to the database and then close and relaunch Event Viewer for those mappings to be used.

- To see IP addresses in the source and destination columns, deselect **View > Show Network Host Objects**.

Configuring Color Rules for a View

You can use color rules to color-code events shown in the event table based on the severity of the event. Color-coding can help you quickly identify the events that you most want to know about.

You can selectively enable and disable color rules by editing them. This allows you to turn them on and off without deleting them.

Tip You can configure color rules for both predefined and custom views. However, you cannot share color rules between views: all color rules are unique to a view. If you want to apply the same rules to multiple views, you must recreate the rules in each view.

To define and enable a color rule, follow these steps:

Step 1 Open the view in which you want to define the color rule (see Opening Views , on page 2714).

Step 2 Click the **Color Rules** tab in the View Settings pane (see Event Monitoring Window , on page 2690).

Step 3 Do any of the following:

- To add a new rule, click the **Add** button. In the Add Color Rule dialog box, configure the rule as follows:
  - Select **Enable** to make the rule active.
  - Select the severity level for which the rule applies from the **Severity** list.
  - Use the **Foreground** (which is the text color), **Background**, and **Font Type** (either Bold or Italics) controls to define how the severity should be presented in the table. The Preview Text area shows how your rule will look.
- To edit a rule, select it and click the **Edit** button.
- To delete a rule, select it and click the **Delete** button.

Creating Custom Views

A custom view is one in which you define the filters in the view settings. Using custom views, you can configure filter rules to pin-point specific areas for monitoring and analysis. Custom views are private and cannot be shared between users.

You basically have two options for creating custom views, creating a view from scratch or from an existing view:

- To create a custom view that has no predefined column filters, do one of the following:
  - Select **File > New View** from the menu bar.
  - Click the **New** button above the view list.

Then, enter a name for the view and optionally a description of the view and click **OK**. The view is added to the My Views folder in the views list.

- To create a custom view based on an existing view, do one of the following:
  - With the desired base view open, click the down arrow on the Save button in the event table toolbar and select **Save As**, or select **File > Save As** from the menu bar.
  - Right-click the desired base view in the views list and select **Save As**.

Then, enter a name for the view and optionally a description of the view and click **OK**. The view is added to the My Views folder in the views list. The new view has the same filters as the base view.

Note View names can be up to 128 characters and contain alphanumeric characters, spaces, hyphens (-), underscore characters (_), plus signs (+), periods, and ampersands (&). The description can be up to 1024 characters.

After you create the new view, you can customize it the same way that you can an existing view:

- Define filters in the view settings. See Creating Column-Based Filters , on page 2722.
- Define color rules in the view settings. See Configuring Color Rules for a View , on page 2717.
- Select the columns to display in the event table. See Columns in Event Table , on page 2694.
- Customize the event table appearance. See Customizing the Event Table Appearance , on page 2715.

Related Topics

- Views and Filters , on page 2679
- Event Table Toolbar , on page 2692
- Editing a Custom View Name or Description , on page 2718
- Deleting Custom Views , on page 2719

Editing a Custom View Name or Description

To change the name of a custom view, or the custom view's description, do one of the following:

- Select the custom view in the view list and click the **Edit** button above the list.
- Right-click the custom view in the view list and select **Edit**.

Then, make the desired changes to the custom view name or description and click **OK**.

Note View names can be up to 128 characters and contain alphanumeric characters, spaces, hyphens (-), underscore characters (_), plus signs (+), periods, and ampersands (&). The description can be up to 1024 characters.

You cannot change the name or description of a predefined view.

Switching Between Real-Time and Historical Views

You can update the events table for any view using either real-time or historical time periods. A real-time view shows events as they are received, whereas an historical view shows a static list of events that is not updated until you click the **Start** button in the event table toolbar.

To switch between real-time and historical time periods in an open view, do the following:

- To see events in real-time, select **View > Mode > Real Time**, or click the Time Selector control in the event table toolbar and select **Real Time**. For help in locating the control on the toolbar, see Event Table Toolbar , on page 2692.
- To see events in an historical period, select the desired time frame from the **View > Mode** menu or from the Time Selector control on the event table toolbar. All options other than Real Time are historical views. For more information, see Selecting the Time Range for Events , on page 2720.

Saving Views

If you edit the settings for a view, you must save it to make those changes permanent. Saving a view saves changes to filters (for custom views only), table preferences such as selected columns, column width, and sort order, the time range, and color rules. If you make filter changes to a predefined view, you must use Save As to create a new custom view.

- To save changes to a view, do one of the following in Event Viewer:
  - Select **File > Save** from the menu bar.
  - Click the **Save** button in the event table toolbar.

You are asked to confirm that you want to save your changes.

- To save your changes as a new custom view, do one of the following to open the Save View As dialog box:
  - Select **File > Save As** from the menu bar.
  - Click the down arrow on the Save button in the event table toolbar and select **Save As**.
  - Right-click the view in the views list and select **Save As**.

Then, enter a name for the view and optionally a description of the view and click **OK**. The view is added to the My Views folder in the views list.

Note View names can be up to 128 characters and contain alphanumeric characters, spaces, hyphens (-), underscore characters (_), plus signs (+), periods, and ampersands (&). The description can be up to 1024 characters.

Deleting Custom Views

You can delete custom views, but you cannot delete predefined views. To delete a custom view, do one of the following:

- Select it in the view list and click the **Delete** (trash can) button above the list.

- Right-click it in the view list and select **Delete**.

You are asked to confirm your deletion.

Filtering and Querying Events

There are many options for filtering the events that appear in the event table. You can reduce the list of events by selecting the appropriate time range, by filtering on elements in specific columns, or even by searching on a text string.

This section contains the following topics:

Selecting the Time Range for Events

Use the Time Selector control in the event table toolbar, or the equivalent **View > Mode** command, to select the time range for displaying events. The event table lists only those events that occur within the selected time range. For help in locating the Time Selector control on the toolbar, see Event Table Toolbar , on page 2692.

Tip For historical views, the time is based on server time, not the time configured on your workstation.

When you change the time range, the table reloads to show events in the selected range. For historical views, you can refresh the events list by clicking **Start** or by doing the other actions described in Refreshing the Event Table , on page 2721.

The following are your options for the time range:

- To view events from the present time into the past, select one of the following time periods: **last 10 minutes**, **last 1 hour**, **last 12 hours**, **last 1 day**, or **last 1 week**.
- To view events from today or yesterday, select **today** or **yesterday**, as desired.
- To view events from a specific day, select **is on** and then select the date from the displayed calendar.
- To view events from a specific date and time range, select **is between** and select the first and last days and times from the displayed calendars.
- To view real-time events, select Real Time.

Using the Time Slider with Filtering

You can use the vertical slider control in the time slider to change the start time for the events shown in the event table. This is particularly useful when you want to locate events and you know the approximate time they occurred.

For details on the operation of the time slider, see Time Slider , on page 2702.

To use the time slider to aid filtering, follow these steps:

Step 1 Open an historical view, or use the Time Selector in the toolbar, or the **View > Mode** command, to select an appropriate time range, such as Last 10 Minutes. For more information, see Selecting the Time Range for Events , on page 2720.

Step 2 Move the vertical slider to the approximate time of the events you want to examine.

The event table is reloaded to display events on or before the time you specified with the vertical slider. This time range is shaded in the time slider, and the length of time selected is based on the length of time selected in the Time Selector (for example, 10 minutes for a Last 10 Minute view, or the same length of time selected for an "is between" view). The time range is noted in the Time Selector control, for example:

Step 3 To locate the events, you can now do any of the following:

- Apply custom column filters. See Creating Column-Based Filters , on page 2722.
- Use the quick filter to search on a text string. See Filtering on a Text String , on page 2725.
- Scroll or page through the event table.
- Use the time slider paging controls to reset the time range forward or back. For more information, see Time Slider , on page 2702.

Note The distance moved forward or back when paging in the time slider depends either on the mode (time range) that is set or the number of events the event table can hold. The position of the vertical slider denotes the most recent event loaded in the event table.

Refreshing the Event Table

When you are using an historical mode, such as "last 10 minutes," the latest events displayed correspond to the time you selected the time range or opened the view. Similarly, if you are in real-time mode and have clicked Stop, the event table does not include events that arrived after you stopped the event stream.

To refresh the events listed in the event table, so that they are current with your selected time range, do any of the following:

- Click **Start** in the toolbar, or select **View > Start**. The table is refreshed based on your currently selected time range. For real-time views, the event stream restarts.
- Select a different time range using the Time Selector in the toolbar or the **View > Mode** command.
- Select a different time slice using the vertical slider or the pagination controls in the time slider below the event table. For more information on using these controls, see Time Slider , on page 2702.

Creating Column-Based Filters

You can filter the event table in Event Viewer based on the contents of specific columns. Column filters are the type of filter contained in the view settings; they define the basic content of the view. Whenever you apply a column filter, the view settings for the view are updated to include the newly selected filter: you must save the view before closing it if you want the new filter to become a permanent part of the view's definition.

There are many ways in which to define a column filter:

- In the View Settings pane, click the **Add** button. You are first prompted to select the column on which to base the filter. When you click **OK**, you are prompted to create the filter.
- In the View Settings pane, select a filter and click the **Edit** button to change it.
- In the event table, click the down arrow button in the heading of a column and select any of the following from the drop-down list:
  - A specific entry. The drop-down list contains all values currently displayed in the events listed in the table.
  - (All). Select (All) to remove a filter from this column. The event table is updated to show the events that meet your other filter criteria.
  - (Custom). Select (Custom) to create a filter that might have multiple values, negative values, or be based on data not currently contained in the column in the current event table. Selecting (Custom) is essentially the same as creating a filter directly in the View Settings pane.
- In the event table, you can right-click a value and select **Filter This Value**. This action has the same effect as selecting the value from the drop-down list for the column.

You can alternatively select **Filter Not This Value** to create a filter that excludes a value,

- In the event table, you can right-click a value and select **Create Filter from Event**. You are prompted to select the specific columns to include; the column on which you right-clicked is initially selected, but you can deselect it.

The following procedure explains how to build a custom column-based filter, one in which you are not simply selecting a value from the column's drop-down list.

Tips

- Column filters are cumulative: for an event to appear in the event table for a view, the event must meet all column filter criteria. You cannot create a set of OR'ed column filters.
- Some columns allow you to select network/host or service policy objects to define the filter criteria. Selecting policy objects can simplify your filters. However, for a policy object to be selectable in a filter, the object must be committed to the database. If you create a new object for filtering purposes, ensure that you submit your changes in Configuration Manager (and if using Workflow mode with an approver, get the changes approved) before attempting to create the filter in Event Viewer.

When using policy objects, the filtering recognizes whether a device-level override is defined for the object. For example, if you use a network/host object that contains 10.10.10.10, and Device A has an override to change the address to 10.10.10.12, events from Device A appear in the list only if the event matches 10.10.10.12. For devices that do not have overrides, the events must match 10.10.10.10. Furthermore, if Device A has an event that matches 10.10.10.10, that event is not listed because it does not match the device-level override.

Thus, using policy objects can provide results that vary by device and therefore match more closely to your policy definitions.

If your organization is using ACS to control user access, you must have the appropriate View Object privileges for network/host, network/host-IPv6, and service objects to use them in filters.

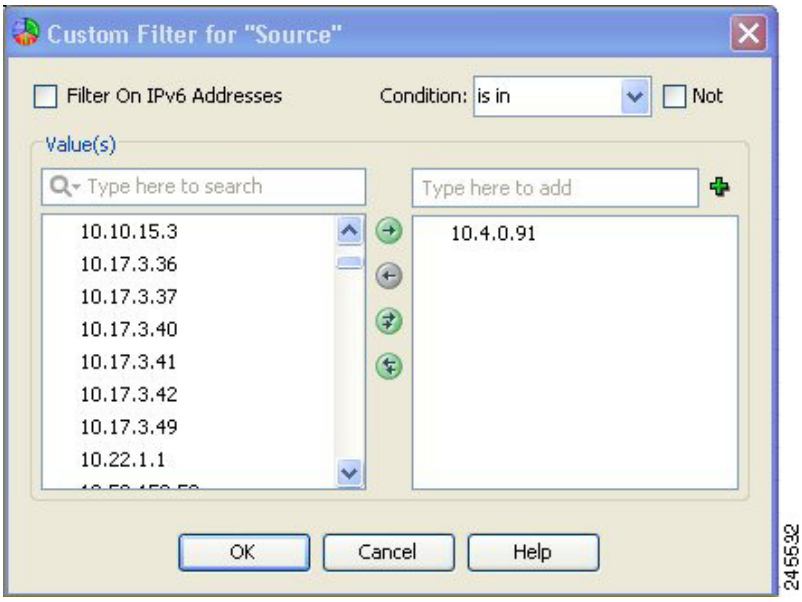
- You can filter on the contents of most but not all columns. If a column does not have a down arrow, you cannot filter on it. For example, you cannot filter on Description, Event Name, Generation Time, or Receive Time.
- The filter icon (a funnel) appears in the heading of a filtered column.
- For a description of the available columns, see Columns in Event Table , on page 2694.

Step 1 Do one of the following:

- In the View Settings pane, click the **Add** button. The Add Custom Filter to a Column dialog box opens. Select the column on which to base the filter and click **OK**.
- In the View Settings pane, select a filter you want to change and click the **Edit** button.
- From the drop-down list for a column, select **(Custom)**.
- Right-click any cell in the desired column and select **Custom Filter**.

The Custom Filter dialog box opens for the selected column.

Step 2 In the Custom Filter dialog box, select the desired values. The following illustration shows a typical example of this dialog box, for the Source column.



Following is a description of the controls you might find in the Custom Filter dialog box. Not all controls appear for every column:

- **Available and Selected Items lists**—In most cases, to select an item you highlight it in the left list, which contains the available values, and click the right arrow to move it to the list of selected values. You can select multiple values. The right list defines the filtered values.

The items listed in the available values column are determined by the values currently present in the events listed in the events table. For address and service fields, the list also includes policy objects. If there are a lot of available values, you can search for the desired value by typing into the edit box above the list; the list is filtered as you type. Click the down arrow next to the Q to change how your search string is evaluated for matches.

You can also select, or deselect, values using the following techniques:

- Type the item into the edit box above the selected values list and click the + button. This technique is useful if there is a large number of available values, or if you want to filter on a value that is not present in the current events list.
- Double-click an item in either list to move it to the other list.
- Click the double-arrow buttons to move all items, regardless of your selection.

Note In a limited number of cases, the Custom Filter dialog box contains a single list. For example, the dialog boxes for the Event Type ID and Device columns contain single selectors. In these cases, make your selection using the check boxes next to the items; selecting a folder selects all items in the folder.

- **Filter on IPv6 Addresses**—For columns that contain addresses, use this option to toggle between listing IPv4 and IPv6 addresses and network/host objects in the available values column. You can filter on either IPv4 addresses or IPv6 addresses, but not both, in a single view.
- **Condition, Not**—Defines the condition applied to the selected items, typically "is in."

To create a negative condition, so that selected values define the events to not include in the events table, select the Not option.

Step 3 Click **OK**.

The view settings are updated to include the new filter, and the events table is updated to show only those events that satisfy all filters.

Filtering Based on a Specific Event's Values

You can base a new filter on information contained within an event, or a single cell within an event, by right-clicking and choosing a filter command. When you filter using these commands, a column filter is added to the view settings. You can do the following:

- To create a filter based on multiple values in the selected event, select **Create Filter from Event**, then select from the dialog box the values on which to filter. The dialog box lists only those columns that are displayed in the table; the current values are shown in parentheses. For an explanation of the columns, see Columns in Event Table , on page 2694.
- To filter on only the value in the cell on which you right-click, select **Filter This Value**.
- To filter to exclude the value in the cell on which you right-click, select **Filter Not this Value**. All events that do not contain the selected value in this column, including all empty cells, are shown in the table.
- To filter on the flow of the selected event, based on source, source service, destination, and destination service, select **Filter This Flow**.

Filtering on a Text String

Use the quick filter to search for text strings in events. As you type a search keyword, the events table automatically excludes non-matching events as you type. You can search on all columns (the default), or you can select a specific column in which to search.

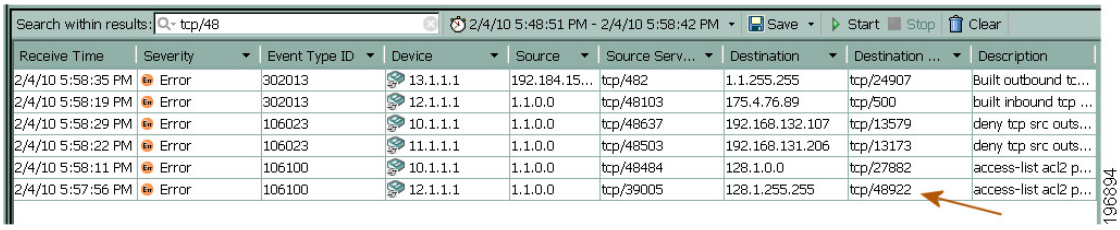
The following illustration shows the quick filter, which is on the right of the event table toolbar (see Event Table Toolbar , on page 2692).

To perform a search, simply type in the search string. To change how the string is evaluated, click the down arrow next to the Q (magnifying glass) in the left of the edit box. You can limit the search scope using these controls:

- Column name—Select a specific column to search only within that column. The list includes all columns currently displayed in the table. The default is to search all columns.
- Case sensitivity—Select **Case sensitive** or **Case insensitive** to control whether capitalization is considered when selecting matches. The default is case insensitive.
- Wild card usage—Select **Use Wild Cards** to have the following characters evaluated as wild cards:
  - * (asterisk)—matches 0 or more characters.
  - ? (question mark)—matches one character.
- Match method—Select one of the following to determine the location within a cell that the search string should reside:
  - Match from start—The string must be at the beginning of the cell.
  - Match exactly—The cell must contain all and only the search string.
  - Match anywhere—The string can appear anywhere within the cell.

To remove the search string, simply delete it from the quick filter edit box.

For example, if you want to find events that relate to ports that start with tcp/48, type **tcp/48** into the quick filter. In the following illustration, note that all but six events are filtered out of the table. In this example, the search string is found in the Source Service column for the first five events, but in the Destination Service column for the sixth event. If you know beforehand that you are interested in destination services only, you could select **Destination Service** from the quick filter drop-down list and the table would show the last event only.



Clearing Filters

When you apply filters to the event table, non-matching events are not displayed. You might find that you need to see the non-matching events. You can either open a different view that applies different (or no) filters, or you can clear filters from the current view.

When clearing filters, the filter definition is removed from the view settings, but the change is not permanent until you click **Save**. Thus, you can remove filters temporarily without redefining the view settings.

You can clear filters one at a time or clear all filters:

- To clear a single filter, so any of the following:
  - Select the filter in the View Settings pane and click **Delete**.
  - Select **(All)** from the drop-down list of a filtered column.
  - Right-click in the filtered column and select **Clear This Filter**.
- To clear all filters, right click in the events table and select **Clear all filters**.

Performing Operations on Specific Events

You can operate upon a single event in the event table in a variety of ways, which include the following:

- **Right-click**—Right-clicking a single event in the event table opens a context menu with commands that you can use on the event. For more information about what you can do from the right-click menu, see the following topics:
  - Event Context (Right-Click) Menu , on page 2727
  - Examining Details of a Single Event , on page 2730
  - Copying Event Records , on page 2730
  - Saving Views , on page 2719
  - Filtering Based on a Specific Event's Values , on page 2724

Note You can hover your mouse over a valid IPv4 address in Event Viewer to launch the IP Intelligence tool for that IP address. The IP Intelligence tool provides various pieces of information about an IPv4 address, such as the fully qualified domain name (FQDN), geographic location information, and WHOIS information. For more information on the IP Intelligence tool, see IP Intelligence, on page 2870.

- **Select an event**—When you click a single event in the event table it is highlighted and the Event Details pane displays details for that particular event. Hold the **Ctrl** key to select additional events, or hold the **Shift** key to select a range of events.
- **Double-click an event**—Double-clicking a single event in the event table opens the Event Details dialog box, which shows the event information in an easier-to-read format. From the Event Details dialog box, you can print the displayed details or copy some, or all, of the details to the clipboard for pasting into another program. You can use the Next and Previous buttons to scroll through the events listed in the event table. For information on the meaning of the attributes, see Columns in Event Table , on page 2694.

Alternatively, you can right-click on an event and select **Show All Details** to open the Event Details dialog box.

Event Context (Right-Click) Menu

When you right-click an event in the Event Table, a context menu appears that provides commands that you can use with the selected event. The specific list of available commands depends on the type of event and also the specific cell on which you right-click. The following table explains all of the available commands.

Note In addition to the right-click options listed below, you can also hover your mouse over a valid IPv4 address in Event Viewer to launch the IP Intelligence tool for that IP address. The IP Intelligence tool provides various pieces of information about an IPv4 address, such as the fully qualified domain name (FQDN), geographic location information, and WHOIS information. For more information on the IP Intelligence tool, see IP Intelligence, on page 2870.

Table 980: Event Context Menu

Command	Description
Clear This Filter	Removes the filter defined for this column. The command is available only if you right-click on a cell that is in a filtered column. The filter is removed from the view settings. You must save the view to make your change permanent.
Clear All Filters	Removes all filters from the view settings. This command is available only if there is at least one column filter. You must save the view to make your change permanent.
Filter This Value Filter Not This Value	Creates a column filter based on the value in the cell that you right click. You can create either a positive or negative filter based on the value. The view settings are updated with the new filter and replace any existing filter for this column. You must save the view to make your change permanent.
Create Filter from Event	Creates a set of column filters based on the values in the selected event. You are prompted to select the specific columns to include; the column on which you right-clicked is initially selected, but you can deselect it. The view settings are updated with the new filters and any existing column filters for the selected columns are replaced. You must save the view to make your changes permanent.
Custom Filter	Creates a custom column filter, as described in Creating Column-Based Filters , on page 2722. The view settings are updated with the new filter and any existing filters for the selected columns are replaced. You must save the view to make your changes permanent.

Command	Description
Filter This Flow	Creates a set of column-based filters that present the events related to a specific traffic flow. Filtered columns are source and source service and destination and destination service. The view settings are updated with the new filter and any existing filters for the selected columns are replaced. You must save the view to make your changes permanent.
Show IPLogs	Opens the IP log for an IPS Alert event using an external packet analyzer tool. You must have a packet analyzer installed and associated with *.pcap file extension.
Show All Details	Opens the Event Details dialog box for the event, which shows all event information in an easier-to-read format. You can also print the details or copy them to the clipboard. The details are the same as those shown in the Event Details pane below the event table.
Copy commands	You can use the following commands to copy event data to the clipboard. You can then paste the data into a spreadsheet or other program for your use. For more information, see Copying Event Records , on page 2730. • **Copy Cell**—Copies the contents of the cell you right-click to the clipboard. • **Copy Selected Events**—Copies the contents of all selected (high-lighted) events to the clipboard. • **Copy All Events**—Copies the contents of all listed events to the clipboard. This command is useful only if you have filtered the event table to a manageable number of events.
Save Selected Events as HTML Save All Events as HTML Save Selected Events as CSV Save All Events as CSV	Saves either all events listed in the event table, or all selected (high-lighted) events, to an HTML or comma-separate values (CSV) file on your workstation. You are prompted to select the folder and enter the file name for the export file. For more information, see Saving Events to a File , on page 2731.
Go To Policy	Finds the policy that generated this event in the device's policy configuration in Configuration Manager. This command is available only for events where a binoculars icon appears in the Event Name cell. For detailed information, see Looking Up a Security Manager Policy from Event Viewer , on page 2731.
Packet Capture	Opens the packet capture tool, where you can define criteria for capturing packets on the device.

Command	Description
Ping and TraceRoute	Opens the Ping, TraceRoute, and NS Lookup tool, where you can use these applications with the device from which the event was sent. For detailed information, see Analyzing Connectivity Issues Using the Ping, Trace Route, or NS Lookup Tools , on page 2862

Tune Signature	Opens the IPS Signature Quick Tune dialog box where you can enable or disable the signature associated with the selected event, and modify the Base Risk Rating of the signature that is assigned to the device or shared policy.
	
	To tune a signature you must create or open a ticket. For more information see Working with Activities/Tickets , on page 148.
	
	The Base Risk Rating value of the signature is calculated by multiplying the fidelity rating and the severity factor and dividing them by 100 (Fidelity Rating x Severity Factor /100). This value is read only; you cannot directly change it. To change the Base Risk Rating, you must alter the Severity and Fidelity values.
	
	• Severity: The severity level that the signature will report: High, Medium, Low, or Informational, where,
	  • High = 100
	  • Medium = 75
	  • Low = 50
	  • Informational = 25
	
	• Fidelity: The Fidelity Rating, or Signature Fidelity Rating (SFR), identifies the weight associated with how well this signature might perform in the absence of specific knowledge of the target. This rating can be any number from 0 to 100, with 100 indicating the most confidence in the signature.
	
	After you enable or disable the signature or modify the Base Risk Rating you must redeploy the configuration to the device, using Configuration Manager, for the change to take effect on the device. Note that such changes will affect only real time events and not the historical events. For information about deploying configuration, see Understanding Deployment , on page 381.

IPS Signature Quick Tune Dialog Box

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

Use the IPS Signature Quick Tune dialog box to enable or disable the signature associated with the selected event, and modify the Base Risk Rating of the signature that is assigned to the device or shared policy.

Navigation Path

In Event Viewer, right-click a row (an event) and click **Tune Signature**. For more information, see Event Context (Right-Click) Menu , on page 2727.

Examining Details of a Single Event

Each event contains a lot of specific information in many separate fields. Typically, you display a subset of these fields in the event table. When you want to see the complete details of an event, you can use either of the following:

- **Event Details pane**—Select the event and open the Event Details pane below the event table. You can open the pane by clicking anywhere in the "Event Details" title row, or you can select **View > Show Event Details** from the menu. The Event Details pane organizes the information in tabs. For more information about this pane, see Event Details Pane , on page 2703.
- **Event Details dialog box**—You can open this dialog box by double-clicking the event, or by right-clicking the event and selecting **Show All Details**. The information is presented as a flat list and shows the information that would be shown on the Details tab in the Event Details pane. For information on the meaning of the attributes, see Columns in Event Table , on page 2694.

The Event Details dialog box includes the following controls:

- Print button—Click this button to print the information. You are prompted to select a printer.
- Copy button—Click the down arrow on this button and select **All Rows** or **Selected Rows**. The information is copied to the clipboard, and you can paste it into another application. Note that the Selected Rows command works only if you select at least one row in the table.
- Next, Previous buttons—Click these buttons to scroll through the events currently displayed in the event table. Next moves up and Previous moves down in the table.

Copying Event Records

You can copy single events, multiple events, all events, or even the contents of a single cell to the clipboard. You can then paste the information into another application, such as a spreadsheet or an e-mail message.

You can do the following from the event table:

- **Copy selected events**—To copy one or more selected events, right-click in the event table and select **Copy Selected Events**. The event you right-click does not matter, the copied events are those that are selected (highlighted) in the table.

Click an event to select it. Hold **Ctrl** key to select additional events, or hold the **Shift** key to select a range of events.

- **Copy the contents of a single cell**—To copy the contents of a single cell in one event, right-click the cell and select **Copy Cell**. You cannot copy cell contents if there is more than one event selected in the table.
- **Copy all events**—To copy all the events shown in the event table, right-click anywhere in the table and select **Copy All Events**.

Saving Events to a File

Rather than copying events to the clipboard and pasting them into another application, you can directly save events to an HTML or comma-separated values (CSV) file. HTML files are useful for viewing information, whereas you can open a CSV file in a spreadsheet application for further analysis and report generation.

When saving event data, you are prompted to select a folder and enter a file name.

You can do the following from the event table:

- **Save selected events**—To save one or more selected events, right-click in the event table and select either **Save Selected Events as HTML** or **Save Selected Events as CSV**. The event you right-click does not matter, the saved events are those that are selected (highlighted) in the table.

Click an event to select it. Hold **Ctrl** key to select additional events, or hold the **Shift** key to select a range of events.

- **Save all events**—To save all the events shown in the event table, right-click anywhere in the table and select either **Save All Events as HTML** or **Save All Events as CSV**.

Looking Up a Security Manager Policy from Event Viewer

In Event Viewer, if an event was generated from an IPS signature policy, or from certain actions related to explicit access rules (such as denied access), you can quickly locate the related signature or access rule from the event itself.

The main reason you would want to perform policy lookup is to adjust a policy based on the events that it is generating. For example, an access rule might be dropping traffic that you actually want to allow. Because you are looking at the event, you know there is a policy that is causing the event, so with a few clicks, you can get from that event to the policy that you need to reconfigure.

You can look up policies from the following types of events:

- Firewall events—You can look up policies for the following syslog messages:
  - 106023—Denied IP packet.
  - 106100—Permit/Denied by ACL.
  - 302013—Built TCP (started a TCP session).
  - 302015—Built UDP (started a UDP session).
- IPS alert events—All IPS events that have valid signature and sub-signature identifiers.

Tips and Caveats

- You cannot look up firewall policies for events that contain IPv6 addresses. You can look up IPS policies for IPv6 addresses, however.
- When a policy that is based on IP address alone and not on a user name triggers an event, the device looks up the IP address in the Active Directory and if a user name is associated with that IP address, the user name is added to the syslog. Hence, even if a policy does not contain a user name, the resulting syslog might contain it. Policies cannot be created with a destination user and, as a result, this field will not be used during policy lookup.

- If an event is generated for a policy that is configured based on source/destination FQDN, the resulting syslog will not contain the FQDN because of a device defect. In such cases, policy lookup will not work.
- If an event is generated for a policy that is based on user groups, the syslog will contain the specific user name that triggered the event and not the user group. In such cases, policy lookup will not work.
- Hash codes are required for successful policy lookups from syslog 106023 and 106100 events. These hash codes are available only if you deployed the configuration using Security Manager. If policy lookup fails, try deploying the configuration (either to the device or to a file), then try the policy lookup again.
- If you had applied a filter to the device's policy table, and the rule or signature that generated an event is filtered from the current view, Security Manager cannot highlight it. Clear the filter and try again.
- If the event is caused by an implicit rule, such as the implicit **deny any** at the end of access rules, Security Manager cannot highlight the rule. It is considered good practice to create an explicit deny any rule at the end of access lists.
- The target policy is always found in Device view, even if the device uses a shared policy. Device view is opened if necessary to highlight the policy.
- For IPS signatures, you might not be able to edit the signature if it is a default signature.
- For access rules, the selected rule is the best match for the event. It is possible that more than one rule would generate the same event if you have overlapping or redundant rules. In these cases, editing the selected rule might not completely eliminate the event, because a subsequent rule might perform the same action. Use the access rules tools to analyze and combine overlapping rules.
- For access rules, multiple rules might permit a packet during session creation, but the first rule only is highlighted.
- If your organization is using ACS to control access, you must have View Device privileges to the device, and also View privileges to the firewall or IPS policy, to perform policy lookup. If you do not have all permissions, you will get an "Unable to Find Matching Rule" error if you try to look up a matching rule.

Step 1 Right-click the event in Event Viewer and select **Go To Policy**.

Tip You can identify whether you can look up policies from the event by looking at the Event Name cell in the table. If there is a binoculars icon before the event name, policy lookup is available. Also, if the Go To Policy command is greyed out, you cannot look up policies for that type of event.

Step 2 Security Manager finds the related access rule or IPS signature for the device and highlights it in the policy table. From here, you can edit the policy to view or change it; for detailed instructions, see Configuring Access Rules , on page 723 and Configuring Signatures , on page 1680.

Your changes do not take effect until you submit and deploy the updated configurations.

Looking Up Events for a Security Manager Policy

You can look up events in Event Viewer that relate to specific firewall access rules or IPS signatures. You can also look up events that relate to specific devices or site-to-site tunnels in Health and Performance Monitor.

When Event Viewer receives events, they are parsed, "sessionized," written to an event buffer, and then written to the database. Sessionizing takes two forms: with a session-oriented protocol, such as TCP, the session encompasses the initial handshake to the connection tear-down; with a sessionless protocol, such as UDP, the session start and end times are based more on first and last packets tracked within a restricted time period—packets that fall outside of the time period are considered parts of other sessions.

Because there is a difference between newly-received and fully processed data, you can look up either real-time or historical events:

- **Real-time**—Because sessionization takes time, keeping an event in cache for up to two minutes, you can use the real-time event query to view events right after parsing, providing access to the most current data received.
- **Historical**—Historical event reports help you identify trends over longer periods of time than is possible with real-time monitoring. For historical events, the Result Format is the All Matching Events option, and the Filter By Time value is set to the previous 10 minutes.

The following topics explain event lookup in more detail:

- Viewing Events for an Access Rule , on page 2733
- Viewing Events for an IPS Signature , on page 2734
- Viewing Events for HPM Devices and Site-to-Site VPNs , on page 2735

Viewing Events for an Access Rule

From the **Firewall > Access Rules** policy in Security Manager, you can select an access rule and view related event information in Event Viewer. You can view real-time or historical events matching the rule. You can view events for ASA (including ASA-SM) and FWSM devices.

Firewall access rules are presented in the form of an ordered list or table. When deployed, this policy becomes an access-control list (ACL), with each entry in the list known as an access-control entry (ACE). (For more detailed information, see Understanding Access Rules , on page 717.)

When deciding whether to forward or drop a packet, a device tests the packet against each access rule in the ordered listed. If you enable logging for an access rule, the results of the test are recording according to your per-rule log settings. Some devices, such as ASA, generate log entries for denied access even if you do not configure logging explicitly. For information on creating access rules, including logging options, see Configuring Access Rules , on page 723.

If logging is enabled for the rule (in the Advanced and Edit Options Dialog Boxes , on page 733), the device sends syslog messages to Event Viewer to record the logged events. This query includes the access-rule parameters, including available keyword information. Reported events do not include connection set-up and tear-down.

To view rule-related events, use the following right-click commands:

- **Show Events > Realtime**—To view real-time query results in Event Viewer for events matching this rule. You can change the query criteria in the Event Monitoring window at any time, applying new parameters to alter the real-time results.
- **Show Events > Historical**—To view historical query results in Event Viewer for events matching this rule. You can change the query criteria in the Event Monitoring window at any time, applying new parameters to alter the historical results.

Security Manager provides the following information to Event Viewer as criteria for access-rule event queries:

- Device details—General information about the device, such as host name, domain name, management IP address, and display name.
- Source addresses—Source addresses of hosts and the network/host objects expanded to display the networks or collections of IP addresses.
- Destination addresses—Destination addresses of hosts and the network/host objects expanded to display the networks or collections of IP addresses.
- Service—Protocol and port information.
- Event Type—"Built/teardown/permitted IP connection" for permit rules and "Deny packet due to security policy" for deny rules.

Notes:

- You can query on only one access rule at a time.
- When NAT or PAT is configured on a security device, the source and destination addresses are mapped to pre-translation and post-translation addresses, respectively, and the translated addresses are used when Security Manager sends a query to Event Viewer. For inbound access rules, the destination address is considered the pre-translation address, and for outbound access rules, the source address is considered the post-translation address.
- Filtering with multiple services (like UDP, TCP, and ICMP) might not give accurate results. To work around this problem, you can remove some of the filters after Event Viewer is launched.
- Filtering based on ICMP sub types is not supported. For example, if an ACE has 'ICMP Echo' in service, the filter is applied only for the protocol (ICMP), but not for type column (Echo) in Event Viewer.
- Service ports with 'eq', 'neq', 'gt', and 'lt' are not supported in cross launch to Event Viewer.

- Viewing Events for HPM Devices and Site-to-Site VPNs , on page 2735

Viewing Events for an IPS Signature

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

When an IPS device detects and reports a network intrusion by comparing incoming traffic to a configured signature, a syslog message is generated on the device. If the device is monitored by Security Manager, an incident is generated in Event Viewer after the log associated with the signature is obtained from the device.

Looking up the events associated with a specific signature lets you quickly identify attacks and tune your device configuration to minimize or prevent intrusions.

To view reported network intrusion events in Event Viewer, you can select one or more entries in the Signatures policy for a device in Security Manager and navigate to the Event Viewer to view real-time and historical events.

Related Topics

- Looking Up Events for a Security Manager Policy , on page 2732
- Viewing Events for an Access Rule , on page 2733
- Viewing Events for HPM Devices and Site-to-Site VPNs , on page 2735

Step 1 (Device view) With an IPS device selected, select **IPS > Signatures > Signatures** to display the Signatures Page , on page 1680.

Step 2 Right-click the desired entry in the signatures table, or select multiple entries before right-clicking one of them, and choose one of the following commands from the **Show Events** menu:

- **Realtime**—To view real-time query results in Event Viewer for events matching this signature. Use this option to view raw events as they stream to Event Viewer.

You can change the query criteria in the Event Monitoring window at any time, applying new parameters to alter the real-time results.

- **Historical**—To view historical query results in Event Viewer for events matching this signature.

You can change the query criteria in the Event Monitoring window at any time, applying new parameters to alter the results.

Tips:

- If a signature is disabled, you are warned and asked if you want to proceed to event lookup.
- Events of type Packet Data and Context Data are not displayed in the query results because these events are not triggered by signature rules.

Viewing Events for HPM Devices and Site-to-Site VPNs

From Health and Performance Monitor, you can quickly access events for a monitored device or for site-to-site VPNs that have had a tunnel up/down event.

To view events for a monitored device, select a device from the All Devices, Firewall Devices, IPS Devices, Priority Devices, or custom device-related view, and with the Summary tab selected in the device details area, click the **View Events** button. Event Viewer opens and the Event Monitoring window lists events filtered by the selected device and the time period specified by the slider bar.

To view related events for a site-to-site VPN that has had a tunnel up/down event, do one of the following:

- From the Site-to-Site Tunnels view, click on the Down notification hyperlink in the Status column.
- From the Alerts view, click on the hyperlink in the Description column for tunnel up/down alerts.

Event Viewer will show IPSec VPN Events for the device within a time range depending on the polling interval for that device. If it is a priority device, the time range will be 5 minutes before until 5 minutes after the first up/down notification was received. For non-priority devices, the time range will be +/- 10 minutes instead of 5 minutes.

Examples of Event Analysis

There are many different techniques you can use to analyze and respond to events generated by your network devices. The examples in this section can help you understand some of the things you can do with the Security Manager Event Viewer.

This section contains the following topics:

- Help Desk: User Access To a Server Is Blocked By the Firewall , on page 2736
- Monitoring and Mitigating Botnet Activity , on page 2738
- Removing False Positive IPS Events from the Event Table , on page 2744

Help Desk: User Access To a Server Is Blocked By the Firewall

In this example, the help desk gets a call from a user who cannot access a server.

There are many reasons that a user might not be able to access a server, such as:

- Problems at the server's end of the network, including server down, no network connection, or the server's firewall is actively preventing access by policy.
- Problems in the network cloud between the user and the server, such as routing problems.
- Problems in the user's network, which could include workstation problems, physical problems with a network connection (for example, broken wires), problems with the switch port or wireless access point, DNS lookup failures, and so forth.

The Security Manager Event Viewer cannot identify or resolve these problems. However, it can identify whether a firewall that you control is blocking access to the server. This can help you either to rule out the firewall as being the source of the problem, or if it is blocking access, to fix the problem or to inform the user that the server is blocked by policy.

This procedure assumes that you have first determined that access to the server is not being denied by policy and that the firewall should allow access to the server.

Step 1 Ask the user for the IP address of the workstation and server.

Step 2 Open Event Viewer, for example, by selecting **Launch > Event Viewer** in Configuration Manager.

Step 3 Double-click the **Firewall Traffic Events** view to open it. Optionally, you can use the **All Device Events** view if you also want to see if there are any IPS events related to the workstation.

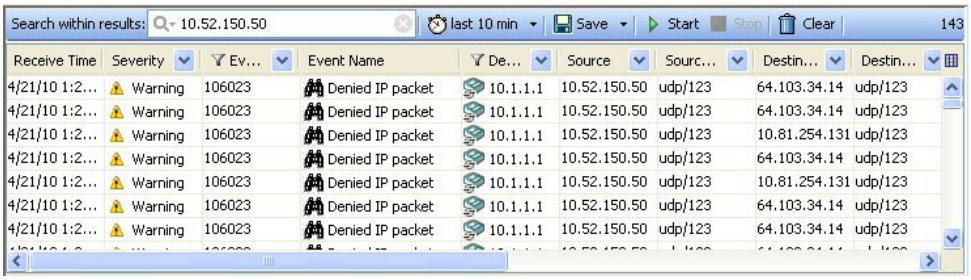
Tip You can also select the **Firewall Denied Events** view to see just denial events. However, you might want to see other events related to the user's workstation.

Step 4 Ask the user to retry the server access.

Step 5 Click the **Start** button, or select **View > Start**, to refresh the event table with the latest events.

Step 6 Type the user's IP address into the **Search within Results** box. The list of events is filtered as you type, and presents events in which the search string appears in any column. In the following illustration, the event list shows all events in the past 10 minutes for the IP address 10.52.150.50.

Figure 62: Restricting the Events List to One IP Address



Tip You can also select the IP address from the Source column's drop-down list, and the server's IP address from the Destination column's drop-down list (or the reverse), to show only events with both the source and destination that interests you. Use the column filters if the search string does not sufficiently reduce the event list for easy analysis.

Step 7 Look for an event that indicates that traffic from the user's workstation to the server, or from the server to the workstation, was denied. Syslog **106xxx** messages indicate denial actions.

Select the event in the table and open the Event Details pane at the bottom of the window. The tabs in this pane show the complete message information and include plain-language explanations and recommended actions.

Step 8 If the event is message **106023** or **106100**, you can quickly locate the access rule that is denying the connection and fix it. You can identify whether you can look up policies from the event by looking at the Event Name cell in the table. If there is a binoculars icon before the event name, policy lookup is available. Also, if the Go To Policy command is greyed out, you cannot look up policies for that type of event.

Tip If the traffic is denied because of the implicit **deny any** rule at the end of the access list, the Go To Policy command cannot take you to the rule. For tips about rule lookup, see Looking Up a Security Manager Policy from Event Viewer , on page 2731.

a) Right-click the event and select **Go To Policy**. You are taken to Device view with the rule selected. You are notified if a matching rule cannot be found.

b) Modify the rule so that it allows the desired access. This might be as simple as deleting the rule, or you might have to add a new rule that specifically allows traffic to or from the destination server (place the permit rule above the deny rule). Your organization's security policy determines the allowable changes. For more information about configuring the access rules policy, see Configuring Access Rules , on page 723.

c) Submit and deploy the updated configuration to the device. For more information on the deployment process, see Deploying Configurations in Non-Workflow Mode , on page 408 or Deploying Configurations in Workflow Mode , on page 414.

Wait for deployment to complete successfully.

Step 9 Ask the user to try to access the server again. If access is again denied, click **Start** in Event Viewer to refresh the events list and find the latest denial event.

Tip There might be more than one access rule that can deny communications with the server. The access rule policy is processed in order, top to bottom, so deleting a rule that prevents access can result in a rule that previously was not being hit suddenly becoming active. If you have a very long access rule policy, you could have several rules that you will have to remove one after the other. Alternatively, you could use the Rule Combiner tool to consolidate and simplify your access rules policy; for more information, see Combining Rules , on page 620.

Step 10 Continue to resolve access denial events until the firewall is no longer blocking access.

Tip You can also use the Packet Tracer tool to simulate traffic going through the ASA device from the workstation to the server. In Device view, right-click the device that is denying access and select **Packet Tracer**. For more information, see Analyzing an ASA or PIX Configuration Using Packet Tracer , on page 2859.

After resolving all events, if the user still cannot reach the server, you know that the firewall is no longer one of the network elements that is blocking access. Consider other intervening network devices; perhaps a router includes an access rule that blocks the traffic.

Monitoring and Mitigating Botnet Activity

After you configure Botnet Traffic Filtering as described in Understanding Botnet Traffic Filtering , on page 907, you want to monitor it and resolve any problems identified in your network. You can use Security Manager and ASDM to monitor Botnet activity, and mitigate identified problems, as explained in the following sections:

Understanding the Syslog Messages That Indicate Actionable Events

Botnet Traffic Filter events use syslog message numbers 338xxx. However, some messages are informational and require no action on your part.

When viewing syslogs for botnet events, you should be most concerned with the following message numbers. For information on dealing with messages that indicate block listed or allowed traffic, see Mitigating Botnet Traffic , on page 2742. For detailed descriptions of syslog messages, see the Syslog Message document for your ASA software version at http://www.cisco.com/en/US/products/ps6120/products_system_message_guides_list.html .

- **338001 to 338004**—Indicate block listed traffic that the ASA is logging, but the ASA is not stopping the traffic. These messages require immediate attention if you want to stop botnet activity that is in progress.

- **338005 to 338008**—Indicate block listed traffic that the ASA is logging and dropping. This indicates that the traffic was covered by a drop rule. Thus, your network is being protected, although you still need to disinfect the victim computer.
- **338201, 338202**—Indicate greylisted traffic that the ASA is logging but not dropping. These messages can indicate an active botnet connection that needs to be handled immediately.
- **338203, 338204**—Indicate greylisted traffic that the ASA is logging and dropping. Your network is protected from this traffic. However, if the greylisted site is legitimate, the fact that the traffic is being dropped might be a problem that requires immediate attention. You can add the greylisted address to the allowed list if you determine it is legitimate and redeploy the configuration, as described in Adding Entries to the Static Database , on page 911.
- **338305 to 338307, 338310**—The ASA could not download the dynamic filter database. Ensure that you configured DNS lookup on the device, and that there is a routable network path to the Cisco Intelligence Security Operations Center. You might need to contact Cisco Technical Support.
- **338309**—The Botnet Traffic Filter license is not current, and you cannot download the dynamic database. Purchase and install the appropriate license. The Botnet Traffic Filter license is time-based, so you might have had a valid license that expired.

Monitoring Botnet Using the Security Manager Event Viewer

You can use the Event Viewer application to blmonitor syslog events generated by an ASA device. The Event Viewer has a predefined view that shows just botnet events.

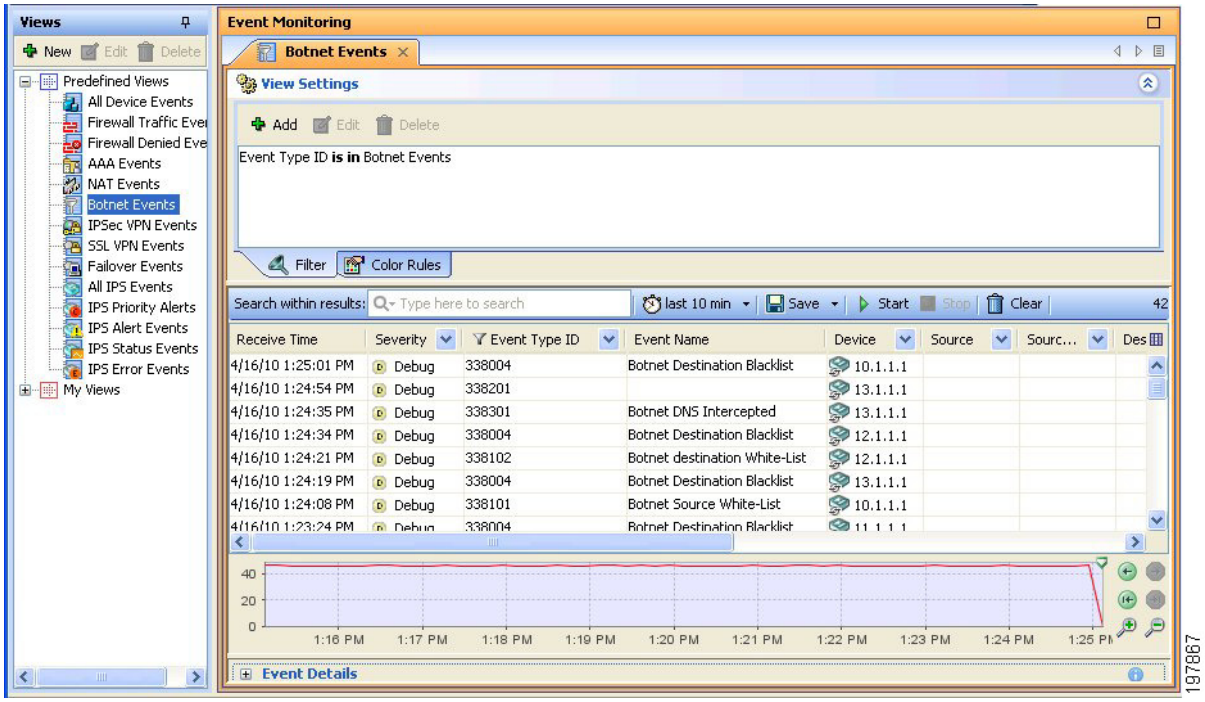
Botnet messages are in the informational to debug severity levels and are numbered 338xxx.

Tip This procedure assumes the Event Manager service is enabled. If it is not, enable it using the **Tools > Security Manager Administration > Event Management** page.

Step 1 Open Event Viewer, for example, by selecting **Launch > Event Viewer** in Configuration Manager.

Step 2 Double-click **Botnet Events** from the list of predefined views in the left pane. You must double-click to activate the view and load it into the right pane. To verify the view has been opened, ensure that the tab name for the view in the right pane says “Botnet Events.” The following illustration shows an example of the botnet events view.

Figure 63: Botnet Events View in the Security Manager Event Viewer

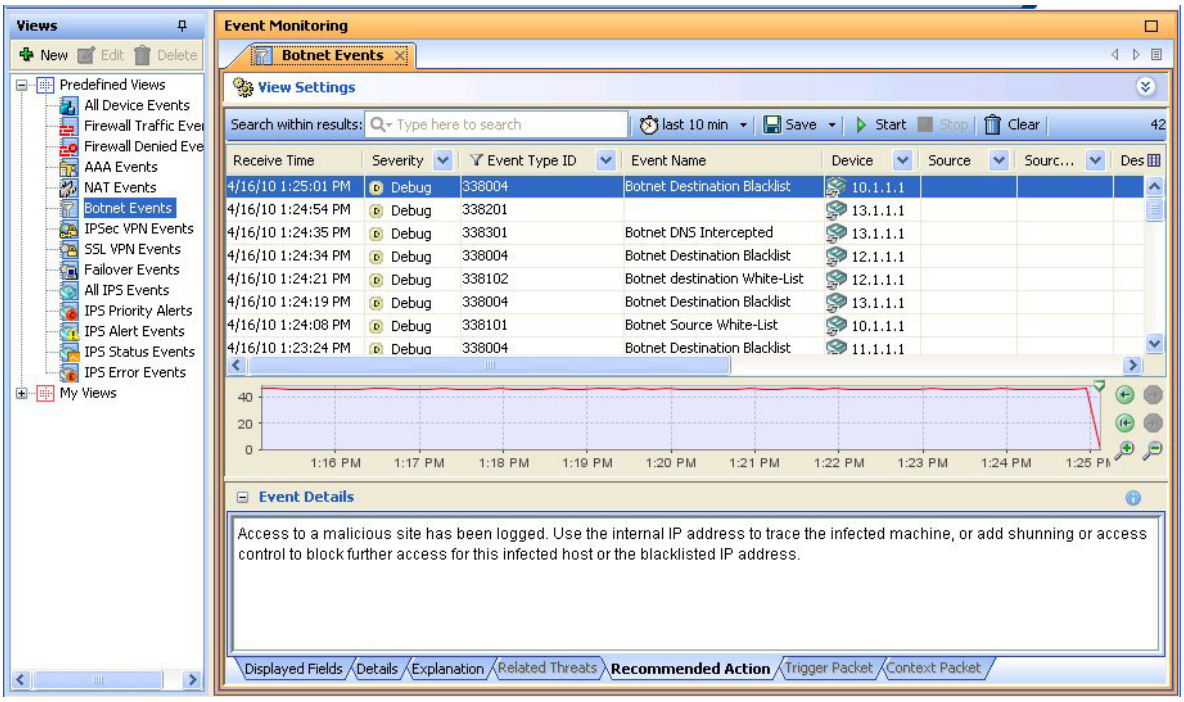


Step 3 To see the details of a specific event, select it in the table. You can then do the following:

- Double-click the event to see the tabular information presented in a more readable format.
- Open the **Event Details** section at the bottom of the window. The details pane shows information about the event organized on tabs. The Explanation and Recommended Action tabs include plain-language information about the event and what you might want to do about it.

The following illustration shows the Event Details pane for the Botnet Destination Blocklist message 338004. In this example, the recommended action is shown. The explanation for this message is "This syslog message is generated when traffic to an IP address in the block list in the dynamic filter database appears." For information on dealing with this type of event, see Mitigating Botnet Traffic , on page 2742.

Figure 64: Botnet Event Details for Message 338004, Botnet Destination Blocklist



Step 4 To narrow the list of events to those generated by a single ASA, click the drop-down arrow in the Device column and select the desired device from the list. If you want to narrow the list to multiple ASAs, select Custom from the drop-down list and select the desired devices in the dialog box that appears.

You can also narrow the list using filters for any of the other columns. Filtering works the same way for all columns: either select the desired value from the drop-down list, or select Custom to create a more complex column filter.

Monitoring Botnet Using the Security Manager Report Manager

You can use the Report Manager application to generate reports on botnet activity. There are predefined reports that show the top infected hosts, the top malware ports, and the top malware sites. For a description of these reports, see Understanding Firewall Summary Botnet Reports , on page 2762.

Tip This procedure assumes the Event Manager service is enabled. If it is not, enable it using the **Tools > Security Manager Administration > Event Management** page.

Step 1 Open Report Manager, for example, by selecting **Launch > Report Manager** in Configuration Manager.

Step 2 Open the desired report from the **System > FW > Summary Botnet** folder. You can open the report by double-clicking it or by right-clicking and selecting **Open Report**.

Step 3 (Optional) Customize the report to select the desired time range and devices to include in the report. For more information, see Editing Report Settings , on page 2769.

If you want to save your custom settings to generate the report again in the future, click **Save As** to create a custom report. For more information, see Creating Custom Reports , on page 2769.

Step 4 Click **Generate Report** to retrieve the collected information and display the graphs and tabular data. For more information, see Opening and Generating Reports , on page 2767.

If you want to generate the report on a regular basis, you can configure a schedule as described in Configuring Report Schedules , on page 2781.

Monitoring Botnet Activity Using the Adaptive Security Device Manager (ASDM)

The Adaptive Security Device Manager (ASDM) includes botnet reporting features. A read-only version of ASDM is installed with the Security Manager client as a device manager, and you can start ASDM from within Security Manager.

Tip You can also install the full ASDM application separately. However, any configuration changes that you perform in ASDM are considered out-of-band changes by Security Manager and are overwritten the next time you deploy configurations from Security Manager. If you ever find a need to make configuration changes using ASDM, be sure to rediscover policies on the device in Security Manager so that Security Manager's view of the configuration is up-to-date.

Step 1 In Device view in Configuration Manager, select the ASA device.

Step 2 Select **Launch > Device Manager** to open an ASDM connection to the ASA. You are warned that you cannot make configuration changes. Click **Yes** to continue.

Step 3 In ASDM, view Botnet Traffic Filter monitoring information in the following areas:

- **Home > Firewall Dashboard** includes a Botnet Traffic Filter summary.
- **Monitoring > Botnet Traffic Filter > Reports** includes charts on the top botnet sites, ports, and infected hosts.
- **Monitoring > Logging > Log Buffer** shows historical syslog messages.
- **Monitoring > Logging > Real-Time Log Viewer** shows syslog messages as they are generated.

Tip You can also search the dynamic database on the **Configure > Botnet Traffic Filter > Botnet Database** page. This page also allows you to manually start a database download or to purge the dynamic database. These actions do not change the device's configuration and do not require policy rediscovery in Security Manager.

Mitigating Botnet Traffic

Botnet traffic mitigation is a two step process:

1. Stop traffic from your network to the botnet control site.
2. Disinfect the victim computers.

The following procedure explains the process in more detail.

Step 1 You see syslog events that indicate that packets are traveling to or from an objectionable address, typically message numbers 338001-338008 or 338201-3382004. For detailed information about these messages, see Understanding the Syslog Messages That Indicate Actionable Events , on page 2738.

Tip Messages 338201-3382004 are for greylisted traffic. You might want to first determine if the greylisted traffic is truly objectionable before stopping the traffic.

Step 2 Stop the botnet traffic:

- Messages 338005-338008 and 338203-338204 indicate that the ASA is already dropping the traffic for you. Traffic classification drop rules cover the addresses that are part of block list or grey list. See Enabling Traffic Classification and Actions for the Botnet Traffic Filter , on page 913.
- Messages 338001-338004 and 338201-338202 indicate that the ASA is logging the event but not dropping the traffic. The first order of business is to stop this traffic.

You have these options for stopping the botnet traffic if the ASA is not already dropping it because of a drop rule:

- (Preferred method.) Configure a drop rule for the botnet site and redeploy the configuration. See Enabling Traffic Classification and Actions for the Botnet Traffic Filter , on page 913.
- (Second best method.) Log into the ASA using an SSH client, enter privileged EXEC mode, and use the **shun** command to prevent traffic to or from the botnet site. You can also issue this command through ASDM in a CLI window, but you cannot do it from Security Manager. The shun command does not create a permanent rule blocking traffic.

For example, if the botnet site is 10.1.14.14, and the internal infected computer is 10.100.10.10, issue the following commands. The first command blocks all incoming traffic from the botnet command center, the second blocks traffic from the infected computer just to the botnet site.

shun 10.1.14.14

shun 10.100.10.10 10.1.14.14

- (Not recommended.) Although the shun command is preferred, you can also create a permanent rule in the interface's access control list (ACL) that denies traffic to or from the botnet site. With the device selected in Security Manager, select **Firewall > Access Rule**, and create two rules: one that denies the botnet site as the source address, with any destination address; one that denies any source address with the botnet site as the destination address. For service, select IP so that all traffic is blocked. You must deploy the configuration for the rule to take effect.

Creating an access rule is not the preferred method because it creates a permanent rule, whereas botnet sites are transient. Using the Botnet Traffic Filter to dynamically block botnet traffic is a better fit for this type of network attack compared to traditional access rules.

Step 3 Shut down network access for the infected computer. For example, find the switch port to which the computer is attached, and shut down the port using the switch's CLI. There might also be wireless access for the computer, so completely shutting down network access might not be a simple task.

Step 4 Inform the owner of the victim computer that it is infected and dispatch IT personnel to disinfect the computer. Tools and techniques for disinfecting a computer are outside the scope of this document.

Removing False Positive IPS Events from the Event Table

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

An IPS appliance or service module (IPS device) triggers an alarm when a given packet or sequence of packets matches the characteristics of known attack profiles defined in the IPS signatures. False positives (benign triggers) occur when the IPS reports certain benign activity as malicious. Because each event requires human intervention to diagnose, spending your time analyzing false-positive events can significantly drain resources.

Due to the nature of the IPS signatures that are used to detect malicious activity, it is almost impossible to completely eliminate false positives without severely degrading the effectiveness of the IPS or severely disrupting the computing infrastructure of an organization (such as hosts and networks). Customized tuning when an IPS is deployed minimizes false positives. Periodic re-tuning is required when the computing environment changes (for example, when new systems and applications are deployed). IPS devices provide a flexible tuning capability that can minimize false positives during steady-state operations.

An example of a false-positive is a network management station that periodically builds a network discovery map by running ping sweeps. A ping sweep triggers the ICMP Network Sweep with Echo signature (signature ID 2100). Thus, ICMP Network Sweep with Echo events that have the IP address of the network management station as the source address are actually expected and desired events.

You have the following options to remove false-positive IPS events from the event table in Event Viewer:

- **Filter out events from known “clean” sources.**

By filtering out the events, you do not stop their generation, but you also do not see them in the table. Because they are still available (you can remove the filter), you can see the events if some particular network behavior requires that you examine activity from the excluded host.

There are two main drawbacks to using this technique:

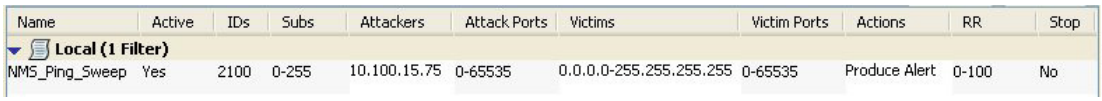
- The events are still generated, adding events to the event store.
- The filter excludes all events from a host. You cannot create a complex filter that excludes a host/signature ID pair.

The procedure below shows how to filter out events from sources that you identify as clean.

- **Create event action filter rules to stop the generation of the false-positive events.**

Event action filter rules are the easiest way to stop generating events, and are thus preferable to editing signatures or creating custom signatures, which is a more difficult task. If you exclude a host in an event action filter rule, the IPS device does not generate alarms or log records when the host triggers the event.

Because you can target specific signatures, rather than making a blanket-exclusion of all events from a host, you can eliminate only those events that you are certain are benign. For example, the following event filter rule removes the Produce Alert action from the ICMP Network Sweep with Echo (2100) signature for the network management station 10.100.15.75. The network management host is identified as the attacker address; the action specified in an event filter rule is actually the action that is removed from the event. Note that if you create an event action override rule to add other alert-producing actions to ICMP Network Sweep with Echo events, you must also remove the override action in this rule.



For more information about configuring event action filter rules, see Event Action Filters Page , on page 1717.

The following procedure shows how to use filtering in Event Viewer to remove false positives from the events list. It uses network/host policy objects to accomplish the filtering.

Tip By creating source or destination address filters using network/host objects, you can update the filters simply by changing the contents of the object. You do not need to add or remove filters from your views. Another advantage is that you can proactively create filters for addresses that do not currently appear in the events table; the source/destination column filter controls in Event Viewer list only those addresses that currently appear in listed events.

Step 1 Create a network/host policy object that includes the IP address of the clean hosts or networks.

a) Select **Manage > Policy Objects** to open the Policy Object Manager window (see Policy Object Manager , on page 232).
b) Select **Networks/Hosts** from the table of contents.
c) Click the **Add Row (+)** button beneath the table of network/host policy objects, and select **Group** as the object type.
d) In the Add Network/Host Group dialog box, enter a name for the object, for example, IPS_Safe_Hosts.
e) Select **Enter IPv4 Address Information** and enter the IP address, for example, 10.100.15.75.
f) Click **Add >>** to add the IP address to the Members in Group list.
g) Click **OK** to create the object.
h) Click **Close** to close the Policy Object Manager window.

Step 2 Select **File > Submit** to submit your changes to the database (non-Workflow mode). Keep in mind that all of your configuration changes are submitted, not just the new policy object.

If you are using Workflow mode, you must submit your activity and have it approved, if necessary.

Tip Event Viewer can see only those policy objects that have been submitted to the database, so you must submit your changes before you can create a filter using the object. If you later change the object, you must also submit your changes for the filter to use the new definition of the policy object.

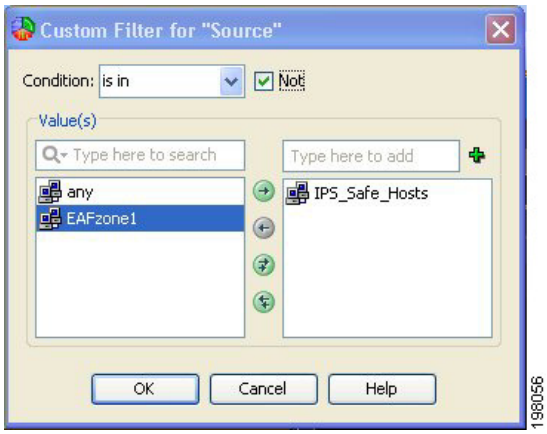
Step 3 Select **Launch > Event Viewer** to open the Event Viewer application.

Step 4 Create a custom view that filters out the network management station:

a) Double-click the predefined view that you want to use as the basis of your custom view, for example, **All IPS Events**. Double-clicking the view in the Views list opens the view. If you already have a custom view that you want to update, open it.
b) Click the down arrow button in the title of the Source column in the events table and select **Custom** to open the Custom Filter for Source dialog box.

Tip: You can also get to this dialog box through the View Settings pane by clicking the **Add** button, then selecting Source in the Add Custom Filter to a Column dialog box and clicking **OK**.

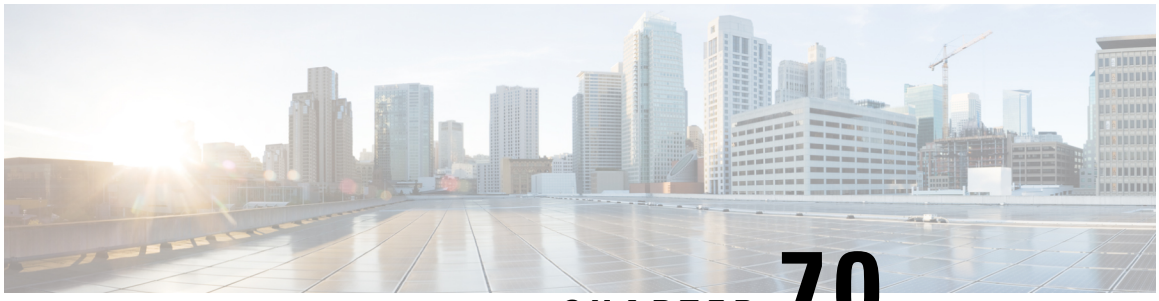
c) In the Custom Filter for Source dialog box, select the policy object you created and click the right-arrow button to move it to the selected list. Also, select the **Not** option next to the Condition option. The following illustration shows how the dialog box should look.



d) Click **OK**. The filter is added to the view settings and is used to remove events from the table.

e) Select **File > Save As** to save the changes as a new custom view. You are prompted for a view name and description; enter the information and click **OK**.

The following illustration shows what the view settings would look like if you started with the All IPS Events predefined view and named your new view Filtered IPS Events.



CHAPTER 70

Managing Reports

Use the Re

Use the Report Manager application to view security and usage reports for devices and remote access IPsec and SSL VPNs.

This chapter contains the following topics:

port Manager application to view security and usage reports for devices and remote access IPsec and SSL VPNs.

This chapter contains the following topics:

Understanding Report Management

Use the Report Manager application to view security and usage reports for devices and remote access IPsec and SSL VPNs. These reports can provide useful information about your network.

The Report Manager aggregates information that is collected from monitored devices by the Event Manager service. Thus, to view reports about a device, you must also be monitoring the device in Event Viewer. Some statistics, such as VPN statistics, are obtained directly from the device through regular polling at five minute intervals. Aggregated data is kept for 90 days with data aggregated at 15-minute, hourly, daily, and monthly intervals; 15-minute aggregated data is kept for up to three days, hourly data up to one week. For more information about data aggregation, see Understanding Report Manager Data Aggregation , on page 2750.

You can use Report Manager to develop reports on the following:

- Adaptive Security Appliances (ASA) running ASA Software releases 8.0 and later. ASA Software 7.x releases are also supported for VPN reports.

Note VPN reports are not available for Cisco Catalyst 6500 Series ASA Services Modules (ASA-SM), which do not support any VPN configuration. Other types of reports are available for the ASA-SM.

- IPS devices running IPS software release 6.1 and later (but not IOS IPS devices). This includes dedicated IPS modules installed in ASAs, routers, and switches.
- Remote access IPsec and SSL VPNs hosted on a supported ASA device.

Note Report Manager does not report on FWSM events even though Event Viewer works with FWSM.

The following topics explain Report Manager and its available reports in more detail, and also describe the other types of reports available in Security Manager:

Understanding the Types of Reports Available in Security Manager

Security Manager provides a variety of reporting capabilities. The following are the types of reports available:

- **Security and Usage Reports (Report Manager application)**—You can use the Report Manager application to view aggregated information collected by the Event Manager service from monitored devices. Some information is also obtained directly from the devices. These reports can provide information on network security and remote access IPsec and SSL VPN usage.
- **Activity (Configuration Session) Change Reports**—These reports provide detailed information about the policies changed within a specific activity (in Workflow mode) or configuration session (in non-Workflow mode). For more information, see Viewing Change Reports , on page 158.
- **Out of Band Change Report**—These reports identify inconsistencies between the configuration that exists on a device and the configuration for the device maintained in Security Manager. You can use this information to proactively address these inconsistencies before deploying configurations, where the change will either be overwritten or the deployment will fail, depending on the behavior you select in the deployment job. For more information, see Detecting and Analyzing Out of Band Changes , on page 426.
- **Audit Report**—This report provides information about changes to Security Manager and the objects contained in the database. The report includes information about the runtime environment, such as logins and authentication failures, changes to objects, such as activity changes and deployments, and changes

to managed devices, such as inventory additions and deletions. For more information, see Generating the Audit Report, on page 498.

- **Inventory Status**—This report provides information on policy deployment status. For more information, see Viewing Inventory Status , on page 2847.
- **Policy Discovery Status reports**—When you discover policies from a device, either while adding it to the inventory or when rediscovering policies on a managed device, the information about the policy discovery is maintained so that you can view it at a later time. For more information, see Viewing Policy Discovery Task Status , on page 188.
- **Deployment Status reports**—When you deploy configurations to managed devices, information about the deployment is maintained so that you can view it at a later time. For more information, see Viewing Deployment Status and History for Jobs and Schedules , on page 405.
- **Deployment and Discovery Status reports for troubleshooting**—You can export deployment and policy discovery status reports in a form suitable for sending to Cisco Technical Support (TAC) to help troubleshoot problems. You might also find these reports useful for your own purposes. For more information, see Generating Deployment or Discovery Status Reports, on page 508.
- **Extranet VPN Configuration Summaries**—You can print, or generate a PDF file of, a summary of the configuration of an Extranet VPN. This summary can include the preshared key used for the connection. You can use this information to maintain a current record of connections between your network and the networks of partners or service providers. For more information, see Viewing a Summary of a VPN Topology's Configuration , on page 1140.
- **Policy Object Usage report**—This report shows you where a policy object is used, including instances where it is referred to by a policy or another policy object. You can use this information to help determine whether a proposed change to the object will provide the desired effect in all cases where it is used. The information is also helpful if you want to delete an object, because you cannot delete an object that is actively being used by a policy or another policy object. For more information, see Generating Object Usage Reports , on page 243.
- **Policy Object Override report**—This report shows you all of the device-level overrides currently defined for a policy object, if the object is defined so that overrides are allowed. You can also create and delete overrides from this report. For more information, see Creating or Editing Object Overrides for a Single Device , on page 248 and Policy Object Overrides Window , on page 249.
- **Device Manager reports**—Security Manager includes read-only versions of individual device managers, such as the Adaptive Security Device Manager (ASDM), for most supported devices. You can start these device managers directly from Security Manager's Configuration Manager application and use any type of report available in those device managers. These reports are for a single device, and can augment the reports available through Report Manager. They can also provide status information for devices that are not directly supported by Event Viewer or Report Manager. For more information, see Starting Device Managers , on page 2849.

Preparing Devices for Report Manager Reporting

Before you can view reports about a device in Report Manager, you must configure the device to send events to Security Manager and configure Security Manager to monitor the device. Report Manager can provide reports only for devices you are monitoring in Event Viewer, so the device configuration for reporting is identical to the configuration for event monitoring.

Step 1 Configure the devices to send events to Security Manager. You can use Report Manager with the following types of devices:

- ASA 8.0 and later—For the detailed configuration steps, see Configuring ASA and FWSM Devices for Event Management , on page 2704.
- IPS 6.1 and later—For the detailed configuration steps, see Configuring IPS Devices for Event Management , on page 2706.

Step 2 Ensure that the devices are selected for event management as described in Selecting Devices to Monitor , on page 2711.

Step 3 Ensure that the Event Manager service is enabled as described in Starting, Stopping, and Configuring the Event Manager Service , on page 2707.

Understanding Report Manager Data Aggregation

Report Manager aggregates information that is collected from monitored devices by the Event Manager service. Thus, to view reports about a device, you must also be monitoring the device in Event Viewer.

Report Manager collects data using two techniques. First, the Event Manager service provides relevant events to Report Manager and then Report Manager decides if it should store those events based on the predefined reports and custom reports that are currently configured. Second, some statistics, such as VPN statistics, are obtained directly from the device through regular polling at five minute intervals.

Table 981: Report Manager Data Sources

Reports	Data Sources
FW Reports	
Top Sources Top Destinations Top Services	Built Syslogs: 302013,302015,302017,302020 Deny syslogs: 106001,106006,106007,106010,106011,106014,106015,106016,106017
Top Malware Sites Top Malware Ports Top Infected Hosts	BOTNET Syslogs: 338001,338002,338003,338004,338005,338006,338007,338008,338201,338202,338
IPS Reports	
All IPS Reports	All IPS Alerts
VPN Reports	

Reports	Data Sources

Top Bandwidth Users (Full-Client)
Top Duration Users (Full-Client)
Top Throughput Users (Full-Client)
	For ASA version 8.3 and earlier:
	`show vpn-sessiondb full svc`
	For ASA version 8.4.1 and later:
	`show vpn-sessiondb full anyconnect`

Top Bandwidth Users (IPSec-RA)
Top Duration Users (IPSec-RA)
Top Throughput Users (IPSec-RA)
	For ASA version 8.3 and earlier:
	`show vpn-sessiondb full remote`
	For ASA version 8.4.1 and later:
	`show vpn-sessiondb full ra-ikev1-ipsec`

Top Bandwidth Users (Clientless) Top Duration Users (Clientless) Top Throughput Users (Clientless)	For all ASA versions: `show vpn-sessiondb full webvpn`
User Report	All above show commands.
VPN Device Usage Report	All above show commands.

Report Manager aggregates this collected information at 15-minute, hourly, daily, and monthly intervals. Fifteen-minute aggregated data is kept a day, hourly data up to five days, and the other data for 90 days.

The aggregation schedule occurs at fixed times: 15-minute aggregation occurs at 00, 15, 30, and 45 minutes past the hour; hourly aggregation occurs on the hour (00 minutes); daily aggregation occurs at the change of day (when midnight is reached, the day is aggregated); monthly aggregation occurs at the change of the month.

The aggregation cycle has implications in what you will see in reports:

- Report data does not cover the immediate past. Instead, it covers the most recently completed whole time period of the selected duration. For example, a one-day report covers yesterday, it does not include data for today. In other words, a one day report is not the previous 24 hours starting from the time the report is generated.
- When configuring reports with a custom time period, you cannot select a time period of less than 15 minutes long. A report will always contain at least 15 minutes of aggregated data. Minute entries are rounded to the nearest aggregation time (that is, 00, 15, 30, or 45). You can configure minutes only for custom reports that start and end on the current day.

Also, because hourly data is kept only up to five days, you can specify hours in a custom time period only for the past five days.

- You cannot generate a report for periods that are longer than the device has been monitored. For example, when you start the Event Manager service for the first time, you will not be able to generate a monthly report until after the month changes. This might be only a few days (for example, if you start the service on the twenty-ninth day of the month), or it might be almost a full month (for example, if you start the service on the first day of the month).

The exception to this rule is the custom time period report. Custom time period reports are generated using daily aggregation data, so you can select any custom time period.

Note Be aware that your first month of aggregated data might be significantly less than one month's worth of data. If you compare monthly reports, this might appear as a significant discrepancy when in reality you are comparing 30 days of data to 15 days (as an example).

You can configure the default time interval for predefined system reports and configure time intervals in individual reports. The following topics explain the time controls:

- Configuring Default Settings for Reports , on page 2776
- Editing Report Settings , on page 2769

Understanding Report Manager Access Control

The user privileges assigned to your username control what you can do in Report Manager. If you use local users, or other types of non-ACS access control, then all users have access to Report Manager and all reports. However, the following access limits are imposed:

- You must have system administrator or network administrator privileges to configure default settings for the predefined system reports. See Configuring Default Settings for Reports , on page 2776.
- You must have system administrator or network administrator privileges to do the following to another user's schedules: see them, enable or disable them, view results generated from them, or delete them. See the following topics:
  - Viewing Report Schedules , on page 2780
  - Viewing Scheduled Report Results , on page 2782
  - Enabling and Disabling Report Schedules , on page 2783
  - Deleting Report Schedules , on page 2783
- You must have system administrator or network administrator privileges to see a list of all custom reports configured on the server and to delete another user's custom report. See Managing Custom Reports , on page 2780.

If you use ACS to control access to Security Manager, you can also control user access to Report Manager. When using ACS:

- You can control access to the Report Manager application using the View Report Manager privilege. Using this privilege, you could prevent certain users from accessing Report Manager, or create roles that allow access to Report Manager without allowing access to Event Viewer.
- Users can view reports on devices only if they have at least View privileges to the device.

For information on integrating Security Manager with Cisco Secure ACS, see the Installation Guide for Cisco Security Manager .

Overview of Report Manager

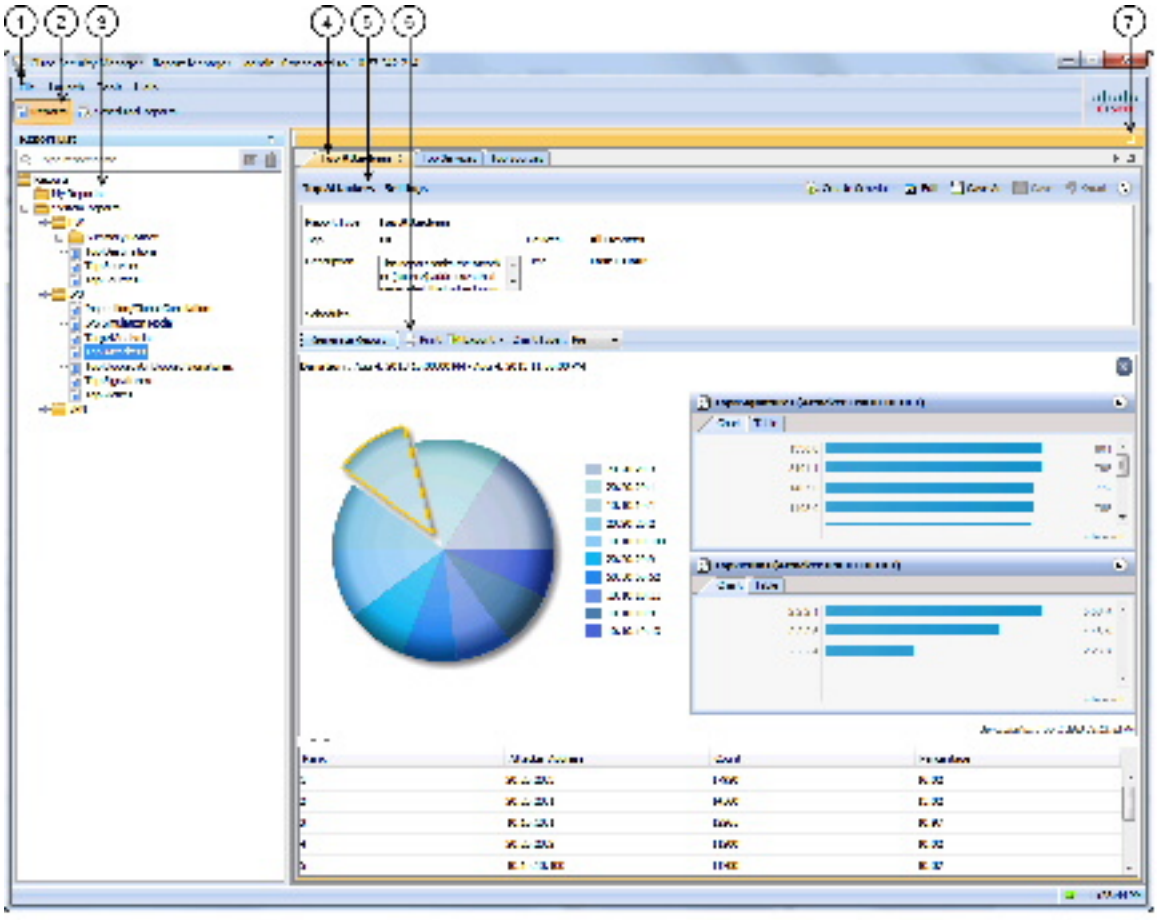
Use Report Manager to create security and usage reports for ASA and IPS devices, and for remote access IPsec and SSL VPNs hosted on ASA devices. For more information about supported devices and the reports you can generate using Report Manager, see Understanding Report Management , on page 2747.

To open Report Manager, do any of the following:

- Select **Start > All Programs > Cisco Security Manager Client > Report Manager** from the Windows Start menu (your exact command path might differ), or double-click the Report Manager icon on the desktop. You are prompted to log in. For more information about starting a Security Manager client application, see Logging In to and Exiting Security Manager , on page 11.
- Select **Launch > Report Manager** from the Configuration Manager or Event Viewer applications. Report Manager is opened using the same user account that you used to log into the other application.

The following illustration and subsequent list explain the basics of Report Manager.

Figure 65: Report Manager Main Window



The following list explains the main Report Manager window and its call-outs in more detail.

- **Menu Bar (1)**—General commands for performing actions in Report Manager. For a description of the commands, see Report Manager Menus , on page 2755.
- **Main Window Tabs (2)**—The main window area consists of the following tabs:
  - Reports—Use the Reports tab to generate reports on demand, to create custom reports, and to perform other report-oriented tasks. The illustration above, and most of the information in this topic, relates to the Reports tab. For information on the tasks you can perform from the Reports tab, see Working with Reports in Report Manager , on page 2766.
  - Scheduled Reports—Use the Scheduled Reports tab to view and manage report schedules. For more information on the Scheduled Reports tab, see Viewing Report Schedules , on page 2780. For information on the tasks you can perform from the Scheduled Reports tab, see Scheduling Reports , on page 2780.
- **Report List (3)**—The left pane of the Reports tab is a list of reports. The list is organized into folders; the System Reports are predefined reports, whereas the My Reports folder contains the custom reports that you create. Double-click a report to open it, select the report and select **File > Open**, or right-click the report and select **Open Report**. For more information about using the report list, see Understanding the Report List in Report Manager , on page 2755.
- **Report Pane (4, 5, 6, 7)**—The right pane of the Reports tab shows the open reports. Each open report is represented on separate tabs (you can have up to five open reports). Note that you can arrange reports horizontally or vertically in this space, or even make a report float to a separate window. For more information about how you can arrange or float reports, see Arranging Report Windows , on page 2777.

You can use the Maximize control (7) above the pane to make it take over the entire workspace (hiding the report list). After maximizing the pane, the control changes to a Restore control to return the main window to a two-pane view.

You can use the right and left arrows, and the Show List icon button, to scroll through the open reports or to go directly to a report. However, clicking the tab with the desired report name is the easiest way to go to a report.

The Report Pane includes these areas for each open report:

-
  - Report Settings pane (5)—The top part of the report shows the report settings, which are the criteria used to generate the report. You can open and close the settings pane by clicking on the heading, or on the expand/collapse icon button. The heading includes a toolbar that has commands that you can perform on the report. For more information about the settings pane, see Understanding the Report Settings Pane , on page 2757.
  - Generated Report Pane and Report Toolbar (6)—Below the settings pane is an additional toolbar used to generate and manipulate report data. Use these controls to generate the report using the criteria defined in the report settings, to print the report or to export it to PDF or CSV format, or to change the type of graphic displayed in the report.

The bottom part of the report pane is the actual report. This area is empty until you click the Generate Report button. The top of the report shows a graphical representation of the information, the lower page shows the tabular data. For more information, see Understanding the Generated Report Pane and Toolbar , on page 2758 and Opening and Generating Reports , on page 2767.

Report Manager Menus

The following table describes the commands on the menus in Report Manager.

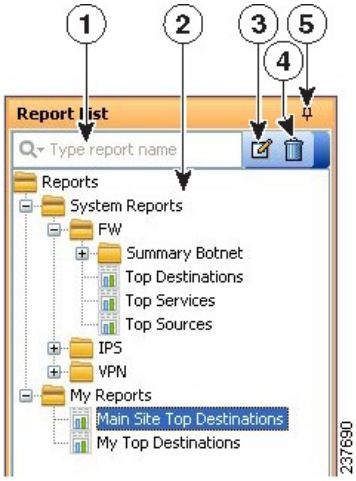
Table 982: Report Manager Menu Reference

Menu	Command	Description
File	Open	Opens the report selected in the report list on the Reports tab. See Opening and Generating Reports , on page 2767.
	Save	Saves changes made to the report settings. This command is available for custom reports only. See Saving Reports , on page 2778.
	Save As	Saves the report as a new report. Use this command to create new reports from existing reports. See Saving Reports , on page 2778.
	Close Report Close All Reports	Closes the active open report, or closes all open reports. See Closing Report Windows , on page 2779.
	Exit	Exits Report Manager.
Launch	Dashboard Configuration Manager Event Viewer Health and Performance Monitor Image Manager	Opens the indicated Security Manager application.
Tools	Default Report Settings	Configures the default settings for predefined system reports. See Configuring Default Settings for Reports , on page 2776.
	Custom Report List	Displays all custom reports configured on the server, not just those that you created. You can manage reports from this window. See Managing Custom Reports , on page 2780.
Help	Help about this page	Opens the online help to a topic relevant to the page currently displayed in the main window.
	About Report Manager	Displays copyright, version, and licensing information for the application.

Understanding the Report List in Report Manager

The left pane of the Reports tab in Report Manager displays a list of available reports, as shown in the following illustration.

Figure 66: Report Manager Report List



The Report List includes the following controls (illustration call-outs cited):

- **Quick Filter search box (1)**—Use the quick filter search box to search for reports in the list. The list is filtered as you type, although folders are not opened automatically. The default is to search for the text string anywhere in the report name. However, you can click the down arrow in the Quick Filter box to select a variety of options to change how your search string is evaluated.
- **List of reports (2)**—The list is organized into folders; the System Reports are predefined reports (explained in Understanding the Predefined System Reports in Report Manager , on page 2760), whereas the My Reports folder contains the custom reports that you create. Double-click a report to open it, or select the report and select **File > Open**. For more information, see Opening and Generating Reports , on page 2767.
- **Right-click shortcut menu (not shown)**—If you right-click on a report, you get a list of additional commands that you can perform, such as opening the report, creating a schedule, or saving the report as a new report.
- **Edit button (3)**—Click the Edit button to change the name of the selected custom report. You can edit custom reports only. For more information, see Renaming Reports , on page 2779.
- **Delete button (4)**—Click the Delete button to delete the selected custom report. You can delete custom reports only. For more information, see Deleting Reports , on page 2779
- **Push Pin button (5)**—Click the Push Pin icon to control whether the report list pane is opened or closed. If the pin is vertical, the report list remains open unless you maximize the report pane (the right pane). If the pin is horizontal, the report list collapses to the left margin, and you must click the Report List heading in the left margin to open the list.

Understanding the Report Settings Pane

The top part of the right side of the Reports tab, with a report open, shows the report settings. These settings define the criteria that are used to generate a report. The following illustration shows an example of the report settings pane.

Figure 67: Report Manager Report Settings

The Report List includes the following controls (illustration call-outs cited):

- **Report tab (3)**—Although not part of the settings per se, each report appears on its own tab. The settings are the top part of the tab. If you right-click the tab itself, you get a menu of commands that allow you to arrange report windows. For more information, see Arranging Report Windows , on page 2777.
- **Heading and toolbar (2)**—The top of the settings pane includes the heading (for example, Top Sources - Settings) and a row of buttons for manipulating the settings. You can open or close the pane by clicking the heading or the up arrow button in the far right of the toolbar. The other buttons have the following functions:
  - Create Schedule button—Creates a new schedule for automatically generating reports based on these settings. For more information, see Configuring Report Schedules , on page 2781

    Edit button—Edits the report settings. For more information, see Editing Report Settings , on page 2769.
  - Save As button—Saves the report as a new report. If you edit the settings for a predefined system report, and you want to save your changes, you must use Save As to create a custom report. For more information, see Saving Reports , on page 2778 and Creating Custom Reports , on page 2769.
  - Save button—Saves changes to the settings. You can save changes for custom reports only. For more information, see Saving Reports , on page 2778.
  - Reset button—Resets the settings to the last saved values.
  - Expand/Collapse button (double up/down arrows)—Toggles between opening and closing the report setting pane.

- **Settings display (1)**—Below the heading and toolbar is a summarization of the report settings. Information includes the type of report, the devices included in the report, the time range, a description, the schedules defined for the report, and other properties unique to the report.

To change the description, type your changes directly into the Description edit box.

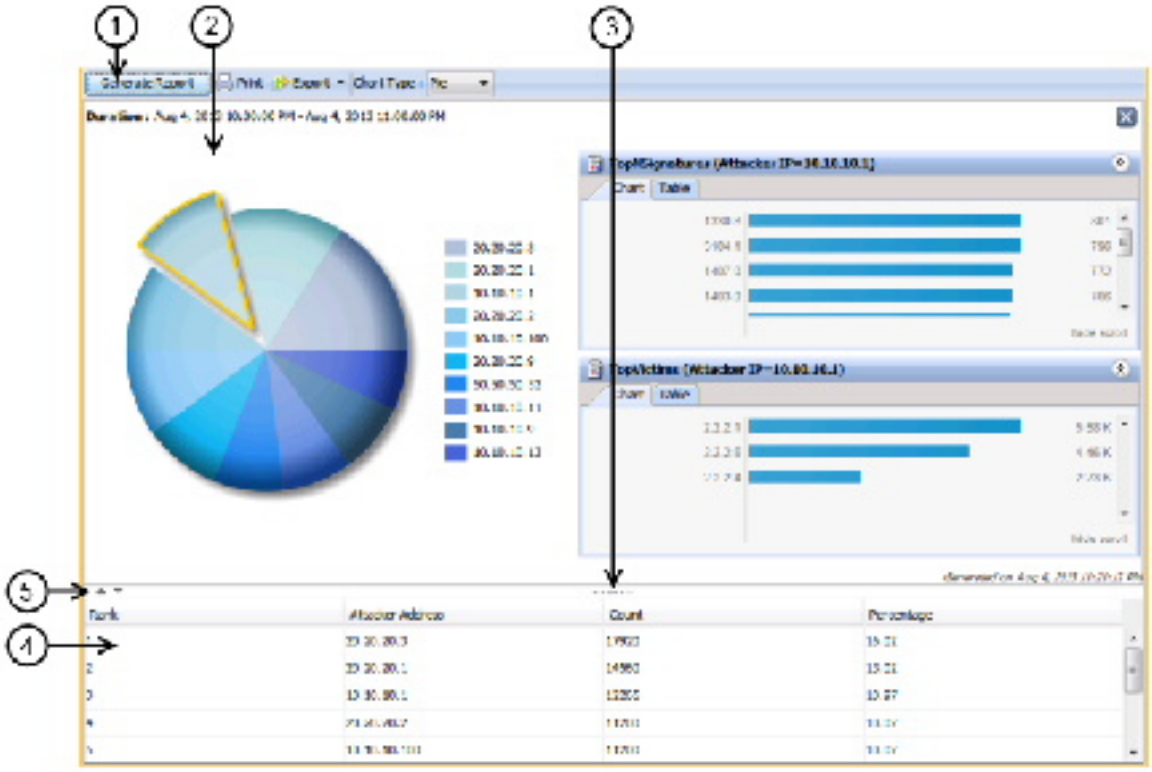
- Scheduling Reports , on page 2780

Understanding the Generated Report Pane and Toolbar

The bottom part of the right side of the Reports tab, with a report open, shows the generated report and report toolbar. This pane displays the results of clicking the Generate Report button.

The following illustration shows an example of the generated report pane and its associated report toolbar.

Figure 68: Report Manager Generated Report Pane and Toolbar



The Report List includes the following controls (illustration call-outs cited):

- **Report toolbar (1)**—The top of the generated report pane is a row of controls for generating and manipulating reports. The controls have the following functions:
  - Generate Report button—Generates a report based on the criteria defined in the report settings (in the upper pane). For more information, see Opening and Generating Reports , on page 2767.
  - Print button—Prints the generated report. For more information, see Printing Reports , on page 2774.
  - Export button—Exports the report. Click the down arrow in the button and select the type of file you want to create: **As PDF** (for Adobe Acrobat) or **As CSV** (for comma-separated values). For more information, see Exporting Reports , on page 2775.
  - Chart Type—Determines the type of graphical chart displayed in the upper part of the report, typically pie, bar, and XY (linear) graphs are available. In some cases, you do not have a choice of chart types. For more information, see Opening and Generating Reports , on page 2767.
- **Graphical view (2, 3, 5)**—The top part of the generated report shows a graphical, color-coded view of the report data, and includes a legend that explains the colors. Also included is the date and time the report was generated.

Note For the Top Destinations, Top Services, and Top Sources firewall reports and the Top Attackers, Top Signatures, and Top Victims IPS reports, you can click on a data point in the Pie, XY, or Bar graph to see additional details for that data point. For example, if you click on a slice in the Pie chart for the Top Signatures report, you will see report details for the top attackers and top victims for the selected signature. For more information, see Drilling Down into Report Data , on page 2773.

At the bottom of the graphical view are the following controls:

- Up and Down arrows (5)—These icon buttons, to the left of the graphic, allow you to open and close the graphical part of the report.
- Window size control (3)—If you hover the mouse pointer over the vertical dashes below the graphic in the center of the window, you can click and move the pointer to change the size of the graphical portion of the report. The graphic is automatically resized as you increase or decrease the size of the area. In fact, you can hover over any part of the top of the table to access this control.
- **Tabular view (4)**—The bottom part of the report is a table that presents the data collected for the report and used to produce the graphic. The columns in the table vary according to the type of report.

You can click a heading to sort the table by the column. There are three sort orders, and clicking the column heading cycles through these orders with an arrow indicating the sort order: ascending (up arrow), descending (down arrow), and no sort (empty). You can use Ctrl+click to create a second sort order on a separate column, which has an effect only if the first sort column repeats one or more entry. Numbers indicate whether the column is the first, second, third, and so on, sort criteria.

Understanding the Predefined System Reports in Report Manager

Report Manager includes several predefined system reports that you can use to analyze your network. You can customize these reports to focus on specific sets of devices and time periods or to focus on other configurable parameters.

This section contains the following topics:

- Understanding Firewall Traffic Reports , on page 2761
- Understanding Firewall Summary Botnet Reports , on page 2762

- Understanding VPN Top Reports , on page 2763
- Understanding General VPN Reports , on page 2763
- Understanding IPS Top Reports , on page 2764
- Understanding General IPS Reports , on page 2766

Understanding Firewall Traffic Reports

Report Manager includes predefined system reports that you can use to identify the top destinations, services, and sources for firewall ACL events. The statistics are based on the events collected by the Event Manager service (as displayed in Event Viewer).

The following reports are available in the **System Reports > FW** folder.

- **Top Destinations**—This report ranks the session destinations of all built/deny firewall events received by Security Manager. The report shows the destination IP address, the count of the number of events for each address, and the percentage of the count compared to the sum of all counts in the report. You can click on a data point in the Pie, XY, or Bar graph that represents a specific destination to see report information about the top sources and top services associated with that destination (see Drilling Down into Report Data , on page 2773).
- **Top Sources**—This report ranks the session sources of all built/deny firewall events received by Security Manager. The report shows the source IP address, the count of the number of events for each address, and the percentage of the count compared to the sum of all counts in the report. You can click on a data point in the Pie, XY, or Bar graph that represents a specific source to see report information about the top destinations and top services associated with that source (see Drilling Down into Report Data , on page 2773).
- **Top Services**—This report ranks the destination services of all built/deny firewall events received by Security Manager. TCP and UDP services include the port number. The report shows the service, the count of the number of events for each service, and the percentage of the count compared to the sum of all counts in the report. You can click on a data point in the Pie, XY, or Bar graph that represents a specific service to see report information about the top destinations and top sources associated with that service (see Drilling Down into Report Data , on page 2773).

The parameters used to define the number of addresses or services to included in the report and the reporting time period are defined in the system defaults as described in Configuring Default Settings for Reports , on page 2776.

You can also edit the report settings and create custom versions of the reports. You can narrow the reports to focus on specific sets of source or destination addresses or services, or on just permit or deny actions, or limit the report to focus on a sub-set of firewall devices, as described in the following topics:

- Editing Report Settings , on page 2769
- Creating Custom Reports , on page 2769

Understanding Firewall Summary Botnet Reports

Report Manager includes predefined system reports that you can use to analyze botnet traffic filtering. The statistics are based on the botnet events collected by the Event Manager service (as displayed in Event Viewer) for blocklisted and gray-listed sites.

For more information about botnet, see Understanding Botnet Traffic Filtering , on page 907.

The following reports are available in the **System Reports > FW > Summary Botnet** folder.

- **Top Infected Hosts**—This report ranks the top infected hosts for traffic originating from infected hosts to black- or gray-listed sites based on all botnet events received by Security Manager. The report shows the IP address of the infected host with the firewall interface name on which the event was detected in parentheses, the count of the number of connections logged to blocklisted or gray-listed sites for each address, the count of the number of connections that were blocked (dropped) by botnet traffic filtering, and the percentage of the count compared to the sum of all counts in the report.
- **Top Malware Ports**—This report ranks the top destination ports for traffic originating from infected hosts to black or gray-listed sites based on all botnet events received by Security Manager. The report shows the destination malware port, the count of the number of connections logged to blocklisted or gray-listed sites for each port, the count of the number of connections that were blocked (dropped) by botnet traffic filtering, and the percentage of the count compared to the sum of all counts in the report.
- **Top Malware Sites**—This report ranks the top botnet sites (black or gray-listed sites) for all inbound and outbound sessions based on all botnet events received by Security Manager. The report shows the following information:
  - IP Address—The IP address that is indicated as the malicious host in botnet events, either on the block list or the grey list.
  - Malware Site—The domain name or IP address in the dynamic filter database to which the traffic was initiated.
  - List Type—Whether the site is on the black list or the grey list.
  - Connections Logged—The count of the number of connections logged or monitored for each site.
  - Connections Blocked—The count of the number of connections that were blocked (dropped) by botnet traffic filtering for each site.
  - Threat Level—The botnet threat level for the site, rom very low to very high, or none.
  - Category—The category of threat the site poses as defined in the botnet database, such as botnet, Trojan, spyware, and so on.

The parameters used to define the number of hosts, ports, or sites in the report and the reporting time period are defined in the system defaults as described in Configuring Default Settings for Reports , on page 2776. You can also edit the report settings and create custom versions of the reports, as described in the following topics:

- Editing Report Settings , on page 2769
- Creating Custom Reports , on page 2769

Understanding VPN Top Reports

Report Manager includes predefined system reports that you can use to identify the top remote access VPN users based on bandwidth usage, duration of connection to your network, and data throughput. Separate reports are provided based on the type of connection made by the user.

These reports are available in the **TelemetryTelemetrySystem Reports > VPN** folder in the **AnyConnect VPN module of Cisco Secure Client**, **Cisco VPN Client (IPsec) Remote Access VPN**, and **Clientless SSL VPN**.

The following reports are available in each folder. Each report is specific to the connection type indicated by the folder name and also included in parentheses in the report name.

- **Top Bandwidth Users**—This report ranks the VPN users who consumed the most bandwidth. The report shows the usernames, the bandwidth in total number of bytes sent and received, and the percentage of reported bandwidth used by each user.
- **Top Duration Users**—This report ranks the VPN users who remained connected to the network for the longest time. The report shows the usernames, the connection duration time in *days hours:minutes:seconds* format, and the percentage of the reported duration by each user. The chart shows duration in seconds.
- **Top Throughput Users**—This report ranks the VPN users who sent and received data at the highest throughput rate. The report shows the usernames, the throughput for each user in kbps, and the percentage of reported throughput by each user. The throughput is calculated as 8.0*(bandwidth of the user in bytes)/(duration for which the user is connected in seconds*1000.0).

The parameters used to define the number of users included in the report and the reporting time period are defined in the system defaults as described in Configuring Default Settings for Reports , on page 2776. You can also edit the report settings and create custom versions of the reports, including focusing on specific users, as described in the following topics:

- Editing Report Settings , on page 2769
- Creating Custom Reports , on page 2769

Understanding General VPN Reports

Report Manager includes predefined system reports that you can use to analyze general remote access VPN usage in your network. These reports are not specific to the connection types used in the VPN.

The following reports are available in the **System Reports > VPN** folder.

- **Connection Profile Report**—This report provides a count of user, session, and summary of the bandwidth utilization and throughput usage for each remote access connection profile.

The default report contains this information for all devices for the previous hour. You can customize the report in several different ways (see Editing Report Settings , on page 2769).

- **User Report**—This report provides a summary of the bandwidth utilization, connection duration and throughput usage for each remote access VPN user. The report shows the usernames, the bandwidth in total number of bytes sent and received, the connection duration time in *days hours:minutes:seconds* format, and the throughput for each user in kbps. The throughput is calculated as 8.0*(bandwidth of the user in bytes)/(duration for which the user is connected in seconds*1000.0).

Beginning with Security Manager 4.7, the User Report provides both **user-level details** and **session-level details**:

- • **User-Level Details**—For a particular user, the **user-level details** represent the combined value of all that user's sessions: Username, Total no. of Sessions, Bandwidth, Duration, and Throughput.

Note Starting from Cisco Security Manager 4.13, the Public IP and Assigned IP details are also displayed as part of the User-Level Details in the general VPN report.

- • **Session-Level Details**—Expanding the tree displays the **session-level details** for each session that a particular user has a VPN connection with; the session-level details encompass the Session ID, Login Time, Logout Time, Bandwidth, Throughput, and Duration of the Session. (Here the logout time is calculated by using the formula **Logout Time = Login Time + Duration**.)

The default report includes information for all connection technologies and all users. You can customize the report to focus on a single technology type or one or more specific users (see Editing Report Settings , on page 2769).

The "Criteria" section of the User Report has filters for Technology (All, Clientless, Full Client, and IPSec RA), Username, and User Session Duration (<= and >= in hours).

- **VPN Device Usage Report**—This report provides a summary of the usage statistics for each device that hosts remote access VPN connections. The report shows the device (using the Security Manager display name), the average number of users logged into the VPN at any given time during the reported time range, the total bandwidth of all users in the VPN in bytes (sent and received), the total connection duration time in *days hours:minutes:seconds* format, and the average throughput in kbps at any given time during this report period.

The default report includes information for all connection technologies. You can customize the report to focus on a single technology type (see Editing Report Settings , on page 2769).

The parameter used to define the reporting time period is defined in the system defaults as described in Configuring Default Settings for Reports , on page 2776. You can also edit the report settings and create custom versions of the reports, as described in the following topics:

- Configuring Default Settings for Reports , on page 2776
- Creating Custom Reports , on page 2769

Understanding IPS Top Reports

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

Report Manager includes predefined system reports that you can use to analyze top attackers, victims, and signatures for IPS alerts in your network.

The following reports are available in the **System Reports > IPS** folder.

- **Top Attackers**—This report ranks the attacker (source) addresses that generated the highest numbers of recorded IPS alerts. The report shows the attacker IP address, the count of the number of alerts for each address, and the percentage of the count compared to the sum of all counts in the report. You can click on a data point in the Pie, XY, or Bar graph that represents a specific attacker to see report information about the top signatures and top victims associated with that attacker (see Drilling Down into Report Data , on page 2773).

The default report includes information for all attackers, victims, and signatures for both blocked and unblocked actions. You can customize the report to focus on subsets of attackers, victims, or signatures, or limit the analysis to blocked only or unblocked only actions (see Editing Report Settings , on page 2769).

- **Top Victims**—This report ranks the victim (destination) addresses that generated the highest numbers of recorded IPS alerts. The report shows the victim address, the count of the number of alerts for each address, and the percentage of the count compared to the sum of all counts in the report. You can click on a data point in the Pie, XY, or Bar graph that represents a specific victim to see report information about the top signatures and top attackers associated with that victim (see Drilling Down into Report Data , on page 2773).

The default report includes information for all attackers, victims, and signatures for both blocked and unblocked actions. You can customize the report to focus on subsets of attackers, victims, or signatures, or limit the analysis to blocked only or unblocked only actions (see Editing Report Settings , on page 2769).

- **Top Signatures**—This report ranks the signatures that fired the highest numbers of alerts. The report shows the signature ID number, the name of the signature, the count of the number of alerts for each signature, and the percentage of the count compared to the sum of all counts in the report. You can click on a data point in the Pie, XY, or Bar graph that represents a specific signature to see report information about the top victims and top attackers associated with that signature (see Drilling Down into Report Data , on page 2773).

The default report includes information for all attackers, victims, and signatures for both blocked and unblocked actions. You can customize the report to focus on subsets of attackers, victims, or signatures, or limit the analysis to blocked only or unblocked only actions (see Editing Report Settings , on page 2769).

- **Top Blocked/Unblocked Signatures**—This report ranks the signatures that blocked the highest numbers of attacks. The report shows the signature ID number, the name of the signature, the count of the number of alerts for each signature, and the percentage of the count compared to the sum of all counts in the report.

The default report shows blocked actions only. However, you can customize the report to show unblocked only or a combination of blocked and unblocked actions (see Editing Report Settings , on page 2769).

If you want to see blocked or unblocked lists that are limited to specific attacker or victim addresses, or to a subset of signatures, use the Top Signatures report instead of the Top Blocked/Unblocked Signatures report. Customize the report to show blocked only or unblocked only signatures.

- **IPS Target Analysis**—This report provides the top targets by signature and frequency of attack. The report shows the signatures that generated the alerts, the number of alerts, and the victim IP address, and is based on an aggregated view of the Top Signatures and Top Victims reports. The report contains up to ten signatures and five attackers. The information is plotted on a scatter plot, which is the only graphical representation available for the report.

The parameters used to define the number of addresses or signatures to included in the report and the reporting time period are defined in the system defaults as described in Configuring Report Schedules , on page 2781.

You can also edit the report settings and create custom versions of the reports, as described in the following topics:

- Editing Report Settings , on page 2769
- Creating Custom Reports , on page 2769

Understanding General IPS Reports

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

Report Manager includes predefined system reports that you can use to analyze general IPS activity in your network.

The following reports are available in the **System Reports > IPS** folder.

- **Inspection/Global Correlation**—This report provides a comparison of alerts generated by global correlation against alerts generated by traditional IPS inspection. The report shows the number and percentage of alerts per IPS inspection method (either Global Correlation or Inspection).
- **IPS Simulation Mode**—This report provides a comparison of alerts in inline (IPS) and promiscuous (IDS or IPS simulation) modes. The report shows the number and percentage of alerts based on mode, either Non Simulation Count (inline) or Simulation Mode Count (promiscuous). The IPS sensor cannot directly block attacks that occur in promiscuous mode.

When working with IPS events, the Report Manager component of Cisco Security Manager reports events individually; the Event Viewer component of Cisco Security Manager displays alerts. In the Event Viewer component, the IPS Summarizer groups events into a single alert, thus decreasing the number of alerts that the IPS sensor sends out.

Tip Cisco IPS Manager Express (IME) and Cisco Security Manager do not summarize events in precisely the same way.

The parameter used to define the reporting time period is defined in the system defaults as described in Configuring Default Settings for Reports , on page 2776. You can also edit the report settings and create custom versions of the reports, as described in the following topics:

- Editing Report Settings , on page 2769
- Creating Custom Reports , on page 2769

Working with Reports in Report Manager

Use the Report Manager application to view security and usage reports for devices and remote access IPsec and SSL VPNs. The following topics explain the basics of creating reports. For information on working with report schedules, see Scheduling Reports , on page 2780.

This section contains the following topics:

Opening and Generating Reports

Reports are not static. When you open a report, it contains no data, although it does contain settings that define the data that shall be used to generate the report. Thus, to view a report, you need to open it and then generate it. This procedure explains the process.

Related Topics

- Overview of Report Manager , on page 2753
- Creating Custom Reports , on page 2769
- Arranging Report Windows , on page 2777
- Troubleshooting Report Manager , on page 2784

Step 1 In Report Manager, do one of the following to open a report:

- Double-click the name of the report in the report list (in the left pane).
- Select the report in the reports list and select **File > Open**.
- Right-click a report in the reports list and select **Open Report**.

The report opens with the report settings pane open and the report content area empty.

Tip You can have five reports at most open at one time. You can also collapse the report settings pane to provide more room for viewing the generated report by clicking on any area of the settings toolbar that is not a button that performs another function.

Step 2 (Optional) Verify that the report settings contain the desired values, for example, the desired time window for the report. The settings for system reports are based on the system defaults (which you can configure as described in Configuring Default Settings for Reports , on page 2776). The settings for custom reports are those that were last saved for the report.

If you need to change the settings, click the **Edit** button in the settings toolbar and make your changes in the Edit Settings dialog box. For more information, see Editing Report Settings , on page 2769.

Tip Be sure to save your changes if you want to make them permanent. If you change the settings for a system report and you want to preserve them, you must use Save As to create a new custom report; you cannot change the settings of a system report from the default settings.

Step 3 Click the **Generate Report** button below the settings pane to retrieve the report data from the reporting database and to display the resulting information. The information is displayed in two formats:

- Graphical—A graphical representation of the data is shown in the top part of the report. You can select different types of graphics from the **Chart** menu above the report data: pie, XY (for linear graphs), and bar. If there are more than 10 items in the report (for example, you configured a Top report to show 25 values), all values after the tenth are summarized in the chart as "others."

Note For the Top Destinations, Top Services, and Top Sources firewall reports and the Top Attackers, Top Signatures, and Top Victims IPS reports, you can click on a data point in the Pie, XY, or Bar graph to see additional details for that data point. For example, if you click on a slice in the Pie chart for the Top Signatures report, you will see report details for the top attackers and top victims for the selected signature. For more information, see Drilling Down into Report Data , on page 2773.

Some reports, such as the IPS Target Analysis report, use scatter plots. For these reports, you do not have the option to select a different graphic type.

- Tabular—The table below the graphic lists the data used to generate the graphic. The table has different columns based on the type of report. Following are some typical columns; for more detailed information about the content of each report, see Understanding the Predefined System Reports in Report Manager , on page 2760.
  - Rank—The order of the information by magnitude. For example, for a firewall top destinations report, a rank of 1 indicates that the destination is the most used in the evaluated events.
  - (Name of reported characteristic)—There is always a column whose name is based on the characteristic targeted by the report, for example, Source/Destination (IP addresses), Service (protocol and port), or User (usernames).
  - Count—The number of times the item appears in an event or related statistic.
  - Percentage—The ratio of the reported characteristic to the total sum of that characteristic in the report. The ratio includes only those numbers included in a report, so for example, you could get a different percentage for the same item in a top 10 verses a top 25 report.

Step 4 (Optional) If desired, you can print the report or export it to a PDF or comma-separated values (CSV) file.

- To print the report, click the **Print** button and select your printer. For more information, see Printing Reports , on page 2774.
- To export the report, click the **Export** button and select the file type, PDF or CSV. For more information, see Exporting Reports , on page 2775.

Tip The report data is not preserved when you close the report. If you want to keep the displayed information, you must print or export the report.

Creating Custom Reports

You can create custom reports to target specific characteristics that require regular analysis or presentation. For example, you might want to create separate Top Destination firewall reports for different groups of firewall devices so that you can separately analyze activity in separate physical sites. You can also use custom reports to analyze sources, destinations, or services that otherwise do not make it into the top reports.

Tip It might take up to one hour for data to be available for a newly-created custom report. If you get the message that no records are found after creating the report, wait an hour and then ensure that the time span for the report is Last 1 Hour.

Related Topics

- Opening and Generating Reports , on page 2767
- Overview of Report Manager , on page 2753

Step 1 Select the report on which you want to base your custom report in the reports list. Open it by double-clicking it, by selecting it and selecting **File > Open**, or by right-clicking and selecting **Open Report**.

Step 2 Click the **Edit** (pencil) button in the settings toolbar to open the Edit Settings dialog box.

Note Do not click the Edit button above the reports list. That edit button allows you to change the name of the report only.

The Edit Settings dialog box is divided into two panes. The left pane lists the available settings pages; the right pane shows the settings for the page selected in the left pane.

Step 3 Configure the settings so that they define the desired report parameters. For more information, see Editing Report Settings , on page 2769.

Step 4 Click the **Save As** button in the settings toolbar, or select **File > Save As**.

Step 5 Enter the name of the report and optionally a description and click **OK**.

Report names can be up to 64 characters and contain alphanumeric characters, spaces, hyphens (-), and the underscore character (_). The description can be up to 1024 characters.

Editing Report Settings

You can change the settings that define the criteria used to generate a report. For custom reports, you can save your changes.

For predefined system reports, you cannot directly save your changes. Instead, you can use Save As to create a new custom report using the updated settings. You can also change the default settings used in all predefined

system reports rather than editing report settings, as described in Configuring Default Settings for Reports , on page 2776.

Related Topics

- Opening and Generating Reports , on page 2767
- Overview of Report Manager , on page 2753
- Creating Custom Reports , on page 2769
- Understanding Report Manager Data Aggregation , on page 2750
- Arranging Report Windows , on page 2777

Step 1 In Report Manager, open the report whose settings you want to change. To open the report, double-click it, select it and select **File > Open**, or right-click it and select **Open Report**.

The report opens with the settings pane open at the top of the report. The settings pane shows the type of report, the devices included in the report, the time range, a description, the schedules defined for the report, and other properties unique to the report.

Step 2 (Optional) Change the Description by typing into the Description edit box in the report settings pane.

Step 3 Click the **Edit** (pencil) button in the settings toolbar to open the Edit Settings dialog box.

Note Do not click the Edit button above the reports list. That edit button allows you to change the name of the report only.

The Edit Settings dialog box is divided into two panes. The left pane lists the available settings pages; the right pane shows the settings for the page selected in the left pane.

Step 4 Edit the settings on the desired pages as follows:

- **Devices**—To change which monitored devices are included in the report. The default is **All Devices**.

If you want the report to reflect a subset of monitored devices, select **Filter Devices** and then select the desired devices or created contexts from the list. If a device is in italics, it means that the device is not currently selected for monitoring in Event Viewer; you can select these devices, and the report will include data for the device if it was monitored during the selected time period. You can select a folder to select all the devices in the folder.

The device list is pre-filtered to show devices of the appropriate type only. For example, if you are editing the settings for a firewall report, IPS devices do not appear in the list of selectable devices.

Note Starting from Cisco Security Manager 4.10, all the created contexts for ASA 9.5(2) and above will be listed under Filter Devices.

- **Time**—To change the time span used to select events and data to include in the report. The time is based on the Security Manager server time. You can select one of the following options to define the time span:
  - Last 1 Hour—The last full one hour on the zeros, for example, if the current time is 11:45 AM, the Last 1 Hour report shows data from 10:00 to 11:00.
  - Last 1 Day—The last full day, from midnight to midnight. For example, if the current day is Tuesday, the Last 1 Day report shows data from Monday.
  - Last 1 Week—The previous Monday through Sunday.

- Last 1 Month—The previous month. For example, if the current date is September 29, the Last 1 Month report shows data from August.
- Custom—Use the Start Date and End Date calendars to select the desired starting and ending times for the report. Click the down arrow, select the desired day and time, then click OK in the calendar widget. Reportable data is kept for 90 days, so you cannot select a date more than 90 days into the past. Additionally, you cannot specify a time if you select a start date more than five days into the past. If you select the current date for the start date, you can also specify minutes for both starting and ending dates, but because report data is aggregated every 15 minutes at 00, 15, 30, and 45 minutes past each hour, minute entries are rounded to the nearest of these figures. The allowed time selection is based on how data is aggregated, as explained in Understanding Report Manager Data Aggregation , on page 2750.

- **Criteria**—To change the other criteria used to define the report. The attributes available on the Criteria settings page are variable. In some cases, there are no selectable criteria. Following is a list of the possible criteria:
  - Top (All "Top" reports.)—The number of items targeted by the report to include. For example, the Top 10 firewall destinations returns the 10 most frequent destinations for firewall events in the configured time range. Select 10, 20, 25, or 50.
  - Service (Firewall reports except Botnet)—The services to include in the report. To specify services, click the Edit button next to the field and select the desired service policy objects. You can select multiple objects.
  - Source IP, Destination IP (Firewall reports except Botnet)—The source and destination IP address fields are separate, but they are functionally the same. They define the IP addresses for sources or destinations to include in the report. You can enter individual addresses, such as 10.100.10.10, or address ranges, such as 10.100.10.10-10.100.10.20. Both IPv4 and IPv6 addresses are accepted. Separate multiple addresses with commas.

You can click the Edit button next to the field to open a dialog box where you can more easily create complex lists of addresses and address ranges. However, you cannot use network/host objects to define addresses.

Note Do not specify values for all of the Service, Source IP, and Destination IP criteria in a single report. You can specify the criteria on which the report is based (for example, Service for the Top Services report) plus one other criteria. If you specify all three values, the report will always contain no data.

- Permit/Deny (Firewall reports except Botnet)—The action reflected in the event, either permitting the matching traffic (Permit), denying the matching traffic (Deny), or either (All). The default is All.
- Signature ID (IPS top attackers, top signatures, top victims)—The signatures to include in the report. To specify signatures, click the Edit button next to the field and select the desired signatures. You can select a folder to select all signatures in the folder.

Note In the predefined system reports, you cannot specify values for all three of the Signature ID, Attacker IP, and Victim IP criteria. You can specify a value for the key attribute of the report (for example, Victim IP for the top victims report) plus one of the other values. If you want to configure values for all three criteria, you must create a custom report.

- Attacker IP, Victim IP (IPS top attackers, top signatures, top victims)—The attacker and victim IP address fields are separate, but they are functionally the same. They define the IP addresses for attackers (sources) or victims (destinations) to include in the report. You can enter individual addresses, such as 10.100.10.10, or address ranges, such as 10.100.10.10-10.100.10.20. Both IPv4 and IPv6 addresses are accepted. Separate multiple addresses with commas.

You can click the Edit button next to the field to open a dialog box where you can more easily create complex lists of addresses and address ranges. However, you cannot use network/host objects to define addresses.

- Blocked (IPS top attackers, top blocked/unblocked signatures, top signatures, top victims)—Whether the event resulted in dropped traffic (Blocked), traffic that was not dropped (Unblocked), or either (All).
- Username (Connection Profile Report and User Report)—The names of the users to include in the report. The default, an empty list, includes all users. If you want the report to focus on specific users, use the Add (+), Edit (pencil), and Delete (trash can) buttons beneath the table to create the desired list of users. Beginning with Version 4.7 of Security Manager, the Username filter supports uppercase/lowercase character sensitivity, wildcard characters, and "NOT" operation support. Please refer to **Enabling Uppercase/Lowercase Character Sensitivity** and **Disabling Wildcard Support** in the paragraphs at the end of this topic.
- Technology (Connection Profile Report, User Report, and VPN Device Usage Report)—The type of remote access technology to include in the report: All, Clientless (SSL VPN), Full Client (SSL VPN), IPsec RA (IPsec remote access VPN).
- Connection Profile (Connection Profile Report)—Allows you to customize a Connection Profile Report in Report Manager by adding or editing a connection profile for a Clientless (SSL VPN), Full Client (SSL VPN), or IPsec RA (IPsec remote access VPN) topology. For more information, see Connection Profiles Page , on page 1333 and Configuring Connection Profiles (ASA, PIX 7.0+) , on page 1331. Beginning with Version 4.7 of Security Manager, the Connection Profile filter supports uppercase/lowercase character sensitivity, wildcard characters, and "NOT" operation support. Please refer to **Enabling Uppercase/Lowercase Character Sensitivity** and **Disabling Wildcard Support** in the paragraphs at the end of this topic.
- Group Policy (Connection Profile Report)—Allows you to customize a Connection Profile Report in Report Manager by specifying a single or multiple group polices in the filter to generate the report for the user who has logged with the specified group policies. For more information, see Configuring Group Policies for Remote Access VPNs , on page 1352. Beginning with Version 4.7 of Security Manager, the Group Policy filter supports uppercase/lowercase character sensitivity, wildcard characters, and "NOT" operation support. Please refer to **Enabling Uppercase/Lowercase Character Sensitivity** and **Disabling Wildcard Support** in the paragraphs at the end of this topic.
- User Session Duration (Connection Profile Report and User Report)—As the title indicates, allows you to specify the duration of a user session as <= or >= a given number of hours.

Step 5 Click **OK** in the Edit Settings dialog box to implement your changes.

You can now click the Generate Report button to retrieve the data defined by the settings and display it in the report. You can also use Save or Save As to permanently save the changes to the settings.

Enabling Uppercase/Lowercase Character Sensitivity

Beginning with Version 4.7 of Security Manager, uppercase/lowercase character sensitivity is available for the Username filter, the Connection Profile filter, and the Group Policy filter. Uppercase/lowercase character sensitivity is disabled by default. If you want to use it, you must enable it by following these steps; note that enabling it for one of these three filters enables it for all three of them:

a. Locate the reporting.properties file. The default location is NMSROOT/MDC/reports/config. (The default value for NMSROOT is C:\Program Files (x86)\CSCOpx

b. Set the parameter reports.reportgeneration.vpnUserReport.casesensitive.enable=true

c. Restart the Report Manager service, which is CsmReportServer

Disabling Wildcard Support

Beginning with Version 4.7 of Security Manager, wildcard support is available for the Username filter, the Connection Profile filter, and the Group Policy filter. Wildcard support is enabled by default. If you do not want to use it, you must disable it by following these steps; note that disabling it for one of these three filters disables it for all three of them:

a. Locate the reporting.properties file. The default location is NMSROOT/MDC/reports/config. (The default value for NMSROOT is C:\Program Files (x86)\CSCOpx

b. Set the parameter reports.reportgeneration.vpnUserReport.wildcard.enable=false

c. Restart the Report Manager service, which is CsmReportServer

Drilling Down into Report Data

The Top Destinations, Top Services, and Top Sources firewall reports and the Top Attackers, Top Signatures, and Top Victims IPS reports allow you to drill down into the report data.

To drill down into one of the supported reports, click on a data point in the Pie, XY, or Bar graph for that report. For example, if you click on a slice in the Pie chart for the Top Signatures report, you will see report details for the top attackers and top victims for the selected signature.

Note The filter criteria you use for a report affects the data available in the associated drill-down reports. If you apply filters to the report data, only one drill-down report will be shown when drilling down into the report data.

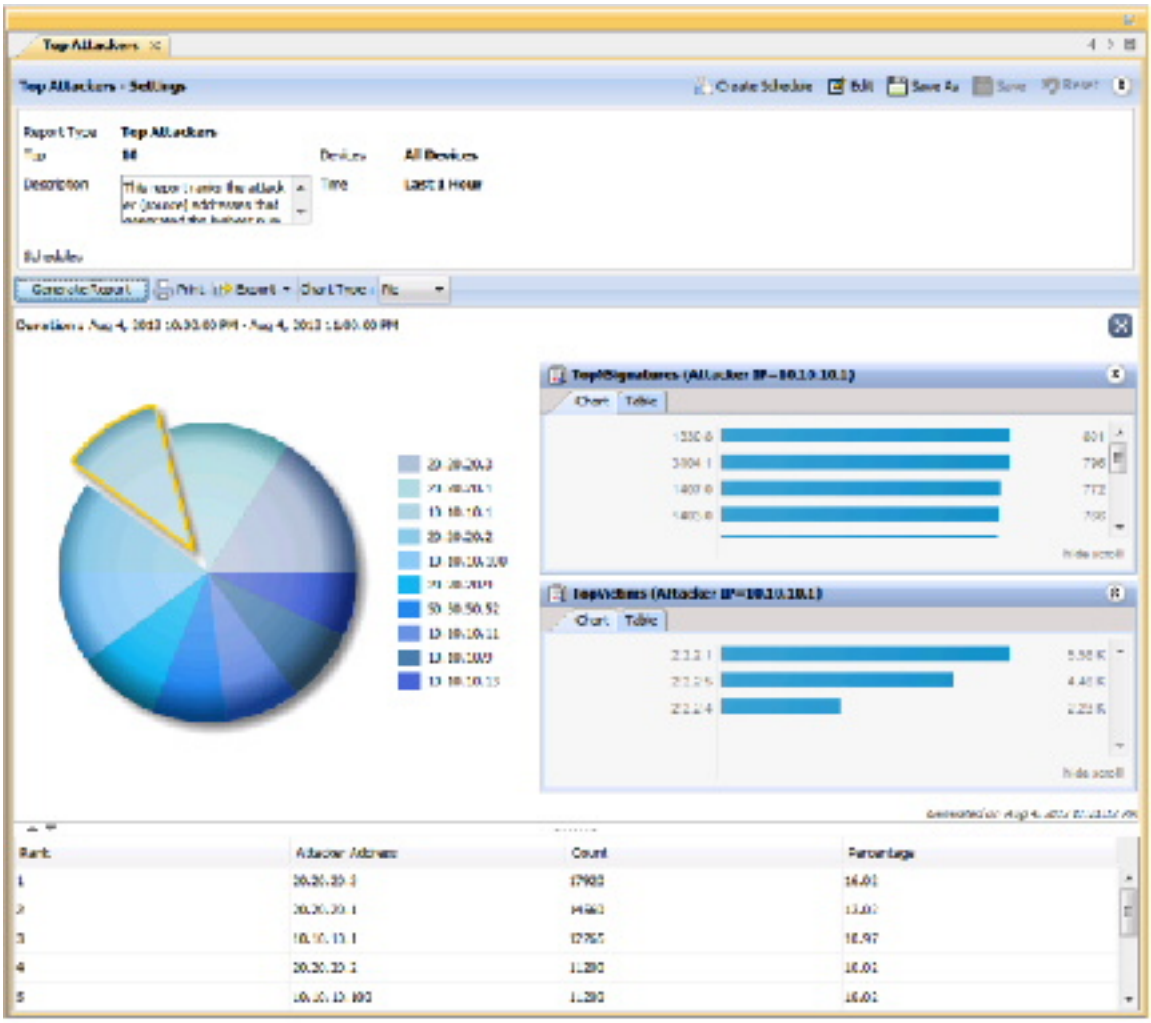
The following table shows the drill-down reports that are shown for each supported report type.

Report Name	Drill-down Reports Shown
Firewall	
Top Sources	Top Destinations, Top Services
Top Destinations	Top Sources, Top Services
Top Services	Top Sources, Top Destinations
IPS	
Top Signatures	Top Attackers, Top Victims
Top Attackers	Top Signatures, Top Victims
Top Victims	Top Signatures, Top Attackers

For each of the drill-down reports, you can view a chart or a table of the drill-down data. If you have drilled down into a specific data point in one of the supported reports, the drill-down report graph and tabular data will be included in the printed report and in the exported report data.

The following illustration shows an example of the drill-down report data for the Top Attackers report.

Figure 69: Top Attackers Drill-down Reports



Related Topics

- Opening and Generating Reports , on page 2767
- Overview of Remote Access VPN Policies for ASA and PIX 7.0+ Devices , on page 1326

Printing Reports

After you generate a report as described in Opening and Generating Reports , on page 2767, you can print it.

Note If you have opened drill-down reports for a specific data point in the Top Destinations, Top Services, or Top Sources firewall reports or the Top Attackers, Top Signatures, or Top Victims IPS reports, the drill-down report graph and tabular data will be included in the printed report. For more information, see Drilling Down into Report Data , on page 2773.

To print the report, click the **Print** button above the report. You are prompted to select a printer.

Exporting Reports

After you generate a report as described in Opening and Generating Reports , on page 2767, you can export it to an Adobe Acrobat (PDF) or comma-separated values (CSV) file.

Exported files include the following information:

- The creation time of the report.
- The settings used to generate the report.
- (PDF only.) The graphical representation of the report data.
- The tabular report data. In PDFs, the information is represented as a table. In CSVs, the information is comma-separated, with the first row being the column headings.

Note If you have opened drill-down reports for a specific data point in the Top Destinations, Top Services, or Top Sources firewall reports or the Top Attackers, Top Signatures, or Top Victims IPS reports, the drill-down report graph and tabular data will be included in the export. For more information, see Drilling Down into Report Data , on page 2773.

To export the report, click the down arrow in the **Export** button above the report and select either **As PDF** or **As CSV**. You are prompted to select a folder for the report. A default file name is provided, but you can change the file name.

Troubleshooting Report Exporting Error

When we try to export, device status report we get the following error.

"Windows cannot find 'acrord32'. Make sure you typed the name correctly and then try again".

First, the above error occurs if Adobe Reader is not installed on the server. Windows cant located the acrord32.exe file as Adobe is not installed.

Second, Even if Adobe reader is installed, the above error might be thrown.This is an issue which exists in windows XP,Vista, 7,8.1 and 10. This is caused due to failure in opening Adobe Reader. it is a known error and can happen to any application and not just Adobe reader. Microsoft hasn't provided patch for this yet.

Reported reasons why this issue can happen are:

1) Corrupt registry entry

2) Problem while installing Adobe

3) Deleting the default Adobe Reader

<B>Symptom:</B>

When we try to export, device status report we get the following error.

"Windows cannot find 'acrord32'. Make sure you typed the name correctly and then try again"

<B>Conditions:</B>

First,the above error occurs if Adobe Reader is not installed on the server. Windows cant located the acrord32.exe file as Adobe is not installed.

Second, Even if Adobe reader is installed, the above error might be thrown.This is an issue which exists in windows XP,Vista, 7,8.1 and 10. This is caused due to failure in opening Adobe Reader. it is a known error and can happen to any application and not just Adobe reader. Microsoft hasn't provided patch for this yet.

<B>Workaround:</B>

1) If Adobe reader is not installed, install it

2) If Adobe reader is installed and error is still thrown, Go to the location where the file is saved and perform

Open with Adobe Reader action. Even though the error is thrown, the file will be created but it will be without a

format. So we can open it using a PDF reader.

<B>Further Problem Description:</B>

Configuring Default Settings for Reports

You can control the default settings that Report Manager uses for System reports. When you change the defaults, you automatically change the settings for all System reports, but the changes do not apply to any reports you saved as custom reports (in the My Reports folder). You must have system administrator or network administrator privileges to change these settings.

While viewing a report, you can edit any system report to specify different values for these settings, either to use temporarily while viewing the report, or to save as a custom report in the My Reports folder.

Note When creating reports in My Reports/Custom Reports, ensure the required filters are applied at the time of report creation because filters cannot be applied after the reports are created.

Tip If you change the settings in a system report, you can return the report to the default settings by clicking the **Reset** button in the Report Settings toolbar.

Step 1 In Report Manager, select **Tools > Default Report Settings** to open the Default Report Settings dialog box.

Step 2 Configure any of the following options:

- **Top**—The number of results listed in any of the “Top” reports, which list the most-often occurring items of the type targeted by the report. For example, if you select 20, the firewall Top Destinations report shows the 20 most often occurring traffic destinations in events reported to Security Manager. The default is 10.

If you select more than 10, all items after the tenth are summarized as "others" in charts, although the detailed information for each additional item is listed in the report table.

- **Time Range**—The time window for events included in the report:
  - Last 1 Hour—The last full one hour on the zeros, for example, if the current time is 11:45 AM, the Last 1 Hour report shows data from 10:00 to 11:00.
  - Last 1 Day—The last full day, from midnight to midnight. For example, if the current day is Tuesday, the Last 1 Day report shows data from Monday.
  - Last 1 Week—The previous Monday through Sunday.
  - Last 1 Month—The previous month. For example, if the current date is September 29, the Last 1 Month report shows data from August.

For more information on the implications of the time range setting, see Understanding Report Manager Data Aggregation , on page 2750.

- **Default Email Address**—The email address used as the default destination for scheduled reports.

If you decide you want to return to the installation default values, click **Restore Defaults**.

Step 3 Click **Apply** to save your changes, then click **Close** to close the dialog box.

Arranging Report Windows

You can open up to five report windows at one time. Reports are opened as tabbed windows in the right pane of the main Report Manager window, in the most recently used area ("tabbed group") if there is more than one area. The commands to arrange the windows appear if you right-click the tab for the report window as shown in the following illustration.

You have many options for arranging report windows based on your requirements. For example, you might want to compare two reports side-by-side, or remove a report from the main window without closing it.

You can use the following techniques to arrange the report windows to get the view that you desire:

- Floating a report—To remove a report from the main Report Manager window without closing it, right-click the report tab and select **Floating**. The report is moved to its own window.

If you have already floated a report, you can select **Floating to** and choose one of the already-floated windows. The report becomes a new tab in that window.

- Docking a report—To move a floating report back to the main Report Manager window, right-click the report tab and select **Docking**.
- Arranging reports horizontally or vertically for side-to-side comparison—To create a vertical or horizontal arrangement of reports to allow for easy comparison, without floating the reports, right-click the report tab and select **New Horizontal Group** or **New Vertical Group**. These commands split the current tabbed group into the selected layout. You must have at least two reports open to use these commands. If you have more than two open reports, and you want all of them in separate windows, you need to use the command multiple times.
- Move reports to different tabbed groups—If you have several open reports, and you have arranged them into horizontal or vertical groups, you can move reports among the groups by right-clicking the report tab and selecting **Move to Next Tab Group** or **Move to Previous Tab Group**. The commands appear only if reports are arranged in a manner where such movement is possible:
- Change the orientation of groups—You can switch between horizontal and vertical layouts by right-clicking the report tab and selecting **Change Tab Groups Orientation**.

Saving Reports

If you edit the settings for a report, you must save it to make those changes permanent. However, to save changes to predefined system reports, you must save the report as a custom report.

Tip When you save a report, you are saving the settings that define the report. You are not saving the generated content of the report. If you want to save the generated content of the report, that is, the graphs and the report data, you must export the report rather than save it.

- To save changes to a custom report, do one of the following in Report Manager:
  - Select **File > Save** from the menu bar.
  - Click the **Save** button in the Report Settings toolbar.
- To save your changes as a new custom report, do one of the following to open the Save Report As dialog box:
  - Select **File > Save As** from the menu bar.
  - Click the **Save As** button in the Report Settings toolbar.
  - Right-click the report in the reports list and select **Save As**.

Then, enter a name for the report and optionally a description of the report and click **OK**. The report is added to the My Reports folder in the reports list.

Note Report names can be up to 64 characters and contain alphanumeric characters, spaces, hyphens (-), and the underscore character (_). The description can be up to 1024 characters.

Renaming Reports

You can change the name of custom reports, but you cannot change the names of predefined system reports.

Related Topics

- Overview of Report Manager , on page 2753
- Understanding the Report List in Report Manager , on page 2755

Step 1 In Report Manager, select the report whose name you want to change from the reports list. You do not need to open the report; simply select it in the list.

Step 2 Click the **Edit** (pencil) button above the reports list to open the dialog box that allows you to change the report name.

Step 3 Enter the new name and click **OK**.

Report names can be up to 64 characters and contain alphanumeric characters, spaces, hyphens (-), and the underscore character (_).

Closing Report Windows

You can close any report by clicking the X icon on the report tab. For reports that you have floated, you can simply click the X icon in the window's title bar.

Tip When you close a report, none of the generated report data is preserved. If you want to preserve the generated data, you must print it or export it before you close the report window.

You can also use the following techniques to close the report windows without exiting Report Manager:

- Close a report—Select **File > Close Report** to close the currently-viewed report, or right-click the desired report tab and select **Close**.
- Close all reports—Select **File > Close All Reports**, or right-click any report tab and select **Close All**.
- Close all reports except one—Right-click the report tab of the report you want to keep open and select **Close Others**.

Deleting Reports

You can delete custom reports, but you cannot delete predefined system reports.

To delete a custom report, select it in the reports list and click the **Delete** (trash can) button above the reports list. You are asked to confirm your deletion.

Tip Deleting a report also deletes any schedules for that report.

If you need to delete another user's custom report, see Managing Custom Reports , on page 2780.

Managing Custom Reports

If you have system administrator or network administrator privileges, you can view a list of custom reports created by all Report Manager users on this Security Manager server.

To view the list of custom reports, select **Tools > Custom Report List** to open the Manage Custom Reports dialog box. The list shows the report name, the type of report, the type of device analyzed by the report, and the username of the person who created the custom report.

You can use the following controls to manage custom reports from this page:

- **Pagination controls**—If there are a lot of custom reports, use the pagination controls to move through the list. You can click the buttons to move to the first page, previous page, next page, or last page, or type the page number into the Page X of Y edit box. You can also click the down arrow in the edit box to change the edit box to work by record number rather than page number.
- **Delete button**—Click this button to delete the selected report. Any schedules (and schedule results) that use the report are also deleted.
- **Refresh button**—Click this button to update the list with the latest information.

Scheduling Reports

You can create schedules to regularly generate reports from Report Manager.

This section contains the following topics:

- Viewing Report Schedules , on page 2780
- Configuring Report Schedules , on page 2781
- Viewing Scheduled Report Results , on page 2782
- Enabling and Disabling Report Schedules , on page 2783
- Deleting Reports , on page 2779

Viewing Report Schedules

You can view a list of report schedules that are configured in Report Manager. If you have system administrator or network administrator privileges, the list includes all schedules configured on the server, whether you configured them or another user configured them. Users with lesser privileges can see their own schedules only.

To view the list of report schedules, select the **Scheduled Reports** tab, and if necessary, the **Schedule List** sub-tab. The list shows the schedule name, description, the report that will be generated by the schedule, the frequency of report generation, the e-mail addresses to which reports are sent (if any), whether the schedule is enabled or disabled, and the username of the person who created the schedule.

You can use the following controls to manage report schedules from this page:

- **Pagination controls**—If there are a lot of schedules, use the pagination controls (below the table to the left) to move through the list. You can click the buttons to move to the first page, previous page, next page, or last page, or type the page number into the Page X of Y edit box. You can also click the down arrow in the edit box to change the edit box to work by record number rather than page number.

- **Add button**—Click this button to add a new schedule. For more information, see Configuring Report Schedules , on page 2781.
- **Edit button**—Click this button to edit the selected schedule. For more information, see Configuring Report Schedules , on page 2781.
- **Delete button**—Click this button to delete the selected schedule. For more information, see Deleting Report Schedules , on page 2783
- **Refresh button**—Click this button to update the list with the latest information.
- **Enable button**—Click this button to enable the selected schedule. The button is active only if the selected schedule is disabled. For more information, see Enabling and Disabling Report Schedules , on page 2783.
- **Disable button**—Click this button to disable the selected schedule. The button is active only if the selected schedule is disabled. For more information, see Enabling and Disabling Report Schedules , on page 2783.

Configuring Report Schedules

You can create schedules to automatically generate reports at set times. The generated reports are e-mailed to identified recipients and are also stored and available for viewing from Report Manager. By scheduling reports, you can easily and efficiently create regular milestone views of network security and usage. This procedure explains how to set up a schedule for a report.

Related Topics

- Overview of Report Manager , on page 2753
- Opening and Generating Reports , on page 2767
- Viewing Report Schedules , on page 2780
- Troubleshooting Report Manager , on page 2784

Step 1 In Report Manager, do one of the following:

- On the Reports tab, open the report for which you are creating a new schedule by double-clicking the name of the report in the report list (in the left pane). Then, click the **Create Schedule** button in the report settings toolbar.

Note You cannot edit an existing schedule from the Reports tab.

- On the Reports tab, right-click the report on which you are creating a schedule and select **Create Schedule**. If the report is not already open, it is opened.
- On the Scheduled Reports tab, Schedule List sub-tab, click the **Add** button below the list of schedules to create a new schedule. To edit an existing schedule, select it in the list and click the **Edit** button.

The Add or Edit Report Schedule dialog box opens.

Step 2 Configure the following options in the dialog box:

- **Schedule Name**—A name for the schedule, up to 64 characters.

- **Report Name**—Select the name of the report to be generated by the schedule. When you create a schedule from the report settings pane, the name is pre-selected and you cannot change it.
- **Schedule**—Select whether the report shall be generated daily, weekly (once per week), or monthly (once per month). Then, enter the day and time for generating the report:
  - Daily schedules—Select whether the schedule is for Monday through Friday (five days) or Monday through Sunday (all seven days). Enter the time of day (in 24-hour notation) to generate the report.
  - Weekly schedules—Select the day of the week and enter the time of day in 24-hour notation.
  - Monthly schedules—Select whether to generate the report on the first day of the month, the last day, or custom. If you select Custom, enter the day number. Then, enter the time of day in 24-hour notation.
- **Email To**—The email addresses that should be sent the report. Separate multiple addresses with commas. If you do not want reports e-mailed, ensure that the field is empty. Note that for e-mails to be sent successfully, you must configure SMTP on the Security Manager server as described in Configuring an SMTP Server and Default Addresses for E-Mail Notifications , on page 27.

If the report fails to generate for some reason, notification of the failure is sent to these e-mail addresses.

- **Export Report Format**—Whether to generate the report in Adobe Acrobat (PDF) or comma-separated value (CSV) format. The PDF includes graphics, the CSV does not. For more information on export formats, see Exporting Reports , on page 2775.
- **Description**—A description of the schedule.
- **Status**—Whether the schedule is enabled (reports will be generated) or disabled (reports will not be generated).

Step 3 Click **OK** to save the schedule. New schedules are added to the schedules list on the Schedules tab.

Viewing Scheduled Report Results

Typically, report schedules include e-mail addresses to which generated reports are sent. You can also view reports generated from schedules in Report Manager. If you have system administrator or network administrator privileges, you can view results generated by other users' schedules.

Tip Report Manager maintains a copy of the last report generated by the schedule. You cannot retrieve previously generated reports.

Related Topics

- Overview of Report Manager , on page 2753
- Opening and Generating Reports , on page 2767
- Viewing Report Schedules , on page 2780
- Troubleshooting Report Manager , on page 2784

Step 1 In Report Manager, select the **Scheduled Reports** tab.

Step 2 Select the **Results** sub-tab.

All results that you are authorized to see are listed on this tab. The list shows the schedule name, the name of the report that was generated, the frequency of report generation, the date and time of the last schedule run (when the report was generated), the status of the report generation (Success or Failed), a link to the generated report (in the Last Report column), and the username of the person who created the schedule.

Tip If the status of a report is Failed, click the link to see the reason for failure.

Step 3 Double-click the icon link to the report in the Last Report column to open it. While viewing the report, you can save it to your workstation.

If you cannot find the report you are looking for, click the **Refresh** button to update the list with the latest information.

Enabling and Disabling Report Schedules

You can enable or disable report schedules to change whether reports are generated based on the schedules. By disabling a schedule, you can prevent reports from being generated without deleting the schedule. If you have system administrator or network administrator privileges, you can enable or disable another user's schedule.

Related Topics

- Overview of Report Manager , on page 2753
- Viewing Report Schedules , on page 2780

Step 1 In Report Manager, select the **Scheduled Reports** tab, then if necessary, the **Schedule List** sub-tab. This tab lists all currently-defined schedules that you are authorized to see.

Step 2 Select the schedule whose status you want to change and click either the **Enable** or **Disable** button.

Deleting Report Schedules

You can delete report schedules if you no longer need them. If you have system administrator or network administrator privileges, you can delete another user's schedule.

Tip If you do not want to generate reports from a schedule, but you want to keep the schedule definition, you can disable the schedule. Disabled schedules do not generate reports.

Step 1 In Report Manager, select the Scheduled Reports tab, then if necessary, the Schedule List sub-tab. This tab lists all currently-defined schedules that you are authorized to see.

Step 2 Select the schedule and click the **Delete** button below the list. You are asked to confirm the deletion.

When you delete a schedule, any results of the schedule are also deleted from the server and they are removed from the Results tab.

Troubleshooting Report Manager

Following are some problems you might encounter when using the Report Manager application, and some ways to resolve the problems.

Problem: Report Manager does not open, you get the message "Not able to connect to server."

Solution: Report Manager requires that the csmReportServer, rptDbEngine, and rptDbMonitor processes be started. Report Manager also relies on the Event Management service VmsEventServer. Ensure that all services are started and running correctly on the Security Manager server.

To view the current state of the processes, log into the Security Manager web interface using http://*SecManServer* :1741, where *SecManServer* is the DNS name of the server. From the Security Management Suite home page, click the **Server Administration** link to open CiscoWorks Common Services at the Admin page. Click **Processes** in the TOC on the left side of the window to open the list of processes that displays their current states. Select these processes and click **Start** to start them. If necessary, you might want to stop them, and then restart them. Wait for the processes to fully restart, then try again to open Report Manager.

Problem: When generating a report, you get the message "No records found."

Solution: This message indicates that there were no event records in the event data storage location that relate to the report type and the configured settings, or that the required Report Manager aggregation cycle has not completed. Investigate the following:

- Ensure that devices of the appropriate type are selected for monitoring as described in Selecting Devices to Monitor , on page 2711.
- Ensure that these devices are appropriately configured for sending events to Security Manager, and that events from the device appear in Event Viewer. Ensure that the device and Security Manager are using the same syslog port. For information on configuring the devices, see Configuring ASA and FWSM Devices for Event Management , on page 2704 and Configuring IPS Devices for Event Management , on page 2706. To check the syslog port that Security Manager is using, view the setting on the **Tools > Security Manager Administration > Event Management** page in Configuration Manager.
- For IPS devices, ensure that the certificate has not expired. Check the certificates table by selecting **Manage > IPS > IPS Certificates** in Configuration Manager and regenerate the certificate if necessary.
- The report settings might specify a time period in which no aggregated data exists for the report. Data is aggregated every 15 minutes, 1 hour (on the hour), and 1 day (at midnight). Try changing the time parameters of the report. See Editing Report Settings , on page 2769. Consider the following:
  - To see a Last 1 Hour report, a change of hour must occur since initially starting the Event Manager service. For example, if you start the service at 10:05, hourly reports are available only after 11:00.
  - To see a Last 1 Day report, a change of day must occur since initially starting the Event Manager service. For example, if you start the service at 10:05, you must wait until after midnight to see a daily report.
  - To see a Last 1 Week report, at least one full day cycle must occur. Weekly reports are based on daily reports.

- To see a Last 1 Month report, at least one full month must pass since starting the service.
- To see a custom time period report, at least one daily cycle must occur.

- If you create a new custom report, it might take up to one hour for data to become available. Also, ensure that the time period is Last 1 Hour until the report is old enough to have data for other time periods.

Problem: You cannot get reports for a specific device.

Solution: Investigate the following:

- The device must have been selected for event management during the reporting time-frame as described in Selecting Devices to Monitor , on page 2711. Even if a device is selected, Report Manager might not support all devices that are supported for Event Viewer. For information on the supported device types, see Understanding Report Management , on page 2747.
- The report settings might exclude the device. Unless the report settings indicate that All Devices are considered in the report, check the device selection to ensure the device is included. See Editing Report Settings , on page 2769.
- The report settings might specify a time period in which no data exists for the device. Try changing the time parameters of the report. See Editing Report Settings , on page 2769.
- If your organization uses Cisco Secure ACS to control access to the application, you can view reports on a device only if you have at least View privileges to the device. Check whether you have the required permissions.

Problem: You cannot see data in certain IPS predefined reports after specifying values for each of signature, victim IP, and attacker IP.

Solution: The top attackers, top victims, and top signatures predefined reports include criteria for signature, victim IP address, and attacker IP address. However, you cannot configure all three criteria in a predefined report. Instead, you can configure the criteria on which the report is based (for example, victim IP address for the top victims report) plus one, and only one, of the remaining values. Note that this limitation does not apply to the other criteria, such as Blocked and Top.

Problem: You cannot see data in certain Firewall predefined reports after specifying values for each of service, source IP, and destination IP.

Solution: The top destinations, top services, and top sources predefined reports include criteria for service, source IP address, and destination IP address. However, you cannot configure all three criteria in a predefined report. Instead, you can configure the criteria on which the report is based (for example, service for the top services report) plus one, and only one, of the remaining values. Note that this limitation does not apply to the other criteria, such as Permit/Deny and Top.

Problem: Statistics for VPN reports are not available.

Solution: VPN statistics are partially obtained directly from the device rather than from events stored in the event data storage location. To obtain the statistics, Report Manager must be able to log into the device and use show commands. Ensure that the device properties for your VPN devices have the correct credentials for logging in.

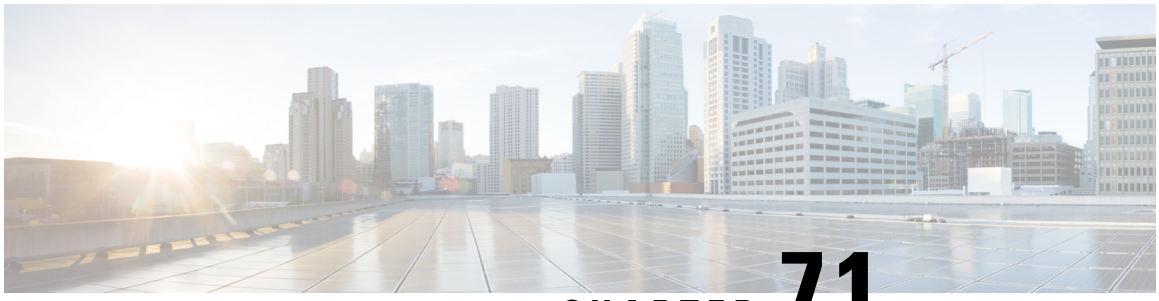
Problem: Scheduled reports are not getting sent to recipients.

Solution: Ensure that the SMTP server is configured correctly and that a valid source e-mail address is configured for Security Manager. For more information, see Configuring an SMTP Server and Default Addresses for E-Mail Notifications , on page 27.

Problem: When exporting the device status report, you get the following error. "Windows cannot find 'acrord32'. Make sure you typed the name correctly and then try again".

Solution: Execute the following:

- Install Adobe Reader on the server, if it is not installed already. MS-Windows will not be able to locate the acrord32.exe file if Adobe Reader is not installed.
- Though Adobe Reader is installed, the error might be thrown if you are using Windows XP, Vista, 7,8.1 or 10. This is a known error of Microsoft Windows. Microsoft is yet to provide patch for this error. Do the following:
  - Go to the location where the exported report file is saved. Right-click and choose Open with > Adobe Reader. Despite the error, the file is created without the defined format. Hence, you can open it using a PDF reader.



CHAPTER 71

Health and Performance Monitoring

The Health and Performance Monitor (HPM) application lets you monitor key health and performance data for ASA devices, IPS devices, and VPN services by providing network-level visibility into device status and traffic information.

A variety of views are provided—All Devices, Firewall Devices, IPS Devices, VPN Summary, and so on—and you can create your own customized views. A configurable listing of device alerts is also available.

This ability to monitor key network and device metrics lets you quickly detect and resolve device malfunctions and bottlenecks in the network.

This chapter contains the following topics:

Health and Performance Monitor Overview

The Health and Performance Monitor is a stand-alone application that you can launch from the other stand-alone Security Manager applications (Dashboard, Configuration Manager, Event Viewer, Report Manager, and Image Manager) or from the Cisco Security Manager Client login screen accessed from the Windows Start menu.

The HPM application complements the Event Viewer and Report Manager applications, as follows:

- **Event Viewer** – Monitors your network for syslog (system log) events from ASA and FWSM devices and their security contexts, and for SDEE (Secure Device Event Exchange) events from IPS devices and virtual sensors. These events include firewall traffic information, NAT events, failover events, IPS alerts, and so on. Event Viewer collects and displays this information, organized into a variety of views. See Introduction to Event Viewer Capabilities , on page 2677 for more information.
- **Report Manager** – Collects, displays and exports network usage and security information for ASA and IPS devices, and for remote-access IPsec and SSL VPNs. These reports aggregate security data such as

top sources, destinations, attackers, victims, as well as security information such as top bandwidth, duration, and throughput users. Data is also aggregated for hourly, daily, and monthly periods. See Understanding Report Management , on page 2747 for more information.

- **Health and Performance Monitor** (HPM) – Monitors and displays key health, performance and VPN data for ASA and IPS devices in your network. This information includes critical and non-critical issues, such as memory usage, interface status, dropped packets, tunnel status, and so on. You also can categorize devices for normal or priority monitoring, and set different alert rules for the priority devices.

You can add notes to displayed alerts, you can "acknowledge" them, and you can clear them. When an alert is cleared, it is removed from the Alerts display; however, the alert information is retained in a database for 30 days. See Alerts: Acknowledging and Clearing , on page 2829 for more information about adding notes, and acknowledging and clearing alerts.

Note You can use the Alerts History window to access and view previously cleared alerts, as described in Alerts: History , on page 2829.

This section contains the following topics:

Trend Information

The Health and Performance Monitor periodically polls monitored devices for status and performance data. This information is used for alert generation, and to display real-time views and historical trends based on aggregated data.

Trends are displayed graphically for a specific set of metrics. Each trend for the currently selected device is represented as a graph generated for a chosen time interval. Comparing current values with the weekly averages for CPU and memory usage, for example, can provide an operational context for the selected device. Available trend intervals for monitored devices are one hour, 24 hours, and one week.

Metrics used for generating trends include:

- CPU usage
- Memory usage (only for single-context devices)
- Connections per second (firewall devices)
- Translations per second (firewall devices)
- Inspection load (IPS devices)
- Missed packets as a percentage (IPS devices)
- Number of VPN tunnels
- Number of RA VPN sessions
- Total VPN throughput

- Firewall throughput
- Total dropped packets (firewall interfaces)

For additional graphical information about the health and performance of a specific device, you can launch the related device manager by right-clicking the entry for a device, a cluster node, or the system context for a multi-context device, and then choosing **Device Manager** from the pop-up menu. See Starting Device Managers , on page 2849 for more information about the device managers.

Monitoring Multiple Contexts

The Health and Performance Monitor can monitor single- and multiple-context ASA devices. For multiple-context devices, each context is monitored and displayed as if it was a separate device.

Each context will be polled separately for all applicable metrics, with HPM polling a maximum of five contexts at a time from any given device. For devices with more than five contexts, data will be acquired from each successive batch of five contexts, with each batch being polled progressively during successive polling cycles. This means that all contexts may not be updated at the same time.

For multiple-context devices, basic device health—memory usage, device status, and so on—is monitored only on the physical device (that is, from the system context), while traffic data—number of connections, number of translations, dropped packets and so on—are monitored at context level.

For virtual contexts, CPU usage data are used only for pattern analysis, not for alert generation. Only interface-status alerts will be generated for virtual contexts.

HPM Access Control

The privileges assigned to your user name control what you can do in Health and Performance Monitor. If you use local users, or other types of non-ACS access control, then all users have access to HPM. However, the following access limits are imposed:

- You must have system administrator privileges to enable or disable Health and Performance Monitoring in Security Manager, as described in Health and Performance Monitor Page , on page 547.
- You must have system administrator, network administrator, or approver privileges to select or deselect devices for monitoring, as described in Managing Monitored Devices , on page 2791.
- You also must have system administrator, network administrator, or approver privileges to configure alerts and notifications, as described in Alerts: Configuring , on page 2821.

If you use ACS to control access to Security Manager, you can also control the following:

- You can control access to the Health and Performance Monitor application using the View > Health and Performance Monitor privilege (part of Role Management in ACS). Using this privilege, you could prevent certain users from accessing HPM, or create roles that allow access to HPM without allowing access to Event Viewer or Report Manager. All default ACS roles are permitted to use the Health and Performance Monitor application.
- Use the Modify > Policies > HPM Monitoring privilege to control which users can select and deselect the devices that are monitored (see Managing Monitored Devices , on page 2791), configure alerts and notifications (see Alerts: Configuring , on page 2821), and annotate and acknowledge alerts (see Alerts: Acknowledging and Clearing , on page 2829). All default ACS roles except Help Desk and Super Admin have this permission.

- Users can view health and performance information for a device only if they have at least View privileges for the device.
- You can control access to the Health and Performance Monitoring administrative settings page (in Security Manager's Configuration Manager) where HPM is enabled or disabled, as described in Health and Performance Monitor Page , on page 547. The user must have the Modify > Policies > HPM Admin privilege to access this page (or any other administrative settings page). All default ACS roles except Help Desk can view the page, but only System Administrators can change the setting.

For information on integrating Security Manager with Cisco Secure ACS, see the Installation Guide for Cisco Security Manager .

Preparing for Health and Performance Monitoring

In order to use the Health and Performance Monitor (HPM), you must configure Security Manager, enable the HPM application, and configure device monitoring, as follows:

- Basic Threat Detection must be enabled on ASA 8.0+ devices in order to monitor metrics such as ACL Dropped Packets, Scanning Threat Dropped Packets, Inspection Dropped Packets, and Syn Attack Dropped Packets. (Basic Threat Detection is enabled by default on these ASA devices.)
- To receive alert notifications via email, you must have configured the SMTP server and administrator email ID on the **System Preferences** page of the Security Manager server. See the *Installation Guide for Cisco Security Manager for more information.* (Specifying email addresses for alert notifications from the Health and Performance Monitor application is described in Alerts: Configuring , on page 2821.)
- Health and Performance Monitoring must be enabled in Security Manager, as described in Health and Performance Monitor Page , on page 547.
- In HPM, specify the devices to be monitored, in both Normal and Priority modes, as described in Managing Monitored Devices , on page 2791.

Note To prevent read time-outs for ASAs, those devices must be configured to use only certain SSL/TLS protocol versions when acting as a server, as described in Setting Up SSL (HTTPS) on PIX Firewall, ASA and FWSM Devices , on page 59.

- Enable and configure the device threshold values and state-change rules that define when alerts and email notifications are triggered. This process is described in Alerts: Configuring , on page 2821.

Note We also recommend configuring monitored devices to use a Network Time Protocol (NTP) server for synchronized timing. See NTP Page , on page 2021 for more information.

After you have completed these steps, HPM begins polling the specified devices and displays health information and alerts.

Launching the Health and Performance Monitor

Use the Health and Performance Monitor (HPM) to view status information and alerts collected from monitored firewall and IPS devices across your network. For more information about selecting devices for monitoring, see Managing Monitored Devices , on page 2791.

To launch HPM, do any one of the following:

- Choose **All Programs** > **Cisco Security Manager Client** > **Cisco Security Manager Client** from the Windows Start menu (your command path may differ slightly), and then select **Health and Performance Monitor** as the Default View during login.
- Choose **Launch** > **Health and Performance Monitor** from the Configuration Manager, Event Viewer, Image Manager, or Report Manager applications.
- Click the Health and Performance Monitor button on the quick-launch toolbar in the Configuration Manager or Image Manager window.

If you are currently not logged into a Security Manager application, you are prompted to log in. (For more information about starting and logging into a Security Manager client application, see Logging In to and Exiting Security Manager , on page 11). Otherwise, the HPM Window , on page 2792 is opened using the same user account you used to log into the other application.

Note As described above, you can "cross-launch" HPM from any of the other Security Manager client applications. You can similarly cross-launch any of the other client applications from Health and Performance Monitor by choosing the desired application from the **Launch** menu, or clicking the appropriate quick-launch button.

Managing Monitored Devices

The HPM device selector is used to add and remove devices from both the "normal" and "priority" monitoring lists. You can also use the device selector to transfer devices between the two lists.

Note After enabling a device for monitoring in HPM, it can take up to 5 minutes for priority devices and 10 minutes for non-priority devices before actual values for HPM parameters can be seen in the device summary.

To use the HPM device selector:

Step 1 Choose **Device Selector** from the Tools menu to open the device selector window; the device-management screen is displayed.

The All Devices section on the left lists all ASA and IPS devices in the Security Manager inventory that can be monitored. (For example. HPM supports monitoring of version 7.0.1 and later IPS sensors only. Earlier IPS versions are not displayed in the device selector.)

All devices currently assigned to the Normal monitoring list and the Priority monitoring list are displayed in the two sections on the right side of the window.

Step 2 To add a device to the Normal list, select the device in the All Devices list and then click the > button between the All Devices list and the Normal Monitored Devices list.

The procedure for moving a device to the Priority Monitored Devices list is the same: use the > button between the All Devices list and that list.

Step 3 To remove a device from either Monitored list, returning it to the All Devices list, select the device and then click the appropriate < button.

Step 4 To transfer a device from one Monitored list to the other, highlight that entry and click the Up or Down button to move it to the upper or lower list respectively.

Step 5 Click Next at the bottom of the window to display the VPN-selector screen.

All monitored devices and their individual contexts, if any, are listed; each entry includes a checkbox for remote-access (RA) and one for site-to-site (S2S) VPN selection.

Note Starting from Cisco Security Manager 4.10, all the contexts for ASA 9.5(2) and above will be listed in the Device Selector. From the Device Selector, you can now monitor the RA and site-to-site VPN for all user contexts by enabling the corresponding check box.

You can use the List Filter field on this page to filter the list, as described in Using The List Filter Fields , on page 2805.

Step 6 Select the types of VPN to be monitored on specific devices by checking the appropriate boxes.

Step 7 Click **Save** to save and apply your changes, and close the device selector.

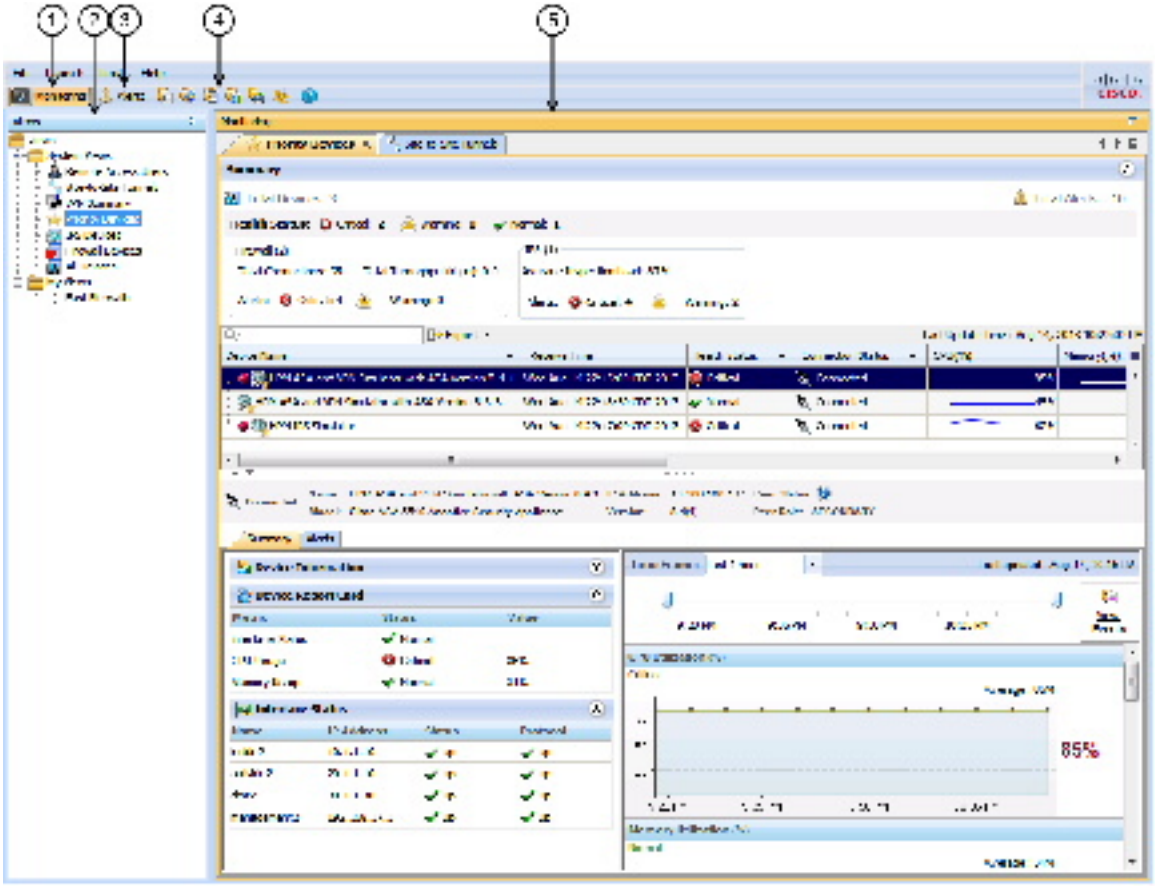
HPM Window

The Health and Performance Monitor (HPM) application window is where you view status information and alerts collected from monitored firewall and IPS devices, as well as remote-access (RA) and site-to-site (S2S) VPN information, across your network.

Note See Managing Monitored Devices , on page 2791 for information about specifying the devices to be monitored.

The following illustration presents the primary features of the HPM window.

Figure 70: Health and Performance Monitor Window



Health and Performance Monitor Window

1	**Monitoring button.**	4	**Quick-launch buttons.**
2	Views	5	Monitoring/Alerts display area.
3	Alerts button.		

The HPM window consists of three main elements:

- **Monitoring button (1)** – Click this button to view device and VPN health and performance data. See HPM Window: Monitoring Display , on page 2811 for more information.
- **Views (2)** - When in the Monitoring view, the left pane of the HPM main window displays a list of available views. See Managing Device Views , on page 2807 for more information.

as shown in the following illustration.

- **Alerts button (3)** – Click this button to view a table of alerts in the window's display area. See HPM Window: Alerts Display , on page 2819 for more information.

- **Quick-launch buttons (4)** – Click any button to cross-launch the related Security Manager client application.
- **Monitoring/Alerts display area (5)** – This section of the window displays either Monitoring information for devices and VPNs, or a table of alerts generated by monitored devices. The Monitoring and Alerts buttons are used to switch back and forth between these two displays.

Working with Table Columns

You can customize the different tables of information presented in HPM as follows:

- Sort a table such entries in a particular column are in ascending or descending order.
  - Click a column heading—anywhere but on a drop-down menu button—to sort the table such that the column entries are in ascending order (indicated by a small grey up-arrow).
  - Click the heading again to sort the entries are in descending order (indicated by a small grey down-arrow).
  - Click the heading again to return the table to its original order of display (the direction icon is removed).
- Hide and show various columns; the columns available for display depend on the particular table.
- Apply a column filter, meaning the table displays only entries that fit the specified criteria.

This section contains the following topics:

- Showing and Hiding Table Columns , on page 2794
- Column-based Filtering , on page 2803

Showing and Hiding Table Columns

You can customize the different tables presented in HPM by hiding and showing various columns of information; the columns available for display depend on the particular table.

Note The column headings are menus that you can use to further filter the table by hiding or showing entries according to chosen parameters, as described in Column-based Filtering , on page 2803.

To show or hide specific columns displayed for a table:

1. Click the Columns button on the right side of the column headings to open the Choose Columns to Display dialog box.

All columns available for the current view are listed.

1. Select and deselect the columns to be shown and hidden.
2. Click **OK** to close the dialog box.

Only the selected columns are displayed for this table.

The following topics describe the individual columns available for various tables:

- Table Columns: Device-related Views , on page 2795
- Table Columns: VPN-related Views , on page 2798
- Alert Table Columns , on page 2802

Table Columns: Device-related Views

You can customize the tables presented in the Monitoring pane for the device-related views by hiding and showing various columns of information; the columns available for display depend on the particular view.

The order of the entries in the Choose Columns to Display dialog box reflects the ordering of the columns when displayed. (However, the ordering of the rows in the following table does not necessarily reflect ordering of the columns as displayed.) See Showing and Hiding Table Columns , on page 2794 for information about opening the Choose Columns to Display dialog box.

The following table presents all available data columns for the device-related Monitoring views: Priority Devices, IPS Devices, Firewall Devices, All Devices, and all custom views based on these system views. Some of the listed columns are not available for specific views, as indicated.

Table 983: Available Table Columns for Device-related Views

Column Name	Available in View	Description
Device Name	IPS, Firewall	Name assigned to the device; that is, the Host Name as defined on the Device Properties: General Page , on page 110 of the Device Properties window. Column-based Filtering , on page 2803 is available. The Name is preceded by an icon indicating device type. This icon in turn may be preceded by a device-alerts indicator: a red dot indicates one or more critical alerts (and possibly warnings), while a yellow dot indicates one or more warnings only. The area is blank for a device with no alerts. You can "hover" the mouse pointer over the dot to view a pop-up displaying the number of critical alerts and the number of warnings on the device. A gold star is added to the device icon itself to indicate Priority monitoring.
Receive Time	IPS, Firewall	Poll date and time for this entry (format is: day-of-week MMM DD HH:MM:SS your-time-zone YYYY).
IP Address	IPS, Firewall	IP address of this device. Column-based Filtering , on page 2803 is available.

Column Name	Available in View	Description
Health Status	IPS, Firewall	Current overall health of the device: Critical, Warning, or Normal. Column-based Filtering , on page 2803 is available. **Note** Overall health is defined by the most critical of any of the health metrics. For instance, if all the selected metrics on the device are normal except for one that is critical, overall device health becomes critical.
Connection Status	IPS, Firewall	Indicates HPM's ability to connect to/poll the device: Connected, Authentication Error, Certificate Mismatch Error, Connection error, Timeout during Read operation, or Service unavailable. Column-based Filtering , on page 2803 is available. **Note** If the device is not selected as a Normal or Priority Monitored Device in HPM (Tools > Device Selector), this status will not apply. Changes to Monitored Device selection may take several minutes to become effective and be reflected on screen. Any information displayed for a non-"Connected" device is from the indicated Receive Time, prior to connection failure.
Memory (%)	IPS, Firewall	Memory usage as a percentage of the total available.
CPU (%)	IPS, Firewall	CPU usage as a percentage of the total available.
Model	IPS, Firewall	Device type and model number. For example, ASA 5510, or IPS 4270.
Version	IPS, Firewall	Software version running on this device. Column-based Filtering , on page 2803 is available.
Inspection Load (%)	IPS	Inspection load on the device when polled, as a percentage.
Missed Packet(%)	IPS	Dropped packets as a percentage of total packets inspected.
Sensor App Status	IPS	Current Sensor App (Analysis Engine) status: Up or Down. Column-based Filtering , on page 2803 is available.
Main App Status	IPS	Current Main App status: Up or Down. Column-based Filtering , on page 2803 is available.
Collaboration App Status	IPS	Current Collaboration App status: Up or Down.
License Expiration Status	IPS	Status of the sensor's license, based on red and yellow threshold values set on the sensor: Normal, Warning, or Critical. Column-based Filtering , on page 2803 is available.
In Bypass Mode	IPS	Whether bypass mode is enabled on the sensor: Yes or No. Column-based Filtering , on page 2803 is available.

Column Name	Available in View	Description
Event Retrieval Status	IPS	Status of the IPS event retrieval: Normal, Warning, or Critical. Column-based Filtering , on page 2803 is available.
Global Correlation Status	IPS	For a sensor participating in global correlation, its update status: Normal (last update was successful), Warning (no successful update within the past day [86,400 seconds]), or Critical (no successful update within the last three days [259,200 seconds]). Column-based Filtering , on page 2803is available.
Signature Update	IPS	The number of the most recent signature update applied to this sensor; for example, S574. Column-based Filtering , on page 2803 is available.
Firewall Mode	Firewall	Operating mode of this device: Routed, Transparent, or Mixed. Column-based Filtering , on page 2803 is available.
Context Mode	Firewall	Context mode of this device: Single or Multiple. Column-based Filtering , on page 2803 is available.
Connections	Firewall	Number of active connections when device was polled.
Xlates	Firewall	Address translation counter.
Connections/second	Firewall	Number of connections established per second.
Translations/second	Firewall	Number of translations per second.
Failover Status	Firewall	If this device is part of a failover pair, its current state: Active or Standby. Column-based Filtering , on page 2803 is available.
Failover Host Role	Firewall	If this device is part of a failover pair, its current role: Primary or Secondary. Column-based Filtering , on page 2803 is available.
Failover Peer Role	Firewall	If this device is part of a failover pair, current role of its peer device: Primary or Secondary. Column-based Filtering , on page 2803 is available.
Failover Peer Status	Firewall	If this device is part of a failover pair, current status of its peer: Active or Standby Ready. Column-based Filtering , on page 2803 is available.
Used Memory (MB)	Firewall	Amount of memory (in megabytes) in use when device was polled. Column-based Filtering , on page 2803 is available.
Free Memory (MB)	Firewall	Amount of memory available (in megabytes) when device was polled. Column-based Filtering , on page 2803 is available.
Max. Connections	Firewall	Peak number of connections. Not available for ASA groups.
Max. Xlates	Firewall	Peak number of address translations. Not available for ASA groups.

Column Name	Available in View	Description
Throughput (Kbps)	Firewall	Average device throughput in kilobits per second. For an ASA 9.0+ cluster, this the total throughput for all interfaces in the group.
ACL Dropped Packets	Firewall	The number of packets dropped because they failed an access control list rule. Available only at cluster level for ASA clusters; not available for individual nodes.
Scanning Threat Dropped Packets	Firewall	If scanning threat detection is enabled, the number of packets dropped because they failed scanning threat inspection. If not enabled, "NA" is displayed. Available only at cluster level for ASA clusters; not available for individual nodes.
Inspection Dropped Packets	Firewall	If application inspection is enabled, the number of packets dropped because they failed application inspection. If not enabled, "NA" is displayed. Available only at cluster level for ASA clusters; not available for individual nodes.
Syn Attack Dropped Packets	Firewall	Number of packets dropped because of SYN flooding. Available only at cluster level for ASA clusters; not available for individual nodes.
Total Interface Dropped Packets	Firewall	Total number of dropped packets on all interfaces. Available only at cluster level for ASA clusters; not available for individual nodes. **Note** You can view the number of per-interface dropped packets on the tabbed Interface panel presented in the detail section for the selected device.
Analysis Engine Memory (%)	IPS	Percentage of memory assigned to the Analysis Engine currently in use.
Role in Group	Firewall	The role of this member of an ASA load-balancing group: Group, Control, or Data. A group is managed by Security Manager as a single device with multiple nodes. Thus, each group is displayed in HPM as single entry, which you can expand in order to view a list of nodes.
* All of these columns are available in the All Devices and Priority Devices views.		

Table Columns: VPN-related Views

You can customize the tables presented in the Monitoring pane for the VPN-related views by hiding and showing various columns of information; the columns available for display depend on the particular view.

The order of the entries in the Choose Columns to Display dialog box reflects the ordering of the columns when displayed. (However, the ordering of the rows in the following table does not necessarily reflect ordering of the columns as displayed.) See Showing and Hiding Table Columns , on page 2794 for information about opening the Choose Columns to Display dialog box.

The following table presents all available data columns for the VPN-related Monitoring views: Remote Access Users (RA), Site-to-Site Tunnels (S2S), VPN Summary, and all custom views based on these system views. Some of the listed columns are not available for specific views, as indicated.

When a device sends trap message, Cisco Security Manager captures the trap and posts it to the Site to Site Tunnels page in Health and Performance Monitoring application. Till Cisco Security Manager version 4.16, devices used to send the trap messages over IPv4 only. Beginning with Cisco Security Manager 4.17, the SNMP traps are captured using IPv6. Thus, Cisco Security Manager receives the trap messages; maps the IPv6 address of the device to the device details; displays an alert about the trap in Site to Site Tunnels page of the Health and Performance Monitoring application. The status is displayed in the Health and Performance Monitoring application after couple of refresh cycles.

Note Beginning with Security Manager version 4.9, the Health and Performance Monitoring application monitors and displays the site-to-site tunnels that have IPv6 address configured, in addition to the IPv4 based tunnels. Also the Email and Trap notifications now contain IPv6 addresses in addition to IPv4 addresses.

Table 984: Available Table Columns for VPN-related Views

Column Name	Available in View	Description
Receive Time	RA, S2S, VPN Summary	Poll date and time for this entry (format is: day-of-week MMM DD HH:MM:SS your-time-zone YYYY).
Firewall Name	RA, S2S, VPN Summary	Name of this device, as provided in the Security Manager inventory. Column-based Filtering , on page 2803 is available.
User Name	RA	User log-in name used to establish this session. Column-based Filtering , on page 2803 is available.
User Group Policy	RA	The name of the ASA VPN user group to which this user belongs. Column-based Filtering , on page 2803 is available.
Gateway	RA	IP address of the VPN gateway to which the user is connected. Column-based Filtering , on page 2803 is available.
Assigned IP	RA	Private IP address assigned to the remote client for this session; also known as the “inner” or “virtual” IP address.
Public IP	RA	Publicly routable IP address assigned to the client. Column-based Filtering , on page 2803 is available.
Connection Initiation Time	RA	Time and date (HH:MM:SS day-of-week MMM DD YYYY) when connection was initiated. Time is displayed in 24-hour Coordinated Universal Time (UTC) notation.
Duration	RA	Elapsed time (HH:MM:SS) between the session initiation and the most-recent device poll.

Column Name	Available in View	Description
Client Version	RA	VPN client software, and version, running on the remote peer; for example, AnyConnect Windows 3.0, or Mozilla 4.0. Column-based Filtering , on page 2803 is available.
EndPoint OS	RA	Operating system in use on remote peer; for example, Windows or Windows NT. Column-based Filtering , on page 2803 is available.
Authentication Method	RA	User password, certificate, or preshared key. Column-based Filtering , on page 2803 is available.
Encryption	RA, S2S	Data encryption algorithm this session is using. Column-based Filtering , on page 2803 is available..
Tunnel Type	RA, VPN Summary (as “Type” only)	Type of tunnel or connection. These include Clientless, IPsec, and Secure Client. Column-based Filtering , on page 2803 is available.
Throughput (Kbps)	RA, S2S	Bytes received plus bytes transmitted, in kilobits per second.
Session ID	RA	Identifier assigned to this session.
Inactive Time	RA	Amount of time this session has been inactive.
IP Address	S2S, VPN Summary	IP address of this device. Column-based Filtering , on page 2803 is available.
Local Endpoint	S2S	IP address of local tunnel interface.
Remote Endpoint	S2S	IP address of remote tunnel interface.
Local Subnet	S2S	Address of local protected subnet.
Remote Subnet	S2S	Address of remote protected subnet.
Uptime	S2S	Current duration of this tunnel.
Connection Time	S2S	Time and date (HH:MM:SS day-of-week MMM DD YYYY) when connection was initiated. Time is displayed in 24-hour Coordinated Universal Time (UTC) notation.

Column Name	Available in View	Description
Status	S2S	Tunnel connection status; this will be Up or Down. An alert is issued when a tunnel goes down a specified number of times; see Column-based Filtering , on page 2803 for more information. **Tip** You can click on a Down notification hyperlink in the Status column to view the IPSec VPN Events for that device in Event Viewer. Event Viewer will show IPSec VPN Events for the device within a time range depending on the polling interval for that device. If it is a priority device, the time range will be 5 minutes before until 5 minutes after the first down notification was received. For non-priority devices, the time range will be +/- 10 minutes instead of 5 minutes.
Health Status	VPN Summary	Current overall health of the underlying device: Critical, Warning, or Normal. Column-based Filtering , on page 2803 is available.. **Note** Overall health is defined by the most critical of any of the health metrics. For instance, if all the selected metrics on the device are normal except for one that is critical, overall device health becomes critical.
Connection Status	VPN Summary	Remote connection status; this will always be Connected. (HPM cannot present information about previous connections.) Column-based Filtering , on page 2803 is available.
Monitoring Type	VPN Summary	Types of VPN connections being monitored. Column-based Filtering , on page 2803 is available.
Active Sessions	VPN Summary	Current active sessions (S2S, IPSec RA, client-based SSL RA, and clientless SSL RA).
Peak Sessions	VPN Summary	Peak numbers of concurrent sessions (S2S, IPSec RA, client-based SSL RA, and clientless SSL RA).
Total Users	VPN Summary	Current remote user total (S2S, IPSec RA, client-based SSL RA, and clientless SSL RA).
Inactive Sessions	VPN Summary	Number of inactive sessions.
Total VPN Throughput (Kbps)	VPN Summary	Sum of all VPN traffic; that is, sum of RA and S2S throughput values, in kilobits per second. Column-based Filtering , on page 2803 is available.

Column Name	Available in View	Description
ACL Name	Site-to-Site Tunnels	Beginning with version 4.9, Security Manager enables you to view the Access Control List (ACL) name that is associated with the selected Site-to-Site tunnel. This column name is selected by default. **Note** In the Health and Performance Alerts Display, Tunnel up/down Alert now also displays the ACL Name in the Description column. Similarly, Email and Trap notifications also display the ACL Name in the Description column.
Remarks	Site-to-Site Tunnels	(Optional) This column displays the remarks corresponding to the ACL Name. **Note** Alert, Email, and Trap notifications do not contain Remarks as part of the description field.
Limitation: When Cisco Security Manager Daemon Manager service is started, the HPM application uses the latest configuration from the Configuration Archive to extract the ACL Name and Remarks associated with the Site-to-Site VPN tunnel. When the VPN tunnel is identified by HPM, it uses the extracted data to display the ACL Name and Remarks columns in the S2S view. If the VPN tunnel comes up before the data is available in HPM, the ACL Name and Remarks columns may not display the data until the next UI refresh. Similarly, the Alerts Display may not show the ACL Name in the Description column if the Alert is generated before the data is extracted by HPM. This might occur during upgrade to Security Manager version 4.9 from a previous version. If the same Alert appears in the next polling, the ACL Name is added to the Description. **Tip:** Sometimes you may notice discrepancy in the content of the Remarks column. Check if the latest configuration from the Configuration Archive contains the Remarks. If the Remarks are added or updated by Out-of-Band changes, you must perform rediscovery of the device.		

Alert Table Columns

You can customize the Alerts table by hiding and showing various columns of information.

The order of the entries in the Choose Columns to Display dialog box reflects the ordering of the columns when displayed. (However, the ordering of the rows in the following table does not necessarily reflect ordering of the columns as displayed.) See Showing and Hiding Table Columns , on page 2794 for information about opening the Choose Columns to Display dialog box.

Table 985: Available Data Columns for the Alerts Table

Column Name	Description
Device Name (always selected)	Name of this device on which this alert was triggered, as provided in the Security Manager inventory. Column-based Filtering , on page 2803 is available.
Node	The Node Name if this alert was generated by a member of an ASA load-balancing cluster Column-based Filtering , on page 2803 is available.

Column Name	Description
Device Type	Type of device: ASA or IPS. Column-based Filtering , on page 2803 is available.
Severity	Alert severity: Critical, Warning, or Normal. Column-based Filtering , on page 2803 is available.
Status	Current device status: Active or Acknowledged. Column-based Filtering , on page 2803 is available.
Description	Description of the alert. For example, “Device Health Critical” or “Device Polling: Authentication Error.”
First Seen	Date and time when this alert was first logged (day-of-week MMM DD, YYYY HH:MM:SS AM/PM). Time is based in your time zone. Column-based Filtering , on page 2803 is available.
Last Seen	Date and time when this alert was first logged (day-of-week MMM DD, YYYY HH:MM:SS AM/PM). Time is based in your time zone. Column-based Filtering , on page 2803 is available.
Notes	You can annotate an alert when you acknowledge it. Any annotations are displayed in this field. See Alerts: Acknowledging and Clearing , on page 2829 for more information.

Column-based Filtering

You can filter the various tables in HPM based on the contents of specific columns. When you apply a column filter, the table is filtered to include only those entries with the specified criteria in that column.

Note See Working with Table Columns , on page 2794 for other methods of altering table displays.

Tips

- Column filters are cumulative: for an entry to appear in the filtered table, it must meet all column filter criteria. You cannot create a set of ORed column filters.
- You can filter on the contents of most but not all columns. If a column does not have a down arrow, you cannot filter on it. For example, you cannot filter on Receive Time in All Devices view.
- The filter icon (a funnel) appears in the heading of a filtered column.
- For a description of the available columns, see Showing and Hiding Table Columns , on page 2794.

To filter a table according to a particular column parameter:

Click the down-arrow in the heading of a column and choose one of the following from the drop-down menu:

- **All** – Choose **All** to remove or “undo” a filter from this column. The table is updated to show all entries for this parameter. For example, if you filtered the Severity column of the Alerts table to display only Critical alerts, choosing this option will re-display all Critical and Warning alerts.

- **Custom** – Choose **Custom** to open the Custom Filter dialog box where you can create a custom filter based on the information in that column. See Custom Filtering , on page 2804 for more information.
- A specific entry – The drop-down menu includes all values relevant to the column; choose one to display only that group of entries. For example, choosing **Critical** from the Severity column of the Alerts table filters the table to display only Critical alerts.

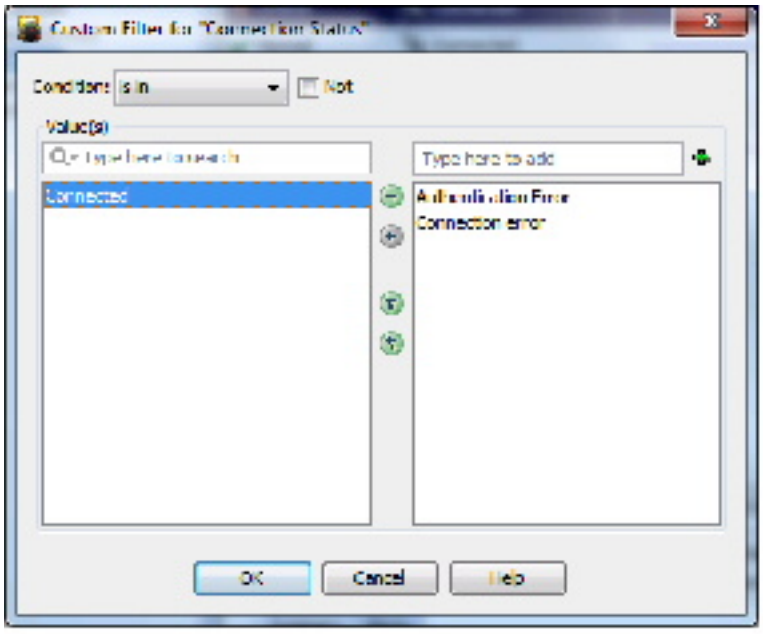
Custom Filtering

The following procedure explains how to create a custom column-based filter, one in which you are not simply selecting a value from the column's drop-down list. Refer to HPM Window: Alerts Display , on page 2819 for information about other column-based filtering options.

Step 1 Click the down-arrow in the heading of a column and choose **(Custom)** from the drop-down menu.

The Custom Filter dialog box for that column opens.

Step 2 In the Custom Filter dialog box, select the desired values. The following illustration shows a typical example of this dialog box.



These are the controls you might find in the Custom Filter dialog box (not all controls appear for every instance):

- **Condition** – Choose the condition applied to the selected Values.

Typically this is **is in**, meaning each of the Values you select must be "in" a column in order for that entry to be displayed in the filtered table.

- **Not** – Check this box to create a negative Condition.

With **is in** as the chosen Condition, this would mean the selected Values cannot be in the column. In other words, the table is filtered such that entries with these Values in the column are not displayed.

- **Values** list – A few instances of the dialog box present one list of Values from which to select: simply check the desired options.

Available and selected **Values** lists – In most cases, the dialog box presents two Values lists, as shown in the previous illustration. To select a value for the custom filter, highlight it in the left list, which contains available values for the column, and click the right arrow to add it to the list of selected values on the right. You can select multiple values.

The items in the available Values list are determined by the values currently present in the selected column of the source table.

If there are a lot of available values, you can search for a specific value by typing in the List Filter field above the list. For more information, see Using The List Filter Fields , on page 2805.

You can also select, or deselect, values using the following techniques:

- Type a Value name into the text field above the selected Values list and click the + button; the Value is added to the selected Values. This technique is useful if there is a large number of available Values, or if you want to filter on a value that is not present in the available Values list.
- Double-click an item in either list to move it to the other list.
- Click one of the double-arrow buttons to move all items from one list to the other, regardless of any selected values.

Step 3 Click **OK** to close the dialog box.

The table is updated to show only those entries that satisfy all currently applied filters.

Using The List Filter Fields

A List Filter field is provided above the devices and VPNs lists in the Monitoring display, above the alerts table in the Alerts display, above the device list on the VPN page of the Device Selector, and in the View Cleared Alerts window. In each case, you can use the List Filter field to quickly locate any entries in the related table that contain a specified text string.

Note The found text can be part of any data field associated with an entry. For example, as you type “license” into the Alerts List Filter field, the Alerts table is filtered to show only those alerts related to imminent license expiration. (Any matched entries are listed even if the relevant data column—in this example, Detail—is not displayed, which could cause confusion. See Showing and Hiding Table Columns , on page 2794 for more information about hiding table columns.)

Figure 71: Health and Performance Monitor: List Filter Field

1	Filter-parameters button	2	Clear button

To search for a specific text string in the devices list, the VPNs list, the Alerts table, or the View Cleared Alerts window:

- Click in the List Filter field to place the text cursor, and then begin typing.

These are "live filter" fields. That is, as you type each character, entries that do not include your current text string are removed from the list or table. For example, suppose in an extensive list of alerts there is one with a Status of "Device Health Critical," and that none of the other alerts include any text strings containing the letters *hea* . You want to use the List Filter field to quickly locate that one alert, so you begin to enter the word "health." That alert is the only one displayed after you have typed the first three letters.

To clear a List Filter field:

- Click the clear button at the right side of the field.

This button appears when you begin typing in the field. (You also can highlight the characters and press the Delete or Backspace key on your keyboard.)

When you clear the List Filter field, all entries in the list are again displayed.

You can tune the filter results by specifying the information (columns) searched, by selecting case sensitivity or insensitivity, by allowing wildcards or regular expressions, and by specifying where in a returned string your characters must be located.

To change the List Filter criteria:

1. Click the filter-parameters button (magnifying glass) at the left side of the List Filter field to open the parameters menu.
2. Choose an option.

The menu consists of four sections:

- A list of all available information types—these entries correspond to the columns that can be displayed for that particular list or table. You can choose **All**, or alternatively you can choose individual entries.
- **Case sensitive** and **Case insensitive** – Choose one or the other. If you choose **Case sensitive**, found text must match not only the characters you enter, but also their as-typed case.
- **Use wildcards** and **Use regular expression** – Choose one or the other. The following wildcards are recognized:
- ***** (asterisk) – Match zero or more characters at that location in the string.
- **?** (question mark) – Match one character at that location in the string.

- **Match from start**, **Match exactly**, and **Match anywhere** – Choose one. **Match from start** means that the string you enter must be found at the beginning of an entry, although it can be part of a larger set of characters. **Match exactly** requires that the string you enter exactly match the entire column entry. **Match anywhere** means the string can be found anywhere within an entry, and it can be part of a larger set of characters.

- Repeat Steps 1 and 2 to change another parameter.

Monitoring Devices

The HPM Monitoring display presents View controls, view panels, and detailed information about the currently selected device, as described in HPM Window: Monitoring Display , on page 2811.

To switch to the Monitoring screen:

- Click the **Monitoring** button below the HPM menu bar.

(Click the **Alerts** button to return to the Alerts screen.)

Note See Managing Device Views , on page 2807 for information about specifying the devices to be monitored.

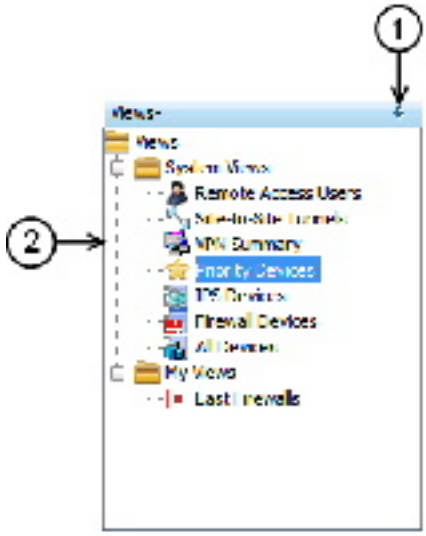
This section contains the following topics:

Managing Device Views

"Views" provide the means to filter and organize the information displayed in the Monitoring pane of the HPM application. Various system views are provided—for example, All Devices, Firewall Devices, Remote Access Users Details, and so on—and you can create custom views that organize the information in other ways, such as geographic device location.

The left pane of the HPM main window displays a list of available views as shown in the following illustration.

Figure 72: Health and Performance Monitor: Views Pane The Views pane includes the following controls:



- **(1) Push Pin button** – Click the Push Pin button to control display of the Views list. When the list is displayed as a pane of the HPM window (the pin is vertical), click the button to collapse the pane into the left edge of the window, leaving a labeled tab; the Monitoring pane is expanded to fill the HPM window.

You can "hover" your mouse pointer over the tab to "pop out" the Views list; it remains visible as long as the pointer is over the tab or in the list area (the pin is horizontal). You also can click anywhere in the title bar—except on the pin itself—to keep the list "popped out."

Click the pin once again to re-establish the Views list as an open pane; the Monitoring pane contracts to make room for it.

- **(2) List of views** – The list is organized into folders: System Views and My Views. Click an entry in either folder to open that view in the Monitoring pane, as described in Views: Opening and Closing , on page 2809. See Views: Custom , on page 2810 for information about creating new views in the My Views folder.
- **Right-click shortcut menu** – You can right-click any entry in the View list to access a pop-up menu of view-related commands:
  - **Edit** – Edit the name and description of the existing custom view. See Views: Custom , on page 2810.
  - **Save As** – Save the view as a new custom view. See Views: Custom , on page 2810.
  - **Delete** – Delete that custom view.
  - **Set as default view** – Use this command to designate the view that is always displayed whenever you launch the HPM application.

This section contains the following topics:

- Views: Tiling Horizontally or Vertically , on page 2809
- Views: Floating and Docking , on page 2810
- Views: Custom , on page 2810

Views: Opening and Closing

All available views are listed in the Views pane, on the left side of the HPM window. The Monitoring pane displays open views, with each open view presented as a separate tabbed panel. (See HPM Window: Monitoring Display , on page 2811 for more information about this window.)

Note You can detach views so they "float" in separate windows. For more information, see Views: Floating and Docking , on page 2810.

To display a new view in the Monitoring pane:

- Click the desired entry in the Views list.

The view appears as a tabbed panel in the Monitoring pane; it is automatically selected and displayed.

To switch to another open view:

- Click the desired tab in the Monitoring pane; that view is displayed.
- Right-click any tab and choose **Next** or **Previous** to display the view to the right or left of that tabbed view.
- Click the Scroll Back and Scroll Forward buttons to the right of the tabs to display the view to the left or right of the current view.

To close a view:

- Click the close button in that tab.
- Right-click the tab and choose the **Close**.
- Right-click the tab and choose **Close Others** to close all open views except the one you right-clicked.
- Right-click any tab and choose **Close All** to close all open views.

Views: Tiling Horizontally or Vertically

Rather than displaying a single view such that it fills the Monitoring pane, you can tile two or more of the views, either horizontally or vertically, for easy comparison.

For example, if you tile two views horizontally, one view fills the upper half of the Monitoring pane, while the other fills the lower half. Similarly, tiling two views vertically fills the left-hand half of the pane with one view, with the other view filling the right half. Further, you can tile more than two views—the pane is subdivided equally for each view.

To create two horizontal or vertical tiles:

- Right-click one of the tabs and choose **New Horizontal Group** or **New Vertical Group**.

The selected view and the other view(s) are distributed to share the Monitoring pane equally, either horizontally or vertically depending on your choice.

Note that if there are more than two views open when you choose one of these commands, the selected view is tiled, with the remaining group of tabbed views displayed as the other tile. You can then repeat this process with the remaining tabbed views, increasing the number of visible tiles, as desired.

You can also move an existing tile to another tile:

- Right-click the tab and choose **Move to Next Tab Group** or **Move to Previous Tab Group**.

The selected view is added to the next tile (below or to the right, depending on tile orientation), or to the previous tile (above or to the left). These commands are available only if the tiled views are arranged in a manner where such movement is possible.

To change the orientation of the views, switching from horizontal to vertical tiling, or vice versa:

- Right-click any tab and choose **Change Tab Groups Orientation**.

This command is available only when two or more tiled views are displayed.

Views: Floating and Docking

You can detach tabbed views so they "float" as separate windows, and you can "dock" floating views, returning them to the Monitoring pane as tabbed views.

To detach a view as a floating window:

- Right-click that tab and choose **Floating**.

A standard window opens, displaying the selected view.

To move another tabbed view from the Monitoring pane to an already-open floating-view window:

- Right-click the tab and choose the window from the **Floating to** submenu.

The right-clicked view is added to the existing window as another tabbed panel.

To return a floating view to the Monitoring pane as a tabbed panel:

- Right-click the view's tab in the window and choose **Docking**.

That view is returned to the Monitoring pane.

Note As a standard window, you can minimize, maximize and close a floating view, as you would any other window.

Views: Custom

The Health and Performance Monitor provides seven System Views. In addition, you can create any number of custom views, each of which is based on an existing view. You also can edit and delete custom views.

The various views are presented in the Views pane of the Monitoring display, organized into two folders: System Views and My Views (the latter folder contains your custom views). The Monitoring display is described in HPM Window: Monitoring Display , on page 2811.

Follow these steps to create a new custom view:

1. In the Views list, select the view on which the new view is to be based.

This can be a System View or an existing custom view.

1. Choose **Save As** from the File menu to open the Save View As dialog box.

You also can right-click the selected view and choose **Save As** from the pop-up menu to open the dialog box.

1. Provide a *Name* for the new view, and optionally a *Description* .
2. Specify the devices to be monitored for this view: check and clear entries in the device-selector area of the dialog box.
3. Click **Save** to close the dialog box and add the new view to the My Views folder.

Follow these steps to edit an existing custom view:

1. Under My Views, select the view.
2. Choose **Edit** from the File menu to open the Save View As dialog box.

You also can right-click the selected view and choose **Edit** from the pop-up menu.

1. Edit the *Name* and *Description* , as necessary.
2. Check and clear entries in the device selector to change the devices monitored for this view.
3. Click **Save** to close the dialog box.

Follow these steps to delete an existing custom view:

1. Under My Views, select the view.
2. Choose **Delete** from the File menu.

You also can right-click the selected view and choose **Delete** from the pop-up menu.

1. Confirm that you want the view deleted.

That view is removed from the Views list.

HPM Window: Monitoring Display

The HPM window provides two different information displays: Monitoring and Alerts. Click the Monitoring button to access the Monitoring display.

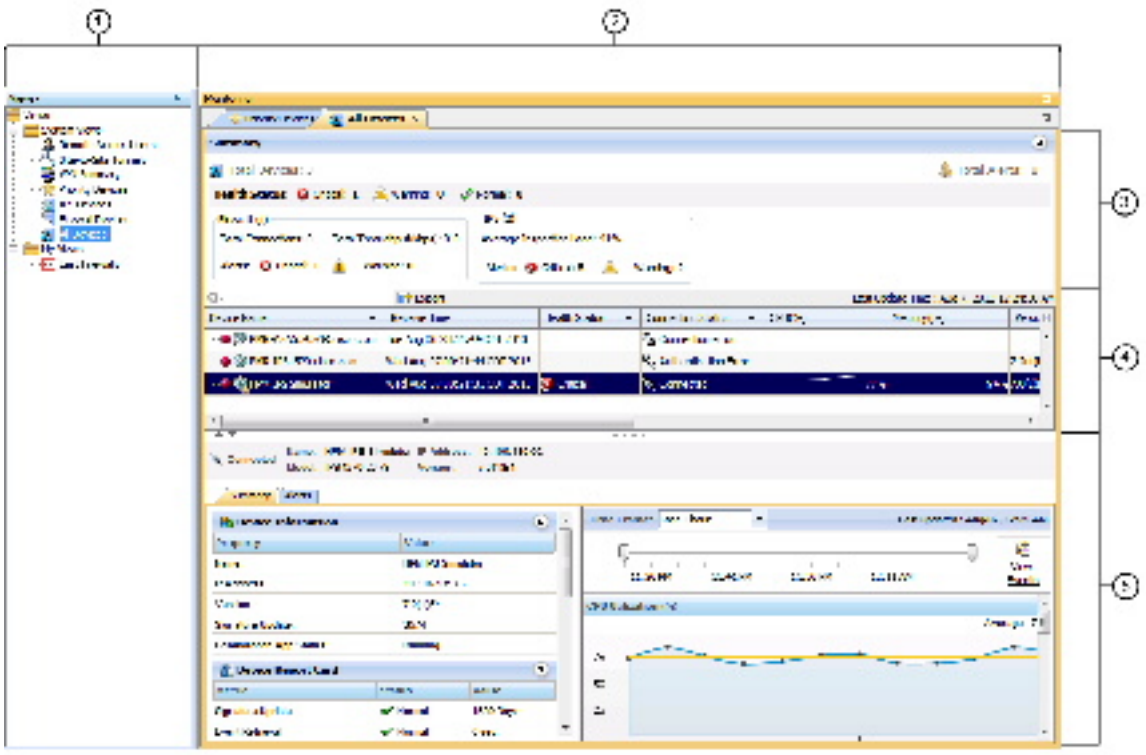
The Monitoring display consists of two primary panes: Views and Monitoring. The Views pane presents a list of available views. Click an entry in this list to open that View as a tabbed panel in the Monitoring pane.

The Monitoring pane can present multiple tabbed views, most of which display several sections. Click a tab to bring that view to the front.

Note The Remote Access Users and the Site-to-Site Tunnels views each display only a single table of information, as described in Monitoring Views: VPN, RA and S2S , on page 2816. The following descriptions focus mainly on the other available system views.

The following illustration presents the primary features of the Monitoring display and the panel sections.

Figure 73: Health and Performance Monitor: the Monitoring Display



1	**Views list.**	**4**	**Status of devices or VPNs.**
2	Monitoring view controls.	5	Selected device details.
3	Summary of all devices.		

The Monitoring display consists of five main elements:

- **Views list (1)** – This pane lists all views available—click an entry in this list to open that view in the Monitoring pane. The views are organized into System Views, provided as part of the Health and Performance Monitor, and My Views, which are custom views you have created. See Managing Device Views , on page 2807 for information about the Views pane, and Views: Custom , on page 2810 for information about managing custom views.
- **Monitoring view controls (2)** – A labeled tab appears here for each view you open; click any tab to bring that view to the front. You also can use the Scroll Backward and Scroll Forward buttons to step

backward or forward through the tabbed views. Alternately, open the Show List drop-down menu on the right and choose a label to make that the active view.

- **Summary of all devices or VPNs (3)** – Provides aggregate information for all devices or VPNs represented by this view. Expand or collapse this section by clicking the button on the right side. The device-summary section is described in greater detail in Monitoring Views: Devices or VPNs Summary , on page 2813.
- **Device-status list (4)** – All devices or VPNs included in this view are listed here; see Monitoring Views: Device or VPN Status List , on page 2813 for more information about this list. Use the List Filter field in this section to filter the list, as described in Using The List Filter Fields , on page 2805.
- **Selected device or VPN details (5)** – This section provides detailed information about the device or VPN currently highlighted in the device list. The details section is described in greater detail in Monitoring Views: Device or VPN Details , on page 2814.

This section contains the following topics:

Monitoring Views: Devices or VPNs Summary

The HPM Monitoring display presents tabbed views, each of which provides detailed information about the device or VPN currently selected, as described in HPM Window: Monitoring Display , on page 2811. All device-related views (that is, all but the Remote-Access Users and Site-to-Site Tunnels views), include a Summary section, as described here.

This devices summary, or VPN Summary, which you can show and hide by clicking the button on the right side of its title bar, displays a snapshot of the aggregate Health Status and Alert Status for all the devices or VPNs relevant to the current view. For example, if you are viewing the Firewall Devices panel, the status summaries are for all monitored firewall devices only.

Monitoring Views: Device or VPN Status List

The HPM Window: Monitoring Display , on page 2811 presents detailed information about the device or VPN currently selected (in a specific device view, or the VPN Summary view, respectively). All device-related views and the VPN Summary view include a table of monitored devices or VPNs relevant to the current view.

This table displays “at-a-glance” status information for every monitored device or VPN—each is represented by an entry in this table. Note that ASA clusters are presented as expandable entries: click the + icon in front of the cluster entry to expand it and view indented entries for each cluster node.

Again, the list includes only those elements relevant to the current view. For example, the list in the Firewall Devices view does not include entries for IPS devices. The Remote-Access Users and Site-to-Site Tunnels views do not include this status display.

You can resize the table columns, you can show and hide columns, and the column headings are menus you can use to filter the table by hiding or showing devices according to chosen parameters. See Showing and Hiding Table Columns , on page 2794 for more information about these options.

When you select an entry in this list, detailed information for that device is displayed in the device-details area below the table, as described in Monitoring Views: Device or VPN Details , on page 2814.

Tip With the All Devices, Firewall Devices, IPS Devices, and Priority Devices views (and any custom device-related views), you can right-click the highlighted entry and choose **Device Manager** from the pop-up menu to open the appropriate external device manager for that device—that is, ASDM for an ASA, and IDM for an IPS sensor—where you can "drill down" into the health and performance data for that device. See Starting Device Managers , on page 2849 for more information about the device managers.

Monitoring Views: Device or VPN Details

The HPM Window: Monitoring Display , on page 2811 presents views and detailed information about the currently selected device or VPN. All device-related views and the VPN Summary view provide three or four tabbed panels of detailed information for the individual device or VPN currently selected in the device-status table above it. (The Remote-Access Users and Site-to-Site Tunnels views do not provide this details panel.)

The information presented for each type of view follows.

For the All Devices, Firewall Devices, IPS Devices, Priority Devices, and custom device-related views, the tabbed panels are:

- **Summary** - The Summary tab consists of four sections that provide information about the device and the device's status:
  - **Device Information** – This section provides a read-only listing of device-specific information such as device name, IP address, device type and model number, and so on. A read-only listing of Failover information is also presented. If an ASA cluster is selected, the Failover listing is replaced with a listing of cluster-related information.
  - **Device Report Card** - This section provides a collection of metrics that indicate the current status of the device. For more information about the metrics shown here, see Table Columns: Device-related Views , on page 2795.
  - **Interface Status** – This section provides a listing of all interfaces defined on the device, with current status information.
  - **Device Health Graphs** - This section provides a "snapshot" of device status using graphic displays for certain metrics such as CPU and memory usage. It also presents device-specific traffic information, for example, average number of connections and number of translations for firewall devices (over the most-recent polling period), and average inspection load and percentage of missed packets for IPS sensors (over the most-recent polling period).You can specify the time frame (Last 1 hour, Last 24 hours, or Last 7 days) to use for these graphs from the Time Frame list. You can focus in on a specific time frame by using the slider bar above the graphs.To view events for the selected device, click the **View Events** button. Event Viewer opens and the Event Monitoring window lists events filtered by the selected device and the time period specified by the slider bar.

Note For IPS devices, certain health-metric thresholds must be configured separately on the individual devices—that is, outside of HPM. Therefore, it is possible for the health of an IPS device to be critical, for example, without any indication in HPM. See Alerts Configuration: IPS , on page 2822 for additional information.

- **Alerts** - The Alerts tab lists all alerts for the selected device. You can show and hide various columns of information for each alert. See Alerts and Notifications , on page 2818 for more information about alerts. For information about the fields available on this tab, see HPM Window: Alerts Display , on page 2819.

For the All Devices, Firewall Devices and Priority Devices the tabbed panels are

- **Summary**-The Summary tab consists of four sections that provide information about the device and the device's status:
  - **Device Information** – This section provides a read-only listing of device-specific information such as device name, IP address, device type and model number, and so on. A read-only listing of Failover information is also presented. If an ASA cluster is selected, the Failover listing is replaced with a listing of cluster-related information.
  - **Device Report Card** - This section provides a collection of metrics that indicate the current status of the device. For more information about the metrics shown here, see Table Columns: Device-related Views , on page 2795.
  - **Interface Status** – This section provides a listing of all interfaces defined on the device, with current status information.
  - **Device Health Graphs** - This section provides a "snapshot" of device status using graphic displays for certain metrics such as CPU and memory usage. It also presents device-specific traffic information, for example, average number of connections and number of translations for firewall devices (over the most-recent polling period), and average inspection load and percentage of missed packets for IPS sensors (over the most-recent polling period).You can specify the time frame (Last 1 hour, Last 24 hours, or Last 7 days) to use for these graphs from the Time Frame list. You can focus in on a specific time frame by using the slider bar above the graphs.To view events for the selected device, click the **View Events** button. Event Viewer opens and the Event Monitoring window lists events filtered by the selected device and the time period specified by the slider bar.

Note For IPS devices, certain health-metric thresholds must be configured separately on the individual devices—that is, outside of HPM. Therefore, it is possible for the health of an IPS device to be critical, for example, without any indication in HPM. See Alerts Configuration: IPS , on page 2822 for additional information.

- **Alerts** - The Alerts tab lists all alerts for the selected device. You can show and hide various columns of information for each alert. See Alerts and Notifications , on page 2818 for more information about alerts. For information about the fields available on this tab, see HPM Window: Alerts Display , on page 2819.

- Flow-offload- The Flow-offload tab displays basic information about the offload engine, the load percentage on offload cores and information on active offloaded flows- the number of offloaded flow created, the offloaded active flows, their rewrite rules and data.
- Flow- offload Statistics- The Flow-offload Statistics tab displays the counts for transmitted, received and dropped packets and statistics for the virtual NIC used.

For the VPN Summary view, the tabbed panels are:

- **VPN Usage** – Several graphs presenting information such as active site-to-site tunnels, active remote-access sessions, and total throughput. This includes historical trending information for active Site-to-Site tunnels, active IPSec remote-access users, active SSL VPN clientless users, and active SSL VPN with client users.
- Cluster Resource Usage – Displays the usage details of cluster resources—resource names, its current, peak, and usage limits. It also provides the number of denied packets and the contexts. This feature is applicable only for Cisco Firepower 9K devices.
- Cluster Distribution Details – Displays the cluster mode of the VPN. If it is centralized, an error message is displayed mentioning that the destination mode is not VPN distributed. If it is distributed, it displays the respective member I and member II details. This feature is applicable only for Cisco Firepower 9K devices.
- **License Information** – A read-only listing of license information by VPN type, or IPSec and SSL license and load information, depending on your selection in the table above. For the System context of a multiple-mode device, VPN Licensing and allocation are shown; for individual contexts, VPN allocation Limits and VPN licensing usage are shown.
- **Other Details** – A listing of certificate and TrustPoint details.

See Managing Monitored Devices , on page 2791 for information about selecting devices for VPN monitoring.

Monitoring Views: VPN, RA and S2S

The HPM Monitoring display presents a variety of device- and VPN-related data views, as described in HPM Window: Monitoring Display , on page 2811. These include the Remote Access Users and Site-to-Site Tunnels views, which unlike the other views, are simply tables of current users and tunnels.

See Managing Monitored Devices , on page 2791 for information about selecting devices for VPN monitoring.

In both of these views, you can resize the table columns, you can show and hide columns, and the column headings are menus you can use to filter the table by hiding or showing entries according to chosen parameters. See Showing and Hiding Table Columns , on page 2794 for more information about these options.

The Remote Access Users view lists the remote-access users currently logged into network resources via the devices being monitored by HPM. Note that remote-access user information is updated every 20 minutes (for normal monitoring; for Priority monitoring the interval is 15 minutes), rather than the five minutes that is standard for the other views. Also, no historical or trending data is available for remote-access users.

Further, you may notice a mismatch between RA user count in the VPN Summary view and the Remote Access Users view. This is because the VPN Summary is updated at ten-minute/five-minute (normal/Priority) intervals.

Tip In the Remote Access Users view, you can right-click a user entry and choose **Log Off User** from the pop-up menu to terminate that remote-access connection.

The Site-to-Site Tunnels view provides current VPN tunnel information through all monitored devices. Note that to enable tunnel Up/Down alerts for a device or context, you must configure SNMPv3 on the device, as described in SNMP Credentials Dialog Box , on page 118.

Tip In the Site-to-Site Tunnels view, you can click on a Down notification hyperlink in the Status column to view the IPSec VPN Events for that device in Event Viewer. Event Viewer will show IPSec VPN Events for the device within a time range depending on the polling interval for that device. If it is a priority device, the time range will be 5 minutes before until 5 minutes after the first down notification was received. For non-priority devices, the time range will be +/- 10 minutes instead of 5 minutes.

For clusters of ASA 9.0+ devices, information is shown for the director device only, since VPN processing is not load-balanced across the nodes and is thus limited to centralized support in the cluster.

Note VPN polling occurs on a fixed time interval, so it is not possible to log status changes within that time interval. For example, if a site-to-site tunnel goes down immediately after polling and comes back up just before the next poll, that status change cannot be detected.

Exporting HPM Data

You can save a "snapshot" of the device-status information in the current View as a PDF, HTML, or CSV (comma-separated values) file.

Note Beginning with Security Manager version 4.9, the exported data in PDF, HTML, or CSV format also contain the IPv6 tunnel information.

The following steps describe exporting the current View data in either a PDF, HTML, or CSV file:

Related Topics

- HPM Window , on page 2792
- Showing and Hiding Table Columns , on page 2794

Step 1 Click the appropriate tab to display the View you want to export (that is, Priority Devices, VPN Summary, All Devices, or another).

Tip To export the data for a subset of all entries in a particular view, create a custom view that includes only the desired devices. See Views: Custom , on page 2810 for information.

Step 2 Click the down-arrow beside the Export button next to the List Filter field (above the device- or VPN-status list) and choose **As PDF**, **As HTML**, or **As CSV** from the drop-down menu.

The Export dialog box opens.

Step 3 Select the specific information to be exported by checking the appropriate columns in the dialog box.

The following topics describe the individual columns available for various views:

- Table Columns: Device-related Views , on page 2795
- Table Columns: VPN-related Views , on page 2798

Step 4 If you chose **As PDF** from the Export drop-down list, at the bottom of the Export dialog box you can choose the desired **Page Size** for the PDF file: A1, A2, A4, Letter, or Legal.

The pages of the PDF file will be the selected size, with the presented information formatted accordingly.

Step 5 If you chose **As CSV** from the Export drop-down list, Security Manager exports the information in a CSV file that you can save as required. Beginning with version 4.8, Security Manager provides the Export Trend Charts checkbox that you can select to export trend information in CSV file format. You can then chose the Time Frame from available time range of last one hour, last 24 hours, and last seven days.

Step 6 Click **Export** to close the Export dialog box.

The Save file dialog box opens.

Step 7 Provide a name for the file, and specify where it is to be saved.

The default file name is the current system time (as a long integer); you can change this to something informative. On Windows systems, the default location is My Documents; you can specify any location.

Step 8 Click **Save** to close the Save dialog box and export the selected data.

Alerts and Notifications

The Health and Performance Monitor (HPM) provides trend information, alerts, and notifications regarding the performance and health of monitored devices. You can monitor the overall health of your network—including network user and device resource utilization—by quickly scanning the status of individual devices and groups of devices.

Specific device-level trend information is available for hourly, daily and weekly intervals. Alerts are displayed prominently, with easy navigation to the relevant HPM data. You also can acknowledge and annotate individual alerts.

Note When a node from a cluster is deleted and then the cluster is rediscovered in Security Manager, the node will be removed from monitoring in HPM if currently enabled. However, any alerts generated on the node will still be shown in HPM. You must manually clear the alerts from HPM.

These alerts are based on threshold values and state-change rules that you have configured: you specify thresholds that define Critical, Warning, and Normal levels for various metrics, and you can configure rules for certain state changes such as interface failure.

Further, there are two levels of device monitoring. Initially all devices are unmonitored. However, you can designate devices to be monitored at a “normal” level, or at a “Priority” level—you define a separate set of

alert definitions for each level. Priority devices are polled and reported on more frequently (five-minute intervals versus ten for “normal” devices), and failure parameters are more stringent.

You also can enable email alert notifications. If configured, an email is sent to the specified address(es) whenever an alert is generated. You can provide multiple addresses for each category of alerts (Firewall and IPS).

Note An email notification is sent the first time an alert is logged, and when the severity of an alert changes from warning to critical (but not vice-versa). No notification is issued if a device returns to the Normal state.

This section contains the following topics:

- HPM Window: Alerts Display , on page 2819
- Alerts: Configuring , on page 2821
- Alerts: Viewing , on page 2827
- Alerts: Viewing , on page 2827

HPM Window: Alerts Display

The HPM window provides two different information displays: Monitoring and Alerts. Click the Alerts button to access the Alerts display.

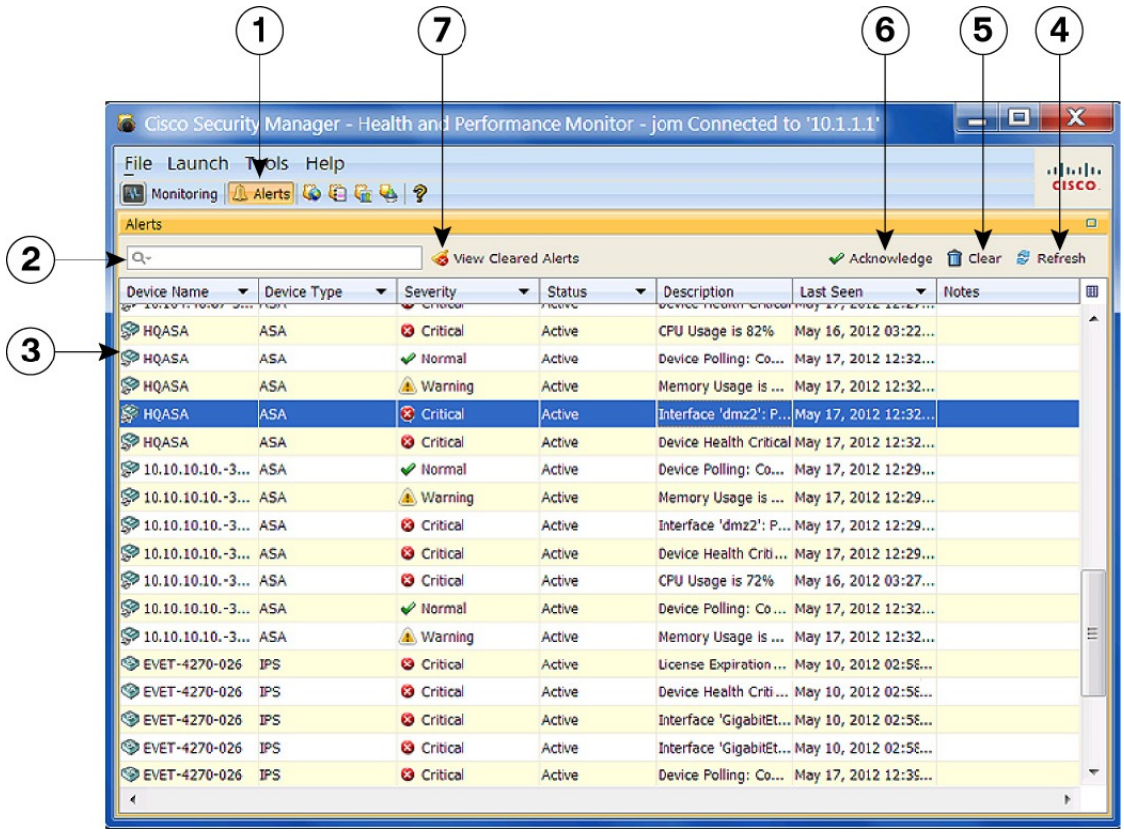
Note A device-specific view of alert data is available on the Alerts tab when viewing details for a specific device (see Monitoring Views: Device or VPN Details , on page 2814). With a few exceptions, you can perform many of the same functions from the device-specific alert view as you can from the primary Alerts display.

The following illustration presents the primary features of the Alerts display.

Related Topics

- Alerts: Configuring , on page 2821

Figure 74: Health and Performance Monitor: Alerts Display



1	**Alerts button.**	**5**	**Clear button.**
2	List Filter field.	6	Acknowledge button.
3	Alerts table.	7	View Cleared Alerts button.
4	Refresh button.		

The Alerts display consists of seven main elements:

Note With the exception of the List Filter field and the View Cleared Alerts button, these same elements are available to you on the Alerts tab when viewing details for a specific device (see Monitoring Views: Device or VPN Details , on page 2814).

- **Alerts button (1)** – The HPM window displays either Monitoring information for devices and VPNs, or a table of alerts generated by monitored devices. Click the Alerts button to view the alerts table.
- **List Filter field (2)** – You can use this field to filter the alerts displayed in the table; only those alerts containing the specified text are listed. Refer to Using The List Filter Fields , on page 2805 for more information.

- **Alerts table (3)** – This table lists all alerts for all currently monitored devices. The alerts displayed can be filtered using the List Filter field. You also can show and hide various columns of information for each alert. See Alerts and Notifications , on page 2818 for more information.
- **Refresh button (4)** – Click this button to update all alerts ahead of the normal polling cycles.
- **Clear button (5)** – When one or more alerts are selected, you can click this button to open the Clear dialog box. Click the Clear button in the dialog box to close it and clear the highlighted alerts from the table.

Note See Alerts: Acknowledging and Clearing , on page 2829 for additional information about clearing and acknowledging alerts.

- **Acknowledge button (6)** – When one or more alerts are selected, you can click this button to open the Acknowledge dialog box. If desired, you can enter a note that will be applied to the selected alerts. Click the Acknowledge button to close the dialog box and mark all highlighted alerts as acknowledged.

Tip You can add a note to any previously acknowledged alert. Click the Note field for that alert to open the Enter Notes dialog box. This is the only method of accessing the Enter Notes dialog box.

- **View Cleared Alerts button (7)** – Click this button to open the View Cleared Alerts window where you can access and view previously cleared alerts; you specify a set of devices and a time range. See Alerts: History , on page 2829 for more information about using this window.

Alerts: Configuring

The alerts and email notifications provided by HPM are based on threshold values and state-change rules that you configure in the Alerts Configuration dialog box.

The Alerts Configuration dialog box consists of three tabbed panels: **IPS** for IPS sensor-related alerts, **FW** for firewall-related alerts, and VPN for tunnel-status alerts. Each panel presents groups of options in sections—use the expand/collapse button to show or hide a particular section.

Note You can enable and disable a particular alert without expanding that section; simply check or clear the box preceding the section heading—the current settings are used and retained.

There are two levels of device monitoring: normal or “standard” priority and “active” priority. Active priority devices are polled and reported on more frequently, and failure parameters are more stringent. You can designate up to 10% of all monitored devices for Priority monitoring. See Managing Monitored Devices , on page 2791 for more information about device selection.

Follow these steps to configure alert reporting and notifications for both Standard and Priority devices:

Step 1 Choose Alert Configuration from the Tools menu to open the Alerts Configuration dialog box.

Step 2 On the IPS panel, configure IPS-related alerts—if necessary, click the IPS tab to display the panel.

a. To enable email Notifications when IPS alerts are generated, enter one or more valid addresses in the Email Addresses field; separate multiple addresses with commas.

b. Use the checkboxes in the section headings to enable and disable specific alerts. Expand a section to update those alert definitions. The IPS parameters are described in Alerts Configuration: IPS , on page 2822.

Note An email notification is sent the first time an alert is logged, and when the severity of an alert changes from warning to critical (but not vice-versa). No notification is issued if a device returns to the Normal state.

Step 3 On the FW panel, configure firewall-related alerts—click the FW tab to display the panel.

a. To enable email Notifications when firewall alerts are generated, enter one or more valid addresses in the Email Addresses field; separate multiple addresses with commas.

b. Use the checkboxes in the section headings to enable and disable specific alerts. Expand a section to update those alert definitions. The FW parameters are described in Alerts Configuration: Firewall , on page 2823.

Step 4 On the VPN panel, configure tunnel-status alerts—click the VPN tab to display the panel.

a. To enable email Notifications when tunnel-down alerts are generated, enter one or more valid addresses in the Email Addresses field; separate multiple addresses with commas.

b. Use the checkbox in the section heading to enable and disable tunnel-status alerts. Expand the section to update those alert definitions. The VPN parameters are described in Alerts Configuration: VPN , on page 2825.

Note To enable these tunnel-status alerts for a device or context, you must first configure SNMP on the device, as described in Configuring SNMP for S2S Polling , on page 2826.

Step 5 Click **Save** to save your changes and close the dialog box.

Alerts Configuration: IPS

Note From version 4.17, Cisco Security Manager does not support IPS devices.

The alerts and status information collected from monitored IPS devices are configured on the IPS panel of the Alerts Configuration dialog box. Refer to Alerts: Configuring , on page 2821 for information about opening the dialog box, accessing the IPS panel, and providing email addresses for IPS-related Notifications.

The IPS-alert configuration parameters are grouped into sections that can be expanded and collapsed. Each section includes a checkbox next to its heading; use this checkbox to enable or disable that alert. When expanded, each section provides access to the settings used to define the alert.

The IPS alert and status configuration parameters are described in the following table. Each parameter can be configured separately for Priority Devices and Standard Devices. (Specifying devices for priority and standard monitoring is described in Managing Monitored Devices , on page 2791.)

Note Some of the following alert settings require specific related parameters to be configured on the monitored IPS sensors themselves. For example, if **license-expiration-policy** (**health-monitor** command) is not enabled on a particular sensor, license-expiration messages are not generated by that sensor and therefore no occurrences are tallied for it by HPM.

Table 986: IPS Alerts Configuration

Setting	Description
Collaboration App Status	Errors generated by the Collaboration App application are tallied. Alerts and Notifications are generated when the number of errors tallied reaches the specified Occurrences value.
Sensor App Status	Errors generated by the Sensor App application are tallied. Alerts and Notifications are generated when the number of events reaches the specified Occurrences value.
Bypass Mode	Any time bypass mode is triggered, one Occurrence is tallied for this setting. Alerts and Notifications are generated when the number of Occurrences reaches the value specified.
Interface Status	The status of each enabled interface is polled periodically. Each “down” result for any given interface is tallied as one Occurrence for that interface. Alerts and Notifications are generated when the number of Occurrences reaches the value specified.
License Expiration	A license-expiration threshold can be configured on each IPS sensor, and whenever this threshold is crossed, a status message is issued.
Memory Usage	A memory-usage threshold can be configured on each IPS sensor, and whenever this threshold is exceeded, a status message is issued. An Occurrence is tallied for each memory-usage message. Alerts and Notifications are generated when the number of Occurrences reaches the value specified here.
Missed Packets	A missed-packets threshold can be configured on each IPS sensor, and whenever this threshold is exceeded, a status message is issued. An Occurrence is tallied for each missed-packets message. Alerts and Notifications are generated when the number of Occurrences reaches the value specified here.
Inspection Load	A traffic inspection-load threshold can be configured on each IPS sensor, and whenever this threshold is exceeded, a status message is issued. An Occurrence is tallied for each load-exceeded message. Alerts and Notifications are generated when the number of Occurrences reaches the value specified.

Alerts Configuration: Firewall

The alerts and status information collected from monitored firewall devices are configured on the **FW** panel of the Alerts Configuration dialog box. Refer to Managing Monitored Devices , on page 2791 for information

about opening the dialog box, accessing the FW panel, expanding and collapsing sections, and providing email addresses for FW-related Notifications.

The firewall-alert configuration parameters are grouped into sections that can be expanded and collapsed. Each section includes a checkbox next to its heading; use this checkbox to enable or disable that alert. When expanded, each section provides access to the settings used to define the alert.

Some section headings also include **Consider for Device Health** checkboxes. Checking one of these boxes means that particular information is considered when determining overall health of each device.

The FW alert and status configuration parameters are described in the following table.

Table 987: Firewall Alerts Configuration

Setting	Description
Failover Peer Status	The status of the link to the device's failover peer is polled periodically. Each failed contact attempt is tallied as one Occurrence. Alerts and notifications are generated when the number of occurrences reaches the values specified here. For Priority devices and for Standard devices: choose **Critical** or **Warning** to specify the type of alert generated, and then specify the number of occurrences necessary to trigger the alert.
Interface Status	The status of each enabled interface is polled periodically. Each "down" result for any given interface is tallied as one Occurrence for that interface. This monitoring is per stand-alone device, and per node of an ASA cluster. Alerts and notifications are generated when the number of occurrences reaches the values specified here. For Priority devices and for Standard devices: choose **Critical** or **Warning** to specify the type of alert generated, and then specify the number of occurrences necessary to trigger the alert. **Note** Check **Consider for Device Health** in the header to include these data in device-health calculations.
Master Changed	An Occurrence is tallied each time the device designated as the controlling unit node of an ASA cluster changes. Alerts and notifications are generated when the number of occurrences reaches the values specified here. For Priority devices and for Standard devices: choose **Critical** or **Warning** to specify the type of alert generated, and then specify the number of occurrences necessary to trigger the alert.
Cluster Node Status	An Occurrence is tallied each time the Connection Status of an ASA cluster node changes (comes up or goes down). Alerts and notifications are generated when the number of occurrences reaches the values specified here. For Priority devices and for Standard devices: choose **Critical** or **Warning** to specify the type of alert generated, and then specify the number of occurrences necessary to trigger the alert.

CPU Usage	An Occurrence is tallied each time CPU usage exceeds the specified Threshold percentage. This is per stand-alone device; per node of a single-context cluster; and per node for the system context only in a multi-context cluster. Alerts and notifications are generated when the number of occurrences reaches the values specified here. **Note** Check **Consider for Device Health** in the header to include these data in device-health calculations. For Priority devices and for Standard devices, you can enable either or both **Critical** and **Warning** CPU Usage alerts: **1.** Check the appropriate box to enable the **Threshold** and **Occurrence** fields. **2.** Specify a **Threshold** percentage by clicking the up or down arrows, or by highlighting the existing value and typing a number. **3.** In the **Occurrence** field, specify the number of times the specified Threshold must be exceeded before the critical or warning alert is issued.
Memory Usage	An Occurrence is tallied each time memory usage exceeds the specified Threshold percentage. This is per stand-alone device; per node of a single-context cluster; and per node for the system context only in a multi-context cluster. Alerts and notifications are generated when the number of occurrences reaches the values specified here. **Note** Check **Consider for Device Health** in the header to include these data in device-health calculations. For Priority devices and for Standard devices, you can enable either or both **Critical** and **Warning** Memory Usage alerts: **1.** Check the appropriate box to enable the **Threshold** and **Occurrence** fields. **2.** Specify a **Threshold** percentage by clicking the up or down arrows, or by highlighting the existing value and typing a number. **3.** In the **Occurrence** field, specify the number of times the specified Threshold must be exceeded before the critical or warning alert is issued.

Alerts Configuration: VPN

The generation of alerts for site-to-site (S2S) tunnels on monitored devices and contexts is enabled and configured on the **VPN** panel of the Alerts Configuration dialog box. Refer to Alerts: Configuring , on page 2821 for information about opening the dialog box, accessing the VPN panel, and providing email addresses for VPN-related Notifications.

Tip When VPN alerts are enabled, HPM polls the monitored devices and contexts at normal and Priority intervals (ten and five minutes, respectively), according to your normal/Priority designations. You also can enable SNMP monitoring which updates HPM tunnel status immediately upon processing the traps. See Configuring SNMP for S2S Polling , on page 2826 for more about enabling SNMP processing for HPM.

The tunnel-status configuration parameters are grouped into a section that can be expanded and collapsed. When expanded, you have access to the alert settings. The checkbox next to the heading is used to enable or disable the alert.

The VPN alert parameters are described in the following table.

Table 988: VPN Alerts Configuration

Setting	Description
Tunnel Status	The status of each monitored S2S tunnel is updated whenever it comes up or goes down, based on periodic polling or SNMP trap processing. Each "down" result for any given tunnel is tallied as one Occurrence. An alert is generated when the number of occurrences reaches the values specified here. For Priority Devices and for Standard Devices, you can separately configure both Critical and Warning tunnel-down alerts: choose **Critical** or **Warning** to specify the type of alert generated, and then in the **Occurrence** field, specify the number of times a tunnel is down when polled before the critical or warning alert is issued.

Configuring SNMP for S2S Polling

The Health and Performance Monitor (HPM) application uses SNMP to poll site-to-site (S2S) VPN tunnels for up/down status updates. The generation of alerts for site-to-site (S2S) tunnels on monitored devices and contexts is configured on the **VPN** panel of the HPM Alerts Configuration dialog box. Refer to Alerts: Configuring , on page 2821 for information about opening the dialog box, accessing the VPN panel, and providing email addresses for VPN-related Notifications.

Configuring SNMP in Security Manager to provide S2S polling is outlined here. The basic steps are:

1. Enable and configure SNMP on the SNMP Page , on page 1945 for the device or individual context; specifically: check Enable SNMP Servers and provide and confirm the Read Community String.
2. In the SNMP Trap Configuration Dialog Box , on page 1947, check **IPSEC Start** and **IPSEC Stop** on the Other panel.
3. In the Add/Edit SNMP Host Access Entry Dialog Box , on page 1950, provide Interface Name, IP Address, Community String (and Confirm it), and choose the SNMP Version (1 or 2c).

Versions 1, 2c and 3 are supported for S2S polling, but version 3 must be configured separately, as described in the next section.

1. Configure SNMP credentials for the device or individual context in the SNMP Credentials Dialog Box , on page 118.

For versions 1 and 2c, provide and confirm the RO Community String.

For version 3, Security Manager supports three modes; which to use is determined from your input:

- noauthnopriv (no authentication, no privacy) – User name is mandatory, others are optional.
- authnopriv (authentication, no privacy) – User name, Password, Auth Algorithm, and Engine ID are required.
- authpriv (authentication and privacy) – User name, Password, Auth Algorithm, Privacy Password, Privacy Algorithm, and Engine ID are required.

Again, configuration of SNMP v3 is performed separately, as described in the next section.

Configuring SNMP v3 for Security Manager Device

You cannot configure SNMP v3 directly in Security Manager; you must use CLI commands or set up a FlexConfig. The steps are:

1. Configure an SNMP server group.

```
snmp-server group group-name v3 [auth | noauth | priv]
```

The auth keyword enables packet authentication. The noauth keyword indicates no packet authentication or encryption is being used. The priv keyword enables packet encryption and authentication. There are no default values for the auth or priv keywords.

1. Define a new SNMP user.

```
snmp-server user username group-name{v3 [encrypted]
[auth {md5 | sha]} auth-password
[priv [des | 3des | aes] [128 | 192 | 256] priv-password]
```

The v3 keyword specifies that the SNMP Version 3 security model is used, and enables the use of the encrypted , priv , and auth keywords. The encrypted keyword indicates the password is in encrypted format. Encrypted passwords must be in hexadecimal format.

The auth keyword specifies which authentication level (md5 or sha) is used.

The priv keyword specifies the encryption level. There are no default values for the auth or priv keywords.

For the encryption algorithm, you can specify either des , 3des , or aes . You can also specify which version of the AES encryption algorithm to use: 128 , 192 , or 256 . The auth-password specifies the authentication user password. The priv-password specifies the encryption user password.

1. Specify the recipient of SNMP notifications.

```
snmp-server host interface {hostname | ip_address} [version 3 username]
```

Indicates the interface from which traps are sent. Identifies the name and IP address of the NMS or SNMP manager that can connect to the device.

Related Topics

- Configuring SNMP , on page 1942

Alerts: Viewing

All alerts generated for monitored devices are displayed as a table in an alternate screen of the HPM window. The Alerts table is updated automatically as devices are polled for status information. You can also click the Refresh button, above the table on the right side, to update the table.

These alerts are based on the threshold values and state-change rules you have configured. See Alerts: Configuring , on page 2821 for more information.

Note See Managing Monitored Devices , on page 2791 for information about specifying the devices to be monitored.

To switch to the Alerts screen:

- Click the **Alerts** button below the HPM menu bar.

(Click the **Monitoring** button to return to the Monitoring screen.)

Note You can also view alerts that apply to a specific device from the Alerts tab when viewing details for that device (see Monitoring Views: Device or VPN Details , on page 2814).

The Alerts listing is a basic table, consisting of rows and columns, with each row representing one alert from a given device. Each column provides specific information about that alert: device name, alert severity, time recorded, and so on. (See HPM Window: Alerts Display , on page 2819 for more about the Alerts screen.)

Note The column headings are menus that you can use to filter the table by hiding or showing alerts according to chosen parameters. For example, you might choose to display alerts for only a particular device, and then choose only critical alerts for that device. See Working with Table Columns , on page 2794for more information.

Tip You can click on the hyperlink in the Description column for tunnel up/down alerts to view the IPSec VPN Events for that device in Event Viewer. Event Viewer will show IPSec VPN Events for the device within a time range depending on the polling interval for that device. If it is a priority device, the time range will be 5 minutes before until 5 minutes after the first up/down notification was received. For non-priority devices, the time range will be +/- 10 minutes instead of 5 minutes.

In addition to scrolling the Alerts table, you can view sets of specific alerts:

- Use the List Filter field above this table to filter the list. See Using The List Filter Fields , on page 2805 for more information.
- Use the View Cleared Alerts window to view previously cleared alerts for a selected set of devices over a specified time range. See Alerts: History , on page 2829 for more information.

You also can acknowledge alerts, clear alerts, and edit alert notes:

- You can acknowledge an alert, or clear it, as described in Alerts: Acknowledging and Clearing , on page 2829.
- To add to an existing alert note, click Notes field for that entry in the table to open the Enter Notes dialog box—used to view and add notes to an alert. Available only when a single alert with an existing note is selected in the table.

Alerts: Acknowledging and Clearing

All alerts generated for monitored devices are displayed in the Alerts table, as described in Alerts: Viewing , on page 2827. You can add notes to individual alerts, and you can acknowledge or clear alerts individually or in groups.

To select an alert, click that entry in the Alerts table. You can Shift-click another alert to select the group between the two, and you can Ctrl-click various rows to select multiple non-contiguous alerts.

When an alert is selected in the table, you can:

- Click the **Acknowledge** button to open the Acknowledge Alert dialog box, used to add a note to, and then mark the selected alert(s) as acknowledged. You can acknowledge multiple alerts at one time.

Enter text in the Notes field in this dialog box (this is optional), and then click **OK**. The dialog box closes and the alerts are marked as acknowledged with a timestamp displayed in the Notes column.

- Click the **Clear** button to open the Clear Alert dialog box, used to add a note to, and then remove the selected entries from the Alerts table.

Enter text in the Notes field in this dialog box (this is optional), and then click **OK**. The dialog box closes and the selected alerts are removed from the Alerts table.

Note Alerts can be cleared automatically by HPM if you change the relevant threshold(s). Like alerts you have cleared, these alerts can be viewed in the View Cleared Alerts window (see Alerts: History , on page 2829).

Notes and other information for cleared alerts are saved in an Alerts database for 30 days.

Alerts: History

All alerts generated for monitored devices are displayed as a table in the HPM window. You can filter the table by any visible column parameter, as described in Alerts: Viewing , on page 2827.

You also can use the View Cleared Alerts window to access and view previously cleared alerts; you specify a set of devices and a time range. (Clearing alerts is described in Alerts: Acknowledging and Clearing , on page 2829.)

Note Notes and other information for cleared alerts is maintained in an Alerts database for 30 days—you cannot access alerts more than 30 days old.

Follow these steps to open and use the View Cleared Alerts window:

1. In the Alerts screen, click the View Cleared Alerts button next to the List Filter field to open the View Cleared Alerts window. (See Alerts: Viewing , on page 2827 for more information about accessing the Alerts screen of the HPM window.)
2. Specify the alert View Settings; these define the set of alerts you wish to view:
   - Specify the devices of interest; **All** devices are selected by default. To select a particular set of devices:

- Click the **Select** button to open the Select Devices dialog box.
- Select the desired device(s); deselect any devices you wish to exclude.
- Click **OK** to close the Select Devices dialog box.
- Specify the types of Alerts to display: select or deselect **Critical**, **Warning** and **Normal**.
- Define the desired **Time Range** by choosing a From date and time, and a To date and time. All alerts with a First Seen time within this range will be displayed.

From and To each present a standard drop-down calendar used to select a month and day.

Use the time field below each calendar to specify the precise start or end time, respectively. Highlight a digit and click the up or down arrow, or simply type the desired number. You can also click the **Now** button to specify the present moment.

1. Click the **Search** button to display the defined set of alerts.

Note that the View Cleared Alerts window provides a List Filter field that you can use to filter the cleared-alerts display. Using this field is described in Using The List Filter Fields , on page 2805.

Refer to Working with Table Columns , on page 2794 for other methods of filtering this table.

SNMP Trap Forwarding Notification

In 4.6 and earlier versions of Security Manager, e-mail notifications were sent to users when Health and Performance Monitor alerts were generated for ASA, IPS, and VPN.

This framework has been enhanced for Security Manager 4.7 to send SNMP trap notifications in addition to e-mail notifications. Security Manager 4.7 converts the alerts to traps and sends them to the centralized SNMP trap server. SNMP v1, v2c, and v3 are supported. A trap is generated the first time an alert is seen and again if the severity increases, resulting in a trap being generated a maximum of 2 times, as is done with e-mail notification.

SNMP trap forwarding notification has the following pre-requisites:

1. An SNMP trap receiver (server) is available. More than one server can be used for a given Security Manager installation.
2. An ASA device is available.
3. An IPS sensor running IPS 7.0.x or later is available.
4. Health and Performance Monitor is enabled.

Tip To verify that Health and Performance Monitor is enabled, navigate to Configuration Manager > Tools > Security Manager Administration... > Health and Performance Monitor.

1. Normal or priority monitoring for the ASA device and the IPS sensor Device is enabled in Health and Performance Monitor.
2. The alert settings for firewall, IPS, and VPN are enabled.

Tip To enable the alert settings for firewall, IPS, and VPN, navigate to Health and Performance Monitor > Tools > Alert Configuration.

MIB Documentation

The information in this section documents which MIB Security Manager uses to send the trap notification and what OID the user has to look for to get the particular alert information.

For the SNMP trap, Security Manager uses "CISCO-DEVICE-EXCEPTION-REPORTING-MIB"

The following list contains the OID details and the information that it contains:

- iso.org.dod.internet.mgmt.mib-2.system.sysUpTime.0 (shows how long the HPM server has been up and running) – calculated using the formula, System Up time = Current Security Manager server time - HPM Service start up time.
- snmpTrapOID (1.3.6.1.4.1.9.9.224.2.0.1)
- .1.3.6.1.4.1.9.9.224.1.1.5.1.2 (lists the alert rule name like memory usage)
- .1.3.6.1.4.1.9.9.224.1.1.5.1.3 (constant value of 1, specifies IP address type)
- .1.3.6.1.4.1.9.9.224.1.1.5.1.4 (device display name – device type and if any cluster node, then its name)
- .1.3.6.1.4.1.9.9.224.1.1.5.1.5 (severity of the alert)
- .1.3.6.1.4.1.9.9.224.1.1.5.1.6 (time stamp of the alert) – Current Security Manager server time - Alert first seen time
- .1.3.6.1.4.1.9.9.224.1.1.5.1.7 (maximum 1024 char string describing the alert)
- .1.3.6.1.4.1.9.9.224.1.1.5.1.8 (Security Manager Server name)

This section contains the following topics:

- SNMP Trap Entries Dialog Box, on page 2831
- Add/Edit/Copy SNMP Trap Entries Dialog Box, on page 2832

SNMP Trap Entries Dialog Box

Use the SNMP Trap Entries dialog box as your launching point for SNMP trap forwarding notifications.

Navigation Path

In Health and Performance Monitor, select **SNMP Trap Configuration** from the Tools menu. The SNMP Trap Entries dialog box contains the following areas:

- The Settings table, which displays the traps that are currently configured.
- Add, Edit, and other options for working with SNMP trap entries.

Field Reference

Table 989: The Settings table and other options in the SNMP Trap Entries dialog box

Field	Description
Forward Trap To table	
Status column	Enabled or Disabled. A maximum of 5 trap forwarding hosts can be enabled at any given time.
IP/Host column	IP address or hostname of the centralized SNMP trap server. Neither the local host nor the Security Manager server is allowed to be used as the SNMP server, in order to avoid problems with performance.
PORT column	The port used by the centralized SNMP trap server
SNMP Version column	v1, v2c, or v3. The default value is v2c.
Username column	The username for authentication to the SNMP server
Authentication Algorithm column	MD5 or SHA
Encryption Algorithm column	DES, 3DES, AES128, AES192, and AES256
Add	Used to add a new configuration. The Add button opens the Add Trap Settings dialog box.
Edit	Used to edit an existing configuration. The edit button opens the Edit Trap Settings dialog box.
Copy Settings	Used to copy all the settings in an existing configuration. The Copy Settings button opens the Copy SNMP Trap Settings dialog box.
Delete	Used to delete an existing configuration
Enable	Used to enable an existing configuration
Disable	Used to disable an existing configuration

Add/Edit/Copy SNMP Trap Entries Dialog Box

Use the Add/Edit/Copy SNMP Trap Entries dialog box to add, edit, and otherwise work with and configure SNMP traps.

Navigation Path

In Health and Performance Monitor, select **SNMP Trap Configuration** from the Tools menu. Then select **Add**, **Edit**, or **Copy Settings**.

The Add/Edit/Copy SNMP Trap Entries dialog box contains the following areas:

- The IP/Host and Port area
- The Trap Settings area for FW Alerts, IPS Alerts, and VPN Alerts

- The Trap Settings area for SNMP Options

Field Reference

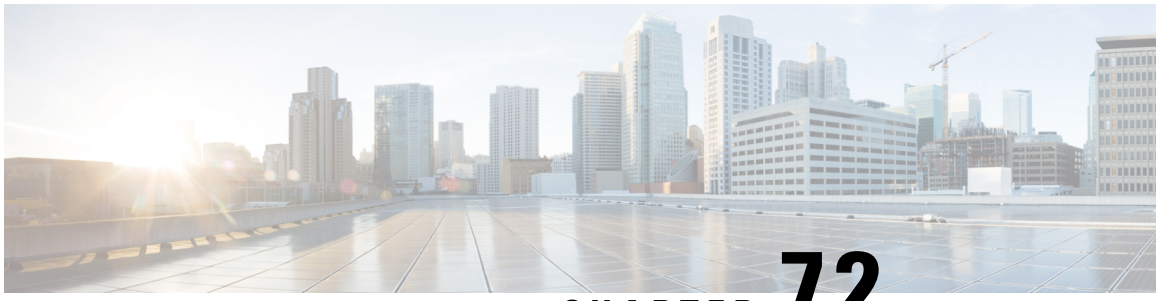
Table 990: The Trap Settings area and other options in the Add/Edit/Copy SNMP Trap Entries dialog box

Field	Description
Trap Settings	Used to select all or only selected alerts for FW, IPS, and VPN, described in the following topics: • Alerts Configuration: Firewall , on page 2823 • Alerts Configuration: IPS , on page 2822 • Alerts Configuration: VPN , on page 2825
SNMP Options	
RO Community String (SNMP version v1 and v2c only)	The password used for authentication in SNMP version v1 or v2c.
Group Type (SNMP version v3 only)	NOAUTH, AUTH, or PRIV.
Engine ID (SNMP version v3 only)	The SNMPEngineID identifier used for authentication in v3.
User Name (SNMP version v3 only)	The username for authentication to the SNMP server.
Authentication Password (SNMP version v3 only)	The password for authentication to the SNMP server.
Authentication Protocol (SNMP version v3 only)	MD5 or SHA.
Encryption Password (SNMP version v3 only)	The password for MD5 or SHA encryption.
Encryption Protocol (SNMP version v3 only)	DES, 3DES, AES128, AES192, and AES256.

NOTE: In order to use AES192, AES256, or 3DES, you must follow these steps:

1. Download the unlimited strength cryptography policy .jar files from http://www.oracle.com/technetwork/ > Downloads > Java SE > Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for JDK/JRE 7. (Click the download button to download the files by accepting the license agreement.)
2. Replace local_policy.jar and US_export_policy.jar on your Security Manager server in the folder CSCOpx\MDC\vms\jre\lib\security.

3. Restart your Security Manager server.



CHAPTER 72

Using External Monitoring, Troubleshooting, and Diagnostic Tools

A high degree of network availability is a requirement for large enterprises and service providers. Network managers face various challenges in maintaining network availability, including unscheduled down time, lack of expertise, insufficient tools, complex technologies, business consolidation, and competing markets. Network monitoring, problem diagnosis, and troubleshooting are essential to meeting and overcoming these challenges.

Monitoring involves the study of network activity and device status to identify anomalous events and behaviors. Quickly diagnosing and correcting network and system faults such as outages and degradations increase service availability, and thus tools to isolate, analyze and correct problems are essential.

The main Security Manager tools for monitoring device events are the Health and Performance Monitor (see Chapter 71, “Health and Performance Monitoring”) and the Event Viewer (see Chapter 69, “Viewing Events”).

In addition to Health and Performance Monitor and Event Viewer, the following topics describe additional monitoring, troubleshooting and diagnostic tools that are available with Security Manager:

Dashboard Overview

Beginning with Version 4.5, the Security Manager client has a new launch point—a configurable dashboard, for which this topic presents an overview.

The dashboard is one of the six client applications that you can select as your default client application when you start the Security Manager client. (The others are Configuration Manager, Event Viewer, Report Manager, Health and Performance Manager, and Image Manager; there is also an application designed for mobile devices called CSM Mobile.) The dashboard is a convenient way for you to accomplish tasks that are found in several

other areas of Security Manager, such as the IPS Health Monitor page, Report Manager, Health and Performance Monitor, and IP Intelligence Settings.

The dashboard contains the widgets shown in the following table, categorized by whether they are for use with IPS, firewalls, or both. (Not all of these widgets are shown by default). In addition to the original dashboard, you can create new, additional dashboards, which are displayed as tabs. You can customize all dashboards, both the original dashboard and any new, additional dashboards that you create. To customize a dashboard, you can drag and drop widgets from the list of available widgets into any dashboard.

Table 991: Widgets for IPS, Firewalls, and Both

Widgets for IPS	• **IPS Inspection Load Trends** • **Top 10 Reports for IPS Attackers, Victims, and Signatures** • **IPS Missed PacketTrends** • **IPS License** • **IPS Update Packages** • **IPS Sensors Out of Date**
Widgets for Firewalls	• Top 10 Reports for Firewall Sources, Destinations, and Services • Top 10 Reports for Botnet Malware Sites, Ports, and Hosts • Firewall CPU Usage Trends
Widgets for Both IPS and Firewalls	• Device Health Summary • Memory Usage Trends • Deployment • IP Intelligence

The way in which you use the dashboard and its widgets depends upon your goals in using Security Manager. For example, you can use the following four widgets to observe device health trends:

- IPS Inspection Load Trends
- IPS Missed Packet Trends
- Memory Usage Trends
- Firewall CPU Usage Trends

Individual widgets are described in the following table. One of the key widgets is the Device Health Summary widget. One reason it is important is that it provides the same information accessible through CSM Mobile, which is designed specifically for mobile devices. For more information about CSM Mobile, see CSM Mobile, on page 2846. For information on enabling or disabling CSM Mobile, see CSM Mobile Page , on page 520.

Table 992: Description of Individual WidgetsDashboard widgetswidgets for IPS in Dashboardwidgets for firewall in dashboard

IPS Inspection Load Trends	**A measure of the IPS inspection load trends. The inspection load trend data will appear in this widget only when an IPS device issues an alert because of inspection load, and the data will disappear when the alert is cleared.** **Indicates how much traffic inspection capacity the sensor is using. 0 indicates that there is no traffic backup, and 100 indicates that the buffers are completely backed up. Inspection load trends are affected by the following things:** • **Rate of traffic that needs inspection** • **Type of traffic being inspected** • **Number of active connections being inspected** • **Rate of new connections per second** • **Rate of attacks being detected** • **Signatures active on the sensor** • **Custom signatures created on the sensor** **You can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.**
Top 10 Reports for IPS Attackers, Victims, and Signatures	Pre-defined system reports that you can use to analyze top attackers, victims, and signatures for IPS alerts in your network. **Clickable Link**—In the Top Attackers widget, the IP address is an active hyperlink; click it to display IP intelligence. For details on IP intelligence in Security Manager, refer to IP Intelligence, on page 2870>. **Clickable Link**—In the Top Signatures widget, the Signature ID is an active hyperlink; click it to display signature information. To use these reports, use Report Manager (Launch > Report Manager...). To cross-launch Event Viewer from one of these top ten reports, select a particular attacker, victim, or signature, and click the number of occurrences. The number of occurrences is listed for the last 24 hours by default; you can change it to the last hour if desired. **Note** When you cross-launch Event Viewer, the event query time in Event Viewer will be shown as the last 10 minutes despite its being the last 24 hours or the last hour in the Summary Dashboard. You can change the event query time in Event Viewer from the last 10 minutes to another value by using the dropdown list.
IPS Missed Packet Trends	A measure of the IPS missed packets trends. The missed packets trend data will appear in this widget only when there is an alert based on missed packets, and the data will disappear when the alert is cleared. You can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.

IPS Inspection Load Trends	**A measure of the IPS inspection load trends. The inspection load trend data will appear in this widget only when an IPS device issues an alert because of inspection load, and the data will disappear when the alert is cleared.** **Indicates how much traffic inspection capacity the sensor is using. 0 indicates that there is no traffic backup, and 100 indicates that the buffers are completely backed up. Inspection load trends are affected by the following things:** • **Rate of traffic that needs inspection** • **Type of traffic being inspected** • **Number of active connections being inspected** • **Rate of new connections per second** • **Rate of attacks being detected** • **Signatures active on the sensor** • **Custom signatures created on the sensor** **You can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.**
IPS License	Displays IPS devices for which the license will expire in 30 days or 60 days. (Use the dropdown list to choose 30 days or 60 days.) If the license will expire in 30 days or 60 days (whichever you select) this widget displays the license expiry date.
IPS Update Packages	Displays sensor updates and signature updates that are available on Cisco.com or on a local download server but not downloaded to the Security Manager server. If there are many such updates, then this widget displays only the 10 most recent updates.
IPS Sensors Out of Date	Sensors requiring a signature update.
Top 10 Reports for Firewall Sources, Destinations, and Services	Pre-defined system reports that you can use to identify the top destinations, services, and sources for firewall ACL events. The statistics are based on the events collected by the Event Manager service (as displayed in Event Viewer). To use these reports, use Report Manager (Launch > Report Manager...).
Top 10 Reports for Botnet Malware Sites, Ports, and Hosts	Pre-defined system reports that you can use to analyze botnet traffic filtering. The statistics are based on the botnet events collected by the Event Manager service (as displayed in Event Viewer) for sites on the block list and gray list. To use these reports, use Report Manager (**Launch** > **Report Manager**...).
Firewall CPU Usage Trends	A measure of the firewall CPU usage trends. The CPU usage trend data will appear in this widget only when a firewall issues an alert because of CPU usage, and the data will disappear when the alert is cleared.

IPS Inspection Load Trends	**A measure of the IPS inspection load trends. The inspection load trend data will appear in this widget only when an IPS device issues an alert because of inspection load, and the data will disappear when the alert is cleared.** **Indicates how much traffic inspection capacity the sensor is using. 0 indicates that there is no traffic backup, and 100 indicates that the buffers are completely backed up. Inspection load trends are affected by the following things:** **• Rate of traffic that needs inspection** **• Type of traffic being inspected** **• Number of active connections being inspected** **• Rate of new connections per second** **• Rate of attacks being detected** **• Signatures active on the sensor** **• Custom signatures created on the sensor** **You can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.**
Device Health Summary	

IPS Inspection Load Trends	**A measure of the IPS inspection load trends. The inspection load trend data will appear in this widget only when an IPS device issues an alert because of inspection load, and the data will disappear when the alert is cleared.** **Indicates how much traffic inspection capacity the sensor is using. 0 indicates that there is no traffic backup, and 100 indicates that the buffers are completely backed up. Inspection load trends are affected by the following things:** • **Rate of traffic that needs inspection** • **Type of traffic being inspected** • **Number of active connections being inspected** • **Rate of new connections per second** • **Rate of attacks being detected** • **Signatures active on the sensor** • **Custom signatures created on the sensor** **You can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.**
	Shows current high- or medium-severity active alerts generated by HPM. Alerts can be grouped by Alert-Description, Predefined-Category, Device, or Alert Technology. **Clickable Link**—The device name is an active hyperlink; click it to display the Device Summary dialog box in the Dashboard. This link works for any option in the **Group by _____** dropdown list: Alert, Category, Device, or Technology. To configure these alerts, use HPM (Launch > Health and Performance Monitor...). **Note** After enabling a device for monitoring in HPM, it can take up to 5 minutes for priority devices and 10 minutes for non-priority devices before actual values can be seen in the Device Health Summary. **Acknowledge Alert**—To acknowledge an alert, follow these steps: **1.** Use the **Group by _____** dropdown list to choose Alert, Category, Device, or Technology. **2.** Expand the alert, category, device, or technology that you are interested in. Doing this will show you an alert, category, device, or technology for each device that you are monitoring in Security Manager. **3.** Click the **Details** icon (pictured at the end of this topic). Doing this will open the Alert dialog box. **4.** Click **Acknowledge Alert** **Clear Alert**—To clear an alert, follow these steps: **1.** Use the **Group by _____** dropdown list to choose Alert, Category, Device, or Technology. **2.** Expand the alert, category, device, or technology that you are interested in. Doing this will show you an alert, category, device, or technology for each device that you are monitoring in Security Manager. **3.** Click the **Details** icon (pictured at the end of this topic). Doing this will open the Alert

IPS Inspection Load Trends	**A measure of the IPS inspection load trends. The inspection load trend data will appear in this widget only when an IPS device issues an alert because of inspection load, and the data will disappear when the alert is cleared.** **Indicates how much traffic inspection capacity the sensor is using. 0 indicates that there is no traffic backup, and 100 indicates that the buffers are completely backed up. Inspection load trends are affected by the following things:** • **Rate of traffic that needs inspection** • **Type of traffic being inspected** • **Number of active connections being inspected** • **Rate of new connections per second** • **Rate of attacks being detected** • **Signatures active on the sensor** • **Custom signatures created on the sensor** **You can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.**
	dialog box. 4. Click **Clear Alert** You can also access device health summary information from mobile devices. To do this, use the CSM Mobile application. The information available to you from CSM Mobile is the same as that available in the Device Health Summary widget in the Dashboard. For information on enabling or disabling CSM Mobile, see CSM Mobile Page , on page 520.
Memory Usage Trends	A measure of IPS health status or firewall health trends. For IPS devices, you can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.
Deployment	Shows the deployment status for all devices for the past 24 hours You can also monitor deployment status by using Deployment Manager (Configuration Manager > Manage > Deployments...) .
IP Intelligence	Information about an IP address related to the following things: • IP Geolocation • FQDN through DNS reverse lookup • WHOIS information For IP Intelligence settings in Security Manager, navigate to Configuration Manager > Tools > Security Manager Administration > IP Intelligence Settings.

IPS Inspection Load Trends	**A measure of the IPS inspection load trends. The inspection load trend data will appear in this widget only when an IPS device issues an alert because of inspection load, and the data will disappear when the alert is cleared.** **Indicates how much traffic inspection capacity the sensor is using. 0 indicates that there is no traffic backup, and 100 indicates that the buffers are completely backed up. Inspection load trends are affected by the following things:** • **Rate of traffic that needs inspection** • **Type of traffic being inspected** • **Number of active connections being inspected** • **Rate of new connections per second** • **Rate of attacks being detected** • **Signatures active on the sensor** • **Custom signatures created on the sensor** **You can set monitoring parameters on the IPS Health Monitor page at [IPS device in Device View] Platform > Device Admin > Health Monitor.**
CSM Monitor	Shows server information in three categories: • CSM Server Statistics. This information is self-explanatory; for example, the operating system boot time is listed. • CSM User Related Information. This information consists of only one item, the number of users logged in. • CSM DB Backup Related Information. This information tells you if the CSM Monitor widget has found a dangling backup lock file. Knowing if you have a dangling backup lock file is important for the following reason: When a CSM backup is performed, it fails with an error similar to this: "Backup failed.ERROR(383): C:\PROGRA~2\CSCOpx\backup.LOCK file exists." The solution can be described as follows: Security Manager creates a new lock file (backup.LOCK) in the backup directory before it starts a backup. If a backup is interrupted or fails, the file does not get cleaned up. You must delete the current backup.LOCK file from the Security Manager server, and then execute the backup process again. The CSM Monitor widget makes it faster and more convenient for you to detect a dangling backup lock file. For detailed information, refer to the Cisco TAC document at the following URL: http://www.cisco.com/en/US/products/ps6498/products_tech_note09186a0080c13cdd.shtml

Note In some cases, Top Infected Hosts, for example, the dashboard report has a slightly different appearance than the report generated by Report Manager. This is caused by a difference in sorting, but the data is identical. Such a case will occur when more than one entry in the dashboard report has the same count.

Basic dashboard operations are listed in the following table:

Table 993: Basic Dashboard OperationsDashboard operations

Launch Dashboard	**Configuration Manager or other Security Manager client application > Launch > Dashboard...**
Add a new dashboard	File > New Dashboard
Re-arrange Dashboard Tabs for a Default View	You can re-arrange the dashboard tabs so that you can set a default view. For example, you might want the IPS tab to be first (on the extreme left): **1.** Click a tab that you are interested in, e.g., Summary, Firewall, or IPS. **2.** While your tab of interest is still selected, right-click to see the following context menu options: Move to Left, Move to Right, Move to First, Move to Last. **3.** Click your choice. **4.** You do not need to save your changes, and your changes will be persistent--the individual dashboard tabs will be arranged in the same way the next time you launch the Dashboard.
Display a different dashboard	Click the tab for the desired dashboard, such as Summary, Firewall, or IPS.
Show or hide widgets	File > Show Widgets or File > Hide Widgets
Add a widget	Drag-and-Drop Method: **1.** File > Show Widgets **2.** Drag and drop the desired widget onto the dashboard. Menu Method: **1.** File > Show Widgets **2.** Select the desired widget by clicking it. **3.** Click **Add** in the Description bar. **4.** Click **Done** in the Description bar. **Note** When using the menu method, the widget will be added to the upper left-hand corner of the Dashboard. If desired, you can rearrange all the widgets by dragging and dropping them.
Remove a widget	Click the **Remove** icon in the title bar of the widget that you want to remove.

Launch Dashboard	Configuration Manager or other Security Manager client application > Launch > Dashboard...
Expand a widget	If a widget is shown in the dashboard, you can expand it with the down arrow. The down arrow becomes visible when you hover the mouse pointer over the right side of the widget title bar. The tooltip for the down arrow is labeled "Expand." **Note** A special consideration applies when you 1) collapse a widget, 2) exit the dashboard, and then 3) launch the dashboard again. In this case, you will find that the widget is still collapsed, but the down arrow (normally used to expand it) is not present; only the up arrow (normally used to collapse it) is present. To expand the widget in this case, click the up arrow, note that the down arrow re-appears, and then click the down arrow as usual.
Collapse a widget	If a widget is shown in the dashboard, you can collapse it with the up arrow. The up arrow becomes visible when you hover the mouse pointer over the right side of the widget title bar. The tooltip for the up arrow is labeled "Expand" (not "Collapse").
Group by _____ (Device Health Summary widget only)	A dropdown list offering you the following choices: • Group by Alert • Group by Category • Group by Device • Group by Technology **Note** In the Group by _____ dropdown list, you can click the display name of a device (underlined to indicate that it is a hyperlink) to see an information box on the health of that device in terms of memory and other parameters. The information box contains an address field; the address can be either Host.Domain or the IP address: if Host.Domain is configured, that information will be displayed; otherwise, the IP address will be displayed.

In the Dashboard, many of the icons can be clicked to accomplish a particular action, such as "Refresh" or "Add Dashboard." Most of these "clickable" icons have a tooltip to document the action that clicking the icon will accomplish, but a few do not. Clickable icons that have no tooltip in the dashboard are documented in the following table.

Table 994: Clickable Icons that have no Tooltip in the DashboardDashboard iconsicons without tooltips in Dashboard

Icon	Appearance	Widget	Description
	Black exclamation point (bang) on a yellow background in a triangle.	Deployment widget	**Deploying** icon. Indicates that a job is in the deploying state. Click this icon to open/close the job description: • Created date and time • Job Name • Description • State • User • Job Type
	White rectangle (a document) with red and yellow dots.	Deployment widget	**Status Report** icon. Click this icon to see a detailed Deployment Status report
	White checkmark in a green circle with a grey border.	Deployment widget	**Succeeded** icon. Indicates that a job is in the success state. Click this icon to open/close the job description: • Created date and time • Job Name • Description • State • User • Job Type
	White "X" in a red circle with a grey border.	Deployment widget	**Failed** icon. Indicates that a job is in the failed state. Click this icon to open/close the job description: • Created date and time • Job Name • Description • State • User • Job Type

Icon	Appearance	Widget	Description
	Clipboard with a pencil making annotations on a sheet of paper.	Device Health Summary widget	**Details** icon. Click this icon to open/close the job description: • Created date and time • Job Name • Description • State • User • Job Type

CSM Mobile

Beginning with Version 4.5, Cisco Security Manager has an application called CSM Mobile.

CSM Mobile allows you to access device health summary information from mobile devices. The information available to you in this way is the same as that available in the Device Health Summary widget in the Dashboard: current high or medium severity active alerts generated by Health and Performance Monitor. Alerts can be grouped by Alert-Description, Predefined-Category, Device, or Alert Technology. For more details on device health summary information in the Dashboard, see Dashboard Overview, on page 2835.

The principal users of CSM Mobile are expected to be those who use an Apple iPad, an Apple iPhone, the Google Chrome browser, or the Apple Safari browser.

CSM Mobile must be enabled for you to use it. For information on enabling or disabling CSM Mobile, see CSM Mobile Page , on page 520.

Note If the CSM Mobile feature is not enabled, you will be redirected to the default Security Manager login page (which is provided by the CiscoWorks Common Services framework software); you will not receive an error message.

The home page for CSM Mobile has the following alert categories:

- Device Not Reachable
- Interface Down
- Overall Device Health Alerts
- High Memory Utilization
- Firewall—High CPU Utilization
- IPS—High Inspection Load
- IPS—High Missed Packets
- IPS—Bypass Mode

- Other Alerts

Navigation and other tasks in CSM Mobile are accomplished by using a few simple screens and icons:

- **Login**—A screen reading "Cisco Security Manager Mobile—Version 4.5.0" with fields for username and password and a button for login.
- **Logout**—On the CSM Mobile home page, a white X icon on a blue background. This icon is located in the upper left-hand corner.
- **Refresh**—On the CSM Mobile home page, a white circular arrow icon on a blue background. This icon is located in the upper right-hand corner.
- **Alert Detail**—For each type of alert on the CSM Mobile Home page, an grey arrow icon to the right of the alert count.
- **CSM Mobile Back Button**—On each alert detail page, a white angle arrow on a blue pentagon-shaped background [available only on alert detail pages]. The CSM Mobile back button is functionally equivalent to your browser's back button.

Note The CSM Mobile display does not refresh itself automatically; you must manually click the refresh button to obtain up-to-date alert data.

Viewing Inventory Status

You can view a summary of device properties for all devices that you are authorized to view. The summary includes device contact information and all device configurations, indicating which settings are local and which are using a shared policy, and indicating any policy object overrides in effect. You can also view the status of configuration deployment to the device.

The report is in table format, allowing you to organize information by filtering, sorting, reordering and removing columns. You can also export the table contents to a comma-separated values (CSV) file on the Security Manager server.

Step 1 In Device view, select **Tools > Inventory Status** to open the Inventory Status Window , on page 2848.

Step 2 Select the device whose detailed status you want to view in the upper table. The detailed information is shown in the tabs in the lower pane. The information is organized into folders; click the +/- icons to open and close folders, or double-click the folder name. The following tabs are available:

- Inventory—Lists summary information about the selected device's device properties, deployment methods, device group membership, and the parent device for modules.
- Policy—Lists the current status of the policies that can be configured for the selected device, whether the policy is unassigned (not defined), a local policy, or a shared policy.
- Policy Object Overrides—Lists policy objects that have overrides defined for the selected device.
- Status—Lists status messages from Security Manager deployment jobs for the selected device, organized by event type.

An **event** is a notification that a managed device or component has experienced an abnormal condition. Multiple events can occur simultaneously on a single monitored device or service module.

Security Manager displays only the most-recent event of each type. To view historical status information, use the Deployment Manager.

Step 3 Click **Close** to close the Inventory Status window.

Inventory Status Window

Use the Inventory Status window to view device properties and status for the devices that you are allowed to view. This window summarizes device information so that you do not have to open the device properties for each individual device.

In addition to device property information, you can view summary information about how the policies on each device are configured (whether local, shared, or not configured) and the policy objects that have overrides for each device. You can also view the status of configuration deployment to the device.

The Inventory Status window contains two panes. Use the upper pane to view a complete listing of all devices, to sort the devices by attribute, or to filter out certain ones. Use the lower pane to view the device property details of the device selected in the upper pane.

Navigation Path

Select **Tools** > **Inventory Status**.

Field Reference

Table 995: Inventory Status Window

Element	Description
Device Summary Information for All Devices (Upper Pane)	
Export button	Click this button to export the inventory as a comma-separated values (CSV) file. You are prompted to specify a file name and to select a folder on the Security Manager server. You can use the export file for reference or analysis.
Display Name	The name of the device as it is displayed in Security Manager.
Deployment	The status of the configuration deployment for the device.
OS Type	The family of the operating system running on the device, for example, IOS, IPS, ASA, FWSM, or PIX.

Element	Description
Running OS Version	The version of the operating system running on the device.
Target OS Version	The target OS version for which you want to apply the configuration. Configurations are based on the commands supported by this version.
Host Name.Domain Name	The DNS host and domain names for the device.
IP Address	The management IP address of the device.
Device Type	The type of device.
Details for the Selected Device (Lower Pane) The detailed information is shown in the tabs in the lower pane. The information is organized into folders; click the +/- icons to open and close folders, or double-click the folder name.	
Inventory	Lists summary information about the selected device's device properties, deployment methods, device group membership, and the parent device for modules.
Policy	Lists the current status of the policies that can be configured for the selected device, whether the policy is unassigned (not defined), a local policy, or a shared policy.
Policy Object Overrides	Lists policy objects that have overrides defined for the selected device. For more information on policy object overrides, see Policy Object Override Pages , on page 124.
Status	Lists any deployment status messages for the selected device. Events are organized by event type. Event details include timestamp, description, and recommended action. The time stamp indicates the time of the last change in status for the device, not the time of the latest polling of the device. Also shown is the highest severity level of the status messages.
Navigation buttons	Click the navigation buttons to move through the inventory list. From left to right, buttons mean go to the first device in the list, go to the previous device, go to the next device, and go to the last device. The center field indicates which device is currently selected based on the row number (for example 5/10 means the fifth of 10 devices in the list).

Starting Device Managers

You can start a device manager to view a device's configuration and status from within Security Manager. You can start device managers for ASA, ASA-SM, PIX, FWSM, IPS, and IOS devices.

Each device manager includes several monitoring and diagnostic features that provide information regarding the services running on the device and a snapshot of the overall health of the system. You can use these device managers to view the existing device configuration and to monitor current status, but you cannot use it to apply configuration changes to the device.

Note You cannot start device managers for IPS virtual sensors.

Note In Cisco Security Manager 4.16, due to upgrade of JRE 1.7 build 161, support to some of old applets are dropped. Hence, beginning from Cisco Security Manager 4.16 you cannot launch PIX 6.3, IDS/IPS versions 5.x to 7.x, and FWSM 2.x directly.

Note Beginning with version 4.21, Cisco Security Manager supports cross-launch of ASDM for ASA 9.14(1) and earlier devices. However, to avail this feature, ensure the CLI `http server basic-auth-client Java` is configured manually in ASA.

To start a device manager, select the device in Device view, right-click and select **Device Manager**. You can also start the device manager by selecting **Launch > Device Manager**. (These commands are disabled when you select an ASA CX device, and the **Prime Security Manager** commands are enabled. Cisco Prime Security Manager is used to configure and manage ASA CX devices. See Launching Cisco Prime Security Manager or FireSIGHT Management Center , on page 2856 for more information.)

When you start a device manager from Security Manager, the device manager executable is downloaded to your client system; the device manager does not need to be installed on the network device. The first time you start a device manager, it takes time to download the software to your workstation (you are shown a progress bar). (If you run into problems, review the tips in Troubleshooting Device Managers , on page 2851.)

Security Manager selects the most appropriate device manager version based on the operating system running on the network device. Subsequent communications with the selected device are completely transparent. Connections are made through the Security Manager server; that is, the Security Manager server acts as a proxy server. By starting a device manager from Security Manager, you eliminate the need to open an HTTPS connection between your client system and the device you want to monitor.

Tip When you start a device manager session, Security Manager opens a version of the manager that is appropriate for the operating system software version running on the device (See ASA and ASDM Compatibility Per Model for more information). However, Security Manager might not open the most recently-available version of the device manager if new device manager versions have been released after the release of the Security Manager version you are using. When you start the device manager, check its version (for example, select **Help > About** in the device manager window); if there is a more recent device manager available with features that you require, you must install and use that device manager outside of Security Manager to use those new features.

Keep in mind that if you use an external device manager running on the device to modify device configurations directly, these changes are considered out-of-band by Security Manager, and might be subsequently overwritten when you next deploy configurations from Security Manager. For more information about out-of-band changes, and what you can do to identify and recreate them, see the following topics:

- Understanding How Out-of-Band Changes are Handled , on page 392
- Detecting and Analyzing Out of Band Changes , on page 426

Security Manager starts only one instance of a device manager per device, and closes the device manager when you exit Security Manager, or when the idle-session timeout period is exceeded. You can have more than one device manager window open at one time (connected to different devices).

The following table outlines the device managers you can launch from Security Manager.

Table 996: Device Managers Available in Security Manager

Device Manager	Description
IDM	The IPS Device Manager (IDM) lets you monitor IPS sensors and modules that are part of the Security Manager inventory. See the IDM documentation for more information about using this device manager.
PDM	The PIX Device Manager (PDM) lets you monitor PIX 6.x devices and early FWSMs, specifically FWSM releases 1.1, 2.2 and 2.3 in single- or multiple-context modes. See the PDM documentation for more information about using this device manager.
ASDM	The Adaptive Security Device Manager (ASDM) lets you monitor ASA, ASA-SM, PIX 7.x+, and FWSM 3.x+ devices. See the ASDM documentation for more information about using this device manager.
SDM	The Security Device Manager (SDM) lets you monitor Cisco IOS-based resources. SDM requires no previous experience with Cisco devices or the Cisco command-line interface (CLI). Cisco SDM supports a wide range of Cisco IOS software releases. See the SDM documentation for more information about using this device manager.

The following topics explain more about troubleshooting and using device managers:

- Troubleshooting Device Managers , on page 2851
- Access Rule Look-up from Device Managers , on page 2853
- Navigating to an Access Rule from ASDM , on page 2854
- Navigating to an Access Rule from SDM , on page 2855

Troubleshooting Device Managers

If you can successfully deploy configurations to a device, Security Manager should be able to open a device manager session with the device (as described in xre Starting Device Managers , on page 2849).

Note Beginning with version 4.21, Cisco Security Manager supports cross-launch of ASDM for ASA 9.14(1) and earlier devices. However, to avail this feature, ensure the CLI `http server basic-auth-client Java` is configured manually in ASA.

However, if you have problems making a connection or using one that is open, consider the following troubleshooting tips, which are divided into basic tips and tips for using multiple device managers.

Basic Device Manager Troubleshooting Tips

- Generally, the credentials configured for the device in the Security Manager inventory are used to start the device manager. However, some versions of SDM require that you enter a user name and password when the device manager is started. If you get an error that says device credentials are missing, or they are not valid, update the Device Properties Credentials page with a username and password that can log into the device. In Device view, right-click the device and select **Device Properties**. For more information, see Viewing or Changing Device Properties , on page 109 and Device Credentials Page , on page 114.
- All users associated with any of the CiscoWorks Common Services roles have permission to start device managers from Security Manager, with the exception of the Help Desk role or any of the predefined Cisco Secure ACS roles. Ensure you have appropriate permissions.
- SSL/HTTPS must be enabled on the target device to provide secure communications between Security Manager and the device. An error message is displayed if SSL is not enabled on the device. See Understanding Device Communication Requirements , on page 57 for more information.
- You might need to modify Cisco Security Agent, or other anti-virus and network firewall software, on the Security Manager system and on your workstation to allow the device manager service (**xdm-launcher.exe**) to be started.
- Ensure that Security Manager is correctly configured for contacting and communicating with the target device. Specifically verify device properties such as identity, operating system and credentials. Select the desired device, right-click and choose **Device Properties**. Verify the settings on the General and Credentials pages. You can test whether Security Manager can connect to the device by selecting the Credentials tab and clicking **Test Connectivity** (see Testing Device Connectivity , on page 457).

Note If you run the packet tracer when the **Running OS Version** field under the Operating System frame of **General** tab under **Device Properties** is blank, CSM incorrectly checks for the device liveness using the **Running OS Version** field and considers the ASA device to be dead.

- Device managers can be started for FWSMs and ASAs running in transparent mode (Layer 2 firewall) or routed mode (Layer 3 firewall), and supporting a single security context or multiple security contexts. For FWSM and ASA devices running multiple security contexts, you must define a unique management IP address for each security context.
- If you get a message saying that the platform is not supported for device manager launch, but you believe the platform should be supported based on information in this guide, consider the relative newness of the operating system version running on the device and the age of the Security Manager software version you are using. If you are using very recent operating systems, but a relatively older version of Security Manager, you might need to upgrade Security Manager (or apply a service pack), contact Cisco Technical Support, or simply install the latest device manager on the network device and use it outside of Security Manager. Before using a device manager outside of Security Manager, review the information on out-of-band changes in Starting Device Managers , on page 2849.

Multiple Device Manager Sessions Troubleshooting Tips

- Starting multiple device managers might affect the performance of both the Security Manager server and your client. On the client, memory requirements and performance impact are proportional to the number

of device managers launched. On the server, a large number of requests to start device managers or retrieve current information from the device can have an adverse impact on performance.

- The maximum number of persistent HTTPS connections that can be established with any one device from all clients depends on the device type and model. An error message is displayed if you attempt to exceed this limit.

For example, a single PIX 6.x allows multiple clients to each have one browser session open, supporting up to 16 concurrent PDM sessions. An FWSM (1.1, 2.2, or 2.3) allows up to 32 PDM sessions for the entire module, with a maximum of five concurrent HTTPS connections per context.

Refer to the appropriate device documentation for information about specific limits.

Access Rule Look-up from Device Managers

A set of access rules is associated with each device interface. These rules are presented in the form of an ordered list or table. This list is often referred to as an access-control list (ACL), with each rule in the list known as an access-control entry (ACE). When deciding whether to forward or drop a packet, the device tests the packet against each access rule in the order listed. When a rule is matched, the device performs the specified action, either permitting the packet into the device for further processing, or denying entry. If the packet does not match any rule, the packet is denied.

Activity on your firewall or router can be monitored through syslog messages. If logging is enabled on the device, whenever an access rule that is configured to generate syslog messages is matched—for example, a connection was attempted from a denied IP address—a log entry is generated.

Note For the device to generate log entries, logging must be enabled on the device (on the Logging Setup Page , on page 2046 for ASA/PIX devices and the Logging policies for IOS devices, described in Logging on Cisco IOS Routers , on page 2515), and the individual access rules must be configured to generate log messages when they are matched (in the Advanced and Edit Options Dialog Boxes , on page 733).

You can monitor syslog messages in device managers launched from Security Manager. For certain device managers, you can also look up the access rule in Security Manager that generated a particular message from the monitoring window. The access rule that triggered the syslog entry is highlighted in Security Manager on a first-match basis, even if there are multiple matches.

This access rule look-up is available through SDM for all managed routers running IOS, and through ASDM for managed PIX and ASA devices (including ASA-SM) running version 8.0(3) and above, and FWSM devices running version 3.1 and above.

The following topics describe how to look up access rules in Security Manager from a device manager:

- Navigating to an Access Rule from ASDM , on page 2854
- Navigating to an Access Rule from SDM , on page 2855

Navigating to an Access Rule from ASDM

Note Beginning with version 4.21, Cisco Security Manager supports cross-launch of ASDM for ASA 9.14(1) and earlier devices. However, to avail this feature, ensure the CLI `http server basic-auth-client Java` is configured manually in ASA.

In an ASDM device manager launched from Security Manager, you can monitor system log messages in the Real-time Log Viewer window and the Log Buffer window. You can select a syslog message displayed in either window and navigate to the access-control rule in Security Manager that triggered the message, where you can update the rule as necessary.

The Real-time Log Viewer is a separate window that lets you view syslog messages as they are logged. The separate Log Buffer window lets you view messages present in the syslog buffer.

You can look up access rules associated with the following syslog message IDs:

- 106023 – Generated when an IP packet is denied by the access rule. This message appears even when logging is not enabled for the rule.
- 106100 – If logging is enabled for a matched access rule (in the Advanced and Edit Options Dialog Boxes , on page 733), this message provides information about the traffic flow, depending on the parameters set. This message provides more information than message 106023, which logs only denied packets.

This procedure describes how to look up an access rule in Security Manager from ASDM's Real-time Log Viewer or Log Buffer windows.

Related Topics

- Access Rule Look-up from Device Managers , on page 2853
- Navigating to an Access Rule from SDM , on page 2855

Step 1 Select a PIX, ASA, ASA-SM, or FWSM in the Security Manager device inventory.

Step 2 Select **Launch > Device Manager** to start ASDM. For more information about starting device managers, see Starting Device Managers , on page 2849.

Note Beginning with version 4.21, Cisco Security Manager supports cross-launch of ASDM for ASA 9.14(1) and earlier devices. However, to avail this feature, ensure the CLI `http server basic-auth-client Java` is configured manually in ASA.

Step 3 In the ASDM window, click the **Monitoring** button to display the Monitoring panel; click **Logging** in the left pane to access the log-viewing options.

Step 4 Select either **Real-time Log Viewer** or **Log Buffer**.

Step 5 Click the **View** button to open the selected log-viewing window.

Note The View button is not displayed if logging is not enabled on the device.

Each syslog message listed in the window includes the following information: message ID number, date and time the message was generated, the logging level, and the network or host addresses from which the packet was sent and received.

Step 6 To view the access rule that triggered a specific syslog message, select the message and click the **Show Rule** button in the ASDM toolbar (or right-click the message and choose **Go to Rule in CSM** from the pop-up menu).

The Security Manager client window is activated and the Access Rules page appears with the rule highlighted in the rules table. If the syslog entry was triggered by an access rule not referenced in the current Security Manager activity, an error message appears.

Navigating to an Access Rule from SDM

In an SDM device manager launched from Security Manager, you can view a log of events categorized by security level under the Syslog tab of the Logging window. You can select a syslog message and navigate to the access-control rule in Security Manager that triggered the message, where you can update the rule as necessary.

The Monitor > Logging option in SDM offers four log tabs; Syslog is the only one of these offering the Security Manager access-rule look-up option. The router contains a log of events categorized by severity level. The Syslog tab displays the router log, even if log messages are being forwarded to a syslog server.

On Cisco IOS devices, syslog messages are generated for access rules configured with the **log** or **log-input** keywords. The **log** keyword produces a message when a packet matches the rule. The **log-input** keyword produces a message that includes ingress interface and source MAC address, in addition to the packet's source and destination IP addresses and ports. When identical packets are matched, the message is updated at five-minute intervals with the number of packets permitted or denied in the previous five minutes.

This procedure describes how to look up an access rule in Security Manager from the Syslog tab of SDM's Logging panel.

Related Topics

- Access Rule Look-up from Device Managers , on page 2853
- Navigating to an Access Rule from ASDM , on page 2854

Step 1 Select an IOS router in the Security Manager device inventory.

Step 2 Select **Launch > Device Manager** to start SDM. For more information about starting device managers, see Starting Device Managers , on page 2849.

Step 3 In the SDM window, click the **Monitoring** button to display the Monitoring panel; click **Logging** in the left pane to access the log-viewing options.

The Logging pane appears with Syslog tab displayed.

Step 4 To view the access rule that triggered a specific syslog message, select the message and click the **Go to Rule in CSM** button above the table of log messages.

The Security Manager client window is activated and the Access Rules page appears with the rule highlighted in the rules table. If the syslog entry was triggered by an access rule not referenced in the current Security Manager activity, an error message appears.

Launching Cisco Prime Security Manager or FireSIGHT Management Center

The ASA CX is an Adaptive Security Appliance module that provides advanced ConteXt-aware security, extending the ASA platform to provide in-depth "who-what-where-when-how" application visibility and control. The ASA FirePOWER module supplies next-generation firewall services, including Next-Generation IPS (NGIPS), Application Visibility and Control (AVC), URL filtering, and Advanced Malware Protection (AMP).

The ASA CX devices are managed by the Cisco Prime Security Manager (PRSM) application and the ASA FirePOWER modules are managed by the FireSIGHT Management Center application—they cannot be directly managed by Cisco Security Manager. However, Security Manager has been enhanced to allow you to discover the presence of these modules on ASA devices; to "cross launch" PRSM and FireSIGHT Management Center from the Configuration Manager application; and to share Policy Object data between Security Manager and PRSM.

Note PRSM and FireSIGHT Management Center are browser-based applications; that is, they are launched and operate within a browser window. Therefore, when you cross-launch PRSM or FireSIGHT Management Center from the Configuration Manager client, the host system's default browser is opened and the management application initiated. However, some browsers have not been certified with PRSM or FireSIGHT Management Center and you may need to change the default browser on the Security Manager client's host system prior to cross-launching. See "Browser Requirements" in the PRSM or FireSIGHT Management Center installation guide for more information.

Before You Begin

In order to cross-launch PRSM or FireSIGHT Management Center, Security Manager must be aware of the presence of the modules. This is accomplished through discovery of either new ASA devices, or of modules which have been added to existing ASAs. This process is outlined in Detecting ASA CX and FirePOWER Modules , on page 2857.

Also, you can enable and configure "single sign-on" (SSO) to allow Security Manager users direct access to PRSM or FireSIGHT Management Center without logging into the applications separately. To allow this, the appropriate user credentials must be defined in both applications. (Note that SSO is not necessary to cross-launch PRSM or FireSIGHT Management Center.) See Security Manager's Single Sign-on Configuration Page, on page 581, and "Configuring Single Sign-On for Cisco Security Manager" in the *User Guide for ASA CX and Cisco Prime Security Manager* (Cisco ASA CX Context-Aware Security End-User Guides) for more information.

Related Topics

- Single Sign-on Configuration Page, on page 581
- Detecting ASA CX and FirePOWER Modules , on page 2857
- Sharing Device Inventory and Policy Objects with PRSM , on page 2858

To monitor and manage your ASA CX devices or FirePOWER Modules, cross-launch PRSM or FireSIGHT Management Center:

Step 1 Select a previously discovered ASA CX device or ASA with FirePOWER module in Configuration Manager's Device view—in either the device-selector tree, or the table of devices in the content area.

Again, discovering ASA CX devices or FirePOWER modules in Security Manager is described in Detecting ASA CX and FirePOWER Modules , on page 2857.

Step 2 Right-click the selected device and choose **Prime Security Manager** or **FireSIGHT Management Center** from the pop-up menu. Alternatively, you can choose **Prime Security Manager** or **FireSIGHT Management Center** from the Configuration Manager's **Launch** menu. (These commands are available only when you have selected an ASA CX or an ASA with a FirePOWER module.)

The browser-based PRSM or FireSIGHT Management Center window appears, displaying the device screen for the selected device.

Note The URL used by Security Manager to launch PRSM incorporates the management IP address of the CX module (obtained during device detection), and includes the string /admin/mgmt?rtp . During cross-launch, this type of request is redirected to the appropriate PRSM central server, if one exists. Otherwise, the "on-box" version of PRSM is launched. (To directly launch the on-box version of PRSM yourself, you must type **https://**<*management_IP_address*> , where <*management_IP_address*> is the management address of the desired CX module, into your browser's address field.)

Information about using PRSM can be found on the Cisco ASA CX Context-Aware Security End-User Guides page of cisco.com and information about using FireSIGHT Management Center can be found on the Cisco FireSIGHT Management Center page of cisco.com.

Detecting ASA CX and FirePOWER Modules

Prior to being able to share Policy Object data between Security Manager and PRSM, and to cross-launch PRSM or FireSIGHT Management Center from Configuration Manager, you must ensure that Security Manager is aware of the module.

Detection of a CX or FirePOWER module is automatic when you discover a new ASA device by selecting the relevant options in the New Device wizard, as described in Adding Devices to the Device Inventory , on page 77.

When you add a CX or FirePOWER module to an ASA device already in the inventory, you can detect the new module without affecting the existing policies on the host ASA, as follows:

1. Select one or more ASA devices in Configuration Manager's device-selector tree.

   You can detect more than one module at once—any selected devices that are not ASAs, or that are ASAs which do not include a CX or FirePOWER module, are ignored.

2. Right-click any selected device and choose **Detect ASA-CX/FirePOWER Module** from the pop-up menu.

   The Create Discovery Task dialog box or Bulk Rediscovery dialog box appears, with the *Detect ASA-CX/FirePOWER Module* option selected—none of the other discovery options are available.

   See Create Discovery Task and Bulk Rediscovery Dialog Boxes , on page 185 for more information about using this dialog box.

3. Click **OK** on the Create Discovery Task dialog box or click **Finish** on the Bulk Rediscovery dialog box to close the dialog box and begin module detection.

   You may be warned that discovery will replace existing policies; you can safely click Yes to close the warning and proceed.

   The Discovery Status dialog box opens automatically displaying discovery progress; see Viewing Policy Discovery Task Status , on page 188 for more information about this process.

When a CX or FirePOWER module is detected on an ASA, the management IP address of the module itself is fetched and the ASA-CX/FirePOWER Module section of the Device Properties window is updated; see Device Properties: General Page , on page 110. The management IP address is used to cross-launch PRSM or FireSIGHT Management Center. (Cisco Prime Security Manager, or PRSM, is the application used to configure and manage ASA CX devices and FireSIGHT Management Center is the application used to configure and manage ASA FirePOWER modules, as described in Launching Cisco Prime Security Manager or FireSIGHT Management Center , on page 2856.)

Note The URL used by Security Manager to launch PRSM incorporates the management IP address of the CX module (obtained during device detection), and includes the string /admin/mgmt?rtp . During cross-launch, this type of request is redirected to the appropriate PRSM central server, if one exists. Otherwise, the "on-box" version of PRSM is launched. (To directly launch the on-box version of PRSM yourself, you must type **https://**<*management_IP_address*> , where <*management_IP_address*> is the management address of the desired CX module, into your browser's address field.)

Upon completion of the detection process, all ASAs with CX modules installed are indicated in the various Security Manager displays by presentation or inclusion of the PRSM icon:

. For example, here is the ASA CX icon used in the Device selector:

Caution You also can detect the presence of a CX or FirePOWER module on an existing ASA by choosing **Discover Policies on Device(s)** from the selected-device right-click menu, or by choosing **Discover Policies on Device** from the Policy menu. Depending on the number of devices selected and which command you choose, the Create Discovery Task dialog box, or the Bulk Rediscovery Task dialog box, opens and all discovery-rediscovery options are available. This means you can potentially overwrite any shared policies already established on the selected device(s). Be sure to deselect all options except **Detect ASA-CX/FirePOWER Module**, unless you are sure you want to rediscover existing policies. See Discovering Policies on Devices Already in Security Manager , on page 181 for more information.

Sharing Device Inventory and Policy Objects with PRSM

You can export the current device inventory, and the current set of policy objects, as defined in Security Manager for import into Cisco Prime Security Manager (PRSM).

Exporting the Device Inventory

To share the Security Manager device inventory with PRSM, export the inventory as a comma-separated values (CSV) file, as described in Exporting the Device Inventory, on page 483. Be sure to specify "Cisco Security Manager" as the format type for the export file.

Exporting Networks/Hosts and Services Policy Objects

To export Security Manager policy objects—specifically Networks/Hosts objects, or Services objects; PRSM does not support Port List objects—for import into PRSM, you must execute a Perl script on the Security Manager server host to create a CSV file.

The Perl script is included in the Security Manager server installation, and its use is described in detail in Importing and Exporting Policy Objects , on page 253. The basic procedure is as follows:

1. Log into the computer running the Security Manager server, open a Cmd window, navigate to the Perl-script location, and then execute the Perl-script command at the command prompt.

Here is an example of the command as used to export Networks/Hosts objects: perl PolicyObjectImportExport.pl -u *user* -p *password* -o export -t network -f C:\CSM_Net_objects.csv -e true

1. Copy the CSV file to the PRSM client system.

This file can be edited, if necessary.

1. Launch PRSM and import the CSV file. For information about this process, see the section "Importing Objects" in the "Managing Policy Objects" chapter of the PRSM user guide.

Analyzing an ASA or PIX Configuration Using Packet Tracer

Note From version 4.17, though Cisco Security Manager continues to support PIX features/functionality, it does not support any bug fixes or enhancements.

Packet tracer is a policy debugging tool for ASA and PIX security appliances running version 7.2.1+ that are operating in router mode.

The packet tracer inspects the active policies currently running on the appliance. Without having to generate real traffic, you can analyze how traffic between two addresses traverses the security appliance, whether it is dropped or allowed. If the result is unexpected, you can determine where the issue exists and update the corresponding policy in Security Manager to resolve it.

Packet tracer presents a step-by-step analysis of how a simulated packet is processed by the security appliance's active configuration. It traces the packet's flow through the active firewall modules, such as route lookup, access lists, NAT translations, and VPN. The set of active modules changes based on the type of packet configured and the active configuration. For example, if no VPN policies are configured, the VPN module is not evaluated.

You can inspect the simulated packet's traversal rather than having to generate network traffic, enable syslog messages, and manually review resulting syslog messages. Packet tracer details the actions enforced by the active configuration on the packet. If a configuration command causes the packet to be dropped, the reason is provided, such as "Drop-reason: (telnet-not-permitted) Telnet not permitted on least secure interface."

You can trace the life span of a simulated packet through the security appliance to see whether the packet is behaving as expected. Packet tracer uses include the following:

- Debug all packet drops in a production network.
- Verify the configuration is working as intended.
- Show all rules applicable to a packet including the CLI that defines the rule.
- Show a time line of packet changes in a data path.
- Trace packets in the data path.
- If the packet is blocked or permitted by some explicit access rule, you can use a short-cut to go to the policy so that you can edit the rule.

Tips:

- Packet Tracer is also available in the ASDM application and the ASA command line, and the Security Manager version is equivalent to the ASDM version. For an example of using Packet Tracer from ASDM and the CLI to analyze a configuration, see PIX/ASA 7.2(1) and later: Intra-Interface Communications .
- Before you can use packet tracer on a device, you must submit your policy changes at least once after adding the device to the inventory.
- Packet tracer analyzes only the active configuration running on a device. Therefore, you cannot use packet tracer to test proposed configurations before they are deployed and running on the device. Do not use packet tracer on a device with pending configuration changes—deploy the changes first and then use packet tracer to ensure the packet tracer results are valid.

To use Packet Tracer:

Step 1 (Device view) Right-click on the ASA or PIX 7.2.1+ device and select **Packet Tracer** on the shortcut menu to open the Packet Tracer window.

Step 2 Select the interface you want to test from the **Interfaces** list. The list contains all interfaces defined on the device.

Step 3 Model the packet that you want to trace by configuring the following fields:

- **Packet Type**—Select whether you are tracing a TCP, UDP, ICMP, IP, or ESP packet.

Note Beginning with 4.16, Cisco Security Manager supports tracing of a ESP packet from ASA 9.9.1 devices.

- **Source, Destination IP Address**—Select from the following address types and enter the host addresses for both ends of the communication (from source to destination):
  - IP Address of the host. This can be IPv4 or IPv6 addresses. Packet tracer with IPv6 is not supported for devices running ASA software version lower than 8.4(2).
  - User (source only). For example, DOMAIN\Administrator. The IP address mapped to the user is used for the trace. You must enable identity-aware firewall by configuring identity options to use this type of address.
  - FQDN, or fully-qualified domain name, of the host. For example, host.example.com. You must configure DNS to use this type of address.
  - Security Name (ASA 9.x+ only).

- Security Tag (ASA 9.x+ only).

- **Source, Destination Port (TCP and UDP only)**—Enter, or select, the port numbers that represent the traffic type. The selection list uses names that equate to the standard port numbers for the named application. For example, selecting **http** and entering **80** is the same.
- **Type, Code, ID (ICMP only)**—When modeling an ICMP packet, you must enter values in all of these fields:
  - **Type**—Select the ICMP packet type or enter the equivalent number. The list includes all main ICMP types. For a complete list of types and related codes, see RFC 1700 at http://www.ietf.org/rfc/rfc1700.txt and search for "ICMP Type Numbers."
  - **Code**—Enter **0** unless you are modeling a packet type that has non-zero codes. These are destination unreachable (type 3, codes 0-12), redirect (type 5, codes 0-3), time exceeded (type 11, codes 0-1), and parameter problem (type 12, codes 0-2). See RFC 1700 for code explanations, and note that additional codes might have been introduced in other RFCs.
  - **ID**—You must enter a value for ID even though the field is used for a limited number of message types only. The ID is used for ICMP types that include request and reply versions, such as echo and echo request, to help match replies to requests. The value should be between 1-255.
- **Protocol (IP only)**—Enter the number that identifies the next level protocol. For a complete list of protocol codes, see RFC 1700 at http://www.ietf.org/rfc/rfc1700.txt and search for the "Protocol Numbers" heading. As of the writing of this topic, numbers 1-54 and 61-100 represent values assigned to actual protocols from the accepted range of 0-255.
- VLAN ID (1- 4096)—Enter the VLAN ID for the flow. The VLAN ID determines, which VLAN the packet belongs to. Cisco Security Manager validates the ID range to be between 1 and 4096.

Note Beginning with Version 4.13, Cisco Security Manager Packet tracer supports the transparent FW devices. Vlan ID is the new parameters introduced in Version 4.13 to support the packet tracer on devices 9.7.1 onwards.

- Destination MAC—Enter the destination MAC address for the flow. Cisco Security Manager validates the MAC address for its format.
- Enter the SPI (ESP only)—Enter the security parameter index. It is the arbitrary value used (together with the destination IP address) to identify the security association of the receiving party. Enter a numeric value between 0 and 4294967295.

Step 4 From the Tracing Packet drop-down list, select the relevant option:

- bypass-checks—bypasses all security checks for the simulated packet
- decrypted—treats simulated packet as IPsec/SSL VPN decrypted
- persist—enables long term tracing and follow tracing in cluster
- transmit—allows simulated packet to be transmitted from device

Step 5 If you want to see the progress of the trace while it is happening, select **Show animation**. Otherwise, the window is not updated with the results until the trace is completed.

Step 6 Click **Start** to trace the packet.

The policies are examined, and the bottom of the window shows the results in two forms: graphical and detailed information. The graphical view summarizes the phases evaluated in the packet's path. Checkmarks indicate the packet passed the phase, a red X indicates the packet was dropped at that point.

The detailed information organizes the results in folders that correspond to the phases, with an Action column that indicates the results of the phase (checkmark for passed, red X for dropped). To open a folder, click its heading. Detailed information can include the specific configuration commands evaluated and the data derived from **show** commands. The final folder, named Result, summaries the results of the trace.

Tips:

- If the packet is allowed or denied by an explicit access rule, then you can jump to that rule. Select the Access-List folder to open it, then click the **Show access rule** link at the top of the section. You are taken to the Access Rule policy with the rule highlighted; you can edit the rule as desired. If a packet is dropped due to an implicit drop rule, the Show access rule link is not available because the rule does not exist in the policy table.
- If the device is shut down or not reachable due to a network failure during the analysis, an error message stating "Device Connectivity is Failed" appears.
- If you start a new trace, the information shown is cleared automatically. However, you can clear it yourself by clicking **Clear**.

Analyzing Connectivity Issues Using the Ping, Trace Route, or NS Lookup Tools

You can use the Ping or Trace Route tools to investigate and troubleshoot your network configuration and connectivity. You typically run these commands in the device, from within Security Manager by specifying specific launch points and parameters. This causes Security Manager to generate the corresponding command. NS Lookup, on the other hand, is typically run from the Security Manager client.

Note Beginning with Version 4.13, Cisco Security Manager trace routes supports IPv6 address. From ASA version 9.7.1, traceroute for IPv6 address is supported.

Table 997: Profiles of the Ping, Trace Route, and NS Lookup Troubleshooting Commands

Tool	Profile
Ping	Use Ping to test whether a particular host is reachable across an IP network and to measure the round-trip time for packets sent from the local host to a destination computer. This can include measuring the local host's own interfaces using ICMP messages. See Analyzing Configuration Using Ping , on page 2863for details on using this tool.
Trace Route	Use trace route to show the route taken by packets across an IP network. The system returns the number of hops taken and the addresses of each device traversed. See Analyzing Configuration Using TraceRoute , on page 2864 for details on using this tool.

Tool	Profile
NS Lookup	Use NS lookup (namespace lookup) to issue an NS lookup command from a device so you can test the contents of the DNS server that the queried device uses. See Analyzing Configuration Using NS Lookup , on page 2866 for details on using this tool.

Applicability

The Ping tool is applicable on the following devices: ASA (7.0 – 8.3), PIX [6.3(1-5) to 8.0(2-4)], FWSM [2.2(1) – 4.1(1)], all IOS. It is not applicable to IPS.

The Trace Route tool is applicable on the following devices: ASA [7.2(1) and onward], PIX [6.3(1-5) to 8.0(2-4)], and all IOS. It is not applicable to FWSM nor IPS.

The NS Lookup tool is not supported in any of the devices managed by Cisco Security Manager; rather, you run it from the Cisco Security Manager client using the Windows API.

Analyzing Configuration Using Ping

The ping tool, by default uses the ICMP echo request and echo reply messages to test reachability to a remote system. You can also choose to employ TCP to ping. In its simplest form, ping simply confirms that an IP packet is capable of getting to and getting back from a destination IP address. A ping is sent to an IP address and it returns a reply. This process enables network devices to discover, identify, and test each other. From within Security Manager, you can designate both the network device from which to issue the ping command, and the target of the echo request. This tool generally returns two pieces of information: whether the source can reach the destination (and, by inference, vice versa), and the round-trip time (RTT, typically in milliseconds).

You can use the Ping diagnostic tool in a variety of ways, including:

- **Pinging to a security appliance**—Ping an interface on another security appliance to verify that it is up and responding.
- **Loopback testing of two interfaces**—Initiate a ping from one interface to another on the same security appliance, as an external loopback test to verify basic “up” status and operation of each interface.
- **Pinging through a security appliance**—Ping packets originating from the Ping tool may pass through an intermediate security appliance on their way to a device.The echo packets also pass through two of its interfaces as they return. You can use this to perform a basic test of the interfaces, operation, and response time of the intermediate unit.
- **Pinging to test intermediate communications**—Initiate a ping from a security appliance interface to a network device that is known to be functioning correctly and returning echo requests. If you receive the echo, you confirm physical connectivity and the correct operation of any intermediate devices.

Tip From within the Event Manager, you can right-click on an event to open the Ping Tool and ping the associated device.

Step 1 In Device view, select **Tools > Ping, TraceRoute and NS Lookup . . .**.

The Ping, TraceRoute and NS Lookup dialog box appears.

Step 2 From the device selector, select the device from which to issue the **Ping** command.

The selected device is listed in the top right of the dialog box.

Note To employ TCP for the ping, select TCP for the Packet Type. (The default packet type is ICMP)

Step 3 In Hostname/IPv4address, enter the IP address of the host network/host policy object to be pinged.

Alternatively, click **Select** to choose a host network/host object that defines the host network/host policy object to be pinged.

Step 4 Enter a timeout value. [Optional]

Step 5 Click **Ping**.

The results are displayed in the lower window area.

Example Ping output:

Example:

```
Sending 5, 100-byte ICMP Echos to out-pc, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

Example Ping unsuccessful output:

Example:

```
Sending 5, 100-byte ICMP Echos to 10.132.80.101, timeout is 2 seconds:
?????
Success rate is 0 percent (0/5)
```

You can click **Clear Output** to remove the previous response from the Ping output area.

For additional details on the **ping** command, see Troubleshooting TCP/IP on Cisco.com.

Analyzing Configuration Using TraceRoute

The Traceroute tool helps you to determine the route that packets will take to their destination. The tool prints the result of each probe sent. Every line of output corresponds to a TTL value in increasing order.

Traceroute can return useful information about TCP/IP connectivity across your network. The following table shows some of the codes that can be returned by the Traceroute utility, along with their possible cause.

Table 998: Traceroute Output Symbols

Output Symbol	Description
*	No response was received for the probe within the timeout period.
nn msec	For each node, the round-trip time (in milliseconds) for the specified number of probes.
!N.	ICMP network unreachable.
!H	ICMP host unreachable.

Output Symbol	Description
!P	ICMP unreachable.
!A	ICMP administratively prohibited.
?	Unknown ICMP error.

Step 1 In Device view, select **Tools > Ping, TraceRoute and NS Lookup . . .**.

The Ping, TraceRoute and NS Lookup dialog box appears.

Tip From within the Event Manager, you can right-click on an event to open the TraceRoute page and trace the route of the associated device.

Step 2 Select the **Trace Route** tab.

The Trace Route page appears.

Step 3 From the device selector, select the host from which the route is traced.

Step 4 Enter the **IP Address/Hostname** to specify the address or name of the host to which the route is traced.

Alternatively, click **Select** to choose a host network/host object that defines the IP address.

Note Beginning with Version 4.13, Cisco Security Manager trace routes supports IPv6 address. Till Version 4.12, the Syslog server was configured with Devices having IPv4 address. From Device version 9.7.1, traceroute for IPv6 address is supported. The Syslog server can be configured with IPv6 syslog address with devices having IPv6 addresses.

Step 5 Specify values, as required, for the following:

Table 999: Traceroute Fields

Field	Description
Timeout[optional]	The amount of time, in seconds, to wait for a response before the connection times out. The default is three seconds.
Port[optional]	The destination port used by the UDP probe messages. The default is 33434.
Probes per hop[optional]	The number of probes to be sent at each TTL level. The default is three.
TTL Min[optional]	The minimum TTL value for the first probes. (Default is 1.)
TTL Max[optional]	The maximum TTL value for the first probes.(Default is 30.)

Step 6 If desired, select **Specify Source Interface or IP Address**, and then do one of the following:

- Select a source **Interface** from the drop-down list

Note If an IPv6 address is specified in the IP Address/ Hostname field, the source Interface field is not applicable.

- Enter an **IP Address**

Step 7 If desired, select **Reverse Resolve** to reverse between displaying the address or hostname.

Step 8 If desired, select **ICMP** to use that protocol rather than IP.

Step 9 Click **Trace**.

The traceroute terminates when the packet reaches the destination or when the TTL Max value is reached. The hops taken and the device address corresponding to each hop are displayed.

Analyzing Configuration Using NS Lookup

You use the NS Lookup tool to look up a remote host address when you have the hostname, or to look up the hostname when you have the address.

Unlike the Ping and Traceroute tools, NS Lookup is done on the Security Manager client.

Step 1 In Device view, select **Tools > Ping, TraceRoute and NS Lookup . . .**.

The Ping, TraceRoute and NS Lookup dialog box appears.

Step 2 Select the **NS Lookup** tab.

Step 3 Enter an address or hostname in IPv4Address/Hostname.

Alternatively, click **Select** to choose a host network/host object that defines the IP address.

Step 4 Optionally, to employ a particular DNS server in the lookup, enter the server's name or address in DNS Server.

Step 5 Click **Lookup**.

The system displays the particular address/hostname pair, as well as the DNS server used in the lookup.

Using the Packet Capture Wizard

You can use the Packet Capture Wizard to configure, run, view, and save captures for troubleshooting errors. The captures can be run using preconfigured access lists or using match criteria of packet parameters such as source and destination addresses/ports on one or more interfaces. The wizard runs one capture on each of the ingress and egress interfaces. You can save the captures on the Cisco Security Manager client computer to examine them using a packet analyzer.

The Packet Capture Wizard also supports packet captures on ASA clusters. If you run the Packet Capture Wizard on the control unit of an ASA cluster, you are given the option of capturing data for just the selected device or all devices in the cluster. After running the capture for a cluster, you can view summary information for the cluster and also view or download capture buffers for specific devices in the cluster.

Note If the director has changed, it should be updated in Security Manager before running the Packet Capture Wizard. If not, capture for the members will contain errors. You can update the director for a cluster using the **Retrieve From Device** button on the **Device Properties > Cluster Information** page. For more information, see Group Information Page , on page 120.

The captures can be run using pre-configured access-lists or using match criteria of packet parameters such as source, destination address/port on one or more interfaces.

Please note the following:

- You can only use the Packet Capture Wizard on firewall devices (PIX, ASA, or FWSM).
- Packet capture based on packet match criteria is only supported on devices running ASA version 7.2(3) or later. For other devices, packet capture can only be performed based on access-lists.

To use the Packet Capture Wizard:

Step 1 Launch the Packet Capture Wizard using one of the following methods:

- Select **Tools > Packet Capture Wizard**.
- (Device view) Right-click on an ASA, PIX, or FWSM device and select **Packet Capture** on the shortcut menu. Proceed to Step 3, on page 2867.
- (Event Viewer) Right-click on an event from an ASA, PIX, or FWSM device and select **Packet Capture** on the shortcut menu. Proceed to Step 3, on page 2867.

Step 2 If you launched the Packet Capture Wizard from the Tools menu, select the device on which you want to capture packets. The Security Devices list contains only devices on which packet capture can be run.

Step 3 If you selected a device that is the director unit of an ASA cluster, specify whether to run the capture for the selected device only or for the entire cluster, and then click **Next**.

Step 4 Select the ingress interface from the drop-down list.

Note You cannot select the same interface as ingress and egress in the same wizard.

Step 5 Select the **switch packet capture** checkbox option to capture packet path and its content when the packets pass-through third-party apps, snort, or Lina.

Configure the following optional parameters:

- **Inner Vlan**—Enter value in the range of 1-4096.
- **Outer Vlan**—Enter value in the range of 1-4096.

Note This option is applicable only for Secure Firewall 3100 devices.

Important Access list gets disabled if **switch packet capture** is selected.

Step 6 Select the Capture control packets on cluster interface check box to capture the cluster control plane packets sent by the interface.

Note This optional field is introduced in Cisco Security Manager 4.19 for ASA 9.12.1 and later devices, to capture only cluster control plane packets. This information is useful to troubleshoot issues on cluster especially in multi-context mode.

Step 7 In the Packet Match Criteria area, do one of the following:

- To specify the access list to use for matching packets, select the **Access-List** radio button, and then choose the access list from the drop-down list.
- To specify packet parameters, select the **Packet Parameters** radio button and complete the following fields:

- Specify the source and destination in the Source Host / Network and Destination Host / Network fields, respectively. You can use any of the following to specify the source or destination:
- Source Host/ Network object. Enter the name of the object or click **Select** to select it from a list. You can also create new network/host objects from the selection list.

Note Starting from Cisco Security Manager 4.18, the packet parameters are supported with All-Address (any), All-IPv4-Address(any4), and All-IPv6-Address(any6).

- Host IP address, for example, 10.10.10.100.
- Network address, including subnet mask, in either the format 10.10.10.0/24 or 10.10.10.0/255.255.255.0.
- Choose the protocol type to capture from the drop-down list. Available protocol types to capture are ah, eigrp, esp, gre, icmp, icmp6, igmp, igrp, ip, ipinip, nos, ospf, pcp, pim, snp, tcp, or udp.

If the protocol is ICMP, select the ICMP type from the drop-down list. Available types include ALL, alternate-address, conversion-error, echo, echo-reply, information-reply, information-request, mask-reply, mask-request, mobile-redirect, parameter-problem, redirect, router-advertisement, router-solicitation, source-quench, time-exceeded, timestamp-reply, timestamp-request, traceroute, or unreachable.

If the protocol is TCP or UDP, specify the source and destination port services. Available options include the following:

- To include all services, choose All Services.
- To indicate specific services, choose an appropriate operator from the drop-down list (=, !=, >, <, or range) and then select one of the following: aol, bgp, chargen, cifs, citrix-ica, ctiqbe, daytime, discard, domain, echo, exec, finger, ftp, ftp-data, gopher, h323, hostname, http, https, ident, imap4, irc, kerberos, klogin, kshell, ldap, ldaps, login, lotusnotes, lpd, netbios-ssn, nfs, nntp, pcanywhere-data, pim-auto-rp, pop2, pop3, pptp, rsh, rtsp, sip, smtp, sqlnet, ssh, sunrpc, tacacs, talk, telnet, uucp, whois, or www. The >, <, and range operators function based on the port number assigned to the selected service.

When using the range operator, a second drop-down list is enabled. Use the two drop-down lists to select the starting and ending services in the range you want to specify. The service with the lower corresponding port number should be selected in the first drop-down list, and the service with higher corresponding port number should be selected in the second drop-down list.

Step 8 Click **Next** to proceed to the Select egress interface step.

Step 9 Select the egress interface from the drop-down list.

Note You cannot select the same interface as ingress and egress in the same wizard.

Step 10 Select the **switch packet capture** checkbox option to capture packet path and its content when the packets pass-through third-party apps, snort, or Lina.

Configure the following optional parameters:

- **Inner Vlan**—Enter value in the range of 1-4096.
- **Outer Vlan**—Enter value in the range of 1-4096.

Note This option is applicable only for Secure Firewall 3100 devices.

Important Access list gets disabled if **switch packet capture** is selected.

Step 11 Select the Capture control packets on cluster interface check box to capture the cluster control plane packets sent by the interface.

Note This optional field is introduced in Cisco Security Manager 4.19 for ASA 9.12.1 and later devices, to capture only cluster control plane packets. This information is useful to troubleshoot issues on cluster especially in multi-context mode.

Step 12 In the Packet Match Criteria area, do one of the following:

Note The Packet Match Criteria option (Access-list or Packet Parameters) you selected for the ingress interface will also be used for the egress interface. Also, if you used packet parameters for matching on the ingress interface, the protocol definition you used will also be used for the egress interface.

- If you are using an access list to match packets, choose the access list from the drop-down list.
- If you are using packet parameters to match packets, the parameters used for ingress are also used for egress.

Step 13 Click **Next** to proceed to the Set buffer parameters step.

Step 14 Specify the buffer parameters by configuring the following fields:

In the Buffer Parameters area, you specify the buffer size and packet size. The buffer size is the maximum amount of memory that the capture can use to store packets. The packet size is the longest packet that the capture can hold. We recommend that you use the longest packet size to capture as much information as possible.

- **Read capture buffer every 10 seconds**—Select this option to automatically retrieve captured data every 10 seconds. You must use the circular buffer when selecting this option.
- **Use a circular buffer**—Select this option to continue capturing packets after the buffer is full. When you choose this setting, if all the buffer storage is used, the capture starts overwriting the oldest packets.
- **Buffer Size**—Enter the number of bytes (between 1534 and 33554432) that the capture can use to store packets.
- **Maximum Packet Size**—Enter the number of bytes (between 14 and 1522) that the capture can use to store a single packet. Use the largest value, 1522,to capture as much information as possible.

Step 15 Click **Next** to proceed to the Summary step, which shows the traffic selectors and buffer parameters that you have entered.

Step 16 Click **Next** to proceed to the Run, View & Save step.

Step 17 From the Run, View & Save step, you can do the following:

- Click **Start Capture** to begin capturing packets.
- Click **Stop Capture** to stop capturing packets.
- To fetch the next set of captured packets, do one of the following:
  - For individual devices, click **Display Capture Packets** to fetch the next set of captured packets from the device and update the buffer status bar. This button is only enabled if the Read capture buffer every 10 seconds option was not selected during the Set buffer parameters step.
  - For clusters, click **Get Cluster Capture Summary** to fetch the next set of captured packets from the devices in the cluster and update the buffer status bar. This button is only enabled if the Read capture buffer every 10 seconds option was not selected during the Set buffer parameters step.
- When running a capture for an ASA cluster, the following option are available for working with the capture buffers of the devices in the cluster:

- To view the captured packets from a device in the cluster, select the device in the Device Name list under Get Capture Buffer, and then click **Get Capture Buffer**.

The capture information for the selected device is displayed. Refer to the other options in this list for the actions you can perform on this data.

- To remove the capture content for a specific device or all devices in the cluster and allow room in the buffer to capture more packets, select the device or **--All--** in the Device Name field under Clear Capture Buffer, and then click **Clear Capture Buffer**.

Note We recommend saving captures prior to clearing the device buffers. If you do not save captures prior to clearing the device buffers, captured data will be lost.

- Click the **Launch Network Sniffer** button above the Ingress Capture window or the Egress Capture window to view the corresponding ingress or egress capture using an external packet analyzer tool. You must have a packet analyzer installed and associated with *.pcap file extension.
- Click **View Data in Larger Window** to view the packet capture data side-by-side in a larger window.
- Click **Save captures** to display the Save Capture dialog box. Choose the format in which you want to include the captures: ASCII or PCAP. You have the option of saving either the ingress capture or the egress capture.
- Click **Clear Device Buffer** to remove the current content and allow room in the buffer to capture more packets.

Note We recommend saving captures prior to clearing the device buffers. If you do not save captures prior to clearing the device buffers, captured data will be lost.

- Click **Refresh Capture Buffers** to fetch the next set of captured packets for a device in a cluster and update the buffer status bar.

Step 18 Click **Finish** to exit the wizard.

IP Intelligence

Network security devices managed by Cisco Security Manager generate large amounts of security logs and security events containing the IP address information of the attacker or victim machines or both.

Useful details about an IP address, collectively referred to as IP intelligence, can be discovered by using tools such as ping, trace route, and NS lookup. Often, however, it is desirable to augment these somewhat rudimentary tools with more advanced tools.

Beginning with Version 4.5, Security Manager provides advanced tools that furnish critical details about an IP address in real time or in generated reports. These critical details are provided by Security Manager in the following categories:

- Reverse DNS (FQDN) Lookup Service
- GeoIP Lookup Service
- Whois Lookup Service

Note IP intelligence for IPv6 addresses is not supported.

These IP intelligence categories are described in the following table:

Table 1000: IP Intelligence Categories

IP Lookup Provider	Information Source	Real Time or Manual/Limitations
Reverse DNS (FQDN) Lookup Service	DNS servers	Real time **Note** External DNS configuration is an additional option that you can configure, but you will need to evaluate your individual situation.
GeoIP Lookup Service	External third-party commercial vendor	Real time, till Cisco Security Manager version 4.18. GeoIP Lookup Service upgraded their database to GeoIP2; Cisco Security Manager is yet to upgrade. Hence, the auto update of GeoIP for the previous versions of Cisco Security Manager and the default GeoIP package in Cisco Security Manager 4.19 will only have the database of December 2018.
Whois Lookup Service	Provided by free whois server, a third-party web server.	Real time Limitations: • Whois is a query and response protocol that is widely used for querying databases that store the registered users or assignees of an Internet resource, such as a domain name, an IP address block, or an autonomous system. There are five regional internet registry (RIR) organizations that manage the allocation and registration of IP addresses. • ARIN (American Registry for Internet Numbers), RIPE (Réseaux IP Européens Network Coordination Centre), and APNIC (Asia-Pacific Network Information Centre) are the 3 RIR's that Security Manager will use to query directly; they also provide the referred URL. For RIPE and APNIC, if there is any parsing error, only the direct URL link will be shown. • Clicking on the provided URL will display the details for the given IP address in web browsers. If an IP address belongs to LACNIC (Latin America and Caribbean Network Information Centre) or AfriNIC (African Network Information Centre) , the web browser will display the homepage of the respective RIR. • In some cases (such as dns query getting blocked by windows firewall or invalid proxy has configured in the cco settings page) , Whois may not work even though it is enabled. In such scenario as a "Fail-safe" method it will provide only the referred url.

Before you begin looking up IP intelligence, you must enable the necessary services at **Configuration Manager > Tools > Security Manager Administration... > IP Intelligence Settings**. Refer to IP Intelligence Settings Page , on page 553.

IP intelligence lookup can be done by using any of the following methods:

- Use the IP Intelligence dialog box: Navigate to **Configuration Manager > Tools > IP Intelligence...** and then enter a valid IPv4 address in the search field of the IP Intelligence dialog box that pops up. (You must press **Enter** after typing the IP address.)
- Use "Quick Launch" by mousing over (hovering over) a valid IPv4 address in the Security Manager interface. You can do this in Event Viewer, for example; in general, you can do this in all GUI tables in which an IP address is part of the data displayed. If more than one IP address is displayed in one cell of a GUI table, only the first IP address is displayed.

Note You may experience a second or two of latency with Quick Launch before you see the "IP Intelligence" option in the GUI.

Note You can enable or disable Quick Launch by selecting or clearing the "Enable Quick Launch" check box in the IP Intelligence dialog box at **Configuration Manager > Tools > IP Intelligence...**.

- Use the IP Intelligence widget in the Dashboard (**Launch > Dashboard...**). This method is equivalent to using the IP Intelligence dialog box described above.
- Use Report Manager (**Launch > Report Manager...**) to see IP intelligence in any of the following reports:
  - **FW/Summary Botnet**—Top Infected Hosts
  - **FW/Summary Botnet**—Top Malware Sites
  - **FW**—Top Destinations
  - **FW**—Top Sources
  - **IPS**—Target Analysis
  - **IPS**—Top Attackers
  - **IPS**—Top Victims

Note There are several points to note about these reports: 1) They will not contain Whois information. 2) If you have disabled all the providers at **Configuration Manager > Tools > Security Manager Administration... > IP Intelligence Settings**, then none of the IP intelligence-related columns will be displayed in the report. 3) If you enable *all* the services, only the reverse dns (FQDN) and GeoIP details will be displayed in the report. 4) If you enable only *one* service, then that service only will be displayed in the report.

Note The generated report in both PDF and CSV formats will contain the IP intelligence details.

Note All these reports require the necessary services to be enabled. Refer to IP Intelligence Settings Page , on page 553.

Integrating CS-MARS and Security Manager

While Cisco Security Manager lets you centrally manage security policies and device settings in your network, the Cisco Security Monitoring, Analysis and Response System (CS-MARS) is a separate application that monitors devices and collects event information, including syslog messages and NetFlow traffic records, with much more extensive network monitoring capabilities than Security Manager. CS-MARS aggregates and presents massive amounts of network and security data in an easy-to-use format. Based on information derived from CS-MARS reports, you can edit device policies in Security Manager to counter security threats.

Specifically, if you use Security Manager to configure firewall access rules and IPS signatures, you can configure CS-MARS to collect information related to those policies and make it available to Security Manager users. By registering the CS-MARS servers with Security Manager, users can navigate directly from a specific access rule or IPS signature to a CS-MARS report window, pre-populated with query criteria for that rule or signature.

Similarly, CS-MARS users can view the Security Manager policies related to specific CS-MARS events. This bi-directional mapping of specific events to the policies that triggered them, combined with the ability to immediately modify the policies, can dramatically reduce the time spent configuring and troubleshooting large or complex networks.

To enable this cross-communication, you must register your CS-MARS servers with Security Manager, and register your Security Manager server with the CS-MARS servers. You must also register the specific devices with each application. Then, when working with firewall access rules or IPS signatures for a device, a Security Manager user can quickly view real-time and historical event information related to that rule or signature.

The following sections explain how to enable and use CS-MARS and Security Manager cross-communication:

- Checklist for Integrating CS-MARS with Security Manager , on page 2873
- Looking Up CS-MARS Events for a Security Manager Policy , on page 2878
- Looking Up a Security Manager Policy from a CS-MARS Event , on page 2882

Checklist for Integrating CS-MARS with Security Manager

To enable the cross-communication between CS-MARS and Security Manager (as described in Integrating CS-MARS and Security Manager , on page 2873), you must identify the applications to each other and ensure that devices managed by both applications are configured appropriately. The following table describes the integration steps.

If you have problems with cross-communications, see Troubleshooting Tips for CS-MARS Querying , on page 2877.

Table 1001: Integrating CS-MARS and Security Manager

Task	Description
Add the devices to Security Manager and CS-MARS	See Adding Devices to the Device Inventory , on page 77 for information about adding devices to Security Manager. See the Device Configuration Guide for Cisco Security MARS for information about adding devices to the CS-MARS inventory. A device must be supported by both applications to provide cross-communication for the device. Supported device types generally are those providing Firewall > Access Rules, or IPS > Signatures policies. (These include: PIX, ASA and FWSM appliances, Cisco IOS routers, Cisco IPS sensors and modules, and Cisco Catalyst switches.)
Configure the devices as required by each application	See Understanding Device Communication Requirements , on page 57 for information about basic configuration requirements for Security Manager. See Device Configuration Guide for Cisco Security MARS for the more extensive requirements for CS-MARS.
Register Security Manager with CS-MARS	For information on configuring CS-MARS to communicate with Security Manager, see User Guide for Cisco Security MARS Local and Global Controllers . You might want to create a CS-MARS user account specifically for linking with Security Manager. See Configuring the Security Manager Server to Respond to CS-MARS Policy Queries , on page 2874.
Register CS-MARS controllers with Security Manager	For information on registering CS-MARS controllers with Security Manager, see Registering CS-MARS Servers in Security Manager , on page 2875.
Link CS-MARS controllers to the devices in Security Manager	In Security Manager, you can proactively discover the CS-MARS controllers that monitor a particular device by clicking **Discover CS-MARS** on the device's Device Properties page, as described in Discovering or Changing the CS-MARS Controllers for a Device , on page 2876. Otherwise, the appropriate controller is discovered automatically when a user attempts to look up events for the device (the user is prompted to select a controller if more than one monitors the device).

Related Topics

- Viewing CS-MARS Events for an Access Rule , on page 2879
- Viewing CS-MARS Events for an IPS Signature , on page 2881
- Looking Up CS-MARS Events for a Security Manager Policy , on page 2878

Configuring the Security Manager Server to Respond to CS-MARS Policy Queries

CS-MARS must be allowed access to the Security Manager server so that it can perform policy lookup queries and obtain policy information.

- If you are using Common Services AAA authentication on the server (for example, Cisco Secure ACS), you must update the administrative access settings to ensure that CS-MARS has the necessary client access to the Security Manager server.
- Define a user account in Security Manager that CS-MARS can use to perform queries. A separate account is recommended to provide a specific audit trail on the Security Manager server. This account must be assigned one of the following Common Services roles:
  - Approver
  - Network Operator
  - Network Administrator
  - System Administrator

Users with the Help Desk security level can only view the policy look-up table in CS-MARS; that is, they cannot cross-launch Security Manager to modify policies.

Note When you register a Security Manager server with CS-MARS, if you choose to prompt for Security Manager credentials for policy table look-up, a separate CS-MARS account in Common Services for authentication purposes might not be necessary.

For more information on adding users and associating roles with them in Common Services, see the *User Guide for CiscoWorks Common Services* .

Related Topics

- Registering CS-MARS Servers in Security Manager , on page 2875
- Discovering or Changing the CS-MARS Controllers for a Device , on page 2876

Registering CS-MARS Servers in Security Manager

As described in Checklist for Integrating CS-MARS with Security Manager , on page 2873, you must register your CS-MARS controllers with Security Manager to enable cross-communication between the applications if you intend to use the applications together.

Then, when a user looks up events for a device, Security Manager identifies the CS-MARS controller that is collecting events for that device. If more than one CS-MARS controller is collecting events for a device, the user can select which to use. You can also specify the correct CS-MARS controller to use in the Device Properties window for each device. (See Discovering or Changing the CS-MARS Controllers for a Device , on page 2876 for more information.)

Note For information about the CS-MARS versions explicitly supported by Security Manager, see the Release Notes for Cisco Security Manager for this version of the product. If you do try to use a version that is not explicitly supported, you cannot use CS-MARS versions earlier than 4.3.4 or 5.3.4.

Step 1 Choose **Tools > Security Manager Administration** and select **CS-MARS** in the table of contents to display the CS-MARS Page , on page 518.

Step 2 Click the **Add** button to add a CS-MARS server. The New CS-MARS Device dialog box opens (see New or Edit CS-MARS Device Dialog Box , on page 519 for detailed information).

Step 3 In the New CS-MARS Device dialog box, enter the IP address or fully qualified DNS host name of the server, and a user name and password for logging into the server. If you add a local controller, the user name you enter can be either a local account or a global account. Choose the type of account from the User Type list.

Tip If you are using CS-MARS Global Controllers, add them instead of individual Local Controllers. By adding Global Controllers, Security Manager can identify the correct Local Controller for a device, without you having to add each Local Controller. When you add a Global Controller, do not add the individual Local Controllers monitored by the Global Controller.

Click **Retrieve From Device** to get the server's authentication certificate. Click **Accept** when the certificate is presented to you.

Click **OK** when finished. The New CS-MARS Device dialog box closes and the server is added to the CS-MARS device list.

Step 4 From the **When Launching CS-MARS** list, choose whether you want users to be prompted to log in to the CS-MARS server when they request event status, or whether Security Manager should automatically log in to CS-MARS using the credentials provided when the user logged in to Security Manager.

If you elect to use Security Manager credentials, the necessary user accounts must be configured in CS-MARS. Refer to the CS-MARS documentation for more information.

Step 5 Click **Save** on the CS-MARS page to save your changes.

Discovering or Changing the CS-MARS Controllers for a Device

If you use the Cisco Security Monitoring, Analysis and Response System (CS-MARS) controllers to monitor devices, you can register them in Security Manager and then view syslogs and events that are related to firewall access or IPS signature rules for individual devices.

Security Manager can automatically discover the CS-MARS controllers that monitor a device when you try to view events related to a rule. If more than one controller monitors a device, you are prompted to select which controller to use.

You can also proactively select the CS-MARS controller for a device in its Device Properties window. Similarly, if you ever need to change the CS-MARS controller assigned to a device, you can change the selection in its Device Properties window. This procedure explains how to discover or change the CS-MARS controller for a device from its Device Properties window.

Before You Begin

The CS-MARS controller that monitors the device must already be registered with Security Manager on the CS-MARS administration page (**Tools > Security Manager Administration > CS-MARS**). For more information, see Registering CS-MARS Servers in Security Manager , on page 2875.

Step 1 In Device view, do one of the following in the Device selector to open the Device Properties dialog box:

- Double-click a device.
- Right-click a device and choose **Device Properties**.
- Select a device and choose **Tools > Device Properties**.

Step 2 Click **General** in the table of contents to open the General properties page (see Device Properties: General Page , on page 110).

Step 3 In the CS-MARS Monitoring group, click **Discover CS-MARS**. Security Manager determines which registered controller is monitoring the device, if any. If there are more than one, you are prompted to select which CS-MARS controller to use.

Troubleshooting Tips for CS-MARS Querying

Use the following troubleshooting tips to help you identify and resolve problems you might encounter when using CS-MARS and Security Manager together:

- HTTPS is required for communication between the Security Manager server and CS-MARS.
- Interface names are not case-sensitive in Security Manager, but they are in CS-MARS. For example, “outside” and “Outside” are considered exclusive by a CS-MARS appliance, while they are equivalent in Security Manager. Further, syslog messages use lower case for all interface names. As a result, when you perform a query for a Security Manager policy from an event generated in CS-MARS, the interface name logged in the syslog event might not match the interface name in that policy in Security Manager. To avoid this problem, use lower case for all interface names, and in the definition of interface roles, in CS-MARS.
- To query for CS-MARS events from Security Manager policies, the Security Manager client must be on the same side of a network address translation (NAT) boundary as the CS-MARS appliance and the Security Manager server.

Similarly, when the CS-MARS client is not on the same side of a NAT boundary as the CS-MARS appliance and the Security Manager server, you can look up Security Manager policies, but in read-only mode. However, you cannot start the Security Manager client from the read-only policy look-up table. The Security Manager client must be on the same side of the NAT boundary as the CS-MARS appliance and the Security Manager server if you want to start the client from CS-MARS to modify a matching policy.

- For FWSM, PIX and ASA devices on which multiple independent security contexts exist, to query for CS-MARS events, you must define a unique management IP address in Security Manager for each security context. Also, the host name and reporting IP address for each virtual context must be configured before adding it to CS-MARS. Otherwise, event look-up from policies on these contexts fails.
- For all IPS device and service policies, a default signature policy is assigned to the device when you do not discover IPS policies, or when you remove the configured policies from the device. If you try to perform event look-up from the default signature, a “Policy not found” error message is displayed. However, if you edit the default signature and save it, you can then navigate to events in CS-MARS.
- If object grouping or rule optimization is enabled for an access rule defined in Security Manager and the associated access-list commands on the device do not match the optimized rules, no events are displayed in CS-MARS.
- If logging is not enabled for an access rule, a warning message is displayed, and you can only look up traffic-flow events for those rules.

- When supported by the device, Security Manager uses access-control entry (ACE) hashcodes as additional keywords when querying CS-MARS for syslog messages generated by an ACE, and large access-control lists (ACLs) might contain thousands of such hashcodes. If the number of keywords, or the sum of the number of sources, destinations, and protocols for an ACE or a signature exceeds the query limit of 150, an error message is displayed. The error message indicates the probable cause and recommended action.
- Problems with the synchronization between rules and reported events can occur in the following situations:
  - The device has been added to Security Manager, but the configuration or changes to it have not been saved to the database. This is especially true for access rules that have been changed but not deployed since the device was added to CS-MARS.
  - Access rules exist on the device for which there are no corresponding rules in Security Manager, and vice versa. Be sure all devices are added to Security Manager, and that access rules are configured on them using Security Manager.
  - Traffic in the "wrong" direction triggering events for which there is no defined rule. For example, outbound traffic on a higher-security-level interface on which only inbound-traffic rules have been defined.
- If you perform a policy lookup from CS-MARS and the Security Manager client is active, the query is performed on all policies within the open activity or configuration session plus what is saved in the database (the committed configurations). If the Security Manager client is not active, only committed policies are considered.

Related Topics

Looking Up CS-MARS Events for a Security Manager Policy

After you integrate CS-MARS and Security Manager, you can look up events in CS-MARS that relate to specific firewall access rules or IPS signatures.

When CS-MARS receives events, they are parsed, "sessionized," written to an event buffer, and then written to the database. Sessionizing takes two forms: with a session-oriented protocol, such as TCP, the session encompasses the initial handshake to the connection tear-down; with a sessionless protocol, such as UDP, the session start and end times are based more on first and last packets tracked within a restricted time period—packets that fall outside of the time period are considered parts of other sessions.

Because there is a difference between newly-received and fully processed data, you can look up either real-time or historical events:

- **Real-time**—Because sessionization takes time, keeping an event in cache for up to two minutes, you can use the real-time event query to view events right after parsing, providing access to the most current data received.

When you query for real-time events, the query is run automatically, based on the policy values obtained from Security Manager, and the results are displayed in the CS-MARS Query Results window. This real-time event viewer lets you monitor CS-MARS traffic in near real-time, as raw events streaming to CS-MARS, before

they are sessionized, with a maximum delay of five seconds. You also can elect to view the sessionized event stream by clicking Edit in the Query Results window and then choosing "Sessionized events" from the Realtime drop-down menu. Note that more delay is possible when there are many events in a session.

- **Historical**—Historical event reports help you identify trends over longer periods of time than is possible with real-time monitoring. When you query for historical events, the CS-MARS Query Criteria: Result window opens. You can either run the query immediately, or save the criteria as a "report" to run at a later time. For historical events, the Result Format is the All Matching Events option, and the Filter By Time value is set to the previous 10 minutes.

The following topics explain event lookup in more detail:

- Viewing CS-MARS Events for an Access Rule , on page 2879
- Viewing CS-MARS Events for an IPS Signature , on page 2881

Viewing CS-MARS Events for an Access Rule

From the **Firewall > Access Rules** policy in Security Manager, you can select an access rule and view related event information in CS-MARS. You can view real-time or historical events matching the rule, the traffic flow, the source address, or the destination address. You can view events for any device that supports access rules, including ASA, PIX, FWSM, routers, and switches.

Firewall access rules are presented in the form of an ordered list or table. When deployed, this policy becomes an access-control list (ACL), with each entry in the list known as an access-control entry (ACE). (For more detailed information, see Understanding Access Rules , on page 717.)

When deciding whether to forward or drop a packet, a device tests the packet against each access rule in the ordered listed. If you enable logging for an access rule, the results of the test are recording according to your per-rule log settings. Some devices, such as ASA, generate log entries for denied access even if you do not configure logging explicitly. For information on creating access rules, including logging options, see Configuring Access Rules , on page 723.

You can query CS-MARS for real-time or historical events related to an access rule for the following types of traffic. To use the commands, right-click the rule and select them from the context menu.

- **Flow**—A traffic flow is defined by the rule's source and destination IP addresses, protocol, and ports. The reported flow events include connection set-up and tear-down. Logging need not be enabled for the access rule to record this information.

To view flow-related events, use the following right-click commands:

- **Show MARS Events > Realtime > Matching this Flow**—To view real-time query results in CS-MARS for events matching this traffic flow. You can change the query criteria in the CS-MARS window at any time, applying new parameters to alter the real-time results.
- **Show MARS Events > Historical > Matching this Flow**—Opens the historical query criteria page in CS-MARS with fields populated based on the selected rule's traffic flow. Edit the rule parameters and query criteria as desired, and click **Apply** to continue. Next, in the Query window, you can submit the query or save it for later submission and re-use.
- **Rule**—If logging is enabled for the rule (in the Advanced and Edit Options Dialog Boxes , on page 733), the device sends syslog messages to CS-MARS to record the logged events (assuming CS-MARS monitors the device). This query includes the access-rule parameters, including available keyword information. Reported events do not include connection set-up and tear-down.

To view rule-related events, use the following right-click commands:

- **Show MARS Events > Realtime > Matching this Rule**—To view real-time query results in CS-MARS for events matching this rule (flow parameters plus keywords); results begin scrolling within five seconds. You can change the query criteria in the CS-MARS window at any time, applying new parameters to alter the real-time results.
- **Show MARS Events > Historical > Matching this Rule**—Opens the historical query criteria page in CS-MARS with fields populated based on the access rule (flow parameters plus keywords). Edit the rule parameters and query criteria as desired, and click **Apply** to continue. Next, in the Query window, you can submit the query, or save it for later submission and re-use.
- **Source or Destination**—If you right-click the Source or Destination cell in an access rule entry, you also can choose to view real-time or historical events matching the rule's source or destination IP address.

To view events for a source or destination address, right-click the address in the Source or Destination cell and choose one of the following commands (the specific command differs depending on the cell you select):

- **Show MARS Events > Realtime > Matching this Source/Destination**—To view real-time query results in CS-MARS for events with a matching source or destination address. You can change the query criteria in the CS-MARS window at any time, applying new parameters to alter the real-time results.
- **Show MARS Events > Historical > Matching this Source/Destination**—Opens the historical query criteria page in CS-MARS with fields populated based on the access rule's source or destination address. Edit the rule parameters and query criteria as desired, and click **Apply** to continue. Next, in the Query window, you can submit the query, or save it for later submission and re-use.

Security Manager provides the following information to CS-MARS as criteria for a traffic-flow or access-rule event queries:

- Device details—General information about the device, such as host name, domain name, management IP address, and display name.
- Source addresses—Source addresses of hosts and the network/host objects expanded to display the networks or collections of IP addresses.
- Destination addresses—Destination addresses of hosts and the network/host objects expanded to display the networks or collections of IP addresses.
- Service—Protocol and port information.
- Event Type—"Built/teardown/permitted IP connection" for permit rules and "Deny packet due to security policy" for deny rules.
- Keyword (rule events only, not provided for traffic-flow queries)—ACL name and ACE hashcode, if available, connected by the logical operator OR.

On Version 7.0 or later PIX and ASA devices, each access rule is assigned an MD5 hashcode, which is included in the syslogs generated by that rule. Large ACLs can include thousands of access rules. Used as query keywords, these hashcodes can help produce more-accurate event matches. If a device does not support hashcodes, a warning is displayed that query results might be inaccurate because of keyword ambiguity; you can proceed with the query, and then edit the query keyword list and resubmit.

Tips:

- You can query on only one access rule at a time.

- When NAT or PAT is configured on a security device, the source and destination addresses are mapped to pre-translation and post-translation addresses, respectively, and the translated addresses are used when Security Manager sends a query to CS-MARS. For inbound access rules, the destination address is considered the pre-translation address, and for outbound access rules, the source address is considered the post-translation address.
- If the device is monitored by multiple CS-MARS controllers, you are prompted to select the CS-MARS instance to be used.
- Depending on how credentials verification is set up on your system, you might be prompted to log into CS-MARS. For more information, see Registering CS-MARS Servers in Security Manager , on page 2875.

Related Topics

- Looking Up a Security Manager Policy from a CS-MARS Event , on page 2882
- Viewing CS-MARS Events for an Access Rule , on page 2879

Viewing CS-MARS Events for an IPS Signature

Note From version 4.17, though Cisco Security Manager continues to support IPS features/functionality, it does not support any bug fixes or enhancements.

When an IPS or IOS IPS device detects and reports a network intrusion by comparing incoming traffic to a configured signature, a syslog message is generated on the device. If the device is monitored by CS-MARS, an incident is generated in CS-MARS after the log associated with the signature is obtained from the device. Looking up the events associated with a specific signature lets you quickly identify attacks and tune your device configuration to minimize or prevent intrusions.

To view reported network intrusion events in CS-MARS, you can select one or more entries in the Signatures policy for a device in Security Manager and navigate to the CS-MARS Query page to view real-time and historical events.

When you look up real-time events for a signature, the query is run automatically and the results displayed in CS-MARS. However, when you look up historical events for a signature, the values sent by Security Manager to CS-MARS are used to populate the query fields. You can modify the query fields as desired, and then run the query, or save it for later use.

Security Manager provides the following signature information to CS-MARS as query criteria:

- Device details—General information about the device, such as host name, domain name, management IP address, and display name.
- Keyword—Signature ID, subsignature ID, and virtual sensor name, if applicable.

For virtual sensors, the name of the sensor is included as a keyword criterion along with other device information and signature parameters.

Related Topics

• Looking Up a Security Manager Policy from a CS-MARS Event , on page 2882
• Viewing CS-MARS Events for an Access Rule , on page 2879

Step 1 (Device view) With an IPS or IOS IPS device selected, select **IPS > Signatures > Signatures** to display the Signatures Page , on page 1680.

Step 2 Right-click the desired entry in the signatures table, or select multiple entries before right-clicking one of them, and choose one of the following commands from the **Show MARS Events** menu:

- **Realtime**—To view real-time query results in CS-MARS for events matching this signature; results begin scrolling within five seconds. Use this option to view raw events as they stream to CS-MARS.

You can change the query criteria in the CS-MARS Query Results window at any time, applying new parameters to alter the real-time results.

- **Historical**—Opens the historical query criteria page in CS-MARS with fields populated based on the signature parameters. Edit the parameters and query criteria as desired, and click Apply to continue. Next, in the Query window, you can submit the query or save it for later submission and re-use. You can edit the query and save it as a report if you want to run it again later.

Tips:

- If a signature is disabled, you are warned and asked if you want to proceed to event lookup.
- If the device is monitored by multiple CS-MARS controllers, you are prompted to select the CS-MARS instance to be used.
- Depending on how credentials verification is set up on your system, you might be prompted to log into CS-MARS. For more information, see Registering CS-MARS Servers in Security Manager , on page 2875.
- All custom signatures are categorized as “Unknown Device Event Type” events in CS-MARS.
- A default signature is assigned to an IPS device if you elect not to discover IPS policies when adding the device to the Security Manager inventory, or when you remove configured IPS policies from the device. If you try to look up events from the default signature, a “Policy not found” error message is displayed. However, if you edit the default signature and save it, you can then query for related events in CS-MARS.
- Events of type Packet Data and Context Data are not displayed in the query results because these events are not triggered by signature rules.

Looking Up a Security Manager Policy from a CS-MARS Event

The User Guide for Cisco Security MARS Local and Global Controllers contains detailed information about how to look up policies based on events shown in CS-MARS. The information includes extensive troubleshooting information to help resolve any problems you might have, plus a checklist of what you must configure in CS-MARS to enable the interaction.

The main reason you would want to perform policy lookup is to adjust a policy based on the events that it is generating. For example, an access rule might be dropping traffic that you actually want to allow. Because you are looking at the event, you know there is a policy that is causing the event, so with a few clicks, you can get from that event to the policy you need to reconfigure.

The general process for looking up a policy based on a device-generated event is as follows. Note that the Security Manager client must be installed on your system to perform policy lookup.

Related Topics

- Viewing CS-MARS Events for an Access Rule , on page 2879
- Viewing CS-MARS Events for an IPS Signature , on page 2881

Step 1 Find the event in CS-MARS in the Query Results or Incident Details pages.

For more information on the syslog and NetFlow events you can use for querying access rules, see the following topics:

- System Log Messages Supported for Policy Look-up , on page 2883
- NetFlow Event Reporting in CS-MARS , on page 2885

Step 2 Click the Security Manager icon in the Reporting Device cell for the event. You might be prompted to log into Security Manager, based on how you configured CS-MARS.

If more than one device in Security Manager matches the event characteristics, you are prompted to select a device.

Step 3 Detailed information is obtained from Security Manager and presented based on whether the event is for an access rule or IPS signature:

- **Access rule**—The access rules are displayed in CS-MARS in a read-only window with the rule that matches the event highlighted.

If you decide to edit a rule, click the rule number, and you are taken to the rule in the Access Rule policy in the Security Manager client. You can then make your edits, save them, and then deploy configurations. Remember that your changes are not made to the device until you deploy them.

For more information on configuring access rules, see Configuring Access Rules , on page 723.

- **IPS Signature**—Signature details are displayed in CS-MARS in a read-only window.

To edit the signature, click **Edit Signature**, and you are taken to the signature in the Signatures policy, where you can make your changes. For more information, see Editing Signature Parameters (Tuning Signatures) , on page 1700.

If you decide you want to instead remove specific actions from an event, or remove the event entirely, and prevent further processing by the sensor, click **Add Filter**. This opens the Add Event Filter dialog box in Security Manager, where you can configure an event filter. For more information, see Filter Item Dialog Box , on page 1719.

As with access rules, your changes do not take effect until you deploy the new configuration.

System Log Messages Supported for Policy Look-up

When you configure access rules on security appliances and IOS devices, you can configure logging options in the Advanced and Edit Options Dialog Boxes , on page 733 that generate system log (syslog) messages. On devices with multiple contexts, each security context includes its own logging configuration and generates its own messages. If Security Manager is configured to interoperate with CS-MARS, these messages are reported to CS-MARS and you can query for the reported information on a per-rule basis.

For additional information about each of these message IDs, see the System Message Guide of the relevant product documentation.

Security-appliance messages

Security-appliance syslog messages begin with a percent sign (%) and are structured as follows:

```
%{ASA | PIX | FWSM}-Level-Message_number: Message_text
```

For example:

```
%ASA-2-302013: Built outbound TCP connection 42210
for outside:9.1.154.12/23 (9.1.154.12/23) to inside:2.168.154.12/4402 (192.168.154.12/4402)
```

Note that additional information, such as date and timestamp, precedes these messages. The specific additional information depends on the type of device.

A unique six-digit number identifies each message (*302013* in the preceding example). The following security-appliance syslog message IDs are supported for Security Manager-to-CS-MARS queries. If you change the logging level of a security appliance, be sure these messages are generated at the new level.

Message ID	Message
106023	An IP packet was denied by the access rule. This message is recorded even if logging is not enabled for the rule; this is the Default Logging option.
106100	An IP packet was permitted or denied by the access rule. Additional information is provided, based on the logging level defined for the rule in the Advanced and Edit Options Dialog Boxes , on page 733.
302013	A TCP connection between two hosts was created.
302014	A TCP connection between two hosts was torn down.
302015	A UDP connection between two hosts was created.
302016	A UDP connection between two hosts was torn down.
302020	A ICMP connection between two hosts was created.
302021	A ICMP connection between two hosts was torn down.

Router messages

On Cisco IOS routers, syslog messages are also generated for access rules. The first packet that triggers the access list causes an immediate logging message, and subsequent packets are collected over five-minute intervals before they are displayed or logged. Each logging message includes the access list number, whether the packet was permitted or denied, the source IP address of the packet, and the number of packets from that source permitted or denied in the prior five-minute interval.

The following IOS syslog message IDs are supported for Security Manager-to-CS-MARS queries.

%SEC-6-IPACCESSLOGP	A packet matching the log criteria for the given access list was detected: TCP and UDP.

%SEC-6-IPACCESSLOGS	A packet matching the log criteria for the given access list was detected: IP address.
%SEC-6-IPACCESSLOGDP	A packet matching the log criteria for the given access list was detected: ICMP.
%SEC-6-IPACCESSLOGNP	A packet matching the log criteria for the given access list was detected: all other IPv4 protocols.

Note If an excessive number of syslog messages are being generated and reported to CS-MARS, use the Advanced and Edit Options Dialog Boxes , on page 733 to change the logging level for those access rules that are producing the largest number of messages. You can also look at changing the logging policies on the device to limit the types of messages generated.

NetFlow Event Reporting in CS-MARS

Event reporting in CS-MARS can include NetFlow events from an ASA 8.1+ device.

NetFlow Security Event Logging uses NetFlow version 9 fields and templates to efficiently deliver security telemetry in high-performance environments. NetFlow Security Event Logging scales better than syslog messaging, while offering the same level of detail and granularity in logged events. The ASA NetFlow implementation exports only significant events in the life of a flow, rather than exporting data about flows at regular intervals. The following flow events are exported:

- Flow creation
- Flow tear-down
- Flows denied by an access rule

The ASA also exports syslog messages that contain the same information. If you enable NetFlow on a device, you can consider disabling the equivalent syslog messages. Disabling equivalent syslog messages can help avoid the potential performance degradation caused by generating and processing both NetFlow records and syslog messages representing the same event. The following table lists syslog messages with an equivalent NetFlow event; the NetFlow Event IDs and Extended Event IDs are included. For information on how to disable NetFlow equivalent syslog messages, see Server Setup Page , on page 2053.

Syslog ID	Syslog Description	NetFlow Event ID	Extended Event ID
30201330201530201730202O	TCP, UDP, GRE, and ICMP connection creation.	1 = Flow Created.	0 = Ignore.
30201430201630201830202I	TCP, UDP, GRE, and ICMP connection tear-down.	2 = Flow Deleted.	0 = Ignore, or> 2000 = ASP drop reasons.
710003	An attempt to connect to the device's interface was denied.	3 = Flow Denied.	1003 = To-the-box flow denied due to configuration.

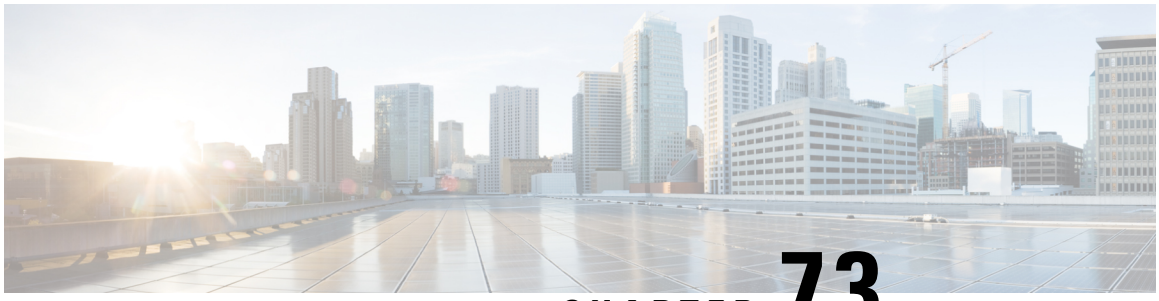
Syslog ID	Syslog Description	NetFlow Event ID	Extended Event ID
106015	A TCP flow was denied because the first packet was not a SYN packet.	3 = Flow Denied.	1004 = Flow denied because first packet was not a TCP SYN packet.
313001	An ICMP packet to the device was denied.	3 = Flow Denied.	1003 = To-the-box flow denied due to configuration.
313008	An ICMP v6 packet to the device was denied.	3 = Flow Denied.	1003 = To-the-box flow denied due to configuration.
106023	A flow was denied by an access list attached to an interface with the access group command.	3 = Flow Denied.	1001 – Flow denied by Ingress ACL.1002 – Flow denied by Egress ACL.
106100	An access rule was hit.	1 = Flow Created (if ACL permitted the flow).3 = Flow Denied (if ACL denied the flow).	0 – If Flow permitted by ACL.1001 – Flow denied by Ingress ACL.1002 – Flow denied by Egress ACL.

For the Flow Denied NetFlow event, an Extended Event ID indicates the reason for denial, as shown in the following table.

Extended Event ID	Event	Description
1001	FLOW DENIED	The flow was denied by an Ingress ACL.
1002	FLOW DENIED	The flow was denied by an Egress ACL.
1003	FLOW DENIED	The security appliance denied an attempt to connect to the interface service. For example, this message appears (with the service SNMP) when the security appliance receives an SNMP request from an unauthorized SNMP management station.
1004	FLOW DENIED	The flow was denied because the first packet was not a TCP SYN packet.
> 2000	FLOW DELETED	Values above 2000 represent various reasons for a flow being terminated.

PART VIII

Image Management



CHAPTER 73

Using Image Manager

Image Manager is a tool to simplify the distribution and management of images on internal and edge firewall devices in your network. It enables you to:

Download and maintain a repository of different types and versions of images

Evaluate images

Analyze impact of upgrading images to the devices in the network

Prepare for and plan an upgrade

Reliably upgrade devices, with sufficient fallback and recovery mechanisms built in to ensure minimal network downtime

This chapter contains the following topics:

Getting Started with Image Manager

Image Manager contains sections that are used for managing your images, working with the devices that you will need to update, and performing image installations on those devices.

For more information on these areas of Image Manager, see the following topics:

- Working with Images , on page 2898
- Working with Bundles , on page 2901
- Working with Devices , on page 2904
- Working with Jobs , on page 2921

Before working with Image Manager, you should review the sections that follow:

- the platforms that are supported by this feature,

- the configuration settings you can change to control how the feature works, and
- the steps that are necessary to ensure your devices are configured to work with Image Manager.

This section contains the following topics:

Image Manager Supported Platforms and Versions

Caution From version 4.18, Cisco Security Manager does not support SFR from ASA 9.10(1) onwards for ASA 5512, ASA 5506, ASA 5506H and ASA 5506W models. Therefore, if you upgrade to 9.10(1) through Image Manager, the exiting SFR configuration will be lost.

Image Manager is available only for ASA devices. The following devices support Image Manager:

- All legacy ASA models—ASA 5505/10/20/40/50/80
- ASA 5585
- ASA 5515/25/35/45/55
- ASA-SM module for Catalyst 6K
- 5516-X
- Adaptive Security Virtual Appliance (ASAv)

Beginning with Cisco Security Manager 4.20, Image Manager supports the following Firepower devices, that operate in Appliance Mode, running on ASA 9.13(1) and higher devices:

- Cisco Firepower 1140 Security Appliance
- Cisco Firepower 1150 Security Appliance
- Cisco Firepower 1010 Security Appliance
- Cisco Firepower 2140 Security Appliance
- Cisco Firepower 2120 Security Appliance
- Cisco Firepower 1120 Security Appliance
- Cisco Firepower 2110 Security Appliance
- Cisco Firepower 2130 Security Appliance

The following devices are not supported and are filtered out in the devices tab of the Image Manager unified view:

- PIX firewall
- FWSM blade
- ASA device managed by AUS
- Devices unmanaged in Security Manager
- Other device types—IPS and Routers

Image Manager supports image upgrade for ASA device version from 7.x onwards. The target image version that can be used to upgrade is not restricted. Image upgrade to the highest ASA version supported in Security Manager 4.4, that is ASA version 9.0(1) and 9.1(1), has been tested.

Prior to version 4.9, the Image Manager application listed all the images of the supported device type. You could select and download any image that you required. Beginning with version 4.9, the Image Manager application lists only the specific versions of images.

The latest images of ASDM, †Remote Access Plugin and Host scan are listed in Image Manager. For AnyConnect version 3.x and 4.x, the latest images are listed.

For ASA devices, the following images are listed:

ASA Device Model	ASA Images listed in Image Manager
5512-x,5515-x,5525-x,5545-x,5585x	9.4.1 9.3.3 9.3.2 9.3.1.SMP 9.2.3.SMP 9.2.2.4.SMP 9.2.1.SMP.ED 9.1.4.SMP.ED 9.1.5.SMP.ED 9.1.6.SMP.ED 9.1.2.SMP.ED 9.0.4.SMP.ED 8.4.6.SMP.ED

ASA Device Model	ASA Images listed in Image Manager
5580-x	9.1.6.SMP 9.1.5.SMP.ED 9.1.4.SMP.ED 9.1.2.SMP.ED 9.0.4.SMP.ED 8.4.6.SMP.ED
5555-x	9.4.1 9.3.3 9.3.2 9.3.1.SMP 9.2.3.SMP 9.2.2.4.SMP 9.2.1.SMP.ED 9.1.2.SMP.ED 9.0.4.SMP.ED
5505,5510,5520,5540,5550	9.1.6 9.1.5.ED 9.1.4.ED 9.1.2.ED 9.0.4.ED 8.4.6.ED
5506-X	9.4.1, 9.3.3, 9.3.2
5506H-X	9.4.1
5506W-X	9.4.1
5516-X	9.4.1
Adaptive Security Virtual Appliance (ASAv)	9.3.1, 9.3.2, 9.4.1

Note Image manager ASA image upgrade will be supported for Appliance mode devices for firepower series.

Danger Image downgrade is not restricted, but is done at your own risk. Image Manager does not validate downgrade cases.

Device Configurations supported by Image Manager

In addition to supporting image updates on standalone ASA devices, Image Manager manages the filesystem and supports seamless image update for ASA devices specially configured for high availability and scalability. Following configurations are supported:

- **Multiple context mode**—ASA in multiple context mode where a single ASA can be partitioned into multiple virtual devices/firewalls. Refer to http://www.cisco.com/en/US/docs/security/asa/asa91/configuration/general/ha_contexts.html . Each of these virtual firewalls are represented in Security Manager as independent devices. When Image Manager updates the image on the physical unit hosting these virtual devices, it updates device properties of all virtual devices with the new image information.
- **Failover configuration**—Two identical ASA devices configured to failover for high availability. They can be configured to be in Active/Active or Active/Standby failover. Refer to http://www.cisco.com/en/US/docs/security/asa/asa91/configuration/general/ha_overview.html . Image update on an Active/Active failover pair is not supported in Image Manager. In order to use Image Manager to update the images on an Active/Active failover pair, the Active/Active failover pair has to temporarily be converted to Active/Standby by making all the failover groups active on one unit, and the corresponding failover groups standby on the other unit. After upgrade, you can convert the failover pair back to Active/Active.
- **Cluster configuration**—Multiple ASAs (up to 8 ASAs) can be grouped together as a single logical unit called a **cluster** for achieving increased throughput and redundancy. The purpose of clustering devices is to simplify manageability and to increase processing speed. By using clusters you are able to scale to a multitude of simultaneous connections that work together to load balance the connections. Clustering feature has been introduced starting from ASA version 9.0(1). For more information see http://www.cisco.com/en/US/docs/security/asa/asa91/configuration/general/ha_cluster.html .

Note Clustering is only supported on ASA 5580 and ASA 5585.

Starting from release 4.4, Security Manager supports Clustering. In Configuration manager and Image Manager, all the devices/members in a cluster or a failover pair are managed as a single device. That is, when you change the configuration on a control unit, the change is automatically made to all the devices in the cluster. Similarly, Image Manager updates image on each of the physical unit that is part of failover or cluster in a single operation.

Image Management for Multi-Context ASA

Beginning with version 4.12, the Image Manager Device Tree view displays all the user contexts (Admin and User contexts) of the multi-context firewall devices running the ASA software version 9.6(2) or later.

You can select a User context and view the storage-url information of the selected context on the Storage tab.

On the Compatible Images tab, you can view only the Secure Client images for the selected User Context. However, all image types are displayed for the System Contexts.

Image Manager Supported Image Types

Image Manager supports the following types of images:

- ASA System software
- ASDM image
- VPN images [includes Cisco Secure Desktop (CSD), Secure Client, and Hostscan]
- SSLVPN Plug-in images (For example: RDP, SSH, ICA, and others)

Image Manager completely manages the ASA system software and the ASDM images on the ASA devices, i.e., it performs loading of the image, activating the image by modifying configuration, and even reloading the device if required to complete the image upgrade process.

For the User Context devices Security Manager supports only Secure Client images for copying and installation.

Image Manager does not support the ASA–CX images. This includes both the system images, for example asacx-sys-9.1.1-1.pkg, and also the boot images, for example asacx-5500x-boot-9.1.1-1.img. Using Image Manager, you cannot add any CX images to the Image Manager repository and cannot push any CX images to the device .

Handling of SSL VPN Images

Image Manager only reliably copies SSL VPN images to the ASA device. No configuration or activation commands are added for SSL VPN images by Image Manager. The configuration of the images must still be done using Configuration Manager.

The following files are not managed in Image Manager and have to be configured and deployed from Configuration Manager as in earlier versions of Security Manager:

- CSD Configuration XML
- Secure Client Profile files
- DAP Configuration XML
- Full Customization XML files

After the SSL VPN images have been copied to the device using Image Manager, the remote access VPN policies must be configured in Configuration Manager to make use of these images. The Remote Access VPN policies that must be configured are located at the following paths in Configuration Manager:

- **CSD Package**—Remote Access VPN > Dynamic Access > Cisco Secure Desktop group box
- **HostScan Package**—Remote Access VPN > Dynamic Access > Cisco Secure Desktop group box
- **Secure Client Image**—Remote Access VPN > SSL VPN > Other Settings > Client Settings tab
- **Plug-ins**—Remote Access VPN > SSL VPN > Other Settings > Plug-in tab

The SSL VPN binary files must be present on the device flash before you reference them in VPN policy. If not, Security Manager will present an activity validation warning informing the user of the preference to use

Image Manager to push these files reliably to the device before deploying the configuration. If the user ignores the activation warning and goes ahead, Configuration Manager defaults to the old behavior and pushes the images or files as was done in the earlier versions of Security Manager before deploying the configuration referring to these files. But the user cannot leverage the following advantages of using Image Manager for copying these files:

1. Capability to use external disks like disk1 to copy the files. Configuration Manager only copies the files to disk0 and does not recognize or support external disks.
2. Image Manager preempts errors during the image copy by validating that there is enough free space on the disk to copy the selected images and does not allow creation of a job unless there is sufficient space is to copy the images. User can make space by using the Image Manager to delete unwanted images.

Note Image Manager does not validate the compatibility of the SSL VPN files that are pushed to the ASA. But Configuration Manager will complain when incompatible files are referenced in the Remote Access VPN policies.

Administrative Settings for Image Manager

Image Manager introduces new administrative settings. These administrative settings must be configured as part of Configuration Manager.

Configuring Cisco.com Certificates

Beginning with version 4.4, Security Manager has a certificate trust management feature. This feature helps you with improved handling of Cisco.com certificates. For detailed documentation of this feature, refer to Certificate Trust Management, on page 495.

To configure administrative settings for Image Manager, do the following:

Step 1 Go to **Configuration Manager > Tools > Security Manager Administration**.

The Cisco Security Manager - Administration page appears.

Step 2 Configure workflow settings:

Tip Refer to the Configuration Manager documentation for workflow control setting information.

a) Select **Workflow**.
b) To require that Install Jobs be approved explicitly by an assigned approver before they are installed on devices, select **Require Deployment & Install Image Approval**. If you select this option, make sure you configure appropriate email notification settings. For more information, see the Workflow Page , on page 590.

Note To allow the submitter to approve deployment jobs, select Submitter can Approve Deployment Job.

c) Click **Save.**

Step 3 Configure debug settings:

a) Select **Debug Options** and from the drop-down list for Image Manager Debug Level, select the debug level you want.

Tip The levels include: Severe, Error, Warning, Info and Debug. The default log level is Error.

Note The log files are stored as follows:

- The server logs are located at: **%NMSROOT%\MDC\log\operation\vmssharedsvcs.log** and **%NMSROOT%\MDC\tomcat\logs\stdout.log**
- The client logs are located at: **<Client Install Dir>\logs*.log**

b) Click **Save.**

Step 4 Configure Cisco.com credentials:

a) Select **Image Manager**.

The Image Manager page appears.

b) If you have credentials to connect to Cisco.com configured already at Tools > Security Manager Administration > IPS Updates > Update Server and wish to reuse the same for Image Manager, then check the **Use IPS Updates Settings** check box. This is also the default behavior.

Note Only Cisco.com is supported, not Local Server.

c) On the Image Manager page, deselect the **Use IPS Updates Settings** check box if you want to specify a set of credentials for Image Manager explicitly.

The fields on the Image Manager page become operable.

d) Complete the following fields:

- Username
- Password
- Confirmation

e) Optionally, complete the Proxy Server Settings to configure a proxy, if required.

1. Select the **Enable Proxy** check box.
2. Complete the following fields to define the proxy:
3. IP or Hostname
4. Port
5. Username
6. Password
7. Confirmation (of Password)

f) Click **Test Connection** test connectivity to Cisco.com with the configured settings.

g) Click **Save**.

Step 5 Configure Purge Interval for Image Install Jobs

a) Select Image Manager.

b) Enter a purge value to specify how many days should pass between purges, in the Purge Jobs Older Than field.

Note Pressing the Purge Now button immediately purges the Image Installation jobs satisfying the Purge Interval criteria.

Step 6 Configure Image Backup Settings

a) Select Image Manager.

b) To include the repository as part of the standard backup, select **Include Repository**.

Caution Ensure that you have sufficient hard disk space on the Security Manager server as the image files consume a lot of space.

Note You can click the Reset button to reset the values to the last saved values before the current change.

c) Click **Save**.

Step 7 Click **Close** to close the Administration window.

Bootstrapping Devices for Image Manager

The bootstrapping in Image Manager is essentially the same as that which you perform in Configuration Manager for ASA devices.

To bootstrap a device for Image Management, do the following:

Step 1 Configure HTTPS on the device(s) to manage ASA in Security Manager.

a) Ensure that the HTTP server is enabled.

b) Add the Security Manager server IP address as an allowed host for HTTP management on the device.

Step 2 Ensure that the configuration register setting is set to boot with the image list in the running configuration.

a) Register value: 0x1,0x3,0x5, 0x7, 0x9

Note Register value: 0x1 is the recommended setting.

b) Do not set to boot to **rommon** mode. (Otherwise device will not be rebooted and the image upgrade will be aborted.)

Step 3 In Security Manager, go to Tools > Security Manager Administration > Device Communication > SSL Certificate Parameters. In the SSL Certificate Parameters area, set PIX/ASA/FWSM Device Authentication Certificates to Do not use certificate authentication.

Step 4 Ensure that there is sufficient space in the flash memory of the device(s) to hold the images you intend to load.

Tip If necessary, you can delete other images you do not intend to use from the device(s).

Step 5 We recommend that you unmanage the Boot-Image/Configuration policy for ASA, as follows:

a) In Security Manager, navigate to Tools > Administration > Policy Management.

b) Uncheck the Boot Image/Configuration policy selection.

Note Image Manager configures boot image and ASDM image as part of the image installation job. So, if the Boot Image/Configuration policy is not unmanaged, then any configuration deployment after the image installation will remove these boot commands added by Image Manager. To prevent this, the Boot Image/Configuration policy should be unmanaged in Security Manager. This can be done from Security Manager administration settings -> Device Exception Settings -> Firewall Policies node.

Step 6 We recommend that the device not be set as a priority monitored device in HPM.

Step 7 Ensure that all configuration changes on the device are submitted and deployed.

Working with Images

Image Manager provides access to images on Cisco.com as well as images on your network. When an image shows a location of Repository, it means that image has already been downloaded (either from Cisco.com or from a local file system). Conversely, an image that shows location as Cisco.com has not been downloaded into the repository. Navigating to the Repository Images in the Images section of the selector enables you to examine a list of all the images. You can also filter, sort, and search the images available. Filtering, in particular, is a good way to navigate within Image Manager. Beginning with all images, you can use the headings in the main repository view to locate images by a variety of attributes including name, version, and type.

Image Manager does not manage ASA-CX images. Any CX images available on Cisco.com will not be shown in Image Manager for download. You also cannot add any CX images from the file-system.

Note Only images that are downloaded to the Image Repository can be used for image upgrade jobs.

Note Beginning with Security Manager release 4.4, when Security Manager contacts Cisco.com to update images or to check on the availability of image updates, an additional certificate validation is performed. The update or download fails if you have not accepted the most recent certificate. You must retrieve, view, and accept the most recent certificate before you can proceed with other operations. For more information on the certificates, see Managing Device Communication Settings and Certificates , on page 460.

This section contains the following topics:

View All Images

When you first open Image Manager, or when you select All Images from the selector, the system displays a complete list of images. This list includes both those images in the repository as well as those on Cisco.com (which have not yet been downloaded). Some of the VPN image files are bundled with the Security Manager installation and are shown in the repository from the first time onwards. Image Manager will display a warning about credentials not being configured when the Image Manager client is launched for the first time, or until the credentials are configured under Security Manager administration settings for Image Manager.

Note In earlier releases of Security manager, only the prepackaged SSL-VPN images already existing in the Image Manager repository could be seen. If you do not have a repository connection, beginning with Security Manager release 4.4, on a freshly installed Security Manager, Image Manager shows not only the prepackaged SSL-VPN images in the repository, but also lists supported ASA images available on Cisco.com. The prepackaged files are available at: CSMRoot>\MDC\athena\ccometadata . Thus, even if you do not have initial connectivity to Cisco.com, you can view the latest images that are available at the time of release of the Security Manager. You have to have Cisco.com connectivity and should configure credentials to Cisco.com to either check for the latest updates on Cisco.com or to download the images from Cisco.com, or both. This prepackaged information about image availability enables users not having Cisco.com connectivity to still view the latest images available on Cisco.com (at least the ones published on Cisco.com by the Security Manager release). This also lets you view compatible images for a particular device type/platform.

Note CSM lists all of the supported latest images in the **All Images** window. You must use the appropriate image installation from the list for your device to avoid any installation error or device shutdown.

This view can be re-ordered by any of the listed image attributes. For example, you can list the images by size. The attributes that you can sort on include:

- Download State - This is the first column and is shown as icons. The icons are actionable, and you can double-click the icon in this column to start the download of an image from Cisco.com, or to abort an ongoing image download, or to delete an image from the repository. Note that the icons change during each of these actions. (A green arrow indicates an image on Cisco.com, a red cross indicates an image that has already been downloaded, and another icon indicates that a download is in progress.)
- Image (name)
- Type
- Version
- Location
- Size
- Description
- Comments (you can add and edit comments for an image).

To view all images, do the following:

Step 1 Check for new images available on Cisco.com

a) Configure the credentials for reaching Cisco.com by navigating to Tools > Security Manager Administration > Image Manager.
b) In the upper right corner, click the double arrow **Check for Updates** icon.
c) Ensure that the CCO account has permissions to download crypto images. Otherwise, navigate to the link and accept the agreement, and then retry the operation.

The system displays "**Updating**" while it checks for updates. When finished, it reads: **Last updated at: <timestamp>**, and you can view the new images available in the All Images view.

Step 2 If you have not already accepted the most recently issued Cisco.com certification, the system notifies you that you must retieve, view, and accept the latest certificate before any communication with Cisco.com by Image Manager can occur.

Step 3 Click **All Images** in the selector.

The system displays the image list.

Step 4 To re-order the list, click on any of the column headings.

The list of images is reordered according to the selected attribute.

Step 5 To filter the list, use the Image Manager's search window to enter a key string. For example, you could enter the digits of a version number.

Note Also, you can use the filter settings in some of the column headings to filter the list shown.

Download Images to the Repository

You can download images to the repository either from Cisco.com or from a local file system.

Note Beginning with version 4.4, Security Manager has a certificate trust management feature. This feature helps you with improved handling of Cisco.com certificates. For detailed documentation of this feature, refer to Certificate Trust Management, on page 495. You must have accepted the latest certificate from the image download site on Cisco.com to proceed. The certificate of the site from which the image is to be downloaded may be different from the site that is contacted for "Check for updates" to obtain the latest meta-data information about images. Thus, even if you have accepted the certificate from the "Image Meta-data Locator" URL, the image download may fail with an error to accept the certificate of the image download URL. You must retrieve and accept the certificate from the download URL given in the error message to proceed with the image download.

Note Beginning with version 4.9, Security Manager mandates you to read and accept the End User License Agreement (EULA) before you can proceed to downloading images from cisco.com.

In earlier versions of Security Manager, the End-User License Agreement (EULA) and K9 prompts had to be accepted for all image downloads. However, beginning with version 4.23, EULA and K9 prompts does not appear every time you are attempting to download an image.

Tip Images can also be downloaded from the Compatible Images tab. For details see Manage Images on a Device , on page 2906.

To add an image file to your Security Manager repository, do the following:

Step 1 To download images from Cisco.com, do the following:

a) From the All Images view double-click the **Start Download** icon in the first column.

Tip Ensure that the credentials to Cisco.com are configured and you have authorization to download the images.

Note Image Manager displays an error message if the image to be downloaded already exists in the repository. The system skips the download when the file name and checksum are identical.

The Downloads window appears showing the progress of the download.

Tip The progress icons may change as the download progresses. A green check icon with the word Deployed indicates success. A red X icon indicates failure. In case of failures, you can view the cause of the failure for that image in the Downloads window. You can double click the message to view the complete details of the error.

b) When completed, select Repository Images and view the image in the listing.

Tip You can also select multiple images and download them all at once by right-clicking them and using the context-sensitive menu.

Tip By sorting the list on Update Time, you can easily view the most recent image.

Step 2 To download images from a local file system, do the following:

a) From the toolbar in the Repository Images view, click the **Download image from file system** icon (found on the far left).

The Download from File System dialog box appears.

b) Use the Browse feature to select the Import location and to select the image to be imported.
c) Click **OK**.
d) Click **OK** in the Download image from file system dialog box.
e) Observe the progress of the download.

Note If the image to be downloaded already exists in the repository, the system displays an error.

f) When completed, select a device group in Security Manager and view the image in the listing.

Tip By sorting the list on Update Time, you can easily view the most recent image.

g) Alternatively, you can download an image file using the drag-and-drop method. For example, you can drag one or more files from your desktop and simply drop it on the Image Manager application.

Working with Bundles

Bundles are groups of compatible images that you define. You can use bundles to simplify repetitive operations, by grouping images that are pre-validated to work together as a logical group. For example, you might define bundles that reflect ASA and ASDM pairs to ensure that you deploy both types in a single operation. The following types of images can be part of a bundle:

- ASA system software

- ASDM image
- VPN images (including csd, Secure Client, Hostscan)
- Plug-ins (including rdp, ssh, ica, owa, and others)

Multiple system software images cannot be included in the same bundle.

Caution The Image Manager does not stop you from adding incompatible images as part of a bundle. You must determine this compatibility. The ASA and ASDM Compatibility matrix is located at: http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html#wp42231 .

Tip Throughout Image Manager there are operations where you can choose to apply an image, multiple images, or a (predefined) bundle of images.

This section contains the following topics:

Creating Bundles

You can define bundles of images to simplify your Image Manager. Bundles are particularly useful when you have a group of images upon which you regularly operate.

To create a bundle, do the following:

Step 1 From the Bundles heading in the selector, click the **Add Bundle** (plus sign) icon.

Step 2 In the Create Bundle dialog box that opens, enter the name for the new bundle.

Step 3 Click **OK**.

The bundle is listed under the Bundles heading in the selector.

Step 4 From the Images section of the selector, select an image to be bundled. Then click on the Release Notes tab. Finally, examine the compatibility table in the applicable release notes to ensure there are no conflicts with the other images to be bundled.

Caution The Image Manager does not stop you from adding incompatible images as part of a bundle. It is the responsibility of the user to determine this compatibility. The ASA and ASDM Compatibility matrix is located at: http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html#wp42231 .

Step 5 With compatibility determined, drag and drop each image onto the bundle.

Note Multiple system software images cannot be included in the same bundle.

Tip You can select a range of images to drag and drop by selecting the first image in the range and then, with the Shift key pressed, selecting the last image in the range. You can select multiple images by clicking those images while keeping the Ctrl key pressed. You can also select a range of images and then add additional images to your selection by using the Ctrl key method. To move multiple images to a bundle, drag using the right mouse button.

View Images by Bundle

You can view the images that have been added to a bundle.

To view the images in a bundle, do one of the following:

Step 1 To view the images contained within all bundles:

a) Under the Bundles heading in the selector, click the top-level Bundles folder.

All the bundles are listed, together with the images contained within each.

b) You can expand or collapse any of the bundles to make viewing easier. To expand all bundles or collapse all bundles, use the Expand All and Collapse All buttons at the top of the main window.

Step 2 To view the images for a specific bundle:

a) Under the Bundles heading in the selector, select a bundle.

The list of images for the selected bundle is displayed in the main window.

Step 3 To view a particular bundle:

a) In the Bundles section of the selector, click **Search** (the magnifier icon).

b) Enter the bundle name in the search field under the Bundles banner.

The list of bundles displays only the specified bundle.

Renaming Bundles

Bundles can easily be renamed to provide better organization or to more accurately reflect the contents of the bundle.

To rename a bundle, do the following:

Step 1 From the Bundles heading in the selector, select a bundle.

Step 2 Right-click the bundle name and, from the drop-down list, select **Rename Bundle**.

The Rename Bundle dialog box appears.

Step 3 Type the new bundle name.

Step 4 Click **OK.**

The new bundle name appears in the selector under Bundles.

Deleting Bundles

Bundles that are no longer needed can be deleted.

To delete a bundle, do the following:

Step 1 Select the bundle.

Step 2 From the Bundles heading in the selector, click **Delete** (the red X icon). Alternatively, right click on the selected bundle and select **Delete Bundle**.

Deleting Images from Bundles

If you wish to change the contents of a bundle, you can delete any of the images that are defined as part of a bundle.

To delete images from bundle, do the following:

Step 1 Select the bundle.

Step 2 Right-click on the image(s) to be removed.

Step 3 Select **Delete Image from Bundle**. Alternatively, click the Delete button at the top of the table.

Working with Devices

The following topics explain how to work with devices in Image Manager.

Note For a cluster, only the control unit supports the download of files from storage.

This section contains the following topics:

Viewing Device Inventory

You can use the Device Summary page to quickly view the devices on your network and their attributes.

Within the selector panel on the left is an area called Devices. From that area you can display all devices by selecting All (or you could select a location or group of devices you have defined). After you have chosen the scope of device selection, the corresponding devices are displayed in the upper panel of the Device Summary page. The upper window of the Device Summary page displays the following attributes, as applicable, for each device:

- Device Display name
- Mode (for example, Standalone, Active-Active. Active-Standby, Cluster)
- System SW Version
- ASDM Version
- Secure Client Version
- Secure Desktop Version
- Hostscan Version

The Device Summary table includes a Mode column. This column specifies such modes as Cluster, Standalone, Active-Active, and Active-Standby.

For configurations in which multiple physical devices are grouped together, as in failover and cluster configuration, each physical unit/ member has its own file system. And these file systems can be different. The details of the file systems of each physical device/ member are viewable within Image Manager.

Details of individual cluster members, including storage and image status, are shown in the Security Manager user interface. During discovery of image management inventory data, details are discovered regarding each cluster member's storage and running image details.

When a Failover or Cluster device is selected in the Device Summary page, the individual physical members in the group are displayed in the middle Device View table. The Device View table for Cluster device displays the following information about the cluster members:

- **Name**—Device or cluster member name.
- **ID**—Cluster Member ID.
- **Status**—Role of the member in the cluster. For example, Cluster Control or Cluster Data.
- **Serial Number**—Serial number of the cluster device.
- **Running OS Version**—Version of OS on the particular member.
- **CCL IP**—Cluster Link IP address.
- **CCL MAC**—Cluster Link MAC address.
- **Site ID**—Site ID of the Cluster device.

The Device View table for a *Failover device* has columns that include Name, Status (for example Standby or Active), Serial Number, RAM size, and Running OS Version. The Failover Device table lists these elements by Primary and Secondary devices for the failover pair nodes.

When you select a particular device in the device summary page, then the lower window displays the following tabbed pages for the details of that device.

- **Summary**—Display Name, Device Type, IP Address, Hostname, Domain Name, Serial Number, Running OS Version, Target OS Version, RAM, Failover Mode, Image Install Location
- **Compatible Images**—Images compatible to the device—Image, Type, Version, Location, Size, Description, Comment.
- **History**—Chronological view of Image Installation Jobs and Configuration Deployment Jobs that have been executed on the device—Job Name, Changed By, State, Last Action, Tickets

When you select a particular member of a failover or cluster device in the middle Device View, the lower window displays the following tabbed details for that physical device.

- **Summary**—Running OS Version, Target OS Version, RAM
- **Storage**—The number and capacity of flash memory units. Name, Size, Path, Type, Disk Usage
- **Running Images**—The images presently operating. Name, Type, Version, Path, Size

Manage Images on a Device

You can use the Image Management tool to review, download, and remove the images on the ASA device(s) you select.

To review, download, or remove ASA images on a device, do the following:

Step 1 Select a device group from the Devices area of the selector panel.

The main window displays the Device Summary. The Device summary lists the devices and the associated system software versions.

Tip Alternatively, you can select the search function (magnifier icon) from the Devices banner and then enter the device name in the search field that appears.

Step 2 From the upper pane of the Device Summary page, select a device.

Note If a particular device is part of a cluster, you can navigate through the cluster to view device details.

The lower pane displays details of the selected device.

Step 3 Select the Storage tab in the lower pane and then check the amount of free space listed under Disk Usage.

Note If a particular device is part of a cluster, you can navigate through the cluster to view device storage details.

Tip The device may have more than one storage area, for example, disk1. Be sure to scroll down to see secondary (flash) storage capacity.

Step 4 Note the available disk space on the device.

Step 5 To remove one or more images from the device to free up space, select one or more images in the Storage Tab and click **Delete** at the top of the Storage Tab.

Tip Alternatively, you can select one or more images, right-click and click Delete.

Tip If you delete an image that is currently active and is being referenced, Image Manager displays a warning message.

Step 6 To download an image from the device, select the image and click **Download** at the top of the Storage tab. Select the location on the local file system to which to download the image and click **OK**.

Note For a cluster device, download of images is only supported on the Control unit. Similarly, for a failover device, download of images is only supported on the active device in the pair.

A dialog appears showing the progress of the download from the device. After the download is completed, the downloaded image is shown in Explorer.

Step 7 Select the Compatible Images tab in the lower pane.

The system displays images that are compatible to the device.

Step 8 To install the compatible image(s) onto the device do the following:

a) Select the image to be added to the device.

b) Double-click the download icon.

The image is downloaded to the repository.

c) Select the image and then select **Install** from the context menu.

The Install wizard appears and the system installs the image. Please see Install Compatible Images on Devices , on page 2919 for details.

View Device Memory

You can use Image Manager to determine the memory capacity and application of a device in your network.

Note Only physical devices can display memory capacity, clusters do not.

To view the details of the memory on a device, do the following:

Step 1 From the Devices area of the selector panel, choose the device to examine.

Details of the selected device appear in upper window of the Device Summary page.

Step 2 In the upper panel, examine the RAM listing.

Caution Image Manager warns you if there is insufficient RAM on a device to load the new image. However, the system does not stop you from performing such an image upgrade. (This is in contrast with Configuration deployment, where the deployment job stops if there is insufficient RAM.)

Configuring the Image Install Location

ASA devices have a default flash (disk0) where all the images reside. By default, Image Manager copies images to disk0 of the ASA device. When the ASA device is configured with an external disk (that is, disk1), Image Manager allows you to choose between the two disks, disk0 or disk1, when loading images on the ASA device.

Note The capability to load images on an external disk is very useful for storing large images such as those for Secure Client and CSD, as disk0 can run out of space quickly with even a few of these larger images.

For configuring Image Manager to use the external disk, do the following:

Step 1 Select the device from the Devices area of the selector.

Step 2 View the Summary information on the right pane.

The available disks on the device are listed in the Image Install Location drop-down list. For a device with external disk, disk0 and disk1 would be listed.

Step 3 Select the external disk, disk1, from the Image Install Location drop-down list and click **Apply**. For a user context device, you can select shared or private label to apply the default Install location.

All future image installation jobs for the device will load the images to disk1.

Tip The configuration of the external disk can be verified by performing an image install operation. After the job is complete, view the contents of disk1 in the Storage tab of the device in Image Manager. It should list the newly installed images.

Note For cluster and failover devices, and multi-context devices, if all the physical member devices do not have the disk that is selected as the Image Install location, then there will be a validation error when you try to copy or install images. You need to select the Image Install location to be a disk that is present on every member device to proceed with copying or installing images.

About Image Updates on Devices Using Image Manager

How does Image Manager update images on an ASA device?

Image Manager follows the standard documented procedure to upgrade the stand-alone ASA devices with several built-in checks to ensure reliable image upgrade. Please refer to: http://www.cisco.com/en/US/products/ps6120/products_configuration_example09186a008067e9f9.shtml#maintask2 for the procedure for image upgrade.

Note You must have accepted the latest Cisco.com certificate to enable Image Manager to interface with cisco.com. You must accept the certificate from both the "Image Meta-data locator" site and the download site of the images to start downloading images successfully (see Image Manager Page , on page 552).

Image Manager uses the HTTPS protocol to copy images to the ASA device, performs configuration changes to activate the new image (ensuring fallback to the older image in case of any error), and finally reloads the device if required, with the new image.

How does Image Manager update images on an ASA configured for failover?

Updating the images in an Active/Standby failover pair is accomplished by creating an image upgrade job on the active device of the pair, and then running the image upgrade job.

Image update on an Active/Active failover pair is not supported in Image Manager. The Active/Active failover pair has to be converted to Active/Standby by making all the failover groups active on one unit, and the corresponding failover groups standby on the other unit. Only then can Image Manager update the image on the pair of devices.

To upgrade devices in an Active/Active failover pair:

1. Manually convert the pair to active/standby by forcing all the failover groups on one device to be **active** and on the other device to be **standby**.

Note Do not discover the devices in Security Manager.

Note For additional details on how to convert an active/active failover pair to active/standby, see http://www.cisco.com/en/US/products/ps6120/products_configuration_example09186a0080b20f35.shtml#Actact .

2. Create an image upgrade job on the active device of the pair, and run the image upgrade job.
3. After the upgrade has occurred, manually convert the pair back to active/active configuration, as existed before the upgrade, by making the required failover groups active on one unit and the remaining failover groups to be active on the other physical unit.
4. Rediscover in Security Manager only the device inventory for the unit that was converted to standby.

Image Manager follows the upgrade procedure as detailed at:http://www.cisco.com/en/US/products/ps6120/products_configuration_example09186a0080b20f35.shtml . The image is copied to both the units and then configuration change is done to activate the image that is synced to both units. First the standby is reloaded via the active unit and after ensuring that the standby has been upgraded successfully to the new version, the current active is reloaded. After both the units are upgraded to the new version, the failover pair or cluster upgrade is marked successful.

Note During the current active reload and until the standby ASA takes over, the traffic going through the failover pair will be impacted.

There are restrictions for image upgrade in failover ASA pair. We recommend that, while performing image upgrades on a failover ASA pair or cluster using Image Manager, you ensure the following restrictions are satisfied:

- The two units in a failover configuration should have the same major (first number) and minor (second number) software version.
- **Maintenance Release**: You can upgrade from any maintenance release to any other maintenance release within a minor release. For example, you can upgrade from 7.0(1) to 7.0(4) without first installing the maintenance releases in between.
- **Minor Release**: You can upgrade from a minor release to the next minor release. **You cannot skip a minor release.** For example, you can upgrade from 7.0 to 7.1. Upgrading from 7.0 directly to 7.2 is not supported for zero-downtime upgrades; you must first upgrade to 7.1
- **Major Release**: You can upgrade from the last minor release of the previous version to the next major release. For example, you can upgrade from 7.9 to 8.0, assuming that 7.9 is the last minor version in the 7.x release.

How does Image Manager update images on an ASA cluster?

Image updates follow the procedure previously established for hitless upgrades that ensures that all members of a cluster are upgraded to a new version in a single user operation without affecting traffic flow. During an image upgrade:

- The data units of a cluster are first loaded with the new image from the control unit. Images are copied to all members of a cluster while being connected only to the control unit. Such propagation through a cluster does not require switchovers of each device to control unit status and, thereby, minimizes traffic disruption.
- Configuration is changed on the contorl unit to add the boot command to load with the new image. The configuration, once changed on the control unit, automatically gets synced on all the data units.
- All the data units reboot with the new image sequentially via the control unit.
- All the data units come online and rejoin the cluster.
- The control unit is then made into a data unit (with the next data unit taking over the control unit role).
- Via the new control unit, the old control unit is reloaded with the new image.

This procedure for image update followed by Image Manager ensures minimal switchovers and minimal disruption of traffic.

Device State Changes During and After Image Update

Image upgrade is a critical operation and hence there is a need to depict visually, and inform users of, all image update operations. Thus, three new device states have been introduced:

- **Upgrade In Progress**—The device is put into this state whenever an image install job starts on the device. This state is automatically reset by the system after the image update operation is completed on the device.
- **Maintenance**—The device is put into Maintenance state when the image install job fails on the device and the device becomes unreachable after the image install operation. You need to manually reset this state to normal/operational state after taking necessary steps to bring back the device online by manually correcting issues due to upgrade or by rolling back the image.
- **Configuration Required**—For certain cases of image upgrade (like from ASA 8.2 to ASA 8.3), there are significant changes in the device configuration as part of the image upgrade which renders the policy

configuration model in Security Manager incompatible with the device configuration. In such cases, even if the image upgrade operation may be successful, you must perform some operations, like rediscovery of device, to ensure that after upgrade, Security Manager's configuration policy model and the device configuration are in tandem. Thus, after an image upgrade, if some additional configuration is required to be made in Configuration Manager to make the device operational, the device is put into *Configuration Required* state. Even in the case where VPN images are deployed using Image Manager, the device is put into *Configuration Required* state since this requires the user to configure these images in the VPN policies using Configuration Manager. The *Configuration Required* state indicates that there are changes to be done in Configuration Manager to make the device functional in Security Manager after the image update operation. You can make the suggested changes and, after you are satisfied with your configuration changes, you can manually bring the device back to *Operational* state.

Note Refer to the Troubleshooting Image Management , on page 2925 for more scenarios that can put the device in the Configuration Required mode.

Whenever the device state is changed to any of these three states, the state is indicated in the device selector with an explicit icon. This change in device state can be seen in both Configuration Manager and Image Manager. The normal state of the device when there is no image update operation on the device is the *Operational* state.

Tip To manually reset the device state to normal or *Operational* status, select the device(s) in the device selector in Configuration Manager or Image Manager, right click, and select Make Device Operational.

This section contains the following topics:

Validating a Proposed Image Update on a Device

You can validate the image update job on one or more devices prior to actually performing it. The following list details the various validations that are performed:

- Insufficient disk space on the ASA device to accommodate the selected images.

An error is displayed in this case. You must navigate to the Storage tab for that device and delete one or more images to make space. Then retry the upgrade validation operation.

Note The disk space on each of the members in the Cluster and both active and standby units in a Failover are evaluated for sufficient space to accommodate the selected images. When a single member or device does not have sufficient space, an error is displayed and you cannot proceed to creating a job on the device. You must navigate to the Storage tab for that particular member and make space by deleting one or more unwanted images.

- Insufficient RAM on the device to run the new image as recommended in: Release Notes for the Cisco ASA 5500 Series, 8.4(x).

Note Image Manager will warn you if there is insufficient RAM on the device to load the new image. However, this will not stop you from performing an image upgrade. This is in contrast with Configuration deployment, wherein the deployment job stops if there is insufficient RAM.

- If the flash device (disk0 or disk1) that is selected for Image Install Location is not present on any of the devices/members in cluster/failover setup, then and error is displayed and the job is aborted.
- Configuration changes that have been submitted but not yet deployed to the device. These changes need to be deployed before starting the image update job. Otherwise, the configuration changes may become incompatible with the upgraded image version on the device.
- Warn if the selected image(s) is (are) incompatible with the device type, for example, if non-SMP images are selected for ASA 5585 device types.

Note This warning only occurs when you are using the drag-and-drop method. For other flows, the incompatible images/devices are filtered out in step 2 of the Image Install Wizard.

Note This validation was skipped in Cisco Security Manager 4.3 if Check for updates is not performed due to the unavailability of meta-data information about images on Cisco.com compatible with MDF IDs. In Cisco Security Manager 4.4, the meta-data information are prepackaged with Cisco Security Manager install and hence even if Check for updates is not performed, Image manager will validate the compatibility of images for device types and warn the user when an incompatible image-device combination is chosen.

- Warn if the device is being updated to a version that is unsupported on Security Manager.
- Warn if the new image version is the same as or lower than the version running on the device.
- An image upgrade to ASA Version 8.3 from any lower version would require the device to be re-discovered in Security Manager. There were major changes in the NAT configuration introduced in ASA version 8.3 that are incompatible with previous ASA versions. Likewise, there were major changes to the NAT policy model in Security Manager for Version 8.3. Hence, when a device is upgraded to ASA 8.3, that device is put into the Configuration Required state to indicate to the Configuration user that some changes are required in Configuration Manager to make the device operational. After rediscovering the device

in Security Manager, the user can right-click the device in the device tree and select Make Device Operational to bring it back to normal state.

- An image upgrade from ASA Version 8.3.x to 8.4.2 or later versions also requires rediscovery of the device in Security Manager because of incompatible changes in PAT configuration in ASA Version 8.4.2. In this case also, the device state is changed to the Configuration Required state after the image upgrade.
- An image upgrade from ASA Version 8.x to 9.0.1 or later requires rediscovery of the device in Security Manager because of incompatible changes in Unified access rules, inspection, and NAT rules.
- An image upgrade from ASA Version 7.x to 8.x introduces major changes in the SSLVPN configuration both on the device and in Security Manager. Because of these incompatible changes, the device must be deleted from Security Manager after the image upgrade and then added again. The device is put into the Configuration Required state to notify the user to act upon these warnings.
- Any VPN image, such as an Secure Client, CSD, or Hostscan image, being loaded using Image Manager warns the user if the existing VPN image was part of a shared policy being assigned to the current device or other devices. A warning is issued to also copy the new image to all the devices to which the shared policy is assigned so that the shared policy can be updated for all the devices seamlessly without the loss of policy sharing.
- Warn when the standby unit in a failover pair in not reachable. This is an error that will cause the job to be aborted.
- Warning for upgrade of Active/Standby failover pair. The version being upgraded should comply with the recommendations listed at: ASA/PIX: How to Use the CLI to Upgrade the Software Image on a Failover Pair .

Note The same warnings are also applicable for an ASA in cluster configuration.

- Warning for upgrade of Active/Active failover pair that the image update job will be aborted unless the pair is converted to Active/Standby (that is, if all the failover groups are active on one physical unit).

Note Additional validations are required for a "device" that is a designated control unit. In addition to a check that is similar to that for Active/Standby Failover, there is also a check that the cluster image is compatible with supported platforms. A cluster cannot be downgraded to a version less than 9.x.

To validate an image installation, do the following:

Step 1 From the File menu, select **Validate.**

The Validate Image Assignments window opens.

Step 2 Click **Add Assignment**.

The Image Assignment window opens.

Step 3 In the Image Assignment window, from the drop-down list, select either:

- Select Images and Assign to Devices
- Select Devices and Assign to Images

Tip The same result is obtained by assigning images to devices or by assigning devices to images.

Step 4 Select one or more items (images or devices) by moving them to the window on the right.

Tip You can use pre-defined bundles rather than images by clicking **Bundles** and selecting the bundle.

Step 5 Click **Next** and assign the other item (images or devices).

The Confirm Assignments window appears.

Step 6 Examine and confirm the assignments that you have specified.

Tip You can continue to add or remove assignments, as required.

Step 7 Click **Finish.**

The Validate Assignments window appears.

Step 8 Click **Start Validation**.

The validation status of the assignment is shown in the Validation column. It shows either Warning or Successful or Error.

Step 9 Click on the display of Warning or Successful or Error.

A lower pane window opens.

Step 10 According to the validation status, do one of the following:

- **Error**—Examine the potential reasons for the error and correct as necessary.
- **Warning**—Examine the potential reasons for the warning and correct as necessary.
- **Successful**—No action required.

Tip Be sure to display and examine all the errors or warnings by using the window slider bar on the right.

Step 11 After addressing the warnings or errors shown, you can proceed to create the job using the Image Install wizard.

Step 12 Optionally, you can right-click on an assignment element in the Validate Image Assignments window and modify or delete it before proceeding.

Step 13 You can also right-click on an assignment and select **Copy Table**. This copies the assignment details and the validation status and notes. You can then paste the contents to Notepad or another program as a CSV file to be used as reference.

Using the Image Installation Wizard to Install Images on Devices

You can use this feature to create a job to assign and install images on devices. An assignment is simply an association of an image and a device that defines an installation job.

Note If you have the workflow function enabled, you must perform the additional steps described for obtaining authorization before you can accomplish installation.

Note You can choose to operate upon any arbitrary set of devices.

To create a job to install images on devices, do the following:

Step 1 Go to Files > Open Image Installation Wizard.

The Image Installation Wizard dialog box appears.

Tip The Image Installation Wizard can be invoked in several ways. In addition to invoking the Wizard from the menu, as described here, you can invoke it when you do any one of the following things: (1) install images by the drag-and-drop method; (2) right-click on a device or bundle; or (3) select a device, navigate to the Compatible Image tab, select one or more images from the table, right-click, and select the **Install** option.

Step 2 On the lower left, click **Add Assignment**.

The Image Assignments dialog box appears.

Step 3 From the drop-down list on the top, select whether you want to assign images to devices, or devices to images.

Step 4 Move items (devices or images) from the list on the left to the selected items list on the right. Then click **Next**. You can also select bundles, instead of images, by clicking the Bundles tab.

Tip When pairing images and devices to define assignments, you can proceed with images and then devices, or devices and then images. The order of this selection does not matter.

Step 5 Review the assignment definition in the Confirm Assignments dialog box and click **Finish.**

Tip At this point you can choose to add additional assignment pairs, as desired, by clicking **Add Assignment**.

Step 6 When you are finished defining assignments, click **Start Validation.** Wait until the system displays Validation Complete.

Step 7 Examine the status in the Validation column on the Assignments tab of the Wizard dialog box. It shows either Warning or Successful or Error.

Step 8 Determine what steps are necessary according to the status:

- **Error**—Examine the potential reasons for the error and correct as necessary.
- **Warning**—Examine the potential reasons for the warning and correct as necessary.
- **Successful**—No action required.

Step 9 Right-click on the assignment for more options:

- **Move Up/Move Down**—Select these options for a multi-device job when you want to change the order in which the devices will get updated. This feature can be used to order or sequence the devices when the Install Images to Devices job option is set to Sequential.
- **Delete/Delete All**—You choose these options to remove one or all devices from the image upgrade job.

- **Copy Table**—Use this to copy the warning messages to some text editor or spreadsheet program for reference.
- **Test File copy**—Use this option to check whether files can be copied between Security Manager Image repository and ASA device flash using https protocol.

Tip Be sure to display and examine all the errors or warnings by using the windows slider bar on the right.

Step 10 If you want the installation job scheduled for a particular time, select the **Schedule** tab and specify the date and time.

Step 11 To set properties of the installation job, select the **Properties** tab.

a) Edit the **Name**, if desired. (The default is Image install Job—<timestamp>)
b) Edit the **Description**, if desired.
c) Select a **Ticket ID**, if desired.

Tip Starting from release 4.4, Ticket ID field in Image Manager has been decoupled from Config Manager. It is now just a 'tag' and can be any arbitrary string. Ticket ID field is an editable combo box with auto completion that shows tickets created earlier both in Image Manager and Configuration Manager. Also, there is no dependency on Ticketing mode in Configuration Manager for Ticket ID field. Ticket ID is an optional field and can be left blank. Global search in Configuration Manager also supports tickets used in Image Manager and lists the Image Installation jobs with which the ticket is associated.

d) Set the **On Error** option. (Default is Stop Installation, alternative is Continue Operation.)
e) Set the **Backup Current Image** option. (Default is Yes, alternative is No.)

Tip This is only applicable for system software images

f) Set the **Install images to devices in** option. (Default is parallel, alternative is Sequential.)
g) Select one of three operations:

- Install image and reboot device
- Install image but do not reboot device
- Only copy image onto devices
  - Select the Non-Intrusive: Does not trigger failover check box to copy the image without switching the failover devices.

h) If you are using Workflow, you can optionally configure the following approval options:

Tip These are located in the top frame in Job properties for the job.

- **Action**—
- Approve
- Reject
- Deploy
- Submit

If you reject a job, the status is set to Rejected, after which you discard the job. When you discard a job the status is shown as Discarded and all the job's action buttons are disabled.

If you approve a job, the status is set to Approved. Then, you must click Deploy to start the image upgrade job.

i) Beginning with version 4.12, Security Manager provides an option to select the Storage URL for ASA multi-context devices running the software version 9.6(2) or later. You can select either Shared or Private Storage URL for the selected user context. By default, Shared is selected.

Tip You can the check running commentary by selecting the Details tab. and clicking **Show Progress**.

After you deploy a job, the job status is shown as either Deployed or Failed. The History tab in the bottom pane (for the selected job) only is activated in WF mode and displays one of two job action flows:

- Creating/ Edit-In-use/ Submitted/ Rejected/ Discarded
- Creating/Edit-In-use/ Submitted/ Approved/ Deploying/ Deployed (or Failed)
- **Submit the job**—This is checked by default
- **Approver email**—The email address list of approvers
- **Submitter email**—The email address of the person submitting the job

j) You can change job properties by clicking **Edit.**

k) Refer to Viewing Install Jobs , on page 2922 for additional job viewing options.

Step 12 Click **Install**.

The Jobs page appears and the install job is shown with its status as Deploying.

Note If a schedule was selected for the job, the job state is shown as Scheduled. The job will start deploying at the scheduled time and, at that time, the job state changes to Deploying.

Note If workflow is enabled for Image Install Jobs, then the job state is changed to either Submitted or Edit-in-Use. In this mode, the job can be deployed only after it has been approved. Please refer to Image Installation Job Approval Workflow , on page 2924 for details on the job states in the workflow mode.

Tip You can halt the job by clicking **Abort**. Please see Aborting an Image Installation Job , on page 2923 for important information about aborting an installation job.You can discard a job before the scheduled run time by clicking **Discard**.

Step 13 When the job starts deploying, notice the change in the state of the devices to *Update in progress* state in the device tree in Configuration Manager and Image Manager. A green progress icon appears beside the device in the device tree.

Step 14 View the details of the job and its progress while it is in deploying state. Please see Viewing Install Jobs , on page 2922 for details.

Step 15 Wait for the job to complete.

The job state is changed to *Deployed* if all the devices are successfully updated. The job state is changed to *Failed* if one or more devices failed in the job.

Step 16 Notice the change in state of the device(s) in the device tree after the job is complete.

If the image update is successful and there are no further configuration changes required in Configuration Manager, the device will be moved back to *Operational* state. If there are configuration changes required on the device after the update, then device is moved to *Configuration Required* state. Clicking on the device in the device tree brings up a balloon tip with details of the state and actions to be taken to move the device state back to *Operational* .If the image update fails on the device and the device is rendered unreachable during the image update operation, the device is put to *Maintenance* state.

Step 17 Verifying the image update:

a) Click on the device in the device tree in Image Manager.
b) Go to the Summary tab to view the updated Running OS version.
c) Go to the Running Images tab to view the new running images after the image update.
d) Select the device in Configuration Manager.
e) Right-click the device and select **Device Properties**.
f) Notice the new image version updated in Running OS Version field.
g) Go to **Configuration Manager > Manage > Configuration Archive**.
h) From the device CLI, enter **sh ver**

   The updated OS version should be displayed.

i) Select the device in the left device tree.
j) View the Configuration Archive versions in the right pane and notice the latest entry with the Archival Source as *Image Manager* .
k) Select the archived entry and click **View.**
l) Compare this entry with the previous archived version to view the configuration changes made by Image Manager during image update. You can view the boot commands being prepended for the new ASA system software image and/or ASDM image command being added for the new ASDM image.
m) Email notification will be sent to configured recipients with the status of the Image Upgrade job if email notification is configured in Image Manager administration settings.

Step 18 If the device is set to *Configuration Required* or *Maintenance* state after the image update operation, follow the steps below to complete the post-image update requirements to make the device functional from Configuration Manager:

a) Click on the device in the device tree in Configuration Manager or Image Manager.

   A balloon tip appears showing the device information.

b) View the contents of the balloon tip. Review the reason for the device being set to the *Configuration Required* or *Maintenance* state. Review also the recommended actions to be taken.
c) Perform the recommended actions.
d) Right-click the device in the device tree and select **Make Device(s) Operational**.

   The device is moved to *Operational* state and the icon beside the device in the device tree is removed.

   Note Before initiating an install job for Cisco Firepower 1000 and 2000 series devices operating in Appliance Mode, you must ensure to select the **No** option for the **Backup Current Image** field in the Properties panel.

Install Bundled Images on Devices

You can use the Image Manager tool to assign and install compatible images that are grouped as bundles. Bundles simplify repetitive operations and can ensure consistent actions are taken on a group of devices.

To selectively install an image bundle on a device or device group, do the following:

Step 1 Drag and drop the bundle onto a device or device group.

The Install images on devices dialog box appears with device and images in the bundle pre-assigned. If the bundle is dropped onto a device group, all the devices in the group are automatically selected and assigned to the images in the bundle.

Step 2 Investigate any assignment validation errors or warnings listed in the Install images on devices dialog box.

Tip You can choose to schedule the job and also modify the default properties for the job. Please see Using the Image Installation Wizard to Install Images on Devices , on page 2914 for details on scheduling a job and configuring job properties.

Step 3 When your warnings are corrected (or you determine them to be insignificant), click **Install.**

Note Alternatively, you can right-click a bundle and select **Install** to launch the Image Installation wizard with the bundle pre-selected. You can then choose the devices and click **Install** to install the bundle on the selected devices.

Install Compatible Images on Devices

You can use Image Manager to install compatible images on devices.

To selectively install one or more compatible images on a device or device group, do the following:

Step 1 Select a device in the Devices area of the selector and navigate to the Compatible Images tab.

Step 2 Select one or more Repository images in the Compatible Images tab.

Step 3 Right-click a selected image and click **Install**.

The Image Installation wizard appears with the selected images pre-assigned or moved to the right pane in the Select Image page.

Step 4 Click **Next**.

The Select Devices page of the wizard is displayed.

Step 5 Select the devices to which you want to install, and then click **Next**.

The Confirm Assignments page of the wizard is displayed.

Step 6 Confirm the devices and images assignments, and then click **Finish**.

The Install images on selected devices dialog box appears with the devices and image(s) assigned.

Step 7 Click **Start Validation** in the upper-right corner of the Assignments tab. Investigate any assignment validation errors or warnings listed in the Install images on devices dialog box.

Beginning with version 4.9, Security Manager provides an enhanced validation procedure for installing images on devices:

- If you have downloaded the images from CCO using the Image Manager, before installing the images to the device, the serial number of the device is verified for the service contract. If the device has a valid service contract, the image will proceed with the installation or upgrade process. If the device does not have a valid service contract, the image will not proceed with the installation or upgrade process.
- If you have copied the images from the local file system to Image Manager, the service contract validation will not be performed for the device and you can proceed to install the image on the device.

Tip You can choose to schedule the job and also modify the default properties for the job. Please see Using the Image Installation Wizard to Install Images on Devices , on page 2914 for details on scheduling a job and configuring job properties.

Step 8 When your warnings are corrected (or you determine them to be insignificant), click **Install**.

The image installation job is created. Please see Using the Image Installation Wizard to Install Images on Devices , on page 2914 for the remaining steps to monitor the job progress and verify the image update.

Note Alternatively, to install one or more images on a device or device group, you can drag multiple images from the Repository view and drop them onto a device or device group. Then, click **Install** to install the selected image(s) on the selected device(s).

Install Images on Selected Devices

You can use Image Manager to upgrade the images on a set of devices that you select.

To install images on a selected set of devices, do the following:

Step 1 Select a device group in the Devices area of the selector.

Step 2 View the listing of devices in the group in the right pane.

Step 3 Select one or more devices from the list.

Tip Use the Shift and Control keys to select multiple devices.

Step 4 Right-click a selected device and click **Install**.

The Image Installation wizard appears with the selected devices pre-assigned or moved to the right pane in the Select Devices page.

Step 5 Click **Next**.

The Select Images page of the wizard is displayed.

Step 6 Select the images you want to install, and then click **Next**.

Tip You can also select a bundle in the Bundles tab.

The Confirm Assignments page of the wizard is displayed.

Step 7 Confirm the devices and images assignments, and then click **Finish**.

The Install Images on selected devices dialog box appears with the devices and image(s) assigned.

Step 8 Click **Start Validation** in the upper-right corner of the Assignments tab. Investigate any assignment validation errors or warnings listed in the Install images on devices dialog box.

Tip You can choose to schedule the job and also modify the default properties for the job. Please see Using the Image Installation Wizard to Install Images on Devices , on page 2914 for details on scheduling a job and configuring job properties.

Step 9 When your warnings are corrected (or you determine them to be insignificant), click **Install**.

The image installation job is created. Please see Using the Image Installation Wizard to Install Images on Devices , on page 2914 for the remaining steps to monitor the job progress and verify the image update.

Working with Jobs

This section details the set of functions that assists in the performance of the image installation jobs. An image installation job may be immediately run, or it may be scheduled to run at a specified time and date. As Image Manager jobs tend to be time-consuming, the job management functions enable you to perform these operations in the background. Image Manager incorporates an optional ticketing system that enables you to easily locate a job or jobs by means of a unique Ticket ID.

You should understand that the details of a particular job are defined and validated before being run.

This section contains the following topics:

Viewing Image Installation Job Summary

You can use the Image Manager tool to monitor image installation and deployment jobs. You can view the history and status of jobs that Image Manager has performed, as well as the summary, details, or history of any particular job.

Note Comprehensive details of job state changes are available in Configuration Manager (see Job States in Non-Workflow Mode , on page 385 or Job States in Workflow Mode , on page 387). For an Audit Report navigate to Configuration Manager > Manage > Audit Report.

To view a summary of image installation jobs, do the following:

Step 1 In the selector, under Jobs, click **Install Jobs**.

The main window displays the Jobs list in the upper pane.

Step 2 Examine the details of the Jobs list, which may include:

- **Name**—The name of the job. By default the name includes a time stamp.
- **Last Action**—Date of the last action.
- **Status**—Whether the job has deployed, failed, or is underway.
- **Changed By**—Who started the job.
- **Description**—Job description.

- **Schedule**—Job schedule.
- **Ticket ID(s)**—Tickets are just tags attached to Image Manager job to track changes. These tickets may be tickets created in Configuration Manager, but are not mandated to be so.

Step 3 Optionally, you can find and select a single job about which more information is then displayed in the lower pane. This includes:

- Summary
- Details
- History

Tip While viewing the lower pane Details tab, you can select a device and then view a log of the job in the lower right pane.

Note These are dockable windows. You can customize the default view.

Viewing Install Jobs

You can view the details associated with a particular Image Management job.

To view the details associated with a job, do the following:

Step 1 In the selector, under Jobs, click **Install Jobs**.

Tip The Status column in the Jobs selector indicates whether a job is Submitted, Approved, Deployed, In Progress, or Failed.

The main window displays the Jobs list in the upper pane.

Step 2 Select a job to examine.

Tip To find a particular job, you can sort the Jobs list by any of the column headings, including Name, Last Action (chronology), Status (e.g., Deployed, Failed), Description, and so forth. You can also find a particular job by using the search window to enter a filtering string.

Note The location of the jobs folder is CSM-ROOT\files\vms\jobs directory.

Step 3 Examine job summary information by clicking **Summary** in the lower pane.

The lower pane displays job summary information including Image Management Job Name, Devices to be Deployed, Devices Deployed Successfully, and Devices Deployed with Errors.

Step 4 Examine job summary details by clicking **Details** in the lower pane.

Details of the Devices, New Image, Old Image, and the device status are displayed.

Step 5 Examine the Commentary on the devices in the job by clicking on the vertical **Commentary** tab on the far right. This shows the progress of the image install operation on the device.

Step 6 Examine the Transcript of the devices in the job by clicking on the vertical **Transcript** tab on the far right. This shows the chronology of the commands executed on the device and their responses.

Step 7 Examine job history details by clicking **History** in the lower pane. This shows the history of the transition in the job state.

Note This information is visible only in the workflow mode.

Aborting an Image Installation Job

You can abort an image installation job by clicking **Abort** from the Jobs page. This option is effective only for multi-device jobs:

Note If the job involves a single device, then Abort will have no effect after the job begins and the job will always run to completion.

- If the Sequential option is selected, then all the devices on which the job has not yet started will be aborted.
- If Parallel is selected, then all the devices till that batch will undergo image upgrade. All devices from the next batch onwards will be aborted.

Retry a Failed Image Install Job

If your attempts to deploy an image to one or more devices fails, you can retry the job. However, you should retry the entire job and not attempt to simply continue from a failed step.

To retry a failed job, do the following:

Step 1 To determine that an installation job has failed, go to the Jobs section in the selector and click **Install Jobs**.

The Jobs page appears.

Step 2 Determine the status of the job in question by examining the Status column.

Tip A green check icon with the word Deployed indicates success. A red X icon indicates failure.

Step 3 Investigate possible reasons for job failure.

Step 4 Select the failed image install job from the job list and click **Retry** from the toolbar atop the upper pane.

The Install Images on Devices window appears. You can observe the validation warnings as you would in a normal install job.

Step 5 As required, you can change the images, devices, schedule, or job properties to be used.

Step 6 From within the Install Images on Devices window click **Install.**

Step 7 Determine that the retried attempt is successful by observing the newly created job.

Roll Back a Deployed Job

You can roll back the changes from a deployed image installation job.

To roll back a Deployed job, do the following:

Step 1 From the job list, select the image install job to be rolled back and click **Rollback** from the toolbar atop the upper pane.

The Install Images on Devices window appears. You can observe the validation warnings as you would in a normal install job.

Step 2 As required, you can change the images, devices, schedule, or job properties to be used in the rollback.

Step 3 From within the Install Images on Devices window click **Install**.

Step 4 Determine that the rollback attempt is successful by monitoring the newly created job.

Image Installation Job Approval Workflow

Image update is a critical operation that has the potential to cause downtime for devices and your network. Hence, change control and management for image install operations is crucial. Change management for image installation jobs is done using the Deployment Workflow framework of Configuration Manager. This ensures that all image installation jobs need to be approved before getting executed or deployed.

To use workflow with image installation jobs, do the following:

Step 1 Enable workflow for image installation jobs:

a) In Configuration Manager, select **Tools** > **Security Manager Administration** > **Workflow**.
b) If workflow is not already enabled, select **Enable Workflow**.
c) Select **Require Deployment & Install Image Approval**.
d) Configure the email address of the person responsible for approving the image installation job in the Job/Schedule Approver field. For more information, see Workflow Page , on page 590.
e) Click **Save** and then **Close**.
f) Launch Image Manager and navigate to **Install Jobs**. Notice the new buttons available in the Menu bar for job state transitions in workflow mode: Submit, Approve, Reject, and Deploy.

Step 2 To create and execute an image installation job with workflow enabled:

a) Use any of the previously documented procedures to create an image installation job. See About Image Updates on Devices Using Image Manager , on page 2908.

Note There is an additional option in the Properties tab to Submit the Job. Check this option to automatically submit the job for approval after creation of the job.

b) Once the image installation job is created, note the state of the job in the Image Install Jobs View.
c) Select the job and click **Submit** to submit the job for approval if automatic submit option was not selected while creating the job.

The job Approver (user with Approver role/privileges) receives an email notification to approve the job.

d) The Approver can log in to Security Manager, launch Image Manager, and navigate to the job.

e) The Approver clicks **Approve** to approve the job after reviewing the details of the upgrade, that is, image being upgraded to, job properties, schedule, and so on.

Job state is changed to *Approved* . The creator of the job receives an email that the job has been approved. Now the job can be deployed.

f) If the Approver is not convinced after reviewing the job details, he can choose to reject the job by clicking **Reject**.

The job state is moved to *Rejected* . The creator of the job receives an email that job has been rejected. A rejected job will not be deployed.

Note A rejected job will not be deployed. It can be edited and resubmitted for approval or it has to be discarded.

g) Once the job is approved, the job can be deployed by clicking **Deploy**.

The job state is changed to *Deploying* and image install job execution is started.

h) If the job is rejected or any other changes are required to be made for a job, the job can be edited by clicking **Edit**.

The Image Assignments page of the wizard showing all the devices and images is displayed. The user can modify the Job Properties, schedule and even delete some device-to-image assignments and submit the job for approval again by clicking **Submit**.

i) If a job has not started executing, then the user can dismiss the job by clicking **Discard**.

The job is moved to *Discarded* state. A discarded job does not execute and cannot be edited or moved to any other state.

j) If the changed job is acceptable to the approver, he can approve the job this time and the job can be deployed as mentioned above.

k) Once the deploying job completes execution it will be moved to *Deployed* state if the image installation is successful or it will be moved to *Failed* state if the image installation operation fails.

Troubleshooting Image Management

This section addresses steps you can take to troubleshoot Image Management in response to particular symptoms.

Image installation job might show as failed due to the configured reboot time.

For cluster and failover devices, the reboot time between the standby device and primary device is, by default, set to 15 minutes. If the devices have large configurations, the Image installation job might show as failed due to the configured reboot time. The device will be updated with the image after the configurations are complete. However, due to inconsistencies in reboot time, Security Manager will show the job as failed.

To modify the reboot time, do the following.

##MAX_RELOAD_WAIT_TIME for the primary or cluster device

#default time will be 15 mins (15*60*1000)

reloadTime = 900000

No data for devices in Image Manager, after Security Manager upgrade. Any one of the following operations that first contacts the device will collect the image inventory for the device:

- Rediscover the device choosing to discover only Device Inventory

- Perform a live deployment to device
- Perform an Image Install operation to the device

Image Download from Cisco.com Fails

- Go to Configuration Manager > Tools > Security Manager Administration.
- Select Image Manager.
- Click **Test Connection** to ensure the server is reachable.
- Check **%NMSROOT%/MDC/athena/config/****-CCOMetaData.xml** for error in downloading metadata information for particular MDF IDs.

Update or Image Download fails due to certificate mismatch, unavailability, expiration, or other cause.

- Employ the recommended actions cited by the error message. Use the failed download URL from the error message to retrieve the certificate.
- View the stored certificate at **%NMSROOT%/MDC/certificates/*.ser** (Serialized object--file contents are unintelligible and cannot be viewed in any editor.)

Image Download from Cisco.com Fails with Message: "User not authorized to download file"

- Go to Configuration Manager > Tools > Security Manager Administration.
- Select Image Manager.
- Click **Test Connection** to ensure the server is reachable.
- Register your acceptance of the Cisco Encryption Software Usage Handling and Distribution Policy.

Tip The policy is found at: http://tools.cisco.com/legal/k9/controller/do/k9Check.x?eind=Y .

Image Download from Cisco.com is Slow

- Ensure proxy is configured
- Trace route from Security Manger to Cisco.com

Check for Updates Fails

Go to the Security Manager administrative settings page and test connectivity to Cisco.com. Check **%NMSROOT%/MDC/athena/config/****-CCOMetaData.xml** for an error in downloading metadata information for particular MDF IDs.

Message: "User not authorized to download file." Go to the Security Manager administrative settings page and test connectivity to Cisco.com. Accept the crypto agreement at http://tools.cisco.com/legal/k9/controller/do/k9Check.x?eind=Y

Image Download from External File System or Network Fileshare Fails

- Check that you have proper permissions/credentials for the external file system or fileshare.
- Open the fileshare on the client, drag the image and drop it on Image Manager.

Image Install Wizard does not Show Compatible Images

- Image Manager uses the information on Cisco.com to determine the compatibility of the images for the MDF IDs. Please download the latest images available on cisco.com by performing 'Check for Updates'. If the image is available on Cisco.com and listed as compatible for the platform, you should now be able to view these images for the device in the Image Install Wizard and also in the Compatible Images tab for the device.
- Even the Compatible Images tab for the device may not show some images that are actually compatible to the device.
- If you still don't see the images in the Install Wizard, either because you do not have Cisco.com connectivity or images are not updated on Cisco.com for that platform, you can use the drag and drop procedure to install the images on the device. You would be warned that the image is not compatible, but you can still go ahead and install the image by dragging the image and dropping it on to the device and creating a job.

Image Copy Failure –"HTTP 413 Error"

- Right-click **Device** in Image Manager > Test File Copy To Device
- Check Error Message in vmssharedsvcs.log
- If you encounter an HTTP 413 error, split the job to contain a smaller number of images in one job

Image Copy Failure –"Not enough space on disk"

- Check Device > Storage View for files on device and free space in the Image Install Location.
- If Device > Storage View shows files, then delete files from Storage to make space and retry.
- If Device > Storage View does not show files, either because it is a greenfield device or it is a Security Manager upgrade setup, rediscover only the device inventory on the device and then delete files from Storage view to make space.

Image Install Job failure –Error: "Invalid flash device"

- Check if flash exists on the device:
  - Right-click on device in IM > Test File Copy to Device
  - Connect to device, and check whether it is a multiple-context device that is being managed as a single context device in Security Manager
  - Rediscover the device selecting to discover **System Context**. Then, retry the image install job.

Image Upgrade Job on Active/Standby pair fails

- Error: **"This host is not the 'active' device in the failover pair"**- Ensure that the failover pair is managed in Security Manager via the IP address of the active device in the failover pair and not the IP address of the standby device.
- Error: **"Secondary device is not in standby-ready state"** - Ensure that the devices in the failover pair are up and the standby device is in standby-ready state. Job will abort if standby device is in failed state

Image Install Job failure –Error: "SWIM1114: Device could not be reached after upgrade"

- Manually check if device is reachable. Solution: After image upgrade, device has to be re-added in Security Manager or change the Admin option to "Do not check certificate authentication"
- Check whether Tools > Admin > Device Communication > SSL Certificate Parameters > PIX/ASA/FWSM Device Authentication Certificates is set to "Retrieve while adding devices."
- After image upgrade, ensure the device has been re-added in Security Manager. Otherwise, change the Admin option to "Do not check certificate authentication."

Note You must have accepted the latest Cisco.com certificate to enable Image Manager to interface with cisco.com. You must accept the certificate from both the "Image Meta-data locator" site and the download site of the images to start downloading images successfully (see Image Manager Page , on page 552).

No data for devices in Image Manager after Security Manager upgrade

- Rediscover the device choosing to discover only Device Inventory
- Perform a live deployment to device
- Perform an image install operation to the device

Trying to retry or rollback a job fails

- Check if any of the devices in the job are deleted from Security Manager
- Check if none of the images to be retried or rolled back to are unavailable in Security Manager. Add the images to the Security Manager repository and retry the operation
