

Acquire End-User Credentials

This chapter contains the following sections:

- [Overview of Acquire End-User Credentials, on page 1](#)
- [Authentication Best Practices, on page 2](#)
- [Authentication Planning, on page 2](#)
- [Authentication Realms, on page 10](#)
- [Authentication Sequences, on page 26](#)
- [Failed Authentication, on page 28](#)
- [Credentials, on page 34](#)
- [Troubleshooting Authentication, on page 36](#)

Overview of Acquire End-User Credentials

| Server Type/Realm | Authentication Scheme | Supported Network Protocol | Notes |
|-------------------|------------------------------|--|---|
| Active Directory | Kerberos NTLMSSP Basic | HTTP, HTTPS Native FTP, FTP over HTTP SOCKS (Basic authentication) | Kerberos is only supported in Standard mode. It is not supported in Cloud Connector mode. |
| LDAP | Basic | HTTP, HTTPS Native FTP, FTP over HTTP SOCKS | — |

Authentication Task Overview

| Step | Task | Links to Related Topics and Procedures |
|------|---------------------------------|--|
| 1 | Create an authentication realm. | <ul style="list-style-type: none">• How to Create an Active Directory Authentication Realm (NTLMSSP and Basic), on page 14• Creating an LDAP Authentication Realm, on page 16 |

| Step | Task | Links to Related Topics and Procedures |

| 7 | Create policies to manage Web requests from the users and user groups for which you created Identification Profiles. | <ul style="list-style-type: none"> • Managing Web Requests Through Policies Best Practices |

Authentication Best Practices

- Create as few Active Directory realms as is practical. Multiple Active Directory realms require additional memory usage for authentication.
- If using NTLMSSP, authenticate users using either the Web Security appliance or the upstream proxy server, but not both. (Recommend Web Security appliance)
- If using Kerberos, authenticate using the Web Security appliance.
- For optimal performance, authenticate clients on the same subnet using a single realm.
- Some user agents are known to have issues with machine credentials or authentication failures, which can negatively impact normal operations. You should bypass authentication with these user agents. See [Bypassing Authentication with Problematic User Agents , on page 29](#).

Authentication Planning

Active Directory/Kerberos

| Explicit Forward | Transparent, IP-Based Caching | Transparent, Cookie-Based Caching |
|---|---|--|
| <p>Advantages:</p> <ul style="list-style-type: none"> • Better performance and interoperability when compared to NTLM • Works with both Windows and non-Windows clients that have joined the domain • Supported by all browsers and most other applications • RFC-based • Minimal overhead • Works for HTTPS (CONNECT) requests • Because the passphrase is not transmitted to the authentication server, it is more secure • Connection is authenticated, not the host or IP address • Achieves true single sign-on in an Active Directory environment when the client applications are configured to trust the Web Security appliance | <p>Advantages:</p> <ul style="list-style-type: none"> • Better performance and interoperability when compared to NTLM • Works with both Windows and non-Windows clients that have joined the domain • Works with all major browsers • With user agents that do not support authentication, users only need to authenticate first in a supported browser • Relatively low overhead • Works for HTTPS requests if the user has previously authenticated with an HTTP request | <p>Advantages:</p> <ul style="list-style-type: none"> • Better performance and interoperability when compared to NTLM • Works with both Windows and non-Windows clients that have joined the domain • Works with all major browsers • Authentication is associated with the user rather than the host or IP address <p>Disadvantages:</p> <ul style="list-style-type: none"> • Each new web domain requires the entire authentication process because cookies are domain specific • Requires cookies to be enabled • Does not work for HTTPS requests |

Active Directory/Basic

| Explicit Forward | Transparent, IP-Based Caching | Transparent, Cookie-Based Caching |
|---|--|--|
| <p>Advantages:</p> <ul style="list-style-type: none"> • Supported by all browsers and most other applications • RFC-based • Minimal overhead • Works for HTTPS (CONNECT) requests • Because the passphrase is not transmitted to the authentication server, it is more secure • Connection is authenticated, not the host or IP address • Achieves true single sign-on in an Active Directory environment when the client applications are configured to trust the Web Security appliance <p>Disadvantages:</p> <ul style="list-style-type: none"> • Passphrase sent as clear text (Base64) for every request • No single sign-on • Moderate overhead: each new connection needs to be re-authenticated • Primarily supported on Windows only and with major browsers only | <p>Advantages:</p> <ul style="list-style-type: none"> • Works with all major browsers • With user agents that do not support authentication, users only need to authenticate first in a supported browser • Relatively low overhead • Works for HTTPS requests if the user has previously authenticated with an HTTP request <p>Disadvantages:</p> <ul style="list-style-type: none"> • Authentication credentials are associated with the IP address, not the user (does not work in Citrix and RDP environments, or if the user changes IP address) • No single sign-on • Passphrase is sent as clear text (Base64) | <p>Advantages:</p> <ul style="list-style-type: none"> • Works with all major browsers • Authentication is associated with the user rather than the host or IP address <p>Disadvantages:</p> <ul style="list-style-type: none"> • Each new web domain requires the entire authentication process because cookies are domain specific • Requires cookies to be enabled • Does not work for HTTPS requests • No single sign-on • Passphrase is sent as clear text (Base64) |

Active Directory/NTLMSSP

| Explicit Forward | Transparent |
|--|---|
| <p>Advantages:</p> <ul style="list-style-type: none"> • Because the passphrase is not transmitted to the authentication server, it is more secure • Connection is authenticated, not the host or IP address • Achieves true single sign-on in an Active Directory environment when the client applications are configured to trust the Web Security appliance <p>Disadvantages:</p> <ul style="list-style-type: none"> • Moderate overhead: each new connection needs to be re-authenticated • Primarily supported on Windows only and with major browsers only | <p>Advantages:</p> <ul style="list-style-type: none"> • More Flexible <p>Transparent NTLMSSP authentication is similar to transparent Basic authentication except that the Web Proxy communicates with clients using challenge and response instead of basic clear text username and passphrase.</p> <p>The advantages and disadvantages of using transparent NTLM authentication are the same as those of using transparent Basic authentication except that transparent NTLM authentication has the added advantage of not sending the passphrase to the authentication server and you can achieve single sign-on when the client applications are configured to trust the Web Security appliance.</p> |

LDAP/Basic

| Explicit Forward | Transparent |
|---|--|
| <p>Advantages:</p> <ul style="list-style-type: none"> • RFC-based • More browser support than NTLM • Minimal overhead • Works for HTTPS (CONNECT) requests <p>Disadvantages:</p> <ul style="list-style-type: none"> • No single sign-on • Passphrase sent as clear text (Base64) for every request <p>Workarounds:</p> <ul style="list-style-type: none"> • Failed Authentication, on page 28 | <p>Advantages:</p> <ul style="list-style-type: none"> • More Flexible than explicit forward. • More browser support than NTLM • With user agents that do not support authentication, users only need to authenticate first in a supported browser • Relatively low overhead • Works for HTTPS requests if the user has previously authenticated with an HTTP request <p>Disadvantages:</p> <ul style="list-style-type: none"> • No single sign-on • Passphrase is sent as clear text (Base64) • Authentication credentials are associated with the IP address, not the user (does not work in Citrix and RDP environments, or if the user changes IP address) <p>Workarounds:</p> <ul style="list-style-type: none"> • Failed Authentication, on page 28 |

Identifying Users Transparently

Traditionally, users are identified and authenticated by prompting them to enter a user name and passphrase. These credentials are validated against an authentication server, and then the Web Proxy applies the appropriate policies to the transaction based on the authenticated user name.

However, you can configure the Web Security appliance to authenticate users transparently—that is, without prompting the end user for credentials. Transparent identification authenticates the user by means of credentials obtained from another trusted source, with the assumption that the user has already been authenticated by that trusted source, and then applies the appropriate policies.

You might want to identify users transparently to:

- Create a single sign-on environment so users are not aware of the presence of a proxy on the network.
- To apply authentication-based policies to transactions coming from client applications that are incapable of displaying an authentication prompt to end users.

Identifying users transparently only affects how the Web Proxy obtains the user name and assigns an Identification Profile. After it obtains the user name and assigns an Identification Profile, it applies all other policies normally, regardless of how it assigned the Identification Profile.

If transparent authentication fails, you can configure how to handle the transaction: you can grant the user guest access, or you can force an authentication prompt to appear to the user.

When an end user is shown an authentication prompt due to failed transparent user identification, and the user then fails authentication due to invalid credentials, you can choose whether to allow the user guest access.

**Note**

When you enable re-authentication and a transaction is blocked by URL filtering, an end-user notification page appears with the option to log in as a different user. Users who click the link are prompted for authentication. For more information, see [Failed Authorization: Allowing Re-Authentication with Different Credentials, on page 32](#).

Understanding Transparent User Identification

The available methods of transparent user identification are:

- **Transparently identify users with ISE** – Available when the Identity Services Engine (ISE) service is enabled (Network > Identity Services Engine). For these transactions, the user name and associated Secure Group Tags will be obtained from an Identity Services Engine server. See [Tasks for Certifying and Integrating the ISE Service](#).
- **Transparently identify users with ASA** – Users are identified by the current IP address-to-user name mapping received from a Cisco Adaptive Security Appliance (for remote users only). This option is available when AnyConnect Secure Mobility is enabled and integrated with an ASA. The user name will be obtained from the ASA, and associated directory groups will be obtained from the authentication realm or sequence specified on the Web Security appliance. See [Remote Users](#).
- **Transparently identify users with authentication realms** – This option is available when one or more authentication realms are configured to support transparent identification using one of the following authentication servers:
 - **Active Directory** – Create an NTLM or Kerberos authentication realm and enable transparent user identification. In addition, you must deploy a separate Active Directory agent such as Cisco's Context Directory Agent. For more information, see [Transparent User Identification with Active Directory, on page 7](#).

- **LDAP** – Create an LDAP authentication realm configured as an eDirectory, and enable transparent user identification. For more information, see [Transparent User Identification with LDAP, on page 8](#).

AsyncOS for Web communicates at regular intervals with eDirectory or an Active Directory agent to maintain mappings that match authenticated user names to their current IP addresses.

Transparent User Identification with Active Directory

Active Directory does not record user log-in information in a format that is easily queried by other systems such as the Web Security appliance. Active Directory agents, such as Cisco's Context Directory Agent (CDA), are necessary to query the Active Directory security event logs for information about authenticated users.

AsyncOS for Web communicates with the Active Directory agent to maintain a local copy of the IP-address-to-user-name mappings. When AsyncOS for Web needs to associate an IP address with a user name, it first checks its local copy of the mappings. If no match is found, it queries an Active Directory agent to find a match.

For more information on installing and configuring an Active Directory agent, see the section "Setting Up an Active Directory Agent to Provide Information to the Web Security Appliance" below.

Consider the following when you identify users transparently using Active Directory:

- Transparent user identification with Active Directory works with an NTLM or Kerberos authentication scheme only. You cannot use it with an LDAP authentication realm that corresponds to an Active Directory instance.
- Transparent user identification works with the versions of Active Directory supported by an Active Directory agent.
- You can install a second instance of an Active Directory agent on a different machine to achieve high availability. When you do this, each Active Directory agent maintains IP-address-to-user-name mappings independently of the other agent. AsyncOS for Web uses the backup Active Directory agent after three unsuccessful ping attempts to the primary agent.
- The Active Directory agent uses on-demand mode when it communicates with the Web Security appliance.
- The Active Directory agent pushes user log-out information to the Web Security appliance. Occasionally, some user log-out information is not recorded in the Active Directory security logs. This can happen if the client machine crashes, or if the user shuts down the machine without logging out. If there is no user log-out information in the security logs, an Active Directory agent cannot inform the appliance that the IP address no longer is assigned to that user. To obviate this possibility, you can define how long AsyncOS caches the IP-address-to-user mappings when there are no updates from an Active Directory agent. For more information, see [Using the CLI to Configure Advanced Transparent User Identification Settings, on page 9](#).
- The Active Directory agent records the `sAMAccountName` for each user logging in from a particular IP address to ensure the user name is unique.
- The client IP addresses that the client machines present to the Active Directory server and the Web Security appliance must be the same.
- AsyncOS for Web searches only direct parent groups for a user. It does not search nested groups.

Setting Up an Active Directory Agent to Provide Information to the Web Security Appliance

Because AsyncOS for Web cannot obtain client IP addresses directly from Active Directory, it must obtain IP-address-to-user-name mapping information from an Active Directory agent.

Install an Active Directory agent on a machine in the network that is accessible to the Web Security appliance, and which can communicate with all visible Windows domain controllers. For best performance, this agent

should be physically as close as possible to the Web Security appliance. In smaller network environments, you may want to install the Active Directory agent directly on the Active Directory server.

**Note**

The Active Directory agent instance used to communicate with the Web Security appliance can also support other appliances, including Cisco's Adaptive Security Appliance and other Web Security appliances.

Obtaining, Installing, and Configuring Cisco's Context Directory Agent

You can find information about downloading, installing, and configuring the Cisco Context Directory Agent here: http://www.cisco.com/en/US/docs/security/ibf/cda_10/Install_Config_guide/cda10.html.

**Note**

The Web Security appliance and Active Directory agent communicate with each other using the RADIUS protocol. The appliance and the agent must be configured with the same shared secret to obfuscate user passphrases. Other user attributes are not obfuscated.

Transparent User Identification with LDAP

AsyncOS for Web can communicate with an eDirectory server configured as a Lightweight Directory Access Protocol (LDAP) realms maintaining IP-address-to-user-name mappings. When a user logs in through an eDirectory client, the user is authenticated against the eDirectory server. When authentication succeeds, the client IP address is recorded in the eDirectory server as an attribute (`NetworkAddress`) of the user who logged in.

Consider the following when you identify users transparently using LDAP (eDirectory):

- The eDirectory client must be installed on each client workstation, and end users must use it to authenticate against an eDirectory server.
- The LDAP tree used by the eDirectory client log-in must be the same LDAP tree configured in the authentication realm.
- If the eDirectory clients use multiple LDAP trees, create an authentication realm for each tree, and then create an authentication sequence that uses each LDAP authentication realm.
- When you configure the LDAP authentication realm as an eDirectory, you must specify a Bind DN for the query credentials.
- The eDirectory server must be configured to update the `NetworkAddress` attribute of the user object when a user logs in.
- AsyncOS for Web searches only direct parent groups for a user. It does not search nested groups.
- You can use the `NetworkAddress` attribute for an eDirectory user to determine the most-recent log-in IP address for the user.

Rules and Guidelines for Transparent User Identification

Consider the following rules and guidelines when using transparent user identification with any authentication server:

- When using DHCP to assign IP addresses to client machines, ensure the IP-address-to-user-name mappings are updated on the Web Security appliance more frequently than the DHCP lease. Use the `tuiconfig` CLI command to update the mapping update interval. For more information, see [Using the CLI to Configure Advanced Transparent User Identification Settings, on page 9](#).

- If a user logs out of a machine and another user logs into the same machine before the IP-address-to-user-name mapping is updated on the Web Security appliance, then the Web Proxy logs the client as the previous user.
- You can configure how the Web Proxy handles transactions when transparent user identification fails. It can grant users guest access, or it can force an authentication prompt to appear to end users.
- When a user is shown an authentication prompt due to failed transparent user identification, and the user then fails authentication due to invalid credentials, you can choose whether to allow the user guest access.
- When the assigned Identification Profile uses an authentication sequence with multiple realms in which the user exists, AsyncOS for Web fetches the user groups from the realms in the order in which they appear in the sequence.
- When you configure an Identification Profile to transparently identify users, the authentication surrogate must be IP address. You cannot select a different surrogate type.
- When you view detailed transactions for users, the Web Tracking page shows which users were identified transparently.
- You can log which users were identified transparently in the access and WC3 logs using the `%m` and `x-auth-mechanism` custom fields. A log entry of `SSO_TUI` indicates that the user name was obtained by matching the client IP address to an authenticated user name using transparent user identification. (Similarly, a value of `SSO_ASA` indicates that the user is a remote user and the user name was obtained from a Cisco ASA using AnyConnect Secure Mobility.)

Configuring Transparent User Identification

Configuring transparent user identification and authorization is detailed in [Acquire End-User Credentials, on page 1](#). The basic steps are:

- Create and order authentication realms.
- Create Identification Profiles to classify users and client software.
- Create policies to manage web requests from the identified users and user groups.

Using the CLI to Configure Advanced Transparent User Identification Settings

AsyncOS for Web provides the following TUI-related CLI commands:

- **tuiconfig** – Configure advanced settings associated with transparent user identification. Batch mode can be used to configure multiple parameters simultaneously.
 - **Configure mapping timeout for Active Directory agent** – Length of time, in minutes, IP-address-to-user mappings are cached for IP addresses retrieved by the AD agent when there are no updates from the agent.
 - **Configure proxy cache timeout for Active Directory agent** – Length of time, in seconds, proxy-specific IP-address-to-user mappings are cached; valid values range from five to 1200 seconds. The default and recommended value is 120 seconds. Specifying a lower value may negatively affect proxy performance.
 - **Configure mapping timeout for Novell eDirectory** – Length of time, in seconds, IP-address-to-user mappings are cached for IP addresses retrieved from the eDirectory server when there are no updates from the server.
 - **Configure query wait time for Active Directory agent** – The length of time, in seconds, to wait for a reply from the Active Directory agent. When the query takes more than this value, transparent user identification is considered to have failed. This limits the authentication delay experienced by the end user.
 - **Configure query wait time for Novell eDirectory** – The length of time, in seconds, to wait for a reply from the eDirectory server. When the query takes more than this value, transparent user

identification is considered to have failed. This limits the authentication delay experienced by the end user.

The Active Directory settings apply to all AD realms using an AD agent for transparent user identification. The eDirectory settings apply to all LDAP realms using eDirectory for transparent user identification.

If validation fails for any one parameter, none of the values will be changed.

- **tuistatus** – This command provides the following AD-related subcommands:
 - **adagentstatus** – Displays the current status of all AD agents, as well as information about their connections with the Windows domain controllers.
 - **listlocalmappings** – Lists all IP-address-to-user-name mappings stored on the Web Security appliance, as retrieved by the AD agent(s). It does not list entries stored on the agent(s), nor does it list mappings for which queries are currently in progress.

Configuring Single-Sign-on

Obtaining credentials transparently facilitates a single-sign-on environment. Transparent user identification is an authentication realm setting.

For Internet Explorer, be sure the Redirect Hostname is the short host name (containing no dots) or the NetBIOS name rather than a fully qualified domain. Alternatively, you can add the appliance host name to Internet Explorer's Local intranet zone (Tools > Internet options > Security tab); however, this will be required on every client. For more information about this, see [How do I properly set up NTLM with SSO \(credentials sent transparently\)?](#)

With Firefox and other non-Microsoft browsers, the parameters **network.negotiate-auth.delegation-uris**, **network.negotiate-auth.trusted-uris** and **network.automatic-ntlm-auth.trusted-uris** must be set to the transparent-mode Redirect Hostname. You also can refer to [Firefox is not sending authentication credentials transparently \(SSO\)](#). This [article](#) provides general information about changing Firefox parameters.

For information about the Redirect Hostname, see [Configuring Global Authentication Settings, on page 21](#), or the CLI command `sethostname`.

Authentication Realms

Authentication realms define the details required to contact the authentication servers and specify which authentication scheme to use when communicating with clients. AsyncOS supports multiple authentication realms. Realms can also be grouped into authentication sequences that allow users with different authentication requirements to be managed through the same policies.

- [External Authentication, on page 11](#)
- [Creating an Active Directory Realm for Kerberos Authentication Scheme, on page 11](#)
- [How to Create an Active Directory Authentication Realm \(NTLMSSP and Basic\), on page 14](#)
- [Creating an LDAP Authentication Realm, on page 16](#)
- [About Deleting Authentication Realms, on page 21](#)
- [Configuring Global Authentication Settings, on page 21](#)

Related Topics

- [Authentication Sequences, on page 26](#)
- [RADIUS User Authentication](#)

External Authentication

You can authenticate users through an external LDAP or RADIUS server.

Configuring External Authentication through an LDAP Server

Before you begin

Create an LDAP authentication realm and configure it with one or more external authentication queries.
[Creating an LDAP Authentication Realm, on page 16.](#)

Step 1 Enable external authentication on the appliance:

- a) Navigate to **System Administration > Users**.
- b) Click **Enable** in the External Authentication section.
- c) Configure the options:

| Option | Description |
|---|---|
| Enable External Authentication | — |
| Authentication Type | Select LDAP. |
| External Authentication Cache Timeout | The number of seconds AsyncOS stores the external authentication credentials before contacting the LDAP server again to re-authenticate. Default is zero (0). |
| LDAP External Authentication Query | A query configured with the LDAP realm. |
| Timeout to wait for valid response from server. | The number of seconds AsyncOS waits for a response to the query from the server. |
| Group Mapping | For each group name in the directory, assign a role. |

Step 2 Submit and commit your changes.

Enabling RADIUS External Authentication

See [Enabling External Authentication Using RADIUS](#).

Creating an Active Directory Realm for Kerberos Authentication Scheme

Before you begin

- Ensure the appliance is configured in Standard mode (not Cloud Connector Mode).
- Prepare the Active Directory Server.
 - Install Active Directory on one of these servers: Windows server 2003, 2008, 2008R2 or 2012.

- Create a user on the Active Directory server:
 - Create a user on the Active Directory server that is a member of the Domain Admins or Account Operators group.
- Or
- Create a user name with the following permissions:
 - Active Directory permissions Reset Password
 - Validated write to servicePrincipalName
 - Write account restrictions
 - Write dNShost name
 - Write servicePrincipalName

These are the minimal Active Directory permissions required by a user name to join an appliance to the domain and ensure its complete functioning.

- Join your client to the domain. Supported clients are Windows XP, Windows 7 and Mac OS 10.5+.
- Use the kerbtray tool from the Windows Resource Kit to verify the Kerberos ticket on the client:
<http://www.microsoft.com/en-us/download/details.aspx?id=17657>.
- Ticket viewer application on Mac clients is available under main menu > KeyChain Access to view the Kerberos tickets.
- Ensure you have the rights and domain information needed to join the Web Security appliance to the Active Directory domain you wish to authenticate against.
- Compare the current time on the Web Security appliance with the current time on the Active Directory server and verify that the difference is no greater than the time specified in the “Maximum tolerance for computer clock synchronization” option on the Active Directory server.
- If the Web Security appliance is managed by a Security Management appliance, be prepared to ensure that same-named authentication realms on different Web Security appliances have identical properties defined on each appliance.
- Web Security appliance configuration:
 - In explicit mode, the WSA host name (CLI command `sethostname`) and the proxy name configured in the browser must be the same.
 - In transparent mode, the WSA host name must be the same as the Redirect Hostname (see [Configuring Global Authentication Settings, on page 21](#)). Further, the WSA host name and Redirect Hostname must be configured prior to creating a Kerberos realm.
- Be aware that once you commit the new realm, you cannot change a realm’s authentication protocol.
- Note that single sign on (SSO) must be configured on client browsers; see [Configuring Single-Sign-on, on page 10](#).
- To simplify use of logs, customize the access log to use the %m custom field parameter. See [Customizing Access Logs](#).

- Step 1** In the Cisco Web Security Appliance web interface, choose **Network > Authentication**.
- Step 2** Click **Add Realm**.
- Step 3** Assign a unique name to the authentication realm using only alphanumeric and space characters.
- Step 4** Select **Active Directory** in the Authentication Protocol field.
- Step 5** Enter up to three fully-qualified domain names or IP addresses for the Active Directory server(s).

Example: `ntlm.example.com`.

An IP address is required only if the DNS servers configured on the appliance cannot resolve the Active Directory server hostname.

When multiple authentication servers are configured in the realm, the appliance attempts to authorize with up to three authentication servers before failing to authorize the transaction within this realm.

- Step 6** Join the appliance to the domain:

- a) Configure the Active Directory Account:

| Setting | Description |
|-------------------------|---|
| Active Directory Domain | The Active Directory server domain name. Also known as a DNS Domain or realm. |
| NetBIOS domain name | If the network uses NetBIOS, provide the domain name. Tip If this option is not available use the <code>setntlmsecuritymode</code> CLI command to verify that the NTLM security mode is set to "domain." |
| Computer Account | Specify a location within the Active Directory domain where AsyncOS will create an Active Directory computer account, also known as a "machine trust account," to uniquely identify the computer on the domain. If the Active Directory environment automatically deletes computer objects at particular intervals, specify a location for the computer account that is in a container, protected from automatic deletion. |

- b) Click **Join Domain**.

Note If you attempt to join a domain you have already joined (even if you use the same credentials), existing connections will be closed, as the Active Directory will send a new set of keys to all clients including this WSA. Affected clients will need to log off and log back in again.

- c) Provide login credentials (user name and passphrase) for the account on the Active Directory, and click **Create Account**.

- Step 7** (Optional) Configure transparent user identification.

| Setting | Description |
|--|---|
| Enable Transparent User Identification using Active Directory agent | Enter both the server name for the machine where the primary Context Directory agent is installed and the shared secret used to access it. (Optional) Enter the server name for the machine where a backup Context Directory agent is installed and its shared secret. |

Step 8 Configure Network Security:

| Setting | Description |
|-------------------------|---|
| Client Signing Required | Select this option if the Active Directory server is configured to require client signing. With this option selected, AsyncOS uses Transport Layer Security when communicating with the Active Directory server. |

Step 9 (Optional) Click **Start Test**. This will test the settings you have entered, ensuring they are correct before real users use them to authenticate. For details on the testing performed, see [Using Multiple NTLM Realms and Domains, on page 21](#).

Step 10 Troubleshoot any issues found during testing. See [Troubleshooting Tools for Authentication Issues](#)

Step 11 Submit and commit your changes.

What to do next

Create an Identification Profile that uses the Kerberos authentication scheme. [Classifying Users and Client Software](#).

How to Create an Active Directory Authentication Realm (NTLMSSP and Basic)

Prerequisites for Creating an Active Directory Authentication Realm (NTLMSSP and Basic)

- Ensure you have the rights and domain information needed to join the Web Security appliance to the Active Directory domain you wish to authenticate against.
- If you plan to use “domain” as the NTLM security mode, use only nested Active Directory groups. If Active Directory groups are not nested, use the default value, “ads”. See `setntlmsecuritymode` in the Command Line Interface appendix of this guide.
- Compare the current time on the Web Security appliance with the current time on the Active Directory server and verify that the difference is no greater than the time specified in the “Maximum tolerance for computer clock synchronization” option on the Active Directory server.
- If the Web Security appliance is managed by a Security Management appliance, be prepared to ensure that same-named authentication realms on different Web Security appliances have identical properties defined on each appliance.
- Be aware that once you commit the new realm, you cannot change a realm’s authentication protocol.
- The WSA needs to connect to the domain controllers for all trusted domains, and to the configured domain controllers into the NTLM realm. For authentication to work correctly, you need to open the following ports to all domain controllers on the internal domain and on the external domain:
 - LDAP (389 UDP and TCP)
 - Microsoft SMB (445 TCP)
 - Kerberos (88 UDP)
 - End-point resolution – port mapper (135 TCP) Net Log-on fixed port
- For NTLMSSP, single sign on (SSO) can be configured on client browsers. See [Configuring Single-Sign-on, on page 10](#).

About Using Multiple NTLM Realms and Domains

The following rules apply in regard to using multiple NTLM realms and domains:

- You can create up to 10 NTLM authentication realms.
- The client IP addresses in one NTLM realm must not overlap with the client IP addresses in another NTLM realm.
- Each NTLM realm can join one Active Directory domain only but can authenticate users from any domains trusted by that domain. This trust applies to other domains in the same forest by default and to domains outside the forest to which at least a one way trust exists.
- Create additional NTLM realms to authenticate users in domains that are not trusted by existing NTLM realms.

Creating an Active Directory Authentication Realm (NTLMSSP and Basic)

Step 1 Choose **Network > Authentication**.

Step 2 Click **Add Realm**.

Step 3 Assign a unique name to the authentication realm using only alphanumeric and space characters.

Step 4 Select **Active Directory** in the Authentication Protocol and Scheme(s) field.

Step 5 Enter up to three fully-qualified domain names or IP addresses for the Active Directory server(s).

Example: `active.example.com`.

An IP address is required only if the DNS servers configured on the appliance cannot resolve the Active Directory server hostname.

When multiple authentication servers are configured in the realm, the appliance attempts to authorize with up to three authentication servers before failing to authorize the transaction within this realm.

Step 6 Join the appliance to the domain:

a) Configure the Active Directory Account:

| Setting | Description |
|-------------------------|---|
| Active Directory Domain | The Active Directory server domain name. Also known as a DNS Domain or realm. |
| NetBIOS domain name | If the network uses NetBIOS, provide the domain name. |
| Computer Account | Specify a location within the Active Directory domain where AsyncOS will create an Active Directory computer account, also known as a “machine trust account”, to uniquely identify the computer on the domain. If the Active Directory environment automatically deletes computer objects at particular intervals, specify a location for the computer account that is in a container, protected from automatic deletion. |

b) Click **Join Domain**.

Note If you attempt to join a domain you have already joined (even if you use the same credentials), existing connections will be closed, as the Active Directory will send a new set of keys to all clients including this WSA. Affected clients will need to log off and log back in again.

- c) Enter the sAMAccountName user name and passphrase for an existing Active Directory user that has rights to create computer accounts in the domain.

Example: "jazzdoe" Do not use: "DOMAIN\jazzdoe" or "jazzdoe@domain"

This information is used once to establish the computer account and is not saved.

- d) Click **Create Account**.

Step 7

(Optional) Configure transparent authentication.

| Setting | Description |
|--|---|
| Enable Transparent User Identification using Active Directory agent | Enter both the server name for the machine where the primary Context Directory agent is installed and the shared secret used to access it. (Optional) Enter the server name for the machine where a backup Context Directory agent is installed and its shared secret. |

Step 8

Configure Network Security:

| Setting | Description |
|-------------------------|---|
| Client Signing Required | Select this option if the Active Directory server is configured to require client signing. With this option selected, AsyncOS uses Transport Layer Security when communicating with the Active Directory server. |

Step 9

(Optional) Click **Start Test**. This will test the settings you have entered, ensuring they are correct before real users use them to authenticate.

Step 10

Submit and commit your changes.

Creating an LDAP Authentication Realm

Before you begin

- Obtain the following information about LDAP in your organization:
 - LDAP version
 - Server addresses
 - LDAP ports
- If the Web Security appliance is managed by a Security Management appliance, ensure that same-named authentication realms on different Web Security appliances have identical properties defined on each appliance.

Step 1

Choose **Network > Authentication**.

Step 2

Click **Add Realm**.

Step 3

Assign a unique name to the authentication realm using only alphanumeric and space characters.

Step 4

Select **LDAP** in the Authentication Protocol and Scheme(s) field.

Step 5 Enter the LDAP authentication settings:

| Setting | Description |
|---|--|
| LDAP Version | <p>Choose the version of LDAP, and choose whether or not to use Secure LDAP.</p> <p>The appliance supports LDAP versions 2 and 3. Secure LDAP requires LDAP version 3.</p> <p>Choose whether or not this LDAP server supports Novell eDirectory to use with transparent user identification.</p> |
| LDAP Server | <p>Enter the LDAP server IP address or hostname and its port number. You can specify up to three servers.</p> <p>The hostname must be a fully-qualified domain name. For example, <code>ldap.example.com</code>. An IP address is required only if the DNS servers configured on the appliance cannot resolve the LDAP server hostname.</p> <p>The default port number for Standard LDAP is 389. The default number for Secure LDAP is 636.</p> <p>If the LDAP server is an Active Directory server, enter the hostname or IP address and the port of the domain controller here. Whenever possible, enter the name of the Global Catalog Server and use port 3268. However, you might want to use a local domain controller when the global catalog server is physically far away and you know you only need to authenticate users on the local domain controller.</p> <p>Note: When you configure multiple authentication servers in the realm, the appliance attempts to authorize with up to three authentication servers before failing to authenticate the transaction within that realm.</p> |
| LDAP Persistent Connections (under the Advanced section) | <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • Use persistent connections (unlimited). Use existing connections. If no connections are available a new connection is opened. • Use persistent connections. Use existing connections to service the number of requests specified. When the maximum is reached, establish a new connection to the LDAP server. • Do not use persistent connections. Always create a new connection to the LDAP server. |

| Setting | Description |
|---------------------|--|
| User Authentication | <p>Enter values for the following fields:</p> <p>Base Distinguished Name (Base DN)</p> <p>The LDAP database is a tree-type directory structure and the appliance uses the Base DN to navigate to the correct location in the LDAP directory tree to begin a search. A valid Base DN filter string is composed of one or more components of the form <code>object-value</code>. For example <code>dc=companyname,dc=com</code>.</p> <p>User Name Attribute</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • uid, cn, and sAMAccountName. Unique identifiers in the LDAP directory that specify a username. • custom. A custom identifier such as <code>UserAccount</code>. <p>User Filter Query</p> <p>The User Filter Query is an LDAP search filter that locates the users Base DN. This is required if the user directory is in a hierarchy below the Base DN, or if the login name is not included in the user-specific component of that users Base DN.</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • none. Filters any user. • custom. Filters a particular group of users. |
| Query Credentials | <p>Choose whether or not the authentication server accepts anonymous queries.</p> <p>If the authentication server does accept anonymous queries, choose Server Accepts Anonymous Queries.</p> <p>If the authentication server does not accept anonymous queries, choose Use Bind DN and then enter the following information:</p> <ul style="list-style-type: none"> • Bind DN. The user on the external LDAP server permitted to search the LDAP directory. Typically, the bind DN should be permitted to search the entire directory. • Passphrase. The passphrase associated with the user you enter in the Bind DN field. <p>The following text lists some example users for the Bind DN field:</p> <pre>cn=administrator,cn=Users,dc=domain,dc=com sAMAccountName=jdoe,cn=Users,dc=domain,dc=com.</pre> <p>If the LDAP server is an Active Directory server, you may also enter the Bind DN username as "DOMAIN\username."</p> |

Step 6

(Optional) Enable Group Authorization via group object or user object and complete the settings for the chosen option accordingly:

| Group Object Setting | Description |
|--|--|
| Group Membership Attribute Within Group Object | <p>Choose the LDAP attribute which lists all users that belong to this group.</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • member and uniquemember. Unique identifiers in the LDAP directory that specify group members. • custom. A custom identifier such as <code>UserInGroup</code>. |
| Attribute that Contains the Group Name | <p>Choose the LDAP attribute which specifies the group name that can be used in the policy group configuration.</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • cn. A unique identifier in the LDAP directory that specifies the name of a group. • custom. A custom identifier such as <code>FinanceGroup</code>. |
| Query String to Determine if Object is a Group | <p>Choose an LDAP search filter that determines if an LDAP object represents a user group.</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • objectclass=groupofnames • objectclass=groupofuniquenames • objectclass=group • custom. A custom filter such as <code>objectclass=person</code>. <p>Note: The query defines the set of authentication groups which can be used in policy groups.</p> |
| User Object Setting | Description |
| Group Membership Attribute Within User Object | <p>Choose the attribute which list all the groups that this user belongs to.</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • memberOf. Unique identifiers in the LDAP directory that specify user members. • custom. A custom identifier such as <code>UserInGroup</code>. |
| Group Membership Attribute is a DN | <p>Specify whether the group membership attribute is a distinguished name (DN) which refers to an LDAP object. For Active Directory servers, enable this option.</p> <p>When this is enabled, you must configure the subsequent settings.</p> |
| Attribute that Contains the Group Name | <p>When the group membership attribute is a DN, this specifies the attribute that can be used as group name in policy group configurations.</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • cn. A unique identifier in the LDAP directory that specifies the name of a group. • custom. A custom identifier such as <code>FinanceGroup</code>. |

| User Object Setting | Description |
|--|--|
| Query String to Determine if Object is a Group | <p>Choose an LDAP search filter that determines if an LDAP object represents a user group.</p> <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • objectclass=groupofnames • objectclass=groupofuniquenames • objectclass=group • custom. A custom filter such as <code>objectclass=person</code>. <p>Note: The query defines the set of authentication groups which can be used in Web Security Manager policies.</p> |

Step 7 (Optional) Configure external LDAP authentication for users.

- Select **External Authentication Queries**.
- Identify the user accounts:.

| Base DN | The Base DN to navigate to the correct location in the LDAP directory tree to begin a search. |
|---|--|
| Query String | <p>The query to return the set of authentication groups, for example:</p> <pre>(&(objectClass=posixAccount)(uid={u}))</pre> <p>or</p> <pre>(&(objectClass=user)(sAMAccountName={u}))</pre> |
| Attribute containing the user's full name | The LDAP attribute, for example, <code>displayName</code> or <code>gecos</code> . |

- (Optional) Deny login to expired accounts based on RFC 2307 account expiration LDAP attributes.
- Provide a query to retrieve group information for users.

If a user belongs to multiple LDAP groups with different user roles, AsyncOS grants the user the permissions for the most restrictive role.

| Base DN | The Base DN to navigate to the correct location in the LDAP directory tree to begin a search. |
|---|---|
| Query String | <code>(&(objectClass=posixAccount)(uid={u}))</code> |
| Attribute containing the user's full name | <code>gecos</code> |

Step 8 (Optional) Click **Start Test**. This will test the settings you have entered, ensuring they are correct before real users use them to authenticate. For details on the testing performed, see [Using Multiple NTLM Realms and Domains, on page 21](#).

Note Once you submit and commit your changes, you cannot later change a realm's authentication protocol.

Step 9 Submit and commit your changes.

What to do next

Create an Identification Profile that uses the Kerberos authentication scheme. See [Classifying Users and Client Software](#).

Related Topics

- [External Authentication, on page 11](#)

Using Multiple NTLM Realms and Domains

The following rules apply in regard to using multiple NTLM realms and domains:

- You can create up to 10 NTLM authentication realms.
- The client IP addresses in one NTLM realm must not overlap with the client IP addresses in another NTLM realm.
- Each NTLM realm can join one Active Directory domain only but can authenticate users from any domains trusted by that domain. This trust applies to other domains in the same forest by default and to domains outside the forest to which at least a one way trust exists.
- Create additional NTLM realms to authenticate users in domains that are not trusted by existing NTLM realms.

About Deleting Authentication Realms

Deleting an authentication realm disables associated identities, which in turn removes those identities from associated policies.

Deleting an authentication realm removes it from sequences.

Configuring Global Authentication Settings

Configure Global Authentication Settings to apply settings to all authentication realms, independent of their authentication protocols.

The Web Proxy deployment mode affects which global authentication settings you can configure. More settings are available when it is deployed in transparent mode than in explicit forward mode.

Before you begin

- Be familiar with the following concepts:
 - [Failed Authentication, on page 28](#)
 - [Failed Authorization: Allowing Re-Authentication with Different Credentials, on page 32](#)

-
- | | |
|---------------|---|
| Step 1 | Choose Network > Authentication |
| Step 2 | Click Edit Global Settings . |
| Step 3 | Edit the settings in the Global Authentication Settings section:. |

| Setting | Description |
|--|--|
| Action if Authentication Service Unavailable | <p>Choose one of the following values:</p> <ul style="list-style-type: none"> • Permit traffic to proceed without authentication. Processing continues as if the user was authenticated. • Block all traffic if user authentication fails. Processing is discontinued and all traffic is blocked. |
| Failed Authentication Handling | <p>When you grant users guest access in an Identification Profile policy, this setting determines how the Web Proxy identifies and logs the user as a guest in the access logs.</p> <p>For more information on granting users guest access, see Granting Guest Access After Failed Authentication, on page 31.</p> |
| Re-authentication (Enable Re-Authentication Prompt If End User Blocked by URL Category or User Session Restriction) | <p>This setting allows users to authenticate again if the user is blocked from a website due to a restrictive URL filtering policy or due to being restricted from logging into another IP address.</p> <p>The user sees a block page that includes a link that allows them to enter new authentication credentials. If the user enters credentials that allow greater access, the requested page appears in the browser.</p> <p>Note: This setting only applies to authenticated users who are blocked due to restrictive URL filtering policies or User Session Restrictions. It does not apply to blocked transactions by subnet with no authentication.</p> <p>For more information, see Failed Authorization: Allowing Re-Authentication with Different Credentials, on page 32.</p> |
| Basic Authentication Token TTL | <p>Controls the length of time that user credentials are stored in the cache before revalidating them with the authentication server. This includes the username and passphrase and the directory groups associated with the user.</p> <p>The default value is the recommended setting. When the Surrogate Timeout setting is configured and is greater than the Basic Authentication Token TTL, then the Surrogate Timeout value takes precedence and the Web Proxy contacts the authentication server after surrogate timeout expires.</p> |

The remaining authentication settings you can configure depends on how the Web Proxy is deployed, in transparent or explicit forward mode.

Step 4 If the Web Proxy is deployed in transparent mode, edit the settings as follows:

| Setting | Description |
|-----------------------|--|
| Credential Encryption | <p>This setting specifies whether or not the client sends the login credentials to the Web Proxy through an encrypted HTTPS connection.</p> <p>This setting applies to both Basic and NTLMSSP authentication schemes, but it is particularly useful for Basic authentication scheme because user credentials are sent as plain text.</p> <p>For more information, see Failed Authentication, on page 28.</p> |

| Setting | Description |
|---|---|
| HTTPS Redirect Port | <p>Specify a TCP port to use for redirecting requests for authenticating users over an HTTPS connection.</p> <p>This specifies through which port the client will open a connection to the Web Proxy using HTTPS. This occurs when credential encryption is enabled or when using Access Control and users are prompted to authenticate.</p> |
| Redirect Hostname | <p>Enter the short hostname of the network interface on which the Web Proxy listens for incoming connections.</p> <p>When you configure authentication on an appliance deployed in transparent mode, the Web Proxy uses this hostname in the redirection URL sent to clients for authenticating users.</p> <p>You can enter either the following values:</p> <ul style="list-style-type: none"> • Single word hostname. You can enter the single word hostname that is DNS resolvable by the client and the Web Security appliance. This allows clients to achieve true single sign-on with Internet Explorer without additional browser side setup. Be sure to enter the single word hostname that is DNS resolvable by the client and the Web Security appliance. For example, if your clients are in domain mycompany.com and the interface on which the Web Proxy is listening has a full hostname of proxy.mycompany.com, then you should enter proxy in this field. Clients perform a lookup on proxy and they should be able to resolve proxy.mycompany.com. • Fully qualified domain name (FQDN). You can also enter the FQDN or IP address in this field. However, if you do that and want true single sign-on for Internet Explorer and Firefox browsers, you must ensure that the FQDN or IP address is added to the client's Trusted Sites list in the client browsers. The default value is the FQDN of the M1 or P1 interface, depending on which interface is used for proxy traffic. |
| Credential Cache Options: Surrogate Timeout | <p>This setting specifies how long the Web Proxy waits before asking the client for authentication credentials again. Until the Web Proxy asks for credentials again, it uses the value stored in the surrogate (IP address or cookie).</p> <p>It is common for user agents, such as browsers, to cache the authentication credentials so the user will not be prompted to enter credentials each time.</p> |
| Credential Cache Options: Client IP Idle Timeout | <p>When IP address is used as the authentication surrogate, this setting specifies how long the Web Proxy waits before asking the client for authentication credentials again when the client has been idle.</p> <p>When this value is greater than the Surrogate Timeout value, this setting has no effect and clients are prompted for authentication after the Surrogate Timeout is reached.</p> <p>You might want to use this setting to reduce the vulnerability of users who leave their computers.</p> |

| Setting | Description |
|---|--|
| Credential Cache Options: Cache Size | Specifies the number of entries that are stored in the authentication cache. Set this value to safely accommodate the number of users that are actually using this device. The default value is the recommended setting. |
| User Session Restrictions | <p>This setting specifies whether or not authenticated users are allowed to access the Internet from multiple IP addresses simultaneously.</p> <p>You might want to restrict access to one machine to prevent users from sharing their authentication credentials with non-authorized users. When a user is prevented from logging in at a different machine, an end-user notification page appears. You can choose whether or not users can click a button to login as a different username using the Re-authentication setting on this page.</p> <p>When you enable this setting, enter the restriction timeout value, which determines how long users must wait before being able to log into a machine with a different IP address. The restriction timeout value must be greater than the surrogate timeout value.</p> <p>You can remove a specific user or all users from the authentication cache using the <code>authcache</code> CLI command.</p> |
| Advanced | When using Credential Encryption or Access Control, you can choose whether the appliance uses the digital certificate and key shipped with the appliance (the Cisco Web Security Appliance Demo Certificate) or a digital certificate and key you upload here. |

Step 5 If the Web Proxy is deployed in explicit forward mode, edit the settings as follows:

| Setting | Description |
|-----------------------|---|
| Credential Encryption | <p>This setting specifies whether or not the client sends the login credentials to the Web Proxy through an encrypted HTTPS connection. To enable credential encryption, choose “HTTPS Redirect (Secure)”. When you enable credential encryption, additional fields appear to configure how to redirect clients to the Web Proxy for authentication.</p> <p>This setting applies to both Basic and NTLMSSP authentication schemes, but it is particularly useful for Basic authentication scheme because user credentials are sent as plain text.</p> <p>For more information, see Failed Authentication, on page 28.</p> |
| HTTPS Redirect Port | <p>Specify a TCP port to use for redirecting requests for authenticating users over an HTTPS connection.</p> <p>This specifies through which port the client will open a connection to the Web Proxy using HTTPS. This occurs when credential encryption is enabled or when using Access Control and users are prompted to authenticate.</p> |

| Setting | Description |
|---|---|
| Redirect Hostname | <p>Enter the short host name of the network interface on which the Web Proxy listens for incoming connections.</p> <p>When you enable Authentication Mode above, the Web Proxy uses this hostname in the redirection URL sent to clients for authenticating users.</p> <p>You can enter either the following values:</p> <ul style="list-style-type: none"> • Single word hostname. You can enter the single word host name that is DNS resolvable by the client and the Web Security appliance. This allows clients to achieve true single sign-on with Internet Explorer without additional browser side setup. Be sure to enter the single word host name that is DNS resolvable by the client and the Web Security appliance. For example, if your clients are in domain mycompany.com and the interface on which the Web Proxy is listening has a full host name of proxy.mycompany.com, then you should enter proxy in this field. Clients perform a lookup on proxy and they should be able to resolve proxy.mycompany.com. • Fully qualified domain name (FQDN). You can also enter the FQDN or IP address in this field. However, if you do that and want true single sign-on for Internet Explorer and Firefox browsers, you must ensure that the FQDN or IP address is added to the client's Trusted Sites list in the client browsers. The default value is the FQDN of the M1 or P1 interface, depending on which interface is used for proxy traffic. |
| Credential Cache Options: Surrogate Timeout | <p>This setting specifies how long the Web Proxy waits before asking the client for authentication credentials again. Until the Web Proxy asks for credentials again, it uses the value stored in the surrogate (IP address or cookie).</p> <p>Note that it is common for user agents, such as browsers, to cache the authentication credentials so the user will not be prompted to enter credentials each time.</p> |
| Credential Cache Options: Client IP Idle Timeout | <p>When IP address is used as the authentication surrogate, this setting specifies how long the Web Proxy waits before asking the client for authentication credentials again when the client has been idle.</p> <p>When this value is greater than the Surrogate Timeout value, this setting has no effect and clients are prompted for authentication after the Surrogate Timeout is reached.</p> <p>You might want to use this setting to reduce the vulnerability of users who leave their computers.</p> |
| Credential Cache Options: Cache Size | <p>Specifies the number of entries that are stored in the authentication cache. Set this value to safely accommodate the number of users that are actually using this device. The default value is the recommended setting.</p> |

| Setting | Description |
|---------------------------|---|
| User Session Restrictions | <p>This setting specifies whether or not authenticated users are allowed to access the Internet from multiple IP addresses simultaneously.</p> <p>You might want to restrict access to one machine to prevent users from sharing their authentication credentials with non-authorized users. When a user is prevented from logging at a different machine, an end-user notification page appears. You can choose whether or not users can click a button to login as a different username using the Re-authentication setting on this page.</p> <p>When you enable this setting, enter the restriction timeout value, which determines how long users must wait before being able to log into a machine with a different IP address. The restriction timeout value must be greater than the surrogate timeout value.</p> <p>You can remove a specific user or all users from the authentication cache using the <code>authcache</code> CLI command.</p> |
| Advanced | <p>When using Credential Encryption or Access Control, you can choose whether the appliance uses the digital certificate and key shipped with the appliance (the Cisco Web Security Appliance Demo Certificate) or a digital certificate and key you upload here.</p> <p>To upload a digital certificate and key, click Browse and navigate to the necessary file on your local machine. Then click Upload Files after you select the files you want.</p> |

Step 6 Submit and commit your changes.

Authentication Sequences

- [About Authentication Sequences, on page 26](#)
- [Creating Authentication Sequences, on page 27](#)
- [Editing And Reordering Authentication Sequences, on page 27](#)
- [Deleting Authentication Sequences, on page 28](#)

About Authentication Sequences

Use authentication sequences to allow single Identities to authenticate users via different authentication servers or protocols. Authentication sequences are also useful for providing backup options in case primary authentication options become unavailable.

Authentication sequences are collections of two or more authentication realms. The realms used can have different authentication servers and different authentication protocols. For more information on authentication realms, see [Authentication Realms, on page 10](#).

After you create a second authentication realm, the appliance automatically displays a Realm Sequences section under Network > Authentication and includes a default authentication sequence named All Realms. The All Realms sequence automatically includes each realm you define. You can change the order of the

realms within the All Realms sequence, but you cannot delete the All Realms sequence or remove any realms from it.

When multiple NTLM authentication realms are defined, the Web Security appliance uses the NTLMSSP authentication scheme with only one NTLM authentication realm per sequence. You can choose which NTLM authentication realm to use for NTLMSSP within each sequence, including the All Realms sequence. To use NTLMSSP with multiple NTLM realms, define a separate Identification Profile for each realm.

Which authentication realms within a sequence get used during authentication depends on:

- The authentication scheme used. This is generally dictated by the type of credentials entered at the client.
- The order in which realms are listed within the sequence (for Basic realms only, as only one NTLMSSP realm is possible).

Tip For optimal performance, authenticate clients on the same subnet using a single realm.

Creating Authentication Sequences

Before you begin

- Create two or more authentication realms (see [Authentication Realms, on page 10](#)).
- If the Web Security appliance is managed by a Security Management appliance, ensure that same-named authentication realms on different Web Security appliances have identical properties defined on each appliance.
- Be aware that AsyncOS will use the realms to process authentication sequentially, beginning with the first realm in the list.

-
- Step 1** Choose **Network > Authentication**
 - Step 2** Click **Add Sequence**.
 - Step 3** Enter a unique name for the sequence using alphanumeric and space characters.
 - Step 4** In the first row of the Realm Sequence for Basic Scheme area, choose the first authentication realm you want to include in the sequence.
 - Step 5** In the second row of the Realm Sequence for Basic Scheme area, choose the next realm you want to include in the sequence.
 - Step 6** (Optional) Click **Add Row** to include another realm that uses Basic credentials.
 - Step 7** If an NTLM realm is defined, choose an NTLM realm in the Realm for NTLMSSP Scheme field.
The Web Proxy uses this NTLM realm when the client sends NTLMSSP authentication credentials.
 - Step 8** Submit and commit your changes.
-

Editing And Reordering Authentication Sequences

-
- Step 1** Choose **Network > Authentication**.

- Step 2** Click the name of the sequence you wish to edit or re-order.
- Step 3** Choose a realm name from the Realms drop-down list on the row corresponding to the position number you want the realm to occupy in the sequence.
- Note** For the All Realms sequence, you can only change the order of its realms, you cannot change the realms themselves. To change the order of realms in the All Realms sequence, click the arrows in the Order column to reposition the corresponding realms.
- Step 4** Repeat **Step 3** until all realms are listed and ordered as required, ensuring that each realm name appears in one row only.
- Step 5** Submit and commit your changes.
-

Deleting Authentication Sequences

Before you begin

Be aware that deleting an authentication sequence also disables associated identities, which in turn removes those identities from associated policies.

- Step 1** Choose **Network > Authentication**.
- Step 2** Click the trash can icon for the sequence name.
- Step 3** Click **Delete** to confirm that you want to delete the sequence.
- Step 4** Commit your changes.
-

Failed Authentication

- [About Failed Authentication](#), on page 28
- [Bypassing Authentication with Problematic User Agents](#), on page 29
- [Bypassing Authentication](#), on page 30
- [Permitting Unauthenticated Traffic While Authentication Service is Unavailable](#), on page 30
- [Granting Guest Access After Failed Authentication](#), on page 31
- [Failed Authorization: Allowing Re-Authentication with Different Credentials](#), on page 32

About Failed Authentication

Users may be blocked from the web due to authentication failure for the following reasons:

- **Client/user agent limitations.** Some client applications may not properly support authentication. You can bypass authentication for these clients by configuring Identification Profiles that do not require authorization and basing their criteria on the clients (and, optionally, on the URLs they need to access).
- **Authentication service is unavailable.** An authentication service might be unavailable due to network or server issues. You can choose to allow unauthenticated traffic in this circumstance.
- **Invalid credentials.** Some users may be unable to supply valid credentials for proper authentication (for example, visitors or users awaiting credentials). You can choose to grant these users limited access to the web.

Related Topics

- [Bypassing Authentication with Problematic User Agents](#) , on page 29
- [Bypassing Authentication](#), on page 30
- [Permitting Unauthenticated Traffic While Authentication Service is Unavailable](#), on page 30
- [Granting Guest Access After Failed Authentication](#), on page 31

Bypassing Authentication with Problematic User Agents

Some user agents are known to have authentication issues that can impact normal operations.

You should bypass authentication via the following user agents:

- Windows-Update-Agent
- MICROSOFT_DEVICE_METADATA_RETRIEVAL_CLIENT
- Microsoft BITS
- SLSSoapClient
- Akamai NetSession Interface
- Microsoft-CryptoAPI
- NCSI
- MSDW
- Gnotify
- msde
- Google Update

Note The access policies will still filter (based on URL categories) and scan (McAfee, Webroot) traffic as per the access policy setup.

Step 1 Configure the Identification Profile to bypass authentication with the specified user agents:

- a) Select **Web Security Manager > Identification Profile**.
- b) Click **Add Identification Profile**.
- c) Enter information:

| Option | Value |
|----------------------------------|--|
| Name | User Agent AuthExempt Identification Profile |
| Insert Above | Set to the first profile in the processing order |
| Define Members by Subnet | Leave blank. |
| Define Members by Authentication | No Authentication Required. |

- d) Click **Advanced > User Agents**.
- e) Click **None Selected**.
- f) Under Custom user Agents, specify the problematic User Agent strings.

Step 2 Configure the Access Policy:

- a) Choose **Web Security Manager > Access Policies**.
- b) Click **Add Policy**.
- c) Enter information:

| Option | Value |
|-------------------------------|--|
| Policy Name | Auth Exemption for User Agents |
| Insert Above Policy | Set to the first policy in the processing order. |
| Identification Profile Policy | User Agent AuthExempt Identification Profile |
| Advanced | None |

Step 3 Submit and commit your changes.

Bypassing Authentication

| | Step | More Information |
|---|---|--|
| 1 | Create a custom URL category that contains the affected websites by configuring the Advanced properties. | Creating and Editing Custom URL Categories |
| 2 | Create an Identification Profile with these characteristics: <ul style="list-style-type: none"> • Placed above all identities that require authentication. • Includes the custom URL category. • Includes affected client applications. • Does not require authentication | Classifying Users and Client Software |
| 3 | Create a policy for the Identification Profile. | Creating a Policy |

Related Topics

- [Bypassing the Web Proxy](#)

Permitting Unauthenticated Traffic While Authentication Service is Unavailable

Note

This configuration applies only when an authentication service is unavailable. It will not bypass authentication permanently. For alternative options, see [About Failed Authentication, on page 28](#)

Step 1 Choose **Network > Authentication**.

Step 2 Click **Edit Global Settings**.

Step 3 Click the **Permit Traffic To Proceed Without Authentication** in the Action If Authentication Service Unavailable field.

Step 4 Submit and commit your changes.

Granting Guest Access After Failed Authentication

Granting guest access requires that the following procedures are completed:

1. [Define an Identification Profile that Supports Guest Access, on page 31](#)
2. [Use an Identification Profile that Supports Guest Access in a Policy, on page 31](#)
3. (Optional) [Configure How Guest User Details are Logged, on page 32](#)

Note If an Identification Profile allows guest access and there is no user-defined policy that uses that Identification Profile, users who fail authentication match the global policy of the applicable policy type. For example, if MyIdentificationProfile allows guest access and there is no user-defined Access Policy that uses MyIdentificationProfile, users who fail authentication match the global Access Policy. If you do not want guest users to match a global policy, create a policy above the global policy that applies to guest users and blocks all access.

Define an Identification Profile that Supports Guest Access

- Step 1** Choose **Web Security Manager > Identification Profiles**.
- Step 2** Click **Add Identification Profile** to add a new identity, or click the name of an existing identity that you wish to use.
- Step 3** Check the **Support Guest Privileges** check box.
- Step 4** Submit and commit your changes.
-

Use an Identification Profile that Supports Guest Access in a Policy

- Step 1** Choose a policy type from the Web Security Manager menu.
- Step 2** Click a policy name in the policies table.
- Step 3** Choose **Select One Or More Identification Profiles** from the Identification Profiles And Users drop-down list (if not already chosen).
- Step 4** Choose a **profile** that supports guest access from the drop-down list in the Identification Profile column.
- Step 5** Click the **Guests (Users Failing Authentication)** radio button.

Note If this option is not available it means the **profile** you chose is not configured to support guest access. Return to step 4 and choose another, or see [Define an Identification Profile that Supports Guest Access, on page 31](#) to define a new one.

Step 6 Submit and commit your changes.

Configure How Guest User Details are Logged

Step 1 Choose **Network > Authentication**.

Step 2 Click **Edit Global Settings**.

Step 3 Click a Log Guest User By radio button, described below, in the Failed Authentication Handling field.

| Radio button | Description |
|----------------------------------|--|
| IP Address | The IP address of the guest user's client will be logged in the access logs. |
| User Name As Entered By End-User | The user name that originally failed authentication will be logged in the access logs. |

Step 4 Submit and commit your changes.

Failed Authorization: Allowing Re-Authentication with Different Credentials

- [About Allowing Re-Authentication with Different Credentials, on page 32](#)
- [Allowing Re-Authentication with Different Credentials, on page 32](#)

About Allowing Re-Authentication with Different Credentials

Use re-authentication to allow users the opportunity to authenticate again, using different credentials, if the credentials they previously used have failed authorization. A user may authenticate successfully but still be prevented from accessing a web resource if not authorized to do so. This is because authentication merely identifies users for the purpose of passing their verified credentials on to policies, but it is the policies that authorize those users (or not) to access resources.

A user must have authenticated successfully to be allowed to re-authenticate.

- To use the re-authentication feature with user defined end-user notification pages, the CGI script that parses the redirect URL must parse and use the Reauth_URL parameter.

Allowing Re-Authentication with Different Credentials

Step 1 Choose **Network > Authentication**.

Step 2 Click **Edit Global Settings**.

Step 3 Check the **Re-Authentication Prompt If End User Blocked by URL Category Or User Session Restriction** check box.

Step 4 Click **Submit**.

Tracking Identified Users

Note When the appliance is configured to use cookie-based authentication surrogates, it does not get cookie information from clients for HTTPS and FTP over HTTP requests. Therefore, it cannot get the user name from the cookie.

Supported Authentication Surrogates for Explicit Requests

| Surrogate Types | Credential Encryption Disabled | | | Credential Encryption Enabled | | |
|-----------------|--------------------------------|-----------------------|------------|-------------------------------|-----------------------|------------|
| | HTTP | HTTPS & FTP over HTTP | Native FTP | HTTP | HTTPS & FTP over HTTP | Native FTP |
| No Surrogate | Yes | Yes | Yes | NA | NA | NA |
| IP-based | Yes | Yes | Yes | Yes | Yes | Yes |
| Cookie-based | Yes | Yes*** | Yes*** | Yes | No/Yes** | Yes*** |

Supported Authentication Surrogates for Transparent Requests

Note See also the description of the Authentication Surrogates options in [Classifying Users and Client Software](#).

| Surrogate Types | Credential Encryption Disabled | | | Credential Encryption Enabled | | |
|-----------------|--------------------------------|----------|------------|-------------------------------|----------|------------|
| | HTTP | HTTPS | Native FTP | HTTP | HTTPS | Native FTP |
| No Surrogate | NA | NA | NA | NA | NA | NA |
| IP-based | Yes | No/Yes* | No/Yes* | Yes | No/Yes* | No/Yes* |
| Cookie-based | Yes | No/Yes** | No/Yes** | Yes | No/Yes** | No/Yes** |

* Works after the client makes a request to an HTTP site and is authenticated. Before this happens, the behavior depends on the transaction type:

- **Native FTP transactions.** Transactions bypass authentication.
- **HTTPS transactions.** Transactions are dropped. However, you can configure the HTTPS Proxy to decrypt the first HTTPS request for authentication purposes.

** When cookie-based authentication is used, the Web Proxy cannot authenticate the user for HTTPS, native FTP, and FTP over HTTP transactions. Due to this limitation, all HTTPS, native FTP, and FTP over HTTP requests bypass authentication, so authentication is not requested at all.

*** No surrogate is used in this case even though cookie-based surrogate is configured.

Tracking Re-Authenticated Users

With re-authentication, if a more privileged user authenticates and is authorized, the Web Proxy caches this user identity for different amounts of time depending on the authentication surrogates configured:

- **Session cookie.** The privileged user identity is used until the browser is closed or the session times out.
- **Persistent cookie.** The privileged user identity is used until the surrogate times out.
- **IP address.** The privileged user identity is used until the surrogate times out.
- **No surrogate.** By default, the Web Proxy requests authentication for every new connection, but when re-authentication is enabled, the Web Proxy requests authentication for every new request, so there is an increased load on the authentication server when using NTLMSSP. The increase in authentication activity may not be apparent to a user, however, because most browsers will cache the privileged user credentials and authenticate without prompting until the browser is closed. Also, when the Web Proxy is deployed in transparent mode, and the “Apply same surrogate settings to explicit forward requests” option is not enabled, no authentication surrogates are used for explicit forward requests and increased load will occur with re-authentication.

**Note**

If the Web Security appliance uses cookies for authentication surrogates, Cisco recommends enabling credential encryption.

Credentials

Authentication credentials are obtained from users by either prompting them to enter their credentials through their browsers, or another client application, or by obtaining the credentials transparently from another source.

- [Tracking Credentials for Reuse During a Session, on page 34](#)
- [Authentication and Authorization Failures, on page 35](#)
- [Credential Format, on page 35](#)
- [Credential Encryption for Basic Authentication, on page 35](#)

Tracking Credentials for Reuse During a Session

Using authentication surrogates, after a user authenticates once during a session, you can track credentials for reuse throughout that session rather than having the user authenticate for each new request. Authentication surrogates may be based on the IP address of the user’s workstation or on a cookie that is assigned to the session.

For Internet Explorer, be sure the Redirect Hostname is the short host name (containing no dots) or the NetBIOS name rather than a fully qualified domain. Alternatively, you can add the appliance host name to Internet Explorer’s Local intranet zone (Tools > Internet options > Security tab); however, this will be required on every client. For more information about this, see [How do I properly set up NTLM with SSO \(credentials sent transparently\)?](#)

With Firefox and other non-Microsoft browsers, the parameters **network.negotiate-auth.delegation-uris**, **network.negotiate-auth.trusted-uris** and **network.automatic-ntlm-auth.trusted-uris** must be set to the

transparent-mode Redirect Hostname. You also can refer to [Firefox is not sending authentication credentials transparently \(SSO\)](#). This [article](#) provides general information about changing Firefox parameters.

For information about the Redirect Hostname, see [Configuring Global Authentication Settings, on page 21](#), or the CLI command `sethostname`.

Authentication and Authorization Failures

If authentication fails for accepted reasons, such as incompatible client applications, you can grant guest access.

If authentication succeeds but authorization fails, it is possible to allow re-authentication using a different set of credentials that may be authorized to access the requested resource.

Credential Format

| Authentication Scheme | Credential Format |
|-----------------------|--|
| NTLMSSP | <code>MyDomain\jsmith</code> |
| Basic | <code>jsmith</code> <code>MyDomain\jsmith</code> Note If the user does not enter the Windows domain, the Web Proxy prepends the default Windows domain. |

Credential Encryption for Basic Authentication

About Credential Encryption for Basic Authentication

Enable credential encryption to transmit credentials over HTTPS in encrypted form. This increases security of the basic authentication process.

The Web Security appliance uses its own certificate and private key by default to create an HTTPS connection with the client for the purposes of secure authentication. Most browsers will warn users, however, that this certificate is not valid. To prevent users from seeing the invalid certificate message, you can upload a valid certificate and key pair that your organization uses.

Configuring Credential Encryption

Before you begin

- Configure the appliance to use IP surrogates.
- (Optional) Obtain a certificate and unencrypted private key. The certificate and key configured here are also used by Access Control.

-
- Step 1** Choose **Network > Authentication**.
- Step 2** Click **Edit Global Settings**.
- Step 3** Check the **Use Encrypted HTTPS Connection For Authentication** check box in the Credential Encryption field.
- Step 4** (Optional) Edit the default port number (443) in the HTTPS Redirect Port field for client HTTP connections during authentication.
- Step 5** (Optional) Upload a certificate and key:
- Expand the Advanced section.
 - Click **Browse** in the Certificate field and find the certificate file you wish to upload.
 - Click **Browse** in the Key field and find the private key file you wish to upload.
 - Click **Upload Files**.
- Step 6** Submit and commit your changes.
